PROCEEDINGS

Part B: APRIL 18-19

Continuing Medical Education Activity - *AMA PRA Category 1 Credits*™ available

Proceedings of the AACR
April 2023
Part B: Tuesday, April 18 and Wednesday, April 19, 2023

TABLE OF CONTENTS

PRESENTATIONS: TUESDAY, APRIL 18

- Combination Therapies for Cancer
- Community-based Research and Biobanking Research
- Diagnostic and Prognostic Biomarkers 4
- Immune-based Biomarkers for Prognostic and Predictive Benefit
- Immunomodulatory Agents and Interventions
- Increasing the Clinical Utility of Cell-Free DNA Testing
- Inflammation, Immunity, and Cancer
- Liquid Biopsies: Circulating Nucleic Acids and Circulating Tumor Cells 4
- Molecular Targeted Therapies 2
- New Approaches in Radiodiagnostics and Theranostics
- Precision Oncology in Pediatric Cancer: From Genomics to Databases to Real World Evidence
- Spatial Profiling, Tumor Classification, and Response Assessment
- Spatial Proteomics and Transcriptomics 1
- The Next Wave of Precision Oncology: New Drugs, Databases, and Analytics to Refine Care
- Therapeutic Antibodies, Including Engineered Antibodies

ENDOCRINOLOGY

- Endocrine-related Cancers and Nuclear Receptors: Molecular Biology, Biomarkers, and Genomics

EXPERIMENTAL AND MOLECULAR THERAPEUTICS

- Anticancer Approaches Targeting Signal Transduction Pathways
- Anticancer Approaches: Antibody-Drug Conjugates, Epigenetics, and Tumor Environment
- Drug Resistance in Molecular Targeted Therapies 3

- Drug Resistance in Molecular Targeted Therapies 4 / Regulation of Gene Expression in Drug Resistance
- Identification of Molecular Targets 1
- Identification of Molecular Targets 2 / New Nonclinical Models for Targets
- Molecular Targets
- New Tricks for Known Targets: Novel Approaches to Inhibit Oncogenic Signaling
- Novel Antitumor Agents, PI3K/AKT Inhibitors, Proteasome Inhibitors, and Topoisomerases
- Novel Targets and Pathways
- Oncogenes and Tumor Suppressor Genes as Targets for Therapy 3
- Targeting Protein Kinases and Phosphatases for Therapy 1
- Targeting Protein Kinases and Phosphatases for Therapy 2
- Theranostics and Radionuclides / Pharmacologic Approaches
- Tyrosine Kinase and Phosphatase Inhibitors 1
- Tyrosine Kinase and Phosphatase Inhibitors 2

IMMUNOLOGY

- Adoptive Cell and Natural Killer Cell Therapy
- CAR T-cell Therapy 2
- Combination Immunotherapies 1
- Combination Immunotherapies 2
- Determinants of Immunotherapeutic Effectiveness
- Developments in Anticancer Immunotherapy
- Inflammation and Immunity in the Tumor Microenvironment
- Modifiers of the Tumor Microenvironment
- New Opportunities for Combinatorial Immunotherapies
- Novel Preclinical Models for Cancer Immunotherapy

MOLECULAR/CELLULAR BIOLOGY AND GENETICS

- Cancer and Metabolism 1
- Cancer and Metabolism 2
- Chromatin Structure and Function in Cancer
- Epigenetic Mechanisms as Drivers of Tumorigenesis
- Gene Regulation and Transcription Factors in Cancer
- Gene Regulation in Cancer
- Non-coding RNAs in Brain, Melanoma, Lung, and Head/Neck
- Non-coding RNAs in Breast and Gynecological/Urinary Tract Cancers and New Techniques/Technologies
- Non-coding RNAs in Gastrointestinal, Blood, and Bone Marrow Cancers
- Oxidative Stress, Metabolism, and Cell Senescence
- Responses to Hypoxic, Proteotoxic, and Other Novel Forms of Cell Stress
- Role of Mitochondria and Signaling Pathways in Cancer

MULTIDISCIPLINARY

- AACR Project GENIE Use Cases

POPULATION SCIENCES

- Cancer Screening and Health Equity
- Descriptive Epidemiology and Environmental Risk Factors
- GWAS/Post-GWAS
- Survivorship and Biomarkers of Prognosis

PREVENTION / EARLY DETECTION / INTERCEPTION

- Behavioral and Biological Opportunities to Improve Cancer Prevention, Early Detection, and Disparities
- Diet, Nutrition, Lifestyle, and Environment and Cancer Prevention

- Dietary Derivatives and Repurposed and New Drugs for Cancer Prevention

TUMOR BIOLOGY

- 3D and Tissue Recombinant Models
- Advances in Angiogenesis
- Evaluating Tumor Progression via 3D and Spatial Approaches
- Inflammation and Tumor Progression
- Novel Targets, Biomarkers, and Models for Cancer
- Patient-Derived Xenograft Models
- Pediatric Cancer 2: Biology and Therapeutics
- Pediatric Cancer 3: Genomes and Novel Tumor Models
- PET, MRI, and CT Imaging
- Regulation of Invasion and Migration
- Signaling Pathways That Impact the Tumor Microenvironment
- Single Cell and Spatial Considerations of the Tumor Microenvironment
- Spatial Considerations of the 3D Tumor Microenvironment
- Stem Cells and the Microenvironment

PRESENTATIONS: WEDNESDAY, APRIL 19

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE

- Bioinformatics Applications in Cancer Biology 3
- Databases, Platforms, and Tools
- Integrative Spatial and Temporal Multi-omics of Cancer

CLINICAL RESEARCH EXCLUDING TRIALS

- Immune Checkpoints

- Immune Monitoring and Responses to Therapy
- Liquid Biopsies: Circulating Nucleic Acids and Circulating Tumor Cells 5
- Preclinical Therapies and Clinical Observations in Pediatric Oncology
- Retrospective Clinical Analyses 2
- Spatial Proteomics and Transcriptomics 2
- Vaccines

EXPERIMENTAL AND MOLECULAR THERAPEUTICS

- Apoptosis and Growth Factor Receptors as Therapeutic Targets
- Cell Death Pathways and Treatment / Molecular Classification of Tumors for Diagnostics, Prognostics, and Therapeutic Outcomes
- DNA Damage Response
- DNA Repair / Molecular Classification of Tumors for Diagnostics, Prognostics, and Therapeutic Outcomes / Others
- DNA-reactive Agents, HDAC and Methyltransferase Inhibitors, and Tubulin Agents
- Epigenetics
- Growth Factor Receptors as Therapeutic Targets

IMMUNOLOGY

- Anticancer Immunotherapeutics
- Immune Checkpoints
- Immune Mechanisms Mediated by Other Therapies
- Immunotherapy Strategies and Mechanisms

MOLECULAR/CELLULAR BIOLOGY AND GENETICS

- Cyclin-dependent Kinases and Cyclin-dependent Kinase Inhibitors
- DNA Methylation Changes in Cancer

- Metabolism and Metabolomics of Cancer
- Multi-omics Tumor Profiling
- Targeting DNA Damage Response and Novel Pathways

POPULATION SCIENCES

- Diet, Alcohol, Tobacco Use, and Other Lifestyle Factors
- Novel Factors Associated with Cancer Mortality

PREVENTION / EARLY DETECTION / INTERCEPTION

- Early Detection and Molecular Markers of Prevention

TUMOR BIOLOGY

- Cancer Stem Cells and Therapeutic Resistance
- Cell Adhesion and Cell Signaling in Cancer and Drug Resistance
- Crosstalk between Cancer Cells, Immune Cells, and Fibroblasts
- Immunotherapy and Cellular Interactions in the Tumor Microenvironment
- Interactions Between the Microbiome, Cancer Cells, and Tumor Stromal Components
- Methods to Measure Clonal Evolution
- Tumor-Stromal Cell (Including Immune Cell) Interactions and Therapy Responses

Tuesday, April 18, 2023

Prediction of cancer transcriptomes from whole-slide images with Vis-Gene

Yuanning Zheng[1], Marija Pizurica[1], Francisco Carrillo-Perez[1], Christian Wohlfart[2], Wei Yao[3], Nadia Shamout[3], Olivier Gevaert[1], Antoaneta Vladimirova[3]. *[1]Stanford Center for Biomedical Informatics Research (BMIR), Stanford, CA,[2]Roche Diagnostics GmbH, Penzberg, Germany,[3]Roche Molecular Systems, Inc., Santa Clara, CA*

Introduction: Whole slide images (WSIs) are a crucial tool used by pathologists for diagnosing and grading cancers. In recent years, deep learning techniques have revolutionized the area, helping pathologists in the detection and classification of cancers. Earlier studies have related morphological features of tissues to molecular profiles, such as mutations and gene expression, and several machine learning-based approaches have been proposed to use WSIs to predict gene expression. However, most of the established methods treat different parts of the tissues in an isolated manner, not using the spatial relation between the tiles. In this work, we proposed Vis-Gene, a deep learning approach using a vision transformer for predicting gene expression from WSIs.
Methods: WSIs and RNA-seq data of five cancer types from the TCGA project were used for training and evaluation, including brain (GBM, n = 212), lung (LUAD, n = 520), kidney (KIRP, n = 295), colon (COAD, n = 290) and pancreas (PAAD, n = 180). The datasets were split into 80% for training and 20% for testing. In addition, data from healthy lung and brain tissues were obtained from the GTEx project. WSIs were split into tiles of 256 X 256 pixels, and 4,000 tiles of each image were used for training. Image features of each tile were extracted using a pre-trained Resnet-50. We clustered similar tiles using the k-Means algorithm, and the mean feature value of each cluster was used. We then used a vision transformer to “translate” image features to gene expression. To improve accuracy, we leveraged a transfer learning approach by pretraining the vision transformer on data from healthy tissues.
Results: We carried out five-fold cross-validations to assess the performance of Vis-Gene in each cancer type. The root-mean-squared error (RMSE) of the top 500 most accurately predicted genes in GBM was 0.12, and the standard deviation (SD) was 0.007. The RMSE of the top 100 most accurate genes in LUAD was 0.58 (SD: 0.02), KIRP was 0.63 (SD: 0.02), COAD was 0.53 (SD: 0.03), and PAAD was 0.56 (SD: 0.04). In all the tested cancers, Vis-Gene achieved significantly lower RMSE values and higher correlation coefficients (r) compared to a baseline model and existing computational models. Gene set analysis showed that the top accurately predicted genes in GBM were related to neuropeptide signaling pathway, gliogenesis, and inflammatory response. The top accurate genes in LUAD were related to NF-kappaB signaling and regulation of cell adhesion. Using spatial transcriptomic datasets, we further validated the results of Vis-Gene in predicting intra-tumoral heterogeneity of gene expression.
Conclusion: We established a new machine learning framework that can accurately predict gene expression from WSIs. This allows us to link histology features of cancers to molecular phenotype. Vis-Gene has the potential to identify clinically relevant endpoint expressions of the target genes.

#4271

A new methodological approach to discovering biomarkers of mammographic breast density using pathway-guided lipid amalgamation

Chongliang Luo, Jingqin Luo, Kayla R. Getz, Myung Sik Jeon, Adetunji T. Toriola. *Washington University in St. Louis, St Louis, MO*

Introduction: High mammographic breast density (MBD) is a risk factor for breast cancer. Studies are evaluating the associations of various multi-omic biomarkers, in well-defined pathways with MBD, but the existing methodological approaches have drawbacks. For example, multivariate association analysis adjusting for covariates may identify too many biomarkers and lacks proper biological interpretation. On the other hand, simple amalgams (e.g., combination or sum) of species within pathways may result in few associated pathways, as the species within a pathway could have different directions of associations. Variable selection approaches such as the least absolute shrinkage and selection operator **(**Lasso) select individual species without considering prior knowledge of the pathway structure. We propose a new pathway-guided amalgamation method to form species clusters that could enhance biological interpretation.
Methods: The plasma concentration of 982 lipid species in 14 super-pathways was measured in the blood samples of 705 premenopausal women drawn during their annual screening mammogram. We aimed to identify amalgams of lipid species that are associated with the volumetric percent density (VPD, in log scale). The proposed method utilizes the fused Lasso algorithm which penalizes the differences between effects for the lipid species within the same pathway and hence induces equality among similar effects. The lipid species with the same effects can be amalgamated to form clusters of species as new biomarkers. The number of clusters was chosen by cross-validation. Besides amalgamation, the method also facilitates variable selection by singling out influential individual species.
Results: The proposed method identified 11 amalgams formed by 744 species, with 3 amalgams in Cholesteryl Esters (CE), and 1 amalgam each in Phosphatidylcholines (PC), Lysophosphatidylcholines (LPC), Phosphatidylinositols (PI), Dihydroceramides (DCER), Hexosylceramides (HCER), Lactosylceramides(LCER), Diacylglycerols (DAG), and Triacylglycerols (TAG). Amalgams in the same pathway can have opposite directions of association: 2 of the 3 amalgams in CE had negative associations with VPD while the third showed a positive association. Species with small effects in the same direction of associations may be combined: an amalgam comprising 518 species in the TAG pathway was identified with each presenting a small negative association with VPD but collectively, forming one amalgam with a large effect.
Conclusions: The proposed amalgamation method provides a flexible and interpretable variable selection and clustering approach to discover lipidomic biomarkers for MBD. The amalgamation is especially preferred when multiple biomarkers species within one pathway share similar effects, or species within one pathway show opposite directions of associations.

Pan-cancer analysis of intra-tumor heterogeneity in 9,116 cancers using a novel regularized likelihood model

Yujie Jiang[1], Kaixian Yu[2], Matthew D. Montierth[3], Shuangxi Ji[2], Seung Jun Shin[4], Shuai Guo[2], Shaolong Cao[2], Yuxin Tang[5], Scott Kopetz[2], Pavlos Msaouel[2], Jennifer R. Wang[2], Marek Kimmel[5], Peter Van Loo[2], Hongtu Zhu[6], Wenyi Wang[2]. *[1]The University of Texas MD Anderson Cancer Center/Rice University, Houston, TX,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]The University of Texas MD Anderson Cancer Center/Baylor College of Medicine, Houston, TX,[4]Korea University, Seoul, Korea, Republic of,[5]Rice University, Houston, TX,[6]University of North Carolina at Chapel Hill, Chapel Hill, NC*

Subpopulations of tumor cells characterized by mutation profiles may confer differential fitness and consequently influence the prognosis of cancers. Understanding subclonal architecture has the potential to provide biological insight in tumor evolution and advance cancer precision treatment. Recent subclonal reconstruction methods require heavy computational resources, prior knowledge of the number of subclones, and extensive postprocessing. These drawbacks can be addressed by using a regularized likelihood modeling approach, which is novel to the field. Therefore, we propose a model-based method, **Cl**onal structure **i**dentification through pair-wise **P**enalization, or CliP, to address these drawbacks. To evaluate the performance of CliP against other methods, we generated a benchmark dataset of 4,050 simulated samples with varied tumor purity, read depth, copy number alteration rate, and true numbers of clusters. Our results suggest that CliP outperforms popular methods such as PhyloWGS in accuracy and shows similar robustness in most scenarios. We further compared CliP performance against 10 other subclonal reconstruction methods to the consensus subclonal reconstruction results on whole-genome sequencing (WGS) data from the Pan-Cancer Analysis of Whole Genomes (PCAWG, n = 1,993). Our result shows that of all 11 methods, CliP achieves the highest correlation with the consensus calls. In terms of speed, CliP can finish running a sample with 5,000 SNVs within one minute, which is ~1,000 times faster than MCMC-based algorithms. Next, we profiled the subclonal structures of 7,711 patient samples with well-annotated clinical outcomes from The Cancer Genome Atlas (TCGA) across 32 cancer types applying CliP to the whole-exome sequencing (WES) data. This is the largest and most complete pan-cancer characterization of intratumor heterogeneity (ITH) through the lens of subclonal reconstruction. We further used CliP outputs to address a commonly asked question on which sequencing platform to use for cancer evolution studies: the cost-effect WES data at higher read depth versus the more comprehensive WGS data at lower read depth. There were a total of 588 tumor samples from 21 cancer types, for which both PCAWG and TCGA have profiled using the WGS and WES platform, respectively. Using both datasets to compare results from these samples as benchmark, we observed that for most cancer types, subclonal reconstruction from WES is as informative as that from the matched WGS data. In summary, our study represents a significant methodological advancement in subclonal reconstruction and highlights the importance of measuring tumor subclone structure.

Integration with benchmark data of paired bulk and single-cell RNA sequencing data substantially improves the accuracy of bulk tissue deconvolution

Shuai Guo[1], Xuesen Cheng[2], Andrew Koval[1], Shuangxi Ji[1], Qingnan Liang[2], Yumei Li[2], Leah A. Owen[3], Ivana K. Kim[4], John Weinstein[1], Scott Kopetz[1], John Paul Shen[1], Margaret M. DeAngelis[3], Rui Chen[2], Wenyi Wang[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX,[3]SUNY University at Buffalo, Buffalo, NY,[4]Harvard Medical School, Boston, MA*

The accuracy of current deconvolution methods largely relies on the quality of cell-type expression references. However, single-cell (sc) and single-nuclei (sn) RNA-seq data used for building the reference are usually generated from independent studies that are distinct from the bulk RNA-seq data to be deconvolved. This study design inherently introduces technical confounding factors as unwanted variations, which is not fully addressed by current methods. To evaluate the impact of this variation on deconvolution accuracy, we generated a benchmark dataset where bulk and snRNA-seq profiling were performed from the same aliquot of single-nuclei that were extracted from 24 healthy retina samples. All donor eye samples were collected within six hours post-mortem and were absent of any disease. This study design guarantees the matched sequencing data to present the same cell-

type compositions, so that cross-platform technical artifacts become the remaining confounding factor. We used the benchmark dataset to evaluate the performance of seven current deconvolution methods and found they performed much worse in matched real-bulk data than in matched pseudo-bulks that were summations of the single-cell data. This finding suggests that none of these methods have fully addressed the major technical artifacts between bulk and single-cell sequencing platforms. We therefore propose DeMix.SC, a new deconvolution framework that optimizes deconvolution parameters using a small set of matched bulk and sc/snRNA-seq data from the same tissue type. DeMix.SC includes two major steps. First, we measure the technical variations across genes and across platforms using the benchmark data. Second, we introduce a new weight function for each gene that produces a ranking order that accounts for both the platform-specific technical variations and cell-type specific expressions at gene level. Using the benchmark data for retina, we applied DeMix.SC to previously published human retinal RNA-seq data from 523 individuals with different stages of age-related macular degeneration (AMD). We observed that DeMix.SC can accurately capture the cell-type composition shifts in the AMD retina. DeMix.SC revealed a significant drop of rod cells as well as increased astrocytes, bipolar cells, and Müller cells in the AMD retina compared to the non-AMD group. The proportion changes of the later three minor cell types were not identified by other methods, while DeMix.SC could reveal such tendency. In summary, DeMix.SC integrates benchmark data to improve the deconvolution accuracy in retina samples. Our method is generic and can be applied to other disease conditions, such as deciphering the cell-type heterogeneity in cancer. We expect DeMix.SC will help revolutionize the downstream cell-type specific analysis of bulk RNA-seq data and identify cellular targets of human diseases.

Functional dissection of complex tissue microenvironment using spatial transcriptomics data

Xinyu Zhou[1], Alexander White[2], Tingbo Guo[3], Pengtao Dang[3], Yuhui Wei[2], Xiao Wang[1], Kaman So[4], Chi Zhang[4], Sha Cao[4]. *[1]Indiana University Bloomington, Bloomington, IN,[2]Indiana University, Indianapolis, IN,[3]Purdue University, Indianapolis, IN,[4]Indiana University, School of Medicine, Indianapolis, IN*

Spatial transcriptomics (ST) data holds enormous potential to provide new perspectives for biologists seeking to understand the tumor tissue microenvironments. Cells in the same microenvironment are always exposed to biochemical conditions displacing specific spatial patterns. To truly dismantle the tissue microenvironment heterogeneity as well as cells' diverse responses to the variable microenvironment, we rely on spatial information to dissect the tissue into different functional regions, which are spatially dependent and biologically meaningful.
We have developed a statistical method, smooth Low Rank approximation and Clustering (smoothLRC) to model the spatial transcriptomic data as its low-rank approximation with spatial smoothness. smoothLRC accomplishes this by extracting the latent low-rank structure of the expression profiles. We present a regularized maximum likelihood estimator approximating the noisy observed expression matrix. This estimator incorporates spatial information and addresses expression dropout. It uses a low-rank Poisson distribution to account for the noise that plagues ST-based gene expression data with severe dropout events and a spatial smoothness penalty to encourage neighboring cells to fall into the same functional region. A dropout is an event where genes expressed in a given cell or region are incorrectly measured as unexpressed.
SmoothLRC has the following key features: 1) it is a statistically rigorous method; 2) the spatially smooth low-rank subspace could enable meaningful functional dissection, which is an unprecedented capability; 3) the low-rank structures could be used to recover the original expression, saving many expression values that are not captured.

#4275

Averon: informatics platform to discover Actionable Vulnerabilities Enabled by Rewired Oncogenic Networks

Andrey A. Ivanov, Haian Fu. *Pharmacology and Chemical Biology, Emory University School of Medicine, Atlanta, GA*

Missense mutations can change protein structure, cellular localization, and functions. Such changes lead to the rewiring of protein-protein interaction (PPI) networks, activation of oncogenic pathways, and acquisition of cancer hallmarks. However, the translation of the landscape of oncogenic mutations into clinically actionable biological models for cancer target discovery remains a major challenge. We address this challenge by leveraging the power of computational systems biology supported by high-throughput screening technologies. While some mutations can disrupt the PPIs, others may induce new PPIs that are not natural for the wild-type counterparts. Recently, we have established a quantitative High Throughput differential Screening (qHT-dS) platform [1] to discover such mutant-enabled or neomorph PPIs (neoPPIs). The screening of more than 13,000 mutant interactions revealed a landscape of gain-of-interactions encompassing both oncogenic and tumor suppressor mutations. This emerging neoPPI landscape may offer new mutant-directed therapeutic approaches for precision medicine. However, to infer clinically actionable mechanistic insights into how neoPPIs promote tumorigenesis special computational tools are needed. To inform the neoPPI-based target discovery, we develop a set of innovative informatics tools for discovering Actionable Vulnerabilities Enabled by Rewired Oncogenic Networks (Averon). Implemented in a widely-used Jupyter Notebook format, the Averon streamlines the identification of the oncogenic programs and clinically significant genes that are regulated by neoPPIs in cancer patients. The Averon can recapitulate well-established connectivity between known mutant-dependent PPIs and specific oncogenic pathways and reveal new, previously unknown mechanisms of neoPPI-mediated oncogenic signaling. To inform new therapeutic strategies in neoPPI-dependent cancers, Averon connects neoPPI-regulated genes with available approved drugs and clinical compounds. Together, the Averon provides a powerful informatics environment to determine therapeutically actionable vulnerabilities created by mutant-regulated protein-protein interactions to inform new personalized therapeutic strategies in cancer.

Recovering false negatives in CRISPR fitness screens with JLOE

Merve Dede, Traver Hart. *Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX*

It is widely accepted that pooled library CRISPR-Cas9 knockout screens offer greater sensitivity and specificity than prior technologies in detecting essential genes whose disruption leads to fitness defects, a critical step in identifying candidate cancer targets. However, the assumption that CRISPR screens are saturating has been largely untested and it is still poorly understood whether possible systematic biases in CRISPR screens affect our understanding of human cell-intrinsic gene

essentiality. In the absence of a ground truth, the actual true positive, false positive and false negative rates of a typical genome-wide CRISPR-Cas9 knockout screen are still unknown. Through integrated analysis of screen data in hundreds of cancer cell lines generated by the Cancer Dependency Map, we examine some of the biases characteristic of genome-wide CRISPR-Cas9 knockout screening. With our computational modeling approaches, we estimate the true positive rate, false positive rate and show that a typical CRISPR screen has a ~20% false negative rate, in addition to library-specific false negatives. Furthermore, replicability of essential gene hits falls sharply as gene expression decreases, while cancer subtype-specific genes within a tissue show distinct profiles compared to false negatives. With our cumulative analyses across tissues, we identified an improved new set of core essential genes, which, like the previous set, can be used as a metric for the quality control of genome-wide CRISPR-Cas9 knockout screens. Our results also suggest only a small number of lineage-specific essential genes, with the overwhelming majority of genes showing overlap between related tissues and are enriched for transcription factors that define pathways of tissue differentiation. To recover false negatives in these genome- wide CRISPR knockout screens, we introduce a method called Joint Log Odds of Essentiality (JLOE), which extends fundamental concepts from our Bayesian framework of BAGEL algorithm to improve analysis across multiple cell line screens. JLOE uses information derived from previous screens to update the probability of essentiality of each screen based on prior observations. We show that JLOE selectively rescues the false negatives without an increased false discovery rate and improves screen concordance with the Sanger dataset, reducing the number of background-specific essential genes. Overall, our methods offer a significantly improved analysis of genome-wide CRISPR-Cas9 knockout screens, detecting and correcting for the previously unidentified false negatives and enhancing our identification of cancer-specific vulnerabilities as therapeutic targets.

Measuring proliferation rates of distinct tumour clones using single-cell DNA sequencing

Olivia Lucas[1], Sophie Ward[2], Rija Zaidi[1], Mark Hill[2], Emilia Lim[2], Haoran Zhai[1], Abigail Bunkum[1], Sonya Hessey[1], Michelle Dietzen[1], Andrew Rowan[2], Cristina Naceur-Lombardelli[1], Nnenna Kanu[1], Mariam Jamal-Hanjani[1], Charles Swanton[1], Simone Zaccaria[1]. *[1]Cancer Institute, University College London, London, United Kingdom,[2]Francis Crick Institute, London, United Kingdom*

Background**:**
Tumour proliferation rate is a key phenotypic feature of cancer, with higher rates linked to poorer clinical outcomes. Thus far, proliferation rates have been measured using pathological or experimental techniques on bulk tumour samples. However, while tumours are heterogeneous compositions of distinct clones with varying levels of fitness, measuring the proliferation of individual clones has not been possible to date. We hypothesise that enabling the identification of the most proliferative clones would reveal genomic hallmarks of aggressive clones, or the prediction of their potential phenotype, e.g., metastatic potential.

Methods:
We have developed SPRINTER (Single-cell Proliferation Rate Inference in Neoplasms Through Evolutionary Routes), a novel computational method to measure proliferation rates in individual tumour clones using single-cell whole-genome DNA sequencing. To assess the accuracy and power of SPRINTER, we have also developed an experimental approach to DNA sequence >18,000 single cells, accurately separated in different DNA-replication phases. We have sequenced and applied SPRINTER to >10,000 non-small cell lung cancer cells from longitudinal and metastatic tumour samples within the TRACERx study and PEACE autopsy programme. We have further analysed published data from >10,000 breast cancer cells.

Results:
We demonstrate that SPRINTER can accurately identify subpopulations of cells with different proliferation rates using relatively small numbers of cells, in contrast to previous preliminary approaches. While our estimates are concordant with previous bulk experimental studies (5-40%), we importantly have identified clonal heterogeneity in proliferation rates. Using bulk analysis, we have identified patterns of dissemination of tumour clones in non-small cell lung cancer. Integrating this with single-cell data, our results indicate that more widely disseminating tumour clones have higher proliferation rates, suggesting a link between proliferation and dissemination potential. We additionally find that clones are more proliferative in the metastatic versus the primary setting. Furthermore, we have identified high proliferation clones that may have a selective advantage in a breast tumour, and have inferred that they likely arose recently in cancer evolution.
Conclusions:
We have developed a novel method that enables accurate identification of proliferation rates of individual tumour clones using single-cell DNA sequencing data, allowing the investigation of genomic hallmarks in highly proliferative clones that might lead to higher fitness.

Transcriptome-driven combination design: A computational approach
Christina Gavazzi, Mikhail G. Grushko, Jeremy M. Goldstein, Mahta Samizadeh, Zakary Y. ElSeht, Katherine Arline. *Shepherd Therapeutics, Boston, MA*

While rational drug combination design seeks to improve patient outcomes by leveraging biological synergy, outcomes from combination trials often fail. Only 12.4% of phase 1 trials eventually achieve regulatory approval. *In vitro* evidence has provided the rationale for the drug combinations in 36.6% of phase 1 combination trials, but none of those trials progressed past phase 3 (from a study by Paller CJ et al., 2019). A review of DrugCombDB, a publicly available database of experimental synergy results, supports the idea that such outcomes are mirrored in preclinical data. Analysis of the similarity of synergy scores within indication-specific subsets of cell lines from data in a 2022 paper by Douglass, et al. show that in both breast and lung cancer, combinations predicted to be synergistic in at least one cell line from that indication failed to be synergistic in the majority of indication cell lines more than half of the time.
SHEPHERD's Gene Cluster Voting Algorithm (GCVA) was adapted to improve upon current drug combination design and anticipate transcriptome changes as the result of drug treatment. GCVA relates drug sensitivity to the transcriptome by calculating a list of biomarkers that contribute to sensitivity and resistance for specific drugs, enabling the prediction of drug sensitivity on patient transcriptomic data captured via bulk RNAseq.
Via this method, 15,137 publically available synergy data points in the Douglass paper were compared to predictions by our computational approach. For all synergy metrics contained within the dataset (ZIP, Bliss, Loewe, and HSA), the synergistic predictions made by application of GCVA have significantly higher synergy scores compared to the antagonistic predictions made by GCVA ($p < .001$). These test results support the potential for the application of GCVA to intelligent combination design with the ultimate goal of deployment on a patient-by-patient basis.In addition, analysis of GCVA's drug efficacy predictions for the cell line DU145 showed that treatment with 9 kinase inhibitors consistently potentiated the predicted efficacy of between 5 and 11 additional drugs. Dasatinib, temsirolimus, and cabozantinib were newly predicted effective after treatment with each and every kinase inhibitor. This data suggests an avenue for the design of intelligent drug combinations based on anticipated transcriptomic changes that may improve on existing synergy prediction methods.

#4279

Method for identifying microsatellite instability high DNA abnormality samples

Dilmi Perera, Sahand Khakabi, Ka Mun Nip, Sonal Brahmbatt, Adrian Kense, Kevin Tam, David Mulder, Melissa McConechy, David Huntsman, Ruth Miller, Rosalía Aguirre-Hernández. *Imagia Canexia Health, Vancouver, BC, Canada*

Introduct**ion:** Tissue samples with high microsatellite instability (MSI-H) can be indicators of cancerous tumors that are sensitive to certain types of cancer treatments (e.g., immune modulation-checkpoint inhibitor treatment). MSI-H regions can be identified with Polymerase Chain Reaction (PCR) based assays and next-generation sequencing (NGS). However, these MS regions are susceptible to PCR and sequencing errors. We developed a computational method for detecting microsatellite instability high (MSI-H) tumors using next-generation sequencing (NGS) data to accurately identify true MSI-H samples from MS-Stable samples based on an analysis of these MS regions.

Methods: We developed a method for classifying a tissue sample as being microsatellite instability high (MSI-H) without using normal tissue from the same person which doubles the sequencing cost. Furthermore, the algorithm was designed for amplicon targeted assays where it is not always feasible to choose the most predictive MS sites. The machine learning classifier (ML) algorithm is a random forest algorithm with a training set of known MSI-H and MS-Stable samples to learn the relationship between the MSI status and the distribution of repeats in microsatellite regions of genomes using 21 MS loci. A negative control was used to normalize the ML features and therefore reduce the effects of PCR and sequencing errors in noisy MS sites.

Results: The MSI detection algorithm was validated in analytical and clinical samples achieving an accuracy greater than 98%. Analytical samples consist of commercial reference standard samples and well characterized FFPE treated cell-lines. Clinical samples consists of clinical FFPE tumor samples from cancer patients that were orthogonally validated using immunohistochemistry (expression of mismatch repair genes, i.e., MMRnormal vs MMRd) on tumor tissue and/or the Promega MSI PCR using matched tumor/normal. All experiments were performed in the Imagia Canexia Health CAP, CLIA, DAP certified laboratory using the Find It assay standard operating procedures for detecting genomic mutations in solid tumor tissue.

Conclusions: The MSI detection algorithm can accurately identify samples with MSI-H tumors. When used in a clinical setting, these patients can then be directed to treatments such as immune-checkpoint inhibitors.

Automatic identification of cancer cell-cell interfaces at the pixel level

Jie Zhou, Jan Martinek, Zichao Liu, Ali Foroughi pour, Te-Chia Wu, Santhosh Sivajothi, Paul Robson, Karolina Palucka, Jeffrey Hsu-Min Chuang. *The Jackson Laboratory for Genomic Medicine, Farmington, CT*

Deciphering cell-cell interactions is critical for understanding the role of the tumor immune microenvironment. Although multiplex imaging methods are increasingly used for spatial characterization of cell communities and tissue morphologies, quantification of the interface between contacting cells has been mostly unexplored. Here we design an unsupervised pixel-level clustering method that accurately detects the contacting interface between cells. First, we observed pixel-level clusters with cell type specific phenotypes including tumor, immune infiltrates and extracellular structures in two independent melanoma datasets using cytometry time-of-flight (CyTOF) imaging mass cytometry (IMC) images. More importantly, our pixel-level approach identified clusters with mixed phenotypes, which are demonstrated to be direct contacts between T

cells and myeloid cells. Specifically, pixels in the interface clusters simultaneously express T cell ($CD3^+$, $CD4^+$ or $CD8^+$) and myeloid cell ($CD68^+$) phenotypic markers at comparable levels. Spatial mapping of the pixels in interface clusters shows that interface pixels are in the physical contact regions between T cells and myeloid cells. In addition, the abundance of T cell and myeloid cell interface clusters is correlated with positive response to immune checkpoint inhibitors (ICIs) ($p<0.05$). We also identified other clusters indicating interfaces between the stroma, tumor cells, and immune infiltrates. Our work enables reliable delineation of cell interactions at high resolution, and therefore can unravel new information about how cancer cells interact with their environment.

Data driven refinement of gene signatures for enrichment analysis and cell state characterization

Alexander T. Wenzel, Pablo Tamayo, Jill P. Mesirov. *UC San Diego, San Diego, CA*

The use of gene expression data has been crucial to the functional characterization of changes in molecular pathway activity and for identifying targets for novel treatments. However, the interpretation of this data is complicated by its high dimensionality and the difficulty of identifying biological signals within a list of differentially expressed genes. Gene Set Enrichment Analysis (GSEA) is a standard method for identifying pathway enrichment in gene expression data by testing whether a set of genes whose expression would indicate the activity of a specific process or phenotype are coordinately up- or downregulated more than would be expected by chance. As GSEA relies on high quality gene sets with coordinately regulated member genes, we maintain the Molecular Signatures Database (MSigDB) which contains 9 collections of curated gene sets representing different biological pathways and processes. Over time, we have observed that some of the MSigDB gene sets, especially those that are manually curated or defined in a very specific biological context, may not provide a sensitive and specific enough co-regulation signature. In response, we have created a data-driven, matrix-factorization-based refinement method to build more sensitive and specific gene sets. This method incorporates large-scale datasets from multiple sources such as the Cancer Dependency Map as well as curated protein-protein interaction networks. We will present the initial results of this refinement method and our ongoing work which will yield a new collection of refined gene sets that will be made freely available in MSigDB for use with GSEA and many other applications.

Total RNA sequencing of frozen biopsies combined to *k*-mer sequence analysis identify new hallmarks of immune checkpoint therapy response in melanoma

Hugues Hermann[1], Séverine Roy[2], Sandrine Agoussi[1], Emilie Routier[3], Céline Boutros[3], Djaouida Belkadi[3], Haoliang Xue[4], Antoine Lainé[4], Stephan Vagner[5], Daniel Gautheret[4], Caroline Robert[6].
[1]INSERM U981, Gustave Roussy, Villejuif, France,[2]INSERM U981 & Department of Cancer Medicine, Gustave Roussy, Villejuif, France,[3]Department of Cancer Medicine, Gustave Roussy, Villejuif, France,[4]Institute for Integrative Biology of the Cell (I2BC), Université Paris-Saclay, CNRS, CEA, Université Paris-Saclay, Gif-sur-Yvette, France,[5]CNRS UMR3348 & INSERM U1278, Curie Institute, Orsay, France,[6]INSERM U981 & Department of Cancer Medicine, Gustave Roussy & Paris Saclay University, Villejuif, France

Introduction: Predicting response to immune checkpoint inhibitors (ICI) is key for stratifying patients and identifying factors of resistance. The main recognized ICI response biomarkers in melanoma are T-cell gene expression signatures, PD-L1 expression and tumor clonal mutational

burden, all of which are specific of responding tumors but nevertheless not robust enough to guide therapeutic strategies. Biomarkers of progression (eg. TGF-B) are scarce and inconsistent across studies. All current gene expression-based biomarkers of ICT-response are based on formalin-Fixed paraffin-embedded (FFPE) samples, sequenced using RNA capture or polyA+ libraries. This technique is known to incompletely represent RNA populations.
Patients, Material, Methods: Here we introduce the first total RNA-seq dataset from fresh frozen biopsies collected from 80 advanced melanoma patients, prior to treatment with anti PD-1 or combined anti-PD-1/anti-CTA4 therapy. The cohort included 43 responders and 37 non-responders based on RECIST best objective response. To ensure all possible RNA biomarkers are captured, we applied a k-mer based computational protocol that extracts all subsequences of fixed size (31 nt) from the raw RNA-seq reads and performs differential expression statistics on k-mers. This identifies response-specific RNA sequences independently of annotated genes, enabling identification of novel RNAs and RNA isoforms.
Results: In responding patients, this analysis identified a large number of immunoglobulin and HLA mRNA fragments, consistent with an immune-active microenvironment. However, the most remarkable finding was the specific expression in non-responding tumors of centromeric satellite repeats (HSAT-II and ALR elements) and of a set of intergenic loci which independently described the progressor population. Altogether, total RNA-seq biomarkers were found in most non-responding patients, providing the basis for a strong predictor of resistance. This contrasted with results in FFPE/capture seq data that showed few notable k-mers in the progressor group, due to the incomplete RNA sequencing. Our approach revealed a number of other unexpected markers, including a set of circular RNAs in responders and a mutant of the PRAME tumor-specific antigen in progressors. Our main finding is that the combination of frozen sample conservation and total (ribodepleted) RNA sequencing reveals a unique source of non-coding RNAs produced from pervasive transcription of intergenic and repeated regions, likely associated to chromatin derepression, that are not detected by the usual FFPE/capture seq methods.
Conclusion: We argue that these novel RNA sequences will be instrumental in the development of improved ICI-response predictors and a better understanding of resistance to ICI.

scMSI: Accurately detect the sub-clonal micro-satellite instability by an integrative Bayesian model

Yuqian Liu[1], Yan Chen[1], Huanwen Wu[2], Xuanping Zhang[1], Xin Lai[1], Xin Yi[3], Zhiyong Liang[2], Jiayin Wang[1]. *[1]Xi'an Jiaotong University, Xi'an, China,[2]Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[3]Geneplus Beijing Institute, Beijing, China*

Microsatellite instability (MSI) is an important genomic biomarker for cancer diagnosis and treatment. For some cancers with high-degree of heterogeneity, e.g. endometrial cancer, the existing approaches always fail to identify the micro-satellite instability on one or multiple sub-clones, which would deprive the chance for patients to benefit from treatments. However, it is a computational challenge to estimate the sub-clonal MSI because multiple sub-clones may share the genomic status. Herein, in this paper, we propose an accurate and efficient algorithm, named scMSI, to estimate the sub-clonal microsatellite status. scMSI adopts an alternating iterative model to de-convolute the length distribution, which is a mixture of sub-clones. During the deconvolution, an optimized division of each sub-clone is achieved by a heuristic algorithm, which is bounded to the clonal proportions best consistent with the known clonal structure. To evaluate the performance, we conducted a series of experiments on simulation datasets. The results supported that scMSI solved the detection problem of MSI on sub-clones. It outperforms the existing approaches on multiple metrics. In addition, we collected a cohort of 16 endometrial cancer patients, who have positive

responses on the treatment but with negative MSI status. We sequenced these patients. scMSI reported MSI on sub-clones according the sequencing data, which are further validated by the conclusions on immunohistochemistry. Thus, scMSI could provide a powerful tool for MSI analysis.

Enhancing subclonal reconstruction algorithm for resolving complex tumor phylogenies from multi-sample tumor DNA sequencing

Helena Winata[1], Daniel Knight[1], Juber A. Patel[2], Nicholas K. Wang[1], Pier Selenica[2], Stefan E. Eng[1], Caroline Kostrzewa[2], Jaron Arbet[1], Yingjie Zhu[2], Ronglai Shen[2], Jorge Reis-Filho[2], Pedram Razafi[2], Paul C. Boutros[1]. *[1]UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA,[2]Memorial Sloan Kettering, New York, NY*

Cancer is characterized by the ongoing accumulation of somatic mutations, providing selective advantages that may lead to dysregulated cellular proliferation. While the cancer genome at diagnosis has been extensively studied, many cancer types still lack strong prognostic biomarkers. The continuous acquisition and selection for driver mutations in a population of cancer cells acts as a Darwinian process, resulting in clonal expansions of progressively more aberrant and fit phenotypes. Reconstructing tumor evolution allows us to understand key events that drive cancer progression and patterns of mutation co-occurrence within clones. These evolutionary features guide our understanding of fundamental mechanisms that lead to disease lethality. Inferring tumor evolution from DNA sequencing data is becoming part of routine analysis in cancer research. As sequencing costs drop, sequencing multiple tumor samples from a patient becomes routine. These multiple samples can represent different spatial regions of a tumor, longitudinal samples from a single region or a combination of both. This provides an opportunity to study tumor evolution in much greater detail and accuracy than was previously feasible through single-sample datasets. The most widely used methods to reconstruct the subclonal evolution of a tumor utilize stochastic-search algorithms. These approaches iterate through a parameter space to select phylogenetic solutions that maximize the likelihood of observed sequencing data. They are optimized for low complexity cases, where the size and number or subclones are relatively limited. As tumor subclonal structure increases in complexity, the parameter space grows exponentially, and stochastic-search algorithms become computationally intractable. For instance, recent benchmarking studies have revealed that many methods fail to reconstruct clone trees for data with as few as ten subclones. To circumvent current computational limitations, we developed a deterministic algorithm for subclonal reconstruction that leverages fundamental principles of cancer biology to encode heuristics that reduce the solution space to biologically plausible phylogenies. When applied to samples (4-36 tumors; median 16) from 12 patients with metastatic breast cancer, our method reduced the average runtime ten-fold. We were able to delineate the evolutionary history of up to 57 distinct subclones per patient, which is infeasible with most current methods. Benchmarking using methods developed for the SMCHet DREAM challenge on real and simulated datasets further quantifies the accuracy, resolution, and scalability. We have thus presented a novel method for rapid and optimized reconstruction of tumor evolutionary histories.

#4286

A statistical learning method for simultaneous copy number estimation and subclone clustering with single cell sequencing data

Feifei Xiao[1], Fei Qin[2], Guoshuai Cai[2]. *[1]University of Florida, Gainesville, FL,[2]University of South Carolina, Columbia, SC*

The availability of single cell sequencing (SCS) enables us to assess intra-tumor heterogeneity and identify cellular subclones without the confounding effect from mixed cells. Copy number aberrations (CNAs) have been commonly used to identify subclones in SCS data since cells comprising a subpopulation are found to share genetic profile. However, currently available methods may generate spurious results (e.g., falsely identified CNAs) in the procedure of CNA detection, hence diminishing the accuracy of subclones identification from a large complex cell population. In this study, we developed a CNA detection method based on a fused lasso model, referred to as FLCNA, which can simultaneously identify subclones in single cell DNA sequencing (scDNA-seq) data. Spike-in simulations were conducted to evaluate the clustering and CNA detection performance of FLCNA benchmarking to existing copy number estimation methods (SCOPE, HMMcopy) in combination with commonly used clustering methods. FLCNA was also applied to a real scDNA-seq dataset with breast cancer and clusters identified using FLCNA showed clearly different genomic variation patterns. In conclusion, FLCNA provided superior performance in subclone identification and CNA detection with scDNA-seq data.

#4287

The combination of statistical methods to compare observed and simulated data allowed to assess effectively the validity of mathematical model predictions in a context of a EGFR+ lung adenocarcinoma

Evgueni Jacob, Laura Villain, Nicoletta Ceres, Jean-Louis Palgen, Adele L'Hostis, Claudio Monteiro, Riad Kahoul. *NOVADISCOVERY, Lyon, France*

Introduction

In silico models proved to be a promising tool to complement and optimize clinical trials. These models should be validated to assess their capacity to reproduce real life behaviors. Opposed to real-life clinical trials where the amount of available data might be low, in silico approaches give us the possibility to simulate virtual populations of thousands of patients. This data size heterogeneity might be an issue. Moreover, in real life data, patients are seen at scheduled visits, leading to an observation time uncertainty (OTU), which is not the case in simulated data.In the context of the validation of a EGFR-mutant Lung Adenocarcinoma mathematical model, we depicted the interest of using combined validation methods to assess the capacity of the model to predict the time to tumor progression, from heterogeneous clinical trials datasets.

Methods

In this context, to overcome the limitation of using default log-rank test that could lead to biased results, 4 bootstrapped methods have been used:

- 2 methods based on the log-rank test where the ratio of significant tests at a given alpha risk level is assessed, taking into account the OTU: The “default Log-rank test” and the “modified test” based on a combination of weighted log-rank tests (MaxCombo).
- 2 methods based on prediction intervals. The “raw coverage”, which corresponds to the proportion of the observed time-to-event curve included in the prediction interval and the “juncture metric” which corresponds to the proportion of the observation period where the prediction interval overlaps with an interval bound between the observed data and the same data shifted by the OTU.

Results

As each one of the validation approaches has its own strengths and weaknesses and conditions of application, the validation process has been based on the combination of well selected methods. Validation metrics showed that the model reproduces successfully real life data depending on a given context. When all the metrics give the same result, we were able to easily conclude. But when it was not the case, this led us to investigate the origin of these discrepancies, taking into account method robustness.

Conclusion
The validation process is of the utmost importance to assess the level of credibility of the model. We showed that in order to fully evaluate the model, a combination of validation approaches is preferable. The use of multiple metrics highlights the eventual inconsistencies in model predictions and validation dataset's content that would not have been detected by only a single approach.
The drawback of combining metrics is that it complexifies the decision making, implying that the final decision, regarding whether the model is validated or not, is assumed by the user, without forgetting that the validation is not an end objective per se but a stepwise process.

Predicting DNA methylation in cervical cancer using somatic mutations in a classified mixed model prediction

Jairo D. Ramos[1], J. Sunil Rao[2]. *[1]Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL,[2]Public Health Sciences - Division of Biostatistics, University of Miami, Miami, FL*

In cervical cancer, the promoter CpG islands of several tumor suppressor genes have been found with abnormal DNA methylation (DNAm) levels, which results in transcriptional silencing. Genetic databases from tumor samples are available without the corresponding DNAm profile. To fulfill this gap and contribute to deciphering the link between genetic variants and DNAm, we performed this study to find a good statistical model for predicting DNAm using genetic data. To address this, we downloaded from the TCGA dataset the genes with significant somatic mutations, as reported by the BROAD Institute, and the DNAm beta values, in known CpG sites, from 307 Cervical Squamous Cell Carcinoma and Endocervical Adenocarcinoma (CESC) samples. Clinical data were also downloaded from patients, including race, age, gender, and cancer stage. We tested five mixed models containing both fixed and random effects to include the unmeasured source of variations in DNAm, for which we used the clustering of samples based on DNAm patterns. Models tested were: Classified mixed model prediction (CMMP), Linear regression model (LM), High dimensional shrinkage estimator based on the elastic net (ENET), a combination of CMMP - ENET, and Random Forest prediction (RF). Besides the significantly mutated genes, the clinical variables were also included as covariates to predict DNAm. We used shared random effects to borrow strength across racial groups, which improves predictive accuracy. Models were enhanced by combining other types of cancers to increase data heterogeneity and the number of samples. Lung Adenocarcinoma (LUAD) and Liver Hepatocellular Carcinoma (LIHC) were selected using Gini and Gap statistics for optimal clustering. Model fitting was evaluated using the average mean squared prediction error (MSPE). Results revealed that the CMMP model with CESC LIHC and LUAD data combined showed the best prediction results (lowest MSPE). The plot of the averaged estimated ENET coefficients indicated that the most important-significantly mutated genes to predict DNAm were *CTNNB1*, *DMD, XIRP2, and PIK3CA*. SNPs in these genes linked to cervical cancer include rs121913396, rs121913403 (*CTNNB1*), rs867262025, and rs121913279 (*PIK3CA*).In summary, we developed a mixed-effects model for accurately predicting DNAm levels in cervical cancer, using genes with significant somatic mutations (SNVs and INDELs). These results also align with growing evidence suggesting that genetic variation plays a role in DNAm.

Long-read, assembly-based characterization of rearranged cancer karyotypes

Ayse Keskus[1], Tanveer Ahmad[1], Ataberk Donmez[1], Yi Xie[2], Isabel Rodriguez[2], Rose Milano[2], Nicole Rossi[2], Hong Lou[3], Laksh Malik[4], Kimberley Billingsley[5], Cornelis Blauwendraat[5], Michael Dean[2], Mikhail Kolmogorov[1]. *[1]Center for Cancer Research, National Cancer Institute, NCI,*

Bethesda, MD,[2]Division of Cancer Epidemiology and Genetics, National Cancer Institute, NCI, Rockville, MD,[3]Leidos Biomedical Research, National Laboratory for Cancer Research, Frederick, MD,[4]Center for Alzheimer's and Related Demetias, National Institutes of Health, Bethesda, MD,[5]Center for Alzheimer's and Related Dementias, National Institutes of Health, Bethesda, MD

Introduction: Recent pan-cancer whole-genome sequencing studies revealed the rich landscape of structural variants (SV), from simpler indels to complex events involving multiple breakpoints and sequence gain/loss. SVs may contribute to tumorigenesis through direct modification of coding sequence or deregulation from copy number alterations, enhancer hijacking, or topological domain modification.
A substantial part of the variation in the human genome is not accessible to short reads due to mapping ambiguities. Recent benchmarking studies reported that the best short-read methods only have 30-70% SV sensitivity. Long-read sequencing (such as PacBio or Oxford Nanopore) can overcome the limitations of short reads, however the current methods were not designed for the analysis of rearranged cancer genomes with complex copy number profiles.
Methods: We developed BGA (Breakpoint Graph Assembler), a method that combines the ideas from long-read assembly and breakpoint graph frameworks. BGA detects abnormally mapped reads and builds a breakpoint graph that characterizes the structure of derived cancer karyotypes. Complex events with multiple breakpoints form connectivity clusters and are classified based on the subgraph properties. BGA also takes advantage of phased haplotypes and can incorporate multiple related datasets (such as in tumor-normal comparison or multi-site tumor sampling). BGA is freely available at: *https://github.com/KolmogorovLab/BGA*.
Results: We first analyzed three cancer cell lines and corresponding matching normal DNAs (HCC1954, H2009, and COLO829). In each cell line, we identified 8-56 somatic rearrangement clusters involving more than two breakpoints and at least 1kb of sequence. In H2009, we identified a chromoplexy event involving chr13 and chr1, consistent with previous FISH experiments. COLO829 showed the lowest number of somatic rearrangement clusters (n=8), including translocation and inversion events between chr3, chr10, and chr12 within the *RARB*, *BICC1*, and *TRHDE* genes. Homologous recombination deficient HCC1954 has the highest number of complex events including the chr17q arm which hosts ERBB2, chromoplexy between chr8, chr5, and chromothripsis in chr21.
In addition, we analyzed three other HPV-infected cell lines (CaSki, SCC152, SNU1000). In each of them, we observed complex clusters of HPV-HPV and HPV-human breakpoints that formed cycles, suggesting extrachromosomal amplification. The HPV fragments had many interactions with chromosomal DNA in CaSki and SC152, but not in mostly episomal SNU1000 cells. We also observed karyotype-scale changes that did not involve HPV sequences, such as the simultaneous exchange of six chromosome arms of chr2, chr7, and chr17 in CaSki.

ReCorDE: A novel computational framework to discover potential combinations of anti-cancer drugs

Emily T. Ghose[1], August John[1], Huanyao Gao[2], Krishna R. Kalari[2], Liewei Wang[2]. *[1]Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN,[2]Mayo Clinic, Rochester, MN*

Background**:** Cancer is usually treated with a combination of drugs rather than a single agent. Treating cancer with a drug combination decreases the likelihood of the cancer acquiring resistance to therapy. It also allows for lower dosages of individual drugs, which reduces the occurrence and severity of side effects. Using public datasets, we investigated potential anti-cancer drug

combinations using a novel framework, ReCorDE (Recurrent Correlation of Drugs with Enrichment), which identifies correlated drug response patterns for drugs with different primary mechanisms of action.
Methods: 250 drugs from CTRPv2, GDSCv2, and PRISM datasets were examined using normalized logIC50 or AUC measurements. ReCorDE consists of a correlation and an enrichment step. For each dataset, we constructed pairwise drug-drug relationships using Spearman's correlation. Combinations significant ($p < 0.05$) in less than two datasets after Benjamini-Hochberg (BH) correction were pruned. To turn each drug combination into a drug class combination, all drugs were mapped to their corresponding fourth-level Anatomical Therapeutic Chemical (ATC) codes. Then, using a hypergeometric test, for each class combination in the subset of significant drug combinations (the "inside" set), we tested for enrichment of that class combination in the inside set compared to the class combination universe, the distribution of class combinations for all unique pairwise drug-drug associations (250 unique drugs; 31,125 distinct drug combinations mapped to 1596 distinct class combinations). Multiple testing during enrichment was corrected using the BH method with a significance cutoff of $p< 0.05$.
Results: We found 2764 pairs to be significant at $a = 0.05$ using the AUC measure. With a correlation coefficient of 0.77, vincristine and YK-4-279, an EWS-FLI1/RNA Helicase A inhibitor, had the lowest computed p-value of of 1.39×10^{-120}. Adjusted p-values for >15% of these combinations had p-values $< 5 \times 10^{-6}$. Class combination enrichment on the same set showed 132 class pairs were enriched in the inside set compared to the class combination universe after BH correction. Taxanes/Plk1 inhibitors (OR = 69.5, adjusted $p = 5.6 \times 10^{-11}$); Aurora Kinase inhibitors/histone modifying agents (OR=9.2, adjusted $p = 6.13 \times 10^{-11}$); and pyrimidine analogues/CDK inhibitors (OR=3.43, adjusted $p = 0.02$) are a few notable enriched class combinations. The enrichment of these class combinations in the inside set suggests that combinations of drugs from these classes may be particularly effective in treating cancer compared to other drug combinations.
Conclusions: Our framework, ReCorDE, demonstrates that finding potential drug combinations and characterizing novel, frequently perturbed pathways outside of a drug's primary mechanisms of action can be accomplished by identifying correlated drug-drug pairs from large, publicly accessible databases.

Deconvolution of cell type composition in FFPE tissue: Application to benign breast disease
Yuanhang Liu[1], Chen Wang[1], Stacey J. Winham[1], Aditya Bhagwate[1], Robert A. Vierkant[1], Julie M. Cunningham[1], Bryan M. McCauley[1], William A. Jons[1], Derek C. Radisky[2], Amy C. Degnim[1].
[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Jacksonville, FL

Purpose: Benign breast disease (BBD) is viewed as a non-obligate precursor stage in the development of breast cancer (BC). Transcriptome profiling using RNA sequencing (RNA-seq) of bulk formalin-fixed paraffin-embedded (FFPE) tissue blocks has been routinely used in BC research. However, RNA-seq of heterogeneous bulk samples represents an averaged expression profile across all cell mixtures. Downstream analyses, such as biomarker discovery, are likely confounded by differences in cell proportions. There is a lack of research in optimizing strategies for cell type deconvolution especially for FFPE samples. We evaluated and optimized strategies for cell type deconvolution using existing single cell RNA-seq (scRNA-seq) and single nucleus RNA-seq (snRNA-seq) breast tissue references, and applied these to a cohort of BBD FFPE samples to assess risk of subsequent BC.

Methods: 7 scRNA-seq and 3 snRNA-seq public samples from women's breast tissue were normalized using SCTransform, then integrated using Harmony to form a complete reference set. Bioinformatics evaluations examined the performance of existing statistical and deep learning-based deconvolution methods. Computational simulations were conducted to evaluate those methods on three scenarios: 1) baseline; 2) incomplete reference set; 3) FFPE artifacts. FFPE artifacts were simulated based on a generalized additive model using 7 in-house paired FFPE-fresh frozen samples. Finally, we applied the best performing method to our BBD cohort of 62 samples. Differential expression analysis adjusting for cell proportions was performed to identify transcriptomic aberrations in BBD cases.
Results: snRNA-seq was more sensitive in capturing adipocytes, while scRNA-seq was more sensitive in detecting lymphocytes in breast tissue. The median number of detectable genes per cell was higher for scRNA-seq than snRNA-seq before integration (1264 vs 558). Marker gene-based regression methods (e.g. CIBERSORT) displayed higher variance and lower bias compared to methods directly using scRNA-seq data (e.g. SCDC). Incomplete reference data led to increased bias and little effect on variance. FFPE artifacts had a higher impact on performance compared to incomplete reference data. Overall, Scaden, a deep learning-based method, was the top performing method across all simulation scenarios and was especially robust to FFPE artifacts. 59 differential expressed genes (DEGs) were identified with fold change > 1.5 and p value < 0.01. DEGs involved in BC, e.g. S100A8, WNT4 and HIST1H3H, would be left out if cell proportions were not properly adjusted.
Conclusions: We constructed the first complete single cell reference data for women's breast tissue and benchmarked existing cell type deconvolution methods. Compared to analyses not adjusting for cell proportions, we observed substantial differences in perturbed genes and pathways associated with BC risk for BBD patients.

Gene model correction for PVRIG and TIGIT in single cell sequencing data enables accurate detection and study of its functional relevance

Sergey Nemzer[1], Niv Sabath[1], Assaf Wool[1], Zoya Altber[1], Hirofumi Ando[2], Drew M. Pardoll[2], Sudipto Ganguly[2], Yaron Turpaz[1], Zurit Levine[1], Roy Z. Granit[1]. *[1]Computational Discovery, Compugen Ltd., Holon, Israel,[2]Bloomberg-Kimmel Institute for Cancer Immunotherapy, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Single cell RNA sequencing (scRNA-seq) has gained increased popularity in recent years and has revolutionized the study of cell populations; however, this technology presents several caveats regarding specific gene expression measurement. Here we examine the expression levels of several immune checkpoint genes, which are currently assessed in clinical studies. We find that unlike in most bulk sequencing studies, PVRIG and murine TIGIT suffers from poor detection in 10x Chromium scRNA-seq and other types of assays that utilize the GENCODE gene model. We show that the default GENCODE gene model, typically used in the analysis of such data, is incorrect in the PVRIG genomic region and contains also a predicted read-through transcript to which PVRIG reads co-align, causing these to be discarded and hence hindering its proper detection. Moreover, we find that the murine TIGIT 3' UTR is mis-annotated, leading to the loss of legitimate reads. We thus generated a corrected reference genome, by removing the faulty read-through in the case of PVRIG and by extending the TIGIT 3' UTR and demonstrate that by employing these changes we can correctly capture genuine expression levels of these checkpoints, and which align with our findings at the protein level using FACS and CITEseq. Furthermore, we show that specialized read multimap algorithms such as RSEM and STARsolo can also partially improve the detection of PVRIG. Our

study provides means to better interrogate the expression of PVRIG and murine TIGIT in scRNA-seq and emphasize the importance of optimizing gene models and alignment algorithms to enable accurate gene expression measurement in scRNA-seq and bulk sequencing. Moreover, our results support detailed study of the expression of immune checkpoints in clinical and pre-clinical studies towards the development of cancer immunotherapy treatments.

Strategies and resources for applying a quantitative multiplex IHC imaging workflow to characterize immune contexture in solid tumors

Shamilene Sivagnanam, Courtney M. Betts, Nell Kirchberger, Konjit Betre, Lisa M. Coussens. *Cell, Developmental and Cancer Biology, OHSU Knight Cancer Institute, Portland, OR*

Conventional immunohistochemistry (IHC) is a standardized diagnostic technique used in tissue pathology. However, the capacity to label only one marker per tissue section is a critical limitation. Multiplex immunohistochemistry (mIHC) is a powerful imaging technique used in basic, translational research and clinical settings to simultaneously detect the expression of multiple epitopes in a single formalin-fixed paraffin-embedded (FFPE) tissue section, allowing for characterization and quantification of cells while maintaining their spatial location. This technique allows for a comprehensive view of the immune milieu, expression patterns, and interactions between cell types that can help elucidate the complexity of the tumor-immune microenvironment (TiME). Multiplex imaging has emerged as a powerful tool to better understand tumor progression, response or resistance to therapy, and potentially identify predictive biomarkers. However, this technique requires careful tissue considerations and generates enormous amounts of hierarchical data, including single cell marker expressions, locations, and shape features, resulting in complex and challenging analyses. We previously published a validated platform using nine matched primary and recurrent head and neck squamous cell carcinoma (HNSCC) sections stained sequentially with a panel of 29 antibodies identifying malignant tumor cells, and 17 distinct leukocyte lineages and their functional states[1]. Here, we have optimized and consolidated important considerations, including tissue quality and QC steps necessary for generating high quality data from multiplex imaging studies. We demonstrate strategies for a streamline analytic pipeline using our quantitative workflow developed to characterize immune cells and infiltration patterns within spatial compartments of solid tumors in FFPE tissues, and herein, provide strategies and resources to practically adapt and utilize our analytic mIHC pipeline.

Bridging the gap between targeted NGS and FISH gene-level CNV detection capabilities in hematologic malignancies

Christophe N. Magnan[1], Hyunjun Nam[2], Shashikant Kulkarni[3], Segun C. Jung[4]. *[1]NeoGenomics Laboratories, Carlsbad, CA,[2]NeoGenomics Laboratories, San Diego, CA,[3]NeoGenomics Laboratories, Houston, TX,[4]NeoGenomics Laboratories, Aliso Viejo, CA*

Background: Copy Number Variations (CNVs) are prominent features of cancer cells. From a clinical standpoint, their accurate detection at a low cost is a priority. With regular increases in the number of markers to be tested, the cost effectiveness and practicality of gold standard techniques like Fluorescence In Situ Hybridization (FISH) are slowly decreasing. Cost-efficient Next Generation Sequencing (NGS) targeted gene panels can be scaled up but accurately detecting CNVs from the resulting data remains challenging. We demonstrate large amounts of data and machine learning can help bridge the gap between the two techniques.

Methods: We collected the sequencing data of 6,277 patients tested using a custom amplicon based NGS assay designed to detect somatic alterations in 297 hematological cancer relevant genes such that at least one concurrent FISH test was also performed. FISH results were used to infer the gain, loss, or normality information for each corresponding gene. The annotated genes were then used to curate a training set by extracting 20 features per gene from the alignment results. A 3-class random forest classifier was trained using this dataset. The selected model was evaluated on a distinct set of 2,738 patients.
Results: Evaluation results are provided in Table 1 for 8 genes for which the FISH probe used to infer the gain, loss, or normality information directly spanned the gene region. The predicted CNVs are almost a perfect match with FISH for 6 of these genes with a limit of detection at 20% abnormal cells. In most cases, the model reduces discordant calls by over 50% compared to using existing CNV detection software only.
Conclusion: We show the CNV detection capabilities of a targeted NGS assay can closely match the gold-standard FISH technique by analytically correcting the biases introduced by the targeting procedures. The model presented here is used to detect CNVs in ALL patients after a successful formal validation in our laboratory.

Table 1: Evaluation results.

Streamlining the reconstruction of subclonal evolution in DNA sequencing data

Gage Black, Yi Qiao, Xiaomeng Huang, Gabor Marth. *Human Genetics, University of Utah, Salt Lake City, UT*

In many cancer types, the evolution of subclonal malignant cells leads to a diverse tumor population that can affect treatment efficacy. In addition, evolution throughout treatment can lead to resistant subclonal populations and eventual relapse. To effectively treat these cancers, it is essential to understand the subclonal architecture of the tumor, including the somatic mutations that differentiate each population. Many tools have been developed to attempt to cluster mutations or reconstruct the clonal architecture of a given tumor sample. However, few can accommodate multiple samples, which is common in longitudinal or metastasis studies. In addition, these tools typically focus on just one of the steps necessary for a full analysis (e.g., variant clustering, subclone hierarchical tree reconstruction, and tree visualization). Many require non-standard data formats, necessitating data format conversion between each step. These requirements make it very challenging for investigators without a deep understanding of each tool to perform a full subclonal analysis. To make the

identification of temporal and spatial heterogeneity more streamlined and accessible to analysts with basic programming knowledge, we have developed a pipeline that takes somatic mutations in standard VCF file format as input and produces meaningful results that are easy to interpret. Variant data is extracted and formatted for the input to PyClone-VI (Gillis and Roth, 2020), which is used to cluster somatic variants based on their allele frequencies at each time point. SuperSeeker, an improvement on the SubcloneSeeker method developed within our lab (Qiao et al., 2014), implements advanced tumor subclone reconstruction algorithms to jointly analyze multiple samples and construct hierarchical trees that account for all subclones observed in a patient. A sample trace, or the cellular fraction of each subclone found in each sample, is also provided. The output of SuperSeeker is an updated VCF file with the tree and sample trace information added to the header. Finally, a GraphViz rendering of the hierarchical tree is made for easy visualization. In addition to this rendering, the final VCF file can also be used for interactive analysis and visualization of the results using our Oncogene.iobio web tool. This pipeline makes identifying temporal and spatial heterogeneity more efficient, requiring only standard file types as input, and basic command line knowledge. In a recently published study, we investigated subclonal evolution in 38 patients with CLL being treated with a BTKi. The initial subclonal architecture analysis for each patient in this study was laborious and time intensive. Using this pipeline, we can now identify subclonal evolution in these patients and create an interactive visualization more efficiently. This approach can streamline analyses, increase efficiency, and lead to a deeper understanding of a tumor's subclonal evolution.

Fast de novo antibody structure prediction with atomic accuracy

Yining Wang, Xumeng Gong, Shaochuan Li, Bing Yang, Yiwu Sun, Yujie Luo, Hui Li, Le Song.
BioMap, Beijing, China

Background: In the field of antibody engineering, an essential task is to design a novel antibody whose paratopes bind to a specific antigen with correct epitopes. Understanding antibody structure and its paratope can facilitate a mechanistic understanding of its function. Therefore, antibody structure prediction from its sequence alone has always been a highly valuable problem for de novo antibody design. AlphaFold2 (AF2), a breakthrough in the field of structural biology, provides a solution to this protein structure prediction problem by learning a deep learning model. However, the computational efficiency and undesirable prediction accuracy on antibody, especially on the complementarity-determining regions limit its applications in de novo antibody design.
Methods: To learn informative representation of antibodies, we trained a deep antibody language model (ALM) on curated sequences from observed antibody space database via a well-designed transformer model. We also developed a novel model named xTrimoABFold++ to predict antibody structure from antibody sequence only based on the pretrained ALM as well as efficient evoformers and structural modules. The model was trained end-to-end on the antibody structures in PDB by minimizing the ensemble loss of domain-specific focal loss on CDR and the frame aligned point loss.
Results: xTrimoABFold++ outperforms AF2 and OmegaFold, HelixFold-Single with 30+% improvement on RMSD. Also, it is 151 times faster than AF2 and predicts antibody structure in atomic accuracy within 20 seconds. In recently released antibodies, for example, cemiplimab of PD-1 (PDB: 7WVM) and cross-neutralizing antibody 6D6 of SARS-CoV-2 (PDB: 7EAN), the RMSD of xTrimoABFold++ are 0.344 and 0.389 respectively.
Conclusion: To the best of our knowledge, xTrimoABFold++ achieved the state-of-the-art in antibody structure prediction. Its improvement on both accuracy and efficiency makes it a valuable tool for de novo antibody design, and could make further improvement in immuno-theory.

Experimental results on immune antibody dataset with 95% confidence interval.				
Method	RMSD	TMScore	GDTTS	GDTHA
AlphaFold2	3.1254 ± 0.1410	0.8385 ± 0.0055	0.7948 ± 0.0057	0.6548 ± 0.0063
OmegaFold	3.2610 ± 0.1463	0.8384 ± 0.0057	0.7925 ± 0.0059	0.6586 ± 0.0063

OFFONOME: a new notion of genes' on/off

Wonyoung Choi[1], Hyo Young Choi[2], Daivd Neil Hayes[3]. *[1]Center for Cancer Research, University of Tennessee Health Science Center, Memphis, TN,[2]Department of Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN,[3]Department of Medicine, University of Tennessee Health Science Center, Memphis, TN*

Background: RNA-seq is now the most widely used technique for gene expression profiling, which generates nucleotide level genome coverage as well as summary gene expression values. In general, low-expressed genes are excluded in the data processing due to their low signal-to-noise ratio. Nonetheless, it has been shown that low-expressed genes can provide crucial information such as presence of rare cells in bulk tissue samples. To optimize signal to noise in low-expressed genes, we applied a novel approach in which we transform low-expressed genes to a robust dichotomized state of being either "on" or "off".
Methods: To determine the status of genes, we use the shape of base-level read coverage which is expected to be homogeneous across the samples if they are "on", whereas appear to be random noise if they are "off". We model base-resolution RNA-seq data as vectors in high dimensional data space and measure their level of shape similarity (LSS) using angles between samples with lower angles indicating higher similarity which is more likely to be "on" status. Applying this approach to 3 human cancer samples (head and neck squamous cell carcinoma (HNSC), lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC)) from the Cancer Genome Atlas (TCGA), we identified lists of genes, the OFFONOME, that were either always or sometimes "off". Differential OFFONOME genes were queried to address supervised and unsupervised analyses.
Results: Using our technique, we characterized the OFFONOME of HNSC (5851 genes), a set which would typically have been filtering for removal because of low expression. In the HNSC OFFONOME, we observed five gene clusters, each of which was strongly associated with specific gene ontology. One of the clusters identified a rare population of normal myocytes infiltrating otherwise invasive tumors. For the OFFONOME of LUAD (5435 genes) and LUSC (5292 genes), we found clusters enriched with cilia and keratinization-related genes. In the result of integrated analysis, we observed that squamous cell carcinoma (SCC) tumor types shared "on" status for keratinization-related genes known for the cause of SCC. By comparison, LUAD had "on" status genes related to microtubule-based movement related with cilia structure. Strikingly, clustering the OFFONOME with the LSS distinguished 3 tumor types with almost perfect separation, outperforming several competing gene expression measures.
Conclusion: In this study, we applied a new notion of gene expression. This approach enables a robust characterization of "on" and "off" status which can be especially effective for the genes expressed at low level. The OFFONOME from 3 cancer types revealed not only the tissue-specific genes but also the genes shared in similar tumor types. Collectively, OFFONOME can provide new

insights into genes expressed at vanishingly low levels, such as from minor cell populations within bulk tumor analysis.

#4298

Machine learning-based model for survival prediction after immunotherapy in patients with solid tumor

Salma Y. Fala[1], Mohamed Osman[2]. *[1]Suez Canal University, Portsaid, Egypt,[2]Zaazig University, AL-Sharqia, Egypt*

Background: Immune checkpoint inhibitors (ICIs) have led to a paradigm shift in solid tumors treatment. However, not all patients respond favorably to these drugs, highlighting the need for reliable predictions to achieve more personalized care and better management. This study aimed to create and validated ML model to predict survival in solid tumors patients receiving ICIs.
Methods: We obtained clinical and genomic data from cBio Cancer Genomics Portal. Data were randomly divided into a training set (80%) and a validation set (20%). light gradient boosting algorithm was trained to predict patients' survival at different time points.
Results: We identified 1660 patients with a median survival of 18 months. LGB yielded AUCs of 67.91% at 1 year, 79.89.6% at 2 years, and 79.75% at 3 years, respectively. The most important predictors that influenced the performance of the model in predicting 3-year-survival were: Age (22.89%), tumor mutational burden (18.24%), and tumor purity (13.23%). Moreover, multivariate analysis was performed and drug type was identified as an independent prognostic indicator (P< .001). So, a Subgroup analysis was done and the OS rates were: 98.57%, 75.55%, 33.84% in patients who received CTLA-4, 98.57%, 75.55%, 33.84% with PD-1/PD-L1, and 97.99%, 9.94%, 4.62% with combo treatment, at 1-, 3-, and 5 years, respectively.
Conclusion: Our ML-based model that integrates both clinical and genomic data is an improved tool for survival prediction, enabling an accurate risk classification and leading to a more precise decision-making. Moreover, this study highlights the importance of age and tumor microenvironment as the main contributors in making survival prediction in patients receiving ICIs.

Table. Performance in survival prediction among training and testing sets

Survival	Average AUC	Average Accuracy	Survival Duration	Positive Predictive Value (Precision)	Sensitivity (Recall)
1-year	67.91%	63.18%	**<12 months**	58%	54%
			>=12 months	67%	70%
2-years	79.89%	78.70%	**<24 months**	86%	84%
			>=24 months	62%	65%
3-years	79.75%	86.02%	**<36 months**	95%	89%
			>=36 months	45%	65%

Gene expression based machine learning classifier to predict and validate cancer type in patient derived xenograft (PDX) models

Warren Andrews, Long Do, Jonathan Nakashima. *Certis Oncology Solutions, San Diego, CA*

Patient derived xenografts (PDX) are increasingly utilized in translational research and drug development. Characterizing the genomic features of PDX is essential to establishing reliable models for cancer research. Despite great interest, problems remain in PDX tumor data banks

including improper cancer type diagnosis and sample mix-ups. In an effort to improve annotation and quality of PDX models, we developed a machine learning model trained on gene expression data from The Cancer Genome Atlas (TCGA). We then applied the model to corresponding data collected from nearly 300 Certis PDX models plus publicly available data from NCI's Patient-Derived Models Repository (PDMR). The model shows high precision and variable recall and provides a fast and accurate method for cancer type diagnosis.

Targeting DNA methylation in T cells to improve the efficacy of immunotherapy

Pengtao Dang[1], Xiao Wang[2], Haiqi Zhu[3], Jia Wang[2], Tingbo Guo[4], Xinyu Zhou[2], Paveethran Swaminathan[2], Chi Zhang[5], Sha Cao[5]. *[1]Deparment of Electrical Computer Engineering, Purdue University, Indianapolis, IN,[2]Deparment of Computer Science, Indiana University, Bloomington, IN,[3]Department of Computer Science, Indiana University, Bloomington, IN,[4]Deparment of Mathematics, Purdue University, Indianapolis, IN,[5]School of Medicine, Indiana University, Indianapolis, IN*

T-cells are critical mediators of immunity and immunologic memory. Their cell fates are regulated in part through epigenetic mechanisms, including DNA methylation. Recent genome-wide methylation analyses have revealed dynamic alterations in the methylome at various stages of development and differentiation of T cells. At single cell level, it is not easy to simultaneously collect RNA-seq and RBBS methylation profiling. An important task is to understand the expression change of which genes and pathways are regulated by DNA methylations, especially for the ones that are associated with functional variations in the T cells from tumor microenvironment.In this study, we developed a computational approach based on our recently developed metabolic flux estimation to estimate cell-wise global DNA methylation activity level by using scRNA-seq data. We also hypothesize that the global DNA methylation activity level in one cell determines most of the DNA methylation level in gene-specific DNA methylations. Hence, the dependency between gene-specific DNA methylation and expression could be imputed by the dependency between predicted global DNA methylation input level and the gene expression. We validated our method to impute cell-wise global DNA methylation level by using four independent sets of paired gene expression and DNA methylation data. Noted, our prediction of global DNA methylation activity is from a pure metabolic perspective. We found that two metabolic reaction rates, named metabolic flux from methionine to SAM and SAM to SAH, purely predicted by using gene expression data can accurately impute DNA methylation activity in all validating data sets. Our method enables further identification of the disease/cell context specific contributor of DNA methylation, i.e., the genes high contribution to DNA methylations in each individual cell or cell groups. We applied our method on scRNA-seq data of different T cell types extracted from TME of lung, liver, and colon cancer. We have seen that exhausted T cells, especially the ones with decreased Granzymes and PRF1 are associated with increased global DNA methylation level and related genes, suggesting the potential clinical implications in targeting DNA methylation to improve the efficacy of immunotherapies.

Graph representation learning of tumor topology from spatial imaging data

Nicholas Ceglia, Samuel S. Freeman, Maryam Pourmaleki, Andrew McPherson, Sohrab P. Shah. *Memorial Sloan Kettering Cancer Center, New York, NY*

Recently, novel technologies have enabled spatially resolved multiplexed protein profiling of tumors; however, there is an unmet need for unbiased detection of spatial structures within the tissue. By encoding multiplexed images as a graph, we produce an efficient and well-studied graph representation that allows for the application of sophisticated machine learning methods, particularly graph neural networks (GNNs) and graph autoencoders (GAE). While GNNs have recently become popular tools in the analysis of spatial data, current GNN methods are limited by production of cell-level representations rather than graph-level representations. To understand patterns of local tissue structure and protein expression, we implemented a generalizable GAE framework that summarizes marker intensity and morphological values with the local topology of neighboring cells. In this way, each local cellular graph is represented as a single point in the lower dimensional space. We show that our framework generates low-dimensional features that reflect both cellular attributes and tissue structure. We demonstrate that clustering local structure in 318 fields of view from 22 tumor lesions across 7 patients with in-transit melanoma captured using multiplexed immunofluorescence (mpIF) can produce spatial motifs predictive of response to intralesional interleukin-2 (IL-2) immunotherapy. Additionally, we applied our framework to mpIF data of 146 high grade serous ovarian cancer tumors across 50 patients. We identify clusters with higher CD8+ T cell infiltration that associate with homologous recombination deficiency. Our method can be readily applied to various spatially resolved multiplexed imaging platforms, and the resulting embeddings provide a compressed representation of subgraphs that can be used in further classification or regression analysis of patient- and/or image-level histological, clinical, or genomic labels.

Prediction of OncotypeDX high risk group for chemotherapy benefit in breast cancer by deep learning analysis of hematoxylin and eosin-stained whole slide images

Gil Shamai[1], Ran Schley[1], Ron Kimmel[1], Nora Balint-Lahat[2], Iris Barshack[3], Chen Mayer[3].
[1]Technion-Israel Institute of Technology, Haifa, Israel,[2]Institute of Pathology Sheba Medical Center, Ramat Gan, Israel,[3]Institute of Pathology, Sheba Medical Center, Ramat Gan, Israel

Introduct**ion:** Breast cancer is the most common cancer in women, with most patients diagnosed with early-stage disease. While adjuvant therapy should be considered in all fit patients, in many low-risk patients drug toxicity may out-weigh the potential benefit, therefore, identifying these patients is desired. Hematoxylin and eosin (H&E) is the basic staining routinely performed for biopsies. It allows visual examination of the tissue and cells. Such manual examination, however, does not provide information about the molecular profile of the cancer, which is essential for diagnosis and guidance of treatment. The OncotypeDX assay is recommended for patients with node-negative, estrogen receptor-positive invasive breast cancer for determining chemotherapy benefit. It is based on RT-PCR gene expression profiling and provides a recurrence score (RS) that enables patient stratification to non-high risk (RS < 26) and high risk (RS ≥ 26). It was shown that high risk patients are likely to benefit from chemotherapy, while non-high risk are not. Unlike H&E staining, the OncotypeDX assay is costly, time consuming, and inaccessible in low-income countries. Here, we sought to evaluate whether analysis of scanned H&E-stained slides by convolutional neural networks (CNNs) could predict the RS risk group (high versus non-high), which determines eligibility for chemotherapy.
Methods: 684 H&E-stained slides were collected from 430 invasive breast cancer patients who were assayed for OncotypeDX between 2014 and 2020 at Sheba medical center, Israel. The slides were scanned at 0.25 micron/pixel, and automatically segmented and split to 256x256 non-overlapping tiles, resulting in overall 339,986 tile images containing tissue. The patients were randomly split into training (75%) and test (25%) sets, and a CNN model was trained and validated on the training set to classify each tile to non-high risk (RS < 26) versus high risk (RS ≥ 26), in 5-

fold cross-validation. The final model was then applied to the held-out test set, and tile scores were aggregated to produce per-patient prediction scores. The final CNN prediction scores on the test set were compared to the ground truth risk group and the AUC performance was calculated.
Results: The AUC performance of the model on the held out test set for high-risk versus non-high-risk classification based on the H&E images alone was high (0.798, 95% CI: 0.689 - 0.875, P value < 0.001), showing that the H&E image analysis could predict the high risk group.
Conclusions: These results show, for the first time, that CNN-based analysis of H&E images could predict benefit from chemotherapy, thus implying distinct tumor morphologies differing between RS groups. Utilizing such a system may enable physicians in countries that lack genetic profiling capabilities to refine chemotherapy stratification based on H&E images alone.

#5355
Elraglusib response prediction and mechanistic discovery using iterative machine learning
Joseph McDermott[1], Taylor Weiskittel[2], Daniel Billadeau[2], Benedito Carneiro[3], Hu Li[2], Andrew Mazar[4]. *[1]Lantern Pharma Inc., Dallas, TX,[2]Mayo Clinic, Rochester, MN,[3]Brown University, Providence, RI,[4]Actuate Therapeutics Inc, Fort Worth, TX*

Elraglusib is a selective GSK-3 inhibitor that has activity on a broad array of neoplasms as well as their immune microenvironment. However the determinants of tumor response have not been elucidated. Here, we use genomic panels of cancer driver genes to predict patient response to elraglusib therapy as measured by RECIST criteria. Patient response in the Phase I 1801 trial (NCT03678883) was matched to genomic data from patient tumors, with 80 cases used to train Machine Learning models and 26 cases reserved as a test set for model evaluation. When predicting response from mutation status alone our models reached a modest accuracy of 65% in the test set, which we attributed to the sparsity of genomic data. To remedy this, we engineered pathway-based features to provide combinatorial information while ensuring feature stability. To select the optimal combination of features, we designed an iterative design process that first randomized feature combinations and then created refined models from the highest performing pathway features. This resulted in several final models with greater than 88% accuracy. We retained several models of similar accuracy to more comprehensively identify potential biomarkers and combinatorial relationships. These models were then interpreted using SHapley Additive exPlanations (SHAP) where we were able to identify highly predictive features for both the entire pan-cancer cohort and specific histologies. We found the feature constructed from the Reactome pathway “Chromatin Modifying Enzymes” frequently occurred in high performing models with a high-ranking SHAP value. This feature included genes such as *SMARCA4*, *HDAC2*, and *KDM5A*, and was negatively associated with patient response. Another frequently observed high-ranking pathway feature with a negative response association was based on the “Innate Immune System” Reactome pathway. Many of the features highlighted in our models were negatively associated with elraglusib response and thus could be general markers of poor prognosis. To address this, we altered our pipeline to test only positively associated features which substantially reduced our feature pool to only 285 features but still produced models with accuracies of up to 81%. Analysis of key features used by these models identified several positive markers of elraglusib including mutations in the *POLE* gene, which previously has been linked to DNA-damage response deficiency and anti-tumor immune response. In sum, we forecast elraglusib response for a variety of tumor histologies and simultaneously reveal potential mechanisms of elraglusib sensitivity and biological action. In future work we will investigate the utility of using POLE and other identified biomarker candidates to predict the likelihood of patient response to elraglusib, as well as whether our machine learning models will be an effective tool to guide patient stratification.

Collaborating to ensure data-driven drug discovery on the Cancer Genomics Cloud: Realizing the possibilities for MoDaC and ATOM

Soner Koc[1], Vojislav Varjacic[1], Miona Rankovic[1], Marijeta Slavkovic-Ilic[1], Aleksandar Danicic[1], Sean Black[2], Naomi Ohashi[2], Titli Sarkar[2], Zelia Worman[1], Jack DiGiovanna[1], Brandi Davis-Dusenbery[1], Dennis A. Dean[1]. *[1]Seven Bridges Genomics Inc., Boston, MA,[2]Fredrick National Laboratory for Cancer Research, Frederick, MD*

Introduct**ion**. The NCI-funded Cancer Genomics Cloud (CGC) and the NCI Predicative Oncology Model and Data Clearinghouse (MoDaC) advance NCI computing infrastructure and tools that aim to reduce the burden of cancer on patients. The CGC provides a collaborative cloud base computation infrastructure that collocates computation, bioinformatics workflows, and 3+ PB data to researchers. MoDaC provides a publicly available resource generated from the Joint Design of Advanced Computing Solutions for Cancer (JDACS4C) Program and the Accelerating Therapeutics for Opportunities in Medicine (ATOM Consortium). The NCI-sponsored MoDaC program aims to add machine learning toolsets to identifying novel treatments for Cancer Patients. We present our progress collaborating with MoDaC to make machine learning models available on the Cancer Genomics Cloud.

Methods. Our Bioinformatics teams migrated MoDaC tools on the CGC, defined standards for releasing models, and collected recommendations for decreasing the time required to make MoDaC tools available on the Cancer Genomics Cloud. We mirrored the ATOM Modeling Pipeline (AMPL), a drug discovery platform, on the CGC by making the GIT repository cloud accessible through Jupyter Notebook access, supporting interactive analysis. We translated AMPL and JDACS4C models into CWL. Converting these ML models into CWL supports reproducible execution, scalable deployment, and computational portability.

Results. The AMPL drug discovery platform on the CGC includes data ingestion & curation, featurization, model training & tuning, prediction generation, visualization & analysis functionality as Jupyter notebooks and CWL workflows. The release consists of chemo-informatics tools for integrating cancer treatment features in deep-learning graph models. JDACS4C ML Models ported to the CGC include classifiers (tumor and normal-tumor pairs), autoencoders (Gene Expression), drug response predictors (single and combination), and Multitask Convolutional Neural Networks (extract information from cancer pathology reports).

Conclusion. We optimized the MoDaC Drug Discovery and Machine Learning tools into cloud-native resources on the CGC, supporting interactive and GUI-driven analysis. The release supports technical and newer users to machine learning, allowing access to a broader user base than those who traditionally have access to ML toolsets. These MoDaC toolsets will support pre-clinical study evaluation, treatment identification, and experimental design. Moreover, existing MoDaC-AMPL tutorials on the CGC support distributed ML-Drug Discovery training. Lastly, collaborating with MoDaC teams identified standardization approaches that can reduce the time and effort to make these tools widely available across the NIH-NCI computational infrastructure.

Estrogen receptor gene expression prediction from H&E-stained whole slide images

Anvita A. Srinivas[1], Ronnachai Jaroensri[1], Ellery Wulczyn[1], James H. Wren[2], Elaine E. Thompson[2], Niels Olson[3], Fabien Beckers[4], Melissa Miao[4], Yun Liu[1], Cameron Chen[1], David F. Steiner[1]. *[1]Google Health, Palo Alto, CA,[2]Henry M Jackson Foundation, Bethesda, MD,[3]US Navy, Washington, DC,[4]Verily, South San Francisco, CA*

Gene expression profiling (GEP) represents an important approach to inform breast cancer treatment. However, access to GEP involves challenges associated with cost, tissue transportation, and turn around time. In this work, we explore the prediction of estrogen receptor gene (*ESR1*) expression directly from images of hematoxylin and eosin (H&E) stained, formalin-fixed paraffin-embedded (FFPE) breast cancer tissue. Since H&E staining is a fast and inexpensive component of the standard tissue preparation in pathology, this approach is tissue preserving and requires no additional tissue processing. Our method uses a deep multiple instance learning approach to process cropped image patches from whole-slide images (WSI) into a numeric embedding vector summarizing the information in each patch. A gated attention mechanism then aggregates these embeddings into a single prediction for the WSI. We train and tune the model on a site-based split of The Cancer Genome Atlas (TCGA) BRCA dataset, and evaluate it on both a heldout split of TCGA (independent sites) and a separate dataset from a tertiary teaching hospital (TTH). All splits of TCGA have *ESR1* value, immunohistochemistry (IHC) estrogen receptor (ER) status, and limited clinical outcome data. The TTH dataset has IHC-based ER status and clinical outcome, but not *ESR1* expression. On the TCGA heldout test split, our model's root mean square error (RMSE) for predicting normalized gene expression counts (TPM) was 2.90 [95% CI: 2.57, 3.23], and the Pearson correlation was 0.57 [95%CI; 0.46, 0.67]. For predicting IHC-based ER status on the same TCGA split, this weakly-supervised *ESR1*-predicting model had an area under the receiver-operator curve (AUROC) of 0.81 [0.74, 0.87]. This was comparable to a strongly-supervised method directly predicting ER status (AUROC: 0.85 [0.77, 0.92]). Lastly, when evaluated for association with patient outcomes (progression-free interval; PFI) using the independent TTH dataset, this *ESR1*-predicting model had a concordance index (c-index) of 0.59 [0.52, 0.65]. For comparison, the c-index for PFI using the IHC-based ER status for these cases was 0.61 [0.54, 0.66]. This work further demonstrates the potential to infer gene expression from H&E stained images in a manner that shows meaningful associations with clinical variables. Because obtaining H&E stained images is substantially easier and faster than genetic testing, the capability to derive molecular genetic information from these images may increase access to this type of information for patient risk stratification and provide research insights into molecular-morphological associations. Future work incorporating more comprehensive sets of genes remains a valuable next step.

Digital SP263 PD-L1 tumor cell scoring in non-small cell lung cancer achieves comparable outcome prediction to manual pathology scoring

Hen Prizant[1], John Shamshoian[2], John Abel[2], Andrew Beck[2], Laura Chambre[2], Stephanie Hennek[2], Hartmut Koeppen[1], Daniel Ruderman[1], Meghna Das Thakur[1], Michael Montalto[2], Benjamin Trotter[2], Ilan Wapinski[2], Wei Zou[1], Minu K. Srivastava[1], Jennifer Giltnane[1]. *[1]Genentech, Inc., South San Francisco, CA,[2]PathAI, Boston, MA*

Background: Tumor cell (TC) PD-L1 expression is predictive of response to PD-L1-targeted immunotherapy, and accurate scoring is crucial for treatment selection. Scoring relies on manual assessment of immunohistochemically labeled tissue and is subject to subjective variation due to pathologist assessment. As a digital alternative, a clone-agnostic AI-based model for PD-L1 quantification in non-small cell lung cancer (AIM-PD-L1 NSCLC) was developed[1]. AIM-PD-L1 was deployed on samples from a Phase 3 study of anti-PD-L1 atezolizumab combination therapy with carboplatin and paclitaxel, and/or bevacizumab in Stage IV NSCLC (IMpower150; NCT02366143). Digital and manual PD-L1 TC scores were compared and interrogated for their respective potential to predict efficacy to atezolizumab combination treatments.

Methods: AIM-PD-L1 was deployed on images (n=768) digitized from SP263-labeled slides with available manual pathologist TC scores to quantify tissue regions and individual TCs. PD-L1 expression status was determined for each tumor cell and a slide-level TC score was computed. Overall survival (OS) and progression free survival (PFS) analyses of patients at selected cutoffs of 1%, 50%, and across a continuum of cutoffs from 0% to 100% PD-L1 TC by digital and manual methods were conducted, comparing groups treated with or without atezolizumab in combinations with carboplatin and paclitaxel, and/or bevacizumab. Digital and manual scores were compared using agreement rates, Lin's concordance and Spearman's correlation coefficients, and hazard ratios (HRs) were calculated for OS and PFS analysis.
Results: At the slide level, correlation between continuous digital and manual scores was high (r 0.84 [95% CI 0.81-0.86]). Digital assessment of PD-L1 positivity at the 1% cutoff identified more positive patients than manual scoring (70% vs. 55% prevalence, respectively), with comparable treatment benefit (digital OS HR 0.69 [0.53-0.9], and manual OS HR 0.72 [0.54-0.98], digital PFS HR 0.67 [0.54-0.83], and manual PFS HR 0.66 [0.52-0.84]). Continuous digital PD-L1 TC scores showed that treatment benefit improved for patients with scores ≥50% compared to manual scoring. At the ≥50% PD-L1 TC cutoff, numerical improvement was observed in OS and PFS by digital scoring compared to manual (digital OS HR 0.5 [0.29-0.86] compared to manual OS HR 0.64 [0.4-1.02], and digital PFS HR 0.37 [0.24-0.57], compared to manual PFS HR 0.53 [0.37-0.76]).
Conclusions: AIM-PD-L1 scoring was as effective at predicting outcomes as manual using the ≥1% PD-L1 TC expression and at the ≥50% TC cutoff, digital scoring identified a subgroup with enriched efficacy compared to manual. Further evaluation of the accuracy and reproducibility of PD-L1 scoring by digital pathology as well as its potential use for patient enrollment or stratifications in clinical trials is needed.

Translating state-of-the-art deep learning predictions of treatment efficacy to clinical practice
Gustavo Arango-Argoty, Etai Jacob. *Oncology Data Science, AstraZeneca, Waltham, MA*

Despite the clinical success of immune checkpoint blockade therapies, in many patients the disease becomes unresponsive or resistant to treatment. Attempts to predict treatment efficacy and identify determinants of response have suffered from limited accuracy. Here, we introduce a state-of-the-art deep learning method that better captures the complex relationships among the host, the immune system, and tumor biology. Our method, an explainable deep learning framework, is based on transformer architecture that combines data with different feature sets and clinical endpoints for survival prediction or classification. The framework includes(1) a new loss function based on Harrell's concordance-index, (2) an explainability module providing importance score between features based on mutual contribution to predictions, and (3) a transfer learning strategy that enables leveraging diverse clinical data sets in the public or private domain. Using seven data sets comprising more than 140,000 patients from immunooncologic (IO), targeted, and chemotherapy treatments, our method consistently outperformed other methods previously described in the literature, including CoxPH and random survival forest (RF). For example, our framework achieved a concordance index of 0.66 (±0.04) vs. 0.60 (±0.04) of the second-best method (RF) on MYSTIC IO arms using only clinical data. Utilizing our explainability module, we identified key features driving response prediction that are consistent with those in previous publications. For example, in the Chowell et al. data set, we identified albumin, neutrophil-to-lymphocyte ratio, prior-chemo-treatment, and tumor mutation burden as the most important features. We also identified in sparse mutation calls of 469 genes from the Samstein et al. data set, functional modules of several genes, each with a strong predictive power. For example, the functional module with the highest hazard

ratio (HR) (1.43) was the gene pair KEAP1 and STK11, which are well-established drivers of resistance to multiple therapies. We further validated these results across multiple data sets: The Cancer Genome Atlas HR = 1.23), GENIE/anti-PD-L1 (HR = 1.06), and MYSTIC/anti-PD-L1/CTLA-4 (HR = 1.39). Another example is a functional module related to adaptive immunity, comprising the genes AKT2, BTK, CDC73, HLA-B, IKBKE, INPPL1, RFWD2, TRAF2, and WHSC1. This module stratified patients with an HR of 0.58 within the Samstein et al. data set and 0.42 within the independent validation data set. We describe a new deep learning method with state-of-the-art performance in survival prediction and the potential to uncover biological and clinical insights related to disease response and resistance. Our framework simplifies the process of translating complex AI models to clinical practice and may accelerate the identification of targetable drivers of resistance and response.

Improved identification of CHIP mutations from cell-free DNA without matched normal samples using machine learning

Gustavo Arango-Argoty[1], Gerald Sun[1], Aleksandra Markovets[1], Carl Barrett[2], Zhongwu Lai[1], Etai Jacob[1]. *[1]Oncology Data Science, AstraZeneca, Waltham, MA,[2]Translational Medicine Oncology, AstraZeneca, Waltham, MA*

Blood-based liquid biopsies are becoming the standard for noninvasive profiling of tumors from circulating tumor DNA (ctDNA) to facilitate treatment decisions. However, it is known that non-tumor-derived mutations, such as those from clonal hematopoietic (CH) lineage, are also present in cell-free DNA (cfDNA) and can complicate tumor mutation detection and interpretation. Filtering alterations associated with CH can reduce the risk of false positives in ctDNA analysis. Current strategies for filtering CH mutations are based on prior knowledge of those in canonical CH genes, sequencing a matched peripheral blood mononuclear cell sample, or using multiple time points to evaluate changes in allele frequency (AF), with the assumption that AF of CH of indeterminate potential (CHIPs) are unlikely to be impacted by treatments; however, these approaches are either insufficient or cost prohibited. We present a machine learning framework that incorporates prior knowledge from tumor and blood-derived mutations to improve the classification of CH and tumor variants from plasma-only cfDNA samples and that greatly outperforms a simple rule-based approach. We developed a classification framework composed of three main modules to maximize the information gain from ctDNA as non-ctDNA samples: (1) a sequence context-based model where each variant is represented by 128 mutational signatures extracted using a bag-of-words-like modeling (using normal and tumor samples) along with mutational function effect scores from SnpSift and cancer type origin. In total 6,745 CH and 57,210 somatic tumor-derived mutations are used to train a model to distinguish CH, CH-putative cancer driver , and tumor mutations; (2) a ctDNA-context model that includes patient-level information (age, mutational signatures, and variant allele frequencies) from 392 tumor and 481 CH blood-derived mutations extracted exclusively from ctDNA samples to predict blood or tumor origin; and (3) a meta-classifier where models 1 and 2 are aggregated into a single score for predicting the origin of a given mutation. We compared our models against a baseline strategy where mutations were predicted as CH if they fell into a list of 27 canonical CH-related genes. Our proposed metaclassifier that integrates sequence- and ctDNA-based features improved the overall performance of CH detection (AUC = 0.83, compared with the baseline model, AUC = 0.72), highlighting the value of adding ctDNA-derived and mutation-context features to profile somatic mutations. As ctDNA assays and technologies rapidly progress and gain adoption for precision oncology, we anticipate that our work, combined with existing benchmarking efforts, will enable more robust analyses on critical applications such as

early disease detection, minimal residual disease, and mutational profiling to ultimately best inform clinical decision-making.

Deep learning models capture high dimensional features for cell morphology analysis

Kevin B. Jacobs, Kiran Saini, Nianzhen Li, Senzeyu Zhang, Ryan Carelli, Amy Wong-Thai, Stephane C. Boutet, Anastasia Mavropoulos, Andreja Jovic, Jeanette Mei, Mahyar Salek, Maddison Masaeli. *Deepcell Inc., Menlo Park, CA*

Many methods for imaging and sorting tumor cells require biomarker labels that perturb cells and may create a selection bias. The Deepcell platform can characterize and sort cells using only brightfield images of unlabeled single cells, thereby enabling more comprehensive and unbiased assessment of tumor cell morphology and heterogeneity. Cells are imaged with a high-speed camera during microfluidic flow and brightfield images are analyzed in real-time by deep learning models to generate quantitative embeddings, which are reproducible and multi-dimensional descriptions of cell morphology. One of the key technical challenges in building this platform was the development of an AI model to extract features from cell images from diverse human cells without prior knowledge of specific cell types, cell preparation, or other application-specific knowledge for an exploratory approach.

Deepcell's 'Human Foundation Model' (HFM) is a feature encoder that transforms cell images into 128 dimensional embedding vectors. The model backbone, responsible for extracting image features, is based on the ResNet18 convolutional deep neural network architecture. Training utilizes a multi-task semi-supervised training framework that combines the VicReg self-supervised learning model, which learns images features without labels, along with supervised auxiliary models using labeled data. These sub-models enable the backbone model to recognize specific cell attributes such as granulation, pigmentation, characteristics of malignancy, attributes related to cellular states like apoptosis and necrosis. We augment the deep learning embeddings with computer vision derived cellular features, such as area, perimeter, intensity, and texture features to improve model interpretability and accuracy.

Here, we describe how the HFM self-supervised backbone model was trained, the discriminatory power added by the supervised tasks, and validation of the reproducibility and generalization capabilities of the resulting model. We also demonstrate how the resulting embeddings can be visualized using the Deepcell Cloud software and how clusters of cells in our embedding space can be related to cell images, interpretable morphological features, and actionable biological characteristics. Potential applications of the Deepcell platform are diverse and promising, such as label-free enrichment of malignant cells and discovery of morphologically distinct subpopulations of heterogeneous cancer cell samples.

AI-enabled novel workflow to evaluate T-cell activity *in vitro* using 3D spheroid models

Zhisong Tong, Oksana Sirenko, Misha Bashkurov, Angeline Lim. *Molecular Devices, LLC (Moldev), San Jose, CA*

T-cell therapies are designed to help our immune system eliminate cancer cells. Those include CAR T-cells (Chimeric Antigen Receptor engineered T-cells), tumor infiltrating lymphocytes (TIL), and other genetically modified T-cells. In recent years, the field of cell therapy has started to expand, including the launch of the first CAR T-cell therapies to treat blood cancer in 2017, which was a critical milestone in this field. Despite its boom, the discovery of novel immunotherapies that specifically enhance T-cell response against cancer cells remains a challenging task, limited by the

absence of robust in vitro models to evaluate these immunotherapies throughout their development. The use of CAR T-cells on solid tumors has been lagging due to challenges that include tumor heterogeneity, immunosuppressive microenvironments, and the lack of unique tumor antigens that can be recognized by the CAR-T cells. As such, the ability to screen for CAR T-cells (e.g. with CRISPR) that effectively target and kill tumors is an area of active research. Here we describe a method for assessment of T-cell effect and penetration into the multi-cellular 3D tumor spheroids as a proof-of-concept model for in vitro CAR T assays. Spheroids were formed from Hela cell lines in 96-well round bottom plates. We activated the human peripheral blood mononuclear (PBMC) cells with PMA/ionomycin for 6 hours, then treated the spheroids with stimulated PBMC for 72 hours. Samples were imaged with a confocal imager every 2 hours for a 72 hour period. High-content imaging and analysis allowed us to observe and measure phenotypic changes in cancer spheroids and the process of T-cell penetration over a period of 72 hours. To optimize the workflow, we developed an image analysis approach that uses a deep learning-based segmentation model and a machine learning-based classification model to quantify the T-cell induced phenotypic changes in the spheroids using brightfield images. Our results show clear distinct phenotypic changes among different treatment groups and the feasibility of using AI-based analysis workflows to accurately predict the efficacy of T-cells in an in vitro assay. Moreover, the information associated with the penetration of T-cell into the 3D spheroids was explored by calculating the coordinates of the penetrated T-cells and T-cell movements from the nearest edge of the spheroids where the T-cell penetration speed was estimated. Our results show that the stimulated T-cells have much greater penetration speed compared to non-stimulated T-cells. Image analysis also allowed us to measure and quantitate the deterioration of cancer spheroids and changes in their morphology. Overall, our results show that the 3D spheroid models and the high-content analysis workflow may potentially be used as a metric to evaluate the efficacy of cell therapy in vitro.

MicroArray-based MethylationToActivity: Advancing biological knowledges from DNA methylation profiles of patient tumors

Karissa Dieseldorff Jones[1], Waise Quarni[2], Daniel Putnam[1], Shivendra Singh[2], Qiong Wu[2], Jun Yang[3], Xiang Chen[1]. *[1]Computational Biology, St. Jude Children's Research Hospital, Memphis, TN,[2]Department of Surgery, St. Jude Children's Research Hospital, Memphis, TN,[3]Department of Surgery & Department of Pathology, St. Jude Children's Research Hospital, Memphis, TN*

DNA methylation (DNAm) is a relatively stable regulatory epigenetic mechanism. Although accurate DNAm classifiers have been built for early detection of cancer and subtype classifications, its transcriptional regulatory roles remain unclear. To address this challenge, we developed a deep-learning framework MethylationToActivity (M2A) that accurately predicts individual promoter activity from WGBS methylomes. As array-based methylome is the most common epigenetic data from patients' tumor samples, we redesigned M2A's raw features and model topology for array methylomes, which shows an accurate prediction of the promoter activity (R2 = 0.74), approaching its WGBS counterpart (R2 = 0.79). Transfer learning improves the prediction accuracy to 0.77. In a primary rhabdomyosarcoma cohort, M2A prioritized candidate genes with strong subtype-specific alternative promoter usage (APU) and identified distinct isoforms of a subgroup of APU genes including NAV2 expressed in the two major subtypes (aRMS and eRMS). Molecular experiments revealed that PAX3-FOXO1 directly binds to the aRMS-specific promoter and is required for its active transcription. Genetic deletion of PAX3-FOXO1 leads to NAV2 APU. Overexpression of aRMS-specific NAV2 isoform significantly promoted cell proliferation, supporting its oncogenic function. These data indicate that PAX3-FOX1 is critical for APU in aRMS. We conclude that the

new M2A provides vast insight into downstream functional interpretation of differential DNAm patterns.

Language modeling of peptide-HLA interactions achieves state-of-the-art performance on prediction of peptide presentation by HLA Class II

Daniel Sprague, Joshua Klein, Italo Faria do Valle, Olivia Petrillo, Melissa Rotunno, Matthew Davis, Monica Lane, Karin Jooss, Ankur Dhanik. *Gritstone Bio, Inc., Emeryville, CA*

Precise and sensitive prediction of neoantigen presentation to the immune system via human leukocyte antigen (HLA) class II molecules remains a challenge despite the early success of neural networks applied to HLA class I. However, it is necessary to address this modeling challenge because presentation of a neoantigen epitope by both classes of HLA molecules may be valuable to induce a sustained immune response with therapeutic cancer vaccines.
Previously we have developed a machine-learning based platform, EDGE^{TM}, that provides a state-of-the-art model to predict presentation of peptides by HLA Class I. Here we propose a new addition to our EDGE^{TM} platform: a model that leverages structural information of putative epitopes and HLA class II alleles from their *in-situ* context to predict presentation of peptides by HLA class II. Our model achieves this by leveraging the Evolutionary Scale Model pre-trained protein language model (LM), which has been demonstrated to embed protein sequences with rich structural information. The input to the model is a linear peptide consisting of an epitope and its flanking amino acids, concatenated with structurally relevant amino acids from each HLA allele. This allows our model to treat the modeling problem entirely as a natural language processing task, which minimizes imputation of covariates found in prior approaches when performing inference in the context of vaccine design, while maximizing the richness of the LM embeddings on longer linear peptides. Crucially, this also allows our model to generalize to any allele that has a known sequence. Additionally, DR-, DP-, and DQ-specific immunoaffinity purified mass spectrometry multi-allelic (MA) presentation data were generated per tumor or cell line sample, spanning 89 alleles in aggregate. We demonstrate that incrementally decreasing HLA class II allele MA resolution during training results in substantially improved predictions for situations where MA presentation data has completely ambiguous epitope presentation across DR/DP/DQ alleles. Our model achieves an Average Precision (AP) of 0.92 and ROC-AUC of 0.98 on the same benchmark validation data as the current state-of-the-art model BERTMHC, which achieved an AP of 0.81 and ROC-AUC of 0.95. These are the best AP and ROC-AUC for an HLA Class II presentation model on this benchmark dataset to the best of our knowledge. Our model is a significant advancement in HLA class II epitope prediction that allows our EDGE^{TM} platform to bring neoantigen vaccine design optimized for both class I and class II presentation within reach.

Extracting novel knowledge from scientific literature to build a web portal for cancer researchers to keep up with the latest scientific discoveries

Feng Pan[1], Yuan Zhang[1], Xin Sui[2], Donghu Sun[2], Menghan Chung[2], Jinfeng Zhang[1]. *[1]Florida State University, Tallahassee, FL,[2]Insilicom LLC, Tallahassee, FL*

Millions of new papers are published in biomedical sciences every year. In many disciplines, it has become impossible to read all the published new papers to learn what is happening in the frontier of a particular area. This gap is widening as the publishing speed has been accelerating in recent years. To address this challenge, one can convert unstructured text data into a structured form, which can

then support highly accurate information retrieval, information integration, and automated knowledge discovery. A plausible approach for such a task is to use named entity recognition (NER) and relation extraction (RE) methods to identify important biological entities and extract their relations to construct knowledge graphs (KGs). The LitCoin Natural Language Processing (NLP) Challenge was recently organized by NCATS of NIH and NASA to spur innovation by rewarding the most creative and high-impact uses of biomedical text to create KGs. In addition to entities and relations, the manually annotated LitCoin dataset also contains the annotations of relations being new discoveries or background knowledge. Our team participated in the challenge and ranked first place. The novelty prediction model of our pipeline has achieved an F1 score of 0.90. We have applied our model to all the PubMed abstracts published previously and the newly published ones to extract the novel discoveries in each article. A web portal has been created to allow scientists to view the latest discoveries in cancer research. The web portal is updated daily with versatile visualization tools for cancer researchers to quickly grasp the latest discoveries in a particular area. It also offers powerful functions to explore the existing literature and make sophisticated inferences about causal and indirect relationships.

Constructing the largest-scale biomedical knowledge graph using all PubMed articles and its application in automated knowledge discovery

Yuan Zhang[1], Feng Pan[1], Xin Sui[2], Donghu Sun[2], Menghan Chung[2], Jinfeng Zhang[1]. *[1]Florida State University, Tallahassee, FL,[2]Insilicom LLC, Tallahassee, FL*

The number of biomedical publications is growing at an accelerated speed. This ever-increasing amount of scientific literature has made reading all the published articles regularly impossible even for a very specific research area. A solid grasp of existing literature is essential for coming out with novel and plausible scientific ideas. To bridge the gap between the published scientific findings and our incapability of manually processing them, we need to convert the unstructured text into structured form to enable automated methods to use the structured, machine-readable information to generate novel hypotheses, which can then be manually validated. A plausible approach for converting unstructured text into structured form is to use named entity recognition (NER) and relation extraction (RE) methods to identify the biological entities and extract their relations to construct knowledge graphs (KGs). KGs can link concepts within existing research to allow researchers to find connections that may have been difficult to discover without them. The LitCoin Natural Language Processing (NLP) Challenge was recently organized by NCATS of NIH and NASA to spur innovation by rewarding the most creative and high-impact uses of biomedical, publication-free text to create KGs. Our team participated in the challenge and ranked first place. Using the pipelines developed for the LitCoin NLP challenge, we have constructed the largest-scale biomedical KG using all PubMed articles. We further develop advanced deep-learning methods to predict new links from the constructed KG. We demonstrate the power of this new framework using several examples important for drug discovery.

Deep neural networks using protein-protein network information predict multiple myeloma survival

Jiening Zhu[1], Jung Hun Oh[2], Anish K. Simhal[2], Rena Elkin[2], Larry Norton[3], Joseph O. Deasy[2], Allen R. Tannenbaum[4]. *[1]Department of Applied Mathematics & Statistics, Stony Brook University, Stony Brook, NY,[2]Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New*

York, NY,[3]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Stony Brook University, Stony Brook, NY

The modern development of sequencing technologies provides a comprehensive molecular portrait of human cancers. There is a strong need to develop methods to not only improve patient prognosis predictions but also to understand the driving factors for treatment. However, the high-dimension, low-sample size nature of the genomic data poses challenges for typical machine learning algorithms. The systematic understanding of genes with respect to a network (protein-protein interaction (PPI) network) is a way to handle the limit and the nonparametric analysis of geometric properties such as Ollivier-Ricci curvature and associated invariant measure developed by our group have proven to be successful for the prediction of survival in multiple cancers. In this work, we propose a novel supervised deep learning approach combining the aforementioned geometric methods, which benefit from the flexibility provided by deep learning techniques while still preserving much of the interpretability of the geometric analysis. We take advantage of a state-of-the-art graph neural network approach. Sparse connections between layers were inspired by the known biology of the PPI network from the Human Protein Reference Database (HPRD) and pathway information from the Kyoto Encyclopedia of Genes and Genomes (KEGG) database, supplemented with geometric network features which are fed into the network in corresponding layers. The prediction is based on a local-global principle, where highly predictive features are selected from early layers of the network and fed directly to the final layer to produce a multivariable Cox regression. We applied our method to RNA-Seq gene expression data from the CoMMpass study of multiple myeloma (MM). More specifically, 657 patients in the data set were randomly divided into training, validation and set-aside testing sets by a ratio of 6:2:2. We obtained an average C-index 0.66 of the prediction in the testing set from a 10-fold data split. Dichotomizing the testing set by its mean value to define high-risk vs. low-risk yielded a significant p-value of the log-rank test in the set-aside data (p-value =3e-4). We observed that geometric protein network information not only improved the outcome prediction (vs. 6% worse without geometric feature inputs), but was also more robust to fold splitting. From our model, we identified WEE1, CENPE and CENPF as top genes driving survival differences (higher expression of WEE1 increased risk and lower negative curvature between CENPE and CENPF increased risk). WEE1 is a cell cycle-related gene that regulates DNA repair and CENPE and CENPF are components of a fibrous layer of mitotic kinetochores, which have been indicated in the literature to be related to the prognosis as well as possible targets for treatment. While it is therefore logical that these genes would be implicated in the natural history of MM, they were identified entirely on the basis of network analysis.

AI-enabled prediction of lung cancer specific hot spot gene alterations from histology images

Gowhar Shafi[1], Shiva Shivamurthy[2], Anand Ulle[2], Chongtham Cha Chinglemba[1], Sumit Haldar[2], Fauzul Moubeen[2], Mohan Uttarwar[1]. *[1]OneCell Dx Inc, Cupertino, CA, USA and India, Cupertino, CA,[2]Indx.AI Inc, Cupertino, CA, USA and India, Cupertino, CA*

Background**:** The clinical intervention relies on molecular testing of primary biomarkers. We developed an AI enabled platform to predict NCCN guidelines recommended hot-spot genomic alterations from the image analysis using H&E slide.

Methods: AI engine was trained using clinically observed hot spot genomic alterations present in lung cancer patients as a ground truth based on histological FFPE whole-slide images. The H & E stained histological images of the tumor having matching pathogenic mutations were downloaded from the TCGA database for the training and testing purpose. The program extracted

histopathological features, followed by pattern mapping to predict genomics status based on the results of NGS testing from 480 samples. ResNet AI algorithm was trained to predict lung specific hot spot genomic alterations. An H & E stained slide was imaged with a 40x objective lens to obtain a brightfield image as an input data. The input image was segmented into 65 x 10^3 tiles, each of 64 μm^2 in size for an individual pathological class. 80% of the data set was used for training the engine while validation and blinded study was respectively performed on remaining 10% data.
Results: Using single blinded clinical samples. AI model analyzed whole slides. Table 1 summarize parameters for clinically significant variants. Higher sensitivity and specificity was observed for variants encoding mutated cell surface proteins compared to variants encoding intracellular mutant targets when compared on similar training and testing parameters.
Conclusions: AI-enabled prediction of hotspot genomic alterations resulted comparable to NGS with shortest TAT, cost and resources. It predicted actionable gene alterations with high positive and negative prediction values. Table 1

Gene	Sample (n = 480)		Evaluation parameters for tested samples

Detection of ERG:TMPRSS2 gene fusion in prostate cancer from histopathology slides using attention-based deep learning

Mohamed Omar[1], Zhuoran Xu[1], Sophie B. Rand[1], Daniela C. Salles[2], Edward M. Schaeffer[3], Tamara L. Lotan[2], Massimo Loda[1], Luigi Marchionni[1]. *[1]Department of Pathology and Laboratory Medicine, Weill Cornell Medicine, New York, NY,[2]Department of Pathology, Johns Hopkins University, Baltimore, MD,[3]Department of Urology, Feinberg School of Medicine, Northwestern University, Chicago, IL*

ERG:TMPRSS2 fusion is present in almost 50% of prostate cancer (PCa) cases of European ascent and plays an important role in carcinogenesis and disease progression. ERG status is detected using fluorescence in situ hybridization (FISH) or reverse transcription-polymerase chain reaction (RT-PCR), and since these tests are costly and require special training, there is need for innovative tools to decrease the cost and streamline the diagnostic process. For this reason, we have developed a deep learning (DL) system capable of inferring ERG fusion status using only digitized hematoxylin and eosin (H&E)-stained slides from PCa patients, and detecting tissue regions of high diagnostic relevance. To develop the model, we used the PCa TCGA dataset which includes 436 formalin-fixed paraffin-embedded (FFPE) H&E-stained whole slide images (WSIs) from 393 PCa patients who underwent radical prostatectomy. Subsequently, we evaluated the model's performance on an independent cohort of 314 WSIs provided by the Johns Hopkins University (natural history cohort). Slides were divided into tiles of 500X500 px from which feature extraction was performed using a pre-trained ResNet50 model. Feature vectors were then used to train attention-based multiple instance learning framework to predict the slide-level label as either ERG-positive or negative, and to score slide regions based on their contribution to the slide-level representation. Our model can predict the ERG fusion status with an Area Under the ROC Curve (AUC) of 0.84 and 0.73 in the training data and the independent testing cohort, respectively. Also, the model detects tissue regions with high attention score for each class. To decipher the cellular composition in these highly relevant regions for the cases predicted as ERG-positive or negative, we used HoVer-Net model to perform nuclear segmentation and classification into five categories: benign epithelial, tumor, stroma, immune, and necrotic. Notably, we found that the cellular composition of the highly relevant patches can capture prognostic information. Specifically, In the TCGA dataset, a high ratio of neoplastic cells in the relevant patches was significantly associated with worse progression free survival (PFS), while high ratios of necrotic, stromal, and stromal to neoplastic cells were significantly associated with better PFS. Similar findings were also obtained in the natural history cohort in which a high ratio of neoplastic cells was significantly associated with worse overall survival (OS) and metastasis free survival (MFS), while high ratios of immune, stromal, and stromal to neoplastic cells were significantly associated with longer OS and MFS. These results show that ERG fusion status can be inferred from H&E-stained WSIs, ultimately demonstrating the

benefit of DL systems in extracting tissue morphological features of high diagnostic and prognostic relevance.

New oncology target identification and validation platform combining artificial intelligence and preclinical pharmacology

Sebastien Vachenc[1], Nicolas Ancellin[2], Didier Grillot[2], Kenji Shoji[1], Joanna Giemza[1], Nathalie Jeanray[1], Leila Outemzabet[1], Salvatore Raieli[1], Lamine Toure[1], Olivier Duchamp[2], Fabrice Viviani[2], Philippe Genne[1], Jan Hoflack[1], Stéphane Gerart[1]. *[1]Oncodesign Precision Medecine, Dijon Cedex, France,[2]Oncodesign Services, Dijon Cedex, France*

Despite major advances in cancer therapy in the last decades, treatment resistance can develop over time. Precision medicine allows for the successful implementation of targeted therapies and stratification of patients, but treatment resistance remains a major obstacle in patient management. The identification and validation of new targets associated with cancer resistance remains a major challenge. The great diversity of molecular mechanisms involved in treatment resistance phenomena, whether intrinsic (de novo or primary) or acquired (secondary), constitutes a real therapeutic challenge for patient care. A better understanding of resistance mechanisms would allow to explore new therapeutic strategies to circumvent these phenomena in different types of cancer. The OncoSNIPE® project was developed in this context as part of a multicenter and collaborative clinical study (NCT04548960) in more than 800 chemo-naive adult patients. The objective of this project was to identify early and/or late markers of treatment resistance in three different pathologies for which resistance problems are encountered: triple negative breast cancer (TNBC) or luminal B, locally advanced or metastatic non-small cell lung cancer (NSCLC) and pancreatic ductal adenocarcinoma (PDAC). The program included traditional clinical and whole exome sequencing (WES) monitoring of patient biopsies (Exom-seq and RNA-seq) at diagnosis and relapse, monitoring of blood markers (RNA-seq and Proteomics – Cytokine) at diagnosis, and the evaluation of best therapeutic responses and relapse. The program used bioinformatics, artificial intelligence, statistical learning and semantic enrichment approaches to discover the diversity of mechanisms involved in these resistances and to identify new therapeutic targets, through hetero-modal data including clinical, genomic, transcriptomic, immunological and radiomic dimensions. Subsequently, a specific flowchart for target validation was applied to the resulting list, considering the target's developmental potential, its essentiality, prior knowledge (database mining) and home-made score of the link between the target and the disease. Finally, new targets were prioritized using weighting parameter and heuristic approximation based on the Crank algorithm. Experimental work on multiple targets began in the laboratory, initially in vitro, using 2D and 3D cell culture (including cells from patient-derived xenografts) and molecular interference. A wide variety of intrinsic or acquired molecular mechanisms involved in treatment resistance are being evaluated as candidates for diagnostic and therapeutic development.

Modeling single-cell dynamics using stochastic generative models based on neural differential equations

Michael E. Vinyard[1], Anders W. Rasmussen[2], Ruitong Li[1], Luca Pinello[3], Gad Getz[4]. *[1]Chemistry & Chemical Biology, Harvard University, Cambridge, MA,[2]Klarman Cell Observatory, Broad Institute MIT and Harvard, Cambridge, MA,[3]Molecular Pathology Unit, Center for Cancer Research, Massachusetts General Hospital, Charlestown, MA,[4]Broad Institute of MIT and Harvard, Cambridge, MA*

Hematopoietic malignancies arise from driver alterations acquired during specific, often intermediate and transient, differentiation states. When adequately sampled, “snapshot” single-cell measurements can capture dynamic biological processes, including transient states. While there are effective computational modeling solutions to order and capture the relationships among these cell states (often projecting onto a lower dimensional manifold with directionality), methods to infer the causal gene regulatory mechanisms driving cell state transitions remain limited.
Recently, a mathematical framework for modeling cell dynamics from snapshot data using a physics-based drift-diffusion equation was proposed. This drift-diffusion equation framework describes the dynamics of cell distributions with respect to time, wherein stereotypical driving forces (e.g., hematopoietic development) are captured by the drift term, and biological stochasticity is attributed to the diffusion term. The existing modeling solutions within this framework are forced to assume a fixed diffusion parameter across cell states, ascribing all observed dynamics to drift alone. Here, we expand on current drift-diffusion models to learn both the drift and diffusion terms that describe every observed cell state. These models are constructed from stochastic neural differential equations, continuous deep neural networks that approximate the theoretically complex differential equations underlying gene regulatory networks in hematopoiesis.
Lineage-barcoded, multi-time point single-cell RNA sequencing experiments can approximate ground truth cellular dynamics. Using such data, we demonstrate the predictive accuracy of our proposed approach through benchmarking against the state-of-the-art methods. Through our drift-diffusion model, we can now distinguish, for the first time, between the deterministic and stochastic contributions to cell fate decision making. In doing so, we identify genes whose expression is associated with cellular drift and indeed show that they correspond to well-known markers of specific cell types; moreover, we identify genes that are associated with cell states that exhibit notable diffusion. Finally, we demonstrate the potential of such models to capture the essence of the dynamic processes through prediction on out-of-distribution data (referred to as “transfer learning” in the machine learning field). For example, when the model is trained on *in vitro* hematopoiesis data, our model is able to accurately predict cell trajectories in the corresponding *in vivo* mouse model. We anticipate that such insights will be useful in identifying key dynamic and time-dependent regulatory processes in normal development and cancer.

Supervised manifold learning and classification; application to expression data visualization and cancer prediction
James Webber, Kevin Elias. *Brigham and Women's Hospital, Boston, MA*

Background: Manifold Learning (ML) has become essential in recent years for expression data visualization and dimension reduction. ML operates under the assumption that the data points lie on a manifold embedded in Euclidean space. The goal of ML is to learn an inverse embedding function to decipher the manifold structure. Cancer classification is a widely investigated application of expression profile data (e.g., miRNA) currently in the literature. The non-linear ML techniques commonly applied to expression data, such as *t*-distributed Stochastic Neighborhood Embedding (TSNE), Isomap, and Locally Linear Embedding (LLE), are intended for visualization, and cannot easily be applied to classification or unseen data, more generally. Such methods are also unsupervised, and do not factor in class information. Conventional linear ML methods, such as Principal Component Analysis (PCA), while applicable to unseen data and easy to use, are limited and can learn only linear manifolds.

Results: We introduce a novel, non-linear ML technique, which incorporates class memberships, and is readily applicable to unseen data and classification. Specifically, we construct a series of neighborhood graphs which describe the manifold structure locally within each cluster and among the cluster centroids. Our objective function uses the neighborhood graph information to preserve the class separations and manifold structure in reduced dimension space, and we train a neural network to learn an explicit, inverse embedding function. This allows for fast visualization and classification of unseen data. The technique is compared against similar methods from the literature which use neural networks for ML, and is shown to offer improved cancer classification performance on expression data from The Cancer Genome Atlas (TCGA) and The Cancer Proteome Atlas (TCPA).
Conclusion: We present a new, supervised ML technique designed specifically for classification, which can be efficiently applied to unseen data. The results show promise on multiple, large-scale expression data sets, and thus warrant further research into supervised ML methods for cancer classification and expression data visualization.

Autoencoder-based multimodal prediction of survival for non-small cell lung cancer

Jacob G. Ellen[1], Etai Jacob[2], Nikos Nikolaou[2], Natasha Markuzon[2]. *[1]University College London, London, United Kingdom,[2]AstraZeneca Oncology, Waltham, MA*

Most non-small cell lung cancer (NSCLC) prognosis prediction approaches use one data type and do not take advantage of the large amount of multimodal data available. To evaluate and explore the benefits of multimodal data integration, we present a combined feature selection and denoising autoencoder pipeline for NSCLC survival prediction and survival subtype identification using microRNA (miRNA), mRNA, DNA methylation, long non-coding RNA (lncRNA) and clinical data. Survival performance for both lung adenocarcinoma (LUAD) and squamous cell carcinoma (LUSC) patients was compared across modality combinations, data integration time and training data types. Multimodal data combinations outperformed single data modalities, with the early integration of all data modalities achieving concordance indexes (C-indexes) of 0.67 (±.04) and 0.63 (±.02) for LUAD and LUSC, respectively versus corresponding C-index of 0.64 (±.02) and 0.59 (±.03) for the best single cell modality (clinical). Notably, combining just lncRNA and clinical data facilitated effective survival discrimination, with C-indexes of 0.69 (±.03) for LUAD and 0.62 (±.03) for LUSC. Overall, higher performance was achieved by using a single denoising autoencoder for all biological data (early integration) and by training on both LUSC and LUAD patient data together. Two survival subtypes (log rank test p-value=1e-9) were identified, with 991 differentially expressed transcripts in the poorer survival group. Our analysis shows the value of multimodal data integration for predicting NSCLC progression, with especially good performance using the combination of lncRNA and clinical data. Early integration of biological data, with an initial linear feature selection technique and a denoising autoencoder for dimensionality reduction, showed effective survival performance and survival subtype identification. Further research is underway to expand analysis to different cancer types and data modalities and extract more biological interpretability from autoencoder models.

Why only focus on the tumor?: The crucial role of the extra-tumor environment to predict poor responders for locally advanced rectal cancer

Rumi Shin[1], Byunho Jo[1], Inyeop Jang[1], Cheong-Il Shin[2], Jin Sun Choi[3], Seung-Yong Jeong[3], Seung Chul Heo[3], Ji Won Park[3], Min Jung Kim[3], Tae Hyun Hwang[1]. *[1]Department of Artificial*

Intelligence and Informatics, Mayo Clinic, Jacksonville, FL,[2]Department of Radiology, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of

Introduction As total neoadjuvant therapy for locally advanced rectal cancer (LARC) emerged, the possibility of skipping radiotherapy for poorly responsive patients arose. Machine-learning algorithms have focused on the radiopathologic features of tumor segmentation in order to predict responsiveness to radiotherapy. However, in addition to the tumor itself, there are several factors related to responsiveness, such as vasculature affecting hypoxia or MRI-detected extramural vascular invasion status. We aimed to predict poor responders using pretreatment rectal MRI images without segmentation and to identify which factors mainly contribute to the prediction algorithm.
Methods Between Jan 1, 2000, and Dec 30, 2020, 689 consecutive patients were retrospectively included in two hospitals. Poor responders were defined by tumor regression grades (TRG) 2 and 3 that were determined through surgical resection. The ResNet-50 model was trained to predict poor responders from pretreatment rectal MRIs (T2-weighted axial, sagittal, and coronal images). We adopted a tenfold cross-validation for training and testing the model and used Gradient-weighted Class Activation Mapping (Grad-CAM) to highlight the important regions in the MRI scans that help predict poor responders.
Results The number in each group of TRG was 108 (15.7%), 250 (36.3%), 265 (38.5%), and 66 (9.6%) for TRG0, TRG1, TRG2, and TRG3, respectively. There were 618 patients in the training cohort and 71 patients in the validation cohort. In the training and validation cohort, the accuracy for the prediction of poor responders was 85.6% (area under the curve (AUC) 0.856 [95% CI 0.761-0.950]) and 70.2% (AUC 0.703 [0.682-0.724]), although without segmentation. Our prediction model achieved a sensitivity of 0.724 (95% CI 0.700-0.748), a specificity of 0.684 (0.658-0.710), a positive predictive value of 0.697 (0.656-0.737), and a negative predictive value of 0.708 (0.666-0.751) in the validation cohort. Grad-CAM showed that the most important part of the accurately predicted images to contribute to the prediction was not the tumor (7/355, 1.9%) but the pelvic vasculature (353/355, 99.4%), including iliac vessels, femoral vessels, and presacral plexus, and followed by the mesorectum (38/355, 10.7%).
Conclusion The pelvic vasculature contributes more to predicting poor responders to radiotherapy than the tumor itself. Therefore, when creating a prediction model for responsiveness to radiotherapy in LARC, this should be considered.

Learned phenotypic embeddings enable scalable imputation of high-content molecular data elucidating prognostic chromatin signatures
Christopher S. Probert, Zachary R. McCaw, Navami Jain, Daphne Koller. *Insitro, South San Francisco, CA*

Emerging high-content data modalities like functional genomics and spatial proteomics have enormous potential to reveal determinants of phenotypic plasticity that underlie variability in clinical outcomes, but to date these modalities are only collected in modestly sized research cohorts (< 200-400 patients), where we lack power to detect subtype-specific or prognostic signatures.
To study intertumor heterogeneity on a much larger scale (>10,000 patients), we developed a machine learning framework based on self-supervised embeddings that allows scalable imputation of high-content data on large standard of care datasets. Our framework starts by learning a phenotypic embedding of tumor state based solely on H&E histology images, allowing the

embedding to be trained on large patient cohorts regardless of availability of molecular covariates. It then learns to predict genomic or proteomic labels from the lower-dimensional phenotypic embeddings. This model can be used for imputation in much larger cohorts, where only clinical outcome and histology are available.
To demonstrate our method, we use the TCGA ATAC-seq data, which is available for 400 patients across 23 cancer types. By learning self-supervised embeddings of histology, our framework was able to impute ATAC-seq for 5,000 peaks in 11,000 patients across 31 cancer types, with high accuracy in held out samples (R2 = 0.61). To our knowledge, this represents the broadest available pan-cancer chromatin landscape.
The imputed ATAC-seq reveals a subset of peaks that are significantly associated with overall survival (OS) in multiple cancer types (e.g., Breast (BC) ATAC-only HR 1.75, p: 8.6E-3). Genes proximal to these peaks are strongly enriched for well characterized oncogenes, and also several novel genes with functions in cellular metabolism and chromatin remodeling whose expression is not known to be prognostic in our disease settings.
Finally, we developed models to predict OS from H&E slide embeddings and from imputed ATAC-seq, both pan-cancer and in specific tumor types. Both models significantly outperform baseline stage and molecular subtype clinical risk predictors (e.g., BC baseline HR: 2.44, p: 3E-6 vs. embedding/imputed ATAC HR 3.78, 2E-9, p for improvement 2E-9) and, interestingly, we find that adding an ATAC-seq based risk score to an embedding-based risk score significantly improves disease-specific survival prediction (HCC embedding-only HR: 2.13, p: 8E-5 vs. HCC embedding/imputed ATAC HR: 2.65, p: 1E-6). This suggests that histopathology images are a rich source of prognostic information beyond that which is captured by traditional pathologist grading. Overall, our work highlights the ability to use self-supervised embeddings of histopathology to impute biological covariates on large, standard-of-care cohorts, empowering novel insights into disease mechanisms and patient outcome.

Protein structure-based modeling to improve MHC class I epitope predictions

Eric A. Wilson[1], John Kevin Cava[2], Diego Chowell[1], Abhishek Singharoy[3], Karen S. Anderson[4].
[1]Precision Immunology Institute, Icahn School of Medicine at Mount Sinai, New York City, NY,[2]School of Computing and Augmented Intelligence, Arizona State University, Tempe, AZ,[3]School of Molecular Sciences, Arizona State University, Tempe, AZ,[4]School of Life Sciences, Arizona State University, Tempe, AZ

The ability to accurately identify peptide ligands for a given major histocompatibility complex class I (MHC-I) molecule has immense value for targeted anticancer therapeutics. However, the highly polymorphic nature of the MHC-I protein makes universal prediction of peptide ligands challenging due to lack of experimental data describing most MHC-I variants. To address this challenge, we have developed a deep convolutional neural network, HLA-Inception, capable of predicting MHC-I peptide binding motifs using electrostatic properties of the MHC-I binding pocket. By approaching this immunological issue using molecular biophysics, we measure the impact of sidechain arrangement and topology on peptide binding, feature not captured by sequence-based MHC-I prediction methods. Through a combination of molecular modeling and simulation, 5821 MHC-I alleles were modeled, providing extensive coverage across human populations. Predicted peptide binding motifs fell into distinct clusters, each defined with different degrees of submotif heterogeneity. Peptide binding scores generated by HLA-Inception are strongly correlated with quantitative MHC-I binding data, indicating predicted peptides can be ranked, both within and between alleles. HLA-inception also showed high precision when predicting naturally

presented peptides and can be used for rapid proteome-scale MHC-I peptide binding predictions. Finally, we show that the binding pocket diversity measured by HLA inception predicts response to checkpoint blockade.

An integrative prognostic machine learning model in mantle cell lymphoma

Holly A. Hill[1], Preetesh Jain[2], Michael L. Wang[2], Ken Chen[1]. *[1]Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[2]Lymphoma and Myeloma, UT MD Anderson Cancer Center, Houston, TX*

Background: Mantle cell lymphoma (MCL) is an uncommon B-cell lymphoma. The clinical course is highly variable: some patients have aggressive disease and relapse after treatment, while others have indolent disease or respond exceptionally to frontline therapy. Prognostication of MCL patients is dynamic and continues to evolve as novel therapies develop. Current prognostic indicators, such as the MCL international prognostic index (MIPI), were primarily designed with patients treated with chemo-immunotherapies. Using machine learning (ML) and molecular data, we provide a novel predictive method to improve upon conventional clinical markers.
Methods: We studied 785 MCL patients diagnosed at MD Anderson since 2014 and retrospectively classified them as “aggressive MCL” (n=311): relapsed or refractory to frontline treatment, and “mild MCL” (n=474): those who did not relapse after the first treatment (exceptional response) or had indolent disease never requiring treatment. After data extraction and feature engineering, 195 baseline features comprised of clinical, genomic, pathology, and cytogenetic data were integrated into an extreme gradient-boosted ensemble ML model (XGBoost). The dataset containing all patients was split (75/25) into a training and test set. Hyperparameters for the model were tuned using a grid-based, space-filling (Latin hypercube) technique and resampled 10-fold cross-validation from the training set. Training, validation, and testing sets were split using stratification of the classification variable to avoid class imbalance.
Results: Our integrative model achieved area under the curve (AUC) = .82 and accuracy = .76 on the test set and outperformed an XGBoost model using only clinical features (AUC = .78, accuracy = .68). Additionally, the fully integrated model improved on metrics from a similar multivariate logistic model including all patients (AUC = .72, accuracy =.72). Univariate logistic models were fit on the classification variable using the MIPI and other prognostic indices. The integrated ML model significantly outperformed the MIPI (AUC = .62, accuracy = .60) and other indices in predicting patient class. Clinical, pathological, cytogenetic, and genomic data were all represented as impactful features in a variable importance plot (VIP) and Shapley (SHAP) additive values of the fully integrated ML model. This model was used to launch a rest application programming interface (API) in which important features could be entered and a prediction returned.
Conclusion: Our study demonstrates that the current paradigm of using limited features in disease prognostics should be replaced with more advanced ML models that utilize genomic and other molecular data. Future work will include expanding the features included in the model and using the rest API to construct a graphical user interface accessible to clinicians and other researchers to make treatment decisions in precision oncology.

Deep learning enables label-free tracking of heterogeneous subpopulations

Tyler Jost, Andrea Gardner, Amy Brock. *University of Texas at Austin, Austin, TX*

Observing and quantifying the proliferation of subpopulations in cancer is key to understanding how heterogeneous groups of cells interact and respond to therapy, their environment, and each other. Prior research has demonstrated that cell-state properties such as metastatic potential and genotype perturbation are encoded in cellular morphology and can be identified with various machine-learning approaches. This encoding spans multiple imaging modalities such as brightfield, phase contrast, and stained whole-slide images, and phenotype prediction can be accomplished using both classical and deep machine learning methods. Here we show that not only do these prediction capabilities extend to transcriptomic subpopulations, but that they can be used to track these populations in high throughput longitudinal live-cell imaging experiments. Using single-cell RNA sequencing, we observed that, among untreated MDA-MB-231 triple negative breast cancer cells, there exist two transcriptomically distinct populations of cells. Using fluorescence-activated cell sorting based on the differentially expressed surface marker ESAM, we isolated these subpopulations and fluorescently labeled them with mCherry or GFP depending on their transcriptomic cluster. Cells were then grown in monoculture or coculture and imaged every 4 hours at 20x resolution. To identify the associated transcriptomic cluster, we trained an instance segmentation algorithm, Mask R-CNN, to both segment and classify cells. We find that, despite being derived from the same cell line, these phenotypes can be predicted using phase contrast images alone. These results demonstrate that cellular phenotypes manifested by distinctive RNA expression signatures can now be surveilled in a high-throughput manner across multiple samples and conditions without further RNA sequencing or biomarker labeling. We anticipate that this methodology of high throughput tracking will be applicable to other heterogeneous subpopulations, such as isolated therapy-resistant or sensitive cells. Tracking transcriptomically distinct populations using only high-throughput imaging will increase the granularity of population analysis and enable more rapid assessment of cancer cell evolutionary dynamics.

Systematic evaluation and comparison of drug response prediction models: a case study of prediction generalization across cell lines datasets

Alexander Partin[1], Thomas S. Brettin[1], Yitan Zhu[1], Jamie Overbeek[1], Oleksandr Narykov[1], Priyanka Vasanthakumari[1], Austin Clyde[1], Sara E. Jones[2], Satishkumar Ranganathan Ganakammal[2], Justin M. Wozniak[1], Andreas Wilke[1], Jamaludin Mohd-Yusof[3], Michael R. Weil[2], Alexander T. Pearson[4], Rick L. Stevens[1]. *[1]Argonne National Laboratory, Lemont, IL,[2]Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Los Alamos National Laboratory, Los Alamos, NM,[4]Hematology/Oncology, Department of Medicine, University of Chicago, Chicago, IL*

Predictive modeling holds great promise for improving personalized cancer treatment and efficiency of drug development. In recent years**,** deep learning (DL) has been extensively explored for drug response prediction (DRP), outperforming classical machine learning in prediction generalization to new data. Despite the considerable interest in DRP, no agreed-upon methodology for evaluating and comparing the diverse DL models yet exists. Existing papers generally demonstrate the performance of proposed models using cross-validation within a single cell line dataset and compare with baseline models of their choice, substantially limiting the scope and validity of model evaluation and comparison. In this work, we investigate the ability of DRP models for generalizing predictions across datasets of multiple drug screening studies, a more challenging scenario mimicking practical applications of DRP models. Five cell line datasets and six community DRP models with advanced DL architectures have been explored.
Public cell line drug screening datasets have been curated and processed for this analysis, including CCLE, CTRP, GDSC1, GDSC2, and GCSI. For each dataset, the same preprocessing pipeline was

used to generate cell line gene expressions, drug representations, and drug response values. The six DRP models include advanced architectures and feature engineering methods such as transformer, graph neural network, and image representation of tabular data. Systematic model curation and training have been applied, including consistent training and testing data splits across models and hyperparameter optimization (HPO). To cope with the large-scale model training and HPO, automatic workflows have been implemented and executed on high-performance computing systems.
A 5-by-5 matrix of prediction scores, corresponding to the five datasets in both row and column dimensions, has been generated for each model, with off-diagonal values representing the cross-dataset generalization. Despite the advanced DL techniques, all models exhibit substantially inferior performance in cross-dataset analysis as compared with cross-validation within a single dataset.
This result demonstrates the challenge of cross-dataset generalization for DRP and motivates the need for rigorous and systematic evaluation of DRP models, which simulates real-world applications.

A broad-use deep learning model based on multi-dimensional morphology to identify and characterize tumor cell heterogeneity

Emilie C. Schneider, Stephane C. Boutet, Anastasia Mavropoulos, Andreja Jovic, Jeanette Mei, Nianzhen Li, Kiran Saini, Senzeyu Zhang, Chassidy Johnson, Vivian Lu, Ryan Carelli, Kevin B. Jacobs, Mahyar Salek, Maddison Masaeli. *Deepcell Inc., Menlo Park, CA*

Technological advances have ushered in a new multi-omics era that has elucidated more granular information on cell types and functions at single-cell resolution. Integrating morphology as a multi-dimensional readout of cell identity, state, and function is an area of broad interest, since it has been historically difficult to quantify morphological properties. Here, we apply artificial intelligence (AI) and multi-dimensional morphology to characterize a variety of human cell types and states using the Deepcell platform. Captured brightfield images of cells flowing inside a microfluidic channel are analyzed by AI models in real-time and cells of interest can be sorted for downstream molecular or functional analyses.
We developed an AI model, termed ‘Human Foundation Model’ (HFM), for broad use that combines machine learning with computer vision for multi-dimensional morphology analysis to provide interpretable features on a broad range of human cells and diverse sample types. The HFM training and validation datasets, comprising 1.18 million and 4.05 million cell images, respectively, were chosen to capture a comprehensive range of visual features and cover a wide spectrum of biological diversity. Samples included 6μm polystyrene beads (as controls) and multiple immune and carcinoma cell lines. Subsets of these images were labeled for specific cell features then included in the supervised portion of the model training.
We apply the HFM as part of the Deepcell system to identify and characterize the morphological heterogeneity of tumor cells in different types of cancers such as melanoma, non-small cell lung carcinoma, and malignant pleural effusions. We further demonstrate the ability of the platform to distinguish different cell types (epithelial, stromal, immune, and endothelial cells) commonly found in tumors that typically require complex antibody panels.
With the Deepcell platform and the HFM, we determined cell identities using morphological features associated with distinct processes characterized by granules, vesicles, cell size, pigmentation and others. Furthermore, sorted cells of interest are unlabeled and can be retrieved for

further analysis. This AI-powered technology can be applied to diverse areas including drug screenings/mechanism of action, tumor biology, and functional genomics.

Discovery of plasma protein biomarkers associated with overall survival in R/R DLBCL patients treated with loncastuximab tesirine

Francesco Vallania[1], Victoria Cheung[1], Anupriya Tripathi[1], Maggie Louie[1], Thomas Snyder[1], Jimmy Lin[1], Karin Havenith[2], Yajuan Qin[2], Serafino Pantano[2], Jens Wuerthner[2], Patrick H. van Berkel[2]. *[1]Freenome, Inc., South San Francisco, CA,[2]ADC Therapeutics SA, Epalinges, Switzerland*

Plasma proteomics is a non-invasive source of potential biomarkers associated with cancer treatment outcomes, including disease progression and overall survival (OS). Loncastuximab tesirine (lonca) is an antibody-drug conjugate, composed of a humanized anti-CD19 antibody conjugated to a pyrrolobenzodiazepine dimer cytotoxin, for the treatment of relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL). Here, we investigated the association of plasma protein biomarkers with OS of R/R DLBCL patients prior to treatment with lonca (phase 2 trial, NCT3589469, LOTIS-2).Abundances of 888 plasma proteins, including inflammation, cancer and DNA repair associated markers, were measured for 69 patients with R/R DLBCL from plasma samples collected at baseline. Protein markers predictive of OS were selected using a L1 regularized Cox proportional hazards model (CoxPH) incorporating survival time and censoring status. Protein modules associated with OS were discovered by performing principal component analysis (PCA) on scaled protein abundances. Gene Set Enrichment Analysis (GSEA) was performed using Molecular Signatures Database (MSigDB) sets. We initially applied a regularized COX proportional hazards model to our proteomics dataset to identify proteins associated with OS, which revealed 5 protein markers (associated with decreased survival = REG3A, LAP3; associated with increased survival = NPTXR, C1QTNF1, FLT3) which stratified patients into distinct survival groups (p = 2.3e-4). As a complement to this approach and to extend our biological understanding of this cohort, we then applied PCA to the proteomics data to reveal underlying protein modules associated with survival. Our analysis identified principal component 3 (PC3) to have the strongest association to OS (rho= -0.63, FDR = 8.7e-07); with its top loadings consisting of known markers of cancer progression (top 3 proteins: SIGLEC10, IL6, TNFRSF6B). GSEA on PC3 loadings identified 68 significantly enriched gene sets (FDR < 5%). Gene sets reflective of changes in immune activation, increased cytokine activity and interleukin mediated activation (IL6, IL10) were negatively associated with OS, including activation of the following Hallmark pathways: IL6/JAK/STAT3 signaling and inflammatory response pathways.Overall, our results identify proteomics markers associated with DLBCL survival upon treatment with lonca, highlighting the potential of plasma proteins as a source of relevant biomarkers pending additional validation. [FV and VC contributed equally to this work]

A unified computational pathology method to quantify HER2 expression from raw IHC and IF images in breast cancer

Nicolas Brieu[1], Joshua Z. Drago[2], Ansh Kapil[1], Zonera Hassan[1], Anatoliy Shumilov[1], Claire Myers[3], Fatemeh Derakhshan[2], Fresia Pareja[4], Fanni Ratzon[2], Dana Ross[4], Jorge Reis-Filho[4], Thomas Padel[1], Andreas Spitzmuller[1], Christian C. Sachs[1], Felix Fegerer[1], Sihem Khelifa[1], J. Carl Barrett[5], Günter Schmidt[1], Hadassah Sade[1], Mark Gustavson[3], Sarat Chandarlapaty[6]. *[1]AstraZeneca*

Computational Pathology, Munich, Germany,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]AstraZeneca Pharmaceuticals LP, Gaithersburg, MD,[4]Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[5]AstraZeneca Pharmaceuticals LP, Waltham, MA,[6]Medecine, Memorial Sloan Kettering Cancer Center, New York, NY

Background**:** The development of automated quantitative methods to measure biomarker expression such as HER2 aims at reducing the subjective variability of pathologist-performed biomarker assessment of immunohistochemically (IHC) stained tissue slides. As an example, the deep learning-based Quantitative Continuous Scoring (QCS) algorithm [1] enables the objective measurement of biomarker expression based on the detection of individual tumor cells in the tumor regions and - for each cell, on the instance segmentation of its nucleus, cytoplasm, and membrane compartments.
Methods: In order to extend the QCS image analysis to similarly analyze tissue slides stained with immunofluorescence (IF), we re-trained the fully supervised deep-learning models, adjusted the normalization of images on tissue controls to account for variability between different staining batches, and finally used the normalized signal in IF instead of the Optical Density (OD) signal in IHC as a 8-bit grayscale image on which the biomarker expression is estimated. We performed QCS on HER2 IF images (HER2 clone 29D8 [CST], imaged with Vectra [Akoya] in parallel with HER2 IHC clone 4B5 [Roche Tissue Diagnostics]) performed on 26 primary and metastatic breast cancer samples representing the full range of HER2 expression, from null to highly overexpressed.
Results: Our analysis demonstrated that the QCS-based scoring on IHC-HER2 images correlates with the QCS-based scoring on IF-HER2 images. We observed a Pearson correlation of R=0.92 between the median membrane OD in IHC and the median normalized membrane signal in IF. Defining a positive cell as having an estimated membrane expression higher than a given so-called positivity threshold, we found a median Pearson correlation of R=0.85 between the percentage of positive cells detected in IHC and the percentage of positive cells detected in IF for increasing values of positivity thresholds. Correlation of the QCS median normalized membrane signal in IF was R=0.91 with mRNA (ERBB2 transcript levels [Nano String]) and R=0.88 with IHC-based H-scores, against R=0.83 and R=0.87 respectively for the QCS median membrane OD signal in IHC.
Conclusion: We describe the extension of a computational pathology-based approach for biomarker quantification in IHC to IF stained tissue slides. The consistency of the image analysis method translates into the consistency of the measurements in the two imaging methods. The use of IF could enable the improved quantification of expression, co-localization and spatial distribution of multiple proteins on the tissue sample.

Micron-resolution spatial analysis near the tumor-stromal border reveals a distinct density distribution of tumor-infiltrating lymphocytes and related genomic features

Sanghoon Song[1], Gahee Park[1], Sukjun Kim[1], Sangjoon Choi[2], Seokhwi Kim[3], Wonkyung Jung[1], Mingu Kang[1], Mohammad Mostafavi[1], Heon Song[1], Aaron Valero[1], Sérgio Pereira[1], Donggeun Yoo[1], Seulki Kim[1], Seunghwan Shin[1], Ken Nesmith[1], Chan-Young Ock[1]. *[1]Lunit, Seoul, Korea, Republic of,[2]Department of Pathology and Translational Genomics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[3]Ajou University School of Medicine, Suwon, Korea, Republic of*

Tumor-infiltrating lymphocytes (TILs) play a major role in predicting response to immunotherapy in solid tumors. However, few studies have analyzed TIL distribution and associated genomic

signatures based on proximity to the tumor-stromal border (TSB). Here, we describe TIL density, *IFN-γ* signature, and tumor mutational burden (TMB), according to set distances from the TSB, in The Cancer Genome Atlas (TCGA) pan-carcinoma dataset. For spatial TIL analysis, we used Lunit SCOPE IO, an AI-powered H&E whole-slide image analyzer, which identifies and quantifies tumor and lymphocyte cells within cancer or stroma area. In TCGA pan-carcinoma (n=7,468) dataset, the median values of cancer area and cancer stroma were 46.8 (interquartile range [IQR] 21.6-87.0) and 26.6 (IQR 10.9-54.5) mm^2, respectively, and those of TIL density in each area were 72.1 (IQR 34.1-160.1) and 747.2 (IQR 330.4-1575.9) /mm^2, showing 10-fold enrichment in stromal TIL (sTIL) compared to intratumoral TIL (iTIL). Subdividing the cancer area in 10 micron-wide steps from the TSB toward the tumor core, the median proportions of 0-10, 10-20, 20-30 (IT 0-10, IT 10-20, IT 20-30), and greater than 30 microns (IT 30-core) were 17.7%, 20.8%, 13.6%, and 47.9%, respectively. For subdividing the cancer stroma outwards from the TSB, the median proportions of 0-10, 10-20, 20-30 (ST 0-10, ST 10-20, ST 20-30), and greater than 30 microns (ST 30-outside) were 13.6%, 19.4%, 13.5%, and 53.5%, respectively. From the tumor core to TSB, median values of TIL density were 53.4 (IT 30-core), 59.3 (IT 20-30), 69.3 (IT 10-20), 127.4 (IT 0-10) /mm^2, respectively. From the TSB to the remaining stroma, median values of TIL density were 98.7 (ST 0-10), 567.6 (ST 10-20), 708.8 (ST 20-30), and 896.1 (ST 30-outside) /mm^2, respectively. Hence, the density of TIL generally increased from the tumor core to the outside of cancer stroma. Of note, *IFN-γ* signature showed the highest level of correlation with TIL density in IT 10-20 (Spearman's rho [ρ] 0.5146) or IT 0-10 (ρ 0.5143), compared with other subdivided cancer areas (ρ 0.4567-0.4924), and cancer stromas (ρ 0.1454-0.4529). However, TMB was highly correlated with TIL density in ST 20-30 (ρ 0.3162) or ST 30-outside (ρ 0.3278), compared with other subdivided cancer stromas (ρ 0.0588-0.2843) and cancer areas (ρ 0.0784-0.1208). In conclusion, AI-powered analysis of the tumor micro-environment reveals that iTIL density increases from the tumor core to the outside of tumor-stromal border. *IFN-γ* signature is high in the area of the tumor-stromal border on the tumor side, while tumor mutational burden is associated with sTIL far from the tumor-stromal border.

Robust prediction of pan-cancer immune checkpoint blockade response using machine learning

Tiangen Chang[1], Saugato R. Dhruba[1], Yingying Cao[1], Luc G. T. Morris[2], Eytan Ruppin[1]. *[1]NIH-NCI, Bethesda, MD,[2]Memorial Sloan Kettering Cancer, New York, NY*

Immune checkpoint blockade (ICB) has revolutionized our approach to cancer treatment. However, the response rate is still low. With the accumulation of data, efforts to use these data to build machine learning predictors of ICB response are rising. However, as most datasets are still quite small, pertaining machine learning models may often 'overfit' the data, i.e., have a much weaker performance on independent test data than on the data they were learned upon. Here we analyzed ~2000 patient samples from multiple cohorts across 16 solid tumor types. Based on 10 genomic & clinical features, we built different machine learning models, comparing their performance in terms of the Area Under ROC Curve (AUC) and importantly, in terms of the AUC difference between training vs validation sets, using a standard cross validation procedure. As a result, the Linear LASSO Regression (LLR) model outperformed all other models by having the highest AUC on the validation set (0.74) and notably, the smallest AUC difference between training and validation sets (0.02). In contrast, these two AUC values for the FDA approved tumor mutational burden (TMB) biomarker are 0.63 and 0.03. The highest predictive features were, receiving chemotherapy before ICB treatment or not, TMB, cancer type, blood albumin level, blood neutrophil-to-lymphocyte

ratio, and patient age. The LLR score also consistently predicted overall survival and progression-free survival across all individual cancer types. More importantly, ICB response probability increased near-monotonically from 0% to > 43% with the LLR score, which is an important feature for patient exclusion. In contrast, ICB response probability is ~25% when TMB = 0 and not always higher with higher TMB. In summary, the LLR model identifies key features predicting pan-cancer ICB response and survival. The use of combined genomic and clinical features holds potential to further facilitate clinical ICB patient stratification beyond TMB.

Machine learning of cancer type and tissue of origin from proteomes of 1,277 human tissue samples and 975 cancer cell lines

Zhaoxiang Cai[1], Zainab Noor[1], Adel T. Aref[1], Emma L. Boys[1], Dylan Xavier[1], Natasha Lucas[1], Steven G. Williams[1], Jennifer M. Koh[1], Rebecca C. Poulos[1], Peter G. Hains[1], Phillip J. Robinson[1], Rosemary Balleine[2], Roger R. Reddel[1], Qing Zhong[1]. *[1]ProCan, Children's Medical Research Institute (CMRI), Sydney, Australia,[2]The University of Sydney, Sydney, Australia*

Introduct**ion** Cancer type is determined through tumor morphology, aided by immunohistochemical staining. The development of machine learning (ML) models using histology slides has powered the image-based prediction of the site of origin in cancer of unknown primary (CUP). Here, we used ML on proteomic data to predict cancer types and tissue of origin from a sample cohort consisting of 1,277 human tissue samples spanning 44 cancer types. The training proteome datasets included two independent sets of proteomes acquired from a pan-cancer cell line collection and a subset of the tissue cohort for online ML.

Methods All samples were processed using data-independent acquisition mass spectrometry (DIA-MS). Two proteomic profiles from the pan-cancer cell line cohort were generated using two independent sample preparation methods. These were normalized by Combat and merged by averaging the protein abundance, yielding a single training set (D1) with 975 cell lines and 9,688 proteins. Similary, 1,277 tissue samples were processed by DIA-MS, quantifying 9,501 proteins. Celligner was used to align the cell lines (D1) with the tissue cohort. Half of the tissue proteomes were used as a second training set (D2) for online ML and a hold-out test set was constructed by taking the other half of the tissue cohort (T1). A multinomial logistic regression was used to predict cancer and tissue types. Top-k accuracy, as the evaluation metric, computes how often the correct cancer and tissue type class is among the top k classes predicted.

Results As a proof of concept, we defined six cancer types (adenocarcinoma, sarcoma, squamous carcinoma, lymphoma, melanoma and small cell carcinoma) and seven adenocarcinoma tissues of origin (breast, colorectal, liver, lung, ovary, stomach/esophagus and pancreas) for an ML experiment. We learned a classifier using the cell lines (D1) as the baseline training set, and consecutively added 10% of D2 to D1 for online ML. We tested the baseline model and each subsequent new model on the test set T1. We observed a monotonic performance increase from 0.89 (baseline; Top-1 accuracy) to 0.97 (all D2 were used) when predicting the six cancer types. We observed an analogous trend when predicting the seven tissue types (from 0.64 to 0.84). These results suggest that cancer cell lines can be used to predict cancer type and adenocarcinoma tissue of origin.

Conclusion Our proteomic-based ML model can predict cancer type and adenocarcinoma tissue of origin in concordance with existing histopathological classification. It can also assign multiple probabilities to tumor type and tissue of origin, potentially enabling the classification of CUP in future work. By adding tissue samples stepwise to the existing model, its predictive performance

can be further enhanced. This reflects a real-world knowledgebase that will continue to increase in predictive power as additional data are added.

Universal immunohistochemistry positivity classification of cancer cells across multiple cancer types and antibodies using artificial intelligence

Biagio Brattoli[1], Mohammad Mostafavi[1], Sangjoon Choi[2], Taebum Lee[3], Seokhwi Kim[4], Wonkyung Jung[1], Soo Ick Cho[1], Jinhee Lee[1], Keunhyung Chung[1], Jeongun Ryu[1], Seonwook Park[1], Sergio Pereira[1], Seunghwan Shin[1], Chan-Young Ock[1]. *[1]Oncology, Lunit, Seoul, Korea, Republic of,[2]Department of Pathology and Translational Genomics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[3]Department of Pathology, Chonnam National University Hospital, Chonnam National University Medical School, Gwangju, Korea, Republic of,[4]Department of Pathology, Ajou University School of Medicine, Suwon, Korea, Republic of*

Background: Novel cancer therapeutic antibodies targeting tumor-specific antigens are in development. However, precise quantification of target protein expression on Tumor Cells (TC) from immunohistochemistry (IHC) is challenging. Here, we developed an artificial intelligence powered image analyzer, called Universal IHC (UIHC), which robustly detects and quantifies targets of interest expressed in multiple untrained cancer types and antibodies.
Methods: UIHC model can detect TCs and classify IHC positivity across many antibody-cancer pairs, called “domains”. UIHC is trained on four domains: lung cancer (569K/107K) (No. of negative TC / positive TC), bladder cancer (270K/116K), and breast cancer stained with PD-L1 22C3 pharmDx (270K/96K), and breast cancer stained with HER2 4B5 (307K/256K); all annotated by board-certified pathologists. For comparison, we developed four AI models using only a single domain (SD). All models were evaluated on hold-out test sets divided in three groups: “in-domain” included the four training domains; “near-out-domain” contained PD-L1 SP142 and SP263 on lung cancer; “far-out-domain” contained 7 antibodies on 15 cancer types.
Results: For cell detection, the harmonic means of the precision and recall (F1 score) averaged on TC- and TC+ (mF1), formatted as (UIHC; avg-SD [min, max]) were: “in-domain” (72.5%; 68.9% [67.1%-69.9%]), “near-out-domain” (64.8%; 61.6% [59.7%-65.2%]), and “far-out-domain” (70.3%; 62.5% [59.0%-65.9%]).
At image level, cutoffs at 1% and 50% of TPS are applied for PD-L1 22C3 and SP263, thus 3-way accuracy is computed*. In far-out-domain, the mean TPS per antibody is used as a cutoff.
UIHC outperforms SD on most antibodies (Table 1).
Conclusion: We demonstrated that a UIHC, built by merging multiple domains during development, can be effective on untrained domains. UIHC can be applied to novel targets in future clinical research with minimal or no adaptation needed.

Comparison of deep learning approaches applied to hematoxylin and eosin-stained whole slide images from women with benign breast disease to predict risk of developing invasive breast cancer

Monjoy Saha[1], Mustapha Abubakar[1], Thomas E. Rohan[2], Ruth M. Pfeiffer[1], Máire A. Duggan[3], Kathryn Richert-Boe[4], Jonine D. Figueroa[5], Jonas S. Almeida[1], Gretchen L. Gierach[1]. *[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Rockville, MD,[2]Department of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY,[3]Department of Pathology and Laboratory Medicine, University of Calgary,*

Calgary, AB, Canada,[4]Kaiser Permanente Center for Health Research, Vancouver, WA,[5]Usher Institute of Population Health Sciences and Informatics, The University of Edinburgh, Scotland, United Kingdom

Purpose: To compare deep learning (DL) approaches applied to hematoxylin and eosin (H&E)-stained whole slide images (WSIs) from women with benign breast disease (BBD) to predict risk of developing invasive breast cancer (BC).
Method: Two deep convolutional neural networks (CNNs) based on a customized 16-layer CNN (known as VGG-16 by Visual Geometry Group, University of Oxford) and an automated CNN (Google's AutoML) were trained using H&E-stained WSIs to identify distinct histological features on diagnostic BBD biopsies that characterize BBD patients who were (cases, n=347) and were not (controls, n=347) subsequently diagnosed with invasive BC. The CNNs consisted of multiple convolutions, max pooling, fully connected, etc., layers. To incorporate our data into the VGG network, we customized the network architecture and hyperparameters to enhance the classification performances. For AutoML, we used the system's default network with standard hyperparameters. The trained model was then tested on a held-out set of 140 patients (70 cases and 70 controls). The quantitative performance was evaluated using accuracy (ACC), sensitivity (SE), precision (PR), area under the receiver operating characteristic curve (AUROC), etc. For qualitative results, we generated heatmaps using weights and feature maps from the final convolution layer of our customized CNN. Heatmaps were superimposed onto original H&E images to highlight different unique features (such as pattern, texture, color, and morphology).
Results: We found both deep learning methods to demonstrate remarkable ability in predicting case-control status in the held-out set (AUROC= 90% and 89% for customized CNN and AutoML, respectively). However, our customized CNN outperformed AutoML in terms of ACC (83.57% (95% confidence interval (CI): 76-89%) vs 77.86% (95%CI: 70-84%), respectively); SE (82.85% (95%CI: 72-91%) vs 77.86% (95%CI: 70-84%), respectively); PR (84.05% (95%CI: 73-92%) vs 81.97% (95%CI: 70-91%), respectively); F1 score (83.45% (95%CI: 76-89%) vs 76.34% (95%CI: 68-83%), respectively); as well as error rates (0.16% (95%CI: 0.11-0.24%) vs 0.22% (95%CI: 0.16-0.30%), respectively). Heatmaps revealed specific stromal and epithelial features that were distinct between case and control images.
Conclusion: By using routinely available H&E-stained WSIs, we developed a customized CNN that outperformed AutoML in distinguishing future BC cases from controls in a BBD population. The qualitative results identified stromal and epithelial regions in the BBD biopsies that were highly predictive of being a case versus control and vice versa thereby providing etiologic clues into breast cancer development following BBD. Future research will focus on leveraging DL to better understand the histologic basis of BBD progression to invasive BC.

Detecting pulmonary malignancy against benign nodules using non-invasive cfDNA fragmentomics assay
Shun Xu[1], Ji Luo[1], Wanxiangfu Tang[2], Hua Bao[2], Jiajun Wang[1], Shuang Chang[2], Haimeng Tang[2], Zifang Zou[1], Xiaoxi Fan[1], Yang Liu[1], Changrui Jiang[1], Xue Wu[2], Yang Shao[2]. *[1]The Department of Thoracic Surgery, The First Hospital of China Medical University, Shenyang, China,[2]Nanjing Geneseeq Technology Inc., Nanjing, China*

Background: Early screening using Low-Dose Computed Tomography (LDCT) can reduce mortality by non-small-cell-lung cancer (NSCLC), which contributed the most cancer-related death worldwide. Yet ~25% of the "suspicious" nodules identified by LDCT are confirmed to be benign

through resection surgery, which adds to patients' discomfort and the burden of the healthcare system. In this prospective study, we set to develop a non-invasive liquid biopsy assay for distinguishing pulmonary malignancy from benign lung nodules using cfDNA fragmentomic profiling.
Methods: An independent training cohort, which consisted of 193 patients with malignant nodule and 44 patients with benign nodule, was used to construct a machine learning model. Base models employing 4 different fragmentomics profiles were optimized using an automated machine learning (autoML) approach before being ensemble stacked to create the final predictive model. An independent validation cohort included 96 malignant nodules and 22 benign nodules, as well as an external test cohort containing 58 malignant nodules and 41 benign nodules, were used to assess the performance of the ensemble stacked model.
Results: Our machine learning models showed excellent performances in detecting patients with malignant nodules. The AUCs reached 0.857 (0.782 - 0.932) and 0.860 (95% CI: 0.788 - 0.933) in the independent validation cohort and the external test cohort, respectively. The validation cohort achieved an excellent 68.2% specificity (95% CI: 45.1-86.1%) at the targeted 90% sensitivity (89.6%, 95% CI: 81.7-94.9%). An equivalently good performance was observed while applying the cutoff to the external cohort, which reached a specificity of 63.4% (95% CI: 46.9-77.9%) at 89.7% sensitivity (95% CI: 78.8-96.1%). Subgroup analysis for the independent validation cohort showed that the sensitivities for detecting various subgroups of nodule size (< 1cm: 91.7%; 1 - 3cm: 88.1%; > 3cm: 100%; Unknown: 100%) and smoking history (Yes: 88.2%; No: 89.9%) all remained high among the lung cancer group. Additionally, the specificities for successfully identifying the benign nodules among different subgroups decrease as the size increase (< 1cm: 80.0%, 1 - 3cm: 66.7%, > 3cm: 33.3%).
Conclusions: Our cfDNA fragmentomics assay can provide a non-invasive approach to distinguish malignant nodules from the radiographically suspicious but pathologically benign nodules.

Improving survival prediction using flexible late fusion machine learning framework for multi-omics data integration

Nikos Nikolaou[1], Domingo Salazar[2], Harish RaviPrakash[1], Miguel Goncalves[2], Gustavo Alonso Arango Argoty[1], Nikolay Burlutsky[2], Natasha Markuzon[1], Etai Jacob[1]. *[1]AstraZeneca Oncology, Waltham, MA,[2]AstraZeneca Oncology, Cambridge, United Kingdom*

Improving cancer patients Overall Survival (OS) prognosis is critical for personalization of treatment using model-identified drivers of cancer progression. Current cancer prognosis models largely rely on clinical and demographic patient characteristics. Adding 'omics'-based modalities can help improve patient OS prediction and lead to better disease categorization and understanding. We introduce a data driven methodology for combining multi-omics and clinical data, including clinical/demographics, mutations, gene expression, long non-coding and micro-RNA expression, DNA methylation, and proteomics for improving prediction of OS in cancer patients. High dimensionality of 'omics' modalities present challenges to combining them into one model. We propose a late stage modalities fusion where we construct a separate data driven model for OS prediction for each modality, later combining individual predictions in a final linear OS prediction model. With a limited number of patients to develop the model, such an approach helps to better protect against overfitting, and allows to account for different degrees of informativeness of modalities by weighting them according to individual success. We introduce a robust machine learning pipeline with rigorous training, testing and evaluation capabilities, and demonstrate its effectiveness on a suit of TCGA data. When comparing early vs. late fusion of omics and clinical

modalities for survival prediction using NSCLC TCGA data, we observe the C-index improvement from 0.57±.04 to 0.61±.01. Best individual modality performance was at 0.59±.02 using clinical modality. Dominant modalities in unimodal survival analysis varied between cancers, with clinical, RNA, and miRNA for LUAD, and clinical, RNA, and RPPA for LUSC. Using pan-cancer TCGA data for survival prediction, the best C-index = 0.77 was achieved using multi-omics model, followed by 0.76±.01 for clinical, 0.75±.01 for RNA seq, and 0.73±.01 for RPPA unimodal models.

Early detection of ovarian cancer using mRNA sample data to investigate the correlation of specific gene mutations with ovarian cancer

Zahra Saghaie, Christine Richardson, M. Taghi Mostafavi. *UNC Charlotte, Charlotte, NC*

Introduct**ion:** Ovarian cancer (OC) is the second most common gynecologic cancer in the U.S, and is the deadliest cancer of the female reproductive system. Because of the complex nature of OC, diagnoses are often by display of symptoms at late stages of disease. Identifying OC at early stages can increase the 5-year survival rate from 40% in stage IV to 94% in stage I. Therefore, effective screening and detection of OC at early stages is imperative. The main objective of this study is to develop a diagnostic panel of markers that correlate with early-stage OC, and ultimately, improve the survival rate of patients.

Background: Approaches in the past several years to detect malignant OC have focused on processing relevant images or screening genomic data. These studies use liquid-based biopsies, sonographic images, cyst images, CT images, MR imaging and genomics data. Some studies have focused on distinguishing malignant tumors versus benign tumor cells. In addition to statistical methods to examine available genomic datasets, Machine Learning models including K-Nearest Neighbor, K-means, Convolutional Neural Networks, Deep Learning, Support Vector Machine, Random Forest, and Fuzzy algorithms have been used.

Methods: In this study we proposed a method to determine a possible correlation between some actively expressed genes and OC, using publicly available mRNA data sets. The samples were retrieved from the GSE106817 dataset via the NCBI GEO site, with 333 cancerous and 2759 Non-cancerous samples. The objective is to define a set of genes which is able to illustrate prediction of correlation through the use of PCA, NMF and SVD. We further verified our findings by testing on one additional different mRNA datasets. For this, we compared several machine learning algorithms to potentially correlate active genes and OC stages, from the available data.

Results and Discussions: Through our study we have developed Machine Learning models valuable to identify patterns of disease at different stages, thus, potentially be useful in developing predictive models. Our initial experimental results have been demonstrated with a set of mRNA signatures, which may be used to create a panel of biomarkers valuable for detecting early-stage OC. Our results confirm the correlation between OC and PAX8, PEG3, and BIRC5, and MYB and RAC2. Continuation of this study highlights methods towards the early detection of OC and to improve disease identification outcome.

Prediction of conversion surgery completion following neoadjuvant modified FOLFIRINOX in borderline resectable and locally advanced pancreatic adenocarcinoma: machine learning algorithm analysis

Hyunseok Yoon[1], Kyu-Pyo Kim[2], Inkeun Park[2], Jae Ho Jeong[2], Heung-Moon Chang[2], Baek-Yeol Ryoo[2], Changhoon Yoo[2]. *[1]Department of Internal Medicine, Asan Medical Center, University of*

Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Background: Neoadjuvant modified (m) FOLFIRINOX is a standard therapy for medically fit patients with borderline resectable pancreatic cancer (BRPC) and locally advanced unresectable pancreatic cancer (LAPC). Completion of conversion surgery following mFOLFIRINOX is an important prognostic factor. In this study, we evaluated multiple machine learning models to predict completion of conversion surgery following neoadjuvant mFOLFIRINOX in BRPC and LAPC.
Methods: Between January 2017 and December 2020, a total of 647 patients with BRPC and LAPC treated with neoadjuvant mFOLFIRINOX at Asan Medical Center, Seoul, South Korea were enrolled. All demographic and clinicopathological data were retrospectively collected; age, ECOG performance status, BMI, resectability as per the NCCN guidelines, tumor location, tumor size, maximum standardized uptake value assessed by 18F-FDG PET/CT, number of cycles of mFOLFIRINOX, tumor response to mFOLFIRINOX, and serum CA 19-9. Several machine learning models, such as logistic regression and random forest classifier, were trained to predict curative-intent resection and were then internally validated. The relative importance of each variable was analyzed using both Gini importance and permutation importance.
Results: Among 647 patients, 173 (26.7%) underwent curative-intent conversion surgery (R0 or R1) following mFOLFIRINOX. The patients who underwent surgery showed significantly better overall survival (median 42.1 vs 17.2 months, P<0.0001) than those who did not. In multivariable analysis using logistic regression, age, resectability as per the NCCN guidelines, tumor size, number of cycles of mFOLFIRINOX, tumor response to mFOLFIRINOX, and CA 19-9 change rate (percentage change in CA 19-9 after mFOLFIRINOX) were significantly correlated to tumor removal with curative-intent conversion surgery. Random forest classifier showed the best predictive capability with AUC at 0.832. The most important feature was the CA 19-9 change rate.
Conclusions: In this large cohort-based analysis, completion of conversion surgery could be predicted successfully in BRPC and LAPC patients treated with neoadjuvant mFOLFIRINOX using machine learning models. Further external validation is necessary for generalization.

Optimization generator app (OpGen) for radiotherapy treatment planning using case-based reasoning

Reza Reiazi[1], Surendra Prajapati[1], Abdallah Sherif Radwan Mohamed[2], Clifton David Fuller[2], Mohammad Salehpour[1]. *[1]Radiation Physics, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Case-based reasoning (CBR) means adopting previous experiences (i.e, data from previous patients) to meet new demands (new patients). In this scenario, we developed an application named OpGen to generate optimization objective values for head and neck radiotherapy inverse treatment planning, using the previously treated patient with an acceptable outcome. OpGen will be helpful in radiotherapy treatment planning automation and efficiently reducing the required time to reach the target goals and improving the quality and safety of the treatment.OpGen has been developed in Python and has four main modules: 1- Analyzing radiotherapy treatment planning parameters of the previous patients in the database. We have developed (a) a powerful graphical user interface (GUI) that allows quantitative and qualitative analysis of the previous knowledge, including the type of frequently used objective parameter (Min Dose, Max Dose, Min DVH dose, etc.); (b) The

range of values used for each specific objective type, and (c) Histogram of the number of patients vs. values used for a specific objective type. 2- Importing patients from treatment planning and retrieving a user-defined number of treatment planning information from the previously treated patients in the database corresponding to the given patient using the user-defined quantitative features (geometrical, distance or geo-distance) and retrieval algorithms (k-Nearest Neighbor and Random Forest). 3- Generating optimization objective values based on the following available options: (a) The most similar patient in the database; (b)- Average or median value over the number of patients retrieved from the database; and (c) Deep learning generated values using a model trained over 100 similar cases retrieved from the database. 4- Generate a portable database of the objective values and patient geometric information for any inter- or intra-institutional usage of the algorithm. OpGen is compatible with RayStation (RaySearch Laboratories™) treatment planning and can retrieve, analyze and generate treatment planning optimization parameters in less than 3 minutes. OpGen can potentially increase the quality and safety of radiotherapy treatment planning by improving the efficiency of the optimization process.

Deep learning-based ensemble model using H&E images for the prediction of KRAS G12C mutations in non-small cell lung cancer

Sehhoon Park[1], Jongchan Park[2], Minuk Ma[2], Hyun-Ae Jung[1], Jong-Mu Sun[1], Yoon-La Choi[1], Jin Seok Ahn[1], Myung-Ju Ahn[1], Sanghoon Song[2], Gahee Park[2], Sukjun Kim[2], Huijeong Kim[2], Seunghwan Shin[2], Chan-Young Ock[2], Se-Hoon Lee[1]. *[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]Lunit, Seoul, Korea, Republic of*

Background: As the KRAS G12C mutation became targetable in non-small cell lung cancer (NSCLC), tissue based KRAS mutation test is now an essential practice for the treatment decision. Recently, predicting KRAS mutations using deep-learning models with H&E images to potentially increase the pre-test probability has been reported with modest performance. Herein, we conducted a novel approach to improve the performance of KRAS G12C prediction based on an ensemble model trained not solely on H&E images, but also with multi-layered semantic content produced by a pre-trained artificial-intelligence (AI) analyzer, Lunit SCOPE IO.
Methods: The Cancer Genome Atlas LUAD and LUSC (TCGA-Lung) samples were used for model development. A self-supervised vision transformer was used to extract deep features from raw H&E images; and an AI-based pathology profiling analyzer extracted semantic contents such as the spatial information of tumor cells, lymphocytes, cancer epithelium, and cancer stroma. A set of classifiers was trained based on the two features, and the ensemble of these features was used to improve robustness. The final model was evaluated through cross-validation and assessed on independent NSCLC samples from Samsung Medical Center (SMC) who tested KRAS mutation by various methods including whole exome sequencing or target sequencing.
Results: TCGA-Lung dataset (n = 930) includes 150 (16.1%) KRAS driver mutations, and 62 (6.7%) KRAS G12C. The best cross-validation performances of the models predicting KRAS G12C, measured by mean area-under-the-curve (AUC), were 0.768 trained by only H&E images (HE-only), 0.714 by AI semantic content (AISC) with MLP classifier (AI-MLP), and 0.697 by AISC with random forest (AI-RF), respectively. An ensemble of the three models showed an increased AUC of 0.787 in TCGA-Lung by cross-validation. These models were applied to an independent SMC dataset (n = 363), including 54 (14.9%) KRAS driver mutations, and 22 (6.1%) KRAS G12C. The mean AUC to predict KRAS G12C by HE-only, AI-MLP, and AI-RF models were 0.599, 0.644, and 0.678, respectively, implying limited robustness. However, the AUC of an ensemble of the 3 models was 0.745 in the SMC dataset, showing 71.0% sensitivity and 72.7%

specificity. Similar results were observed regardless of the KRAS testing method (TruSight Oncology 500 panel; n = 249; AUC 0.787, other tests; n = 114; AUC 0.720), the tissue size (surgical resection; n = 138; AUC 0.724, biopsy n = 225; AUC 0.763), and histology (excluding squamous cell carcinoma, n = 286; AUC 0.697).
Conclusions: An AI-based ensemble model combining H&E images with semantic contents extracted from pre-developed AI model significantly improved the accuracy and the robustness of KRAS G12C mutation prediction using H&E sample in NSCLC.

Predicting disease progression in inoperable localized NSCLC patients using cfDNA fragmentomics assay

Yin Yang[1], Tao Zhang[1], Jingbo Wang[1], Jianyang Wang[1], Wanxiangfu Tang[2], Hua Bao[2], Haimeng Tang[2], Xue Wu[2], Yang Shao[2], Xin Wang[1], Yuqi Wu[1], Linfang Wu[1], Xin Xu[1], Kunpeng Xu[1], Jingjing Zhao[1], Luhua Wang[1], Nan Bi[1]. *[1]Department of Radiation Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]Nanjing Geneseeq Technology Inc., Nanjing, China*

Background: There is an urgent clinical need to accurately predict the risk for disease progression in post-treatment NSCLC patients. However, the current ctDNA mutation profiling approaches were limited by low sensitivity, while the cfDNA fragmentomics profiling has shown an excellent capability for cancer early detection in NSCLC and therefore exhibits great potential for predicting disease progression. In this retrospective study, we aim to develop a non-invasive liquid biopsy assay utilizing cfDNA fragmentomics profiling for predicting disease progression in inoperable localized NSCLC patients.
Methods: The study cohort retrospectively enrolled 44 patients diagnosed with inoperable localized NSCLC who received first-line chemoradiotherapy/radiotherapy (including 23 disease progression during follow-up). Plasma samples were collected during or post-treatments, including 39 at the fourth week of treatment (TP1), 33 and 25 at 1 (TP2) and 3 (TP3) months post-treatment, respectively. cfDNA fragmentomic profiling, generated based on target sequencing data, was used to fit Regularized Cox Regression models. For each time point, a leave-one-out cross-validation (LOOCV) was performed to evaluate the models' predictive performances, which was subsequently compared against the ctDNA status determined by the mutation-based method.
Results: Our cfDNA fragmentomics assay showed excellent performance detecting patients with a high risk for disease progression. At TP1, the high-risk patients detected by our model showed an increased risk of 3.62 times (hazard ratio [HR] = 3.62, $p = 0.0026$) for disease progression, compared to 3.91 times (HR = 3.91, $p = 0.0022$) and 4.00 times (HR = 4.00, $p = 0.019$) for TP2 and TP3, respectively. These fragmentomics determined HRs were higher compared to the ctDNA mutation-based results (HR = 2.08, $p = 0.074$; HR = 1.49, $p = 0.61$) at TP1 and TP3, albeit being lower at TP2 (HR = 9.47, $p < 0.0001$). At TP1, the predictive model reached 40% sensitivity at 92.9% specificity, which was higher than the mutation-based method (40% sensitivity at 78.6% specificity), while the combination of the two methods reached a higher sensitivity (60%). Finally, a subset of the cohort (N = 19) with data for all three time points (TP1, TP2 and TP3) was examined, and the patients were labelled as high-risk for having a positive prediction or ctDNA status at any time point. The combined methods could predict disease progression with an excellent sensitivity of 88.9% at 80% specificity.
Conclusions: We developed a cfDNA fragmentomics assay for predicting disease progression in inoperable NSCLC patients. This assay showed increased predicting power during and post

treatment compared to the ctDNA mutation-based method, thus illustrating a great clinical potential to guide treatment decisions in inoperable NSCLC patients.

Computational cancer cell gene expression deconvolution from tumor bulk RNA-seq via the machine learning algorithm Helenus

Valentina Beliaeva[1], Ekaterina Ivleva[2], Boris Shpak[2], Daniil Litvinov[2], Anastasia Zotova[2], Krystle Nomie[2], Daniiar Dyikanov[2], Alexander Kuznetsov[2], Maria Savchenko[2], Aleksandr Zaitsev[2], Nathan Fowler[1], Alexander Bagaev[1]. *[1]Bostongene, Corp., Waltham, MA,[2]BostonGene, Corp., Waltham, MA*

Background**:** Biomarker gene expression is becoming more commonly utilized for clinical decision-making in oncology clinical practice. However, complex tumor tissue comprises a population of cancer cells (CC) and the tumor microenvironment (TME), causing expression signals belonging to the CC and TME calculated from bulk RNA-seq of the tumor tissue to be indistinguishable. To circumvent this, Helenus, a gene expression deconvolution tool, was developed to estimate TME-specific gene expression, consequently, providing precise CC-specific gene expression.

Methods: Helenus performs the "subtraction" of TME gene expression from the total expression calculated from bulk RNA-seq of the tumor tissue. To accurately reconstruct the CC expression profile, LightGBM gene models were trained on artificial transcriptomes created from > 1,000 different solid tumor cancer cell lines and > 3,000 samples of various TME cellular proportions. The LighGBM gene models included genes expressed predominantly in the TME (e.g., *CD3E*), both the TME and the CC (e.g., *BCL6*), or in the CC (e.g., *HER2*). The input features included: 1) RNA percentages of TME cell types predicted by the cell deconvolution tool Kassandra (Zaitsev et al., 2022); 2) evaluation of TME target gene expression *via* the estimation of its weighted average expression profile in TME cell populations; and 3) a set of TME- and CC-specific genes. The resulting predictions were adjusted based on the CC cell fraction. To evaluate Helenus' performance, CC and TME RNA were mixed at different ratios using various cancer cell lines and peripheral blood-derived TME cell populations and suspensions of tumor cells prepared from cancer tissue across multiple tumor purity dilutions.

Results: Helenus deconvolution resulted in an increased concordance correlation value from 0.73 to 0.98 between the real gene expression profile of pure CC and the reconstructed CC expression from bulk RNA-seq. Helenus showed high concordance between the gene expression profile of sorted cancer cell lines and the deconvolved gene expression across a wide range of CC RNA concentrations (20-90%) mixed with imitated TME RNA at varying concentrations. Helenus demonstrated high performance calculating gene expression of multiple clinically relevant biomarkers in the TME:cancer cell line mixes: *CD274* (PD-L1) (mean absolute error [MAE] ~3.5-fold reduction); *HLA-A* (~2.8-fold MAE reduction); *MKI67* (Ki-67, ~2.2-fold MAE reduction), *ERBB2* (HER2, ~1.7-fold MAE reduction). Helenus deconvolved CC expression and found significant correlations with CC gene amplifications and deletions (e.g., *BCL-2*, *VNN3*) independent of tumor purity ($p < 0.003$).

Conclusion: Helenus, the CC gene expression deconvolution tool, was developed with high accuracy to contribute to tumor diagnosis, disease monitoring, treatment decisions, and clinically relevant biomarker identification.

Using computer vision to resolve proliferative dynamics within therapeutic responses in large scale screens of patient derived models

Madhavi Kannan, Brian Larsen, Chi-Sing Ho, Jagadish Venkataraman, Martin Stumpe, Ameen Salahudeen. *Tempus Labs, Chicago, IL*

IC50, Emax, and AUC values are commonly used to assess susceptibility for a given therapeutic candidate but are subject to the number of cell divisions for a given in vitro model. When comparing multiple in vitro models and especially patient-derived models such as patient-derived tumor organoids, the degree of intrinsic cell proliferation or doubling time substantially differs and therefore limits conventional metrics as above. Furthermore, assays that directly measure cellular viability can oftentimes overlook therapeutic agents that have cytostatic, versus cytotoxic mechanisms of action and require assays with similar sensitivity and precision to account for this phenotype. Finally, terminal endpoint assays can require tedious temporal optimization to capture the full dynamic range of a given therapeutic which makes cross-therapeutic and cross-model comparisons difficult to interpret. An assay that incorporates these multiple features and in vitro specific doubling time would lead to highly accurate measurements of drug effects and allow the calculation of growth-adjusted IC50 values i.e. GI50 values.

We, therefore, sought to develop a computer vision model that utilizes label-free longitudinal light microscopy images as input to report the total number of nuclei present within a given experimental well, allowing for the monitoring of cell division and any cytostatic effects. To train the neural network, we use Hoechst-stained images as our ground truth. The model used is an extension of the Regularized Conditional Adversarial Network (PMID: 34320344). It takes as input Brightfield images along with the registered Hoescht stained wells. The label for each well is obtained using commercial image processing software to count the total number of nuclei present in each well from the Hoescht stained channel. The model was trained to predict the virtually stained Hoescht well for every Brightfield, as well as the aggregate nuclei count for all organoids present inside the well. The model was trained on 29000 individual sites across 9 distinct cancer types.

Five experiments were conducted during training to test for bit depth and tonality effects of the input training data. Inference on 9240 images showed a pearsonR score of 0.81 on the best-performing model. Results show that the model performs well and can be applied in real-time using only experimental data to correct for differing cell division rates and measure cytostatic phenotypes all while using simple light microscopy. The tool will enable cross-comparison of different therapeutic MoAs as well as enable cross-cancer type/indication comparison for a therapeutic in development to inform early development clinical strategy.

Predicting cancer cell response to TEAD auto-palmitoylation inhibitor using bulk RNA-seq data and a random-forest based algorithm

Adam Kurkiewicz[1], Sebastian Y. Müller[1], Oliver Gibson[1], Sara Castellano[1], Germán Stark[1], Pol A. Vecino[1], Shuirong Zhou[2], Tracy T. Tang[3]. *[1]BioMage Ltd., Edinburgh, United Kingdom,[2]Bio-Research Innovation Center Suzhou, Suzhou, China,[3]Vivace Therapeutics, San Mateo, CA*

TEAD transcription factors are the major effectors of the Hippo-YAP/TAZ pathway essential in controlling organ size and maintaining tissue homeostasis. Upon coactivator YAP/TAZ binding, TEAD transcription factors are activated to induce expression of genes involved in cell proliferation and survival. It has been shown that auto-palmitoylation is required for TEAD interaction with YAP/TAZ and hence activation of transcriptional activity. Potent small molecule

TEAD auto-palmitoylation inhibitors have been reported (Tang *et al*, 2021, *Mol Cancer Ther*.). These TEAD inhibitors disrupt YAP/TAZ-TEAD protein interaction, suppress TEAD transcriptional activity, and selectively block proliferation of *NF2*-deficient mesothelioma *in vitro* and inhibit *NF2* mutant xenograft tumor growth *in vivo*. Although genetic alterations of pathway components (such as, *NF2*) leading to YAP/TAZ constitutive nuclear localization and TEAD activation have been reported in a variety of human malignancies, these alterations are infrequent in most cancers, and increased accumulation of nuclear YAP has been reported in cancers (e.g., hepatocellular carcinoma) that do not harbor pathway mutations. Utilizing *in vitro* efficacy data from cell line screens, gene expression (RNA-Seq) datasets, and a custom bioinformatics data-processing and normalization pipeline, we sought to elucidate gene expression patterns by using a random-forest based classifier. Our classifier, which aims to predict the response (efficacy) of treatment using normalized gene expression of selected genes, was originally trained on the public bulk RNA-seq pan-cancer *in vitro* dataset available in the Cancer Cell Line Encyclopedia (CCLE) from the Broad Institute, as well as a privately obtained TEADi response data for corresponding CCLE cell lines. Binary response labels (responder/non responder) for each cell line were obtained by thresholding efficacy measures. The classifier - evaluated using cross-validation - achieved an average AUC of 0.80. Then from our screen of 50 patient-derived Chinese liver cancer (CLC) cell models (Qiu *et al*, 2019, *Cancer Cell*), both as single agent and in combination with mTOR inhibitor everolimus, we found that TEAD inhibitors (TEADi) were efficacious in several of these liver cancer models. This allowed us to verify the classifier without any re-training on an independent dataset (CLC). In this independent validation scenario, the classifier achieved the AUC of 0.82. Having established efficacy of predictions on both *in vitro* datasets, we re-trained the classifier using both CCLE and CLC datasets as input to achieve maximum predictive performance, and we predicted, post-hoc, response status of 99 responders out of 2056 patient-derived xenograft models. The algorithm showed early promise by retrospectively classifying a model with *in vivo* efficacy as the most likely to respond.

Predicting protein receptor status from H&E-stained images in breast cancer

Geongyu Lee[1], Chungyeul Kim[2], Tae-Yeong Kwak[1], Sun Woo Kim[1], Hyeyoon Chang[1]. *[1]Deep Bio Inc., Seoul, Korea, Republic of,[2]Department of Pathology, Korea University Guro Hospital, Seoul, Korea, Republic of*

Correct prediction of cancer molecular subtype plays a very important role in determining the treatment of cancer patients. In determining the molecular subtype of breast cancer, protein receptors such as estrogen receptors (ER), progesterone receptors (PR), and human epidermal growth factor receptor type 2 (HER2) are used as key factors. These protein receptors also play an important role in determining the treatment method or predicting the prognosis of breast cancer. To confirm this, a test should be performed by immunohistochemical (IHC) staining. In this study, we investigated the morphological relationship between the molecular subtypes and hematoxylin and eosin (H&E) stained whole slide images (WSIs) without IHC stained images, and performed an experiment to evaluate that the protein receptors can be predicted by these morphological features. The TCGA-BRCA data were utilized in this study. There were 728 cases out of the total 1097 cases where the IHC status for ER, PR, and HER2 was either positive or negative. Each individual case is scanned using different scanners and magnifications. In some cases with multiple slides, we use only the first scanned image. The entire WSI was randomly split into 3:1:1, and used for training, tuning, and test, respectively. Individual WSIs was tiled into 1024x1024 patches for this study. The multi-task deep learning model predicts the protein receptor status of individual patches. In this

study, a confidence measure was added to remove the uncertainty of the deep learning model. When learning WSIs, patches of less than 70% based on these confidence scores did not affect WSIs. Specifically, when learning morphological features, we used strong augmentation such as grayscale, gaussian blur, color jitter, and posterization to ensure that predictions were not biased by color alone. Based on individual patches, ER accuracy of 76%, PR accuracy of 65%, and HER2 accuracy of 79% are shown. As a result of prediction by majority voting on WSI images through patch predicted results, ER accuracy of 74.6% PR accuracy of 66%, and HER2 accuracy of 76.6% Through this study, it was confirmed that the sufficiently trained deep learning model predicted ER, PR, and HER2, which are important factors of molecular subtype, relatively well. Through this, it was found that there was some correlation between morphological characteristics and molecular subtypes in H&E stained WSIs. If more data are collected through future experiments, a molecular subtype prediction model can be developed.

An ML-based tool for predicting tissue of origin for cancer of unknown primary (CUP) based on genomic and transcriptomic data

Zoia Antysheva, Daria Kiriy, Anton Sivkov, Alexander Sarachackov, Alexandra Boyko, Naira Samarina, Nara Shin, Jessica H. Brown, Ivan Kozlov, Viktor Svekolkin, Alexander Bagaev, Nathan Fowler, Nikita Kotlov. *BostonGene, Corp., Waltham, MA*

The ability to locate a tumor primary site for patients with a cancer of unknown primary (CUP) is a major obstacle in providing personalized therapeutic options and access to clinical trials. Despite the recent use of molecular-based tools to identify the tumor tissue-of-origin (TOO), overall survival for CUP patients remains low. Here, we present an AI-based tool that predicts the TOO by using genomic and transcriptomic data to classify CUP tumors into hierarchically-organized molecular subgroups. The TOO predictor was composed of DNA, RNA, and Consensus classifiers that were hierarchically organized with respect to molecular diagnosis with upper level clusters based on common molecular features reflecting similar cell of origin, and lower levels containing specific diagnoses for further classification. The ML-based DNA classifier was trained on a dataset of publicly available genomic data generated from 8,000 samples, and independently validated using more than 5,500 samples. The ML-based RNA classifier was trained on a dataset of publicly available transcriptomic data created from more than 10,100 samples with tumor- and normal-specific features for each cancer type, and independently validated using 20,000 samples. The Consensus classifier, combining outputs from both DNA and RNA algorithms, was trained on a dataset of genomic and transcriptomic data from 1,000 samples, and validated on an independent dataset of 2,000 samples. Each classifier contained features selected based on data analysis according to the weighted F1-score, and the best hyperparameters for the final model. The 3-classifier algorithm predicts TOO for 33 cancer types and subtypes belonging to solid neoplasms, independently of sample source, sequencing methods, and cohort. Validation of the Consensus classifier showed a higher accuracy (95% f1-score) compared to the DNA and RNA classifiers (79% and 93% f1-scores, respectively), along with a high sensitivity (95%), specificity (99%), and precision (96%), as it takes into account both genomic events and expression patterns. The TOO predictor was prospectively validated on approximately 298 clinical samples with a known diagnosis using all classifiers. The diagnosis was identified in 90% of clinical cases (295/297) by the Consensus classifier with 90% sensitivity and 94% precision. The call rate for the DNA and RNA classifiers was above 95%. Of note, sensitivity of the top 4 predicted diagnoses was > 90% for all 3 classifiers, and the calculated rule-out accuracy of the Consensus classifier was 97%. In conclusion, an ML-based algorithm was developed that utilizes genomic and transcriptomic data to

accurately predict the TOO for CUP tumors. Utilizing the Consensus classifier after DNA and RNA classifiers helps to identify the TOO of the tumor with high specificity, which can guide precision oncology therapeutic options.

A deep learning enabled digital pathology platform for characterization of cancer-associated thrombosis of ovarian cancer

Ju Young Ahn[1], Wendolyn Carlos-Alcalde[2], Matthew Vasquez[3], Min Soon Cho[2], Vahid Afshar-Kharghan[2], Stephen T. Wong[3]. *[1]Department of Biomedical Engineering, Texas A&M University, College Station, TX,[2]Division of Internal Medicine, Benign Hematology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Systems Medicine and Bioengineering Department, Houston Methodist Neal Cancer Center, Houston, TX*

Purpose: Cancer-associated thrombosis (CAT), characterized by activation, extravasation, and aggregation of platelets in tumor microenvironment, is a common complication observed in ovarian cancer patients. A third of ovarian cancer patients have elevated platelet counts that are associated with poor prognosis. However, the exact mechanism by which platelets preferentially extravasate into tumor microenvironment is unknown, partly owing to lack of tools that can accurately segment and measure platelet counts found in tumor tissues. In this study, we hypothesize that tumor secreted SDF-1 interacts with CXCR4 receptors on platelets and initiates platelet chemotaxis towards tumor microenvironment. We developed a digital pathology (DP) platform with automated whole tissue confocal imaging and deep learning (DL) model that can be used to automatically segment out platelets and calculate platelet density with high precision and consistency in the mouse ovarian cancer tissue sections for supporting hypothesis evaluation.
Methods: A DL algorithm to accurately segment out platelets was developed based on the U-Net structure using our original datasets from the murine ovarian cancer model. Tumor-bearing mice were injected with 5 mg/kg of Plerixafor, a CXCR4 inhibitor, daily for 4 weeks. Then, tumor nodules were resected, stained with CD41a antibody, and imaged using the whole slide confocal microscopy. Using these high-resolution images, we performed manual annotation of platelets to generate the mask dataset and performed further data augmentation to increase the diversity of datasets. We trained our model using 85% of these images and performed validation using the remaining 15%.
Results: Using our DLDP platform, the validation dataset achieved pixel-wise accuracy of 98.7%. A receiver operating characteristic (ROC) curve demonstrated an area under the ROC curve (AUC) of 0.99 with high sensitivity and specificity. Intersection over union (IoU) score of 0.724 was obtained. A statistically significant ($p=0.0467$), 7.03% reduction in the platelet density was shown in the Plerixafor-treated mouse ovarian tumor tissues ($n=8$) compared to the control tumor tissues ($n=9$). Note that the traditional threshold method was not able to find the statistical significance ($p=0.0966$) in the same dataset.
Conclusions: We developed a DLDP platform to segment and quantitate tens of thousands of platelets from whole slide mouse ovarian cancer tissues automatically with high accuracy and consistency. Applying the DLDP platform, we demonstrated that treatment with Plerixafor leads to overall reduction in platelet infiltration within ovarian murine tumors. With high-throughput, accurate, and automated detection of platelets, our DLDP platform can serve as a powerful tool for characterization of CAT by evaluation of platelet density as a potential prognostic biomarker for ovarian cancer.

Chuang[1]. *[1]The Jackson Laboratory for Genomic Medicine, Seattle, WA,[2]Bioinformatics Institute, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore,[3]Seven Bridges Genomics, Inc, Charlestown, MA,[4]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[5]The Jackson Laboratory, Bar Harbor, ME,[6]University of Texas Southwestern Medical Center, Dallas, TX,[7]Leidos Biomedical Research Inc., Frederick National Laboratory for Cancer Research, Frederick, MD,[8]Baylor College of Medicine, Houston, TX,[9]Washington University School of Medicine, St. Louis, MO,[10]The University of Texas MD Anderson Cancer Center, Houston, TX,[11]Brigham Young University, Provo, UT,[12]The Wistar Institute, Philadelphia, PA,[13]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[14]National Cancer Institute, Bethesda, MD,[15]University of California - Davis, Davis, CA*

Patient-derived xenografts (PDXs) model human intra-tumoral heterogeneity in the context of the intact tissue of immunocompromised mice. Histological imaging via hematoxylin and eosin (H&E) staining is performed on PDX samples for routine assessment and, in principle, captures the complex interplay between tumor and stromal cells. Deep learning (DL)-based analysis of large human H&E image repositories has extracted inter-cellular and morphological signals correlated with disease phenotype and therapeutic response. Here, we present an extensive, pan-cancer repository of nearly 1,000 PDX and paired human progenitor H&E images. These images, curated from the PDXNet consortium, are associated with genomic and transcriptomic data, clinical metadata, pathological assessment of cell composition, and, in several cases, detailed pathological annotation of tumor, stroma, and necrotic regions. We demonstrate that DL can be applied to these images to classify tumor regions with an accuracy of 0.87. Further, we show that DL can predict xenograft-transplant lymphoproliferative disorder, the unintended outgrowth of human lymphocytes at the transplantation site, with an accuracy of 0.97. This repository enables PDX-specific investigations of cancer biology through histopathological analysis and contributes important model system data that expand on existing human histology repositories. We expect the PDXNet Image Repository to be valuable for controlled digital pathology analysis, both for the evaluation of technical issues such as stain normalization and for development of novel computational methods based on spatial behaviors within cancer tissues.

AI powered-platform to predict gene modifications from prostate and breast cancer whole slide images

Wei Huang[1], Parag Jain[2], Chensu Xie[2], Hassan Muhammad[2], Hirak Basu[3], George Wilding[2], Rajat Roy[2]. *[1]University of Wisconsin-Madison, Madison, WI,[2]PathomIQ, Cupertino, CA,[3]Department of Genitourinary Medical Oncology, MD Anderson Cancer Center, Houston, TX*

There is little published evidence of predicting cancer genotypes directly from tissue histology, especially for breast and prostate cancers. Artificial intelligence (AI) enables discriminating and extracting morphological features reflective of the underlying genomic alterations at visual and subvisual levels. We have built a morphology-based and AI-powered platform for cancer genotyping, risk stratification and outcome prediction that addresses the needs for treatment decision-making in a cost effective and timely fashion. A cohort of 390 prostate and 742 invasive breast cancer patients with known molecular status of key genes, such as TP53, PIK3CA, MYC, ERBB2, TMPRSS2-ERG and PTEN from The Cancer Genome Atlas were included in this study. Hematoxylin and eosin (H&E) stained whole slide images (WSI) of the cancer tissue sections were available at 20x or 40x. The WSI from the two cancer cohorts were split 2:1 into a training and test dataset, respectively. Our platform involved two different deep Convolutional Neural Network (DCNN) architectures. The platform first divided each WSI into multiple tiles. Each tile was then analyzed using a DCNN that graded the tile and generated a high dimensional vector to provide a mathematical representation of the morphology. The combination of high dimensional vectors across the WSI was then fed into a second DCNN that generated a morphological score, which predicted whether the gene under consideration was wild type or modified. Our platform has achieved 70 - 80% accuracy as defined by the Area under the Curve for the receiver operating characteristics curves for the genetic markers on the test cohorts (Table 1). Our platform can predict genotypes/molecular alterations directly from H&E stained WSI with high accuracy. This technology presents a novel, practical and cost-effective approach for cancer molecular classification and risk stratification, enabling timely and optimal treatment decision-making for positive clinical outcomes.

Genotype Prediction for Breast Cancer (BrCa) and Prostate Cancer (PCa) from WSI

Cohort	Molecular Biomarker	Training Dataset (n)		Test Dataset (n)		Test ROC AUC Score (%)
		Gene Modification/Loss	Intact/Wild type	Gene Modification/Loss	Intact/Wild type	
BrCa	TP53	196	302	96	149	80
	PIK3CA	153	344	75	170	74
	MYC	68	414	33	204	77
	ERBB2	66	416	32	205	78
PCa	TMPRSS2-ERG	104	157	51	78	70
	PTEN	57	201	28	99	73

NuKit: a deep learning platform for histopathological Images

Ching-Nung Lin[1], Christine H. Chung[2], Aik Choon Tan[1]. *[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[2]Head and Neck Endocrine Oncology, Moffitt Cancer Center, Tampa, FL*

Hematoxylin and eosin (H&E) staining is the most common type of histopathological images used for quantitative data analysis. For histopathological image analysis, nucleus segmentation represents one of the initial steps in quantitative data analysis pipelines. Recently, deep learning methods for nucleus segmentation on histopathological images become the mainstream in digital pathology. However, adopting these pre-trained models in digital pathology or clinical research remains limited. Two main factors limit the usage of deep learning methods in routine research: 1) many models required some technical background to execute the programs, and 2) the speed of returning the results to the users. To overcome these limitations, we have developed and implemented NuKit, a deep learning platform which accelerates nucleus segmentation and provides prompt results to the users. NuKit platform consists of two deep learning models coupled with an interactive graphical user interface (GUI) to provide fast and automatic nucleus segmentation “on the fly”. The two deep learning models are: 1) the whole image segmentation model and 2) the click segmentation model. Both deep learning models provide complementary tasks in nucleus segmentation in the NuKit platform. The whole image segmentation model performs whole image nucleus whereas the click segmentation model supplements the nucleus segmentation with user-driven input to edits the segmented nuclei. We used PanNuke as the training data set which contains 160,368 nuclei extracted from 7,901 image tiles. The sources of this data set were curated from The Cancer Genome Atlas (TCGA) and included a very few in-house data. For test sets, we used several popular data sets such as TCGA (not used in the training set). We used DICE coefficient as the metric for comparisons of NuKit with other deep learning methods. For the results, we observed that NuKit achieved comparable results with the state-of-the-art deep learning methods and outperforms those non-deep learning methods. For TNBC and CoNSeP data sets, NuKit achieved DICE 0.793 and 0.854 comparing to HoVer-Net 0.749 and 0.664. For CoNSeP test data set, NuKit achieved DICE 0.860 comparing to Cell Profiler 0.434 and QuPath 0.588. In addition, both pre-trained models were embedded in the NuKit GUI, which provides interactive and prompt response to users in analyzing their histopathological images. The outputs of NuKit are interoperable with other quantitative image analysis tools to facilitate the ecosystem of computational pathology to many formats to combine with other software to construct pipelines. In summary, we have introduced NuKit, an innovation platform which combines two deep learning models coupled with interactive GUI to accelerate nucleus segmentation task in histopathological images. We believe that NuKit provides a new platform to bridge the pre-trained deep learning models into digital pathology and clinical usage.

Predictive biomarker discovery method to bridge the gap between preclinical disease model dose-response and clinical trials

David Futorian, Oren Fischman, Gali Arad, Nitzan Simchi, Omri Erez, Eran Seger, Rozanne Groen, Kirill Pevzner. *Protai, Tel Aviv, Israel*

The translational gap of drug and biomarker discovery remains one of the biggest challenges in the pharmaceutical industry. On one hand high throughput screening and omics methods facilitate the generation of in-vitro and in-vivo data of dose-response for a particular drug or combinations. On

the other hand, clinical omics techniques allow for the creation of large scale treatment-naive clinical datasets, with the TCGA and CPTAC as prominent examples. However, the question of which disease model best represents the response/ resistance mechanisms of an oncology patient remains challenging.
In this study we present a machine learning (ML) based computational technique for integrating omics from preclinical dose-response studies with clinical treatment-naive samples to create putative predictive biomarkers, and exemplify its application 2 case studies - PARP or AKT inhibitors.
We utilize the Cancer Cell Line Encyclopedia (CCLE) and Genomics of Drug Sensitivity in Cancer (GDSC) as a resource for in-vitro dose response data for PARPi and AKTi, coupled with multi-omic molecular data. We utilize the treatment naive molecular characterization from the Clinical Proteomic Tumor Analysis Consortium (CPTAC) data of Breast cancer patients. Multi-omic analysis of these datasets derived 2 putative predictive biomarkers for PARPi and AKTi. The multi-omic analysis resembles the data availability at the critical drug development stage of transition from preclinical response models to a clinical trial. These biomarkers are tested on a validation dataset obtained from the iSPY adaptive clinical trial and achieve superior results compared to the original enrolment biomarkers and even the retrospectively derived biomarkers.
This study presents a novel computational approach to bridge the gap between preclinical dose-response and clinical datasets and suggests an efficient way to discover predictive biomarkers based on data accessible in a preclinical setting.

Efficient development of prognostic tests for detecting cancer risk using proteomic technology

Yolanda Hagar, Leigh Alexander, Jessica Chadwick, Gargi Datta, Joe Gogain, Rachel Ostroff, Clare Paterson, Laura Sampson, Caleb Scheidel, Sama Shrestha, Amy Zhang, Michael Hinterberg.
SomaLogic, Inc., Boulder, Co, CO

Background**:** Prognostic models for assessing future health outcomes can be developed using time-to-event (also known as “survival”) data. This methodology is ubiquitous in statistical literature and in the analysis of cancer outcomes, but its use in high-dimensional analyses tends to be limited as the methods are difficult to implement in a machine learning environment. Additionally, development of certified prognostic clinical tests using proteomic biomarkers for detecting future cancer risk can be time-consuming, prone to overfitting issues, and difficult to navigate. We demonstrate the utility of combining SomaScan® proteomic data with pipeline machine learning tools and survival analysis methodology to identify powerful and robust LDT-certifiable prognostic tests for assessing future risk of cancer.
Methods: Data pipeline and analysis tools were developed using R. In addition to standard machine learning techniques, statistical methods include elastic net AFT models, subsampling survival techniques, and metrics for assessing predictive survival models. The pipeline takes the analyst from data processing and QC through identification of optimal models for prediction of clinical endpoints, and then through validation on a hold-out test set. The tools include an assessment of model robustness against sample handling issues, longitudinal stability, the impacts of assay noise on model performance, effects of putative interferents, and risk of failure during CLIA validation in the lab. We demonstrate the utility of the tools and methods for development of a lung cancer risk model.
Results: Analysis time for validation of an optimal clinical model was reduced by at least 80%, resulting in the development of 7 LDT-certified tests within 3 years, including a test for lung cancer risk. Inclusion of methods that allow for subsampling and penalized regression using AFT models

show improved predictive performance and identification of top features related to clinical endpoints.
Conclusion: Not only are powerful, prognostic tests do-able, but they can be LDT certified in an efficient manner and made to be robust to real-life lab settings. Survival analysis in a machine-learning setting allow us to leverage proteomic technology in new ways, leading to tests that assess future cancer risk, which can be used for precision medicine applications.

Redefined chronic inflammatory responses as prognostic markers in glioma: an explainable artificial intelligence model

Debajyoti Chowdhury[1], Hiu Fung Yip[1], Hao Liu[2], Xuecheng Tai[3], Aiping Lu[1]. *[1]Hong Kong Baptist University, School of Chinese Medicine, Hong Kong SAR, Hong Kong,[2]Department of Mathematics, Hong Kong Baptist University, Hong Kong SAR, Hong Kong,[3]Hong Kong Centre for Cerebro-Cardiovascular Health Engineering, Hong Kong SAR, Hong Kong*

Introduction: Glioma is an aggressive brain tumor. Many inflammatory mediators within the tumor microenvironment (TME) determine its progression. Unfortunately, no ubiquitous prognostic markers reveal the intricacy between TME and chronic inflammatory responses (CIRs). CIRs used to vary among individuals affecting prognosis. And opting for the best-optimized treatment remains challenging.
Methods: We proposed an explainable artificial intelligence (XAI) approach to redefine CIRs as prognostic markers for glioma using 694 and 693 patients' data derived from The Cancer Genome Atlas (TCGA) and the Chinese Glioma Genome Atlas (CGGA), respectively. First, using five curated databases, we identified CIR-related genes those enriched nine HALLMARK pathways using gene set variation analysis (GSVA). Then, we trained the XAI model to characterize the personalized inflammatory mediators (PIMs) using multimodal factors such as transcription factors (TFs) network and cell infiltration markers. It resulted in rationalized typified CIRs. Finally, we used overall survival (OS) analyses to validate them as potential prognostic markers and showed a personalized co-drug discovery strategy by optimizing CIRs.
Results: The proposed XAI model deciphered the PIMs and endorsed the typified CIRs as efficient prognostic markers. It characterized five unique CIR types (p-value<0.0001). The OS analyses indicated the differential prognostic ability of the typified CIRs for glioma, lower-grade glioma (LGG) at p-value<0.0001, and glioblastoma (GBM) at p-value<0.22. We found that patients with higher CIRs had significantly shorter OS than those with lower CIRs. We showed that CIR type 4 and type 2 were highly inflamed and had poor OS for LGG, and GBM, respectively. Chronic pro-inflammatory responses were positively correlated with the poor OS of glioma patients. GSVA indicated lower activation of apoptotic pathways and higher activation of the hypoxia pathway as likely causes. We identified the effector genes within the personalized CIR networks, which demonstrated prognostic ability and may offer potential targets for optimizing the patient-specific CIRs through co-drug intervention. Additionally, we identified their transcriptional regulatory networks comprising TFs (e.g., SMAD3, HIF1A, NFKB1, GATA3, RORA, JUN) contributing to the inflammatory pathways (e.g., TNFα, NF-kβ, IFN-γ, hypoxia).
Conclusions: Our findings highlight a new strategy to redefine CIRs as prognostic markers for glioma and show that optimizing CIRs improves the OS. It opened a new avenue for co-drug discovery to ensure better survival.

AIVE, an artificial intelligence protein miner based on omics data to discover new cancer druggable candidates

Dongwan Hong. *Catholic University of Korea, College of Medicine, Seoul, Korea, Republic of*

Recently, AI software including Alphafold, RoseTTAFold and ESMFold, can predict protein structures based on amino acid sequences, and DeepMind (Alphafold2) and Meta (ESMFold) opened hundreds of millions of protein structures to world-wide clinical researchers. These tools are possible to generate protein structures in a shorter time and less cost than traditional protein study methods. Finally, they can lead to the advent of the *protein rush generation*. To evaluate accurately and quickly the prediction of structures of mutations embedding in protein sequences, we developed an *Artificial Intelligence analytics toolkit for predicting Virus mutation in protEin (AIVE; http://ai-ve.org)* that clinical researchers can use easily on web. An amino acid property eigen selection score (APESS) defined in AIVE is a comprehensive mathematical analysis model, andit was calculated basically by below: 1 artificial intelligence base clustering (AIBC) using predicted aligned error (PAE) and per-residue confidence (pLDDT) values, 2 base level change rate (BLCR)using the probability of occurrence of mutation in each amino acid sequence or nucleotide sequence, 3chemical property eigen score (CPES) using amino acid properties (PH, Residue and Hydrophobic),and 4polarity based feature selection (PBFS) using continuous position of polar amino acids including S, C, N, Q, T, and Y [*APESS = AIBC ´ BLCR ´ CPES ´ PBFS*]. AIVE also calculated the docking score using AlphaFold to estimate protein to protein interaction (PPI) among hosts (or mutations) and provided a graph as final report showing APESS distribution among mutation group, and evaluation of APESS and docking score. For example, according to APESS score in lung cancer, we can find out the feasibility of structure transformation of H-bond in EGFR protein (L858R) tyrosine kinase and also show the differences of tyrosine kinase affinity between each lung cancer patients. However, for the T790M mutation of EGFR protein, there was no significant difference compared with the wild type (790). The execution time of AIVE (GPU based web server platform) depends on the length of the input sequence, and it completes such an example case in an average of 2-3 hours. AIVE can suggest anti-cancer candidates in protein-level and present a precision medicine model which is available to implement close to real time.

Automated detection of high-grade urothelial carcinoma from urine cytology slides using attention-based deep learning

Mohamed Omar[1], David Kim[2], Luigi Marchionni[3], Momin T. Siddiqui[3]. *[1]Weill Cornell Medicine, New York, NY,[2]Department of Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Pathology and Laboratory Medicine, Weill Cornell Medicine, New York, NY*

Urine cytology has long been an effective and non-invasive test for the detection of bladder urothelial carcinomas (UC) routinely performed in cases of unexplained hematuria or for monitoring patients with UC. In cytopathology practice, urine cytology specimens are examined manually with a light microscope to identify morphologic features associated with different diagnostic categories based on the Paris System (TPS) for Reporting Urinary Cytology. Specifically, the diagnosis of high-grade urothelial carcinoma (HGUC) requires the identification of > 5-10 cells with a nuclear/cytoplasm ratio of 0.7 or greater and hyperchromasia together with coarse chromatin or irregular nuclear membranes. However, the task of identifying HGUC involves

a substantial degree of manual review and is often associated with intra-and inter-observer variability. To address this, we have designed an accurate and efficient deep learning system capable of automatically distinguishing between HGUC and non-HGUC using digitized cytology slides. Our model has been developed using a retrospective cohort of 158 digitized urine ThinPrep cytology slides consisting of HGUC (n=98) and negative for HGUC (n=60). The model was then prospectively validated on a cohort of 105 urine cytology slides that were also independently reviewed prospectively in a blinded manner by a cytopathologist and cytotechnologist. Our system uses Otsu's method for automatic image thresholding followed by dividing images into non-overlapping tiles of 500X500 pixels at the highest magnification. Subsequently, we use a pre-trained ResNet50 model to extract features which are used for training our attention-based multiple instance learning framework. For the training task, our retrospective cohort (158 slides) has been divided into 10 different splits each consisting of training (70%), validation (15%), and testing (15%) sets. The training and validation sets were used for the model training and optimalization, respectively, while the testing set was used for assessing the performance. This process yielded 10 different models with an average Area Under the ROC Curve (AUC) of 0.80 in the testing set. The best performing model had an AUC of 0.90 and an accuracy of 0.88. This model was subsequently validated prospectively in an independent testing cohort with 105 slides. In the prospective testing cohort, the model was able to accurately distinguish between HGUC and non-HGUC with an AUC of 0.83, accuracy of 0.76, sensitivity of 0.89, and specificity of 0.62. Additionally, our system can detect slide regions with high attention score for HGUC which are enriched in atypical urothelial cells. These findings show that our system can be utilized to assist cytopathologists in assessing urine cytology slides and to detect regions with high-diagnostic relevance for further assessment which is expected to reduce the time needed for manual review.

AI-driven image analysis enables simplified, label-free cytotoxicity screening

Gillian Lovell[1], Daniel A. Porto[2], Jasmine Trigg[1], Nevine Holtz[2], Nicola Bevan[1], Timothy Dale[1], Daniel Appledorn[2]. *[1]Sartorius, Royston, United Kingdom,[2]Sartorius, Ann Arbor, MI*

The increasing use of precious, patient-derived cells has driven the need for non-perturbing and label-free cell measurements, particularly in the oncology field. To address this we developed the Incucyte® AI Cell Health Analysis Software Module, which uses two pre-trained deep neural networks to perform automated, unbiased analysis of Phase contrast images to segment individual cells and perform label-free Live/Dead cell classification. The neural networks which perform cell instance segmentation and infer cell viability were trained on a wide diversity of cell types with varied morphologies, ensuring that the analysis is applicable across a variety of adherent and suspension tumor cell types. Here, we demonstrate the application of this analysis across diverse and commonly used biological models of breast cancer, glioblastoma, and B-cell lymphoma. In each case, cells were treated with chemotherapeutic compounds or biosimilar antibodies and Phase contrast images were acquired at regular intervals over 3 - 4 days using the Incucyte® Live-Cell Analysis System. Using the Incucyte® AI Cell Health Analysis cells were accurately segmented and the percentage of dead cells were quantified over time without the requirement for a fluorescent reporter or other exogenous label, and with limited user input. Four breast cancer cell lines were treated with a panel of chemotherapeutics designed to target specific expression patterns. AI Cell Health analysis showed that Estrogen receptor (ER) inhibitor Tamoxifen selectively induced >60% cell death only in ER positive cell lines BT474 and MCF7; dual epidermal growth

factor receptor (EGFR/ HER2) inhibitor Lapatinib induced cell death in AU565, BT474 and MCF7 which express these surface markers. In contrast, Lapatinib and Tamoxifen induced morphological change - but minimal cell death - in triple negative MDA-MB-231 cells. Three glioblastoma cell lines A172, U87 and T98G were treated with a larger panel of chemotherapeutic compounds and for four of the active compounds, efficacy was also determined. Cisplatin, doxorubicin, vinblastine and taxol induced concentration-dependent cell death in A172 and T98G cells; U87 cells displayed resistance to each of these compounds with a maximal 46.5% cell death induced by doxorubicin. Ramos B-cell lymphoma cells were exposed to increasing concentrations of monoclonal antibody Rituximab and the biosimilar Truxima®. The antibodies induced specific cell death via the surface marker CD20 in a time and concentration-dependent manner with similar efficacy (IC_{50} Rituximab 94.7 ng/mL; Truxima® 110.3 ng/mL), while antibody control IgG1 remained non-perturbing to cells. These results demonstrate that the Incucyte® AI Cell Health Analysis is applicable to a broad range of cancer types cultured in 2D monolayer. This unbiased method enables accurate, label-free quantification of cytotoxic effects induced by clinically relevant therapeutics.

Deep learning-based mapping of tertiary lymphoid structure scores from H&E images of renal cell carcinoma trained by spatial transcriptomics data

Seungho Cook[1], Haenara Shin[2], Mi-Kyoung Seo[1], Dae Seung Lee[1], Hongyoon Choi[3]. *[1]Portrai, Inc, Seoul, Korea, Republic of,[2]Kim Jaechul Graduate School of AI, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of,[3]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, Korea, Republic of*

Purpose Tertiary lymphoid structures are organized aggregates of immune cells present in the tumor microenvironment (TME) in which novel targets as well as beneficial biomarkers for immunotherapy in cancer were found. Here, we have developed and validated a deep learning model by integrating H&E images of renal cell carcinoma and spatial transcriptomics data to infer spatial mapping of tertiary lymphoid structure scores in TME only using hematoxylin and eosin (H&E) images.

Methods A total of 20 H&E images combined with spatial transcriptomics data of renal cell carcinoma were used to develop a model. Tertiary lymphoid structure scores can be acquired for each spot in spatial transcriptomics by geometric mean of the specific gene expression relevant to B cell, T cell, immunoglobulin, fibroblast, complement, and others. A convolutional neural network using H&E image patches as inputs was developed to predict the tertiary lymphoid structure scores from H&E-stained tissue image patches of renal cell carcinoma acquired by different patients. For the external validation, the model estimated the tertiary lymphoid structure scores from H&E-stained tissue image patches of renal cell carcinoma of The Cancer Genome Atlas (TCGA-RCC).

Results The tertiary lymphoid structure scores inferred by the model using H&E image patches were significantly correlated with those derived by spatial transcriptomics data as an internal validation ($r = 0.68$, $p < 1e\text{-}10$) . The mean value of the deep learning-based tertiary lymphoid structure scores estimated by the TCGA-RCC tissue images was significantly correlated with the tertiary lymphoid structure scores, T cell enrichment scores and immune cell enrichment scores estimated by bulk RNA-seq data from the corresponding TCGA data.

Conclusions A deep learning model to infer spatial tertiary lymphoid structure in the tumor microenvironment using H&E images was developed. As the tertiary lymphoid structure is a key to predict responsiveness of immune checkpoint inhibitors, mapping the score only using H&E images could be clinically translated into image-based biomarkers. This approach can provide

objective and flexible deep learning-based models for characterizing tumor microenvironment related to spatial immune distribution.

Constructing the largest-scale knowledge graph using all PubMed abstracts and its application for highly specific and accurate knowledge retrieval

Xin Sui[1], Yuan Zhang[2], Feng Pan[2], Donghu Sun[1], Menghan Chung[1], Jinfeng Zhang[2]. *[1]Insilicom LLC, Tallahassee, FL,[2]Florida State University, Tallahassee, FL*

Most of the biomedical knowledge the research community has acquired during the past few decades has been deposited in scientific literature as unstructured text. Converting the unstructured text into the structured form will enable novel methodologies and applications for scientific discovery that can fully harness the power of the existing knowledge. To this end, two fundamental questions need to be addressed: named entity recognition (NER) and relation extraction (RE). NER deals with identifying the concepts or entities in texts, such as diseases, genes/proteins, chemical compounds, etc. while RE aims to extract the relations among these entities. Together, the extracted information forms a knowledge graph (KG) where the nodes are entities in the texts and the edges represent their relationships. KGs can link concepts within existing research to allow researchers to find connections that may have been difficult to discover without them. The LitCoin Natural Language Processing (NLP) Challenge was recently organized by NCATS of NIH and NASA to spur innovation by rewarding the most creative and high-impact uses of biomedical text to create KGs. Our team participated in the challenge and ranked first place. We have applied the methods we developed for the LitCoin NLP challenge to all PubMed abstracts and constructed the largest-scale biomedical KG to date. We show that powerful and versatile query functions can be implemented on top of the KG to enable highly specific and accurate knowledge retrieval and inference of causal and indirect relationships.

#5422

Machine learning models identify key histological features of renal cell carcinoma subtypes

Samuel Vilchez, Isaac Finberg, Miles Markey, Shima Nofallah, Kathleen Sucpito, Fedaa Najdawi, Geetika Singh, Ben Trotter, Victoria Mountain, Jake Conway, Robert Egger, Chintan Parmar, Ilan Wapinski, Stephanie Hennek, Jonathan Glickman. *PathAI, Inc., Boston, MA*

Renal cell carcinoma (RCC) is a heterogeneous disease with 16 different subtypes identified and diagnosed by assessment of tumor histology, and specific molecular and genetic markers. Three major subtypes - clear cell, papillary, and chromophobe carcinoma - have different prognoses and treatment regimens. Treatment response has been associated with mutations that may affect the tumor microenvironment (TME). Here, machine learning (ML) models quantified histologic features of the TME directly from RCC hematoxylin and eosin (H&E)-stained whole slide images (WSI). The potential for model outputs to predict clinically-relevant biomarkers was investigated. Machine learning models based on convolutional neural networks were trained using RCC and non-RCC kidney WSI of biopsies and resections from the cancer genome atlas (TCGA), proprietary, and commercial sources (tissue model N=3208; cell model N=789; vessel model N=839) to classify and quantify histologic features of the TME including cells, tissues, and blood vessels. Thousands of human interpretable features (HIFs) were extracted from model predictions that precisely describe the TME across each WSI (e.g., cell density within a tissue region). Associations between HIFs and PBRM1 loss of function (LOF) mutations and VEGFA mRNAseq expression in clear cell RCC were determined using univariate logistic regressions and Spearman

correlations, respectively. False discovery rate in multiple hypothesis testing was controlled using an Empirical Brown's Method and the Benjamini-Hochberg procedure.
ML-models generated 3390 HIFs from 692 TCGA RCC WSI. After quality control to remove features with missing values, outlier slides and de-duplication, 237 HIFs (657 WSI) remained. Major RCC subtypes could be extracted directly from these HIFs using hierarchical clustering ($p<10-6$, chi-squared test). Individual RCC subtypes were distinguished by features describing immune cells and vascularization. A mixed subcluster enriched for higher stage ($p<10-6$, chi-squared test) papillary and clear cell RCC tumors was associated with increased prevalence of sarcomatoid regions and immune cells. In clear cell RCC, significant associations were found between HIFs describing a spatially specific increase in lymphocytes in the cancer epithelium (FDR-corrected $p=0.004$) and decrease in macrophages (FDR-corrected $p=0.004$) in the entire tumor area and PBRM1MUT, a mutation associated with response to immunotherapy; VEGFA expression, predictive of angiogenesis, positively associated with an increased abundance of lymphocytes near erythrocytes (Spearman $r=0.37$).
ML model quantified RCC TME histology allowed identification of spatially specific differences that correlate with histological subtypes, mutations, and vascularization. Complementary ML-based TME assessment and genomic analyses may be used, after further validation, to explore novel biomarkers.

#5423

AI powered quantification of mitotic rate in H&E stained tissue detects significant differences between treatment groups of preclinical pancreas cancer xenografts

Sharon Ruane[1], Lukas Ruff[1], Brian Reichholf[2], Christina Aigner[1], Emil Barbuta[1], Stephan Tietz[1], Olivér Atanaszov[1], Rosemarie Krupar[1], Simon Schallenberg[3], Maximilian Alber[1], Francesca Trapani[2], Frederick Klauschen[4]. *[1]Aignostics GmbH, Berlin, Germany,[2]Boehringer Ingelheim RCV GmbH & Co KG, Vienna, Austria,[3]Institute of Pathology, Charité Universitätsmedizin Berlin, Berlin, Germany,[4]Institute of Pathology, Ludwig Maximilian University, Munich, Germany*

Background: Mitotic rate is a readout routinely used for characterization of tumor samples. Standard methods to quantify cell division include manual pathologist counts based on hematoxylin and eosin (H&E) staining and either manual or automated assessment of immunohistochemistry (IHC) staining using phospho-histone H3 (pHH3). These suffer the drawbacks of high inter-pathologist variability in the case of H&E assessment and time inefficiency and false positive calls in case of pHH3 staining. Aiming to overcome these issues, we developed a mitosis detection model based on H&E-stained tissue sections alone.
Methods: To develop and evaluate the model, we used 1032 H&E-stained tissue sections (156 used for model training) of pre-clinical pancreas cancer xenografts originating from mice that have undergone a series of experiments conducted to examine the pharmacodynamic effect of several anti-cancer protocols. We trained (i) a tissue segmentation model (segmenting tissue regions into 'carcinoma', 'stroma', 'necrosis', and 'other') and (ii) a segmentation model for pixel-level mitosis detection (segmenting 'mitosis' vs. 'non-mitosis'). Regions predicted as mitosis were post-processed to represent individual dividing cells. The tissue segmentation model served as a filter to predict mitotic rate for carcinoma tissue areas only, which has not been accounted for in previous AI-based methods for mitotic rate prediction on H&E tissue. To evaluate the model on detecting mitotic events, the model was compared against a 5-pathologist consensus of mitotic count. The mitotic rates predicted by the model were used to infer differences between treatment groups (various treatments and dosages vs. control).

Results: The mitosis detection model for quantifying rates of cell division in carcinoma regions of H&E-stained tissue sections showed a notable agreement with the 5-pathologist mitotic count consensus (Pearson correlation 0.92). Furthermore, the model correlated well with mitosis counts based on pHH3 IHC staining (Pearson correlation 0.78), which were available for 63 cases. Finally, when used to characterize the entire CDX cohort, the case level mitotic rate predicted by the model showed significant differences between treatment groups in line with or better than using a pHH3 IHC stain.
Conclusion: This study demonstrates the efficacy and scalability of AI-based models for the quantification of mitotic rate based on H&E-stained tissue alone, presenting a time- and cost-efficient approach that also mitigates inter-annotator variability.

A deep learning approach (AI) which accurately identifies breast tumor cells, tumor infiltrating lymphocytes (TILS) and fibroblasts from H&E slides

Luiz Augusto Zillmann da Silva[1], Alistair R. W. Williams[2], Aidan Kubeyev[3], Andrea Giorni[1], Jordan Laurie[1], Prabu Sivasubramaniam[3], Matthew Foster[3], Matthew Griffiths[3], Uzma Asghar[4].
[1]Concr Pty Ltd, Brisbane, Australia,[2]Division of Pathology, The University of Edinburgh, Edinburgh, United Kingdom,[3]Concr Ltd, Cambridge, United Kingdom,[4]Technical, Concr Ltd, Cambridge, United Kingdom

Background: Histopathology assessments of cancers require highly skilled pathologists, are labor intensive and prone to errors without proper training or fatigue. Machine learning can assist pathologists by increasing efficiency and minimizing individual variability. This study adapted a deep learning model to reliably identify 3 cell types from triple negative breast cancers fixed on H&E slides and verified performance with an expert pathologist.
Methods: We apply the U-Net architecture to analyse pathology slides fixed with triple negative breast cancer (TNBC) tissue. The public dataset NuCLS was used for training. Semantic segmentation was used to identify single cells of 3 types: tumor cells, fibroblasts, and tumor infiltrating lymphocyte (TILs). For validation, the pathologist annotated 8 random H&E tiles. The 3 cell types accuracy for NuCLS and the model was evaluated by our pathologist.
Results: Overall, there was a 73% agreement with the pathologists (Pathologist *vs*. NuCLS). A set of 1,555 (90%) TNBC slides were used for training and 173 for validation (10%; unseen data). Table 1 outlines the accuracy metrics for each cell type and for each comparison. Compared to our pathologist, the model accurately identified TILs (62%), followed by fibroblasts (42%) and lastly tumor cells (26%). A significant source of discrepancy was variation in labeled single cell boundaries. The model was better at identifying TILs. The pathologist took 1.5 hours to annotate 8 tiles for the 3 cells and our model 644ms.*Table 1 - Accuracy metrics.*

Quality assessment8 H&E tiles	**Pathologist *vs.* NuCLS**	**U-Net model *vs.* NuCLs**	**U-Net model *vs.* Pathologist**	**U-Net model *vs.* NuCLs (Full)**
Background	86%	71%	62%	73%
Tumour	43%	35%	26%	71%
Fibroblast	45%	39%	42%	31%
TILs	34%	96%	62%	87%
Overall	73%	74%	61%	71%

Conclusion: It is possible to develop a deep learning model to identify breast cancer cells, fibroblasts and TILs from H&E stained slides, with similar accuracy levels as a trained pathologist. The model performed better than a pathologist in identifying TILs, but both struggled with fibroblasts. Accuracy of 71% overall and 87% for TILs, motivates expansion to further datasets and other cancer types.

#5425

Analysis of cancer patients' molecular and clinical data using artificial intelligence and machine learning approaches

Ali Firooz[1], Avery T. Funkhouser[2], Julie C. Martin[3], W. Jeffery Edenfield[3], Homayoun Valafar[1], Anna V. Blenda[2]. *[1]Computer Science & Engineering, University of South Carolina, Columbia, SC,[2]Biomedical Sciences, University of South Carolina School of Medicine Greenville, Greenville, SC,[3]Prisma Health Cancer Institute, Greenville, SC*

Background: Development and clinical course of cancer is multifactorial with influences from the general health status of the patient, germline and neoplastic mutations, co-morbidities, and environment including lifestyle. For effective and individualized treatment of each patient, such multifactorial data must be easy-to-access and easy-to-analyze.
Purpose Statement: Cancers are characterized on a molecular level by the presence of complex gene mutations and other specific molecular markers. Moreover, special importance is placed on so-called cancer-critical genes, mutations of which are involved in the development and progression of various cancers. However, not all detected sequence alterations in these genes are known as cancer-causing mutations; thus, a more detailed and sensitive analysis is prudent. In addition, there is a limited number of established and reliable cancer biomarkers of sera. To that end, a complete analysis of molecular basis of cancer needs to include additional biomarkers such as galectins and glycans, since patients' galectin and glycomic profiles have promising cancer differentiating and diagnostic potential.
Methods: We utilized a Relational Database Management System populated by clinical data from the Prisma Health Cancer Institute Biorepository of ~6,000 cancer patients with at least 66 different cancer diagnoses. Molecular data is available for gene mutations, serum galectin proteins, and glycomic profiles of cancer patients. Mutation status of 50 cancer-critical genes in 1,500 patients, 320 individual patient profiles of 5 serum galectin proteins, and serum and tissue glycomic profiles of 60 patients have been included and will be expanded. In addition, healthy control values for galectin and glycomic profiles were obtained and added for reference. We performed statistical and AI models of Data Analytics using R, Python, and TensorFlow platforms. A comprehensive set of patient data was used to develop a predictive model of patient outcome using the clinical observations as the desired outcome.
Results: The use of typical statistical analyses (linear and logistic regression) revealed insignificant correlation between the predictors and the cancer type of patient outcome. However, the use of the Decision Tree revealed some interesting relationships that can be used for explainability and reliability of the Machine Learning approaches. Finally, Artificial Neural Network approaches provided the best performance in classification of cancer types from the given information.
Conclusion: Our studies provide predictive models that could potentially be used to improve the diagnostic and prognostic power of data collected from patients at presentation. However, the dichotomy of black box AI approaches that perform better than explainable approaches, complicate deployment of these techniques in the domain of medicine and healthcare.

#5426

Multi-omic characterization and predictive features of advanced ovarian cancer patients in a large phase III cohort

Cyril Ramathal[1], David Masica[1], Peter Ansell[1], Bridget Riley-Gillis[1], Jacob Degner[1], Thanh Bui[1], Priya Narayanan[1], Josue Samayoa[1], Xin Huang[1], Robert F. Coleman[2], Jeffrey F. Waring[1]. *[1]AbbVie Inc., North Chicago, IL,[2]US Oncology Research, The Woodlands, TX*

Discovery and validation of biomarkers derived from multi-dimensional clinico-genomic datasets have become critical in precision medicine and oncology drug development. The integration of multi-dimensional genomic and imaging datasets from patients in late-stage oncology clinical trials can be difficult, in part due to limited patient enrollment and sample collection, especially tumor tissue biopsies. The objective of this project was to conduct predictive biomarker discovery on integrated clinico-genomics data spanning tumor genomics, germline genetics, tumor imaging, and circulating blood-based biomarkers for a cohort of 800+ advanced ovarian cancer patients enrolled in the phase III trial of the PARP-1 inhibitor Veliparib (VELIA). Genomic (DNA & RNA) and imaging datasets were generated from 800+ patient-matched tumor biopsies, liquid biopsies and whole blood to enable various biomarker analyses for this study, notably in BRCA-deficient and HRD+ subgroups. Pairwise analysis of individual features with clinical outcomes shows that increased tumor-mutation burden (TMB), RNA-based estimates of immune activity (ICR and MIRACLE scores), CA-125 elimination constant (KELIM score), and image-based estimates tumor-infiltrating lymphocytes (TILs) were each significantly associated with longer PFS and less progressive disease (PD). Similarly, homologous recombination deficiency (HRD) and BRCA alteration were associated with better clinical outcomes, while high CA-125 was associated with worse outcomes. To understand the concerted impact of these features on clinical outcome, we developed multivariate classifiers of PD and regressors (Cox Proportional Hazards) of PFS using XGBoost; using a train-test split of 75/25, we trained the models with 500 rounds of 10-fold cross validation hyperparameter tuning, which resulted in fit models. The PD classifier achieved a validation accuracy of 0.71 and F1-score of 0.78, with high immune activation, high TMB, high KELIM, and HRD and BRCA alteration predicting better outcomes. The PFS survival model achieved a validation C-index of 0.61, with a rank importance of features similar to that of PD classification models; for both models, patients receiving Veliparib had clear benefit relative to that of control arms. Collectively, this study illustrates the value of integrating multi-dimensional datasets with predictive machine learning to identify clinically-relevant biomarkers. CR, DM, PA, BR, JD, TB, PN, JS, XH, and JFW are employees of AbbVie. RLC an employee at The University of Texas MD Anderson Cancer Center and has no funding to disclose. The design, study conduct, and financial support for this research were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the publication.

Improving non-small cell lung cancer segmentation on a challenging dataset

Yi Wei[1], Balaji Selvaraj[2], Mayank Patwari[1], Qin Li[3], Meng Xu[4], Konstantinos Sidiropoulos[1], Zhenning Zhang[4], Leon Fedden[1], Anant Madabhushi[5], Mohammadhadi Khorrami[6], Vidya Sankar Viswanathan[6], Amit Gupta[7]. *[1]AstraZeneca, Cambridge, United Kingdom,[2]AstraZeneca, Chennai, India,[3]Translational Medicine Oncology, AstraZeneca, Waltham, MA,[4]AstraZeneca, Gaithersburg, MD,[5]Georgia Institute of Technology and Emory University and Atlanta Veterans*

Administration Medical Center, Atlanta, GA,[6]Emory University School of Medicine, Atlanta, GA,[7]University Hospitals Cleveland Medical Center, Cleveland, OH

When applied to different datasets, performance of the same deep learning tumor segmentation model can greatly vary. In a non-small cell lung cancer CT scan segmentation study that consists of two datasets, we found that the SwinUNETR model achieves state-of-the-art DICE score on a public dataset NSCLC but performs badly on a private dataset of curated data collected clinically. This performance variation reduces the applicability of such models. To mitigate this gap, through experimentation, we identified a set of techniques and applied them in the following order: (1) normalize a dataset to reduce differences between images. (2) stratify a dataset according to tumor sizes to form a more diverse training set. (3) isolate the lung area before training to help the model focus on the right area. (4) before training, initialize models with self-supervised pre-training weights (5) use a new loss function to give more weights on the cancerous area (6) after a model is trained, perform 3-axis test time flipping augmentation and ensemble the final predictions. In our experiments, our set of techniques improved the test DICE score for both datasets we tested on, where the best improvement was a 53% improvement from 0.32 to 0.49 DICE score.

Skeletal muscle gauge prediction by a machine learning model in patients with colorectal cancer

Jeonghyun Kang. *Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of*

Background: Skeletal muscle gauge (SMG) was recently introduced as an imaging indicator of sarcopenia for the prediction of clinical outcomes, including chemotherapy toxicity and prognosis, in patients with cancer. Computed tomography (CT) is essential for measuring SMG; thus, the use of SMG is limited to patients who undergo CT.
Objective: We aimed to develop a machine learning algorithm using clinical and inflammatory markers to predict SMG in patients with colorectal cancer (CRC)
Methods: The least absolute shrinkage and selection operator (LASSO) regression model was applied for variable selection and predictive signature building in the training set. The predictive accuracy of the LASSO model, defined as LP-SMG was compared using the area under the receiver operating characteristic (AUROC) and decision curve analysis (DCA) in the test set.
Results: A total of 1,094 patients with CRC were enrolled and randomly categorized into training (n=656) and test (n=438) sets. Low SMG was identified in 142 (21.6%) and 90 (20.5%) patients in the training and test sets, respectively. According to multivariable analysis of the test sets, LP-SMG was identified as an independent predictor of low SMG (OR: 1329.431, CI: 271.684-7667.996, p<.001). Its predictive performance was similar in the training and test sets (AUROC: 0.846 vs. 0.869, p=.427). In the test set, LP-SMG showed better outcomes in predicting SMG than single clinical variables, such as sex, height, weight, and hemoglobin, as measured by AUROC and DCA.
Conclusions: LP-SMG, incorporating clinical variables and serum inflammatory indicators, showed superior performance compared to single variables in predicting low SMG. This machine learning model can be used as a screening tool to detect sarcopenic status without using CT during the treatment period. Applying a machine learning model might be beneficial in reducing the effort, cost, and radiation exposure from conventional CT-based diagnosis.

Using machine learning to predict tissue of origin from somatic mutation features

Andrea Giorni[1], Prabu Sivasubramiam[2], Aidan Kubeyev[2], Jordan Laurie[1], Luiz Silva[1], Matthew Foster[1], Uzma Asghar[2], Matthew Griffiths[2]. *[1]Concr Pty Ltd, Brisbane, Australia,[2]Concr Ltd, Cambridge, United Kingdom*

Background: Predicting tissue of origin (ToO) using clinical and molecular data improves diagnostic accuracy up to 95% in patients with Cancer of Unknown Primary (CUP). It is hypothesized that better treatment stratification of CUP patients using omics and machine learning (ML) classifiers may improve prognosis.

Methods: We used publicly available whole exome somatic mutation data from 4733 primary solid tissue samples, across 11 tumor types from the TCGA database, and employed a ML classifier to predict their ToO. We used 5 sets of modeling features:

1) Non-silent somatic mutation burden of 230 cancer-related genes 2) Frequency of SNP substitution type 3) Trinucleotide mutation frequency 4) Copy number variation of the 230 cancer-related genes 5) Presence of hotspot mutations.

We trained a Support Vector Machine on a training subset (80% of samples) and tuned the hyperparameters maximizing a 5-fold cross-validation F1-score. We then tested the model performance on a validation subset (20% of samples) and on a limited (n=6) dataset of metastatic samples present in the TCGA database.

Results: On the primary tumor validation set, we achieved an average AUC of 0.98(std: 0.02) and top 1, top 2 and top 3 accuracies of 80%(std: 0.11), 90%(std: 0.08) and 95%(std: 0.04) respectively, across 11 tumor types. The classification accuracy plateaus after ~300 samples, suggesting further data collection may benefit low performing tumor types. The 2 worst performers: esophageal and stomach cancers were mostly misclassified with colorectal cancers, reflecting their relative similarity. On metastatic samples (n=6) the model achieved a 67% accuracy, this is work in progress.

Conclusion: Our study confirms the potential for a DNA-based machine learning approach to improve prognosis in CUP patients by aiding diagnosis of ToO. To this end, we plan to take this study further by applying this approach to large, independent datasets derived from metastatic samples and liquid biopsies from CUP patient cohorts.

Improved colorectal cancer survival prediction with deep learning-based WSI analysis on PETACC8 and PRODIGE13 cohorts

Jean-Eudes Le Douget[1], Julien Taïeb[2], Paul Jacob[1], Frédéric Bibeau[3], Karine Le Malicot[4], Jean-François Emile[5], Aurélien de Reyniès[5], Mehdi Morel[1], Simon Jégou[1], Côme Lepage[6], Pierre Laurent-Puig[7]. *[1]Owkin, Paris, France,[2]Georges Pompidou European Hospital, Paris, France,[3]Centre Hospitalier Universitaire de Besançon, Besançon, France,[4]FFCD, Dijon, France,[5]AP-HP, Paris, France,[6]INSERM, Dijon, France,[7]INSERM, Paris, France*

Colorectal cancer (CRC) is the third most common cancer worldwide and represents the third leading cause of cancer deaths. Robust postoperative prediction of CRC patient prognosis may prove useful to better stratify patients, guide therapeutic choices and improve clinical trial designs. Deep learning-based analysis of whole slide images (WSI) has recently proved successful at various prediction tasks, including for example survival prediction for malignant pleural mesothelioma.

We developed a deep learning model that predicts overall survival (OS) of CRC patients, using WSI stained with haematoxylin/eosin as input, and also evaluated the difference in prognostic power obtained when combining our model prediction with other clinical factors, namely tumor grade, sex and age. The model was trained on PETACC8 cohort, constituted of 1939 WSI from patients with stage III colon cancer. The PRODIGE13 cohort, constituted of 1155 WSI from patients with stage II and III colon and rectal cancers, was used for validation; only stage III colon cancers (N=428) were selected. Patients from both cohorts received standard chemotherapy treatment, with half of the PETACC8 population also receiving CETUXIMAB antibody treatment. Both cohorts were provided by the FFCD.

Our model first extracts information on small tiles of size 112µm from the WSI, using a deep learning network trained in a self-supervised fashion, then aggregates the information of these tiles using a Multiple Instance Learning model (MIL) at the slide level to establish the final prediction. Our model was able to predict OS from WSI, reaching a c-index of 0.63 [0.61 - 0.66] in cross-validation over the PETACC8 cohort and a c-index of 0.59 [0.53 - 0.65] when transferring the PETACC8-trained model onto the PRODIGE13 cohort. The model was also able to significantly stratify patients into high and low risk groups [HR: 2.67; $p<0.0001$]. We observed

a significant c-index gain when combining our prediction and the pT classification in a linear Cox model as compared to pT alone, with c-index increasing from 0.61 to 0.66 (p=0.03). Overall, we demonstrated that our model is able to robustly predict OS from WSI in stage III colon cancers and provides increased prognostic power, on top of more traditional clinical markers such as tumor grading. Further investigation of the WSI regions targeted by our model could provide valuable insights into postoperative histopathological features of prognostic significance.

3D multiplexed tissue imaging reconstruction and optimized region-of-interest (ROI) selection through deep learning model of channels embedding

Erik Burlingame, Luke Ternes, Eun Na Kim, Joe W. Gray, Young Hwan Chang. *Biomedical Engineering, Oregon Health & Science University, Portland, OR*

Tissue-based sampling and diagnosis is the extraction of information from specifically limited spaces and its diagnostic significance of a certain object. Pathologists deal with issues related to tumor heterogeneity since analyzing a single sample does not necessarily capture a representative depiction of cancer, and a tissue biopsy usually only presents a small fraction of the tumor. Many multiplex tissue imaging platforms (MTIs) make the assumption that tissue microarrays (TMAs) containing small core samples of 2-dimensional (2D) tissue sections are a good approximation of bulk tumors although tumors are not 2D. However, emerging whole slide imaging (WSI) or 3D tumor atlases that employ MTIs like cyclic immunofluorescence (CyCIF) strongly challenge this assumption.
In spite of the additional insight gathered by measuring the tumor microenvironment in WSI or 3D, it can be prohibitively expensive and time-consuming to process tens or hundreds of tissue sections with CyCIF. Even when resources are not limited, the criteria for region-of-interest (ROI) selection in tissues for downstream analysis remain largely qualitative and subjective as stratified sampling requires the knowledge of objects and evaluates their features. Although TMAs fail to adequately approximate whole tissue features, a theoretical subsampling of tissue exists that can best represent the tumor in the whole slide image. To address these challenges, we propose deep learning approaches to learn multi-modal image translation tasks from two aspects: 1) generative modeling approach to reconstruct 3D CyCIF representation and 2) co-embedding CyCIF image and Hematoxylin and Eosin (H&E) section to learn multi-mappings by a cross-domain translation for minimum representative ROI selection. We demonstrate that generative modeling enables a 3D virtual CyCIF reconstruction of a colorectal cancer specimen given a small subset of the imaging data at training time. By co-embedding histology and MTI features, we propose a simple convex optimization for objective ROI selection. We demonstrate the potential application of ROI selection and the efficiency of its performance with respect to cellular heterogeneity. The key takeaway is that this pipeline allows for intelligent representation from H&E images, which enables a plethora of subsequent analyses on this representation space with other multiplexed imaging platforms such as Multiplexed ion beam imaging (MIBI), Imaging Mass Cytometry (IMC) or NanoString GeoMX as only a few ROIs could be selected and analyzed using these platforms.

Validation of spatial gene expression patterns predicted by deep convolutional neural networks from breast cancer histopathology images

Kathy Ton[1], Yinxi Wang[2], Liuliu Pan[1], Kimmo Kartasalo[2], Balazs Acs[3], Philippe Weitz[2], Liang Zhang[1], Yan Liang[1], Johan Hartman[4], Masi Volkonen[5], Christer Larsson[6], Pekka Ruusuvuori[7], Joseph Beechem[1], Mattias Rantalainen[2]. *[1]NanoString Technologies, Inc., Seattle, WA,[2]Karolinska Institute, Stockholm, Sweden,[3]Karolinska Institute, Seattle, WA,[4]Karolinska Instutitute, stockholm, Sweden,[5]Turku University Hospital, Turku, Finland,[6]Lund University, Lund, Switzerland,[7]University of Turku, Turku, Finland*

Molecular profiling is central in cancer precision medicine but remains costly and is only based on tumor average profiles. Morphologic patterns observable in histopathology sections from tumors are determined by the underlying molecular phenotype and therefore have the potential to be exploited for the prediction of molecular phenotypes. Transcriptome-wide expression morphology (EMO) analysis with deep convolutional neural networks (CNN) enables the prediction of mRNA expression and proliferation markers from routine histopathology whole slide images in breast cancer. The NanoString GeoMx® Digital Spatial Profiler (DSP) platform has capabilities of associating crucial spatial information with intratumor variabilities of gene expression, serving as an ideal tool to characterize and validate the prediction of intratumor heterogeneity. The GeoMx platform also provides functionalities of overlaying and aligning hematoxylin and eosin (H&E) whole slide scans on serial tissue sections with morphology marker staining to facilitate region of interest (ROI) selection to match relevant image tiles from the model input, which is a key step to ensure accuracy for the evaluation of the model predictions. The GeoMx RNA Immune Pathways Panel contains 84 gene targets including key genes involved in immune pathways and tumorigenesis and was used to validate the prediction of mRNA expression output from deep CNN models.

Representation learning for histological profiling of lung squamous premalignant lesions and tumors

Rushin Gindra[1], Yi Zheng[2], Regan Conrad[2], Emily Green[2], Sarah Mazzilli[2], Ehab Billatos[2], Mary Reid[3], Eric Burks[4], Vijaya Kolachalama[2], Jennifer E. Beane[2]. *[1]Helmholtz Munich and TranslaTUMedicine, Munich, Germany,[2]Boston Univ. School of Medicine, Boston, MA,[3]Roswell Park Comprehensive Cancer Institute, Buffalo, NY,[4]Boston Medical Center, Boston, MA*

Lung squamous cell carcinoma (LSCC) is preceded by the development of bronchial premalignant lesions (PMLs). PMLs progress through a series of histologic grades characterized by molecular and morphologic alterations. To enhance our understanding of PML progression to lung cancer, we are developing deep learning methods to quantitate PML histologic features and localize PML severity along the histologic disease spectrum.
We leveraged whole slide images (WSIs) of lung tumors (lung adenocarcinoma, LUAD and LSCC) and non-involved adjacent (referred to as ‘normal’) tissue from the Clinical Proteomic Tumor Analysis Consortium (CPTAC), the National Lung Screening Trial (NLST) and the Cancer Genome Atlas (TCGA). The NLST WSIs were used for training a self-supervised contrastive learning (simCLR) model. A graph isomorphism network (GIN) trained on CPTAC WSIs was developed using the features from simCLR and perform WSI-level predictions on tissue subtype (LUAD, LSCC, normal). Model performance was assessed using area under the receiver operating curves (AUC). The model was used to learn WSI-level features of endobronchial biopsies of PMLs from two datasets (PCGA, n=365 samples spanning all histologic grades, and CIS, n=112, only high-grade samples). The features from the final layer of the GIN were used to

compute principal components (PCs) and visualize the relationships between samples using t-SNE and UMAP. To interpret how the GIN processes WSI data, we performed gradient-based class activation mapping (Grad-CAMs) on the graphs.
High model performance was observed on the CPTAC test dataset (Accuracy = 87%, AUC >= 0.89) but dropped slightly on the TCGA dataset (Accuracy = 72%, AUC >= 0.75). The GIN-CAMs identified WSI regions that were highly associated with the output label based on expert pathologist annotation on TCGA cases. Clustering revealed distinct groupings of normal, LUAD and LSCC subtypes (PC1 & PC2, $p<0.01$). Most WSIs from the PCGA data clustered with normal tissues (PC1 & PC2: $p<0.01$ for PCGA v LUAD, PCGA v LSCC). However, a portion of the CIS samples were closely grouped with LSCC tumor cases (74% of CIS WSIs were classified as LSCC tumors. PC1 & PC2: $p<0.01$ for CIS v LUAD; PC1: $p<0.01$ for CIS v LSCC). Additionally, the feature distribution of CIS samples that progressed towards LUSC tumors were significantly different than those that regressed (PC1 & PC3: $p < 0.05$ for Progressive v Regressive).
The GIN recognizes and generates robust features that are distinctly and consistently observed in the different histologic groups across multiple cohorts. These features are also able to stratify progressive and regressive high-grade lesions. The stratification of PMLs is an important step in designing novel interception strategies to prevent the development of lung cancer, and our results suggest that pathology data may be efficacious to include in future biomarkers.

Machine-learning-based epigenetic detection of early-stage lung cancers using the EpiCheck liquid biopsy platform

Dvir Netanely[1], Stephen Lam[2], Anna McGuire[3], Stephen Deppen[4], Eric Grogan[4], Fabien Maldonado[4], Michael Gieske[5], Joseph Seaman[6], Kimberly Rieger-Christ[7], Satish Kalanjeri[8], Luis Herrera[9], Nichole Tanner[10], Garrett B. Sherwood[11], Orna Savin[1], Shacade Danan[1], Sarah Zaouch[1], Nimrod Axelrad[1], Revital Knirsh[1], Ofir Shliefer[1], Keren Manor[1], Radha Duttagupta[12], Aharona Shuali[1], Peter J. Mazzone[13], Gerard A. Silvestri[10], Catherine A. Schnabel[12], Danny Frumkin[1], Adam Wasserstrom[1]. *[1]Nucleix, Rehovot, Israel,[2]Respiratory Medicine, University of British Columbia, Vancouver, BC, Canada,[3]Surgery, University of British Columbia, Vancouver, BC, Canada,[4]Thoracic Surgery, Vanderbilt University, Nashville, TN,[5]Family Medicine, St. Elizabeth Healthcare, Mitchell, KY,[6]Sarasota Memorial Hospital, Sarasota, FL,[7]Lahey Hospital & Medical Center, Burlington, MA,[8]Pulmonary and Critical Care Medicine, Harry S. Truman Memorial Veterans' Hospital, Columbia, MO,[9]Orlando Health, Orlando, FL,[10]Medical University of South Carolina, Charleston, SC,[11]Novant Health, Winston-Salem, NC,[12]Nucleix, San Diego, CA,[13]Pulmonary Medicine, Cleveland Clinic, Cleveland, OH*

Alterations in DNA methylation are one of the earliest, most common signatures of cancer development, making them ideal biomarkers for early detection. Methylation profiling of plasma cell-free DNA (cfDNA) has significant potential to expand the use of liquid biopsies to cancer screening. The EpiCheck platform combines methylation-sensitive restriction endonuclease (MSRE) digestion with whole genome sequencing to comprehensively map genome-wide DNA methylation changes with high fidelity. In this proof-of-concept study, MSRE-NGS was used to interrogate a liquid biopsy atlas focused on early-stage lung cancers to i) identify informative NGS methylation biomarkers in plasma, and ii) develop a machine learning method to discriminate between cancer and high-risk, non-cancer controls. The EpiCheck lung cancer atlas was constructed using biospecimens from academic (UBC, Vanderbilt, Cleveland Clinic) and

commercial biobanks, and from a prospective multi-center study (NCT04968548). Plasma samples were collected from 93 high-risk primary lung cancer patients (62% stage I) and 90 high-risk individuals without cancer. Extracted DNA was digested with methylation-sensitive endonucleases and sequenced at an average depth of 600x. Methylation levels of ~6 million genomic loci were rank ordered using Student's t-test. Gene set enrichment analysis (GSEA) was performed on the top ranking 1000 differentially methylated loci. A logistic regression classifier with Lasso regularization was trained on 100,000 loci, and performance was examined by mean AUC using 5-fold cross-validation. A total of 23,130 loci exhibited significant differential methylation patterns between cancers and controls ($p<0.01$, FDR corrected). Of these, 20,159 and 2,971 lung cancer loci were hypermethylated and hypomethylated, respectively. Biological characterization using GSEA identified enrichments in transcriptional regulation and developmental control. In particular, loci were enriched for Polycomb Repressive Complex regulated genes, suggesting a possible connection to abnormal epigenetic regulation via histone modification in lung cancer. Construction of a machine learning logistic regression model based on the five training folds utilized 224 loci on average, and achieved a mean cross-validation AUC of 0.93 when distinguishing plasma cancer cases vs controls. Our findings demonstrate that the MSRE-NGS EpiCheck platform identified putative biomarkers within the plasma methylome for detecting early-stage lung cancer. A machine learning model trained on methylation targets performed with high accuracy in discriminating lung cancer patients from high-risk healthy individuals. Additional studies are required for defining the strength of the approach and for validating its use in non-invasive lung cancer screening.

Correlating and combining computational radiomics, deep radiomics and transcriptomics data in soft-tissue sarcomas (STS) patients highlight complementary prognostic information

Amandine Crombe[1], Carlo Lucchesi[2], Frédéric Bertolo[2], Michèle Kind[1], Raul Perret[3], Francois Le Loarer[3], Mariella Spalato-Ceruso[4], Maud Toulmonde[4], Audrey Laroche[5], Vanessa Chaire[3], Aurelien Bourdon[2], Antoine Italiano[4]. *[1]Radiology, Institute Bergonié, Bordeaux, France,[2]Bioinformatics, Institute Bergonié, Bordeaux, France,[3]Biopathology, Institute Bergonié, Bordeaux, France,[4]Medical oncology, Institute Bergonié, Bordeaux, France,[5]Sarcoma unit, Institute Bergonié, Bordeaux, France*

Introduction: STS are mostly prognosticated through nomograms relying on age, size, histotype and grade. Radiomics approaches, complemented with deep-learning, deep-radiomics and gene-expression profiling, could help understanding the bridge between STS radiophenotypes and molecular features and provide more efficient prognostic tools. Our goals were to investigate correlations between imaging and transcriptomics patterns, and to develop supervised prognostic models for STS patients.
Methods: We included all consecutive adult patients with newly-diagnosed locally-advanced STS managed at our sarcoma reference center between 2008 and 2020, with contrast-enhanced baseline MRI. After MRI dataset homogenization, we reduced the dimensions of the MRI data space by extracting 138 radiomics features (RFs) and 1024 deep-RFs with computational approach and autoencoder neural networks. Patient RNA was extracted from untreated samples. Following transcriptomic sequence analysis, gene expression levels for each patient were calculated. Complexity Index in Sarcoma (CINSARC) signature was extracted. Unsupervised classifications of patients based on radiomics, deep-radiomics and transcriptomics datasets were built using consensus hierarchical clustering. Differential Gene Expression and oncogenetic

pathways analyses were performed. Associations between the 3 classifications, CINSARC, grade, histotypes and SARCULATOR were explored, as well as their prognostic value. The main outcome was the metastatic-relapse free survival (MFS). The SARCULATOR nomogram and prognostic semantic-radiological features were extracted for benchmarking and understanding models outputs.
Results: 220 patients were included (111 men, median age: 62 years); 60 patients developed metastases after completing curative treatments (data are being updated with 2 additional follow-up years). Transcriptomic analysis was achieved in 54 patients and is being updated with 56 additional samples.
So far, no significant associations were found between the radiomics-based classifications and the transcriptomics-based (including CINSARC).
Nevertheless, the computational radiomics, deep-radiomics, and transcriptomics classifications were associated with MFS, though transcriptomic significance was dampened by the small sample size (P=0.008 [N=220], 0.006 [N=220] and 0.070 [N=54], respectively), suggesting complementary prognostic information.
Supervised models using data-splitting, cross-validated algorithms training, and various combinations of input data are being elaborated to improve the MFS prediction.
Conclusion: Integrating complementary multiomics datasets with computational and deep radiomics should pave the way for better performing and personalized prognostications in STS patients.

Developing artificial intelligence algorithms to predict response to neoadjuvant chemotherapy in HER2-positive breast cancer
Zhi Huang[1], Anil V. Parwani[2], Kun Huang[3], Zaibo Li[2]. *[1]Purdue University, West Lafayette, IL,[2]The Ohio State University Wexner Medical Ctr., Columbus, OH,[3]Indiana University, Indianapolis, IN*

Increasing implementation of whole slide image (WSI) and advances in computing capacity enable the use of artificial intelligence (AI) in pathology, such as quantification of biomarkers, aids in diagnosis and detection of lymph node metastasis. However, predicting therapy response in cancer patients from pre-treatment histopathologic images remains a challenging task, limited by poor understanding of tumor immune microenvironment. In this study, we aimed to develop AI models using multi-source histopathologic images to predict neoadjuvant chemotherapy (NAC) response in HER2-positive (HER2+) breast cancers. First, pretreatment tumor tissues were stained with Hematoxylin and Eosin (H&E) and multiplex immunohistochemistry (IHC) including tumor immune microenvironment markers (PD-L1: immune checkpoint protein; CD8: marker for cytotoxic T-cells; and CD163: marker for type 2 macrophages). Next, we developed an AI-based pipeline to automatically extract histopathologic features from H&E and multiplex IHC WSIs. The pipeline included: A) H&E tissue segmentation based on DeepLabV3 model to generate stroma, tumor, and lymphocyte-rich regions. B) IHC marker segmentation to segment CD8, CD163, and PD-L1 stained cells. C) H&E and IHC non-rigid registration to match H&E and IHC images since they were stained from different levels of tissue. D) Image-based registration and segmentation histopathologic feature construction. A total of 36 histopathological features were constructed to represent tumor immune microenvironment characteristics such as ratios of PD-L1, CD8 and CD163 in tumoral, stromal or lymphocyte-rich regions. They were used to train machine learning (ML) models to predict NAC response in a training dataset with 62

HER2+ breast cancers (38 with complete and 24 with incomplete response). The ML model using logistic regression demonstrated the best performance with an area under curve (AUC) of 0.8975. We also tested ML models using pathologists-derived histopathologic features, but the best performed model showed an AUC of 0.7880. Finally, the developed logistic regression ML model was tested on an external validation dataset with 20 HER2+ breast cancers (10 with complete and 10 with incomplete response) and yielded an AUC of 0.9005. In summary, we described an automatic, accurate and interpretable AI-based pipeline to extract histopathologic features from H&E and IHC WSIs and then used these features to develop machine learning model to accurately predict NAC response in HER2+ breast cancers. The ML model using AI-based extracted features outperformed the model using features manually generated by pathologists.

Vision transformers for breast cancer human epidermal growth factor receptor 2 (HER2) expression staging without immunohistochemical (IHC) staining

Gelan Ayana, Eonjin Lee, Se-woon Choe. *Kumoh National Institute of Technology Education Organization, Gumi, Korea, Republic of*

Purpose: Staging of human epidermal growth factor receptor 2 (HER2) expression is crucial for evaluating the effectiveness of breast cancer treatment. However, it involves an expensive and challenging immunohistochemical (IHC) staining in addition to hematoxylin and eosin (H&E) staining. Here, we argue that customized vision transformers are effective in breast cancer HER2 expression staging using only H&E-stained images.
Methods: Our algorithm has three modules: a localization module to weakly localize the necessary features of an image via spatial transformers, an attention module to learn global features from the image using vision transformers, and a loss module that determines the closest one to a HER2 expression level from input images by calculating the ordinal loss. We utilized a publicly available breast cancer HER2 expression dataset, the breast cancer immunohistochemical image (BCI) dataset, which contains paired H&E and IHC stained images. Results were calculated with 95% confidence intervals and t-test was used to evaluate the significance of the proposed model against other models.
Results: Our approach achieved area under receiver operating characteristics curve (AUC), precision, sensitivity, and specificity of 0.9202±0.01, 0.922±0.01, 0.876±0.01, and 0.959±0.02, respectively, averaged over five-fold cross-validation, in staging HER2 expression. The proposed method showed better performance than the conventional vision transformer model and state-of-the-art convolutional neural network models with statistical significance of $p<0.01$ in all cases.
Conclusion: Our findings are important in assisting HER2 expression staging in breast cancer treatment, while avoiding the need for an expensive and time-consuming IHC staining procedure.

The combination of artificial intelligence and BLEACH&STAIN multiplex fluorescence immunohistochemistry facilitates automated prostate and breast cancer detection

Tim Mandelkow[1], Gisa Mehring[1], Elena Bady[1], Maximilian Lennartz[1], Christoph Fraune[1], Frank Jacobsen[1], Natalia Gorbokon[1], Till Krech[1], Eike Burandt[1], Anne Menz[1], Ria Uhlig[1], Till S. Clauditz[1], Guido Sauter[1], Markus Graefen[2], Sarah Minner[1], Niclas C. Blessin[1]. *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Martini-Clinic Hamburg-Eppendorf, Hamburg, Germany*

Background: Automated prognosis marker assessment in prostate and breast cancer using immunohistochemistry is currently hampered by the lack of a reliable differentiation between benign and malignant glands. To evaluate the patient's risk in routine clinical practice in prostate cancer prognosis parameters such as the Gleason grading, that are accompanied by a high interobserver variability are used. In breast cancer multi-gene panels are used that are influenced by fluctuating tumor purity. A reproducible prognostic evaluation is lacking in both tumor entities.
Design: To enable automated prognosis marker quantification, we have developed and validated a framework for automated prostate and breast cancer detection that comprises three different artificial intelligence analysis steps and an algorithm for cell-distance analysis of multiplex fluorescence immunohistochemistry. Pan-cytokeratin (panCK) antibodies were used to detect epithelial cells and antibodies directed against Myosin and p63 were used to identify basal cells.
Results: The optimal distance between $Myosin^+$ and $p63^+$ basal cells and benign $panCK^+$ cells was identified as 25 µm in breast and 23 µm in prostate cancer and used to exclude benign glands from the analysis combined with several deep learning-based algorithms. Our framework discriminated normal glands from malignant glands with an AUC of 0.96 in breast and 0.98 % in prostate cancer. The approach for automated prostate and breast cancer detection, by excluding benign gland from the analysis, improved the predictive performance of prognosis markers significantly ($p<0.001$). To compare the multiplex fluorescence immunohistochemistry-based (mfIHC) automated prognosis marker assessment with "classical" bright field-based automated prostate cancer detection for prognosis marker assessment in a cohort of 30 biopsies from routine clinical practice prognosis markers were manually assessed and set as gold standard. An excellent agreement between the mfIHC-based automated cancer detection and the reference manual cancer identification was found (intraclass correlation [ICC]: 0.94 [95% CI 0.87 - 0.97]).
Conclusion: Automated prostate and breast cancer identification enables fully automated prognosis marker assessment in routine clinical practice using deep learning and multiplex fluorescence immunohistochemistry. BLEACH&STAIN as well as other multiplex fluorescence immunohistochemistry approaches that enable the simultaneous analysis of 20+ biomarkers can be used to established prognosis panels that can be now assessed in an automated manner.

#5439

Deep understanding of medication events from clinical narratives is essential to building a holistic picture of cancer patient medication history

Jacob Hoffman, Neehar Mukne, Daniela Weiss, Christine Swisher, Max Kaufmann. *The Ronin Project Inc, San Mateo, CA*

MOTIVATION: One of the most complex aspects of providing care to cancer patients is building an accurate list of medications a patient is taking. Medication lists need to capture the necessary clinical context about how the patient uses the drug, such as if they can no longer afford a medication or decide to change the frequency at which they take it due to side effects. While hidden from the medication list, these changes are significant to medical decision making. Moreover, many studies focus on providing cancer medication safely. Still, providers are often not aware of other medications, which clinicians may administer in a different practice than the one providing cancer care. While many solutions attempt to improve the medication list, they frequently ignore one of the highest quality sources of medication information: clinical narratives. In this work, we propose utilizing Natural Language Processing (NLP) to extract medications and medication change events from clinical narratives.
METHODS & DISCUSSION: In this work, we utilize NLP to extract medications and medication change events from clinical narratives. We use the medication event extraction schema from the N2C2 2022 Challenge to train and evaluate various models for two classification tasks. The first is Event Classification (EC), to identify if a medication was changed. The second is Event Context Classification (ECC) to understand the nature of any change.
Using this schema, we can parse a sentence from a clinical note such as “She was experiencing a bad episode of dry cough, so stopped taking lisinopril.” Parsing such a note helps us understand an actor (the patient) initiated an action (stopping the medication) with a temporality (in the past) and with a certainty (not hypothetical).
Our approach for both tasks involved using a pre-trained clinical language model while varying the context window around a medication, masking extraneous drugs, and using mark-up tokens around events. The most performant experiments utilized more extended context around a drug, with irrelevant drug masking. We also note that longer-range encoders had better F1 performance than the original BERT architectures.
We achieved a 92% performance (micro F1) for EC when detecting a medication change. For ECC, we achieved scores of 74%, 90%, 73%, and 88% (micro F1) over the categories of Action, Certainty, Temporality, and Actor.
CONCLUSION: Given the performance observed, this approach could allow clinicians to incorporate additional extracted medication context to improve patient care and provide high-quality treatment plans. Furthermore, we can aggregate this information across patients to give more insights to clinicians and researchers about the actual use of medications.

Deep-learning model for tumor type classification enables enhanced clinical decision support in cancer diagnosis

Madison Darmofal[1], Shalabh Suman[2], Gurnit Atwal[3], Jie-Fu Chen[4], Anna Varghese[5], Jason C. Chang[4], Anoop Balakrishnan Rema[4], Aijazuddin Syed[4], Quaid Morris[6], Michael Berger[4]. *[1]Weill Cornell Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada,[4]Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Computational and Systems Biology, Memorial Sloan Kettering, New York, NY*

Background: Knowledge of a patient's tumor type is essential for guiding clinical treatment decisions in cancer, but histologically-based diagnosis remains challenging for a subset of cancers. Genomic alterations are highly indicative of tumor type and can be used to build classifiers that predict diagnoses, but most genomic-based classification methods use whole genome sequencing (WGS) data which is not feasible for widespread clinical implementation at present. Clinical sequencing is typically performed using cancer gene panels that target individual mutations, often drivers, but previous tumor type classifiers developed using driver-based features alone perform poorly. We hypothesize that a classifier developed using state-of-the-art deep-learning methods and a sufficiently large training cohort would be able to overcome previous accuracy limitations and support the development of a clinically-relevant tumor type prediction model.
Methods: We present Deep Genome-Derived Diagnosis (GDD-ENS), an ensemble-based deep-learning tumor type classification method trained using data from cancer gene panel sequencing. We specifically use data from MSK-IMPACT, an FDA-authorized clinical sequencing assay that reports genomic alterations including mutations, indels, copy number alterations, and gene fusions across 505 cancer-associated genes. We aggregated a discovery cohort of 35,372 patients with solid tumors profiled with MSK-IMPACT across 38 common cancer types and used this set to generate 4,487 somatic mutation features for development.
Results: GDD-ENS achieves 78.8% accuracy on a held out validation cohort of 6971 patients. For the 71.9% of predictions assigned a high confidence by the model, accuracy increases to 92.7%, rivaling WGS-based models. We use Shapley Values to report prediction-specific feature importance, and aggregate them across cancer types to show GDD-ENS identifies known cancer type-genomic alteration trends. GDD-ENS also, with high accuracy, identifies patients with cancer types not included in the 38 common types using metrics derived from ensemble statistics. For patients where non-genomic information could further guide predictions, we implement a customizable prediction-specific adaptive prior distribution and report improved accuracy after adjusting predictions to account for features such as metastatic sample biopsy site. Finally, we apply GDD-ENS to a set of 1,123 patients with Cancers of Unknown Primary (CUP) and return high confidence predictions for 49% of these patients, in some cases matching predictions on CUP samples with diagnoses that were later confirmed through additional sampling and disease progression.
Conclusions: Integrating GDD-ENS into prospective clinical sequencing workflows will enable clinically-relevant tumor type predictions that can guide treatment decisions in real-time.

Cell cycle arrest status predicted from H&E stained images using deep learning

Christina Aigner[1], Brian Reichholf[2], Maxime Emschwiller[1], Marija Pezer[1], Tobias Winterhoff[1], Simon Schallenberg[3], Rosemarie Krupar[1], Lukas Ruff[1], Sharon Ruane[1], Maximilian Alber[1], Frederick Klauschen[4], Francesca Trapani[2]. *[1]Aignostics GmbH, Berlin, Germany,[2]Boehringer Ingelheim RCV GmbH & Co KG, Vienna, Austria,[3]Institute of Pathology, Charité – Universitätsmedizin Berlin, Berlin, Germany,[4]Institute of Pathology, Ludwig Maximilian University, Munich, Germany*

Background: Cyclin-dependent kinase inhibitor p21 is a regulator of cell cycle progression. Due to its capacity to induce cell cycle arrest (CCA) when expressed in the nucleus, it is also considered a tumor suppressor and its presence can be used to evaluate the efficacy of anti-cancer treatment. Since pathologists cannot assess nuclear p21 status of cells using hematoxylin & eosin

(H&E) stained tissue alone, the current state-of-the-art approach requires evaluation using immunohistochemistry (IHC). This process is time-consuming, adds additional cost and usually requires a separate section of the sample tissue. Further, manual evaluation of IHC stainings typically shows high inter-pathologist variability. In this study, we developed a deep learning model that predicts cell-level nuclear p21 status on H&E-stained tissue alone, aiming to bypass the IHC-staining step and all drawbacks associated with it.
Methods: 99 tissue sections of pancreas cancer xenografts were stained by H&E, then restained for p21 (IHC). The samples originated from mice that had undergone experiments conducted to examine the pharmacodynamic effect of anti-cancer treatments. H&E and IHC image pairs were coregistered to micrometer level precision. A tissue segmentation model was trained to detect regions of 'carcinoma' in H&E. This model was used as a filter and only cells within the tumor region were considered for analysis. Individual cells were detected in the H&E image and these locations were transferred to the IHC image. A deep learning model was trained using IHC-informed labels to extract labels at scale from each IHC image. These labels were then transferred to the H&E image and used to train a second deep learning model which predicted nuclear p21 status from H&E alone.
Results: IHC-informed labels were extracted with a balanced accuracy (BA) of 0.93. The resulting 'H&E only' nuclear p21 model achieved a cell-level BA of 0.83. A case level comparison of the share of predicted p21+ nuclei showed a Pearson correlation of 0.72 with the share of p21+ nuclei determined by the IHC-informed extracted labels. Further, when used to characterize all samples, the model detected significant differences between treatment groups.
Conclusion: Nuclear p21 status can be detected at a cellular level in H&E images alone, using a deep learning model. This provides an opportunity to assess samples for cell cycle arrest status at scale in a standardized manner, without the need for IHC staining.

SlideQC: An AI-based tool for automated quality control of whole-slide digital pathology images

Daniela Rodrigues[1], Stefan Reinhard[2], Therese Waldburger[2], Daniel Martin[3], Suzana Couto[4], Inti Zlobec[2], Peter Caie[1], Erik Burlingame[1]. *[1]Indica Labs, Albuquerque, NM,[2]Institute of Pathology, University of Bern, Bern, Switzerland,[3]Genmab, New York, NY,[4]Pathology, Genmab, Princeton, NJ*

Introduction: Artifacts are often introduced during tissue collection and processing, slide preparation, and/or when generating whole slide images (WSI). The presence of artifacts has a negative impact on the digital pathology workflow as artifacts may hinder diagnostic reporting and can lead to false positive and false negative results when using image analysis algorithms or computer-aided diagnosis systems. Manual quality control of WSI is a time-consuming procedure and therefore automated quality control tools, which report and exclude artifacts, are highly desirable to streamline digital pathology workflows. To automate the quality control step, we developed SlideQC, an AI-based quality control tool that automatically detects, reports, and outlines artifacts such as air bubbles, dust/debris, folds, out-of-focus,and pen marks, in both research and clinical workflows. Methods: SlideQC was trained with a DenseNet-based network using 1984 annotations for artifacts including air bubbles, dust/debris, folds, out-of-focus, and pen markers, across 254 Haematoxylin and Eosin (H&E) stained WSI from more than 9 tissue types. A set of 2048 annotations from synthetically generated out-of-focus images was added to supplement the training data. The performance of the SlideQC was evaluated on an external test

cohort of 49 WSI H&E images sourced from the open-source database 'HistoQCRepo', across 375 annotations (tissue and artifact), and compared with the performance of HistoQC, an open-source quality control tool for digital pathology slides. Results: On the external test cohort, SlideQC showed high sensitivity, specificity, and F1-score with average values of 0.93, 0.99, and 0.93, across the five artifact types. In the same cohort, HistoQC attained an average sensitivity, specificity, and F1-score of 0.65, 0.79, and 0.54, respectively. Conclusions: SlideQC achieved high sensitivity, specificity, and F1-score on an external test cohort. SlideQC can add efficiency gains to a workflow by performing quality control on 100% of slides rather than the currently manually performed on only a subset of the slides in clinical pathology departments. SlideQC can allowthe triaging and alerting of slides containing a high level of artifact within a digital pathology workflow. The tool can also be used to exclude the artifact region from downstream analysis by subsequent image analysis algorithms.

Pathomics reveals the molecular and immune evolution from lung preneoplasia to invasive adenocarcinoma

Pingjun Chen[1], Frank Rojas[2], Xin Hu[3], Junya Fujimoto[2], Alejandra Serrano[2], Bo Zhu[4], Lingzhi Hong[1], Rukhmini Bandyopadhyay[1], Muhammad Aminu[1], Maliazurina B. Saad[1], Morteza Salehjahromi[1], Sheeba J. Sujit[1], Neda Kalhor[5], Harvey I. Pass[6], Andre L. Moreira[7], Ignacio I. Wistuba[2], Don L. Gibbons[4], John V. Heymach[4], Luisa M. Solis Soto[2], Jianjun Zhang[4], Jia Wu[1].
[1]Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[5]Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Surgery, NYU Langone Health, New York, NY,[7]Pathology, NYU Langone Health, New York, NY

Introduction: Atypical adenomatous hyperplasia (AAH) is the only recognized preneoplasia of lung adenocarcinoma, which can progress to adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and eventually to invasive adenocarcinoma (ADC). A more complete understanding of the early carcinogenesis of lung cancer is critical for lung cancer early detection and interception. However, studying these lung cancer precursors is challenging because these lesions are often insufficient for molecular and immune profiling. Artificial intelligence (AI)-based studies on H&E histopathology images, termed pathomics, have achieved substantial progress in revealing heterogeneous phenotypic characteristics of various cancers. However, pathomics on lung precancerous progression and their correlation with genomic features remain underexplored.
Methods: We curated FFPE H&E slides from two ethnic groups, including the Caucasian cohort containing 46 lesions with 170 regions of interest (ROI) (74 AAH, 10 AIS, 21 MIA, and 65 ADC) and the Asian cohort containing 128 lesions with 369 ROIs (59 AAH, 84 AIS, 77 MIA, and 149 ADC). We adopted the expert-in-the-loop strategy to develop a deep learning pipeline to segment and annotate the cells within ROI into three categories: epithelial, lymphocyte, and other. Next, we measured the ratio and density of epithelial cells and lymphocytes inside each ROI as pathomics features. Finally, we interrogated ROI-level features and examined their correlation with molecular and immune features in the Asian cohort.

Results: We observed a progressive increase in the ratio and density of epithelial cells and a progressive decrease in the ratio and density of lymphocytes defined by the AI model from AAH to AIS, MIA, and ADC, consistent with the same trends defined by T cell receptor (TCR) sequencing and multiplex immunofluorescence (mIF). When correlating pathomics features with molecular/immune features, the epithelial cell ratio exhibited prominent positive correlations with the frequency of allelic imbalance (rho=0.588, p=4.71e-13) and nonsynonymous mutation burden (rho=0.453, p=1.03e-7). In contrast, the lymphocyte ratio showed a notable negative correlation with copy number variation burden (rho=-0.412, p=1.61e-6).
Conclusion: Employing AI tools to analyze HE images of lung precancerous lesions, we revealed that molecular and immune evolution during early lung carcinogenesis is consistent with the results from complicated, time-consuming, and expensive molecular/immune profiling, which requires a large number of tissue specimens, highlighting the potential of pathomics in the study of cancer biology, particularly in diseases having limited tissue specimens.

Integrated analysis of gene expression signatures and AI-based detection of tertiary lymphoid structures and stromal tumor-infiltrating lymphocytes in breast cancer H&E samples

Nadezhda Lukashevich, Vladimir Kushnarev, Daniil Dymov, Anastasia Zotova, Anna Belozerova, Ivan Valiev, Lev Popyvanov, Anna M. Love, Nathan Fowler, Alexander Bagaev, Ekaterina Postovalova. *BostonGene, Corp., Waltham, MA*

Background: Transcriptomic and morphological features of the tumor microenvironment (TME) are associated with favorable prognosis and can serve as surrogate markers for immune checkpoint inhibitor response in certain breast cancer subtypes. Tertiary lymphoid structures (TLS) and stromal tumor-infiltrating lymphocytes (sTILs) are integral components of the TME. New techniques for TLS characterization could improve reproducibility and automate the current workflow. Here, we correlated AI-based imaging platform predictions of TLS and sTILs on breast cancer H&E whole slide images (WSIs) with expression data.
Design: WSIs from 390 TCGA breast cancer samples were used to detect normalized tumoral TLS and tumor stroma infiltration areas by a convolutional neural network (CNN). High and low groups were defined by IQR1 and IQR3. Gene counts were compared using differential expression analysis followed by gene set enrichment analysis (GSEA) with hallmark gene sets. Kassandra's cell type percentage predictions, functional gene signature (Fges) single-sample GSEA, and PROGENy pathway activity median-scaled scores were compared with the Mann-Whitney U test. The Fges consisted of 4 TLS and 29 TME signatures and were clustered into 4 groups: fibrotic, myeloid, T cell, and TLS. Group medians were analyzed. Somatic deep amplifications, deletions, and missense mutations of cancer pathways were compared with Fisher’s exact test. The FDR method was used to adjust p-values.
Results: *FDCSP, CXCL13, CD79A, CCL19,* and *IGLL5* were upregulated in the TLS-high group (logFC > 1.5, p < 0.003), and *CXCL13, CXCL9, CCL19, CD3E,* and *CD79A* were upregulated in the sTIL-high group (logFC > 2, p < 4e-9). GSEA identified interferon γ and α response and allograft rejection signatures in TLS- and sTIL-high groups (p = 0.006, NES > |2.5|). sTIL-high samples expressed high levels of E2F targets, while the sTIL-low group was enriched with myogenesis and epithelial-mesenchymal transition gene sets.
The TLS-high group was enriched in the TLS Fges cluster (p = 1e-5) and contained high B, $CD4^+$ T, and $CD8^+$ T cell content (p < 2e-4). sTIL samples expressed high levels of B, $CD4^+$ T, $CD8^+$ T,

and myeloid cells ($p < 0.001$) and TLS and myeloid clusters ($p < 1e-5$). TGFβ and VEGF pathways were more active in sTIL-low samples ($p < 0.001$), while JAK-STAT was most active in the sTIL-high group ($p = 0.0006$). In the basal subtype ($p < 0.001$), the TLS-high group was associated with *NOTCH2* amplification; the sTIL-low group had increased *NRG1* deletions; and the sTIL-high group contained *BRCA2* mutations.
Conclusions: RNA-based methods used were concordant with AI-based methods of TLS and sTIL detection. Our CNN-based method of identifying immune structures in the TME with morphological features on H&E WSIs may automate traditional pathology workflows with additional validation.

#5445

Segmentation-free analysis of multiplexed images with unbiased spatial analytics and explainable AI for predicting disease outcomes

Filippo Pullara, Brian Falkenstein, Bruce Campbell, Samantha Panakkal, Akif Burak Tosun, Jeffrey Fine, S. Chakra Chennubhotla. *SpIntellx, Inc., Pittsburgh, PA*

Background: The spatial intratumor heterogeneity (ITH) is widely acknowledged as driving therapeutic response and providing fuel for drug resistance. Currently, patient selection for immunotherapy is driven mostly by PD-1/PD-L1 based IHC tests and mutational analysis. These oversimplified approaches fail to predict the risk of recurrence, therapeutic response and drug resistance with high accuracy. We hypothesize that functional responses of heterogeneous non-random spatial arrangements of tumor, stromal and immune cells in the tumor microenvironment are determined by distinct combinations of their internal states and spatial interactions within neighborhoods. The interactions generate distinct cell-cell communication networks forming functional spatial configurations of cells, termed microdomains, as organizational units of spatial ITH. Deriving the spatial networks within each microdomain with unbiased spatial analytics and the underlying network biology through explainable AI, is key to understanding tumor initiation, tumor progression, and response to therapy.
Problem: There has been an explosion of spatial imaging technologies using immunofluorescence and/or mass spectrometry for intact tissues measuring protein expressions, DNA and RNA probes. To extract high-value knowledge from these multiplexed datasets, a key first step is to segment cells accurately. Despite decades of research, this step remains elusive due to imaging artifacts arising from issues with tile stitching, incorrect registration, signal oversaturation, non-uniform illumination, poor or high-background nuclei signal, defocus, varying cell and nuclear shapes, fluorescence emission efficiency variation, overlapping and/or superimposed nuclei and low resolution (e.g., mass cytometry). Those artifacts may lead to incorrect cell phenotypes, incomplete cell phenotype atlases, and missing rare cell, fusion cell or transition cell types.
Solution: We present TumorMapr™, a segmentation-free, unbiased spatial analytics and explainable AI platform that extracts information and creates knowledge from patient disease pathology samples imaged with any technology including fluorescence, mass spectrometry etc.
Results: We apply TumorMapr on hyperplexed immunofluorescence dataset of colorectal cancer and hyperplexed imaging mass cytometry dataset of triple negative breast cancer to discover functional cell prototypes involving spatial collections of neighboring pixels highly predictive of disease progression and response to therapy, tumor promoting and tumor restraining microdomains and microdomain-specific network biology predictive of disease outcomes. We further compare these results with segmentation-based approaches to showcase the discovery of novel cell prototypes.

#5446

Immune phenotypes classified by deep learning-based H&E tissue analyzer demonstrate distinct immune landscape and transcriptomic features in ovarian cancer

Horyun Choi[1], Youjin Oh[2], Chan-Young Ock[3], Kyunghyun Paeng[3], Young Kwang Chae[2].
[1]University of Hawaii John A. Burns School of Medicine, Honolulu, HI,[2]Northwestern University Feinberg School of Medicine, Chicago, IL,[3]Lunit, Seoul, Korea, Republic of

Introduction: Deep learning-based H&E slide analyzer, Lunit-SCOPE IO can classify the tumor microenvironment as three immune phenotypes (IPs): inflamed, immune-excluded and immune-desert. In our previous study, the IPs demonstrated distinct survival outcome and immunologic landscape in endometrial cancer. To further explore the application of IPs in other type of cancer, we applied Lunit-SCOPE in ovarian cancer (OV) and compared tumor microenvironments based on the IPs.
Methods: H&E slide images, RNA-sequencing data, and clinical data were obtained from TCGA OV cohort. Lunit-SCOPE IO is a H&E slide analyzer using deep learning algorithm and was trained with 1,824 H&E slides of advanced NSCLC. We used the analyzer to classify H&E slide images from TCGA OV cohort to three IPs. Cibersort was used to assess immune cell infiltration across the IPs. The cytolytic activity score was obtained from geometric mean of GZMA and PRF1 RNA expression. We further assessed transcriptomic characteristics across IPs via differentially expressed genes analysis and gene set enrichment analysis (GSEA). Additionally, we compared CD274 gene expression across IPs. Finally, survival analysis was performed to evaluate survival outcome based on IPs. We used Mann-Whitney method to compare non-parametric variables between the IPs.
Results: The proportion of inflamed, immune-excluded and immune-desert group in TCGA OV were 7 (10.2%), 13 (18.8%), and 49 (71%), respectively. Inflamed group showed significantly higher proportion of M1 macrophage compared with immune-desert group (6.6% vs. 2%, P=.012). We observed higher cytolytic activity score in inflamed group compared to immune-desert group (7.21 vs. 5.27, P=.016). In GSEA, inflamed group is significantly enriched in IL6 JAK STAT3 signaling, interferon gamma response, KRAS signaling up, and inflammatory response pathway (NES 2.19; adjusted P=.021, NES 1.70; adjusted P=.021, NES 1.62; adjusted P=.037, and NES 1.52; adjusted P=.037, respectively). Immune-desert is related to upregulated MYC target V2 pathway (NES -1.95; adjusted P=.037). Inflamed group did not show significant difference in CD274 expression, compared with others (Inflamed vs. immune-excluded, 4.97 vs. 4.19, P=.115 and Inflamed vs. immune-desert, 4.97 vs. 3.95, P=.058). Inflamed group did not show any significant difference in overall survival, compared with non-inflamed group (Inflamed vs. non-inflamed, HR 0.98; 95% CI 0.45 - 2.14; P=.958).
Conclusion: Deep learning-based H&E slide analyzer can be used to classify tumor H&E slide images with OV into three IPs. In this study, the classification demonstrated distinct immunologic traits and transcriptomic characteristics in tumor microenvironment. The enrichment of interferon gamma response pathway in inflamed OV group may indicate opportunities for targeted immunotherapy.

Artificial intelligence (AI)-based classification of stromal subtypes reveals associations between stromal composition and prognosis in NSCLC

Fedaa Najdawi, Sandhya Srinivasan, Neel Patel, Michael G. Drage, Christian Kirkup, Chintan Parmar, Jacqueline Brosnan-Cashman, Michael Montalto, Andrew H. Beck, Archit Khosla, Ilan

Wapinski, Ben Glass, Murray Resnick, Matthew Bronnimann. *PathAI, Inc., Boston, MA*

Background**:** Many cancers are known to involve a desmoplastic stromal reaction. While cancer-associated stroma (CAS) has long been appreciated histologically, single-cell molecular analyses have revealed its heterogeneity, and the cellular composition of CAS has been linked to prognosis in several cancer types, including NSCLC. While pathologists have sought to manually classify CAS based on collagen architecture or nuclear density, this approach has not sufficiently captured the heterogeneity of CAS. To this end, we have developed an artificial intelligence (AI)-based model to predict stromal composition in NSCLC from hematoxylin and eosin (H&E)-stained tissue.
Methods: We developed a convolutional neural network-based model to classify CAS as immature, mature, densely inflamed, densely fibroblastic, or elastosis. This model was trained using manual pathologist-derived annotations (N=3019) of H&E-stained whole slide images (WSIs) of PDAC obtained from the TCGA (N=126). This stromal subdivision model was deployed on H&E-stained LUAD (N=468) and LUSC (N=430) WSIs. Model performance was assessed by qualitative review by expert pathologists. Human interpretable features (HIFs) were extracted from the stromal subdivision model (e.g., proportional area of mature relative to total stroma) and were assessed to identify associations with overall survival (OS) using univariate Cox regression analysis after adjusting for age, sex, and tumor stage.
Results: The stromal subdivision model successfully predicted areas of immature, mature, densely inflammatory, and densely fibrotic stroma, as well as elastosis, in LUAD and LUSC. In LUAD, higher combined proportional areas of mature and fibroblastic stroma relative to total cancer stroma was associated with poor OS (p=0.007), while higher combined proportional areas of densely inflamed stroma and elastosis relative to total cancer stroma was associated with improved OS (p=0.007). These findings were validated by stratified tertile analysis based on the corresponding risk direction. Notably, while the average stromal compositions did not differ significantly between NSCLC subtypes, the stromal HIFs were only prognostic in LUAD but not in LUSC.
Conclusions: We developed a first of its kind model to characterize CAS subtypes in NSCLC tissue. Features extracted from this model are related to prognosis in LUAD, but not in LUSC, further confirming the importance of CAS to tumor biology and the importance of considering histologic subtypes. Work is ongoing to identify relationships between stromal HIFs and treatment response in NSCLC as well as other cancer indications.

Clinical Applications of Artificial Intelligence and Mathematical Oncology

Cancer cells subvert fibroblast function to promote a growth factor enriched tumor microenvironment in endocrine therapy resistant ER+ breast cancer
Jason I. Griffiths[1], Patrick A. Cosgrove[1], Eric Medina Castaneda[1], Aritro Nath[1], Jinfeng Chen[1], Frederick R. Adler[2], Jeffrey T. Chang[3], Qamar J. Khan[4], Andrea H. Bild[1]. *[1]City of Hope National Medical Center, Duarte, CA,[2]University of Utah, Salt Lake City, UT,[3]UT Health Sciences Center at Houston, Houston, TX,[4]The University of Kansas, Kansas City, KS*

While endocrine therapy (ET) has considerably improved Stage II/III ER+ breast cancer survival rates, resistance emerges in 30-50% of patients. Recent advances have uncovered numerous cancer intrinsic and tumor-microenvironment mediated mechanisms contributing to ET

resistance. However, the predominant mechanisms that prevent cure and ultimately lead to development of terminal metastatic cancer remain unknown. To reveal the leading causes of ET resistance in early-stage ER+ breast cancers, we used single-cell RNA sequencing to profile serial tumor biopsies from a larger cohort of patients. Patients received either endocrine therapy (letrozole) alone or in combination with a CDK4/6 cell cycle inhibitor (ribociclib). We examined the evolution of tumor composition, cellular communication, and the phenotypic diversity of tumor-associated cancer and non-cancer cells throughout treatment. Our analyses reveal that ET-resistant tumors are fibroblast- and endothelial-enriched and consistently exhibit broad upregulation of growth factor signaling to cancer cells, with consistent activation of ERBB communication across patient tumors. Fibroblasts emerged as the primary source of these additional growth factor signals. Upregulation of fibroblast growth factor signaling (via NRG1/2, EGF and IGF) was commensurate with differentiation to a mesenchymal cancer-associated-fibroblast (myCAF) phenotype, which was itself stimulated by cancer cells through EGF and TGF signaling. In response to growth factor enrichment, cancer cells of ET-resistant tumors showed activation of MAPK signal transduction and downstream transcription factors promoting proliferation including FOS, JUN and TRIB1. These results indicate that ET resistance emerges in patient tumors when cancer cells subvert fibroblast function to promote a growth factor enriched tumor microenvironment permitting estrogen independent cancer proliferation.

Adaptive treatment scheduling of PARP inhibitors in ovarian cancer: Using mathematical modeling to assess clinical feasibility and estimate potential benefits

Maximilian A. R. Strobl[1], Alexandra L. Martin[2], Christopher Gallagher[3], Mehdi Damaghi[4], Mark Robertson-Tessi[5], Robert Gatenby[6], Robert M. Wenham[7], Philip K. Maini[3], Alexander R. A. Anderson[5]. *[1]Moffitt Cancer Center, Tampa, FL,[2]Division of Gynecologic Oncology, West Cancer Center and Research Institute, Memphis, TN,[3]Mathematics, University of Oxford, Oxford, United Kingdom,[4]Stony Brook Cancer Center, Stony Brook, NY,[5]Integrated Mathematical Oncology, Moffitt Cancer Center, Tampa, FL,[6]Cancer Biology and Evolution Program, Moffitt Cancer Center, Tampa, FL,[7]Gynecologic Oncology Program, Moffitt Cancer Center, Tampa, FL*

PARP inhibitors (PARPis) are revolutionizing the treatment of ovarian cancer. Yet for many patients these improvements come at the cost of physical and financial toxicity and responses are typically temporary due to emerging drug resistance. A growing body of pre-clinical and clinical work suggests that when cure is unlikely, it is possible to delay progression and reduce drug use through patient-specific drug scheduling. So-called 'adaptive therapy' dynamically adjusts treatment to preserve drug-sensitive cells which interfere with resistant cells through competition. In a prior study, we developed a mathematical model to describe the treatment response of ovarian cancer cells to the PARPi olaparib in vitro, and we proposed a candidate adaptive PARPi algorithm. Here, we extend our model to capture the dynamics in patients and use it to study the feasibility and potential benefit of adaptive PARPi administration in practice.
Our prior model posited that treatment induces cell cycle arrest that moves cells from the proliferating subset of the population to an arrested compartment. The model predicted that while there is scope for treatment reductions, these need to be carefully timed and prolonged treatment breaks should be avoided. Based on these results we proposed an adaptive treatment algorithm in which the olaparib dose is switched between high and low doses, depending on the tumor's growth rate. To test the translational potential of this strategy, we retrospectively collected data from 53 ovarian cancer patients who received olaparib at the H Lee Moffitt Cancer Center

between 2014 and 2021. Using serum CA-125 as a proxy for tumor burden, we first examined whether our mathematical model could capture the patients' longitudinal dynamics. While the response of some patients was consistent with what we had observed in vitro, in others there was evidence of the emergence of a distinct drug-resistant population, and we extended our mathematical model to account for this. After calibrating and validating the model with the patient data, we tested whether these patients would have benefited from adaptive PARPi treatment. Our simulations suggest that our proposed algorithm is feasible and provides a means for reducing treatment in a patient-specific manner. In addition, in a subset of patients we predict that adaptive therapy could delay progression. Overall, this work corroborates the potential for adaptive PARPi therapy and helps to identify outstanding challenges on the way to clinical translation.

Koelzer[18], Tjalling Bosse[1]. *[1]Pathology, Leiden University Medical Center (LUMC), Leiden, Netherlands,[2]Pathology and Molecular Pathology and Computer Science, ETH Zurich, University Hospital, University of Zurich, Zurich, Switzerland,[3]Gynaecology, Copenhagen University Hospital, Copenhagen, Denmark,[4]Gynaecology, Herlev Hospital, University of Copenhagen, Copenhagen, Denmark,[5]Vascular and Molecular Imaging, Leiden University Medical Center (LUMC), Leiden, Netherlands,[6]Radiation Oncology, Medisch Spectrum Twente, Enschede, Netherlands,[7]Radiation Oncology, University Medical Center Utrecht, Utrecht, Netherlands,[8]Radiation Oncology, Maastricht UMC+, Maastricht, Netherlands,[9]Clinical Oncology, Barts Health NHS Trust, London, United Kingdom,[10]Pathology, Vancouver General Hospital, Vancouver, BC, Canada,[11]Medical Oncology, Peter MacCallum Cancer Center, Melbourne, Australia,[12]Medical Oncology and Hematology, Odette Cancer Center Sunnybrook Health Sciences Center, Toronto, ON, Canada,[13]Medical Oncology, Gustave Roussy Institute, Villejuif, France,[14]Gynecologic Oncology, University of Torino, Torino, Italy,[15]Obstetrics & Gynecology, University Medical Center Groningen, Groningen, Netherlands,[16]Radiation Oncology, Leiden University Medical Center (LUMC), Leiden, Netherlands,[17]Radiation Oncology, Erasmus University Medical Center, Rotterdam, Netherlands,[18]Pathology and Molecular Pathology, University Hospital Zurich, University of Zurich, Zurich, Switzerland*

Accurate risk prediction of distant recurrence (DR) is crucial for personalized adjuvant systemic therapy of endometrial cancer (EC) stage I-III patients, as DR is associated with a 5-year overall survival of 10-20%. Risk stratification and treatment recommendation are currently based on histopathological and molecular markers, which is challenging due to high inter-observer variability and testing costs respectively. Deep Learning (DL) models can predict prognosis by identifying relevant visual features from H&E whole slide images (WSIs) at different resolutions without prior assumptions. Here, we developed and tested the first interpretable state-of-the-art DL model for WSI-based risk prediction of DR of stage I-III EC (DeREC) from the randomized

PORTEC-1/-2/-3 trials and three clinical cohorts with long-term follow-up data. We used one representative H&E WSI each from 1761 EC patients, excluding those who received adjuvant chemotherapy as it lowers the risk of DR. We randomly sampled 20% as a held-out internal test set (N=353 with 62 events; 8.45 year median follow-up) and performed a 5-fold cross-validation on the training set (N=1408). WSIs were partitioned into 360 micron patches at 40x magnification. DeREC combined self-supervised representation learning of patches using a multi-resolution vision transformer and a WSI-level graph attention-based time-to-event prediction model. The model performance of correctly ranking patients by predicted risk scores and true time to DR was measured with the concordance-index and compared with a Cox' Proportional Hazards (CPH) model fitted on histopathological variables (histotype, grade, lymphovascular space invasion, stage). Discriminative quality of the predicted risk groups was investigated with Kaplan-Meier analysis and the log-rank test. Most predictive patches by predicted risk groups were reviewed by an expert gynecopathologist for identification of prognostic morphological features. DeREC achieved a concordance-index of 0.764 [95%CI 0.754-0.773] on 5-fold cross validation and 0.757 on the test set, as compared to 0.704 [95%CI 0.662-0.746] with CPH. Predicted risk groups around quartiles 1 and 3 accurately stratified patients between low (N=89), intermediate (N=175), high (N=89) risk of DR ($p<0.0001$). Among the predicted low-risk group only 3 (3.37%) patients relapsed whereas intermediate and high-risk groups counted 27 (15.43%) and 32 (35.96%) events respectively. DeREC is the first DL model accurately distinguishing EC patients at high risk of DR from those at low risk using one H&E WSI, which would aid decisions on adjuvant treatment. DeREC outperformed standard statistical prediction methods using histopathological variables, indicating that it identified prognostic visual features which can be further investigated. Future development includes the integration of clinicopathological and molecular information.

A prognostic machine learning model for early breast cancer which combines clinical and genetic data in patients treated with neo/adjuvant chemotherapy

Aidan (Amanzhol) Kubeyev[1], Andrea Giorni[2], Prabu Siva[1], Luiz Silva[2], Jordan Laurie[2], Matthew Foster[2], Matthew Griffiths[1], Uzma Asghar[1]. *[1]Concr, Cambridge, United Kingdom,[2]Concr, Brisbane, Australia*

Background: Accurate modelling of the impact of patient-specific features and cancer treatments on survival allows the assignment of targeted therapy. There has not been any effort to build a multi-source model for the survival analysis of breast cancer. We show in this study a prognostic model, which integrates genetic (DNA), clinical and therapy inputs to predict survival for early breast cancer (stages 1-3) for all breast cancer subtypes.
Methods: We used a data-driven Random Survival Forest approach, a statistical non-parametric ensemble learning method, that incorporates censor and time-to-event data. The learning is performed by creating numerous decision trees and selecting the model based on the correct responses in unseen data. We used The Cancer Genome Atlas Breast Cancer (TCGA) dataset and observed improvements in the accuracy when more sources of data were used, in line with the previous research. Integrating the impact of non-silent somatic tumor mutations (whole exome) and gene copy number variation (CNV) were analyzed on all mutations and per particular mutation.
Results: Data from 1096 women with stage 1-3 early breast cancer were inputs to the model n=437 ER+ve HER2-ve, n=123 HER2+ve ER+ve, n=40 HER2+ ER-ve and n=126 TNBC.

Pathological stage 1, n=183; stage 2, n=620; and stage 3, n=249. The following chemotherapy and hormonal treatments were used in the analysis: anthracycline, taxanes, platinum, alkylating and anti-metabolite agents, anti-oestrogen, aromatase inhibitors, ovarian suppression and HER2 antibody treatment.
The model accuracy for predicting survival for early breast cancer using only clinical data was 0.78 for Area Under Curve (AUC) and c-index. The predictive accuracy improved stepwise by adding hormone, genetic and treatment data to AUC of 0.86 and c-index to 0.85. We observed the same trend if the proportion of test data increased from 0.25 to 0.75. Changes in median genes FGFR2 and CDKN2A copy number were strongly prognostic with p=0.0001 and p=0.002, and weaker signals for CBFB p=0.05, HRAS p=0.06, AKT p=0.07.
Conclusion: Using public datasets, we developed a predictive survival model for an individual with early breast cancer up to 5 years from diagnosis using multi-source and patient-specific data. We show that using this approach for survival analysis yields good accuracy.

Predicting response to PD-L1 inhibition in NSCLC using a quantitative systems pharmacology model guided by immunogenomic data

Hanwen Wang, Theinmozhi Arulraj, Aleksander S. Popel. *Johns Hopkins University School of Medicine, Baltimore, MD*

Introduction: Non-small cell lung cancer (NSCLC) is the most common subtype of lung cancer with an overall 5-year survival rate of 26%, which varies by the disease stage. Novel drug combinations involving immune checkpoint inhibitors are being investigated in clinical trials in NSCLC. In this study, we generated about 450 virtual patients that resembled actual patients with NSCLC and simulated tumor growth during PD-L1 inhibition using a quantitative systems pharmacology (QSP) model.
Methods: We recalibrated a previously developed QSP model of the cancer-immunity cycle (1) to NSCLC with parameters estimated by published experimental data. Proportions of CD8, CD4, and regulatory T cells (Tregs), M1 and M2 macrophages in lung adenocarcinoma and lung squamous cell carcinoma were downloaded from iAtlas database and used to calculate the ratios of CD8/CD4, Tregs/CD8, and M1/M2. The three immune subset ratios (observed data) were used to guide the virtual patient generation. We first randomly generated deviations around the baseline model parameters to account for inter-patient variability and then selected virtual patients with model-predicted immune subset ratios statistically matching the observed data. Finally, we simulated tumor growth during PD-L1 inhibition and predicted clinical response in the virtual patient cohort.
Results: Our model predicted an overall response rate of 16.3% with a 95% bootstrap confidence interval of (11.8, 22.4)% for the overall virtual patient cohort. It also showed that CD8 T cells, PD-L1 expression, CD8/CD4, CD8/Tregs, M1/M2 ratios, and the number of NSCLC-specific T cell clones were significantly higher in responders to PD-L1 inhibition. Furthermore, Tregs/CD8 and CD8/CD4 ratios were predicted to be the best predictive biomarkers according to ROC analysis with areas under ROC curve of 0.71 and 0.66.
Conclusion: Immunogenomic analysis of RNA-seq data on iAtlas allowed generation of realistic virtual patients using QSP models in immuno-oncology. With a virtual patient cohort guided by immunogenomic data, our model provided reliable efficacy prediction for immunotherapy and a tool to identify predictive biomarkers in NSCLC. 1. A multicenter study validated an integrated deep learning model for precision malignancy risk assessment and reducing unnecessary biopsies in BI-RADS 4 cases

Chika F. Ezeana[1], Tiancheng He[1], Tejal A. Patel[2], Virginia Kaklamani[3], Maryam Elmi[3], Erica Ibarra[3], Pamela M. Otto[3], Kenneth A. Kist[3], Heather Speck[4], Lin Wang[1], Joe Ensor[5], Ya-Chen T. Shih[6], Bumyang Kim[6], I-Wen Pan[6], David Spak[7], Wei T. Yang[7], Jenny C. Chang[5], Stephen T. C. Wong[8]. *[1]Department of Systems Medicine and Bioengineering, Houston Methodist Neal Cancer Center, Houston Methodist Hospital, Houston, TX,[2]Department of General Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]The University of Texas Health Science Center, San Antonio, TX,[4]The University of the Incarnate Word School of Osteopathic Medicine, San Antonio, TX,[5]Houston Methodist Neal Cancer Center, Houston Methodist Hospital, Houston, TX,[6]Department of Health Services Research, The University of Texas MD Anderson Cancer Center, Houston, TX,[7]Department of Radiology, The University of Texas MD Anderson Cancer Center, Houston, TX,[8]Department of Systems Medicine and Bioengineering, Department of Radiology and Pathology, Houston Methodist Neal Cancer Center, Weill Cornell Medicine, Houston Methodist Hospital, Houston, TX*

Introducti**on:** BI-RADS category 4 is associated with a wide variability in probability of malignancy, ranging from 2 to 95% while biopsy-derived positive predictive value (PPV3) for this category's lesions remains low at 21.1% in the US. A major fallout of these facts is that we have way very high false positive rate leading to too many unnecessary biopsies and their associated costs and emotional burden. We improved our in-house intelligent-augmented Breast cancer RISK calculator (iBRISK), an integrated deep learning (DL) based decision support app and assessed its performance in a multicenter IRB-approved study.

Methods: We improved iBRISK by retraining the DL model with an expanded dataset of 9,700 patient records of clinical risk-factors and mammographic descriptors from Houston Methodist Hospital (HMH) and validated using another 1,078 patient records. These patients were all seen between March 2006 and December 2016. We assessed the model using blinded, independent retrospective BI-RADS 4 patients who had biopsies subsequently after mammography and seen January 2015 - June 2019 at three major healthcare institutions in Texas, USA: MD Anderson Cancer Center, the University of Texas Health Sciences Center at San Antonio, and HMH. We dichotomized and trichotomized the data to evaluate precision of risk stratification and probability of malignancy (POM) estimation translated into biopsy decision augmentation. The iBRISK score as a continuous predictor of malignancy and possible cost savings was also analyzed.

Results: The multicenter validation dataset had 4,209 women, median age (interquartile) was 56 (45, 65) years. The use of iBRISK score as a continuous predictor of malignancy yielded an AUC of 0.97. Among "low" and "moderate" POM patients, only two out of 1,228 patients (0.16%) and 118 out of 1788 (6.6%) were malignant respectively. This translates to an even better precision when compared to newly introduced BI-RADS 4 subcategories 4A and 4B, with associated PPV3s of 7.6% and 22%, respectively. The "high" POM group had a malignancy rate of 85.9% (1,025/1,193). Estimated potential cost savings in the US was over $260 million.

Conclusion: The iBRISK app demonstrated high sensitivity in malignancy prediction and can potentially be used to safely obviate biopsies in up to 50% of patients in low/moderate POM-

groups. This would result in significant healthcare quality improvement, cost savings, and help reduce patient anxiety.

Development and validation of a quantitative systems pharmacology model for prediction of preclinical efficacy of PARP inhibitors rucaparib and talazoparib combined with the ATR inhibitor gartisertib (M4344)

Claire C. Villette[1], Frances Brightman[1], Nathalie Dupuy[1], Astrid Zimmermann[2], Florianne Lignet[2], Frank T. Zenke[3], Nadia Terranova[4], Jayaprakasam Bolleddula[3], Samer El Bawab[2], Christophe Chassagnole[1]. *[1]Physiomics Plc, Oxford, United Kingdom,[2]Merck KGaA, Darmstadt, Germany,[3]EMD Serono, Billerica, MA,[4]Merck Institute of Pharmacometrics an affiliate of Merck KGaA, Darmstadt, Germany*

Introduction: Poly (ADP-ribose) polymerase (PARP) and ataxia telangiectasia and Rad3-related (ATR) inhibitors target key DNA damage response (DDR) kinases. PARP inhibitors (PARPi) suppress the catalytic activity of PARP and trap PARP in a complex with damaged DNA, resulting in the accumulation of unrepaired single-strand breaks (SSBs) and stalled replication forks. Loss of ATR activity blocks cell cycle arrest induced by single-stranded DNA and sensitizes cancer cells to agents that induce DNA replication stress. Thus, PARP inhibition synergizes (through synthetic lethality) with concurrent ATR inhibition by inducing replication fork collapse, double-strand breaks (DSBs), and PARP-DNA complex formation, with simultaneous loss of intra-S and G2/M checkpoints and suppression of DNA-damage repair, leading to mitotic catastrophe. Four PARPi are currently approved for the treatment of various cancers and several ATR inhibitors (ATRi) are in clinical trials either as monotherapies or in combination with other chemotherapeutic agents. We developed and validated a semi-mechanistic quantitative systems pharmacology (QSP) model that represents the mechanisms of action of PARPi and ATRi with minimal parameters, which could be used to inform the optimization of combination regimens.

Methods: A QSP model of a growing cancer cell population was developed by considering SSBs and DSBs, and parallel DNA repair pathways relying on PARP and ATR. PARPi and ATRi mediated saturable inhibitory effects on their respective DDR pathways, while PARP-DNA trapping was represented as an increased conversion rate from SSBs to DSBs. Phenotypic impairments of the DDR such as BRCA mutations were embedded as DDR pathway deficiencies. The model was calibrated using experimental data derived from rucaparib and talazoparib combination studies with gartisertib.

Results: The calibrated model captured well the tumor-growth inhibition observed in the HBCx9 PDX model for rucaparib and gartisertib, either alone or in combination, over average daily doses ranging from 50 mg/kg to 200 mg/kg (QD/BID) of rucaparib and 1-3 mg/kg (QD/BIW/QD alternate weeks) of gartisertib. The model was also able to predict the wide range of responses (from shrinkage to progressive disease) observed in a panel of triple-negative breast cancer PDX models (BRCA-mutant and wild type) treated with talazoparib and gartisertib in combination. The complete DDR model utilized 9 variable parameters, and the mechanisms of action of PARP and ATR inhibition were described by 4 parameters each.

Conclusion: This newly developed QSP model provides a framework that can be applied to optimize the dosing regimens of PARP and ATR inhibitor combinations and help with clinical dosing strategy.

High-throughput 3D tumoroid models for immunotherapy and drug discovery

Duy Nguyen[1], Alexander McGhee[1], Diego Pedro[1], Alfonso Pepe[1], Matthew Schaller[1], Ryan Smolchek[2], Jack Famiglietti[2], Stephanie Warrington[2], W. Gregory Sawyer[1]. *[1]University of Florida, Gainesville, FL,[2]Aurita Bioscience, Gainesville, FL*

The tumor microenvironment (TME) is a complex 3D cellular system comprised of a diverse amalgam of cells. To characterize the TME, we developed a 3D cell culture platform which facilitates imaging-based analysis and cell viability for extended durations. We used this platform to collect in-situ spatiotemporal measurements of cytokine concentrations in the tumor vicinity, track cellular activity, and model local tumor invasion of glioblastoma (GBM) using fast-scanning confocal microscopy. The mechanism by which we achieve long-term 3D culture is perfusion, modeled as flow through a porous medium. Perfusion facilitates regulated transport of nutrients and waste within the soft microgel medium: Liquid-Like Solids (LLS). The interstitial space is tuned to mimic a capillary bed, and surface bioconjugation of the microgels promotes cellular adhesion and migration. To measure cytokine concentrations, GBM tumoroids were grown in LLS and printed into a dispersion of ELISA beads in LLS. The mechanical stability of LLS ensures the tumor and ELISA beads remain stationary without impeding cellular activity. Cytokine on and off-rates were referenced alongside measured bead fluorescence intensities and positions to fit spatiotemporal reaction-diffusion models. Fast-scanning confocal microscopy facilitated in-situ observation of the evolutionary dynamics of tumor progression. Co-culture of patient-derived tumor explants and autologous PBMCs printed into type I collagen-bioconjugated LLS enabled studies of cancer-immune interactions. In-situ cytokine measurements revealed local IL-8 concentrations reached a maximum value of 2 ng ml^{-1} after 10 hours. A cellular production rate was estimated at 2 molecules $cell^{-1}$ s^{-1}. Invasive behavior into the proximal space was determined to be super-diffusive; off-lattice agent-based simulations indicated this behavior is a result of the confinement of invasive fronts to the microgel interstitium. The invading glioblastoma cells used anchorage-dependent migration and were guided by geometric cues to traverse the porous bioconjugated LLS network. Cancer-immune interaction studies revealed average CD8+ speeds greater than 2.8 μm min^{-1} and both chemotaxis and chemokinetic behavior. CD8+ T-cell killing rates were estimated at approximately 3 cancer cells hr^{-1} initially, monotonically falling over 12 hours to roughly 1 cell hr^{-1}. The development of the in-situ 3D ELISA assay and imaging-based analysis techniques have enabled the tracking of tumor-immune cell interactions, observation of dynamic tumor progression, and local cytokine concentration profiling at appreciable spatiotemporal resolutions. The combination of a physiologically relevant 3D culture platform with the capacity for in-situ qualitative and quantitative observation may lead to new, powerful, preclinical models that allow for interrogation of the TME and decrease the rate of false discovery.

Becker[6], John Crawford[7], Robyn D. Gartrell[5], Luca Szalontay[5], Stergios Zacharoulis[8], Zhiguo Zhang[3], Robert Wechsler-Reya[9],

Cheng-Chia Wu[4], Andrea Califano[10], Jovana Pavisic[5]. *[1]Department of Systems Biology, Department of Pathology and Cell Biology, Columbia University Irving Medical Center, New York, NY,[2]Department of Systems Biology, Columbia University Irving Medical Center, New York, NY,[3]Department of Genetics and Development, Columbia University Irving Medical Center, New York, NY,[4]Department of Radiation Oncology, Columbia University Irving Medical Center, New York, NY,[5]Department of Pediatrics, Columbia University Irving Medical Center, New York, NY,[6]Department of Medicine and Institute for Stem Cell and Regenerative Medicine, University of Washington, Seattle, WA,[7]Department of Pediatrics, University of California Irvine & Children's Hospital Orange County, Orange, CA,[8]Department of Pediatrics, Columbia University Irving Medical Center & Bristol Myers Squibb, New York, NY,[9]Department of Neurological Sciences, Columbia University Irving Medical Center, New York, NY,[10]Departments of Systems Biology, Medicine, Biomedical Informatics, Biochemistry & Molecular Biophysic, Columbia University Irving Medical Center, New York, NY*

Diffuse Midline Glioma (DMG) are fatal pediatric brain tumors with no therapies. We leveraged network-based methodologies to dissect the heterogeneity of DMG tumors and to discover Master Regulator (MR) proteins representing pharmacologically accessible, mechanistic determinants of molecularly distinct cell states. We produced the first DMG regulatory network from 122 publicly available RNAseq profiles with ARACNe (Basso et al. Nat Genet 2005), and inferred sample-specific MR protein activity with VIPER (Alvarez et al. Nat Genet 2016) based on the differential expression of their targets. 7 of the top 25 most active MRs found comprise a well-characterized MR block (MRB2) (Paull et al.Cell 2021), frequently activated across aggressive tumors, and enriched in DMG patient MR signatures (Fisher's Exact Test $p=4.4x10^{-18}$). A CRISPR/Cas9 KO screen across 3 DMG patient cell lines identified a set of 73/77 essential genes that were enriched in the MR signature of 80% of patient samples (GSEA p=0.000034). FOXM1 emerged as an essential MR, significantly activated across virtually all patients.

We then generated RNAseq profiles following perturbation with ~300 oncology drugs in 2 DMG cell lines most representative of patient MR signatures, and used this to identify drugs that invert patient MR activity profiles using the NYS/CA Dept. of Health approved OncoTreat algorithm (Alvarez et al. Nat Genet 2018). OncoTreat predicted sensitivity to HDAC, MEK, CDK, PI3K, and proteosome inhibitors in subsets of patients, overlapping with published DMG drug screens. Importantly, 80% of OncoTreat-predicted drugs ($p<10^{-5}$) from 3 DMG patient tumor biopsies showed *in vitro* sensitivity in cultured tumor cells from the respective patients, with overall 68% accuracy among 223 drugs evaluated by both OncoTreat and *in vitro* (Fisher's Exact Test p=0.0449).

Further analysis of DMG intra-tumor heterogeneity via protein activity inference across DMG single cells from 6 published scRNAseq profiles identified 6 tumor clusters with unique MR signatures co-existing in virtually all patients representing distinct cellular states (2 astrocyte-, 1 oligodendrocyte-, and 3 oligodendrocyte precursor cell-like states). Targetable MRs and OncoTreat-predicted drugs were distinct between these states. Bulk RNAseq analysis recapitulated predictions seen in the more prevalent OPC-like states, but failed to capture MR and drug predictions for the AC-like states (*e.g.* JAK1/Ruxolitinib and STAT3/Napabucasin). We are currently validating cell state-specific drug predictions *in vivo* at single-cell resolution in subcutaneous patient-derived xenograft and orthotopic syngeneic DMG models that we have shown recapitulate patient tumor heterogeneity, including with focused ultrasound-mediated drug delivery. This provides a platform to nominate much-needed novel drugs and drug combinations to treat DMG.

Zlotta[7], Christopher Hovens[3], Paul C. Boutros[1]. *[1]Human Genetics, UCLA - University of California Los Angeles, Los Angeles, CA,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Australian Prostate Cancer Research Centre Epworth Richmond, Richmond, Australia,[4]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[5]Pathology and Laboratory Medicine, University of Toronto, Toronto, ON, Canada,[6]Surgery, University of Melbourne, Melbourne, Australia,[7]Princess Margaret Cancer Center, Toronto, ON, Canada*

Inherited genetic variation profoundly influences cancer risk and outcome. While the impact of germline single nucleotide polymorphisms has been well-studied in several cancer types, the effects of germline structural variants (gSVs) on cancer biology and clinical outcomes is largely unknown. From our cohort of 300 men with localized, intermediate risk prostate cancer, we identified 6,003 gSVs present in at least 3% of patients; 48 were associated with recurrent somatic alterations or clinical outcome. Of these, approximately 50% were associated with expression of nearby genes or intersected with exons or regulatory regions. Using external cohorts, we validated three gSVs that were strongly associated with poor clinical outcomes, including an inversion at chr14q24.1 present in ~20% of patients. Notably, a strong synergistic effect on outcome was observed in patients with somatic TP53 alterations or high genomic instability, defining a new aggressive prostate cancer subtype with chr14INV as a novel, recurrent biomarker.

Identifying genetic dependencies of replication stress using interpretable artificial intelligence

Xiaoyu Zhao, Akshat Singhal, Trey Ideker. *UC San Diego, La Jolla, CA*

Rapid proliferation is a hallmark of tumor cells, associated with sensitivity to chemicals that cause DNA replication stress (RS). Due to sustained proliferative signaling and/or defective DNA repair, cancer cells undergo persistent RS making them strongly dependent on the replication stress response (RSR). A consequence of this dependency is that RS becomes an exploitable therapeutic vulnerability in cancer treatment. Classical RS drugs work predominantly by interfering with DNA replication in dividing cells. Recently, an increasing number of drugs have been designed to specifically target RSR proteins. However, molecular pathways responsible for drug response are incompletely understood. Here we build an interpretable deep-learning model aimed at understanding mechanisms of susceptibility and resistance to replicative stress. Instead of associating genetic alterations with drug responses directly, our approach is to project individual mutations on a map of protein complexes and larger molecular assemblies with prior evidence for involvement in cancer. This approach is prompted and supported by the concept that cancer is a network-based disease arising from the action of hallmark cancer pathways. Through systematic interpretation, the model identifies 37 complexes that integrate rare alterations in hundreds of genes for accurate response prediction. The complexes, which cover roles in

transcription, DNA repair, cell-cycle checkpoint, and immunity, are further investigated by directed genetic perturbations, validating 24 for which RS effects are phenocopied by CRISPR guide RNAs. For complexes with poorly characterized functions, further insights are obtained via their profiles of in-silico activation across RS agents. This study creates a library of system-level genetic vulnerabilities governing replication stress, with implications for drug selection and combination.

Integrative molecular subtypes of acute myeloid leukemia

Qianxing (Quincy) Mo, Seongseok Yun, David A. Sallman, Nicole Vincelette, Guang Peng, Ling Zhang, Jeffrey E. Lancet, Eric Padron. *H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Introduction: Acute Myeloid Leukemia (AML) is a heterogenous disease characterized by distinct clinical course and prognosis based on genomics, epigenomics or transcriptomics profile. However, the multi-omics profiles have not been systematically integrated to define the integrative molecular subtypes of AML. There is a great clinical interest to identify the patterns across multi-omics profiles that could be used for prognosis and guiding targeted therapy in AML.
Methods: To identify integrative molecular subtypes (iSubtypes) of AML, we performed an integrative clustering (iCluster) analysis of the AML multi-omics data (n=160) generated by The Cancer Genome Atlas (TCGA), which consisted of somatic mutation, DNA copy number, DNA methylation and RNA-seq gene expression data for 160 AML samples. We identified the multi-omics signatures that drove the molecular classification of AML. Based on the methylation and gene expression signatures, we derived a gene panel for classification of AML and verified the prognostic power of the gene panel using three independent AML datasets (n=1382).
Results: We identified four iSubtypes of AML that featured distinct multi-omics signatures. At the DNA level, the iSubtype 1 was characterized by chromosomal abnormalities and high-frequency mutation of *TP53* (30%) and *RUNX1* (27%); the iSubtype 2 was characterized by chromosomal abnormalities and high-frequency mutation of *CEBPA* (20%) and *FLT3* (26%); while the iSubtypes 3 and 4 were characterized by chromosomal normality and high-frequency mutation of *FLT3* (34%, 41%), *NPM1* (37%, 57%) and *DNMT3A* (20%, 41%). At the epigenomics level, the iSubtypes 1, 3 and 4 were characterized by hypomethylation of subtype driver genes, while the iSubtypes 2 was characterized by hypermethylation of subtype driver genes. At the transcriptomics level, the 4 iSubtypes were distinguished by differentially expressed genes involved in immune process, regulation of immune process, angiogenesis, leukocyte cell activation and migration, wound healing and cell structure organization, etc. The iSubtypes 1 and 4 had the worse overall survival (OS), while the iSubtype 3 had the best and the iSubtype 2 had the middle OS. Based on the subtype-driving methylation and transcription signatures, we derived a 571-gene panel for classification of AML. Using 3 independent AML transcriptomics datasets, we demonstrated that the excellent power of the gene panel in classifying AML into 4 gene expression subtypes with similar survival outcomes.
Conclusions: iSubtypes of AML are jointly determined by multi-omics profiles. The subtype-driving methylation and transcription signature have excellent power in classifying AML into clinically relevant subtypes. This integrative analysis provides insights into the biological processes underling AML.

Cancer as a disease of information

Adam Julian Goldstein. *University of Oxford, Oxford, United Kingdom*

The causes and symptoms of cancer are often described in physical terms, for example as DNA mutations leading to increased cell proliferation. These understandings have been immensely informative, but physical changes are only one of several ways to understand what cancer is and why it behaves the way it does. An alternative perspective builds upon Claude Shannon's work in information theory, and sees cancer as a result of missing, noisy, and/or distorted information. In this talk I summarize existing research and discuss the implications for understanding cancer as a disease of information. I then explain how detecting and treating cancer look different when viewed through this lens. In particular, I discuss how this approach offers the hope for rehabilitating cancer cells by restoring expected information flows, in contrast to some current treatments which exacerbate information disruptions.

Early apoptotic measurements of patient-derived organoids predict patient response to therapy

Kelley E. McQueeney[1], Patrick Bhola[1], Sarah J. Hill[2], Anthony Letai[3]. *[1]DFCI/Harvard Medical School, Boston, MA,[2]DFCI/Brigham and Women's Hospital, Boston, MA,[3]Medical Oncology, DFCI/Harvard Medical School, Boston, MA*

The use of imperfect models and ex vivo culture systems to try to predict patient drug response represents an enormous bottle neck in cancer treatment. Nonetheless, determining how effective an approved drug will be for an individual cancer patient, as well as identifying novel compounds that may be beneficial to a specific population often requires the use of primary tumor cells. Patient-derived organoids represent an intermediate between primary tumor cells, whose limited supply may hinder reliable drug testing, and cell lines, which often do not reflect what happens in vivo. Herein, we describe the development of a novel assay platform, termed 3D-DBP (3D dynamic BH3 profiling), to detect early apoptotic measurements in ovarian cancer patient-derived organoids and present evidence that this method can be used to predict patient response to therapy. We have optimized the use of patient-derived organoids from 16 individual tumors in a microscopy-based imaging assay. We image the BH3 peptide-induced release of cytochrome c from mitochondria, which indicates permeabilization of the outer mitochondrial membrane, in intact organoids. The less cytochrome c retained in each organoid, the more primed that organoid is for apoptosis. By comparing results of drug-treated and untreated cells, we can identify drugs that cause a significant increase in apoptotic priming in organoids. In the 16 patient-derived organoids investigated this 3D DBP technique was an effective means of predicting patient response to carboplatin therapy. In summary, we have not only created a means of visualizing drug response in intact organoids, but also have demonstrated its clinical utility.

Ultra high-plex spatial proteogenomic investigation of giant cell glioblastoma multiforme immune infiltrates reveals distinct protein and RNA expression profiles

Shilah Bonnett, Alyssa Rosenbloom, Giang Ong, Mark Conner, Daniel Newhouse, Felicia New, Hiromi Sato, Chi Pha, Saskia Ilcisin, John Lyssand, Gary Geiss, Joseph M. Beechem. *NanoString Technologies, Inc., Seattle, WA*

The advancement of spatially resolved, multiplex proteomic and transcriptomic technologies has revolutionized and redefined the approaches to complex biological questions pertaining to tissue heterogeneity, tumor microenvironments, cellular interactions, cellular diversity, and therapeutic response. Most spatial technologies yield single analyte proteomic or transcriptomic datasets from separate formalin-fixed paraffin-embedded (FFPE) tissues sections. Multiple studies have demonstrated a poor correlation between RNA expression and protein abundance owing to transcriptional and translational regulation, target turnover, and post-translational protein modifications. Therefore, a workflow that accurately measures RNA and protein simultaneously within a single tissue section with distinct spatial context is critical to a more complete biological understanding of cellular interactions and activities. Such multimodal omic datasets of protein and DNA or RNA have been termed “spatial proteogenomics”. Here we present a novel spatial proteogenomic (SPG) assay on the GeoMx® Digital Spatial Profiler platform with NGS readout that enables ultra high-plex digital quantitation of proteins (147-plex) and RNA (whole transcriptome, > 18,000-plex) from a single FFPE sample. We demonstrated high concordance, $R > 0.85$, and minor change in sensitivity (<11%) between the SPG assay and the single analyte GeoMx Whole Transcriptome Atlas and GeoMx NGS Protein assays. We used the SPG assay to interrogate 23 different glioblastoma multiforme samples across 4 pathologies. We observed clustering of both RNA and protein based on cancer pathology and anatomic location. The in-depth investigation of giant cell glioblastoma multiforme (gcGBM) revealed distinct protein and RNA expression profiles compared to that of glioblastoma multiforme (GBM). Spatial proteogenomics allowed

simultaneous interrogation of critical protein post-translational modifications alongside whole transcriptomic profiles within the same distinct cellular neighborhoods. Within our dataset, we observed >2-fold higher protein expression levels of phospho-GSK3β (Ser9) in gcGBM compared to GBM. Inactivation of GSK3β through phosphorylation has been shown to enhance proliferation of GBM cells. We also observed differential protein expression phosphorylated Tau variants. Phospho-Thr231 Tau was >2-fold higher in GBM compared to gcGBM. Associated with neurodegenerative Alzheimer's disease, changes in Tau expression and phosphorylation have also been observed in glioblastoma. Our study exemplifies the utility of the SPG assay in expanding our understanding of glioblastoma multiforme molecular pathology.

Using multiomics analysis to identify dysregulated transcription factors in non-small cell lung cancer (NSCLC) to drive the expression of a cancer-activated synthetic biomarker

Yue Wendy Zhang, Shireen Rudina, Dariusz Wodziak, Chloe Xia, Maggie Louie, Albert Park, David Suhy. *Earli Inc., Redwood City, CA*

Early detection of cancer is an important driver of increased survival, quality of life and reduced healthcare costs. Earli is developing a highly sensitive, orthogonal approach that uses a genetic construct that usurps dysregulated pathways and actively forces cancer cells to drive the expression of a detectable 'synthetic' biomarker. Identification of abnormally elevated transcription factors (TF) in cancer is crucial when developing a cancer-activated expression platform. Evaluating TF function in a genome wide fashion is a challenge, especially since TF activity is not solely reflected by just its RNA expression or even by protein abundance, but also its post-translational modification including phosphorylation. In this study, we use the publicly available multiomics dataset from Clinical Proteomic Tumor Analysis Consortium (CPTAC) which includes RNA-seq based transcriptional profiling, MS based protein abundance and phosphorylation from 211 paired tumor and normal adjacent samples derived from NSCLC patients. Performing Multiomics Factor Analysis (MOFA) analysis, we identified a short list of 34 dysregulated TFs in NSCLC that displayed high expression levels in at least two of the three

omics platforms relative to normal tissues, six of which scored highly across all three. A subset of candidate TF binding sequences were subcloned as multimers into expression constructs with a basal promoter and empirically evaluated in multiple cancer cell lines, including patient-derived xenograft (PDX) cell lines and normal cell lines.Transfection experiments demonstrated that these novel chimeric synthetic promoters could produce robust levels of expression in PDX-derived cell lines that was 10-20x higher than expression mediated by known cancer-activated promoters such as the endogenous survivin (BIRC5) promoter. Furthermore, levels achieved were only 3-4 fold lower than a control EF-1a promoter, one of the strongest promoters, typically used to drive constitutive expression in mammalian cells. Currently, a small subset of these chimeric constructs is being tested in murine tumor models and in large animal cancer models such as oncopigs. These experiments will further drive the development of this approach for use in early cancer detection.

#4312

Identification of shared mutations across many parallel human and canine cancers based on comprehensive survey of canine cancer mutations and the “caninization” of human mutations from COSMIC

Sharadha Sakthikumar, Salvatore Facista, Derick Whitley, Manisha Warrier, William Hendricks, Guannan Wang. *Vidium Animal Health, a TGen subsidiary, Phoenix, AZ*

Introduction: Vidium Insight™ is a canine cancer genomic biomarker database built from exhaustive curation of peer-reviewed literature describing genomic mutations in canine cancers. This repository catalogs the ever-increasing abundance of cancer mutations and their diagnostic, prognostic, and therapeutic biomarker associations in canine oncology. However, the design of cancer research/clinical studies in dogs and the interpretation of the data, still rely heavily on inferences from human cancers. To leverage the wealth of well-annotated human mutation data and close the canine cancer genomics knowledge gap, we recently "caninized" ~ 400K cancer mutations from the largest human mutation database, COSMIC. Here, we aim to systematically assess the cross-species

conservation status of mutations found in parallel human and canine cancers.
Methods: Human mutations from the COSMIC Cancer Gene Census (CGC) dataset were “caninized”, i.e. structured analysis of protein sequence conservation and conversion of human cancer mutations to their canine homologous sites. Caninized point and indel mutations, as well as copy number alterations, were subsequently intersected with curated primary canine data in Vidium Insight™ to determine if they have been previously reported in canine cancers. Cancer-wise mutation data were also parsed and assessed for any shared mutations in equivalent human and canine cancers.
Results: Over 90% of the coding point and indel mutations in COSMIC CGC were successfully converted to the canine genome, i.e. caninized. We found 436 unique caninized mutations reported in 27 primary canine cancers across 78 studies. Of these, 410 were predicted pathogenic mutations that likely contribute to oncogenesis. Genes affected by copy number alterations in human cancers have published evidence in canine cancers as well. We then assessed concordance in putative cancer driver mutations recorded in both species. Of the 27 primary canine cancers that have mutation data to date, 26 have been shown to share somatic mutations with corresponding human cancers.
Conclusion: It has long been recognized that human and canine cancers share similar etiology, histopathology, clinical manifestations, and treatment responses. We have demonstrated high-level conservation of mutation profiles across many parallel human and canine cancers. Our work suggests that pathogenic mutations found in one species can inform the other's genomic and molecular underpinnings, guide basic/clinical research, drive drug development, facilitate clinical management, and ultimately, empower genomic-guided precision medicine across species.

#4313

A novel gene regulatory network model identifies master regulators in cancer

Praneeth Reddy Sudalagunta[1], Rafael Renatino Canevarolo[1], Mark Meads[1], Maria Coelho Siqueira Silva[1], Xiaohong Zhao[1], Raghunandan Reddy Alugubelli[1], Joon-hyun Song[2], Erez Persi[3], Mehdi Damaghi[2], Kenneth H. Shain[1], Ariosto Silva[1]. *[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]Stony*

Brook Cancer Center, Stony Brook, NY,[3]National Center for Biotechnology Information, Bethesda, MD

Small-scale regulatory networks can model known biological processes; while large-scale genome-wide datasets can identify novel mechanisms. We developed a biophysical modeling framework that combines the accuracy of small-scale networks with the power of large-scale datasets. As a proof of principle, we implemented this framework on a cohort of 844 multiple myeloma (MM) patients' (and 1092 TCGA breast cancer patients) z-normalized RNAseq data using t-Distributed Stochastic Neighbor Embedding to construct a disease-specific transcriptomic map, where genes closer to each other co-express within the cohort. Fuzzy c-means clustering is carried out to identify clusters of genes that are likely regulated by a common transcription factor (TF). We construct a gene regulatory network (GRN) for each cluster of co-expressing genes on a disease-specific transcriptomic map by identifying upstream TFs for each cluster using publicly available databases ENCODE and ChEA, and kinases that phosphorylate these TFs using PhosphoSitePlus and PhosphoPoint. An exhaustive list of TFs and kinases are reduced to a few key predictor variables using regression tree modeling for each gene in that cluster. This leads to a cascading network of kinases that phosphorylate TFs, which regulate expression of genes in a cluster. We derived a mechanistic model from first-principles to define functional relationships governing the GRN; where transcription, translation, and post-translational modifications are modeled using first-order reversible reaction kinetic equations. The patient-specific rate constants of the model are parametrized by single sample gene set enrichment analysis scores of key KEGG pathways like ribosome, protein synthesis, RNA degradation, etc. The system of differential equations, under steady-state, reduce to an algebraic equation that can predict the expression of every gene in a cluster from the expression of its upstream TFs and kinases alone, which is fitted to RNAseq data of 422 MM patients to estimate undetermined parameters. The remaining patients' data is used to estimate the accuracy of the model using Pearson's correlation (model predicted vs actual) coefficient, r. Out of 16,738 genes, 7,936 were predicted accurately ($r>0.5$), while the remaining genes were shown to have a significant overlap (hypergeometric test; p-value<1e-48 and representation factor = 7.27) with genes that have high variability in

chromatin accessibility across patients. A reduced GRN with only accurately predicted genes is obtained for each cluster, followed by linking GRNs to each other through TFs and kinases that are featured in other GRNs; where betweenness centrality measures of the resulting directed graph identifies disease-specific master regulators. MYC, STAT3, CREB1, POLR2A, PLK1, and TP53 are found to be key hubs in MM network; similar analyses are being conducted for other cancers featured in TCGA.

CEACAM7 an early detection biomarker for pancreatic ductal adenocarcinoma

Anupam Dhasmana, Swati Dhasmana, Sheema Khan, Murali M. Yallapu, Meena Jaggi, Subhash C. Chauhan. *Immunology & Microbiology, University of Texas Rio Grande Valley, McAllen, TX*

Background: As per key statistics of American Cancer Society 2021, Pancreatic Cancer (PanCa) affects around 60,430 persons (31,950 men and 28,480 women) a year in the U.S. and is tricky to diagnose and treat. PanCa is the 4th leading cause of cancer death with a 5-year survival rate of only 9%, along with a poor prognosis. Generally (around 85-90%) PanCa are adenocarcinomas, such as Pancreatic ductal adenocarcinomas (PDAC). PDAC is now one of the most challenging tumor entities worldwide, characterized as a highly aggressive disease with dismal overall prognosis with a mortality rate near the incidence rate. For PDAC, no early tumor specific biomarker is available, therefore, novel early detection biomarker strategy is immediately required to upgrade the narrow diagnostic portfolio against PanCa. Considering this alarming situation, our team has identified a novel oncogenic protein, Carcinoembryonic antigen-related cell adhesion molecule 7 (CEACAM7). Our studies suggested high CEACAM7 expression in PDAC tumors and its association with patient survival. In this study we have investigated the potential role of CECAM7 for early PDAC diagnosis and its role in PDAC progression.
Methodology: This study includes bioinformatics pre-screening using publicly available cancer databases followed by molecular biology techniques. To detect the degree of expression of CEACAM7 in normal pancreatic cell (HPNE) and PDAC progressive cellular models, we have minutely scrutinized the PDAC cell panel (HPAF-2, SU86.86 & Panc-1) &

TMAs of PDAC patients, in terms of mRNA & protein expression level of CEACAM7. The confocal microscopy was performed to identify the intensity and localization of CEACAM7 protein. IHC analysis was also performed to identify the protein expressions in the pancreatitis and tumor cores along with their locations, grading and Mean Composite Score.
Results: Bioinformatic results confirmed the relevance of CEACAM7 as a potential early diagnostic and prognostic marker of PDAC. HPAF2 (well differentiated) expressed highest mRNA and protein expression analyses, followed by SU86.86 (moderately differentiated) and very low expression in AsPc1 (poorly differentiated), and Panc1 (poorly differentiated). The IHC analyses of TMAs exhibited negligible or faint staining in pancreatitis (chronic and acute) and most of the positive cases were in tumor grading 1 & 2.
Conclusion: Our observations clearly cite that CEACAM7 can serve as a potential early diagnostic and/or prognostic marker of PDAC and may also potentiate the sensitivity of the existing biomarker panel of PDAC. However, further studies are warranted to determine its clinical significance.
Keywords: Pancreatic cancer, PDAC, CEACAM7, Early detection biomarker, Tumor grading

Exploring the relationship of SSTR2 immunohistochemical and textural features to neuroendocrine tumor grade

Leah Sherbansky, Patrick Savickas, Sharwari Phanse, Jack Casey, Julie Feldstein. *HistoWiz, Brooklyn, NY*

Due to the heterogeneous nature of neuroendocrine tumors, concrete management poses adversity. A pathologic grading system defined by the World Health Organization (WHO) scaled 1-3 offers a means to guide the course of treatment. While Ki-67 is considered a gold standard tumor grading marker, Somatostatin Receptor 2 (SSTR2) has been strongly associated with low-grade neuroendocrine tumors, as it mediates the effects of somatostatin, an anti-cell-proliferation hormone. This study aims to focus on only SSTR2 and its stratified relationship with tumor grade to perform a similar role as Ki-67, given previous association with low-grade tumors. The main purpose of this study is to extract a variety of features from tumor

histology images including SSTR2 expression, as well as textural features. Textural analysis offers an exhaustive method to extract morphologic characteristics from images and explore patterns unrecognizable to the human eye. This study will be accomplished through 3 objectives: first, to explore the relationship of SSTR2 expressive features to tumor grade. Second, to create a classification task to determine if machine learning models are able to accurately predict tumor grade directly from values of SSTR2 expression. The final objective of this study is to incorporate textural features into the classification task, and determine whether adding textural features to the classification dataset will improve the ML models' ability to predict tumor grade. TMAs were stained for SSTR2, then scanned and analyzed to determine various quantifiable values: percent SSTR2, percent 1+ cells, percent 2+ cells, and percent 3+ cells, and H-score. From the data analysis, percent SSTR2 was the only value with nonconcurrent thresholds per grade: 51-98% for grade 1, 24-47% for grade 2, and .03-20% for grade 3. Textural features local binary pattern (LBP) as well as Grey-level co-occurrence matrix (GLCM) were extracted from the tumor images as well. Four separate machine learning algorithms (logistic regression, random forest, naive bayes, and support vector machine) were run on this collected dataset in 3 separate combinations: SSTR2 alone, Textural features alone, and a combination of SSTR2 and textural features. The dataset with the highest average classification metrics was SSTR2 expression alone, with the random forest classifier yielding 100 percent precision and accuracy. Two of the machine learning models improved in precision and accuracy when textural features were added to the SSTR2 dataset. The lowest-performing dataset was the textural features dataset, due to a heavy class imbalance that impacted the performance of the ML models. The results of this study depict a highly stratified relationship between SSTR2 percentage and tumor grade, and that adding textural features to the SSTR2 dataset will increase grade-classification abilities.

#4316

Identification of tertiary lymphoid structures from H&E slides using deep learning analysis of nuclear morphology is associated with favorable survival in colorectal cancer patients

Becky Arbiv, Tal Dankovich, Sun Dagan, Yuval Shachaf, Tomer Dicker, Ron Elran, Avi Laniado, Amit Bart, Ori Zelichov, Ettai Markovits. *Nucleai,*

Tel Aviv, Israel

Background: Tertiary lymphoid structures (TLS) are organized aggregates of immune cells that develop in non-lymphoid tissues and are associated with better prognosis and immunotherapy response across cancer types. Multiple IHC stainings are required for an accurate detection of TLS, making it challenging to implement as a clinical biomarker. Here, we developed a deep learning (DL) model that extracts nuclear morphology features to detect TLS from H&E slides and demonstrated its prognostic role in colorectal cancer (CRC) patients.
Methods: A publicly available dataset consisting of 140 tissue cores from 35 CRC pts stained with H&E and 56 protein markers using the CODEX multiplex immunofluorescence (mIF) system was analyzed. Immune cell aggregates on the H&E were annotated by expert pathologists as either TLS or lymphocyte aggregates (LA), based on marker expression from the mIF stain on the same core. TLS were defined as dense aggregates of CD3+/CD20+/CD21+ cells, while all other immune cell aggregates were defined as LA. Next, HoVerNet was used to perform nuclear segmentation on cells within the TLS and LA on the H&E. Nuclear features including eccentricity, solidity, convexity, and nuclear intensity per cell were extracted and the mean and variance of each feature was summarized per tissue core. Based on these features, a univariate analysis comparing TLS and LA was performed, and a TLS classifier was trained using multivariate logistic regression. The classifier performance was assessed using 5 repeats of 5-fold cross validation and average accuracy and area under the ROC curve (AUC) were calculated. Overall survival (OS) was compared between patients with predicted TLS and LA using a Cox proportional hazard regression analysis.
Results: From the 140 tissue cores, we identified cores with either TLS (n=18), LA (n=34) or none (n=92). No core presented both TLS and LA. In a Mann Whitney univariate analysis, cells in TLS areas demonstrated a higher mean nuclear eccentricity ($p<0.0001$) and solidity ($p=0.01$) along with lower variance in these features ($p<0.0001$ and $p=0.001$, respectively) compared to cells in LA. The multivariate classifier trained on nuclear features exhibited a 90.4% average accuracy ($p<0.0001$) and 94% AUC ($p<0.0001$) in differentiating between TLS and LA. Median OS was significantly higher in patients with at least one predicted TLS (n=13) vs.

patients with at least one predicted LA (n=13) detected on H&E (NR vs. 19 months, HR=0.21, 95% CI 0.06-0.78; p=0.01).
Conclusions: Nuclear based morphological features can be used to accurately detect the presence of TLS and LA from H&E slides, without the need for mIF or IHC stainings. Given the predictive value of TLS presence, this work demonstrates the potential for H&E slides to be used for patient selection for immunotherapy treatments.

#4317

Comparison of Single-Molecule Flow (SiM-Flow) and qRT-PCR for detection of plasma miR-375 and miR-1290 in metastatic castrate-resistant prostate cancer (mCRPC)

Manish Kohli[1], Siva Nalla[2], Chia-Wei Kuo[3], Claire Hanson[1], Matt Larsen[1], Anna Neibling[1], Jennifer Lloyd[1], Julia Batten[1], Neeraj Agarwal[1], Umang Swami[1], Benjamin Maughan[1], Sumati Gupta[1], Rebecca L. Smith[4], Andrew Smith[5]. *[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[2]University of Illinois, Urbana Champagne, Urbana-Champagne, IL,[3]University of Illinois, Urbana-Champagne, Urbana, IL,[4]University of Illinois, Urbana Champagne, Urbana, IL,[5]University of Illinois, Urbana Champagne, Urbana, UT*

Background**:** Plasma microRNA (miR)-375 and miR-1290 levels have been associated with poor survival and resistance to docetaxel chemotherapy. Detection of plasma miRs is typically performed using qRT-PCR, which is time-intensive and laborious. We developed a novel technique, SiM-Flow, that rapidly and accurately quantifies miRs from low blood volumes (~100 uL). SiM-Flow uses a fluorescence-based flow cytometer to digitally count nucleic acids that have been extended and fluorescently tagged. Our goal was to compare plasma miR detection using SiM-Flow with qRT-PCR assays and determine clinical outcomes in mCRPC stage.
Methods: Forty mCRPC patients undergoing state-specific treatment were enrolled prospectively. Uniform processing of plasma was performed on patient blood samples. Total RNA was extracted from 100 µL of plasma and qRT-PCR was performed using TaqMan miRNA assays for targets miR-375 and miR-1290, endogenous controls miR-30a-5p and miR-16, and exogenous control cel-miR-39. SiM-Flow was conducted using a

commercial flow cytometer to count fluorescent barcoded rolling-circle-amplification-extended miR nanoparticles for the same targets. Target miR-375 and miR-1290 were normalized using the geometric means of endogenous controls miR-30a-5p, miR-16, and miR-39 and compared across the two assays by Spearman's rank correlation analysis. Survival analysis was calculated from date of developing mCRPC to death using Cox Proportional Hazard Regression (CPHR) for association with mean of the miR targets normalized by miR-16.
Results: qRT-PCR assays were optimized to detect native targets, endogenous controls, and spike-in miRs from plasma with ≤100 aM limit of detection (LOD), while SiM-Flow was able to detect miRs from plasma with ≤10 aM LOD. After normalization, target miRs in plasma were detected in 26/40 mCRPC patients by qRT-PCR and in 31/40 patients by SiM-Flow. The Spearman Rho for normalized miR-375 was 0.738 and normalized miR-1290 was 0.130. Survival analysis showed a hazard ratio of 1.03 (95% CI 1.01, 1.05) for the mean of miR-375.
Conclusion: Target miR-375 levels detected with SiM-Flow had higher with qRT-PCR, at lower LOD for SiM-Flow. Mean Normalized miR-375 target levels also were associated with poor prognosis in mCRPC.

Cancer cell communication with macrophages prevents T cell activation during emergence of cell cycle therapy resistance
Jason I. Griffiths[1], Patrick A. Cosgrove[1], Eric Medina Castaneda[1], Aritro Nath[1], Jinfeng Chen[1], Frederick R. Adler[2], Jeffrey T. Chang[3], Qamar J. Khan[4], Andrea H. Bild[1]. *[1]City of Hope National Medical Center, Duarte, CA,[2]University of Utah, Salt Lake City, UT,[3]UT Health Sciences Center at Houston, Houston, TX,[4]The University of Kansas Medical Center, Kansas City, KS*

By corrupting signals for growth and survival, evolving cancer cells can engineer the tumor microenvironment (TME) to promote treatment resistance. However, the specific interactions between malignant and non-malignant cells that predispose drug resistance and their changes during treatment remain widely unknown. Here we examine the composition, communication, and phenotypic diversity of tumor-associated cell populations in serial biopsies from early-stage ER+ breast cancers. We used

single-cell RNA sequencing to profile over 400 thousand malignant and non-malignant cells from patient tumor samples obtained before, during and after treatment. The patients received either endocrine therapy (letrozole) alone or in combination with a CDK4/6 cell cycle inhibitor (ribociclib). Our analyses reveal that cancer cells from ribociclib-resistant tumors stimulate macrophage differentiation towards an immune-suppressive phenotype through upregulation of a diversity of cytokines and growth factors. The macrophage phenotype shift leads to reduced crosstalk with cytotoxic T-cells via IL-2/15/18 receptors, diminishing T-cell activation and recruitment. These results indicate that cancer communications promoting an immune-cold TME predispose tumors to develop CDK4/6 cell cycle inhibitor resistance, and that the beneficial effects of blocking cancer cell proliferation must be balanced against their inhibitory effect on immune cell division and activation. An optimal treatment strategy will require coupling the prevention of cancer division with activation of an effective cytotoxic T-cell response.

The need for new publication standards in cancer genomics, lessons from curating COSMIC database

Alexander Holmes[1], Sari A. Ward[2], Zbyslaw Sondka[2]. *[1]COSMIC, Wellcome Sanger Institute, Cambridge, United Kingdom,[2]Wellcome Sanger Institute, Cambridge, United Kingdom*

A consequence of the progress in cancer genomics is the exponential growth in data produced by research and clinical projects. Given the limited capacity within a scientific manuscript to share experimental data, various approaches have been developed: some data are simply excluded from the publication, moved to the supplementary materials, external repositories are used, and big research programmes present their integrated results on dedicated websites. This last approach has been extremely successful in generating comprehensive and unbiased datasets used by legions of scientists to discover new mechanisms driving cancer, biomarkers and drug targets. However, journal publications are still delivering more data globally, especially from rare cancers and underrepresented populations. To bring the full potential of these data and to make all this knowledge fully available, several challenges need to be addressed. COSMIC (Catalogue of

Somatic Mutations in Cancer) has an in-house expert curation team that extracts information about genetic variants, their significance, patients and their response to therapy from publications and integrates it into a standardised cross-referenced database available to the scientific community. Although curators are able to extract data presented in non-standard forms (e.g. manuscript figures), interpret and translate between various data formats, they cannot extract data that are not included in the publication. Approximately one third of manuscripts that are curateable are discarded due to the absence of data generated in the research process but not included in the publication. This clearly shows an urgent need for bringing researchers, publishers, and curators together to develop new publication standards that would allow communities to fully exploit the potential of published data and make them re-usable for further discoveries. We would like to propose several suggestions to start this discussion: - Use accepted naming conventions and standards to make your data interoperable, think about your work as part of the world heritage - Include all data you generate; even if not directly relevant to the manuscript topic, they may be invaluable for somebody else's research - Share full data and use service providers that share all the data with you - When possible, share the data per patient or sample, not per cohort - Publishing a manuscript is not an endpoint, there's a huge potential in your data to be further utilised to fight cancer

A novel digitally directed tissue microdissection platform integrates digital pathology with molecular analysis: Case study in metastatic colorectal cancer.

John H. Butler[1], Bidhan Chaudhuri[1], Katie Konigsfeld[1], Rish Pai[2].
[1]Quantumcyte, Sunnyvale, CA,[2]Dept of Lab Medicine & Pathology, Mayo Clinic, Scottsdale, AZ

Artificial intelligence (AI) based digital pathology has been getting rapid adoption over the last 2 to 3 years. These AI based digital pathology models can analyze samples at high resolution and scale. Retaining that resolution at scale through molecular analysis is key to the discovery of novel biomarkers. We have developed a technology that can integrate AI-supported digital pathology (DP) algorithms to identify informative tissue

regions for selective microdissection to improve molecular analysis of FFPE material. The system is capable of extracting DNA, RNA or proteins with cellular (10 micron) resolution from FFPE tissue sections. The samples are ready for use in off-the-shelf molecular analysis workflows (qPCR, Next Gen Sequencing, etc). The system decreases the tumor cellularity requirements for clinical analysis by extracting only the area enriched for informative biomarkers. To demonstrate the capability of the system we used an AI based digital pathology model that was developed to identify multiple cellular phenotypes from a H&E stained colorectal cancer FFPE tissue sections. We used the digital pathology output to guide the microdissection of RNA from tumor buds, carcinoma, immature stroma and inflammatory stroma in a paired designed RNA seq experiment. The data showed that the system is capable of enriching the tumor-bud tissue content from<1% in the tissue to ~50% purity in the crude lysate. Bioinformatic analysis of the RNAseq signatures showed that the tumor buds had a distinct RNAseq signature relative to the other three cell types and that the gene expression pattern was consistent with EMT pathways. The methodology is scalable, robust, and simpler than current microdissection techniques. This technology can be used to develop novel tests by integrating with AI algorithms, targeting tissue enriched for predictive biomarkers, and enabling low tumor cellularity samples to be analyzed with high precision.

Clinical-grade early detection of esophageal cancer on data from a non-endoscopic device using deep learning

Adam G. Berman[1], Ahmad Miremadi[2], Maria O'Donovan[2], Shalini Malhotra[2], Monika Tripathi[3], Rebecca C. Fitzgerald[4], Florian Markowetz[1].
[1]Cancer Research UK Cambridge Institute, University of Cambridge, Cancer Research UK Cambridge Institute, University of Cambridge, Cambridge, United Kingdom,[2]Pathology, Cambridge University Hospitals, NHS Foundation Trust, Cambridge, United Kingdom,[3]Cancer Research UK Cambridge Institute, Cancer Research UK Cambridge Institute, Cambridge, United Kingdom,[4]Early Cancer Institute, University of Cambridge, Early Cancer Institute, University of Cambridge, Cambridge, United Kingdom

Aim: Our goal was to evaluate a novel deep learning system for integrated human-AI review of whole-slide images (WSIs) from the Cytosponge to predict progression from Barrett's esophagus (BE) to esophageal adenocarcinoma (EAC).
Background: Fewer than 1% of BE patients advance to EAC, therefore delineating the patients at elevated risk is crucial for prioritizing their surveillance and treatment. Previous work has shown that the Cytosponge, a non-endoscopic test, coupled with biomarkers (TFF3, atypia, p53) can be used to identify and risk-stratify individuals with BE. However, the Cytosponge workflow to date has required a time consuming pathology review.
Methods: We collected 1,700 BE Cytosponge WSIs from over 800 patients. We hand-drew over 30,000 digital annotations on the WSIs, a 300-hour collaborative effort between a computer scientist and 4 pathologists. Using these data for training, validation, and testing, we developed a deep learning system to determine whether cellular atypia and/or p53 overexpression is present. We used this system in a machine-assisted (MA) review process to highlight the most diagnostically interesting regions of WSIs for pathologist review. In our proposed system, patients are automatically triaged into high or low confidence positive, and high confidence negative classes for both atypia and p53 status, and only low confidence cases are sent for MA review.
Results: Out of 23 architectures, the best atypia model achieves an accuracy of 0.90, and the best p53 model 0.96. The model was concordant with pathologists in 342/425 (80.5%) validation and 301/330 (91.2%) test-set patients. The system also identified 83 validation cases with atypia and/or p53 that were not previously reported by the pathologists. Of these, 29 (35%) were confirmed abnormal with the ground truth endoscopy biopsies (11 high grade dysplasia or intramucosal carcinoma, 14 low grade dysplasia, 5 indefinite for dysplasia). In the test set 29 results were discordant with pathology including 6 (21%) confirmed abnormal on endoscopy biopsies (3 HGD/IMC, 2 LGD, 1 IND). We used the models' outputs to localize where these "missed" regions lie in the WSIs, and pathologist MA review confirmed the presence of focal abnormalities (cellular atypia +/- p53 aberrance) correctly identified by the algorithm. If pathologists only review cases for which the model had low confidence, this preserves overall performance while reducing pathologist workload

over twenty-fold. MA review on the remaining WSIs is 4.7 times faster than standard review for atypia screening and 16.0 times faster for p53. Conclusion: This work shows the potential of an integrated human-AI WSI review process to drastically expedite a time consuming task and improve on pathologist performance when abnormal regions are easy for human eyes to miss. This work therefore lays the groundwork for similar machine-doctor approaches in other areas of medicine.

AI assisted detection and characterization of tertiary lymphoid structures in patients with colorectal cancer

Samantha Burg[1], Nathaniel Hart[1], Astin Powers[2], Wenjun Zhang[1]. *[1]Pharma Services Assay Development, Ventana Medical Systems, Inc., Tucson, AZ,[2]Pathology, Ventana Medical Systems, Inc., Tucson, AZ*

Tertiary Lymphoid Structures (TLSs) are ectopic immune cell aggregates that form in response to abnormal physiology and inflammation. TLS presence in the tumor environment has been associated with positive clinical outcomes and response to immune checkpoint inhibition therapy. Using a fluorescent multiplex panel consisting of Pan-cytokeratin (PanCK), Programmed Death Ligand-1 (PD-L1), cluster of differentiation (CD) 8, CD3, and CD68 we developed a HALO-based artificial intelligence (AI) classifier to detect TLSs in colorectal cancer (CRC) tissue. In conjunction with cell-type and spatial analyses, we used the AI TLS classifier to characterize several features of the TLS and peri-TLS environment. We trained the AI classifier using 51 examples of TLSs from 8 patients, and applied it to images of 21 CRC patient tissues. TLSs were detected in 9/21 patient samples. We then used cellular detection and spatial analysis to characterize features of the TLS, including the germinal center (GC), T cell zone and peri-TLS area. We detected a higher cell density (Mean=12250 ±2039 SD; cells/mm^2) within the interior of AI-detected GCs relative to the 1st 200 μm outside of the AI-defined GC border (8005±1870). In addition, we examined the spatial distribution of CD3+ and CD8+ T cells relative to the TLS GC. We found elevated CD3+ cell density in the interior of the GC (5784±1649) and within 200 μm of the GC border (5126±2239) which decreased at distances >200 μm from the GC border. We found CD8+ density to be elevated within the 1st 200 μm of the GC border (1903±1182)

and declined 400 μm away from the GC border (963±828). The spatial distribution of T cells surrounding an area of high cell density is indicative of a T cell zone surrounding germinal center. Further analysis of the AI-detected TLS GCs indicated that PD-L1+ cell density was highest within the germinal center (355± 534;9) relative to the exterior of the germinal center (1st 150μm outside germinal center:276± 441). We created an AI classifier that can detect TLS(s) within patient tissue in the absence of a B-cell marker and confirmed that our AI classifier was detecting TLSs by characterizing canonical features of TLSs. Further exploration of the TLS and peri-TLS area may offer insights into immune-tumor interaction within the tumor microenvironment, and paired detection of TLSs in a clinical cohort with outcome data may predict patient response to immune checkpoint inhibitor therapy.

Multiplex immunoassay characterization of 48 cytokines, chemokines, and growth factors in colorectal cancer
Wen-Rong Lie, Harold Steiner, Sasha Williams, Munmun Banerjee, Anthony Saporita, Brooke Gilliam, Qiang Xiao. *MilliporeSigma, St. Louis, MO*

Cytokines, chemokines, and growth factors are critical mediators of immune system function capable of signaling through autocrine, paracrine, and endocrine mechanisms. Their pleiotropic immunomodulatory properties allow these biomolecules to react to diverse stimuli and regulate the immune response. We developed a novel immunoassay, using Luminex xMAP technology, for the simultaneous measurement of 48 cytokines, chemokines, and growth factors in serum, plasma, and cell culture supernatant. Many of these proteins have been proposed as biomarkers of colorectal cancer (CRC) and as key regulators of the tumor microenvironment (TME). While this complex milieu can support antitumor immunity, CRC is frequently characterized by chronic inflammation driving disease progression, with the TME serving as a potent

reservoir from which the cytokines, chemokines, and growth factors exert their influence. The MILLIPLEX Human Cytokine/Chemokine/Growth Factor Panel B (HCYTB-60K) assays were performed in 96-well plates and run on the Luminex LX200™ instrument. Data was acquired via xPONENT v. 4.3 software. Data analysis was performed for all immunoassays using the Belysa Immunoassay Curve Fitting Software. Commercially available serum samples obtained from colorectal cancer patients and healthy controls were evaluated for cytokine, chemokine, and growth factor expression. Of the 48 analytes tested, statistically significant increases in BAFF, sFas, SCF, and MPIF-1 were observed in colorectal cancer serum. In contrast, IL-20 and ENA-78 decreased relative to healthy controls. While the immunoassay was verified for measurement of serum and plasma samples, additional sample types may be of interest to cancer researchers. Therefore, we evaluated the ability of the 48-plex immunoassay to measure these biomarkers in CSF, urine, milk, tumor samples and exosomal isolates, establishing a profile for these proteins in each sample type. Altogether, this study uses a novel multiplex immunoassay to characterize the immunological profile of colorectal cancer serum, focusing on 48 cytokines, chemokines, and growth factors. Additionally, alternative sample types were evaluated to establish the utility of this technology for applications beyond serum, plasma, and cell culture supernatant.

Impact of gut microbial metabolites on colon epithelium

Nobel Bhasin[1], Lakmini Herath Senavirathna[2], Madeline Bresson[1], Lyu Zhe[1], Victoria B. Poplaski[1], Zahraa A. Lami[1], Teresa A. Brentnall,[3], Antone R. Opekun[1], John F. Valentine[4], Britton A. Britton[1], Pan Sheng[2], Ru Chen[1].
[1]Baylor College of Medicine, Houston, TX,[2]University of Texas, Houston, TX,[3]University of Washinton, Seattle, WA,[4]University of Utah School of Medicine, Salt lake city, UT

Inflammatory bowel disease (IBD) is a major risk factor for colorectal cancer (CRC) development. Dysbiosis of the gut microbiome has been implicated in the pathogenesis of IBD and CRC. The gut microbiome and its interaction with the colon may play a significant role in enabling tumor permissive state in an inflammatory environment. However, the functional

impact of colon microbiome on epithelial cells that enables neoplastic transformation under inflammatory condition is not clear. This study seeks to examine the impact of mucosa-adherent microbiota on colon epithelial cells. We used in vitro mini-bioreactor arrays to cultivate mucosa-adherent microbiota from colon biopsies, including biopsies from IBD patients with dysplasia (progressors) and without dysplasia (non-progressors). Paired dysplastic and non-dysplastic tissue from progressors was included in the study. HCT116 cells were exposed to the metabolites derived from the cultivation of microbial communities. Cell lysate and secretome were collected after the treatment of microbial metabolites and analyzed by LC-MS/MS. The differentially expressed proteins were identified using Limma. Over-representation analysis was performed using Reactome in Grofiler. Pathways relating to cell division, mitosis and cell proliferation were enriched in cells treated with microbiome metabolites from progressors. Pathways reflecting a proliferative phenotype were also found enriched in the cell secretomes after treatment with microbiome metabolites from progressors. We functionally verified the proliferative phenotype in cells using BRDU incorporation assay. Microbial metabolites from non-dysplastic biopsy from progressor showed significantly higher cell proliferation compared to non-dysplastic biopsy from non-progressors ($p<0.05$). Furthermore, microbial metabolites from dysplastic tissue showed a significantly higher proliferation compared to non-dysplastic tissue from the same patient ($p<0.01$) and patients without dysplasia ($p<0.0001$). A significantly higher degree of DNA damage was induced by microbial metabolites derived from IBD progressors than non-progressors ($p<0.05$). Together, our findings suggest that microbial metabolites in the dysplastic tissue alter the colon microenvironment to induce higher cellular proliferation and DNA damage, which may contribute to colon neoplastic progression in the IBD patients.

Mass spectrometry-based protein biomarker analysis in chemoimmunotherapy combinations identifies unique immune signatures in pancreatic cancer

Nigel Beaton, Marco Tognetti, Kamil Sklodowski, Roland Bruderer, Lukas Reiter. *Biognosys AG, Schlieren, Switzerland*

Although the combination of chemotherapy with immunotherapy has led to significant improvements in the treatment of some solid tumors, metastatic pancreatic ductal adenocarcinoma (mPDAC) prognosis has remained largely unaffected by such approaches. Recently, PRINCE, a randomized phase 2 clinical study, reported significantly improved 1-year overall survival (OS) for mPDAC patients treated with nivolumab and chemotherapy (nivo/chemo) compared to historical control but not for sotigalimab and chemotherapy (sotiga/chemo) or a combination of the three. Interestingly, the study identified potential improvement to treatment outcome with patient stratification. Here, we report an unbiased mass spectrometry (MS)-based proteomics profiling of a subset of plasma samples from the PRINCE trial (n = 211, 62 individuals from nivo/chemo and sotiga/chemo longitudinal samples). Briefly, plasma samples were depleted, digested to tryptic peptides, measured by MS/MS and quantified using Spectronaut (Biognosys). Data was investigated for both protein and peptide biomarker with an emphasis on baseline biomarkers associated with clinical outcomes. Plasma profiling identified 1,662 proteins and 17,451 modified peptides across the cohorts. First, we developed a model that identified the pharmacodynamic effects of treatment in individual patients. In accordance with the PRINCE study and among the major model contributors, sotiga/chemo increased proteins associated with innate immunity and chemokines (including CCL15) while proteins aiding in T cell activation and immune cell migration increased with nivo/chemo (including CXCL7 and CD115). Second, we looked for markers in the pretreatment plasma samples that could predict OS. Overall, we found 25 predictive markers ($p < 0.05$), with only six shared among the two arms, including attractin and CD58. Among the seven predictive biomarkers specific to nivo/chemo, we found MEGF10 and GALNT1, which are suggested to play a role in neoantigen generation. For sotiga/chemo, we found 12 predictive biomarkers including IGF2, CD304, and periostin (known to support immune responses). Third, we expanded our predictive biomarker search to the identified peptides, an analysis that is currently only possible using an unbiased mass spectrometry-based approach. Using such an approach we identified predictive peptides, likely cleavage products, as well as predictive post-translational modifications. Herein we demonstrate the value of both an unbiased approach, as well as the use of peptide level data for novel biomarker identification. We identify numerous

proteins and peptides that have the potential to be used for better patient treatment stratification in the case of mPDAC and immunotherapy.

Detection of arginine posttranslational modifications by single-molecule protein sequencing on the Quantum-Si platform
Kenneth Skinner, David Kamber, Brian Reed. *Quantum-Si, Guilford, CT*

Aberrant post-translational modifications (PTMs) on arginine residues, such as methylation and citrullination, are closely linked to oncogenic processes. Detection of these PTMs is challenging with current technology and can be hampered by low abundance and mass differences that are difficult to resolve by mass spectrometry. To overcome these challenges, we developed methods for PTM detection using Quantum-Si's Platinum single-molecule protein sequencing platform. Proteins are sequenced on Quantum-Si's Platinum instrument using our library prep protocol. Briefly, proteins are digested into peptide fragments, conjugated to linkers, then immobilized at the bottom of nanoscale reaction chambers on a semiconductor chip, resulting in exposed N-termini for sequencing. During sequencing, the immobilized peptides are exposed to a solution of dye-labeled N-terminal amino acid (NAA) recognizers that reversibly bind to their cognate NAAs with distinct kinetic properties. Aminopeptidases sequentially remove NAAs to expose subsequent amino acids for recognition. Fluorescence lifetime, intensity, and kinetic data are collected in real time and analyzed to determine primary sequence and PTM content. The data output consists of distinct pulsing regions called recognition segments (RSs). Each RS corresponds to a period of time between aminopeptidase cleavage events, during which an NAA recognizer binds on/off to its exposed target NAA. Chemical modification to a NAA or to a nearby downstream amino acid can modulate recognizer affinity, resulting in a characteristic change in the average pulse duration (PD) during an RS. To demonstrate the detection and differentiation of arginine PTMs, we applied our platform to distinguish between asymmetric dimethylarginine (ADMA) and symmetric dimethylarginine (SDMA) and between citrulline and native arginine residues. Sequencing traces revealed that arginine and ADMA bind the arginine recognizer (PS621) with similar PD, whereas SDMA exhibited no binding. These results indicate that SDMA, in contrast to ADMA, has

reduced binding affinity with PS621, providing a clear kinetic difference between these isomeric arginine PTMs. Moreover, citrulline and arginine side chains also exhibited distinguishable kinetic signatures. Citrullination eliminated the N-terminal arginine recognized by PS621 and resulted in a large increase in the median PD of preceding amino acid residues. Taken together, single-molecule protein sequencing offers an alternative approach to detection of arginine PTMs that is not based on m/z, but rather on the kinetic signature of binding between recognizers and N-terminal amino acids. The ability to directly detect arginine PTMs offers potential for biomedical research. We envisage applications using Quantum-Si's platform to key areas of cancer research including biomarker development and drug discovery.

Unmasking aggressive tumor profiles in lung adenocarcinomas through the molecular abundances and catalytic action of serine hydrolases

Tatjana Sajic[1], Stephan Arni[2], Rudolf Aebersold[1], Sven Hillinger[2]. *[1]Swiss Federal Institute of Technology, Zürich, Switzerland,[2]University Hospital Zürich, Zürich, Switzerland*

(a) Current proteomic methods quantify solely the catalytically active portion of enzymes without normalizing the active portion to the total enzyme amount, thus compromising comparison of the results. We take advantage of a SWATH/DIA-MS workflow and describe a method based on depletion-dependent ABPP (dd-ABPP) able to concurrently determine catalytically active enzymes and their total molecular abundances, as well as quantify the contextual sample proteomes.
(b) We monitored high quality peptides of more than 190 SH activities and molecular abundances of around 4000 contextual tissue proteins in advanced lung adenocarcinomas (LUAD). While we found that LUAD tumors display enhanced proteolytic activities compared with control lung tissue, the most prominent characteristic of an aggressive tumor phenotype was enhanced lipolysis of metabolic SHs emphasized by IAH1, ABHD12, LYPLA2 and ABHD10.
(c) Molecular signatures of the activity profiles of 23 SHs and 59 contextual tissue proteins discriminate aggressive tumors at the time of diagnosis. Enhanced detection of S-palmitoylated proteins correlating by active-

enzyme capture uncovers their functional links with the metabolic SHs related to lipoprotein depalmitoylation via enzymes displaying increased de-palmitoylase activities and enhanced fatty acid metabolism in aggressive LUAD. To further validate our findings, we analysed LUAD tumors for panels of saturated and unsaturated fatty acid (C8-C22) levels. Strikingly, we detected a statistically significant increase in monounsaturated palmitoleic acid (C16:1) in the aggressive compared with less-aggressive tumors. Notably, the primary source of palmitoleic acid in the cellular environments results from an excess of free palmitic acid and its conversion by rate-limiting enzyme Stearoyl-CoA desaturase 1 (SCD) that is enhanced in LUAD cancer.
(d) We detected a significant increase in palmitoleic acid levels in aggressive tumors. To a certain extent our data support previous findings on the active process of lipid desaturation in lung adenocarcinoma cells as the main source of energy for cell proliferation. Our approach also revealed that changes in the active lipase fractions between subtypes do not follow changes in enzyme protein quantities, suggesting that lipase regulations are related rather to peculiarities of the enzyme protein sequence, a distorted enzyme-inhibitor equilibrium, or a distorted molecular composition of the tissue itself. Since the inhibitors of serine lipases are promising targets in other RAS-mutant carcinomas, and the inhibitors of a rate-limiting SCD1 enzyme prevent palmitic acid conversion to a monounsaturated form, these metabolic vulnerabilities detected in aggressive LUAD will be helpful for future therapeutic strategies in lung cancer.

Upregulation of the polycomb group protein SCML2 contributes to aggressive prostate cancer

Ava M. Boston[1], Abdulrahman M. Dwead[1], Marwah M. Al-Mathkour[2], Kezhan Khazaw[1], Bekir Cinar[1]. *[1]Biological Sciences, Clark Atlanta University, Atlanta, GA,[2]Miller School of Medicine, University of Miami, Miami, FL*

Advanced prostate cancer (PC) is the leading cause of death in the US because there is no effective treatment due to the poorly understood disease mechanism. Sex comb on midleg-like-2 (SCML2) is a member of Polycomb repressive complex 1 and regulates homeotic gene expression

during development. Using proteomic approaches, we have identified SCML2 as a binding partner of the YAP1 protein complexes isolated from PC cell lines. Both SCML2 and YAP1 regulate basic cellular biology, including stem cell maintenance and carcinogenesis; however, whether SCML2 and YAP1 cooperate to contribute to the aggressive PC in humans remains unknown. We showed that AR-positive cell lines express high levels of SCML2 with a significant increase in castration-resistant PC cells compared to its castration-sensitive cell counter, suggesting a possible role of SCML2 in PC progression. We also showed that androgens regulated the protein-protein interaction between SCML2 and YAP1, as evaluated by proximity ligation assay. In addition, the GST-pulldown assay revealed that SCML2 interacted with the WW/SH3 domain of YAP1, where AR also binds. Besides, our RNAi-aided gene silencing experiment demonstrated that YAP1 and SCML2 might be functionally antagonistic. Moreover, gene silencing and growth assays showed that SCML2 might act as a growth suppressor in castration-sensitive PC cells while acting as a growth mediator or survival factor in castration-resistant PC cells. Furthermore, our analysis of the cancer genome atlas PC data set has indicated that amplification of SCML2 is associated with reduced progression-free survival. These observations suggest that SCML2 and YAP1 interaction is biologically functional, and the degree of their interaction may play a critical role in PC progression downstream of dysregulated androgen/AR signaling.

Development of a plasma biomarker panel for gastric cancer detection based on an autoimmune response signature

Rongzhang Dou[1], Ehsan Irajizad[1], Yining Cai[1], Johannes F. Fahrmann[1], Jody V. Vykoukal[1], Yihui Chen[1], Hiroyuki Katayama[1], Ali H. Abdel Sater[1], Melissa Pizzi[2], Kohei Yamashita[2], Matheus Sewastjanow Da Silva[2], Edwin J. Ostrin[1], Jaffer Ajani[2], Samir M. Hanash[1]. *[1]Clinical Cancer Prevention, UT MD Anderson Cancer Center, Houston, TX,[2]Gastrointestinal Medical Oncology, UT MD Anderson Cancer Center, Houston, TX*

Background**:** Gastric cancer is frequently diagnosed at an advanced stage and is associated with poor outcomes. Harnessing the immune response to

tumor antigens which occurs early during tumor development has potential for the early detection of gastric cancer.
Methods: Plasma samples from gastric cancer patients were collected before and after treatment and from healthy controls for identification of immunoglobin (Ig)-bound antigens using mass spectrometry. Ingenuity pathway analysis(IPA) was utilized to investigate networks and pathways associated with Ig bound proteins identified in plasmas from cases. A combined biomarker panel was established based on a logistic-regression model and ROC analysis was used to assess panel performance.
Results: A total of 65 Ig bound proteins were identified that were upregulated in gastric cancer patients' plasma compared with healthy control. Canonical pathways involving these immunogenic proteins included HIF-1α, VEGF, actin cytoskeleton, and immunogenic cell death signaling which play important roles in both gastric cancer development and progression. Four of the top ten performing proteins exhibited high mRNA levels in gastric cancer tissue. The association of these four Ig bound proteins in gastric cancer plasmas was further validated using as controls a cohort of MEN1 patients plasmas. A blood-biomarker panel based on these four biomarkers was established using a logistic-regression model which yielded an area under the curve (AUC) of 0.963 (95% confidential interval [CI] =0.89-1.00) for gastric cancer discrimination with a sensitivity of 0.889 at 95% specificity.
Conclusion: Our data reveal a panel of plasma Ig-bound antigens associated with the development of gastric cancer with potential application for early detection and monitoring.

Detection and quantification of proteins using protein identification by short-epitope mapping (PrISM)
Torri Rinker[1], Jarrett D. Egertson[1], Steven Tan[1], Aisha Ellahi[2], Jamie Sherman[2], Maria Villancio-Wolter[1], Brittany Nortman[1], Julia Robinson[1], Ahana Dutta[1], Katherine Winters[1], Noah Steiner[1], Elvis Ikwa[1], Hunter B. Boyce[2], James H. Joly[1], Filip Bartnicki[1], Pierre F. Indermühle[1], Christina Inman[1], Shubhodeep Paul[1], Jacinto Villanueva[1], Jennifer McGinnis[1], Aimee A. Sanford[1], Sophia Watts[1], Jessica Nicastro[1], Sonal S. Tonapi[1], Jacob Devine[1], Cara Li[1], Kaitlyn Burke[1], Jonathan Leano[1], Nikola

Kondov[1], Mirella Huber[1], Bilal Ali[1], Carlos Flores[1], Sheri K. Wilcox[1], Parag Mallick[1]. *[1]Nautilus Biotechnology, Inc., San Carlos, CA,[2]Nautilus Biotechnology, Inc., Seattle, WA*

Introducti**on:** Here, we demonstrate Protein Identification by Short-epitope Mapping (PrISM), which aims to provide comprehensive proteome analysis with broad dynamic range at single-molecule resolution by interrogating immobilized, intact proteins in parallel using multi-affinity probes. Improving the dynamic range and scale for protein analyses will enable a deeper understanding of low abundant protein in all stages of cancer progression. In addition, enabling the interrogation of single-molecules will provide a deeper understanding of protein diversity, such as the proteoforms resulting from non-canonical post-translational modifications inherent to cancer[1]. The combination of single-molecule sensitivity with comprehensive proteome coverage could also open the door for highly sensitive and specific diagnostics.
Methods: PrISM uses non-traditional affinity reagents with high affinity and low specificity that bind to short epitopes in multiple proteins. Sample proteins were conjugated to DNA nanoparticles and deposited on a high-density patterned flow cell at optically resolvable locations. Multi-affinity probes were applied to sample proteins over multiple cycles to generate binding patterns for each single-molecule protein, which are translated to protein identifications and quantities using a custom machine learning approach. We acquired PrISM data on native biological and control samples using dozens of multi-affinity probes targeting trimer or tetramer sequences.
Results: We report single-molecule deposition of over 1 billion DNA nanoparticle complexes on a flow cell. We demonstrate how the PrISM methodology identifies individual protein molecules through iterative probing with our multi-affinity probes. Further, we provide an analytical assessment of the sensitivity and specificity of PrISM and demonstrate the ability to accurately estimate the false identification rate of these proteins using a target-decoy based statistical approach.
Conclusions: Combining single-molecule analysis, intact (non-digested) proteins, and iterative probing, PrISM provides a new tool for quantitative proteomics. We demonstrate linear and reproducible quantification of proteins using PrISM, potentially enabling detection of low abundant proteins and proteoforms associated with cancer. The ability to make

comprehensive measurements of intact proteins at single-molecule resolution could accelerate basic cancer research through to the clinic.

Imaging mass cytometry enables identification of distinct tissue phenotypes in highly autofluorescent lung and colon cancer tissues, producing consistent data across serial sections

Smriti Kala[1], Brenna O' Neill[2], James Pemberton[1], James Mansfield[2], Fabian Schneider[2], Clinton Hupple[1]. *[1]Standard BioTools, Markham, ON, Canada,[2]Visiopharm, Hørsholm, Denmark*

Background**:** Successful implementation of immunotherapy requires a deep understanding of the spatial interactions between various cell types in the tumor microenvironment (TME). Most fixed tissues are autofluorescent and staining with cyclic immunofluorescence methods often produces data that are difficult to analyze due to the challenges of background subtraction. Imaging Mass Cytometry™ (IMC™) is a powerful tool for high-plex imaging, utilizing CyTOF® technology to simultaneously assess 40-plus protein markers at subcellular resolution without spectral overlap or background autofluorescence. This study demonstrates a tissue phenotyping workflow in highly autofluorescent lung and colon cancer tissues using high-plex IMC, which produces reliable data that can be easily analyzed.
Methods: Serial sections of lung and colon cancer tissues were stained with a 30-marker panel comprised of structural, tumor, stroma, immune cell, and immune activation markers as well as the IMC Cell Segmentation Kit, for improved nucleus and plasma membrane demarcation. The data analysis pipeline used Phenoplex™ (Visiopharm®) software for straightforward, accurate, and quantifiable phenotyping. The analysis workflow consisted of tissue segmentation (to define tumor, stroma, extracellular matrix, and regions of necrosis), nuclear detection using a deep-learning algorithm pre-trained on IMC DNA channels, cell segmentation, a threshold-based cellular phenotyping step, and spatial analyses. Statistical analyses of the reproducibility between serial sections were performed using a paired t-test.
Results: In this work, we have shown that analysis of IMC images from highly autofluorescent lung and colon cancer tissues can uncover tissue phenotypic signatures of the TME through the determination of distinct

immune cell types found in the vicinity of cancerous cells. Moreover, cell segmentation generated cell counts that were highly consistent across the serial sections, with only 2.7% variability. This demonstrates the power of IMC in generating robust data across adjacent serial sections, which can be easily analyzed without the need to train the analysis software for background subtraction.
Conclusions: Overall, this work demonstrates that by avoiding autofluorescence, IMC can generate high-quality, reproducible data, consistent across serial sections. The images can be easily and accurately analyzed in a streamlined way using the Phenoplex software, thus empowering IMC users to be confident in biological interpretation of high-dimensional proteomic data. This study demonstrates how systematic digital profiling of the spatial TME using IMC leads to repeatable, quantitative results generated through a simplified workflow.

Analysis of extracellular vesicle surface markers as small cell lung cancer biomarkers
Patricia M. M. Ozawa[1], Sarah M. Groves[2], Vito Quaranta[2], Alissa M. Weaver[1]. *[1]Cell and Developmental Biology, Vanderbilt University, Nashville, TN,[2]Department of Biochemistry, Vanderbilt University, Nashville, TN*

Small Cell Lung Cancer (SCLC) is an aggressive tumor type, usually metastatic at diagnosis, with a median survival of less than a year. SCLC tumors are heterogeneous and are composed of neuroendocrine (A, A2, N) and non-neuroendocrine (Y) subtypes, with the cooperation by heterogeneous cells being key to drive tumor survival. Unfortunately, the current SCLC treatment approach does not take tumor heterogeneity into consideration. Importantly, there are no consensus markers that can identify SCLC subtypes or early tumors. Extracellular vesicles (EVs), small vesicles known to promote cell to cell communication, have been investigated as non-invasive biomarkers for cancer diagnostics, staging, and treatment monitoring. EVs are attractive candidates for biomarker research due to the selective packaging of RNA, DNA, and proteins that are then secreted in the blood. Therefore, our aim was to identify new biomarkers based on EV surface proteins with potential for early detection and tumor

characterization. We used differential ultracentrifugation to isolate EVs from four SCLC subtypes A, A2, N, and Y, which were submitted to label-free mass spectrometry (EV-proteomics). We identified a total of 3011 proteins, with the two most distinct subtypes being A2 and N, with 786 differentially expressed EV-proteins. Meanwhile, the 2 most similar subtypes were N and A, with only 75 differentially expressed EV-proteins. Gene set enrichment analysis of EVs derived from the A2 subtype showed an association with pathways in cancer, chemokine signaling, and neuronal systems. In addition, PANTHER analysis identified enrichment in nicotine pharmacodynamic pathways on these EVs, which corroborate the association of A2 cell lines with drug resistance. EVs derived from the N and A subtypes were enriched in spliceosome, RNA processing, and metabolism, while EVs from Y cell lines were enriched in extracellular matrix organization and metabolic pathways, similar to pathways from cell line RNAseq data. 13 proteins were differentially expressed in all group comparisons, including proteins involved in PI3K and nicotinic acetylcholine receptor signaling pathways. Further comparison of EV-proteomics with top genes from CIBERSORT analysis using cell line RNAseq data showed an overlap of 9 surface proteins, with 3 possible SCLC pan markers. In conclusion, EV-proteins isolated from SCLC cell lines presented a unique signature for each subtype, especially EVs derived from A2 subtype, which has a signature associated with drug resistance. We identified surface proteins on SCLC EVs with potential as SCLC pan and tumor characterization, which will be validated on EVs derived from cell lines and patient plasma by Western blotting and single-EV microflow cytometry.

Isolation and validation of small extracellular vesicles from rhabdomyosarcoma cells

Paula R. Quaglietta[1], Ashby Kissoondoyal[1], Ethan Malkin[2], Salvador Mejia[3], Ann Gong[1], David Malkin[1], Reto M. Baertschiger[1]. *[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, Toronto, ON, Canada,[3]Princess Margaret Cancer Center, Toronto, ON, Canada*

Extracellular vesicles (EVs) are nano-sized (30-1000 nm) membranous particles released by nearly all cell types. EV biology is a rapidly growing field, however its relative novelty and the intrinsic heterogeneity of EVs result in a lack of standardized and reproducible protocols. We sought to develop and validate an EV isolation method using rhabdomyosarcoma cell lines, with multiple characterization/validation methods, to improve the reproducibility and reliability of EV research in pediatric cancer research. EVs were isolated and analyzed in triplicate from 4 rhabdomyosarcoma cell lines (RH4, RH18, RH30, RD), of varying clinical characteristics including subtype, TP53 status and FOXO1 fusion status. Cells were grown to 70% confluency in six 175cm^2 flasks, to ensure sufficient EV content for all downstream analyses, then incubated for 48 hours in media containing 10% EV-depleted FBS. The resultant 120mL of conditioned media (CM) per cell line was collected and subject to differential ultracentrifugation to isolate EVs. CM was centrifuged twice, then concentrated to less than 10mL using 3kDa MWCO filter tubes. Concentrated CM was centrifuged twice before passing through a 0.22μm pore-sized syringe filter prior to the final ultracentrifugations. The sample was ultracentrifuged and the EV pellet was carefully washed, re-centrifuged and resuspended in 100μL of PBS. Protein analysis by Western blot confirmed the presence of EV markers (syntenin-1, TSG101) and absence of non-EV markers (calnexin, histone H2Ax). EV quantification and size distributions were evaluated by NanoSight nanoparticle tracking analysis and visualized by transmission electron microscopy. All isolations were positive for EV markers and negative for non-EV markers by Western Blotting. All isolations showed similar size distributions by nanoparticle tracking analysis, within the range of 30-250nm. EVs in each sample with the typical cup-like shape were observed in electron microscope images of EVs. Overall, our method demonstrates good reproducibility of EV isolations from multiple rhabdomyosarcoma cell lines. This methodology can be used as a baseline for other cell lines to provide greater consensus within the field, allowing further discoveries analyzing the secretome of patient-derived cell lines with the potential to translate into more specific diagnostic tools.

An expanded quantitative protein expression atlas of human cancers

Han Liang. *Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX*

The Cancer Genome Atlas (TCGA) and Cancer Cell Line Encyclopedia (CCLE) are the most widely used and deeply characterized resources for cancer research. Despite rich molecular and phenotypic data available for these cohorts, large-scale proteomic data across cancer lineages remain limited. Here we expanded our previous effort to generate high-quality protein expression data of 447 clinically relevant proteins for ~8,000 TCGA patient samples and ~900 CCLE cell line samples using reverse phase protein arrays. We show that the protein expression profiles provide deeper mechanistic insights into cancer dependency and serve as a sensitive functional readout for the fitness effect of somatic mutations, e.g., BRAF mutations. We develop a protein-centered strategy to identify synthetic lethality pairs with high confidence. We identify pro- and anti-metastasis protein markers and demonstrate their prognostic relevance in patient cohorts. Collectively, this dataset provides a valuable resource for elucidating cancer mechanisms, identifying protein biomarkers, and developing therapeutic strategies.

Lipidomic profiling of extracellular vesicles derived from cancer cell lines: Lipid species as potential biomarkers and cellular uptake enhancers

Ruben R. Lopez Salazar[1], Prisca Bustamante[1], Chaymaa Zouggari[2], Yunxi Chen[1], Thupten Tsering[1], Ion Stiharu[3], Catherine Mounier[4], Vahe Nerguizian[2], Julia Burnier[5]. *[1]Pathology, RI MUHC McGill, Montreal, QC, Canada,[2]Electrical, École de technologie supérieure ÉTS, Montreal, QC, Canada,[3]Mechanical, Industrial and Aerospace Engineering, Concordia University, Montreal, QC, Canada,[4]Centre de recherche sur les maladies orphelines (CERMO-FC)), Département des sciences biologiques, Université du Québec à Montréal, Montreal, QC, Canada,[5]Pathology and Oncology, RI MUHC McGill, Montreal, QC, Canada*

Introduction: Extracellular vesicles (EVs) are lipid bilayer-made particles shed by cells to the extracellular space. They carry different cargo proteins,

nucleic acids, and other metabolites. EVs play a role in disseminating cancer to distant organs by communicating with the tumor microenvironment to prepare the metastatic niche and also through horizontal transfer of oncogenic traits to recipient cells. The EV surface, which includes proteins and lipids, plays a role in organotropism and cellular uptake. While proteins have been extensively characterized, lipids have not been explored sufficiently. This work aims to evaluate EV lipids as potential biomarkers and their role in enhancing cellular uptake.
Methods: To detect which lipid species (LS) were differentially expressed, we used two cell models of liver metastatic cells: colorectal cancer (HT29) and uveal melanoma (MP41, MP46, MEL 270, OMM 2.5) cell lines. Colon (CCD18-Co) and fibroblast (BJ) immortalized non-cancerous cells were used as controls. EVs were isolated from culture media by ultrafiltration using 100 kDa units filters. Lipids were extracted by methyl-tert-butyl ether for high-throughput lipidomics. High-resolution 'shotgun' mass spectrometry was performed. Data was analyzed using LipidView software (SCIEX), and the lipid % normalized was reported. MarkerView (SCIEX) was used to perform Principal Component Analysis. The LS segregating cancerous vs. non-cancerous cells were identified. To evaluate the influence on cellular uptake, we used liposomes as EV models with lipid formulations containing the segregating LS to compare them with naturally occurring lipids and EVs using Incucyte live cell imaging.
Results: We identified four LS that segregated EV subpopulations. PE 34:1 and PS 36:1 divided cancerous vs non-cancerous cells, uveal melanoma cells were segregated by PE 36:2, and normal colon cells were segregated by LPC 18:0. We validated the effect of PS 36:1 in cellular uptake by producing liposomes with a lipid formulation resembling the lipid profile of naturally occurring EVs lipid profile with an artificially high DOPS concentration (17% of the total molar ratio). We determined that human hepatocytes preferentially internalized liposomes made of naturally occurring EVs, followed by the ones with a high concentration of DOPS and lastly by a control EV lipid formulation.
Conclusion: This study identified EV LS that segregated cancerous, normal, and melanoma cell lines. We showed that LS could be used to distinguish cell populations. Moreover, we demonstrated that LS alone influences cellular uptake and that adding the segregating LS to lipid formulations in

excess effects cellular uptake. These results pave the way to identify EV lipid biomarkers and better understand EV based cancer dissemination.

#5312

Next generation quantitative proteomic analysis of urothelial lesions reveals novel diagnostic biomarkers to distinguish pathologic pitfalls and protein-protein interactions

Han Suk Ryu, Soo Young Park, Da Sol Kim, Cheng Hyun Lee. *Seoul National University Hospital, Seoul, Korea, Republic of*

There are several unmet needs remained to be solved in bladder urothelial lesions. Especially, the molecular biology of inverted urothelial papilloma (IUP) as a precursor disease of urothelial carcinoma is poorly understood. Also, muscle-invasive urothelial carcinoma (MIUC) of the bladder, showing a highly aggressive tumor behavior, has prompted the quest for robust biomarkers associated with invasion. A total of 265 tissue specimens from urinary bladder were enrolled for proteomic analysis and validation. Candidate biomarkers were selected through bioinformatic analysis, followed by validation. The latter comprised 2D and 3D invasion and migration assays, also a selection of external public datasets to evaluate mRNA expression and an in-house patient-derived tissue microarray (TMA) cohort to evaluate protein expression with immunohistochemistry (IHC). From the overall proteomic landscape, we found divergent ‘NU-like’ (low-risk) and ‘PUC-like’ (high-risk) signatures in IUP. The latter were characterized by altered metabolism, biosynthesis, and cell-cell interaction functions, indicating oncologic significance. Further machine learning-based analysis revealed SERPINH1, PKP2, and PYGB as potential diagnostic biomarkers discriminating IUP from PUC. The immunohistochemical validation confirmed PYGB as a specific biomarker to distinguish between IUP and PUC with inverted growth. For biomarkers predicting invasion, our multilayered platform-based analysis identified tubulin beta 6 class V (TUBB6) as a promising prognostic biomarker predicting MIUC of the bladder. The in vitro 2D and 3D migration and invasion assays consistently showed that inhibition of TUBB6 mRNA significantly reduced cell migration and invasion ability in two BUC cell lines with aggressive phenotype (TUBB6 migration, $P = .0509$ and $P < .0001$; invasion, $P = .0002$ and $P = .0044$; TGFBI migration, $P = .0214$ and

P = .0026; invasion, P < .0001 and P = .0001; T24 and J82, respectively). Validation through multiple public datasets, including The Cancer Genome Atlas (TCGA) and selected GSE (Genomic Spatial Event) databases, confirmed TUBB6 as a potential biomarker predicting MIUC. Further protein-based validation with our TMA cohort revealed concordant results, highlighting the clinical implication of TUBB6 expression in BUC patients (overall survival: P < .001). We propose PYGB and TUBB6 as a novel IHC biomarker to predict IUP diagnosis or invasion and poor prognosis in routine practice, also select the optimal treatment in BUC patients.

#5313

The expression of phospho-Rb S249, N-cadherin, E-cadherin, and B-catenin as a prostate proteomic score for the risk classification of prostate cancer tumors

Sheila M. Valle Cortes[1], Pedro Santiago Cardona[1], Carlos Diaz Osterman[1], Jaileene Perez Morales[2], Darielys Maldonado Maldonado[1], Gilberto Ruiz Deya[1]. *[1]Biochemistry, Ponce Health Sciences University, Ponce, PR,[2]Moffitt Cancer Center, Tampa, FL*

Prostate cancer (PCa) ranks as the second leading cause of cancer-related deaths in American men. Most PCa deaths occur due to aggressive, fast-growing tumors that develop into metastasis when cancer cells spread to other body parts, including the lymph nodes, bones, etc. However, men could also be affected by indolent, slow-growing tumors, which may exist for an extended period without causing any symptoms or death. Current prognostic methods, such as Prolaris, or Oncotype, do not precisely specify how aggressive cancer might be, resulting in overtreating patients with indolent PCa. Therefore, improved ways to differentiate indolent from aggressive tumors are needed. In the presented study, we have validated the clinical potential of phospho-Rb S249, N-cadherin, B-catenin, and E-cadherin to discriminate between indolent and aggressive PCa tumors. We hypothesize that the biomarkers phospho-Rb S249, N-cadherin, E-cadherin, and B-catenin expression in PCa will be a clinical tool for the risk classification of PCa tumors when used as part of a prostate proteomic (PPS) that can predict the risk of the tumor of evolving into an aggressive phenotype. We conducted immunohistochemistry staining of these biomarkers on PCa tumor microarrays and correlated it with the patient's

clinical parameters, such as tumor size, lymph node invasion, metastasis, etc. Also, we correlated it with the PSA levels and created a PPS. The combination of our proteomic biomarkers predicts patient staging by 53.83%. Adding clinical data such as the tumor size, lymph node invasion, and metastasis (TNM) increases the precision of the prediction to 83.21%. In addition, the PSA levels increased as the phospho-Rb S249 expression and N-cadherin rise, accompanied by up-regulation of E-cadherin. Also, the PPS showed to distinguish between normal prostate tissue, hyperplasia, and PCa. Results suggest that these biomarkers could serve as a tool for the risk classification of indolent and aggressive PCa tumors.

#5314

A peripheral blood-based glycoproteomic predictor of checkpoint inhibitor treatment benefit in advanced non-small cell lung cancer

Klaus Lindpaintner, Chad Pickering, Alan Mitchell, Gege Xu, Xin Cong, Daniel Serie. *InterVenn, South San Francisco, CA*

Background**:** Protein glycosylation is the most common and complex form of post-translational protein modification. Glycosylation profoundly affects protein structure, conformation, and function. The elucidation of the potential role of differential protein glycosylation as biomarkers has been limited by the technical complexity of generating and interpreting this information. We have recently established a novel, powerful platform that combines liquid chromatography-mass spectrometry with a proprietary artificial-intelligence-based data processing engine that allows, for the first time, highly scalable interrogation of the glycoproteome. Here we report the performance of this platform to predict likely benefit from immune-checkpoint inhibitor (ICI) therapy in advanced non-small cell lung cancer (NSCLC).

Methods: Our platform was utilized to assess 532 glycopeptide (GP) and peptide signatures representing 75 serum proteins in pretreatment blood samples from a cohort of 123 individuals (54 females, 69 males, age range 30 to 88 years). Inclusion criteria were a diagnosis of unresectable stage 3 or 4 NSCLC, treatment with pembrolizumab monotherapy (26 patients), or treatment with combination pembrolizumab-chemotherapy (97 patients). Overall survival (OS) data were available for all patients.

Results: An ensemble multivariable-model-based glycoproteomic classifier consisting of 7 GP and non-glycosylated peptide biomarker features selected from a generalized additive model for OS was developed using ≈2/3^{rds} of the full cohort (n=88) and validated in the remainder of patients (n=35). The classifier yielded similar statistical significance in Cox regression analysis for separating patients who are likely to benefit from ICI therapy from those who are not, to accurately predict likely ICI benefit with a sensitivity of >95% while performing at a specificity of 33% to predict those who are unlikely to benefit. Results were further analyzed in patients with either non-squamous or squamous NSCLC with first-line therapy (n=98). The classifier yielded a hazard ratio (HR) for prediction of likely ICI benefit of 3.6 with median OS of 13.9 vs. 4.2 months, and of 3.5 with median OS of 13.5 vs. 4.5 months in the entire cohort and the first-line treated patients, respectively.
Conclusions: The glycoproteomic classifier described here predicts with high sensitivity which patients are likely to benefit from ICI therapy. In addition to potentially reducing the use of ICIs in a safe manner in patients who would be unnecessarily subjected to possible adverse drug reactions, our classifier simultaneously has the potential of reducing the burden of health care expenditures. Our results indicate that glycoproteomics holds a strong promise as a predictor for ICI treatment benefit which appears to significantly outperform other currently pursued biomarker approaches.

Identification of urinary proteome signatures associated with triple-negative breast cancer
Michael N. Lombardo[1], Roopali Roy[1], Susan Pories[2], Meg Lotz[2], Rama Aldakhlallah[1], Simon T. Dillon[3], Towia A. Libermann[3], Marsha A. Moses[1].
[1]Vascular Biology Program, Department of Surgery, Harvard Medical School, Boston Children's Hospital, Boston, MA,[2]Hoffman Breast Center, Mount Auburn Hospital, Harvard Medical School, Cambridge, MA,[3]Genomics, Proteomics, Bioinformatics and Systems Biology Center, Beth Israel Deaconess Medical Center, Boston, MA

Triple-negative breast cancer (TNBC), an aggressive breast cancer subtype, accounts for ~15% of all breast cancers and is associated with a poor prognosis and high rates of recurrence and distant metastases. Patients

diagnosed with TNBC have limited treatment options and are often restricted to chemotherapy-based regimens, in stark contrast to patients with other breast cancer subtypes where the development of targeted therapeutics have significantly improved patient outcomes. TNBC is characterized by the loss of estrogen receptor, progesterone receptor and human epidermal growth factor receptor 2. This and the genetic and molecular tumor heterogeneity of TNBC has not only limited advances in the development of targeted therapy but also in the identification of biomarkers that can predict disease status and monitor treatment response. Advances in next-generation sequencing technologies have led to the identification of promising clinically actionable mutations however these tests often require invasive procedures to obtain tumor tissue and lack the ability to monitor treatment efficacy or detect recurrence, highlighting the need for non-invasive markers. A number of serum protein biomarkers have been evaluated in TNBC however none have yet to be successfully deployed in the clinic as indicators of disease. We have previously established that the urinary proteome can serve as a source of highly specific and sensitive biomarkers that can detect disease status and stage of multiple cancer types. Within the context of our global proteomics approach to cancer biomarker discovery, we have utilized the SomaScan discovery platform to identify 281 proteins that are differentially expressed in the urine of patients with TNBC compared to the urine of age- and sex-matched controls. The gene expression profiles of these proteins in TNBC tumor tissue were compared to those of normal breast tissue utilizing the R2 Genomics Platform. Proteins whose gene expression profile was consistent with the proteomic data were validated for the ability to distinguish between TNBC and non-TNBC diagnoses using mono-specific ELISAs of patient urine samples. These results demonstrate that a global proteomics approach coupled with clinical gene expression data can be effectively utilized to identify potential biomarkers for TNBC. These findings identify clinically relevant proteins that should be further explored as potential biomarkers in the development of non-invasive diagnostics for TNBC. (This work was supported by the Breast Cancer Research Foundation and the Nile Albright Research Foundation).

High-throughput Screening, Lead Identification and Optimization, and in Silico Drug Discovery

EU-OPENSCREEN - An open-access initiative in chemical biology to support anti-cancer drug discovery

Bahne Stechmann, Charlotte Wit. *EU-OPENSCREEN ERIC, Berlin, Germany*

Over the past two decades, an increasing number of small molecule drugs that target unique molecular changes underlying a specific cancer have been approved, and small molecule drugs represent a major therapeutic class for cancer treatment. Chemical ‘probes’ are also indispensable tools to advance our understanding of pathologies at the molecular and cellular level and to validate novel drug targets.

A major bottleneck in identifying and developing these chemical compounds in academia is often access to robust disease-relevant assays, high-throughput screening platforms, comprehensive screening libraries, medicinal expertise for the hit-to-lead optimization. In order to democratize access to these resources for a broader scientific community, the publicly funded EU-OPENSCREEN (www.eu-openscreen.eu) initiative has been established with the aim to accelerate drug discovery efforts in an open-access setting in collaboration with researchers from academia and industry. EU-OPENSCREEN’s 30 expert centers offer access to their cancer target-based and phenotypic drug screening expertise, capabilities in developing disease-relevant assays and hit-to-lead optimization capabilities. The identified bioactive ‘hit’ compounds will be progressed into high-quality chemical starting points to be further developed into drug leads or chemical probes for the elucidation of mechanisms of cancer onset, progression, resistance and effects of drug therapy. All generated tool compounds and associated bioactivity data are made available to the global scientific community.

Here we will present an overview of anti-cancer drug discovery projects of EU-OPENSCREEN and explain the opportunities and benefits for other international scientists to collaboratively develop novel anti-cancer drug leads and chemical probes.

EU-OPENSCREEN receives funding from the European Union's Horizon 2020 and Horizon Europe research and innovation programs under grant agreements No 654248 and 101058620.

The RenMice™ HiTS (Hyperimmune target specific) Platform facilitates identification of novel therapeutic antibodies for challenging targets

Xiaoqian Zhang[1], Shufang Fu[1], Shujin Zhang[1], Xin Ji[1], Li Hui[2], James Jin[2], Jing Zhang[1]. *[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd, Beijing, China,[2]Biocytogen Boston Corp, Wakefield, MA*

In recent years, an increasing number of therapeutic antibodies have shown to be effective for the treatment of cancer and other diseases. However, limitations in the traditional discovery process, including immune tolerance of highly homologous genes, challenges with antibody sequence humanization, clone selection, and model selection for drug efficacy and safety evaluation, often hinder the process of identifying new therapeutic antibodies. The RenMice™ HiTS (Hyperimmune Target Specific) Platform is a library of chromosome engineered mice with fully human immunoglobulin variable domains replacing the mouse loci, each with a specific drug target gene knocked out. These mice are designed to establish robust immune responses and generate antibodies that bind to more epitopes of the target protein, including conserved domains. The platform is ideal for challenging targets, such as proteins with high homology across species, or multi-pass transmembrane proteins (e.g. GPCRs/ion channels). Here, we show that the platform can be used to generate antibodies that cross-react with multiple species, like human, monkey, dog, and mouse targets, by immunizing with both human and mouse or dog antigen. We provide examples for newer campaigns, including species cross-reactivity and internalization of novel antibodies targeting NECTIN-4, and high-throughput in vivo efficacy screening of novel anti-PD-1 antibodies in wild-type mice. In the future, we will evaluate the preliminary toxicity of these cross-reactive antibodies in preclinical animal models. Thus, selection of the best antibody candidate based on in vivo efficacy and safety allows for a streamlined and successful preclinical phase. In conclusion, the RenMice™ HiTS platform facilitates the generation of developable antibodies that recognize novel epitopes and challenging targets.

Large scale pan cancer drug combination screening to identify effective and actionable combinations and biomarker hypothesis

Azadeh Bashi[1], Elizabeth A. Coker[2], Krishna Bulusu[1], Marta Milo[1], Claire Crafter[1], James Lynch[1], David Jenkins[3], Howard Lightfoot[2], Brandon Willis[3], Courtney Andersen[3], Omid Tavana[3], Kevin Mongeon[3], Jacob Gordon[3], Paul Smith[1], Simon Barry[1], Ultan McDermott[1], Lisa Drew[3], Susan Critchlow[1], Mathew J. Garnett[2], Jerome Mettetal[3]. *[1]AstraZeneca Oncology, Cambridge, United Kingdom,[2]Wellcome Sanger Institute, Cambridge, United Kingdom,[3]AstraZeneca Oncology, Waltham, MA*

Drug combinations are highly desirable in oncology as they can improve therapeutic response and overcome drug resistance. However, responses can be context-specific, meaning there is a real need for large-scale studies to fully explore the drug combination response landscape.

We present a screen of 109 drug combinations in over 750 diverse cell lines covering 41 hematological and solid tumor types. Each combination was screened in a full 7x7 matrix format, representing over 2.3 million individual data points, the largest such study to date. We took a novel approach to assess combination benefit. Growth inhibition and highest single agent (HSA) and Bliss excess combination heatmaps were generated for all >68,000 combination-cell line pairs, and each was scored for high activity (combination Emax>0.5) and combination benefit/synergy (HSA>0.1). Out of 4578 combination-cancer type pairs 489 met the filtering criteria. We prioritized combinations based on their efficacy and cancer type selectivity to minimize risk of potential tissue toxicity. We identified several known combination-cancer type pairs (e.g. MCL1 inhibitor AZD5991 plus BCL2 inhibitor venetoclax in AML) as well as novel indications for combinations already known to be active in a different cancer type (e.g. AZD5991 plus AKT inhibitor capivasertib in endometrial cancer or AURKB inhibitor AZD2811 plus venetoclax in DLBCL). We selected 4 combinations based on clinical need and validated them further *in vitro* and *in vivo* (selumetinib plus venetoclax or AZD5991, AZD2811 plus venetoclax, and capivasertib plus AZD5991).

To understand how molecular context affects drug response, we also used GDSC tools ANOVA to perform over 5.4 million statistical tests to identify statistically significant associations between drug response metrics and

multi-omics features including mutations, CNAs, gene expression and methylation. Associations were identified with five response metrics, covering both single agent and combination responses. We looked for significant associations across 21 different subgroups of cell lines and 6 molecular 'baskets' (TP53, KRAS, MLL2/KMT2D, PTEN, PIK3CA, and BRAF). We identified 11,611 biomarkers which met the significance criteria (p<=0.001, FDR<=10%, and both positive and negative Glass deltas >=1). Moreover, we used biomarkers of single-agent response to identify any combination Emax or Bliss associated biomarkers that could not be explained by the action of either drug. This resulted in identification of 1,631 'emergent' biomarkers.
In summary, our screen and pipeline have been designed to optimize preclinical interpretation with a focus on actionability, particularly by our unique approach, and to provide a valuable resource for exploration by the wider research community. As a result of this screen, we identified and validated novel combination-tumor types in multiple cancer types.

High throughput chemotherapeutic drug screening system for gastric cancer: cure-GA

Jieun Lee[1], Jung Eun Kim[2], Sanjun Lee[3], Tae-Kyeong Lee[1], In Hee Kim[2], So Hee Yoon[2], Mira Yoo[1], Eunju Lee[1], Doo-Young Hwang[1], So Hyun Kang[1], Bo Sung Ku[2], Dong Woo Lee[2], Young Suk Park[1], Ji-Won K[4], Jin Won Kim[4], Sang-Hoon Ahn[1], Keun-Wook Lee[4], Hyung-Ho Kim[1], Hyun Jung Oh[5], Yun-Suhk Suh[1]. *[1]Department of Surgery, Seoul National University Bundang Hospital, Gyeonggi-do, Korea, Republic of,[2]Department of Precision Medicine, Medical & Bio Decision (MBD Co., Ltd.), Gyeonggi-do, Korea, Republic of,[3]Department of Surgery, Kyung Hee University Hospital at Gangdong, Seoul, Korea, Republic of,[4]Department of Internal Medicine, Seoul National University Bundang Hospital, Gyeonggi-do, Korea, Republic of,[5]Department of Pathology, Seoul National University Bundang Hospital, Gyeonggi-do, Korea, Republic of*

To discover clinically applicable anticancer drugs and predict therapeutic response for advanced gastric cancer, we developed a high-throughput drug (HTD) screening system that could rapidly evaluate drug reactivity using

3D cultured primary cells derived from gastric cancer (GC) patients. Primary cancer cells were isolated from fresh surgical specimens that resected from 143 GC patients using Gentle Max tissue dissociation system. Primary cells were mixed with Matrigel, and placed on a micropillar for three-dimensional (3D) culture. After the primary cells were stabilized in the complete culture medium (CCM) than added various chemotherapeutic drugs containing 5-FU, Oxaliplatin, and Paclitaxel in CCM and incubated for 7 days. Cell viability was determined through calcein staining and quantified scanned images. The IC_{50} for each drug was calculated by a sigmoidal dose-response curve, using the GraphPad Prism 9 program. The average weight of gastric cancer tissue used in the experiment was 300 mg (75 mg ~ 1930 mg), and the average number of dissociated viable cells for each tissue was 3.9 x 10^6 cells/case. About 2.4 x 10^5 live cell was required per drug, we were able to obtain an average of 6.4 (Min.2, Max 14) drug reactivity data per tissue using the HTD screening system. GC tissues obtained from the operating room were dissociated within 16 hours and then loaded into the HTS system within 3 hours. Cells were stabilized for 1 day in 3D culture plate and exposed to the drug for 7 days, and then data reports were made within 3 days. As a result, it was possible to obtain within 14 days from fresh surgical GC tissue to drug response data. Additionally, we confirmed that 3D cultured primary cells derived from GC tissues consistently preserved primary characters using IHC. Similar to their parental cancer tissue, GC 3D cultured primary cells derived from adenocarcinoma large glandular patterns and retain the expression of some marker proteins. In this study, we evaluated the drug response data for 101 cases (success rate 71%; 101/143) to 5-FU, Oxaliplatin, and Palitaxel, etc. using the HTD screening system and it was confirmed that individual patient had a difference response to each drug. Here we established the HTD screening system using 3D cultured GC patient derived primary cells. The advantages of this system were that it is the first model system that directly used patient-derived primary cells for drug screening, and it can rapidly evaluate drug reactivity to various anticancer drugs within 10 days. The HTD screening system based on patient-derived primary cells can provide that information to predict drug response and allow for finding more appropriate therapy for each patient.

Accelerating the drug discovery process with an automated high-throughput protein production and characterization platform for AI-driven antibody development of immunotherapy

Zhehao Xiong, Wei Jiang, Lijun Xia, Jianhua Huang, Cheng-chi Chao.
Biomap, Menlo Park, CA

The demonstrated effectiveness and vast potential of large molecule therapeutics have driven biopharmaceutical companies to change the ways by which they discover and develop novel biologic therapies. While the conventional antibody discovery process via animal immunization and *in vivo* hypermutation can generate sufficient hits for functional screening, this approach can only cover a limited subset of sequence diversity. In silico, artificial intelligence (AI) driven methods, by contrast, have the potential to cover 2-3 orders of magnitude more sequence diversity compared to conventional methods and more rapidly produce a drug candidate with a superior safety and efficacy profile. However, this approach requires wet lab validation of predicted sequences as well as targeted data generation to improve AI-predicted rankings. Traditional wet lab methods for protein generation and characterization are expensive, time consuming, and prone to human error. These limitations restrict the overall potential benefit of the AI-driven antibody discovery process. To accelerate this process, which consists of a complex series of cycles spanning different functional teams, a substantial increase in the throughput of the end-to-end production and characterization workflow is established in-house such that 10^4 antibodies with property data can be generated and analyzed within a short period of time. BioMap has implemented a highly integrated and automated protein expression, purification, and characterization platform linked with a unified informatics system to eliminate as much manual operation as possible. This high-throughput robotic platform interweaves multiple procedures including plasmid preparation, cell dispensing, mammalian transfection, protein purification, and characterization, and it is coupled to our in-house informatics system and database. Empowered by state-of-the-art liquid handling system and well-established experimental protocols, the integrated facility is capable of the delivery of 10^3 protein samples from plasmids in ten days within a single batch. Benefiting from our robust transient expression platform, the production scale ranges from 0.5 to 30 mL with an average antibody yield of 300 mg/L. The high-throughput workflow brings

a challenge to track the provenance of each protein and manage data flow across different stations. To address this bottleneck, a well-defined informatics platform and database have been developed to provide sample registration, interface with lab instruments, experimental process tracking, and automated data recording and analysis. The implementation of this system provides a massive amount of high-quality data available for AI training and validation with a very short turnover time and enables AI-driven development of next-generation biologics.

#5324

Drug repurposing and genetic screening strategies for effective treatment discovery in soft-tissue sarcomas

Mushriq Al-Jazrawe[1], Kathryn Cebula[1], Elisabeth A. Abeyta[1], Haley S. Curtis[2], Jane K. McIninch[2], Jaime H. Cheah[2], James Berstler[2], Lisa Miller[2], James Neiswender[2], Lisa Brenan[2], Mike Burger[2], Francisca Vazquez[2], Jesse S. Boehm[1]. *[1]Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA,[2]Broad Institute, Cambridge, MA*

Treatment advances for soft-tissue sarcomas have been slow. This is, in part, due to their rarity (accounting for 0.7% of all cancers) and heterogeneity (over 50 different diseases fall under this category). Moreover, preclinical models are scarce, often exhibiting slow growth kinetics, which limits their study by large genetic and pharmacological libraries. Here, we present an update on our efforts to harness the power of patient-partnered research to create a platform for rare cancer drug target discovery as a broadly available community resource. We developed a patient-partnered tissue donation pipeline to enable patients anywhere in the United States to participate and piloted our approach for *CTNNB1*-driven desmoid tumors. To overcome challenges in tissue heterogeneity during ex vivo culture, we optimized a multiplexed sequencing protocol to quantitatively track changes in tumor cell fraction across hundreds of media formulations. Following this strategy, we were able to verify and expand three cell lines that preserve the *CTNNB1* mutations at high purity. To identify potential therapeutics, we completed a 6,750-drug repurposing screen, at 2.5uM in duplicate, in two verified cell line models. After extensive quality control assessments and data integration steps to leverage the power of other large scale drug screens, we selected 263 compounds for

follow-up based on potency, selectivity, and association with molecular features associated with desmoid tumors. Approximately 70% of selected compounds were validated by an 8-point, 2-fold dilution, dose-response format with a top concentration of 10uM. Of the confirmed active compounds, 80 showed a strong pattern of selectivity, 20 are FDA approved drugs and 13 investigational compounds show a statistical association with *CTNNB1* hotspot mutation status or transcriptomic features associated with desmoid tumors. To prioritize potential therapeutic targets, we tested an efficient CRISPR/Cas9 all-in-one library design. The reduction of the CRISPR/Cas9 library size was achieved via multiple gene- and guide-level strategies, which enables statistically powered gene essentiality interrogation in slow-growing patient-derived models. We tested several plating and infection parameters and developed an optimized pipeline for the rapid introduction of this library into early patient-derived samples. Established cell lines of mesenchymal and non-mesenchymal origin, which have previously been tested by genome-wide libraries, were used to control for library and lineage effects. We are developing a biologist-friendly web portal that will enable the research community to easily interact with models and data produced by this effort. Our study provides evidence that a systematic patient-powered approach can facilitate discovery of therapeutic hypotheses for these understudied diseases.

Comparison of CAR-T cell-mediated cytotoxicity assays with suspension tumor cells using high-throughput plate-based image cytometry method

Leo Li-Ying Chan[1], Yu-Jun Sun[2], Yi-Chun Chen[2], Wei-Kai Hua[2], Sariena Chiung-Yuan Wu[2]. *[1]Advanced Technology R&D, Nexcelom from PerkinElmer, Lawrence, MA,[2]Research and Development, GenomeFrontier Therapeutics, Taipei City, Taiwan*

In the recent decade, chimeric antigen receptor (CAR)-T cell therapy has revolutionized strategies for cancer treatments due to its highly effective clinical efficacy and response for B cell malignancies. Currently, there are six CAR-T cell products available in the market including Kymriah, Yescarta, Tecartus, Breyanzi, Abecma, and Carvykt. The success of CAR-T cell therapy has stimulated the increase in the research and development of

various CAR constructs to target different tumor types. Therefore, a robust and efficient in vitro potency assay is needed to quickly identify potential CAR gene design from a library of construct candidates. Traditionally, in vitro CAR-T cell-mediated cytotoxicity is assessed using release assays such as 51Cr (radioactivity), calcein (fluorescence), and LDH (enzymatic). However, release assays indirectly measure cell death via molecules released in supernatant and typically limited to only endpoint assays. In addition, handling and disposing of 51Cr hazardous materials is less preferred. Luciferase reporter assay, although highly sensitive, has similar drawbacks as the release assays. Finally, flow cytometry method can directly measure cell death and viability, but can be time-consuming and requires a large number of CAR-T cells when the effector-to-target (E:T) ratio is high. Furthermore, additional steps are required for adherent cells that require trypsinization. Image cytometry methodologies have been utilized for various CAR-T cell-mediated cytotoxicity assay using different fluorescent labeling methods, mainly due to their ease-of-use, ability to capture cell images for verification, and higher throughput performance. In this work, we employed the Celigo high-throughput plate-based Image Cytometer to evaluate and compare two CAR-T cell-mediated cytotoxicity assays using GFP-expressing or fluorescent dye-labeled myeloma and plasmacytoma cells. Performing time- and E:T ratio-dependent CAR-T cell-mediated cytotoxicity assays, the GFP-based method demonstrated higher sensitivity in detecting the
level of cytotoxicity when compared to the CMFDA/DAPI viability method. We have established the criteria and considerations for the selection of cytotoxicity assays that are fit-for-purpose to ensure the results produced are meaningful for the specific testing conditions.

Automated organoid alignment for clonal response characterization in pancreatic ductal adenocarcinoma

Ethan Samuel Lin, Md Shahadat Hossan, Austin Stram, Eleanor E. Riedl, Luke J. Koeppel, Jaimie M. Warner, Jeremy D. Kratz. *Department of Medicine, University of Wisconsin-Madison, Madison, WI*

Background**:** Therapeutic screening Pancreatic Ductal Adenocarcinoma (PDAC) relies on well-level assessment for high throughput response

evaluation. Patient-derived cancer organoids (PCOs) model subclonal populations, however the significance of resistant populations is uncertain when characterized with well-level response. Using a high-throughput screening assay, we present an automated alignment algorithm to characterize populations of organoid growth as compared to validated well-level therapeutic response assays.

Methods: High content imaging was performed in low volume (10uL), 96-well angiogenesis plating format (Ibidi, Inc) at 4x objective with 5-frame Z-stack (600um) with brightfield imaging captured at 0h and 72h. Images underwent processing using Gen5 suite (Biotek, Inc) including Z-projection to render organoids into single two-dimensional planes. Baseline objects were defined between 50µm and 750µm, and filtration based on circularity defined as >0.4. Object alignment was performed based on root-mean-square-deviation (RMSD) between all combinations of objects to optimize match determination. This analysis was performed in drug screen of 80 independent agents in early clinical trials in combination with CDK7 inhibitor, SY-5609. Well level viability was performed using standardized 3D CellTiterGlo (CTG, Promega Inc.) (33% v/v). Response was assessed using descriptive statistics, effect size (Glass's Δ), and Therapeutic Sensitivity Index (TSI) defined as the weighted average between elements with growth from media control versus treated population.

Results: Z projection of 600um in Low-volume plating (10µL) of matrix suspension yielded 1.68 organoids per µL relative to the traditional hanging drop design (50µL) 0.75 organoids per µL ($p<0.005$). Organoid alignment across the continuum of RMSD yielded maximum successful matches at 75µm with 66.1% of objects versus 6.7% based on randomly assigned objects across validation experimental sets (n=1380). An optimal circularity value was determined at 0.4; an increase of circularity by 0.1 yielded a >5% reduction in of matched objects, while a decrease in circularity by 0.1 yielded a <5% reduction in unmatched objects. A poor correlation was seen for the percent of growing organoids within a population and well level normalized viability via CTG ($R = 0.37$). The normalized CTG value had improved in correlation when compared to effect size relative to control ($R = 0.54$) and TSI ($R = 0.56$).

Conclusion: We provide a method for high fidelity alignment of PCOs in low-volume format for matrix-based screening applications. These techniques can be adapted to existing staining protocols to characterize

subclonal response in the context of both molecular heterogeneity and clinical outcomes.

Novel KRAS-specific in-well lysis ELISA for high throughput screening

Hyun Min Park, Jason Poole, Mary Anne Jelinek. *Active Motif, Carlsbad, CA*

RAS is one of the most frequently mutated genes in cancer. Gain–of–function missense mutations promoting oncogenesis cluster at codons 12, 13, and 61 of KRAS, NRAS and HRAS. These result in enhanced GTP binding due to fast exchange of nucleotide and/or impairment of GAP (GTPase Activating Protein) binding. Although these mutants are all activating, they are not equal in their oncogenic potential and differences in patient survival are associated with different RAS mutants and which RAS allele is affected, with KRAS being the most prevalent. Current RAS therapeutic approaches have migrated to be isoform specific. With this in mind, we have developed an activation state specific high throughput screening compatible (HTS) assay that is specific for KRAS. A novel rabbit anti–KRAS recombinant antibody was isolated via cloning of immunoglobulin variable regions from antigen positive B cells isolated from rabbits immunized with a peptide immunogen targeting a region of low homology between the RAS isoforms. Antibody specificity was validated with recombinant HRAS, KRAS and NRAS proteins over a wide concentration range by both immunoblotting and by a bead–based multiplex ELISA where all three RAS isoforms were present. The new assay allows for direct in–well lysis of cells cultured in 96–well plate format, either directly in media or following a PBS wash step. Activated KRAS in the lysate is captured on the assay plate and detected via chemiluminescence using the KRAS specific antibody. Preliminary assay validation has included EGF treatment of HeLa cells to show activation in cells expressing wildtype KRAS and inhibition with the selective non–covalent KRASG12D inhibitor MRTX1133 in Aspc1 cells known to express KRASG12D over a wide range of cell seeding densities. We anticipate that this assay will further the discovery of novel KRAS specific therapeutics.

#5329

High throughput screening strategies in the development of logic gated cell therapies

Li Wang, Sofia Kyriazopoulou Panagiotopoulou, Rona Harari-Steinfeld, Dasmanthie De Silva, Michelle Tan, Laura Lim, Angela Boroughs, Cate Sue, Jon Chen, Jamie Thomas, Mary Chua, Ed Yashin, Christine Shieh, Ryan Fong, Sophie Xu, Grace Zheng, Brendan Galvin, Aaron Cooper, Tarjei Mikkelsen, Nicholas Haining. *Arsenal Biosciences, Inc, South San Francisco, CA*

Chimeric antigen receptor T cell (CAR T) therapy has demonstrated unprecedented therapeutic activity in hematologic malignancies. However, generating potent clinical responses against solid tumors remains a challenge for CAR T therapy. As the field strives to improve the therapeutic efficacy of CAR T cells with novel target antigens and enhanced potency, the risks of on-target toxicity pose a major barrier to progress. To address these challenges, we have developed engineered CAR T cells to target solid tumors through AND logic gates, where CAR expression is conditionally induced by a transcription factor released from a priming receptor (PrimeRTM) upon binding to the PrimeR antigen. The AND gate limits off-tumor toxicity as it requires both CAR and PrimeR antigen expression in the tumor microenvironment.

To ensure PrimeR expression and signal transduction upon antigen binding, while minimizing residual ‘‘leaky’’ CAR induction in the absence of PrimeR antigen, we screened hundreds of PrimeR binders using both arrayed and pooled strategies. In an arrayed strategy, we engineered T cells from four donors in multiwell plates using CRISPR-mediated, non-viral, site-specific integration of logic gates bearing a variable PrimeR binder and a fixed MSLN CAR. In addition, we employed a pooled screening strategy, where we engineered T cells from two independent donors with a pool containing a subset of >300 of the same logic gates.

Engineered T cells from both strategies were co-cultured with cell lines bearing either both CAR and PrimeR antigens or a single antigen, in order to evaluate fidelity and on-target functionality. In the arrayed setting, on-target functionality was quantified based on the levels of CAR induction, cytokine secretion, T cell activation, and target cell killing in the presence of both antigens, while fidelity was assessed based on the absence of these activity signals in the presence of a single antigen. In the pooled setting,

sorting based on functional markers was performed and sequencing was used to quantify the relative abundance of cells with each logic gate in different sorted populations. On-target activity and circuit fidelity were then quantified based on enrichments in different sorted populations.
Results from the pooled and arrayed screens were highly concordant. We combined the screen readouts to nominate a small set of PrimeR binders that exhibited both high fidelity and on-target functionality. We confirmed the desired characteristics of these binders with targeted arrayed screens in additional conditions as well as in in-vivo models. We have applied both screen strategies to select a small set of leads from hundreds of candidate PrimeR binders in the context of a logic-gated MSLN CAR. As pooled and arrayed screens come with different sets of limitations and advantages, both serve as important tools for the effective selection of receptors in the development of novel cell therapies.

#5330

Cell identity, count, and viability for critical quality attributes using the Cellaca PLX image cytometer

Carolina Franco Nitta, Mackenzie Pierce, Aiyana Parker, Sopaul Hem, Timothy Smith, Surbhi Ratnani, Marek Dobrowolski, Srinivas Gundimeda, Bo Lin, Dmitry Kuksin, Leo L. Chan. *Nexcelom Bioscience, Lawrence, MA*

Cell and Gene therapy is one of the fastest growing fields for cancer therapeutics that heavily relies on robust and consistent instrumentations and technologies to verify and validate the critical quality attributes (CQA) that are fit-for-purpose. Some of the key parameters required for satisfying CMC (Chemistry Manufacturing and Controls) criteria standards for cellular therapeutic products are cell identity, count, viability, purity, potency, stability, and microbiological quality, which may be routinely performed using flow cytometry. Some of these critical attributes can be exceedingly trivial for flow cytometric analysis, which can be complex, requires a dedicated user, and may carry a high maintenance cost. In the past decade, affordable image cytometry has been developed for cell characterization and cell-based assays but has not demonstrated the sensitivity required for visualization and analysis of surface markers, cell health, and viability. In this work, we demonstrate the capability of the newly developed Cellaca PLX image cytometry system for population

analysis of surface markers, viability of fluorescent protein expressing cells, and cell health in comparison to flow cytometry. For immunophenotyping assays, PBMCs were stained with anti-human CD3/CD4/CD8 antibodies with Hoechst. Additionally, viability detection of GFP and RFP-containing cell lines was performed by staining with RubyDead and Hoechst. Finally, apoptosis was induced in Jurkat cells with staurosporine and stained with Caspase 3-488, RubyDead, and Hoechst. All assays were imaged and analyzed using the Cellaca PLX image cytometer, and the data generated were compared directly to the CytoFlex flow cytometer. Results show similar percentages of surface marker populations: CD3 (76% and 81%, PLX and CytoFlex, respectively), CD4 (43% and 42%), and CD8 (15% and 17%). RFP and GFP-containing cells showed comparable viabilities on Cellaca PLX and CytoFlex, and the population percentages of Hoechst positive cells stained with Caspase 3 and RubyDead were within 5% of each other. Our experiments demonstrate that the Cellaca PLX can be of significant value to the Cell and Gene Therapy communities providing novel image cytometry methods which may satisfy several CMC criteria including high-throughput, high sensitivity, and low maintenance.

DNA-encoded macrocyclic compound libraries for challenging targets

Ying Zhang[1], Anthony Keefe[1], Paolo Centrella[1], John Cuozzo[2], Holly Soutter[3], Daniel Resnicow[4], Sevan Habeshian[5], Matt Clark[1]. *[1]X-Chem Pharmaceuticals, Waltham, MA,[2]Relay Pharmaceuticals, Cambridge, MA,[3]Broad Institute, Cambridge, MA,[4]Bonito Biosciences, Waltham, MA,[5]Orbis Medicines, Zurich, Swaziland*

Increasingly drug discovery programs require the development of orally available and cell permeable classes of drugs derived from the chemical space beyond Lipinski's rule of 5 (bRO5). The chameleon-like physicochemical properties and differentiated binding modes of bRO5 compounds make them suitable starting points, especially for difficult-to-drug targets beyond traditional small molecule drug discovery. The synthesis of macrocyclic (MC) peptide DNA-Encoded Libraries (DEL) aligns with these efforts and has been an important addition to the rapidly growing field of DNA-encoded small molecule library screening. DEL screening of *de novo* designed bRO5 compounds will aid the exploration of

bRO5 chemical space. X-Chem's macrocyclic compound libraries apply chemistries beyond traditional peptide formation and extend to the inclusion of diverse building block classes. A case study of a successful screening campaign utilizing these MC DEL for Bcl2 will be presented.

Characterization and comparison of acridine orange/propidium iodide and acridine/DAPI viability detection methods for cell and gene therapy development

Yongyang Huang, Samir Patel, Mackenzie Pierce, Carolina Franco Nitta, Bo Lin, Leo Chan. *Nexcelom Bioscience, Lawrence, MA*

Cell viability is one of the critical quality attributes (CQAs) for cell and gene therapy products. Characterization of cell viability, in addition to cell identity, cell count and other CQAs, are essential to ensure the quality, safety and efficacy throughout various developmental stages of cell and gene therapies. To determine cell viability, a variety of viability detection methods have been used, such as trypan blue (TB) exclusion assay, and fluorescence-based dyes including acridine orange / propidium iodide (AO/PI), acridine orange / 4′,6-diamidino-2-phenylindole (AO/DAPI), all of which have been employed on flow or image-based cytometry systems. In this work, we employed the Cellaca MX high-throughput cell counter to characterize and compare AO/PI and AO/DAPI viability detection methods. First, we measured the viabilities of different ratios of viable and non-viable Jurkat cells created via two cell dying processes. Next, viabilities of the stained cells were measured multiple times within a 30 min staining time for each method in order to monitor the trend of viability changes. The viability results showed that the AO/DAPI method were generally higher than AO/PI method with differences ranging from 0% to 24%. We also observed the discrepancy of the measured viability differences between naturally-dying and heat-killed Jurkat cells, suggesting that the viability difference might be dependent on the cell dying process. In the time-dependent viability characterization, results from AO/DAPI method showed increasing dead cell counts leading to decreasing viability, revealing an on-going staining process. In contrast, results from AO/PI method showed more consistent cell count and viability measurements, indicating a more instantaneous staining process. Lastly, we conducted a cell proliferation

assay as an orthogonal method to confirm replicability of the low viability cell samples. The proliferation assay results showed no significant increase in cell concentrations within the 4-day time frame. The viability results before the culture were approximately 0% for both naturally-dying and heat-killed Jurkat cells, using the AO/PI staining method, and 12% and 9% using the AO/DAPI respectively. Furthermore, spiked samples of natural-dying and heat-killed cells with healthy cells (>90% viability) were generated and measured, which showed exponential growth. The viability results of these spiked samples before the culture were 11% and 9% by AO/PI and 17% and 18% by AO/DAPI, respectively. Taken together, these results suggest that cell viability methods need to be optimized for different fluorescent stains in order to generate reliable, robust, and fit-for-purpose results for the downstream assays for cell and gene therapy products..

Combining chemoproteomics with machine learning identifies functionally active covalent fragments for hard-to-drug cancer drivers

Johannes C. Hermann[1], Robert Everley[2], Laura Marholz[2], Matthew Berberich[2], Tzu-Yi Yang[2], Yu-Hsin Chao[2], Abduselam K. Awol[2], Michael Shaghafi[1], Han Yoon[1], Rohan Varma[1], Reed Stein[1], Karsten Krug[1], Emily Lachtara[2], Daniel Erlanson[1], Chris Varma[1], Kevin R. Webster[2]. *[1]Frontier Medicines, South San Francisco, CA,[2]Frontier Medicines, Boston, MA*

a) Many cancer drivers are considered “undruggable” and without targeted treatments because they lack binding sites for conventional small molecules. Here, we introduce The FRONTIER™ Platform applying machine learning (ML), chemoproteomics and covalent chemistry to identify binding sites and cell-active covalent fragments across the human proteome, including against most cancer drivers and previously “undruggable” targets. Molecules tested in functional assays are active and can serve as starting points for new drug discovery initiatives.
b) We are using mass spectrometry and data analysis workflows to perform high-throughput chemoproteomic profiling experiments. These experiments identify hits across the proteome using different cancer-relevant cell backgrounds and characterize binding sites for drug discovery. Customized ML algorithms using chemoproteomic, genomic and structural data to characterize and prioritize identified binding sites for covalent drug

discovery. The performance of the platform allows the profiling of thousands of compounds from a custom-built library that has been optimized by ML for covalent fragment-based drug discovery. The nature of the fragment hits and the ability to map them to and focus on preferred binding sites for covalent drugs enables accelerated lead generation.
c) We show details of the platform highlighting library design concepts and the hotspot map with binding site prioritization algorithms. We show coverage and applicability across important cancer target classes and signaling pathways. Covalent fragment hits have been identified for multiple difficult cancer targets, including KRAS, p53, STAT3, KEAP1, PTPN11 and others. The platform also identifies ligands for novel allosteric binding sites in established oncology targets such as CDK4, PI3KCA and BTK. We will highlight how discovered ligands show functional activity in orthogonal assays, demonstrating their fitness for drug discovery campaigns and target validation experiments.
d) Undruggable targets across a variety of cancer target classes have become druggable.

Targeting the KIF15-TPX2 PPI to overcome KIF11 inhibitor resistance in epithelial ovarian cancer

Benjamin K. Gibbs[1], Justin T. Douglas[2], Rebecca J. Wates[1], Peter R. McDonald[3], Amy M. Whitaker[4], Cornelius N. Ndi[5], Harsh B. Pathak[1], Laurie A. Harned[2], Sarah A. Neuenswander[2], Melinda A. Broward[6], Bret D. Freudenthal[7], Anuradha Roy[3], Frank J. Schoenen[5], Andrew K. Godwin[1].
[1]Department of Pathology and Laboratory Medicine, University of Kansas Medical Center, Kansas City, KS,[2]Nuclear Magnetic Resonance Lab, University of Kansas, Lawrence, KS,[3]Structural Biology Center, University of Kansas, Lawrence, KS,[4]Department of Biochemistry and Molecular Biology, University of Kansas Medical Center, Kansas City, KS,[5]Higuchi Biosciences Center, University of Kansas, Lawrence, KS,[6]Institute for Advancing Medical Innovations, University of Kansas Medical Center, Kansas City, KS,[7]Department of Biochemistry, University of Kansas Medical Center, Kansas City, KS

Most cases of epithelial ovarian cancer (EOC) exhibit extensive molecular heterogeneity, presenting challenges in developing targeted therapies. Despite extensive efforts and incremental successes in developing targeted drugs and immunotherapies for other cancers, chemotherapies continue to be the most used treatment of ovarian cancer. Although seemingly simplistic, identification of drugs targeting cellular machinery independent of genomic and genetic status continues to be a strong clinical need. Previously, we performed an RNAi-based screen of the druggable genome across a diverse histological panel of EOC cell line representing both platinum-sensitive and -resistant tumors (PMID: 23056589). This screen elucidated KIF11 as essential in maintaining EOC cell viability. KIF11, a mitotic spindle assembly motor protein, has been targeted clinically. Although drugs are well tolerated, potent, and specific, the objective response rates to KIF11 inhibitors in clinical trials were commonly less than 10%. The efficacy of KIF11 inhibitors is blunted via a compensatory motor kinesin, KIF15. The overexpression of KIF15 has been shown to compensate for absent KIF11 in the formation of the bipolar spindle apparatus during mitosis. Silencing KIF15 significantly sensitizes cells to KIF11 inhibitors and resensitizes resistant cells to KIF11 inhibitors. We developed a high throughput screening approach using Alpha technology to identify compounds that inhibit the protein-protein interaction (PPI) between KIF15 and TPX2, a unique approach to inhibiting KIF15 from previous efforts. Of the nearly 200,000 compounds screened, 177 compounds were selected to be further characterized based on assay performance and chemical properties. These compounds were screened for TPX2 or KIF15 binding by STD-NMR and waterLOGSY. Three compounds across two chemotypes were confirmed to bind KIF15. No compounds were found to bind TPX2. Additionally, 168 of the 177 compounds were screened for drug synergism *in vitro*. The synergism assay yielded 32 strongly and 8 weakly synergistic hits. The lead compound in each of the two chemotypes revealed by NMR were classified as strongly synergistic (max. bliss score of 8.0 and 29.9). To expand the potential lead compounds identified for further development, an antibody-free cellular thermal shift assay (CETSA) is being completed with 168 compounds. Preliminarily, CETSA has shown that the two lead compounds significantly stabilize KIF15 (ΔTm = 5.6 °C and 9.6 °C). These two lead compounds behaved in a dose-dependent manner in the AlphaScreen (IC_{50}= 2 μM and

6 μM), a favorable characteristic for further development. To date, two chemotypes have been identified as KIF15 inhibitors uniquely targeting the KIF15-TPX2 PPI. The data indicates KIF15 inhibition in combination with KIF11 inhibition is synergistic, thus demonstrating a potential novel treatment approach for people with EOCs.

#5335

circAde: a circRNA-based system for prolonged and more effective treatment of cancer

Eoghan T. O'leary, Sara Vikberg, Emilie Foord, Erik D. Wiklund, Lone Ottesen, Victor Levitsky, Thomas B. Hansen. *Targovax ASA, Lysaker, Norway*

In recently performed phase I/II clinical studies, we have demonstrated successful delivery of vectorized transgene-encoding mRNA payloads to solids tumors with substantial clinical benefit. In patients, persistent and prolonged transgene expression correlated with positive clinical outcome, and thus temporal expansion of the transgene expression profile is expected to improve the therapeutic benefit even further. Recently, circular RNA (circRNA) has been discovered as a novel class of endogenously expressed RNA. CircRNAs, in contrast to mRNAs, are resistant to exo-nucleolytic decay which results in high intra-cellular stability and persistent expression within cells. Therefore, circRNA-based systems serve as an interesting new technology towards prolonged effects of treatment. Here, we show that our proprietary vector system, circAde, allows high expression of circRNAs through spliceosome-dependent biogenesis. By comparing the protein output from circAde and mRNA-based vectors, we show that the circAde-system out-performs conventional mRNA-based design, both in terms of transgene yield and temporal sustainability of expression. Moreover, using a panel of proof-of-concept-reporters, we show that certain design-features greatly influence the circRNA production and subsequent protein expression from the vector. Without the 5’cap, circRNAs are dependent on IRESs (internal ribosome entry sequences) for effective translation. By conducting two orthogonal IRES screens on 1000+ putative IRES elements, we have identified the most effective IRES sequence in melanoma and lung-cancer cells supporting effective circRNA production and high-yield protein expression, thereby improving our circAde vector system even

further. Our results open a new platform towards development of novel, more effective strategies for the treatment of cancer and other settings in which durable transgene expression is desirable.

#5336

Discovery of a novel activin receptor-like kinases (ALKs) inhibitor targeting TGF-β signaling pathways

Mai Arai[1], Mitsuharu Hanada[1], Hideki Moriyama[1], Hiroshi Ohmoto[1], Kazuhito Naka[2], Masaaki Sawa[1]. *[1]Carna Biosciences, Inc., Kobe, Japan,[2]Department of Stem Cell Biology, Research Institute for Radiation Biology and Medicine, Hiroshima University, Hiroshima, Japan*

Introducti**on:** Transforming growth factor β (TGF-β) plays a key role in promoting tumor progression mainly through facilitating angiogenesis, epithelial-mesenchymal transition (EMT) and also inducing immunosuppression in tumor microenvironment, allowing cancer cells to escape immune surveillance. Activin receptor-like kinases (ALKs) consisting of seven type I receptor serine/threonine kinases are responsible for TGF-β family signal transduction by phosphorylating Smad proteins, which can activate target gene expression. Therefore, ALKs are attractive drug targets for intervention in TGF- β signaling pathways as cancer immunotherapy.

Materials and methods: We have produced seven human recombinant ALK proteins (ALK1-7). The in vitro kinase assays for all ALKs have been developed using TR-FRET system. To evaluated cellular potency, TGF-β-dependent Smad3 phosphorylation assays in A549 (human lung adenocarcinoma cell line) and NMuMG (murine normal mammary gland cell line) cells were established. A TGF-β-mediated Treg differentiation assay was performed as an ex-vivo cellular assay using naive CD4+ T cell isolated from mouse spleen. In vivo anti-tumor efficacies of selected compounds, alone or in combination with anti-PD-1 antibody were assessed in a CT26.WT murine colon carcinoma syngeneic model.

Results: We have implemented a high-throughput screening (HTS) against human ALK5 over our in-house compound library. Hit compound **1** was identified from the HTS, and the subsequent Hit-to-Lead study led to a novel thiazole analog 2 as the starting point of lead optimization. Our lead optimization efforts led to advanced lead compound AL1, which exhibited

strong inhibitory potency for ALK5 with an IC50 value of single digit nanomolar. Unfortunately AL1 showed very low oral bioavailability in dogs, we continued the optimization study and identified compound AL2 having improved ADME property. In cellular assays, AL2 strongly suppressed the TGF-β-dependent Smad3 phosphorylation in A549 cells. In addition, treatment with AL2 decreased in the percentage of mouse CD4+/CD25+/Foxp3+ Treg cells dose-dependently in the ex vivo TGF-β-mediated Treg differentiation assay. As a monotherapy and combined with an anti-PD-1 antibody, oral administration of AL2 demonstrated robust in vivo antitumor efficacy in the CT26.WT murine colon carcinoma syngeneic model.
Conclusions: On the basis of its in vitro potencies, PK profiles, and in vivo efficacies, AL2 is currently being further evaluated in preclinical studies.

#5337
Design, synthesis and evaluation of dual-targeted mEGFR and AURK inhibitors as anticancer agents
Dayna Gesinski, Sonali Kurup. *Ferris State University, Big Rapids, MI*

Mutant epidermal growth factor receptor (mEGFR) inhibitors constitute the recommended therapy for mEGFR-positive cancers. However, resistance has developed to mEGFR inhibitors due to newer mutations within the enzyme pocket and redundant signaling pathways that bypass mEGFR inhibition. Recent studies have shown that resistance to mEGFR inhibitors could be overcome if given in combination with aurora kinase (AURK) inhibitors. Dual EGFR/AURK kinase inhibitors provide a novel approach to overcome resistance to EGFR inhibitors. In a previous study, Kurup *et al.* identified **1** as a nanomolar mEGFR inhibitor. Using a structure-based design approach, novel analogs of **1** that incorporated varied sidechains for dual mEGFR and AURK inhibition were designed. The synthesis of the target compounds involved microwave-assisted, copper and palladium catalyzed coupling reactions. This study led to the identification of dual-targeted mEGFR/AURKA and mEGFR/AURKB inhibitors, and compounds with sub-micromolar cellular potencies. The design, synthesis, kinase inhibitory activities and anticancer effects of these novel analogs will be presented. Structure-activity relationships for mEGFR, AURKA and AURKB inhibition will be defined.

#5338

A novel in vitro assay to evaluate the roles of hepatic metabolism on anticancer drug safety and efficacy

Albert P. Li, Hong Wei. *In Vitro ADMET Laboratories, Discovery Life Sciences LLC, Columbia, MD*

It has been well-established that hepatic drug metabolism may have significant impact on the efficacy and off-target toxicity of anticancer drugs. We present here an in vitro assay, the metabolism-dependent cytotoxicity assay (MDCA), for the evaluation of the roles of specific pathways on the efficacy of anticancer drugs. The assay employs a novel in vitro hepatic metabolic system, the permeabilized cofactor-supplemented human hepatocytes (MetMax Human Hepatocytes, MMHH), as an exogenous metabolic activating system for the evaluation of the in vitro cytotoxicity of anticancer agents towards a designated tumor and nontumor cells. MMHH are derived from cryopreserved human hepatocytes isolated from human livers procured for but not used for transplantation provided to our laboratory from the International Institute for the Advancement of Medicine. We have previously demonstrated that MMHH retained all drug metabolizing enzyme pathways present in human hepatocytes. The advantages of MMHH include the following: 1. Drug metabolizing enzyme activities are not affected by cytotoxicity of the drug substrate, a major limitation of intact human hepatocytes; and 2. Drug metabolism pathways can be selected by cofactor specification (e.g. NADPH/NAD+ for phase 1 oxidation; Uridine 5′-diphosphoglucuronic acid (UDPGA) for glucuronidation; 3'-phosphoadenosine 5'-phosphosulfate (PAPS) for sulfation; N-acetyl coenzyme A for N-acetylation). We present here a proof-of-concept study to evaluate the role of various hepatic metabolic pathways towards the cytotoxicity of cyclophosphamide, a commonly used drug for the treatment of renal carcinoma, towards a renal cancer cell line, HEK293 cells. We observed that NADPH enhanced the cytotoxicity, consistent with the known metabolic activation of cyclophosphamide by P450 isoforms (e.g. CYP2B6; CYP3A4) to the known metabolic activation of cyclophosphamide to 4-hydroxycloophosphamide, followed by the formation of the ultimate cytotoxic metabolites phosphoramide mustard and acrolein, which are responsible for its anticancer properties. In addition, we

found that the addition of L-glutathione attenuated cyclophosphamide cytotoxicity towards the HEK293 cells, an observation consistent with the roles of this cellular detoxification system in the resistance of tumor cells to chemotherapeutic agents. Minimal effects were observed for UDPGA and PAPS, consistent with the known noninvolvement of these phase 2 conjugating pathways in cyclophosphamide metabolism. MDCA represents an in vitro experimental system that can be routinely applied towards the discovery and development of novel anticancer drugs to evaluate the roles of drug metabolism in efficacy and safety, with various cancer cells (e.g. prostate carcinoma, neuroblastoma) and cells from normal tissues (e.g. cardiomyocytes, intestinal mucosal cells), respectively, as target cells.

#5339

4-Amino-*N*-phenylbenzamides as dual-targeted mEGFR and AURK inhibitors and anticancer agents

Brianne Rogers, Nicholas Rohde, Justin Mikitaroff, Joshua Matson, Samantha Satawa, Felix Amissah, Sonali Kurup. *Ferris State University, Big Rapids, MI*

Small molecule, mutant epidermal growth factor receptor kinase (mEGFR) inhibitors are rendered ineffective in NSCLC due to mutations within the enzyme binding sites and redundant signaling pathways. The mEGFR inhibitors were found to retain their anticancer effects in NSCLC cells if given concurrently with AURK inhibitors. Dual-targeted small molecules designed to inhibit both mEGFR and AURK could demonstrate improved anticancer effects compared to monotargeted mEGFR inhibitors. We conducted molecular modeling studies to determine if there were similarities between the kinase pockets of mEGFR and AURK that could be exploited to develop dual-targeted mEGFR and AURK inhibitors. An overlap was observed for the active and allosteric sites of the kinase pocket for mEGFR and AURK. A series of compounds were synthesized and evaluated against mEGFR, AURKA, and AURKB. We found the kinase inhibitory profile to vary significantly depending on the substitution pattern ranging from selective mEGFR inhibitors to dual mEGFR and AURK inhibitors. The 4-substituted amino-*N*-phenylbenzamides were identified as dual mEGFR/AURK inhibitors. Dual mEGFR/AURK inhibitors demonstrated varied modes of binding within mEGFR and AURK. The

most potent dual mEGFR and AURK inhibitors displayed nanomolar inhibition of mEGFR and AURK, and single-digit micromolar inhibition of non-small cell lung cancer cells. Target compounds were further evaluated in a 96-kinase screening assay and demonstrated selectivity for target kinases. The synthesis, structure-activity relationship (SAR) analysis and anticancer effects will be presented and discussed.

Data mining of PubChem bioassay data reveals OXPHOS inhibitors with anti-cancer activity

Sejal T. Sharma[1], Liping Feng[1], Nicha Boonpattrawong[1], Lisa M. Barroilhet[1], Manish Patankar[1], Spencer S. Ericksen[2]. *[1]Department of Obstetrics and Gynecology, University of Wisconsin-Madison, Madison, WI,[2]UW-Carbone Cancer Center, Drug Development Core, Small Molecule Screening Facility, University of Wisconsin-Madison, Madison, WI*

High Grade Serous Ovarian Cancer (HGSOC) is a fatal disease that is typically detected at an advanced stage when there are limited modalities for effective treatment. Treatment efficacy against cancer is dependent on tumor metabolism and its adaptation for most therapies. Warburg effect is an important adaptation found in tumors where cells primarily catabolize glucose even in presence of sufficient oxygen and nutrients. Nevertheless, recent evidence suggests cells in tumor microenvironments remain dependent on mitochondrial ATP production via oxidative phosphorylation (OXPHOS). OXPHOS also represents a major metabolic pathway in cancer stem cells and tumor cells of relapse patients. Molecular signatures of glycolysis and OXPHOS are both detected in tumors. This points to the OXPHOS pathway as a potential therapeutic target in cancer. Here we apply a data mining approach to identify OXPHOS inhibitors to evaluate as candidates for therapies against HGSOC. High-Throughput Screening (HTS) on mechanistic targets like OXPHOS are cost prohibitive for academic laboratories. As an alternative, we deployed a data mining pipeline to find active chemical classes among 8415 available OXPHOS-related bioassays in the PubChem data repository. Active compound clusters frequently contain α,β-unsaturated carbonyl groups, which are also observed in both endogenous quinone electron carriers and atovaquone–a potent inhibitor of OXPHOS. Out of 312041 unique compounds tested in

the assays, we selected 6 representative molecules from each of the 6 largest active chemical clusters to test for OXPHOS inhibition, ROS production, and reduced cancer cell proliferation. We assayed cell viability (MTT) to check for proliferation of human (OVCAR3, OVCAR5, OVISE) and mouse (ID8) ovarian cancer cells against 6 compounds, Oryzalin, Allylyestrenol, Esbiothrin, Lacidipine, Coumatetralyl, and CID929419 (MLS000713029), 72 h post treatment. ID8 and OVCAR5 significantly decreased cell proliferation after Lacidipine and Oryzalin treatment. Significant increase in intracellular ROS, a frequent consequence of OXPHOS inhibition, was observed in all cell lines after Lacidipine treatment. Elevated ROS was also observed in ID8 and OVISE cells after Esbiothrin treatment. To confirm OXPHOS inhibition as the mechanism of action, we performed Mito Stress Test on the Seahorse Analyzer and measured Oxygen Consumption Rate. Treatment with Oryzalin, Allylyestrenol, Esbiothrin, and Lacidipine significantly decreased basal respiration rate and ATP production in ID8 and OVCAR3 cells. This suggests that 4 of the 6 compound classes prioritized by the data mining pipeline inhibits OXPHOS in ovarian cancer cells. Thus, our pipeline provides an efficient alternative to HTS for identifying OXPHOS inhibitors. Next, we plan to test the *in-vivo* efficacy of these drugs against ovarian tumors in a mouse model and investigate their molecular mechanisms.

Assessment of polyphenolic secondary metabolites and small molecules against the xenobiotic metabolic and cell cycle regulatory proteins in prostate cancer

Sumit Sheoran[1], Swati Arora[1], Tanmay Basu[2], Naidu Subbarao[3], Atul Kumar Upadhyay[2], Sugunakar Vuree[1]. *[1]Lovely Professional University, Jalandhar, India,[2]Thapar Institute of Engineering & Technology, Patiala, India,[3]Jawaharlal Nehru University, Delhi, India*

Background: Prostate cancer (PCa) is the second most frequent kind of cancer in males globally after Lung Cancer. In clinical practice, medicines that act as antagonists/partial agonists of hormone receptors against prostate tissue are employed in PCa treatment. Cyproterone acetate, Flutamide, and Bicalutamide are prominent medications that induce acute and long-term toxicity and create drug resistance in patients and remission. We

concentrated on flavonoids since they are non-cytotoxic and have substantial showing inhibitory action.
Methodology: We selected 560 flavonoids and small compounds along with 3 targets from the extensive literature review. Three-dimensional (3D) structures of selected proteins were obtained from Protein Data Bank, docked with 560 flavonoids and small molecules 3D structures, obtained from PubChem and CHEMBL database using Gold Docking Software. ADME characteristics were used to determine their bioactivities in the human body and drug-like investigations by using SwissADME and Zinc database, while Lipinski's rule of five was used to evaluate the flavonoids' anti-prostate cancer efficacy. Additionally, we have performed molecular simulation at 100ns and furthermore, we will perform cytotoxicity analysis.
Results: Diosmetin (58.72), Lapatinib Ditosylate (121.61), and Estramustine Phosphate Sodium (143.38) has the highest binding affinity for CDKN2 (4EK3), CYP17A1(3RUK), and CYP19A1(3S79), respectively, and are stable throughout 100ns simulation studies. At present, we are working on cytotoxicity studies on PC3 cell lines. As per the literature review by Ansar et al. 2022 quercetin and thymoquinone induce cytotoxicity in breast, lung, and prostate cancer cells effectively; MCF-7 cells were the most sensitive cells to quercetin with an IC50 value of 50 μM and PC3 cells were more sensitive to thymoquinone with an IC50 value of 20 μM.
Conclusion: As a result of our findings, these four Flavonoids may be viable candidates for additional research into PCa prevention or management.Keywords: Diosmetin, Lapatinib Ditosylatye, Prostate cancer, In-silico, Simulation

Evaluating the screened polyphenolics molecules as potential chemosensitizers against the oncogenic signalling proteins in lung cancer

Swati Arora[1], Sumit Sheoran[1], Tanmayee Basu[2], Naidu Subbarao[3], Atul Kumar Upadhyay[4], Sugunakar Vuree[1]. *[1]Lovely Professional University, Jalandhar, India,[2]Thapar Institute of Engineering & Technology, Patiala, India,[3]Jawaharlal Nehru University, Delhi, India,[4]Thapar institute of Engineering 7 technology, Patiala, India*

Background: Lung cancer is the most commonly diagnosed cancer globally. There are numerous agonists and antagonistic treatment interventions available for therapy. However, all of them possess different detrimental consequences in addition to resistance and remission in sufferers. Medicinal plants have traditionally been employed to treat a wide range of ailments and problems.
Methodology: A total of 550 flavonoids and small molecules retrieved from literature and databases (Chembl, and PubChem) were analysed for molecular docking, biological activities, ADME, and drug-like properties through SwissADME and PreADMET, Molecular Simulation, and cytotoxicity studies. Simultaneously, review literature is employed to identify the novel protein targets viz. ROS1 (3ZBF) & EGFR (6DUK). Additionally, the crystal structures of the proteins were obtained from PDB and their domains and active sites were predicted using ScanProsite, MOTIF Search, metaPOCKET2, and PrankWeb tools. Finally, the proteins and ligands were energy-minimized using Chimera and open babel tool and subjected to virtual screening and molecular docking using GOLD. Furthermore, the molecular simulation was performed at 100ns by utilizing GROMACS, and cytotoxicity studies were performed by employing the A549 Lung cancer cell line.
Results: Diosmin (64.57) and Hesperidin (60.98) had the greatest binding affinity with the identified targets, i.e., ROS1 (3ZBF) and EGFR(6DUK) respectively against Lung Cancer, and remained stable during 100ns of molecular simulation. Furthermore, we have performed cytotoxicity studies on A549 cell lines that show both the compounds have significant anticancer activity and do not affect healthy cells in the range of, i.e., Diosmin (500 µg/ml to 0.024 µg/ml.) and Hesperidin (500 µg/ml to 125 µg/ml).
Conclusion: After the analyses, we can conclude that it has the potential to be exploited as a novel therapeutic agent in the treatment of lung cancer.Keywords: Diosmin, Hesperidin, In-silico, A549, Lung Cancer, Simulation

Novel melanoma leads demonstrate efficacy in A375 xenograft model in nude mice

Dmitriy Minond, Sadeeshkumar Velayutham. *Pharmaceutical Sciences, Nova Southeastern University, College of Pharmacy, Fort Lauderdale, FL*

The purpose of this study was to evaluate efficacy of novel anti-melanoma leads for in vivo efficacy. Despite the recent advances in melanoma therapy, the need for new targets and novel approaches to therapy is urgent. We previously reported novel melanoma leads, 2155-14 and 2155-18, that work via binding and downregulating spliceosomal proteins hnRNPH1 and H2. To determine the therapeutic potential of these compounds we tested them in A375 cell-line derived xenograft in nu/nu mice. For determination of 2155-14 and 2155-18 potency in vivo, nude mice were inoculated subcutaneously with A375 cell line and tumors were allowed to reach $100mm^3$. Animals were then randomized into four groups to receive subcutaneous administration of vehicle, 10mg/kg vemurafenib, and 25mg/kg 2155-14 and 2155-18 three times per week for 15 days. The result revealed that both 2155-14 and 2155-18 significantly decreased the growth of A375 tumors, which was comparable to vemurafenib. These results are well correlated with the exposure of leads in plasma. In summary, these results suggest a therapeutic potential of targeting spliceosomal proteins hnRNPH1 and H2 and support potential of 2155-14 and 2155-18 as drug candidates for treatment of melanoma.

The application of CDK16 inhibitors in the treatment of triple-negative breast cancer
Haihua Xiao, Huangyu Jiang, Kunxian Feng, Mengli Yang, Jinping Yang, Chengfang Jian, Yuan Tian, Natalya Vasilevich, Lichun Sun. *Xiao Haihua (Individual), Shenzhen, China*

Triple-negative breast cancer (TNBC) with estrogen receptor (ER), progesterone receptor (PR) and HER2 (c-erbB-2, neu) being negatively expressed in patient cancer tissues displayed its unique clinical pathological difference from other types of breast cancers. TNBC is more common in younger patients and more likely to have a family history of breast cancer. TNBCs more likely have poor prognosis and postsurgical recurrence, with strong invasiveness and metastasis. However, there is lack of effective and

TNBC-targeting drugs. The non-typical CDK16 was found highly expressed in TNBCs and clearly associated with prognosis and survival of patients. CDK16 could promote the progression and metastasis of TNBC by phosphorylating PRC1. Knockdown of CDK16 could significantly suppress tumor growth and metastasis. Furthermore, in our studies, rebastinib acting as a CDK16 inhibitor displayed its strong suppression of TNBC tumor growth in a dose-dependent manner, indicating rebastinib or its analogs could be druggable and likely used to treat TNBC patients.

Cuozzo[2], Christelle Huguet[8], Shilpi Arora[14]. *[1]X-Chem Inc., Waltham, MA,[2]Relay Therapeutics, Cambridge, MA,[3]Nirogy Therapeutics, Framingham, MA,[4]AstraZeneca, Cambridge, MA,[5]Exo Therapeutics, Watertown, MA,[6]Auron Therapeutics, Waltham, MA,[7]Stablix Therapeutics, New York, NY,[8]Ipsen, Cambridge, MA,[9]DFCI, Boston, MA,[10]Broad Institute, Cambridge, MA,[11]Black Diamond Therapeutics, Cambridge, MA,[12]Cyteir Therapeutics, Lexington, MA,[13]Auron Therapeutics, Cambridge, MA,[14]Transition Bio, Cambridge, MA*

Bispecific degraders (PROTACs) of ERα are expected to be advantageous over current inhibitors of ERα signaling (aromatase inhibitors/SERMs/SERDs) used to treat ER+ breast cancer. Information from DNA-encoded chemical library screening provides a method to identify novel PROTAC binding features as the linker positioning, and binding elements are determined directly from the screen. After screening ~120 billion DNA-encoded molecules with ERα WT and 3 gain-of-function mutants, with and without estradiol to identify features that enrich ERα competitively, the off-DNA synthesized small molecule exemplars

exhibited nanomolar ERα binding, antagonism, and degradation. Click chemistry synthesis on an alkyne E3 ligase engagers panel and an azide variant that rapidly generated bispecific nanomolar degraders of ERα, with PROTACs inhibiting ER+ MCF7 tumor growth in a mouse xenograft model of breast cancer. This study validates this approach toward identifying novel bispecific degrader leads from DECL screening with minimal optimization.

Selective targeting deacetylase 3 (HDAC3) and HDAC8 by PROTACs

Yufeng Xiao, Seth Hale, Nikee Awasthee, Xuan Zhang, Yi Liu, Zhiguang Huo, Dongwen Lyu, Lei Wang, Weizhou Zhang, Megan Mosteiro, Daiqing Liao, Guangrong Zheng. *University of Florida, Gainesville, FL*

Histone deacetylases (HDACs) are enzymes that play an essential role in multiple cellular processes such as DNA transcription, translation, replication, recombination, repair, and metabolism, and their dysregulation can be linked to many different diseases. Most commonly, the overexpression of HDACs is found in various cancer types including hematologic cancers, as well as solid malignancies. Of the many HDACs found in the body, class I HDACs, which consist of HDACs 1, 2, 3, and 8, play an essential role in activating oncogenes underlying tumorigenesis, disease progression, and treatment resistance. Several HDAC inhibitors (HDACis) have been approved for cancer treatment, however, they are pan-inhibitors. This lack of specificity poses many disadvantages for HDACis, including toxicity and other off-target effects. Isozyme-selective inhibitors may reduce these off-target effects and thus enhance their safety. Though favorable, selectivity is difficult to achieve from conventional inhibitors due to the highly homologous catalytic domain among HDAC isozymes. In addition, several HDAC isozymes have deacetylase-independent scaffolding functions that cannot be blocked by traditional inhibitors. Recently, there have been advances in Proteolysis Targeting Chimera (PROTAC), an emerging drug discovery technology designed to hijack cell's existing protein degradation machinery, the ubiquitin-proteasome system (UPS) to selectively degrade target proteins. Selective degradation by PROTAC is a potential solution to many of the concerns associated with current HDACis. Previously, we reported an HDAC3-selective PROTAC, XZ9002, and following that we reported the discovery of PROTAC YX968,

which can degrade both HDAC3 and HDAC8 isozymes with single-digit nanomolar DC_{50}, this highly potent dual degrader exhibits distinct effects on modulating gene expression and is much more potent in inhibiting cancer cell proliferation compared to XZ9002. Based on this, we are further modifying the PROTACs to be selective for HDAC8. The HDAC3, HDAC8 selective degrader and HDAC3 and HDAC8 dual degrader we developed could be useful chemical probes to dissect the complex biological function of HDAC3 and HDAC8 and potential therapeutics for treating cancer.

Targeting MEK, alone and in combination with BRAF, in metastatic $BRAF^{K601E}$-mutated melanoma

Sze Man Chan, Sin Ting Chow, Sai Fung Yeung, Kwok Wing Stephen Tsui.
School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, China

Mitogen-activated protein kinase/ERK signaling pathway has been one of the major mechanisms underlying melanoma haboring BRAF mutation. Of these, K601E mutation belongs to a rare mutation sub-type, comprising only 3% of the BRAF mutations in melanoma. Although patients with BRAF V600E/K mutation respond to MEK inhibitor, whether it also applies to those with BRAF K601E mutation remains elusive. Here, we examined the effects of MEK and BRAF/MEK inhibition on $BRAF^{K601E}$-expressing melanoma cells. Melanoma cell line (MeWo) was transfected with doxycycline-inducible vector encoding wild-type or K601E-mutant BRAF. Subsequently, cells or xenograft-bearing mice were treated with trametinib, dabrafenib plus trametinib or sorafenib plus trametinib. Compared with $BRAF^{WT}$, MTT assay demonstrated that $BRAF^{K601E}$ cells were more sensitive towards drug treatment. The effects of combined treatment were more profound. Tumorigenicity assay showed that trametinib treatment inhibited tumor growth of $BRAF^{K601E}$ xenografts. Our preliminary results demonstrated the therapeutic values of MEK and BRAF/MEK inhibitors against $BRAF^{K601E}$-mutated melanoma. As previous studies report the superior therapeutic effects of BRAF/MEK inhibitors over MEK inhibitor alone, phenotype characterization of the

cells, as well as underlying mechanisms behind such response, worth further investigation.

Isoandrographolide derivative, (3,19)-4-Bromobenzylidene-isoandrographolide induces apoptosis and causes loss of mitochondrial membrane potential in ER positive Breast cancer

Balasubramanyam Karanam[1], Nitesh Tamang[2], Yashwanth Inabathina[1], Sai Kiran Mavileti[3], Lakshminath Sripada[2], Srinivas Nanduri[4], Nageswara Rao Golakoti[3]. *[1]Tuskegee University, Tuskegee, AL,[2]Sri Sathya Sai Institute of Higher Learning, Puttaparthi, India,[3]Chemistry, Sri Sathya Sai Institute of Higher Learning, Puttaparthi, India,[4]National Institute of Pharmaceutical Education and Research, Hyderabad, India*

Natural product, Andrographolide.is diterpene lactone extracted from Andrographis paniculata. In traditional form of medicine, it is being used in India, China and Malaysia for treating various diseases. While in the last two decades there are many reports on andrographolides and its derivatives with various biological activities such as anti-cancer and anti-inflammatory. We synthesized compounds along with isoandrographolide were characterized and tested for their anticancer activity against 60 cancer cell line at NCI. Most compounds were found to be active against leukemia and breast cancer with (3,19)-4-Bromobenzylidene-isoandrographolide having best growth inhibition of 76.90% and 87.54% against leukemia (MOLT-4) and breast cancer (BT-549) respectively. Upon further testing compound (3,19)-4-Bromobenzylidene-isoandrographolide was found to be more activate than the tamoxifen against MCF-7. Compound (3,19)-4-Bromobenzylidene-isoandrographolide arrested cell cycle at G1-Phase of MCF-7 and was observed to be inducing apoptosis and loss of mitochondrial membrane potential. We discuss our studies on crystal structure, cell cycle progression assay, apoptotic studies on ER-positive breast cancer MCF-7.

Naringin nanoparticles inhibit metastasis of lung cancer through TGF-β1-smad2/3 signaling pathway

Wen Chen. *Jiangxi Science and Technology Normal University, Nanchang, China*

Lung cancer causes high mortality due to its high metastasis. Naringin is a naturally occurring flavonoid that is widely found in the various citrus fruits. Naringin is known to have several therapeutic effects including anticancer, anti-pulmonary fibrosis, antimicrobial, anti-inflammatory. However, low bioavailability and solubility of naringin limit its application. This project designed a thermosensitive naringin nanoparticle to investigate whether it might inhibit metastasis of lung cancer by inhibiting TGF-β1-smad2/3 signaling pathway. Cells were treated with various concentrations of naringin nanoparticles and unwrapped naringin for 48 hours. Naringin nanoparticles of 100μmol/L showed obvious inhibitory effect on the larger wound surface of cultured human cancer cells. Westerm blot was used to detect the expression of P-Smad2 , Smad2,and α-SMA in A549 cells. The results showed that naringin significantly reduced the expression of EMT-related protein α-SMA in A549 cells in a concentration-dependent manner. Naringin nanoparticles can reverse the EMT process. naringin nanoparticles can inhibit the expression of P-Smad2 protein in A549 cells, which may play a role in inhibiting lung cancer through TGF-β1/Smad signaling pathway.The animal experiment was performed. The mice were given various concentrations of naringin nanoparticles and unwrapped naringin by IV. the protein expression levels of α-SMA, TGF-β1 and P-Smad3 in mice lung tissue were detected by immunohistochemistry. The results showed that naringin nanoparticles 50um/ml,0.2mL/day/time had significant effect on the inhibition of lung cancer tissue migration, and the different doses of naringin nanoparticles showed a certain dose-dependent trend. The expression of TGF-β1 and P-Smad3 in mice treated with naringin nanoparticles was significantly decreased, suggesting that naringin nanoparticles could inhibit the migration of lung cancer cells by inhibiting TGF-β1/Smad pathway.

Changes in the transcriptome of a triple negative breast cancer cell line following treatment with a water-soluble extract from the leaves of the

indigenous Southern African plant *Tulbaghia violacea*

Zodwa Dlamini[1], Rodney Hull[1], Mohammed Alouna[2], Clement Penny[2].
[1]Pan African Cancer Research Institute, University of Pretoria, Hatfield, South Africa,[2]University of the Witwatersrand, Johannesburg, South Africa

Triple negative breast cancer (TNBC) accounts for approximately 20% of all breast cancer cases. And is defined by the absence of oestrogen, progesterone, and human epidermal growth factor 2 receptors. This makes it difficult to treat and leads to a low five-year survival rate. In South Africa a large percentage of the population still relies on traditional medicine based on the use of medicinal plants. One of these plants, African garlic (*Tulbaghia violacea),* that has been used to treat symptoms similar to that observed in cancer. However, the usefulness of these treatments has yet to be clinically proven. Previous studies have revealed that the water-soluble extract from the leaves of *T. violacea* had anticancer activity against a TNBC cell line. In order to identify the signalling pathways involved in this anti-cancer activity whole transcriptome sequencing was performed using RNA extracted from both TNBC and normal breast cells before and after treatment with the water-soluble *T. violacea* extract. Paired end sequencing was performed at a depth of 10 million bases for 300 cycles. Data analysis was performed using the Galaxy platform/ Sequencing results led us to perform an antibody array assay for proteins involved in the receptor tyrosine kinase pathway. In line with the increased levels of apoptosis previously observed following treatment of the TNBC cell line with the extract, there was an increase in the transcription of genes associated with apoptosis. Decreases were observed in the transcription of genes involved in growth receptor signalling, angiogenesis, and cancer related pathways such as the Wnt, Notch and the PI3K pathway. This work highlights the pathways affected by compounds present within a water-soluble extract of the leaves of *T, violacea.* Combined with the results of our [previous work, this indicates that the compounds isolated from *T, violacea* could serve as lead compounds for the development of future therapeutic treatments for TNBC.

Berberine and emodin synergistically suppress the EGFR signaling cascade by targeting LAMB3 in pancreatic ductal adenocarcinoma

CAIMING XU[1], SILEI SUI[1], Keisuke Okuno[1], Silvia Pascual-Sabater[2], Cristina Fillat[2], Ajay Goel[1]. *[1]Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of City of Hope, Monrovia, CA,[2]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain*

Background: Pancreatic cancer is one of the most devastating malignancies due to the development of intrinsic chemoresistance following chemotherapy. Extracellular matrix (ECM) proteins are intimately linked to cellular proliferation, invasion, and acquisition of chemoresistance in PDAC cells, making them promising therapeutic targets in this malignancy. Naturally occurring dietary botanicals, including berberine (BER) and emodin (EMO), have been shown to suppress ECM as one of the mechanism(s) for their anti-tumorigenic activity, along with their time-tested safety and cost-effectiveness. In addition, both BER and EMO are also known to induce apoptosis by modulating different pathways and regulating pro-apoptotic genes. Herein, we hypothesized that combined treatment with BER and EMO might exhibit synergistic anticancer efficacy by targeting the ECM and apoptotic pathways in PDAC cells.
Methods: We undertook genomewide transcriptomic profiling analysis to identify critical ECM-related genes differentially expressed in PDAC. Subsequently, the TCGA dataset was analyzed to identify the prognostic significance of ECM-associated genes with overall survival (OS) and disease-free survival (DFS) in PDAC. A series of cell culture experiments were performed using PDAC cells, followed by their validation in patient-derived organoids to examine the synergistic anti-proliferative and chemopreventive effects of BER and EMO against PDAC.
Results: Transcriptomic profiling identified that LAMB3 expression was significantly upregulated in PDAC tissue ($P < 0.01$) and was significantly associated with poor OS and DFS in PDAC patients ($P < 0.01$). The combination of BER and EMO displayed superior synergistic anti-tumor potential in PDAC cells vs. individual compounds, as revealed by cell proliferation, clonogenicity, migration, and invasion assays. The combination of BER and EMO also altered the expression of key proteins involved in cellular apoptosis, epithelial-mesenchymal-transition, and EGFR/ERK//AKT growth factor signaling pathways. Finally, these findings were successfully validated in PDAC patient-derived 3D organoids.

Conclusions: We provide the first evidence that combined treatment with berberine and emodin exerts synergistic anti-cancer activity in PDAC, primarily regulated through the LAMB3-mediated interaction with other members of the EGFR-signaling pathway.

#3822

Novel evidence for the role of the p53 signaling pathway in mediating the anticancer effects of aronia berry extract in colorectal cancer cells

Yoh Asahi[1], Keisuke Okuno[1], Caiming Xu[1], Aknobu Taketomi[2], Ajay Goel[1]. *[1]Beckman Research Institute of The City of Hope, Monrovia, CA,[2]Department of Gastroenterological Surgery I, Hokkaido University Graduate School of Medicine, Sapporo, Japan*

Background: The development of safe and effective novel agents remains a critical challenge for improving the prognosis of patients with unresectable colorectal cancer (CRC). Natural products containing polyphenols can be a good source of anti-cancer agents for their potential effect on multiple signaling pathways with anti-cancer effect. Due to its rich polyphenols content, Aronia berry extract (ABE) is gaining increased attention as an anti-cancer agent with its protective effect against cancer cells, including CRC, exerting potent antioxidant and antiproliferative effects. Thus, we hypothesized that ABE could be a novel complementary therapeutic option in patients with CRC by virtue of its ability to modulate multiple key cancer-related pathways.
Methods: First, an MTT assay was performed to prove the antiproliferative effect of ABE in two CRC cells, SW480 and HCT116, and IC_{25} and IC_{50} of ABE in both CRC cells were identified. Next, the anti-cancer effects of ABE were examined by wound healing, colony formation, and invasion assays. Apoptosis studies were performed using the Muse Annexin V & Dead Cell Assay Kit on the muse cell analyzer. RNA-sequencing was performed to clarify the critical regulatory genes and pathways modulated by ABE by comparing genome-wide profiling between CRC cells with and without ABE treatment.
Results: Results of the MTT assay revealed that ABE decreased the viability of both CRC cells, and the IC_{25} and IC_{50} of ABE were 80.0 μg/mL and 130.0 μg/mL for SW480 and 80.0 μg/mL and 140.0 μg/mL for

HCT116. ABE inhibited proliferation, migration, cellular survival, and invasion of CRC cells and induced apoptosis in those cells (SW480 control vs. IC_{25}: $p<0.05$, control vs. IC_{50}: $p<0.01$, HCT116 control vs. IC_{25}: $p<0.01$, control vs. IC_{50}: $p<0.01$). After ABE treatment, the genome-wide transcriptomic analysis identified 439 differentially expressed genes ($p<0.05$ and $|log2FC|>0.5$) in both CRC cells. These differentially expressed genes were used for pathway analysis and some critical cancer-related pathways, including the p53 signaling pathway ($p=0.005$, fold enrichment 3.8), NF-kappa B signaling pathway ($p=0.030$, fold enrichment 2.7), Hippo signaling pathway ($p=0.037$, fold enrichment 2.2), and MAPK signaling pathway ($p=0.011$, fold enrichment 2.0), were detected as significantly activated or suppressed pathways.
Conclusions: We have investigated the anti-cancerous effect of ABE in CRC cells and identified multiple critical cancer-related pathways modulated by ABE, with the p53 signaling pathway as the key mediator for growth suppressive anti-cancer efficacy of this naturally occurring phytochemical. Our findings provide evidence for the use of ABE as a safe and effective complementary and integrative medicine approach against CRC.

#3823

Therapeutic potential of plant-derived nanovesicles for neuroendocrine prostate cancer

Amritha Sreekumar, Matthew Simmons, Tae Jin Lee, Ashok Sharma, Sharanjot Saini. *Augusta University, Augusta, GA*

Background: Neuroendocrine prostate cancer (NEPC) is a highly lethal variant of prostate cancer (PCa) that often emerges after androgen receptor (AR)-targeted therapies such as enzalutamide and abiraterone. NEPC arises via trans-differentiation of prostate adenocarcinomas to neuronal lineage, a process referred to as ‘neuroendocrine trans-differentiation’ (NED), wherein prostate cancer cells show an altered expression of lineage markers such as decreased expression of AR and increased expression of neuronal markers. Currently, there is a lack of effective targeted therapies for NEPC. Current treatment options are limited to highly toxic platinum-based drugs. Hence, there is an urgent need to develop novel treatment strategies to treat NEPC. The focused objective of this study is to develop novel, non-toxic

therapeutic intervention against NEPC. Towards this, we exploited the potential of plant-derived nanovesicles/extracellular vesicles as a novel therapeutic. Extracellular vesicles (EVs) are lipid-bilayer-delimited particles that are released from almost all types of cells, including plant cells, typically between 30-150 nm in size.
Methods: EVs/nanovesicles were isolated from plant-derived sources by ultracentrifugation. Isolated nanovesicles were characterized by Nanoparticle Tracking Analyses and electron microscopy. After characterization, the effects of nanovesicles were tested in NEPC cell lines *in vitro.* Effects on cell viability and apoptosis were assessed by MTS assay and flow cytometry, respectively. To understand the mechanistic basis of EV induced alterations, next generation RNA sequencing was performed in control vs EV treated NCI-H660 cells on Illumina HiSeq platform. Significant targets were further validated by real time PCR and Western blot analyses.
Results: Plant-derived nanovesicles reduced viability and induced apoptosis in NEPC cell lines. Genes involved in ECM-receptor interaction, focal adhesion, proteoglycans in cancer and small cell lung cancer genes were significantly impacted by these vesicles in NEPC cell line. Remarkably, nanovesicles led to significantly attenuated levels of key proneural transcription factors including ASCL1, BRN2 and SOX2. In addition, neuronal markers ENO2 and NCAM1 were downregulated suggesting that treatment with nanovesicles reverse the 'cardinal' genetic alterations that drive NEPC.
Conclusion: Plant-derived nanovesicles can be employed as a novel treatment modality in neuroendocrine prostate cancer.

Remodeling of anaplastic thyroid cancer cell signaling and immune landscape by natural alkaloid berberine
Tara Jarboe, Kaci Kopec, Nicole R. DeSouza, Jan Geliebter, Raj K. Tiwari, Xiu-Min Li. *New York Medical College, Valhalla, NY*

Anaplastic thyroid cancer (ATC) is universally diagnosed as Stage IV with a five-year-survival of 4%, illuminating its dreadful prognosis. ATC is undifferentiated, has an inflammatory tumor microenvironment (TME), and metabolic dysregulation. As it is refractory to all established therapies, we

propose a novel therapeutic - Berberine (BBR), a natural plant alkaloid, with numerous cellular targets that can potentially reprogram ATC's aggressive phenotype. This research comprehensively examines the multitarget efficacy of BBR. Following initial dose response studies, all assays used 100μM concentration of BBR or DMSO vehicle control for 24-hour exposure. To model the ATC tumor microenvironment, monocyte cell line U937 cells were activated and polarized into a proinflammatory macrophage phenotype. In the presence of berberine at the activation and polarization stages, 33 soluble inflammatory mediators were downregulated in the conditioned media compared to controls. Targeting the aggressiveness of anaplastic disease, berberine slowed proliferation by 50% selectively in ATC cells from 48 to 72 hours, while sparing the immortalized normal thyroid cells. BBR also delayed wound healing by 30% in ATC cells after 24, 48, and 72 hours. These observations were substantiated by Western blot analysis of ATC and immortalized normal cells where BBR decreased phosphorylation of MEK, ERK, and ribosomal protein S6, crucial downstream regulators of the pro-proliferative and pro-survival pathways and increased phosphorylation of AMPKα, activating its anti-tumor and regulatory effects. Validation of *in vitro* findings via RNA-Seq was conducted by Genewiz from Azenta Life Sciences and Qiagen's Ingenuity Pathway Analysis was used for *in silico* modeling. Greater than 400 significantly differentially expressed genes were identified suggesting that BBR regulates mitochondrial metabolism, cholesterol biosynthesis, glycometabolism, apoptosis, inflammation, and proliferation. BBR's ability to alleviate inflammatory mediators in the TME, depress overactive cell signaling, and regulate metabolism to make it a more targetable cancer reveals it as an interesting candidate to prime ATC for combination therapy.

Andrographis reverses gemcitabine-associated chemoresistance by regulating calcium signaling in pancreatic ductal adenocarcinoma

Keisuke Okuno[1], Caiming Xu[1], Masanori Tokunaga[2], Cristina Fillat[3], Haiyong Han[4], Yusuke Kinugasa[2], Ajay Goel[1]. *[1]Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of The City of Hope, Monrovia, CA,[2]Gastrointestinal Surgery, Tokyo Medical and Dental University, Tokyo, Japan,[3]Institut d'Investigacions Biomèdiques August Pi i*

Sunyer (IDIBAPS), Barcelona, Spain,[4]Molecular Medicine, The Translational Genomics Research Institute, Phoenix, AZ

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the lethal malignancies due to the acquisition of intrinsic or acquired resistance to chemotherapeutic drugs, such as Gemcitabine (Gem). Recent evidence revealed that calcium signaling significantly contributes to Gem-associated chemoresistance (Gem resistance) in PDAC cells. Andrographis, a labdane diterpenoid isolated from the traditional herb *Andrographis paniculate*, is known to have a potent calcium channel-blocking potential. Accordingly, we hypothesized that Andrographis might facilitate the reversal of Gem resistance in PDAC.
Methods: The critical regulatory pathways associated with the Gem resistance in PDAC were identified by analyzing publicly available cell line-based transcriptomic profiling. Gem resistant (Gem-R) PDAC cells (Gem-R MIA PaCa-2 and BxPC-3) were established by continuously culturing cells with Gem. A series of cell culture experiments were performed using Gem-R PDAC cells to evaluate the Andrographis-mediated reversal of Gem resistance in PDAC cells. At last, the cell culture findings were validated in patient-derived PDAC organoids.
Results: Transcriptomic profiling identified the calcium signaling pathway as one of the key regulators of Gem resistance (Fold enrichment: 2.8, P =0.002). The combination of Andrographis and Gem revealed a superior anti-cancer potential in Gem-R PDAC cells on cell viability, clonogenicity, and migration compared to individual treatments with Andrographis or Gem. The combined treatment potentiated cellular apoptosis in Gem-R MIA PaCa-2 (Andro, Gem vs. Combination, 20.3%, 10.9% vs. 31.4%) and Gem-R BxPC-3 (Andro, Gem vs. Combination, 11.3%, 6.8% vs. 16.1%). The fluo-4 assay demonstrated that Andrographis decreased intracellular calcium concentration in Gem-R PDAC cells, while the combined treatment with Andrographis and Gem decreased its concentration more in Gem-R MIA PaCa-2 (fold change [FC] =0.79 vs. Andrographis; FC =0.54 vs. Gem) and Gem-R BxPC-3 (FC =0.80 vs. Andrographis; FC =0.73 vs. Gem). Finally, the combined treatment with Andrographis and Gem showed anti-cancer activity in patient-derived PDAC organoids.
Conclusions: We have firstly investigated the Andrographis-mediated reversal of chemoresistance against Gem in PDAC cells, possibly through

the regulation of cellular apoptosis and calcium signaling, using a systematic series of Gem resistant cell cultures and patient-derived tumor organoid models. Our findings could provide evidence of the combined treatment with Andrographis and Gem as a complementary therapeutic modality against PDAC.

#3826

Potency of cardiac glycosides by structure in organotypic models of pancreatic and ampullary carcinomas

Md Shahadat Hossan[1], Ethan Lin[2], Austin Stram[1], Jamie Warner[2], Luke Koeppel[2], Ellie Riedl[2], Jeremy Kratz[1]. *[1]Department of Medicine, University of Wisconsin-Madison, Madison, WI,[2]University of Wisconsin-Madison, Madison, WI*

Background**:** Organotypic models have emerged as an important preclinical model for developmental therapeutics in pancreatic and biliary cancer. Naturally derived cardiac glycoside in 2D monoculture exquisite potency, here we describe their activity in cancer and normal liver with patient-derived cancer organoids (PCOs).

Methods: PCOs of pancreatic and ampullary cancers and normal hepatic tissues were generated. Response was assayed with four structurally different cardiac glycoside (cerberin, neriifolin, digitoxin, digoxin; 72h). Response was characterized by growth inhibition (GI_{50}) using 3D CellTiterGlo (CTG) and subclonal population response by high content imaging using normalized change in diameter (n=1038).

Results: Dose response revealed improved potency for cerberin and neriifolin, versus digoxin and digitoxin across models (see table). In a normal liver organoid model, there was no convergence in dose response observed when extended to 1uM of each cardiac glycoside. Ampullary PCO response was assayed using subclonal population analysis. Cerberin at 10nM achieved growth arrest across the population as assayed by median Δ diameter (growth +4.0±32.0, GΔ=0.94, $p<0.005$). Neriifolin at 10nM had subclonal with residual growth representing 72% of overall population as assayed by Δ diameter (growth +18.3%, GΔ=0.65). Traditional cardiac glycosides of digoxin and digitoxin at 10nM had significant portions with residual growth (94.9% and 84.7%, respectively) as well as did not achieve meaningful effect (GΔ=-0.10 and GΔ=0.05, respectively).

Conclusions: CGs have varied potency for anticancer activity between different structural motifs. Cerberin induce population growth arrest in cancer models which differed from normal liver. This work requires dedicated mechanistic modeling to explain differences in anti-cancer activity that may confer sensitivity and in considering models of cardiac toxicity.

Potency of Cardiac Glycosides in Organoid Models.

	GI_{50} (nM) Ampullary	GI_{50} (nM) Pancreatic	GI_{50} (nM) Normal Liver
Cerberin	7.4	7.20	71.0 (NC)
Neriifolin	10.2	7.4	62.0 (NC)
Digoxin	29.6	47.9	55.5 (NC)
Digitoxin	NC	40.0	85.5 (NC)

Schinus terebinthifolius extracts impair migration of BT549 triple negative breast cancer cells _in vitro_

Alexis Tapanes-Castillo[1], Mariacira Di Santi[1], Abel Sousa[1], Jonathan M. Brown[1], Paola M. Gonzalez Rodriguez[1], Thiago P. Leal[1], Leticia Saladrigas[1], Vadym Trokhymchuk[1], Leonardo M. Soto Chumpitaz[1], Andrea Peterson[1], Susana Gutierrez[1], Rolando J. Petit[1], Carlos Planchart[1], Christian Del Corro[1], Daniela A. Ramos[1], Valeria Nazaire[2], Sean Mondesire[3], Maria Pina[1]. *[1]College of Health Sciences and Technology, St. Thomas University, Miami Gardens, FL,[2]School of Science, Miami Dade College, Miami, FL,[3]Institute for Simulation and Training, University of Central Florida, Orlando, FL*

Bark extracts, derived from the Brazilian peppertree (*Schinus terebinthifolius*) were tested on BT549 triple negative breast cancer cells, a model system for invasive, metastatic cancers. Crude extracts, prepared with a 50% ethanol-50% water solvent, were investigated for cytotoxicity and effects on cell migration *in vitro*. Extract-treated cells exhibited statistically significant slower migration velocities than untreated control cells. Crude bark extracts, screened at a concentration of 3.15mg/mL in five

independent experiments, produced an approximate 80% decrease in average migration velocity ($p<0.05$ in every experiment). Three independent tetrazolium based MTT cytotoxicity experiments confirmed that cells exposed to the same 3.15 mg/mL crude extract concentrations displayed similar viability as untreated control cells. Interestingly, these data suggest the Brazilian peppertree bark extract harbors bioactivity that impairs BT549 cell migration without cytotoxic side effects. Current experiments aim to discover which bioactive molecules, present in the crude extract, impede cancer cell migration. Silica-based column chromatography was used to separate the crude extract into fractions of increasing polarity. A wet method, which commenced with hexane, followed by dichloromethane, methanol, ethanol, ethyl acetate, and butanol, was employed. Fractions which retained anti-migratory activity were identified. Gas chromatography Mass Spectrometry (GCMS) was performed on crude extracts, samples with strong anti-migratory activity, and samples with weak anti-migratory activity, solubilized with ethanol, methanol, and acetonitrile. Data from two independent, complete sets of experiments, involving column chromatography, cellular assays with fractionated extracts, and GCMS, replicated results. Compounds that were unique to specific samples, as well as compounds that were found in multiples samples were identified. *Rstudio* software was utilized to organize and visualize data. This work lays down the preliminary foundation for future experiments testing specific purified forms of candidate molecules present in Brazilian peppertree bark extracts for the ability to limit BT549 cancer cell migration *in vitro*. Furthermore, Western blotting and immunocytochemistry experiments are underway to determine cellular signaling pathways targeted by the extract. Funding was provided by St. Thomas University's Summer Research Institute and U.S. Dept. of Education STEM grants P03C110190, P031C160161, and P031C210035.

Herbal extracts from lycii radicis corex and achyranthes japonica prevent multiple myeloma progression

Syed Hassan Mehdi[1], Sun-OK Lee[2], Dam Huh[3], Donghoon Yoon[1].
[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]Food Science, University of Arkansas, Fayetteville, AR,[3]Dongwoodang Pharmacy Co., Yeongchen, Korea, Republic of

Multiple Myeloma (MM) is a plasma cell malignancy that, despite advances in treatment, remains incurable. In over 90% of MM patients, aberrant bone remodeling occurs and results in osteolytic lesions. Korean traditional medicine has a long-standing interest in healthy foods to enhance the immune system, energy-boost, and Yin-and-Yang balance. Traditional medicine has used herbal extracts (HE) from natural plants with fewer side effects and long-term treatment tolerance. In earlier studies, lycii radices cortex (LRC) and achyranthes japonica (AJ) containing HE have demonstrated the ability to enhance cell growth and mineralization of osteoblast cells while also inhibiting osteoclast differentiation. The current study investigated the effects of LRC+AJ containing HE on murine 5TGM1 MM-bearing mice.This HE significantly increased the mouse survivals of both Treatment before Transplant (TbT) and Treatment after Transplant (TaT) groups with median survivals of undetermined and 52.5 days, respectively, while MM control had a median survival of 42 days. The Mantel-Cox test found that TbT and TaT mice were significantly different from the control group (P=0.0014 and 0.0182, respectively). In histomorphometric analysis, the spines were scanned by micro-CT and revealed that TbT and TaT groups had significantly increased bone volume over total volume (BV/TV) than control. To see if HE affects cell growth of myeloma cells and osteoblast cells, we further investigated the HE on preosteoblast cell line MC3T3-E1, mouse MM cell line 5TGM1-Luc, and human MM cell line U-266. Cells were treated with HE, and viability was assessed at 48 and 96 hours post-treatment. Remarkably, LRC+AJ containing HE increased MC3T3-E1 cell growth while it decreased 5TGM1 and U-266 cell viability. In addition, we found the DAP3G in HE used in this study.Our results demonstrated that LRC+AJ HE prevents MM and promotes bone formation in 5TGM1 engrafted NSG mice. We also found that LRC+AJ HE suppresses myeloma cell growth and enhances osteoblast cell survival. Although it is yet to be defined, a correlation of osteoblast activity and myeloma cell inhibition suggests a possible connection of these events to prevent MM progression.

Antioxidant and antiproliferative activities of *Ipomoea cairica* extracts on three breast cancer cell lines

Ayodeji Mathias Adegoke[1], Doreen Kulabako Kyagaba[1], Nomonde Hadebe[1], Nandi Mabaso[1], Relebohile Patricia Lefojane[2], Himansu Baijnath[3], Oyeronke Adunni Odunola[4], Mamello Patience Sekhoacha[1].
[1]Pharmacology, University of the Free State, Bloemfontein, South Africa,[2]Department of Health Sciences, Central University of Technology, Bloemfontein, South Africa,[3]School of Life Sciences, University of KwaZulu-Natal, Durban, South Africa,[4]Department of Biochemistry, University of Ibadan, Ibadan, Nigeria

Introducti**on:** Breast cancer was the top cause of cancer deaths in 2020 with a death toll of 685 000 worldwide. Breast cancer treatments are based on drug specificity for unique receptors on the surface of some breast cancer types, there is a search for alternative treatments that are inclusive of different breast cancer types. Evidence suggests that antioxidants offer a protective effect against certain cancers. Studies on *Ipomoea cairica* have reported potential anticancer activity, hence this study aimed to assess the antioxidant and antiproliferative potentials of the extracts of *Ipomoea cairica* on three breast cancer cell lines.
Materials and Methods- The study protocol was approved by the University of the Free State Health Sciences Research Ethics Committee (HSREC), with approval number: UFS-HSD2022/0353/2607-0001. *Ipomoea cairica* stem and leaves were harvested and identified by Prof. H. Baijnath, Department of Conservation Science, School of Life Sciences, University of KwaZulu-Natal, Durban, South Africa, with specimen number 29 30 DD housed at the Ward Herbarium. The dried plant was extracted sequentially using organic solvents ranging from non-polar to polar and water. The extracts were filtered and concentrated using a rotary evaporator and then evaporated to dryness/lyophilized. Cells were cultured according to standard established procedure. The extracts were subjected to phytochemical analyses. FRAP, DPPH, and ABTS assays were done to examine antioxidant activity and MTT assays were used to evaluate the antiproliferative/cytotoxicity of the extracts against normal (Vero) and breast cancer cell lines (MCF-7, MDA-MB-231, and 4T1).
Results and Discussion- Extracts of *Ipomoea cairica* possess alkaloids, saponins, phenols, flavonoids, phytosterols, tannins, triterpenoids, and anthraquinones. The results from the DPPH and ABTS assays revealed that

the methanol and ethyl acetate fractions had significantly the highest antioxidant potentials while the methanol stem extract exhibited the most significant antioxidant activity in the FRAP assay. The DCM stem extract showed the highest antiproliferative activity against all tested cell lines. **Conclusion-** Extracts of *I. cairica* possess significant antioxidant properties and antiproliferative activities against a wide array of breast cancer types including the most challenging triple-negative breast cancer. The plant would make for a strong herbal candidate for adjuvant therapy with breast cancer medication.

#3830

The anticancer activity of a water-soluble extract from the leaves of the indigenous Southern African plant *Tulbaghia violacea* against a triple negative breast cancer cell line

Rodney Hull[1], Zodwa Dlamini[1], Clement Penny[2], Mohammed Alaouna[2].
[1]SA-MRC Precision Oncology Research Unit (PORU); Pan African Cancer Research Institute (PACRI), DSI/N, University of Pretoria, Pretoria, South Africa,[2]Department of Internal Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

Triple negative breast cancer (TNBC) is difficult to treat and leads to a low five-year survival rate.In South Africa, a sizable percentage of the population still relies on traditional plant-based medicine. One of these plants, *Tulbaghia violacea),* has traditionally been used to treat cancer. In order to establish the usefulness of both methanol and water-soluble extracts from the leaves of this plant, extracts were used to treat a TNBC cell. Cytotoxicity assays were carried out to establish the IC50 values against the TNBC cell line. These concentrations were used to carry out assays to study the ability of these extracts to inhibit cell migration, invasion, as well as the effect of these extracts on the cell cycle and their ability to induce apoptosis in these cells. Finally, the antioxidant activity of these cells was assayed. The IC50 values for the water and methanol soluble extracts was determined to be 400 and 820 µg/mL respectively. Due to the high IC50 value and inconsistent performance of the methanol soluble extract, further studies focussed on the water-soluble extract. Treatment of the TNBC cells with the water-soluble extract led to an increase in apoptosis, with the extract causing approximately 82% of the

TNBC cells to undergo apoptosis compared to only 32% of the normal breast cells. This extract also significantly decreased the ability of the TNBC cells to migrate or penetrate abasement membrane in scratch and invasion assays. These results demonstrate that the water-soluble extract from *T. violacea* leaves contains compounds that are able to preferentially induce apoptosis in TNBC cells while also inhibiting the ability of these cells to metastasize. The exact molecular make up of this extract will need to be determined on order to develop the extract as a potential therapy for TNBC.

#3831

The molecular composition of a water-soluble extract from the leaves of the indigenous Southern African plant *Tulbaghia violacea* that displays anti-cancer activity against a triple negative breast cancer cell line

Mohammed Alaouna[1], Clement Penny[1], Rodney ulll[2], Zodwa Dlamini[2].
[1]Department of Internal Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa,[2]SA-MRC Precision Oncology Research Unit (PORU); Pan African Cancer Research Institute (PACRI), DSI/N, University of tPretoria, Pretoria, South Africa

Approximately 20% of all breast cancer cases are Triple negative breast cancer (TNBC), whichis more difficult to treat and has a higher mortality rate than other types of breast cancer. Thereis an active practice of traditional medicine in in South Africa, in the form of infusions madeusing plant material. Previously we demonstrated that water soluble extracts from the leaves ofone of these plants, African garlic (*Tulbaghia violacea),* is able to induce apoptosis in TNBCcell lines, while also inhibiting the ability of these cells to migrate or penetrate a basementmembrane. In an attempt to isolate the molecular compounds that are present in this extract,water soluble leaf extracts were subjected to Fourier transform infrared spectroscopy (FITR),Gas chromatography–mass spectrometry (GC-MS) and Nuclear magnetic resonance (NMR)spectroscopy. Identified compounds of interest were then used in computational dockingstudies with the anti-apoptotic protein Cox2. The FITR analysis indicated that the extractconsisted of multiple compounds, belonging to a variety of classes. GC-NS and NMRspectroscopy identified 36 and 61 separate compounds respectively. Many of these compoundswere similar in structure to

compounds with known anti-cancer properties. Many compoundswith established medical uses were also identified in the extract. Five compounds identified inthe extract, d-Glycero-d-galacto-heptose, H-Pyran-4-one, 2,3-dihydro-3,5-dihydroxy-6-methyl, and Benzaldehyde and 4-(1-methylethyl)- demonstrated high binding affinity towardsCOX2. With d-Glycero-d-galacto-heptose having a higher docking score than manycommercially available COX2 inhibitors. Based on our findings, the compounds within theextract could be used as the basis for the development of safe and effective drugs for thetreatment of TNBC and other cancers. In order to fulfil this potential, future work shouldexamine the molecular pathways affected by the treatment of TNBC cells with this extract orindividual compounds.

Apoptotic and cell cycle effects of triterpenes isolated from*Phoradendron wattii* on a chronic myelogenous leukemia cell line

Rosa E. Moo-Puc[1], Shirley A. Calderón Sauri[1], Jairo R. Villanueva-Toledo[2], Sergio R. Peraza-Sánchez[3], Antonieta Chávez-González[4].
[1]Farmacología de productos naturales, Unidad de Investigación Médica Yucatán, Unidad Médica de Alta Especialidad, Instituto Mexicano del Seguro Social, Merida, Mexico,[2]Fundación IMSS, Cátedras CONACyT, Merida, Mexico,[3]Unidad de Biotecnología, Centro de Investigación Científica de Yucatán (CICY), Merida, Mexico,[4]Unidad de Investigación Oncológica, Hospital de Oncología, Centro Médico Nacional, Instituto Mexicano del Seguro Social, ciudad de México, Mexico

Introduction: Medicinal plants have been used in traditional medicine practices since ancient times. Mayan traditional medicine uses herbs as treatment to illness that can be related to cancer disease such as *Phoradendron wattii*. As part of the search for novel cancer treatment two triterpene compounds were isolated from *P. wattii*: 3-*epi*-betulinic acid and lupenone with preliminary activity on leukemias. We investigated the cancer treatment abilities of 3-*epi*-betulinic acid and lupenone on human chronic myelogenous leukemia (K562) cell line and monocytes isolated from peripheral blood using flow cytometry methods.

Results: Lupenone showed low effect on both cells with an IC_{50} of 177.60 ± 5.07 µg/mL and a selectivity index (SI) of 0.10 times more on K-562 cell line than on monocytes. Nevertheless, 3-*epi*-betulinic acid showed a moderate anti-CML activity with an IC_{50} of 38.74 ± 5.07 µg/mL, having a SI of 4.10 on K-562 cells when compared to monocytes. These results indicate that 3-*epi*-betulinic acid was 41 times more selective for K-562 cell line than lupenone and it also was 7.45 more selective than etoposide as positive control. Additionally, 3-*epi*-betulinic acid increased cell population in the G_0/G_1 phase of the cell cycle and apoptotic cells, and it inhibited cell proliferation in a dose-dependent manner. Furthermore, the relative expression of genes associated with apoptosis Bax and caspase 3 increased compared to control.
Conclusion: Combined, these results suggest that 3-*epi*-betulinic acid plays an important regulatory role of cell cycle and apoptosis. Finally, the 3-*epi*-betulinic acid investigated in this work is potentially a cheap, safe, and effective alternative to chemotherapy in cancer treatment.

#3833
Leonurine derivatives as a potential novel therapeutic approach to acute lymphoblastic leukemias (ALL)
Joseph W. Schramm, Melanie Ehudin, Bing He, Chingakham Singh, Daniel Bogush, Jeremy Hengst, Diwakar Bastihalli Tukaramrao, Arati Sharma, Dhimant Desai, Sinisa Dovat. *Penn State Health Milton S. Hershey Med. Ctr., Hershey, PA*

Background: Pre-B cell Acute lymphoblastic leukemia (B ALL) high risk (HR) subgroups continue to result in significant mortality and morbidity of pediatric oncology patients. T cell ALL is higher risk and therapy has made less improvement than B ALL with a higher rate of significant poor outcomes. Novel treatment strategies are required to overcome chemotherapy resistance and improve mortality/morbidity for HR B ALL. Leonurine is a bioactive alkaloid that is naturally occurring only in Herbra Leonuri which has been used in traditional herbal medicine. Traditionally, it has been used for menstrual disorders. Research has further described its ability to scavenge oxygen free radicals, anticoagulation properties, and other anti-inflammatory properties[1]. There are investigations in its role for myocardial infarction, stroke, chronic kidney disease, and other

inflammatory disorders[2]. Our research data that suggests that leonurine and its derivatives have antileukemic effects.Methods/Results: We analyzed multiple derivatives of leonurine and selected a potent candidate based on cell viability assays use for further testing designated as investigational leonurine derivative (ILD). WST1 proliferation studies comparing ILD to vehicle were performed in cell lines Nalm6, 697, Molt4, CEM, and JM1 at multiple time points. The half maximal inhibitory concentration (IC50) values was variable depending on the treatment time and cell line although all values were consistently between 1.2-4.4 uM. Apoptosis activity was determined by flow cytometry Anexin/7AAD assays showed increased apoptosis in cell lines treated with ILD for Nalm6, Molt4, and 697 cell lines. Caspase 3/7 activity was increased in cells treated with ILD when compared to vehicle treatment. DNA damage assays were performed which revealed only an increased frequency in single strand breaks and not double strand breaks. Western blot was performed to determine levels of PI3K, p-AKT, BCL2/BCL-XL and caspases. The blots suggest that apoptosis may be a result of increased activation of PI3K/AKT signaling. We performed RNAseq on cells treated with ILD at the 24-hour time point and present gene ontology data for this analysis. Nalm6, 697, and Molt4 cell lines expressing GFP and Luciferase were injected into NRG mice as means for in vivo pharmacologic testing. NRG mice injected with these cell lines were treated with ILD five days a week for a total of 3 weeks. Nalm 6 leukemia cells showed minimal differences between treatment and control groups.Conclusion: In summary, leonurine derivatives have a promising impact on apoptosis and cell survival. Further investigation into mechanisms and pharmacokinetics/dynamics will be more revealing. Study of leonurine derivatives will result in further translational and therapeutic applications.

Antiproliferative activity of substituted chromone-2-carboxamides on MDA-MB-231 cells and their 3D pharmacophore models

Kinfe Ken Redda[1], Madhavi Gangapuram[1], Suresh Eyunni[2], Elizabeth Mazzio[1], Karam F. A. Soliman[1]. *[1]College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL,[2]College of Science and Technology, Florida A&M University, Tallahassee, FL*

After lung cancer, breast cancer is the second leading cause of cancer death in women in the United States, accounting for 12.5 % of all new cancer cases globally. Triple-negative breast cancer (TNBC) remains the hardest breast cancer and is difficult to treat. The current treatment option for TNBC is the surgical removal of the tumor, followed by chemotherapy. However, patients with advanced diseases respond poorly to current treatments. Therefore, discovering more effective and less toxic small drug molecules with a unique mechanism of action is one of the top priorities in drug discovery programs. Chromones have a benzo-pyrone skeleton and display interesting pharmacological activities, such as anti-cancer, anti-HIV, antiviral and anti-inflammatory, with low toxicity. In continuation of our current research work, we report the design and synthesis of substituted chromone-2-carboxamides by attaching substituted phenyl, tetrahydropyridine, and tetrahydroisoquinoline groups as anti-breast cancer agents. The starting material, substituted chromone-2-carbonyl chloride, was obtained by the acylation reaction of corresponding carboxylic acids using phosphorous pentachloride in dry cyclohexane. An equimolar amount of acyl chloride was slowly added to a stirred solution of corresponding substituted N-amino salt in dry THF in the presence of triethyl amine and refluxed at 70 ^{o}C that led to the formation of the ylides. The ylides were reduced using sodium borohydride to yield the desired substituted chromone-2-carboxamides in moderate to good yields. The synthesized compounds were characterized by NMR and elemental analysis. These compounds were evaluated for their cytotoxic effects on MBA-MB-231 ER-ve breast cancer cell lines using a Synergy HTX multi-mode reader (Bio-Tek, Winooski, VT, USA) with excitation/emission wavelength settings at 550/580. Compound MG-KKR-5-140A showed the most potent cytotoxicity with an IC_{50} value of 0.82 µg/mL on the MDA-MB-231 cell line. *In-silico* pharmacophore hypotheses were generated using GALAHAD and PHASE, and the best models with probable bioactive conformation(s) for these compounds were proposed. These confirmations and the alignments of the molecular structures give us an insight into designing compounds with better biological activity. *This research was supported by the National Institute on Minority Health and Health Disparities of the National Institutes of Health under Award Number U54 MD007582. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.*

Discovery of GSTZ1 as a novel target for drug refractory non-small cell lung cancer by using fragment-based chemical proteomics

Yi Liao, Sean Chin Chan, Eric A. Welsh, Bin Fang, Luxin Sun, Ernst Schönbrunn, John M. Koomen, Derek R. Duckett, Eric B. Haura, Andrii Monastyrskyi, Uwe Rix. *Moffitt Cancer Center, Tampa, FL*

A subset of non-small cell lung cancer (NSCLC) patients respond poorly to clinical drugs targeting defined oncogenic driver mutations. To improve the efficacy of these drugs in drug refractory NSCLC, the identification of supporting therapeutic targets and discovery of the binding molecules are urgently needed. Photoreactive fragment-like probes can discover target proteins that constitute novel cellular vulnerabilities and provide the chemical basis for drug discovery. However, the rational design of the fragment probe library, target prioritization, and sample throughput are still challenging. We applied a structurally diverse panel of BioCore fragments fully functionalized with orthogonal diazirine and alkyne moieties. These probes were used for protein crosslinking in live cells and subsequent target identification through label-free quantitative LC-MS/MS analysis. High-confidence targets were queried against a pharmacogenomic database (DepMap) and prioritized through multiple cross-comparison with other probes. The top-ranked probe-binding target was validated using a competitive affinity assay, an enzymatic activity assay, and RNA interference. Proteome-wide tyrosine reactivity was profiled using sulfur-triazole exchange chemistry (SuTEx). The tyrosine phosphorylation of proteins was investigated using a pY-100 antibody and western blotting. Using sotorasib-refractory KRAS G12C H1792 lung cancer cells, we identified 932 probe-enriched proteins from panel-wide cross-comparisons suggesting the high potential of exploring the ligandable proteome. We also performed intensive cross-comparison analysis and identified 31 unique high-confidence targets, with glutathione S-transferase zeta 1 (GSTZ1) identified as a unique target of probe 17. We found that high expression of GSTZ1 was significantly associated with poorer NSCLC patient survival. Probe 17 was validated to physically bind to GSTZ1 and inhibit the enzymatic activity of GSTZ1. In addition, *GSTZ1* gene knockdown sensitized drug-refractory NSCLC cells with KRAS G12C, FGFR1 amplification, and DDR2 mutation to clinical targeted drugs and induced more cell apoptosis in combination with these targeted drugs. SuTEx proteomics suggests modulation of drug resistance pathways leading to the identification of altered KRAS and FGFR1 tyrosine phosphorylation by GSTZ1, which provides a functional insight into the mechanism of drug sensitization. We developed a chemical biology workflow for the simultaneous discovery of high-confidence targets and their binding probe molecules, such as probe 17 and GSTZ1. GSTZ1 was found to cooperate with oncogenic alterations in supporting refractory NSCLC cell survival signaling, which may form the biological basis for developing novel GSTZ1 inhibitors to improve the therapeutic efficacy of oncogene-directed targeted drugs.

High-resolution structural insights into targeting the *MYC* oncogene G-quadruplex with the quinoline derivative PEQ

Jonathan Dickerhoff[1], Jixun Dai[2], Danzhou Yang[1]. *[1]Purdue University, West Lafayette, IN,[2]The University of Arizona, Tucson, AZ*

The transcription of the *MYC* oncogene, a central player of oncogenesis, is strongly controlled by DNA G-quadruplexes in its promoter region (MycG4). Stabilization of MycG4 with small molecules downregulates *MYC* expression and has devastating effects on many cancers. Thus, targeting MycG4 is an attractive anti-cancer strategy especially since the MYC protein is considered a very difficult target. DNA G-quadruplexes are four-stranded secondary structures and enriched in promoters of oncogenes. Their globular shape and high structural diversity distinguishes them from the thread-like and uniform DNA duplex ubiquitously found in the cell. High-resolution structures reveal the molecular interactions between ligands and G-quadruplexes and are the key for structure-based rational design of new and improved drugs. Here, we present the new MycG4 binder PEQ, a

quinoline derivative, and describe its molecular recognition of the MycG4. PEQ is more drug-like than many prominent G-quadruplex binder because it lacks an extensive aromatic moiety. Most of the reported G-quadruplex binding ligands include extended and rigid aromatic moieties with less drug-like properties. We used solution NMR and molecular dynamics calculations to first determine the high-resolution structures of the unbound wild-type MycG4, and next structures of PEQ in complex to wild-type MycG4 or the most commonly studied modified MycG4. This modified MycG4 sequence bears a mutated residue in the binding pocket that is critical for ligand interactions. PEQ binds the MycG4 with a 2:1 stoichiometry and stacks on the G-quadruplex ends. Specific binding pockets are formed in which a flanking residue is recruited by the PEQ to form a joint-plane. The identity of the recruited residue controls the orientation of the ligand and the resulting interactions, as shown by structural comparison of PEQ in complex with either the wild-type or mutated MycG4. Including the PEQ structure, four ligand-MycG4 complexes are now available and we performed the first systematic analysis. We show that despite the dynamic character of the flanking sequences, all ligands recruit DNA bases in a conserved and sequence-specific manner. Moreover, we propose the design of complementary hydrogen bonds to match the recruited DNA base with a drug via structure-based rational design. In conclusion, our work introduces the quinoline PEQ as new lead compound for cancer therapeutics targeting MYC through the MycG4. We present the MycG4-ligand structure with wild-type binding sites as more accurate target and identify important aspects of ligand binding to guide future design of cancer therapeutics.

Development of p300-targeting PROTAC degraders with enhanced selectivity and onset of degradation

Graham P. Marsh[1], Sean Goggins[1], Darko Bosnakovski[2], Michael Kyba[2], Samuel Ojeda[3], Drew A. Harrison[3], Christopher J. Ott[3], Hannah J. Maple[1]. *[1]Bio-Techne Corporation, Bristol, United Kingdom,[2]Lillehei Heart Institute, Minneapolis, MN,[3]Massachusetts General Hospital Cancer Center, Boston, MA*

CREB-binding protein (CBP, CREBBP, KAT3A) and E1A-binding protein (EP300, p300, KAT3B) are paralogous multi-domain proteins that act as chromatin regulators and transcriptional co-activators. They contain a histone acetyltransferase (HAT) domain that catalyzes the histone H3, lysine 27 acetylation (H3K27ac) mark at regulatory elements such as enhancers and promoters. Transcription factors associate with stretches of H3K27ac marks (known as ‘super-enhancer’ elements) and result in gene transcription that ultimately establishes cell identity and fate. They are implicated in cancer pathology, and small molecule inhibition of the bromodomain (BRD) or HAT domain of CBP/p300 are considered promising therapeutic strategies for a number of cancer types. CBP and p300 are highly homologous but have distinct roles that have to date been hard to delineate, since small molecule inhibitors developed to date are unable to selectively target each protein independently. Additionally, small molecule inhibitors that target individual domains are unable to entirely abrogate the full functionality of CBP/p300. A bromodomain-recruiting dual CBP/p300 PROTAC Degrader ‘dCBP1’ was therefore recently developed to provide a chemical tool to explore the phenotypic consequences of CBP/p300 chemical knockdown. A further study demonstrated that it is possible to degrade p300 with some selectivity by converting a CBP/p300 dual HAT-domain inhibitor into a PROTAC, called ‘JQAD1’.
We have used a different HAT-domain recruiting ligand to develop novel PROTACs that elicit proteasome-mediated degradation of p300 with significantly enhanced selectivity over CBP, compared with JQAD1. We additionally demonstrate a faster onset of degradation for lead PROTAC molecules and present data exploring the consequences of selective p300 degradation in CIC-DIX4 sarcoma.

Berberine recognition of the dGMP-bound PDGFR-β promoter G-quadruplex: Structural insight into specific drug targeting

Kai-Bo Wang, Jonathan Dickerhoff, Yichen Han, Danzhou Yang. *Purdue University, West Lafayette, IN*

PDGFR-β (Platelet-Derived Growth Factor Receptor beta) is a receptor tyrosine kinase whose overexpression drives the progression and metastasis of many cancers. It is an established anticancer target and PDGFR-β inhibition via kinase inhibitors has been actively sought-after. However, PDGFR-β kinase inhibitors often lack specificity. The PDGFR-β gene promoter forms DNA G-quadruplexes that are transcription silencer whose stabilization by small molecules represses PDGFR-β expression. Therefore, targeting PDGFR-β promoter G-quadruplexes for transcriptional silencing is a promising alternative strategy for cancer therapy. G-quadruplex is an exciting family of non-canonical DNA secondary structures. DNA G-quadruplex within the PDGFR-β gene promoter forms novel vacancy pockets (vG4) that can be filled-in by guanine metabolites such as dGMP and cGMP. This presents an attractive target for small molecule targeting. Herein, we present the binding of the natural product berberine with the unique PDGFR-β dGMP-vG4 binary complex to form a novel ternary complex, the first case observed in DNA G-quadruplexes. Using circular dichroism, fluorescence, and nuclear magnetic resonance (NMR) spectroscopy, we demonstrated that berberine binds with high affinity and strongly stabilizes the dGMP-fill-in PDGFR-β vG4. Our determined high-resolution NMR structure of this ternary complex in K^+-containing solution reveals a 2:1 binding stoichiometry of berberine to the dGMP-fill-in PDGFR-β vG4. Significantly, one berberine directly stacks upon and extensively covers the dGMP. This direct binding mode provides structural basis for targeting the unique PDGFR-β promoter G-quadruplex by small molecules and suggests an intriguing strategy of designing drug-like, guanine-conjugated molecules to selectively silence the PDGFR-β gene. Because vG4 formation and dGMP fill-in is a unique property of the PDGFR-β promoter G-quadruplex, our study provides a structural basis for rationally designing small molecule drugs to specifically target the PDGFR-β promoter G-quadruplex to inhibit oncogenic PDGFR-β for cancer therapeutics.

Potent human ClpP protease agonists with anticancer properties bind the enzyme with improved structural complementarity and alter the mitochondrial N-terminome

Mark F. Mabanglo[1], Keith S. Wong[1], Marim M. Barghash[1], Lee M. Graves[2], Edwin J. Iwanowicz[3], Walid A. Houry[1]. *[1]Biochemistry, University of Toronto, Toronto, ON, Canada,[2]Department of Pharmacology and the Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Madera Therapeutics LLC, Cary, NC*

The mitochondrial ClpP protease is responsible for mitochondrial protein quality control through specific degradation of proteins involved in several metabolic processes. ClpP overexpression is also required in many cancer cells to eliminate ROS-damaged proteins and to sustain oncogenesis. Targeting ClpP to dysregulate its function using small molecule agonists is a novel strategy in cancer therapy. Here, we synthesized novel imipridone-derived compounds and related chemicals, which we characterized using biochemical, biophysical, and cellular studies. Using X-ray crystallography, we found that these compounds have enhanced binding affinities due to their greater shape and charge complementarity with the surface hydrophobic pockets of ClpP. N-terminome profiling of cancer cells upon treatment with one of these compounds revealed the global proteomic changes that arise and identified the structural motifs preferred for protein cleavage by compound-activated ClpP.

Together, our studies provide the structural and molecular bases by which dysregulated ClpP affects cancer cell viability and proliferation.

A biophysical investigation into the binding interactions of novel anti-cancer inhibitors of atypical protein kinase C (aPKCs)

Radwan Ebna Noor[1], Tracess B. Smalley[2], Mildred Acevedo-Duncan[1]. *[1]University of South Florida, Tampa, FL,[2]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

The aim of this study is to address the challenge of the expression of recombinant atypical protein kinase C (aPKCs) in a bacterial system and understand the binding interactions of novel anti-cancer inhibitors of aPKCs. The Protein kinase Cs (PKCs) expression at a high rate is a key indicator of cancer cell proliferation and survival. In particular, the over-expressions of aPKCs were found to be directly associated with various cancer cells in benign and malignant stages. Several cancer growth blockers (inhibitors) are available for targeted therapy. However, these inhibitors had to pass through rigorous *in silico* screening, *in vitro,* and *in vivo* assays before FDA approval. During the characterization studies of the protein, insights into binding interactions between aPKCs and drug molecules are crucial. For successive studies such as for biophysical characterization, the recombinant bioactive full-length PKC- ι (an aPKC) expression in the bacterial system is still a challenge. In addition, the binding interaction studies of aPKCs with inhibitors in physiological conditions providing structural details are limited to some X-ray crystallography structures and computational studies. Here we addressed these two challenges and report a protocol detailing the bioactive full-length and catalytic domain of PKC- ι expression and purification from the bacterial system. The further characterization of the recombinant protein by the determination of melting temperature, functional activity, and circular dichroism reported here provides important information on the characteristics of the protein in its native state. Moreover, we show the chemical interactions of five novel anti-cancer inhibitors ICA-1S (Nucleosidic homolog) 5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide), ICA-1T (Phosphorylated nucleosidic homolog of ICA-1S, [4-(5-amino-4-carbamoylimidazol-1-yl)-2,3-dihydroxycyclopentyl] methyl dihydrogen phosphate), ACPD (2-acetyl-1,3-cyclopentanedione), DNDA (3,4-diaminonaphthalene-2,7-disulfonic acid) and ζ(ZETA)-Stat (8-hydroxy-1,3,6- naphthalenetrisulfonic acid) to locate their regions of binding on the catalytic domain of the aPKCs (PKC- ι and PKC- ζ). We have utilized the chemical shift changes obtained from various multi-dimensional Nuclear Magnetic Resonance (NMR) experiments. Moreover, we have applied the isothermal calorimetry method to understand the biophysical properties of the aPKCs in presence of these inhibitors. The observed biophysical properties of the protein and chemical shift perturbations in the amide backbone of the catalytic domain upon binding shed light on the molecular recognition process, binding characteristics, and atomic-level structural details of the aPKCs.

Structural mechanisms of how PTEN mutations degrade function at the membrane and life expectancy of carriers of mutations in the human brain

Hyunbum Jang[1], Jiaye Chen[2], Lilia M. Iakoucheva[2], Ruth Nussinov[1]. *[1]Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Department of Psychiatry, University of California San Diego, La Jolla, CA*

PTEN negatively regulates PI3K/AKT/mTOR signaling through dephosphorylation of PIP_3 to PIP_2. PTEN dysfunction triggers disease phenotypes, ranging from cancer and PHTS to NDDs such as ASD. The most common PTEN mutations, nonsense, frameshift, and deletion/insertion, may cause

premature termination of translation. PTEN has a considerable number of missense mutations that may result in loss of protein function through reduced catalytic activity and protein stability. To decipher mechanistic details of the mutations and structural features of the mutant proteins, comprehensive computational studies were performed for PTEN mutants at an anionic lipid bilayer containing PC, PS, PIP_2, and PIP_3. Six PTP mutations (Y68H, H93R, A126T, R130Q, G132D, R173C) and two C2 mutations (F241S, D252G) were considered. The PTP mutations are known to associate with cancer, PHTS, macrocephaly, and ASD, while the C2 mutations are exclusively related to macrocephaly and ASD. Our studies indicate that the PTEN mutants can effectively absorb the anionic lipid bilayer, similar to wild-type PTEN. However, Y68H significantly disrupts the core of PTP domain, reducing protein stability. H93R hijacks the substate PIP_3, interrupting the catalytic site residues recruitment of the substate for catalysis. A126T, R130Q, and G132D in the P loop directly influence the dynamics of the loop, yielding a collapsed loop conformation. The collapsed P loop loses the interaction with the WPD loop, leading to dehydration in the catalytic site. R173C and D252G at the interface between two major domains disrupt the domain-domain interaction, allosterically biasing the P loop dynamics. However, F241S in C2 exhibits less effective allosteric connection to the catalytic site than that observed in the wild type. PCA of the sampled conformations found that the macrocephaly and ASD-related H93R and F241S are likely to sample the conformations present in the wild type. In contrast, the sampled conformations for the cancer and PHTS-related Y68H, A126T, and G132D are different from those for the wild type. These distinct structural features seem to correlate with mutation strength and timing of the expression of the genes that determine the cancer and NDD outcomes. The isoform expression data extracted from the BrainSpan indicate that exon 5 is impacted by NDD or non-NDD mutations. Interestingly, PTEN splicing isoforms that do not carry exon 5 are exclusively impacted by the NDD mutations, F241S and D252G. The increased life expectancy of PTEN variants carriers carrying exons 5 and 7 is highly correlated to increased lifetime risk for certain cancers. Our results underscore the detailed structural and functional mechanisms of PTEN with mutations at the membrane, and suggest that tissue-specific splicing isoform expression should be taken into consideration while predicting the effect of mutations in various diseases.

Target identification of a multi-pass transmembrane G protein coupled receptor using limited-proteolysis coupled mass spectrometry (LiP-MS)

Martin Soste[1], Dominique Kamber[1], Nadine Dobberstein[2], Mirjam Zimmermann[2], Aurelien Rizk[2], Yuehan Feng[1], Yaroslav Nikolaev[2], Nigel Beaton[1]. *[1]Biognosys AG, Schlieren, Switzerland,[2]InterAx Biotech AG, Villigen, Switzerland*

In drug discovery, target identification (ID) after phenotypic screens is a resource-intensive endeavor aimed to understand compound's mechanism of action. Target ID for membrane proteins is particularly challenging due to hurdles such as poor protein solubility, instability and low expression levels. Addressing these hurdles, recent proteomics-based strategies allow to analyze proteins in their native environment, and do not require compound modification or genetic manipulation of target cell lines.

Limited proteolysis coupled to mass spectrometry (LiP-MS) is a peptide-centric strategy that exploits structural protein alterations and steric hindrances induced by drug to detect drug-protein interactions, estimate potency (EC50) and predict binding sites across the proteome. Our previous reports (AACR 2020 and 2021) showed the applicability of LiP-MS on cytosolic proteins such as kinases and phosphatases. Here, LiP-MS workflow was adapted for multi-pass membrane proteins which are often underrepresented in global, unbiased target ID approaches.

For protein targets in the cytosol or intracellular organelles, LiP-MS deploys a dose-response (DR) analysis recorded by incubating cell lysates with a given compound. Here, to monitor proteins in plasma membrane, live cells were treated with the compound in a DR curve for a short period of time before lysis and subsequent LiP-MS analysis. Live cell treatment allows to achieve target ID by 1) locking the receptor in its native conformation to detect the structural difference between the drug-bound and unbound forms and; 2) detecting structural changes in downstream signaling cascades resulting from changes in protein-protein interactions, post-translational modifications or other mechanisms. We evaluated the performance of this workflow using a tool compound (IAX16840) targeting specific G-protein coupled receptors. Our unbiased LiP scoring identified atypical chemokine receptor 3 (ACKR3), the primary known compound target, among the top 3 hits. Additional 82 proteins were perturbed in drug-treated samples based on the LiP scores. Mapping the altered peptides on the GPCR signaling network showed enrichment of perturbations in ACKR3 downstream pathways, providing additional evidence of ACKR3 binding.
Taken together, we demonstrate that the live cell LiP-MS is applicable for target ID of multi-pass membrane proteins. The approach also provides a system-level view of protein and pathway perturbations downstream of a signaling protein (e.g. GPCR), revealing possible mechanisms of its endogenous action. Further optimization of LiP-MS protocol is sought to accommodate different classes of receptors.

Predictive value of CXCL10 for the occurrence of immune related adverse events in patient with renal cell carcinoma

Yuji Miura[1], Takanobu Motoshima[2], Toshiki Anami[2], Hiromu Yano[1], Remi Mito[1], Shinji Urakami[3], Keiichi Kinowaki[4], Hirotake Tsukamoto[5], Ryoma Kurahashi[2], Yoji Murakami[2], Junji Yatsuda[2], Yukio Fujiwara[1], Tomomi Kamba[2], Yoshihiro Komohara[1]. *[1]Cell Pathology, Kumamoto Univ Graduate School of Medical Sci, Kumamoto, Japan,[2]Urology, Kumamoto Univ Graduate School of Medical Sci, Kumamoto, Japan,[3]Urology, Toranomon Hospital, Tokyo, Japan,[4]Pathology, Toranomon Hospital, Tokyo, Japan,[5]Clinical Immunology and Cancer Immunotherapy, Kyoto University, Kyoto, Japan*

Background: Immune checkpoint inhibitors (ICIs) have recently improved the prognosis of various cancers. In contrast, some immune-related adverse events (irAEs) caused by ICIs are fatal and have become problematic. The pathogenesis of irAEs remains unknown and must be elucidated to establish biomarkers.
Materials and Methods: Plasma samples were collected prospectively from patients with advanced and metastatic renal cell carcinoma (RCC) prior to initiation of ICI treatment (baseline) and 2 or 3 weeks after the first cycle of ICI treatment (post-dose 1). Plasma cytokines and chemokines (GRO [CXCL1], IL-17A, IL-1β, IL-6, IL-8, IP-10 [CXCL10], MCP-1 [CCL2], TNFα) were measured by Luminex system, and plasma level of CXCL13 and anti-CD74 autoantibody levels were measured by ELISA. Their association with irAEs was analyzed.
Results: In a discovery cohort of 13 patients, plasma levels of CXCL1, IL-17A, IL-1β, IL-6, IL-8, CXCL10, MCP-1, and TNFα were measured at baseline and post-dose 1. Only CXCL10, at post-dose 1 but not at baseline, was significantly associated with grade 2 or higher irAEs (p=0.0413). Plasma CXCL10 levels were then measured at baseline and post-dose 1 in a validation cohort of 43 RCC patients who received ICI-based treatment. Higher plasma CXCL10 levels both at baseline and

post-dose1 were significantly associated with the occurrence of grade 2 or higher irAEs (p=0.0246 and 0.0137, respectively). We evaluated the relationship between plasma levels of CXCL10 and CXCL13, which we measured in a previous study, and the incidence of irAEs. At baseline, the plasma CXCL13 level was positively associated with the CXCL10 level (p=0.0007), but no significant association was observed post-dose 1 (p=0.2678). Plasma CXCL13 levels were significantly higher in patients with grade 2 or higher irAEs at baseline but not at post-dose 1 (p=0.0037 and 0.052, respectively). No significant association between plasma anti-CD74 autoantibody level and both irAE pneumonitis and any grade 2 or higher irAE was observed. Conclusion: Plasma CXCL10 is significantly associated with the occurrence of irAEs in patients with RCC treated with ICIs. CXCL10 is a potential predictive and on-treatment biomarker for irAEs.

MSI cancer associated DNA (TA)n-dinucleotide repeat expansions and implications for Werner synthetic lethality

Gabriele Picco[1], Shriram Bhosle[1], Maria Kalyva[2], Elena Grassi[3], Freddy Gibson[1], Angham Al Saedi[1], Sara Vieira[1], Mathijs Sanders[4], Livio Trusolino[5], Andrea Bertotti[5], Isidro Cortes-Ciriano[6], Mathew Garnett[1]. *[1]Wellcome Sanger Institute, Hinxton, United Kingdom,[2]European Molecular Biology Laboratory- European Bioinformatics Institute EMBL-EBI, Hinxton, United Kingdom,[3]Candiolo Cancer Institute, Translational Cancer Medicine, Candiolo, Italy,[4]Erasmus University Medical Center, Rotterdam, Netherlands,[5]Candiolo Cancer Institute, Candiolo, Italy,[6]European Molecular Biology Laboratory, Hinxton, United Kingdom*

Microsatellite instability (MSI) is caused by deficient DNA mismatch repair (MMR) and is a ubiquitous feature of cancer. Werner syndrome (WRN) helicase is involved in genome stability and DNA repair. We identified WRN as a synthetic-lethal target in dMMR/MSI cancers and highlighted WRN inhibition as a therapeutic option for dMMR/MSI cancers refractory to available therapies. A previously unappreciated genetic feature of dMMR/MSI cancer cells, DNA (TA)n-dinucleotide repeat expansions, were recently reported to cause vulnerability to WRN depletion. Our mechanistic understanding of TA-dinucleotide repeat expansion biology is limited, and their potential therapeutic implications are unclear. To investigate the landscape of these alterations in cancer, we inferred (TA)-dinucleotide repeat expansions by performing coverage analysis in a collection of hundreds of preclinical cancer models and human tumors (PCAWG) profiled by whole genome sequencing (WGS). We validated our findings in cancer cell lines and organoid cultures by performing long-read WGS. Furthermore, we investigated TA-expansions in single-cell-derived clones from human MSI tumors and cancer organoids. Finally, we inferred TA repeats in laser capture microdissection (LCMB)-derived samples obtained from patients affected by familial cancer predisposition syndromes. Our analysis unveils the landscape of TA-repeats alterations in a large collection of tumors and preclinical models, informing on the level of inter-tumor heterogeneity and their association with variable levels of WRN dependency. In addition, we investigated intra-patient tumor heterogeneity of TA-repeats length both within clonal organoids expanded from normal and neoplastic colorectal stem cells, and within different subclones derived from MSI cancer organoids. Furthermore, analysis of non-neoplastic and neoplastic tissues from patients affected by familial cancer predisposition syndromes revealed the pattern of TA-repeats expansions associated with various DNA-repair pathway alterations. Finally, we will discuss the clinical implications of our findings, as TA-repeats heterogeneity may affect sensitivity and resistance to the future generation of WRN inhibitors. Our data provide fresh insights into the inter and intra-tumoral heterogeneity of TA-dinucleotide repeat expansions in human cancers. These data contribute to understanding the role of MMR in cancer and exploiting Werner as a therapeutic target in cancer.

Er[1], Şerafettin Zenkin[1], Muthukumar Gunasekaran[4], Luis Lara-Mejia[5], Francesco Buemi[3], Feliciano Barron[5], Marisol Arroyo-Hernández[5], Sunjay Kaushal[4], Andres F. Cardona[6], Aung Naing[7], Vincenzo Adamo[3], Oscar Arrieta[5], Rivka R. Colen[1], Christian Rolfo[2].

[1]Hillman Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA,[2]Center for Thoracic Oncology, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY,[3]Medical Oncology Unit, A.O. Papardo & Department of Human Pathology, University of Messina, Messina, Italy,[4]Departments of Surgery and Pediatrics, Ann and Robert H. Lurie Children's Hospital of Chicago, Feinberg School of Medicine, Northwestern University, Chicago, IL,[5]Thoracic Oncology Unit, Instituto Nacional de Cancerología (INCan), Mexico City, Mexico,[6]Luis Carlos Sarmiento Angulo Cancer Treatment and Research Center (CTIC), Universidad El Bosque, Bogota, Colombia,[7]Departments of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Immune-checkpoint inhibitors (ICIs) have improved the clinical benefit of only a subset of patients with advanced non-small cell lung cancer (NSCLC), since tissue PD-L1 has showed low predictive accuracy. We have previously showed that extracellular vesicle (EV) PD-L1 identified durable responders to ICIs and that the radiomics analysis of baseline CT scans improved the EV PD-L1 predictive model. Here, we aim to validate this combination model to identify non-responders to ICIs.

Methods: We enrolled 3 cohorts of patients, cohort (1) included 27 patients receiving ICIs, cohort (2) 17 on ICIs + chemotherapy (ChT), and cohort (3) with 13 undergoing ChT. Baseline and 3rd cycle plasma samples were collected, EV were isolated by ultracentrifugation, and EV PD-L1 dynamics was analyzed by immunoblot. 800 radiomics features were evaluated in baseline CT scans and a set of 6 features identified in cohort 1, were analyzed in cohort 2 and 3. Early and durable responses were assessed in CT scans after the 3rd and the 6-8 treatment cycle, respectively, using RECIST v1.1.

Results: Increased expression of EV PD-L1 during treatment showed good predictive value at identify non-responders to ICIs and was not associated with ChT response. The addition of radiomics features improved the predictive model for early and durable response to ICIs, while similar AUC was observed in particular for durable response in cohort 2. Moreover, these biomarkers outperformed tissue PD-L1 and were unspecific for response to Docetaxel (Table 1). No predictive models could be evaluated for early response to ChT.

Conclusions: We present for the first time, validated evidence of the combination of EV PD-L1 and radiomics as a highly accurate minimally invasive biomarker for predicting response to ICIs. This combinatorial approach outperformed the current standard-of-care tissue PD-L1 and is a promising tool for the stratification of patients to receive ICIs.

A CD5 signature identifies diffuse large B-cell lymphomas (DLBCLs) sensitive to Bruton's tyrosine kinase (BTK) inhibition

Alan Cooper[1], Sravya Tumuluru[1], Kyle Kissick[2], Girish Venkataraman[2], Nikita Kotlov[3], Aleksander Bagaev[3], Andrew Lytle[4], Gerben Duns[4], David W. Scott[4], Christian Steidl[4], Brendan Hodkinson[5], Srimathi Srinivasan[5], Justin Kline[6], James Godfrey[7]. *[1]University of Chicago, Chicago, IL,[2]Pathology, University of Chicago, Chicago, IL,[3]BostonGene, Waltham, MA,[4]Centre for Lymphoid Cancer, British Columbia Cancer, Vancouver, BC, Canada,[5]Janssen Research & Development, Spring House, PA,[6]Medicine, University of Chicago, Chicago, IL,[7]Hematology and Hematopoietic Cell Transplantation, City of Hope, Duarte, CA*

Introduction: Gene expression profiling has identified DLBCLs that bear transcriptional similarity to either non-malignant germinal center B-cells (GCB-DLBCL) or activated B-cells (ABC-DLBCL, i.e. non-GCB-DLBCL). This cell-of-origin (COO) classification has guided precision medicine strategies, including the use of ibrutinib, a BTK inhibitor (BTKi), with ABC-DLBCLs thought to be sensitive to BTKi due to their constitutive activation of NF-kB downstream of the B-cell receptor (BCR). However, the phase III Phoenix trial testing the addition of ibrutinib to R-CHOP chemoimmunotherapy surprisingly failed to demonstrate a survival benefit in non-GCB-DLBCLs. By employing a newly defined genetic classification algorithm (LymphGen), distinct genetic DLBCL subtypes that benefit from this regimen were identified. However, LymphGen is not utilized in the clinic and fails to classify >40% of DLBCLs. To overcome these challenges, we sought to identify a straightforward biomarker of BTKi sensitivity. CD5 was selected as a potential candidate, given its role as a negative regulator of BCR signaling and expression in other BTKi-responsive B-cell lymphomas.

Methods: CD5 IHC was performed on a cohort of 405 DLBCLs, most with paired RNA and targeted mutational sequencing. Comparison of the transcriptomes of $CD5^+$ and $CD5^-$ DLBCLs was used to construct a 60-gene CD5 signature (CD5sig), which was applied to large genomic DLBCL datasets, including pre-treatment biopsies from the Phoenix trial (n = 584) to evaluate its utility in predicting improved response to R-CHOP + ibrutinib.

Results: Twenty-seven DLBCLs were identified as $CD5^+$ by IHC (6% of cases; 12% of non-GCB). Consistent with previous reports, $CD5^+$ DLBCLs were enriched for a non-GCB COO and exhibited inferior progression-free survival to R-CHOP. $CD5^+$ DLBCLs upregulated genes related to BCR signaling and had a significantly higher incidence of *CD79B* BCR-activating mutations. A CD5 signature (CD5sig) was created from differentially expressed genes between CD5 IHC^+ and CD5 IHC^- non-GCB-DLBCLs. When applied to an external dataset of 349 non-GCB-DLBCLs, $CD5sig^+$ DLBCLs (15% of cases) were enriched for BCR-activating mutations and were majority MCD (*MYD88* and *CD79B*) or unclassified by LymphGen. $CD5sig^+$ DLBCLs were largely devoid of *BCL10* activating mutations known to drive BTKi resistance. When applied to the Phoenix study, $CD5sig^+$ DLBCLs selectively benefitted from R-CHOP + ibrutinib by event-free and overall survival. This survival difference was preserved even among LymphGen-unclassified DLBCLs.
Conclusions: Here, we identify CD5 expression as a simple and useful biomarker to identify high-risk, BCR-driven DLBCLs beyond those identified through genetic classification. Based upon unique transcriptional features of CD5 IHC^+ DLBCLs, we developed a novel CD5 signature that identifies DLBCLs vulnerable to BTKi therapy.

Comprehensive analysis of copy number variation and sensitivity to targeted therapy in renal cell carcinoma using in-house cancer gene panel testing

Akhito Takeuchi[1], Mayu Takeda[2], Eiji Sugihara[3], Yoshinari Muto[1], Sachio Nohara[4], Shigeki Tanishima[4], Kenji Zennami[5], Kiyoshi Takahara[5], Tetsuya Tsukamoto[6], Ryoichi Shiroki[5], Hideyuki Saya[7], Makoto Sumitomo[1]. *[1]Fujita Cancer Center and Department of Urology School of Medicine, Fujita Health University, Toyoake, Japan,[2]Fujita Cancer Center and Department of Medical Research for Intractable Disease, Fujita Health University, Toyoake, Japan,[3]Fujita Cancer Center and Research Promotion Headquarters, Open Facility Center, Fujita Health University, Toyoake, Japan,[4]Department of Bio Informatics, Communication Engineering Center, Electronic System Business Group, Mitsubishi Electric Software Corp., Tokyo, Japan,[5]Department of Urology School of Medicine, Fujita Health University, Toyoake, Japan,[6]Department of Pathology School of Medicine, Fujita Health University, Toyoake, Japan,[7]Fujita Cancer Center, Fujita Health University, Toyoake, Japan*

Purpose: Immune checkpoint inhibitors (ICIs) and tyrosine kinase inhibitors (TKIs) are the main drugs used to treat metastatic renal cell carcinoma (mRCC), but there are no effective biomarkers to determine their use. In this study, we aimed to identify factors that correlate with staging of RCC and drug sensitivity to mRCC based on the results of an in-house cancer gene panel test at Fujita Health University.
Methods: 133 patients with RCC (70 non-metastatic RCC and 63 mRCC). DNA was analyzed for mutations in 143 cancer genes using the PleSSision Rapid cancer gene panel test. NextSeq2000 was used as the next-generation sequencer. From the curated reports obtained, factors including each gene mutation information and the correlation between copy number (CN) variation (CNV) cluster analysis information, clinicopathological information, and therapeutic response to ICI or TKI was examined. In this study, the therapeutic response was evaluated with RECIST1.1 and complete response and partial response were determined as objective response (OR). The endpoint was progression-free survival 2 (PFS2) defined as the interval between first-line treatment and the second relapse.
Result: Mutational analysis showed no difference in the pattern of genetic variation with or without metastasis. CNV analyses showed a marked trend toward a decrease in CN on homologous recombination repair genes in a part of mRCCs. Cluster analysis of CNV information for each gene

in response to TKI treatment in mRCC revealed multiple regions of decreased or increased CN. The main regions of increased CN were shown to be those formed by CN gain of oncogenes on chromosomes 7 and 12. Detailed analysis of this hot spot showed that when the cutoff value of sum of CN for *KRAS*, *ERBB3*, *CDK4*, and *MDM2.* for chromosome 12 set to 9, 8 (72.7%) of 11 patients with CN 9 or higher were in OR group, while 4 (7.7%) of 52 patients with CN less than 9 were in OR group, showing a significant difference between the two groups ($P < 0.001$). Similarly, when the cutoff value of sum of CN for *EGFR*, *MET*, and *BRAF* for chromosome 7 set to 8, 5 (83.3%) of 6 patients with CN 8 or higher were in OR group, while 7 (12.3%) of 57 patients with CN < 8 were in OR group, showing a significant difference between the two groups ($P < 0.001$). On the other hand, genetic markers predicting susceptibility to ICI could not be identified. Kaplan-Meier analysis showed that the group of patients with higher CN values for either chromosome 7 or 12 had better PFS2 after TKI treatment than the group of patients with lower CN values for either chromosome 7 or 12 ($P < 0.001$).
Conclusion: Our results from in-house cancer gene panel tests successfully showed an association between RCC progression and cancer-related gene alterations. Furthermore, the results showed the possibility of predicting TKI treatment sensitivity in mRCC by focusing on CN gain of oncogenes in specific chromosomal regions.

Characterizing cancer-associated fibroblasts in prostate cancer using Vizgen's MERSCOPE™ Platform

Ben Patterson, Cheng-Yi Chen, Nicolas Fernandez, Simran Kaushal, Leiam Colbert, Jiang He.
Vizgen, Cambridge, MA

Understanding the spatial complexities within cancer provides crucial information for evaluating individual tumor development and progression; recent research in prostate cancer has shown how critical it is for oncologists to maintain a spatial context while characterizing a highly heterogeneous tumor microenvironment. As more and more research groups acknowledge the need for spatial biology solutions to solve difficult questions surrounding cell identity, heterogeneity, and interaction, Vizgen's MERSCOPE™ Platform provides a powerful tool to illuminate spatial information. Built on Multiplexed Error-Robust Fluorescence in situ Hybridization (MERFISH) technology, Vizgen's MERSCOPE™ enables the direct profiling of the spatial organization of intact tissue with subcellular resolution. Here, we use a 500-gene panel to demonstrate the MERSCOPE's spatial capability, assessing the canonical signaling pathways of cancer, cancer type-specific genes, select immune genes, proto-oncogenes, and tumor-suppressor genes in patient-derived prostate cancer samples. Using the Vizgen Cell Boundary Stain kit, we were able to generate a molecular and cellular atlas of these individual patient tumors by clustering cells based on gene expression and mapping these clusters back onto a spatial representation of the tumor. We found specific clusters relating to prognostic outcomes in cancer-associated fibroblasts (CAFs) and myofibroblasts. Subsequently, we used single-cell RNA-seq datasets to impute related transcriptome data for these various fibroblast clusters to help characterize them more specifically. To understand the heterogeneity intrinsic to CAFs, we performed a neighborhood analysis to determine how proximity to immune cells, tumor cells, and other stromal cells altered gene expression in different CAF clusters. We found gene expression changes associated with inflammation and reactive stromal signaling in CAFs based on their proximity to tumor versus stromal tissue compartments. We also compared the gene expression of tumor cells near CAFs to those more deeply embedded within the tumor compartment. This revealed interesting transcriptional covariations between superficial layers of tumor and their surrounding stromal milieu involved in cell proliferation and signaling. These analyses demonstrate the transcriptional variation possible across fibroblastic stromal cells acting in

tumor-adjacent or stromal contexts. Notably, we were able to map and catalogue different patterns of gene expression relating to inflammation, tumor proliferation, and reactive stromal signaling. These findings demonstrate how the MERSCOPE platform can provide deep insights into the complex heterogeneity observed in the tumor microenvironment.

Spatial analysis of tumor-infiltrating lymphocytes in tumor microenvironment as biomarker for immune checkpoint inhibition in biliary tract cancer

Yeong Hak Bang[1], Kyunghye Bang[2], Jin Ho Shin[3], Hyunseok Yoon[4], Kyu-Pyo Kim[1], Inkeun Park[1], Jae Ho Jeong[1], Heung-Moon Chang[1], Baek-Yeol Ryoo[1], Chiyoon Oum[5], Seulki Kim[5], Yoojoo Lim[5], Gahee Park[5], Chan-Young Ock[5], Changhoon Yoo[1]. *[1]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Division of Hemato-Oncology, Department of Internal Medicine, Chung-Ang University Gwangmyeong Hospital, Gwangmyeong, Korea, Republic of,[3]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[4]Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[5]Lunit, Seoul, Korea, Republic of*

Background: Recently, anti-PD-L1 in combination with cytotoxic chemotherapy has shown significant survival benefit in a randomized phase 3 trial for unresectable or metastatic biliary tract cancer (BTC). However, no biomarker including PD-L1 expression has been established to predict clinical outcomes, and there is an unmet need for a novel predictive biomarker for anti-PD-1 or PD-L1 therapy. Here, we assessed TILs using artificial intelligence (AI)-powered spatial analysis in advanced BTC treated with anti-PD-1 beyond 1st line treatment.
Methods: An AI-powered whole-slide image (WSI) analyzer (Lunit SCOPE IO, Lunit, Seoul, Korea) was used to segment tumor epithelium and stroma, and identification of intratumor TIL (iTIL) and stromal TIL (sTIL). H&E stained WSI from pre-treatment samples was acquired from Asan Medical Center (n =166), and a total of 154 samples (92.8%) after quality control were used for the final analysis. Immune phenotypes (IP) were defined as follow: inflamed as high iTIL and sTIL; immune-excluded as low iTIL and high sTIL; immune-desert as low TIL overall. Among them, 20 patients were available for multi-color flow cytometry analysis (FACS) using peripheral blood mononuclear cells, collected at baseline, C1D8, and C2D1.
Results: All patients (n=154) were treated with anti-PD-1 (pembrolizumab or nivolumab) monotherapy, and 72 of 154 patients (46.8%) were treated as 2nd line. Gemcitabine plus cisplatin (GemCis) was used prior to anti-PD-1 as first-line therapy in all patients. Overall, 15 (9.7%) patients showed inflamed IP. With median follow-up duration of 15.4 months, the inflamed IP group showed better overall survival (17.2 vs. 6.6 months, P=0.03), and progression-free survival (PFS; 4.5 vs. 2.6 months, P=0.09) along with higher PFS rate at 12 months (33.3% vs. 11.5%, P=0.035), and overall response rate (26. 7% vs. 8.6%, P=0.053) than other phenotype groups. There was no significant difference in median PFS with GemCis among IP groups (P=0.74). In the FACS available subgroup, inflamed IP showed higher baseline central memory T (Tcm)+effector memory T (Tem)/Tnaive ratio than other IPs. With the administration of anti-PD-1, Tcm+Tem/Tnaive ratio was increased, while the proportion of PD1+CD8+T, CD39+CD8+T, CD103+CD8+T and Treg were decreased in the inflamed IP group than other phenotype groups.
Conclusions: Immune phenotypes classified by AI-powered spatial TIL analysis was effective to predict the clinical outcomes of patients with advanced BTC treated with anti-PD-1 therapy.

Clever-1/PD-L1 ratio predicts response to Bexmarilimab, a novel macrophage-guided immunotherapy, in immune deprived cancers

Mari L. Björkman[1], Elisa M. Vuorinen[1], Juho Jalkanen[1], Marie-Louise Fjällskog[1], Jussi Koivunen[1], Teppo Huttunen[2], Maija Hollmén[3], Petri Bono[4]. *[1]Faron Pharmaceuticals, Turku, Finland,[2]Estimates, Turku, Finland,[3]MediCity Research Laboratory and InFLAMES Flagship, University of Turku, Turku, Finland,[4]Terveystalo, Helsinki, Finland*

Introduction**:** Clever-1 is an immunosuppressive scavenger receptor expressed on tumor associated macrophages. High levels of Clever-1 are associated with poor survival, T-cell exclusion and dysfunction, and immunotherapy resistance. Bexmarilimab (FP-1305) is a novel humanized anti-Clever-1 IgG4-antibody capable of promoting an immune switch, potentially leading to intratumoral proinflammatory responses in patients. In a first-in-human all-comer single agent Phase I/II study in advanced solid tumors (NCT03733990) approximately 30% of patients in hepatocellular carcinoma, cutaneous melanoma and cholangiocarcinoma achieved immune activation, characterized by an IFNg response, which led to a survival benefit (ASCO 2022). Here, we show that patients getting a therapy benefit have immunologically cold tumors with low PD-L1 staining and high Clever-1 staining.

Methods: Pre-treatment tumor samples were immunohistochemically stained for Clever-1 (4G9, Santa Cruz) using Ventana platform and scored by % of intratumoral positive cells out of all viable cells and PD-L1 (22C3, Agilent) with combined positivity scoring (CPS). Ratio (PD-L1/Clever-1) at baseline was compared using non-parametric Wilcoxon-test according to clinical benefit.

Results: 23 successful baseline biopsies and stainings were obtained, 6 per cutaneous melanoma, 11 per cholangiocarcinoma and 1 per hepatocellular carcinoma, from patients treated with bexmarilimab. Patients had received an average of three previous lines of therapy. At baseline, patients that saw a clinical benefit (CBR) from bexmarilimab had average PD-L1/Clever-1 ratio of 0.2 compared to 4.4 ($p=0.042$, Wilcoxon nonparametric test) in patients that did not respond to the treatment.

Conclusion: PD-L1/Clever-1 IHC staining ratio may be used to predict bexmarilimab responding patients. These patients have a low PD-L1 staining and low IFNg levels as reported previously, and are often refractory to checkpoint inhibitors and other T cell activating agents. Bexmarilimab provides a novel therapy option for a tumor group that is otherwise poorly responsive to immune therapies.

#4335

Repurposing metformin in early-stage high risk prostate cancer to avoid ADT-induced cardiovascular toxicity

Philip Gregory[1], Beatriz Mateo-Victoriano[2], Ling Zhang[1], Cassie Due[3], Marijo Bilusic[4], Priyamvada Rai[5]. *[1]Radiation Oncology, University of Miami, Miami, FL,[2]Radiation Oncology, Sheila and David Fuente Graduate Program in Cancer Biology, University of Miami, Miami, FL,[3]College of Arts and Sciences, University of Miami, Miami, FL,[4]Department of Medical Oncology/Department of Medicine, University of Miami, Miami, FL,[5]Radiation Oncology, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL*

Prostate cancer is the second most common cause of cancer-related deaths in American men. About 20-40% of patients with localized castration-sensitive prostate cancer (CSPC) eventually progress, requiring androgen deprivation therapy (ADT). However ADT inevitably fails, giving rise to castration-resistant prostate cancer (CRPC), which is incurable and fatal. A significant fraction of patients undergoing ADT die of treatment-accelerated cardiovascular disease. Pre-existing metabolic

dysfunction has been implicated in PC disease incidence, higher rates of prostatectomy failure, and accelerated progression to CRPC. Thus, there is an unmet need to counter the adverse sequelae of ADT through alternative CSPC treatments that do not exacerbate metabolic syndrome but prevent PC progression. Few studies have evaluated whether targeting the metabolic dysfunction associated with early-stage PC can prevent progression and thus the need for ADT. In a recent clinical trial spearheaded by Dr. Bilusic, metformin, an affordable and well-tolerated insulin-sensitizing diabetes drug, has recently shown promise as monotherapy in biologically-recurrent CSPC, preventing PSA rise in about 40% of high-risk patients. To identify the molecular mechanisms and biomarkers of positive response to metformin in PC patients, we performed preliminary cytokine profiling of responder vs non-responder patient sera. We found that mitigation of inflammatory factors implicated in cardiovascular disease as well as markers of pro-apoptotic response are associated with positive metformin response. We also found that metformin responders exhibited pre-treatment cytokine signatures associated with inflammatory metabolic diseases, including diabetes and hyperinsulinemia, which are conditions known to benefit from metformin treatment. We have been able to model the variability of metformin treatment response in two well-characterized CSPC cell lines, LNCaP (highly responsive) and LAPC4 (minimally responsive). Metformin induced cell death in LNCaP but not in LAPC4, which possesses mutant p53 and high Bcl-2 levels. LAPC4 instead showed markers of senescence, which is associated with an inflammatory phenotype. Metformin also elevated levels of damaging high-potency (short-lived) ROS in LNCaP to a greater extent than in LAPC4. LAPC4 instead exhibited elevated levels of hydrogen peroxide upon metformin treatment, a ROS associated with inflammation. Thus the cell models show congruence with factors of positive response seen in patients. Our findings shed light on the potential mechanism of positive response to metformin in CSPC patients, and lay the groundwork for further investigation, while insight into biomarkers predicting positive response could be immediately useful in the clinic.

Automation of proximity ligation immunoassay for interaction between PDL1 and PD1 detection in the tumor microenvironment using microfluidic based system

Hampus Elofsson[1], Agata Zieba Wicher[1], Carolina Oses Sepulveda[2], Tony Ullman[2], Maria-Giuseppina Procopio[3], Alix Faillétaz[3], Diego G. Dupouy[3], Charlotte Stadler[2]. *[1]R&D, Navinci Diagnostics AB, Uppsala, Sweden,[2]SciLife Lab, Royal Institute of Technology (KTH), Stockholm, Sweden,[3]R&D, Lunaphore Technologies S.A., Tolochenaz, Switzerland*

The PD-1/PD-L1 signaling pathway is essential for immune control and maintaining immune system balance. PD-1 and PD-L1 proteins exert most functions in cells and tissues by undergoing modifications and forming dynamic complexes – effects that cannot be explored by genomics, transcriptomics, or conventional immunostaining methods. Numerous cancer therapies are being developed that affect PD-1/PD-L1 signaling, and tools to study the PD-1/PD-L1 axis are, therefore, essential. One prerequisite for successfully establishing diagnostic assays is reproducibility, standardization, and, ideally, high sample throughput via automation. Here, we aimed to introduce a new technological solution to allow for the simultaneous detection of PD-L1 and PD-1 interaction and the adjacent immune cell context in tissue samples on the Lunaphore's automated microfluidic staining platform. The assay for detecting PD-1-PD-L1 interaction was developed and technically validated by Navinci Diagnostics. Although the detection of interaction alone provided important information on the immune status in the tumor microenvironment, we believed that PD-1/PD-L1 readout would be most powerful in the context of its cellular ecosystem. Therefore, the PD-1/PD-L1 assay was combined with the analysis of immune and cancer cells to determine their involvement in this signaling. The feasibility of combining multiplex immunofluorescence with proximity ligation assay was conducted and confirmed on human tonsils. The spatial profiling panel included immune

markers for all T-cells (CD3), helper T-cell (CD4), cytotoxic T-cells (CD8), B-cells (CD19/20) and activation/exhaustion markers granzyme B (activated cytotoxic T-cell), Ki67 (proliferating cells), and LAG3 (malignant B cells, CD8 T cells, CD4 T_{regs}). We evaluated, implemented, and optimized the assays on the Lunaphore staining instrument to reduce labor time and cost for the end users. In the next phase, the potential of our assay to be benchmarked as a diagnostic tool in clinical praxis will be thoroughly tested and validated on diagnostic tissue samples from NSCLC patient cohorts. We believe this approach will enable spatial and functional studies of the interface between the tumor and the immune system and provide necessary information about signaling pathway activation in situ, the latest representing a novel state-of-the-art in tissue diagnostics.

Predicting PD-L1 status in solid tumors using transcriptomic data and artificial intelligence algorithms

Ahmad Charifa[1], Alfonso Lam[1], Hong Zhang[1], Andrew Ip[2], Andrew Pecora[2], Stanley Waintraub[2], Deena Graham[2], Donna McNamara[2], Martin Gutierrez[2], Andrew Jennis[2], Ipsa Sharma[1], Jeffrey Estella[1], Wanlong Ma[1], Andre Goy[2], Maher Albitar[1]. *[1]Genomic Testing Cooperative, Irvine, CA,[2]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, NJ*

PD-L1 immunohistochemistry (IHC) is routinely used to predict the clinical response to immune checkpoint inhibitors (ICIs); however, multiple assays and antibodies have been used. This study aimed to evaluate the potential of targeted transcriptome and artificial intelligence (AI) to determine PD-L1 RNA expression levels and predict the ICI response compared to traditional IHC. RNA from 396 solid tumors samples was sequenced using next-generation sequencing (NGS) with a targeted 1408-gene panel. RNA expression and PD-L1 IHC were assessed across a broad range of PD-L1 expression levels. The geometric mean naïve Bayesian (GMNB) classifier was used to predict the PD-L1 status. PD-L1 RNA levels assessed by NGS demonstrated robust linearity across high and low expression ranges, and those assessed using NGS and IHC (Tumor cells (TC), Tumor Proportion Score (TPS) and tumor-infiltrating immune cells (ICs) were highly correlated (Tables 1). RNA sequencing provided in-depth information on the tumor microenvironment and immune response, including CD19, CD22, CD8A, CTLA4, and PD-L2 expression status. Sub-analyses showed a sustained correlation of mRNA expression with IHC (TPS and ICs) across different solid tumor types. Machine learning showed high accuracy in predicting PD-L1 status, with the area under the curve varying between 0.988 and 0.920. Targeted transcriptome sequencing combined with AI is highly useful for predicting PD-L1 status. Measuring PD-L1 mRNA expression by NGS is comparable to measuring PD-L1 expression by IHC for predicting ICI response. RNA expression has the added advantages of being amenable to standardization and avoidance of interpretation bias, along with an in-depth evaluation of the tumor microenvironment.

Correlation between PD-L1 expression levels and PD-L1 IHC results

IHC test results	Variable	Cases (N)	Mean	Median	Range	Lower Quartile	Upper Quartile	10th Percentile	90th Percentile	Std. Dev.

Development of new droplet digital PCR method for MSI assessment with automated analysis pipeline shows concordance in FFPE and plasma

Sarah Kreston, Mai Ho, Claire Gould, Ubaradka Sathyanarayana, Brittany D'Alessio, Janice Riley, Gary A. Pestano. *Biodesix, Inc., Boulder, CO*

Introduct**ion**: Microsatellite instability (MSI) arises when short tandem DNA repeat sequences undergo a length change due to impaired mismatch repair (MMR). MSI is present in many cancers and is an approved biomarker for immune checkpoint inhibitor therapy. In this study, we used 71 clinical specimens to evaluate a new droplet digital (ddPCR) method to assess MSI in tissue and in plasma. The ddPCR assay is designed to detect mutations in BAT25, BAT26, NR21, NR24 and Mono27, and is intended for use in FFPE. Our evaluation extended these analyses to cfDNA in plasma.

Methods: DNA was extracted from ten (10) CRC FFPE samples, fifty-two (52) CRC liquid biopsies, and ten (10) Normal Healthy Donors (NHD) and tested using the new assay. DNA extracts were quantified by fluorescence, and duplicate ddPCR reactions were performed using 2.6 ng input DNA per well. MSI status was determined with a pre-commercial release auto-calling analysis software, which makes a positive call (MSI-High) when two or more of the five MSI markers ($\geq$ 40%) are detected. Markers are called positive if the fractional abundance or copy number is greater than the previously established limit of blank (LOB) in FFPE and plasma, respectively. For FFPE, the LOBs (%) are 2.11 (BAT25), 0.34 (BAT26), 2.38 (NR21), 1.51 (NR24) and 0.56 (Mono27) based on analytic specimen evaluation. For plasma, a marker is positive if one (1) mutant copy is detected.

Results: All 10 FFPE samples were deemed to be concordant with the reference Promega PCR assay at the microsatellite evaluation level. Additionally, the 8 cfDNA samples with reference MSI status yielded 87.5% (7/8) concordant results for microsatellite loci status. A survey of 44 plasma

colorectal donor samples and 10 NHD samples with no reference results, yielded various microsatellite status as expected. The auto calling module for microsatellite loci status in these plasma samples accurately called 85.2 status (n = 54). At the marker level, 87% of BAT25, 98.1% of BAT26, 92.6% of NR21, 79.6% of NR24, and 61.1% of Mono27 calls were concordant between auto-calling and expert review.
Conclusion: The new droplet digital MSI assay coupled with an automated calling module for MSI Status provides a convenient, cost-effective, and reproducible laboratory test method to determine MSI status in FFPE specimens. The utility of the test method and auto calling method for detection of MSI in cfDNA is less clear, with heterogenous clusters that require expert review appearing more often than in FFPE samples.

HLA-B44 motif neoepitope is associated with a favorable tumor immune microenvironment and predicts ICB response in NSCLC

Rui Li[1], Charlene M. Fares[2], Tristan R. Grogan[3], Tianhao Zhang[4], Debory Li[5], Matthew Theisen[6], Maria A. Velez[7], Paige M. Brodrick[7], Jackson P. Lind-Lebuffe[7], Yazeed Radwan[7], Gregory A. Ayzenberg[7], David Elashoff[3], Bin Liu[8], Aaron E. Lisberg[7], Amy L. Cumming[7], Edward B. Garon[7].
[1]Internal Medicine, UCLA David Geffen School of Medicine, Los Angeles, CA,[2]Allina Health Cancer Institute, Saint Paul, MN,[3]General Internal Medicine and Health Services Research, UCLA David Geffen School of Medicine, Los Angeles, CA,[4]Molecular Biology, UCLA David Geffen School of Medicine, Los Angeles, CA,[5]Medicine, Western University of Health Sciences, Los Angeles, CA,[6]Kensho Technologies, Los Angeles, CA,[7]Hematology/Oncology, UCLA David Geffen School of Medicine, Los Angeles, CA,[8]Pulmonary and Critical Care, UCLA David Geffen School of Medicine, Los Angeles, CA

Immune check point blockade (ICB) has recently transformed the treatment of non-small cell lung (NSCLC). However, the majority of patients do not respond to ICB. For ICB to be effective, tumor neoantigens need to be presented in a human leukocyte antigen (HLA) class I-restricted manner. Recent studies by our group and others have shown that HLA-B44 supertype is associated with extended survival in patients treated with ICB. Herein, we hypothesize that HLA-B44-specific motif neoepitopes generate an active tumor immune microenvironment and a favorable ICB response in NSCLC. Utilizing the TCGA database, we found that nearly half of the NSCLC patients have at least one HLA-B44 allele, of whom 36.8% and 37.3% of patients harbor at least one B44 motif neoepitope in lung adenocarcinoma (LUAD) and lung squamous carcinoma (LUSC), respectively. In a pooled analysis of patients with LUAD and LUSC, gene expression of *PD-L1*, *CTLA-4*, *LAG-3*, *CXCL9*, *CXCL10*, *CXCL13*, *CD8A* and cytolytic gene signature (includes *GZMA* and *PRF1*) is elevated in patients with B44 motif neoepitopes compared to those without motif neoepitopes. Immune cell component analysis showed increased infiltration of Th1, Th2 and CD8 T cells in LUAD and regulatory and CD8 T cells in LUSC. Although a linear regression model revealed a positive correlation between tumor mutational burden (TMB) and number of B44 motif neoepitopes, pooled analysis of LUAD and LUSC with similar TMB showed significant elevation of *CTLA-4*, *LAG3*, *CXCL10* and a trend of increased expression of *CXCL9* in motif patients. Upon investigation of possible immune editing, we found a significantly higher proportion of genes containing B44 neoepitope downregulated at the RNA level both in LUAD and LUSC. Lastly, we showed that combining B44 motif with either PD-L1 or TMB improved prediction of progression-free survival in NSCLC patients treated with ICB. In summary, we demonstrate that HLA-B44 motif neoepitopes are associated with a favorable tumor immune microenvironment and can serve as a potential biomarker for ICB benefit in NSCLC patients.

#4341

Indoleamine 2,3-dioxygenase 1 is highly expressed in tertiary lymphoid structures and associated with improved outcome in patients with advanced non-small cell lung cancer treated with anti-PD1/PDL1 inhibitors

Jean-Philippe Guegan[1], Florent Peyraud[2], Christophe Rey[1], Oren Ngouala[1], Ophélie Odin[1], Imane Nafia[1], Isabelle Soubeyran[2], Sylvestre Le Moulec[3], Alban Bessede[1], Antoine Italiano[2]. *[1]Explicyte, Bordeaux, France,[2]Institute Bergonié, Bordeaux cedex, France,[3]Clinique Marzet, Pau, France*

Background**:** Immune checkpoint inhibitors (ICI) has revolutionized the management of patients with non-small cell lung cancer (NSCLC). However, most patients with advanced NSCLC patients displayed primary resistance to ICI. Indoleamine 2,3-dioxygenase 1 (IDO1) may play a role in primary resistance by catabolizing tryptophan to several immunosuppressive metabolites such as kynurenine. The aim of our study was to investigate the role of IDO1 expression in the outcome of NSCLC patients treated with immunotherapy.

Methods: We analyzed the largest NSCLC gene expression (GE) dataset worldwide including 891 pre-treatment tumors from POPLAR and OAK studies, two RCT assessing the efficacy of atezolizumab vs docetaxel in NSCLC. We then confirm our findings with multiplex immunofluorescence (mIF) and digital pathology analysis to investigate the correlation between expression of IDO1 by tumor cells and spatial distribution of CD8+ T cells.

Results: The PFS of $IDO1^{high}$ patients was significantly higher than $IDO1^{low}$ (3.81 vs 1.89months, p=7.13e-09). Strikingly, high IDO1 expression was also associated with better ORR (19.9% vs 5.2%, p=9.93e-05) and improved OS (15.9 vs 9.65 months, p=6.35e-06). When adjusting for covariates (histological subtype, TLS signature, PD-L1 expression), IDO1 remained independently associated with PFS (HR 1.54, p=4.1e-4) and OS (HR 1.43, p=8.2e-3). None of these correlations were observed in the docetaxel arm, suggesting a predictive value of IDO1 GE specifically for response to atezolizumab. Using a deconvolution approach, the tumor microenvironment composition differed significantly between $IDO1^{high}$ and $IDO1^{low}$ tumors. Indeed, $IDO1^{high}$ tumors were characterized by the highest expression of genes specific to immune populations such as interferon-gamma-producing T helper 1 (Th1) cells, CD8+ T cells, natural killer cells, cytotoxic lymphocytes, and B cells. To further validate our findings, we performed mIF on 53 NSCLC tumors. Overall, elevated IDO1 expression by tumor cells was correlated with increased CD8+/PD1+ T cells infiltration (p=0.001). Spatial cell distribution analysis also revealed that the relative distance between tumor cells and CD8+ T cells was significantly lower in $IDO1^{high}$ compared to $IDO1^{low}$ patients. Interestingly, 52% of tumors were characterized by the presence of TLS and IDO1 was observed in most TLS analyzed.

Conclusions: IDO1 expression by tumor cells in NSCLC is associated with improved outcome in patients with NSCLC, independently of PDL1 expression score. IDO1 overexpression in NSCLC is associated with increased immune activity and may represent a negative feedback mechanism to CD8+ T cell infiltration.

Lacher[4]. *[1]Department of Medicine, Washington University, Saint Louis, MO,[2]Washington University, Saint Louis,*

MO,[3]Department of Internal Medicine, Washington University, Saint Louis, MO,[4]Notable Labs, Foster City, CA

Introduction: Offering the optimal frontline treatment to a patient with acute myeloid leukemia (AML) requires trading off expected benefit and risk. Typical standard of care intensive induction chemotherapy (e.g., cytarabine plus idarubicin (7+3)) results in high clinical response rates. However, many patients receive a less intensive regimen (e.g., venetoclax plus decitabine (VenDec)) because their individual toxicity risk is high based on lack of medical fitness. Predicting an individual patient's clinical response prior to treatment has the potential to increase the benefit/risk ratio (therapeutic index) for some patients and optimize their treatment selection. Here, we demonstrate the ability of an automated high-throughput, multi-color flow cytometry predictive precision medicine platform (PPMP) to predict response to 7+3 or VenDec.
Methods: To assess correlation between PPMP-predicted and actual clinical response to 7+3 or VenDec in clinical trial NCT04263181, pre-induction blood samples were collected from 31 patients of which 18 received 7+3 (all newly diagnosed (ND) AML) and 13 VenDec (7 ND AML, 5 secondary AML, 1 MDS). We measured drug effects on leukemic blasts by applying a cutoff at the total blast count that optimizes separation between predicted responders and non-responders ("conventional approach") or by a machine learning (ML) approach considering multiple cell populations. For the former approach, training sets represented 13 patients for 7+3 and 8 for VenDec. Both 7+3 and VenDec models were validated with 5 patients. For the ML approach, the model was trained on all 13 VenDec patients and monitored using leave-one-out cross-validation.
Results: For the conventional approach, predicted and true clinical responses were highly correlated for 7+3 (AUC = 0.91) and VenDec (AUC = 0.81), with 100% precision (positive predictive values (PPV)) for both, i.e., all predicted responders were true clinical responders. Some true clinical responders were not identified (negative predictive value (NPV) = 67% for 7+3 and 57% for VenDec), resulting in an accuracy of 94% (7+3) and 77% (VenDec). To maximize NPV and accuracy for predicting VenDec clinical outcomes, we applied a novel ML-based algorithm to integrate the behavior of malignant and non-malignant cell populations, yielding a model with 100% accuracy (100% PPV and NPV). Additional outcome data, including overall survival, are under evaluation.
Summary: Total blast-based predictions yielded accuracies of 94% for 7+3 and 77% for VenDec. An ML algorithm for VenDec considering additional cell populations increased the accuracy to 100%. Further studies will expand patient numbers. We plan to use this platform to inform our frontline decision making with the goal to maximize the therapeutic benefit/risk ratio and ensure that the most appropriate frontline therapy is used for each individual patient.

Development of an *APC* and *TP53*-based duplex sequencing assay to positively predict colorectal cancer response to EGFR inhibitors

Mingli Yang[1], Michael J. Schell[2], Lance Pflieger[3], Jesse Salk[4], Timothy J. Yeatman[1]. *[1]Department of Surgery, University of South Florida, Tampa, FL,[2]Moffitt Cancer Center and Research Institute, Tampa, FL,[3]Phenome Health, Seattle, WA,[4]TwinStrand Biosciences, Seattle, WA*

Two well-characterized EGFR inhibitor (EGFRi) therapies (cetuximab, panitumumab) have been FDA approved for metastatic colorectal cancer (CRC). Unfortunately, the extended RAS/RAF testing required in the drug labels, identifies only non-responders, and only ~50% of treated patients will respond to therapy. Thus, there is an unmet need to develop additional biomarkers to identify EGFRi sensitive patients. Using an innovative hybrid approach fusing gene expression and DNA sequencing, we recently reported that combined mutations in *APC* and *TP53* were strongly correlated with a validated gene expression signature measuring cetuximab sensitivity in CRC

human tumors (Yang et al. *Cancer Epidemiol Biomarkers Prev.* 2019), suggesting a potential positive biomarker role of *APC* + *TP53* mutations. This finding prompted us to develop a DNA test designed to positively select EGFRi-responsive patients as augmentation to currently used negative predictors for CRC patients. By leveraging the TwinStrand Duplex Sequencing (DS) technology, we recently developed an ultrasensitive custom 6-gene panel (*APC, TP53, KRAS, BRAF, NRAS*, and *HRAS*) CLIA-certified assay for FFPE CRC tissues. The assay has been analytically validated using reference cell lines (n=10) which were individually sequenced to >3,000x Duplex depth. The 6-gene DS assay yielded exceptionally high assay performance: (1) accuracy (passed, $r^2 = 0.98$ for Duplex VAF vs. target VAF for Positive Control mutations); (2) sensitivity (passed, all mutations >1/5,000 were detected in all Positive Control replicates; 1 mutation at 1/5,000 was detected in 2/3 replicates), (3) specificity (passed, 2 mutations detected in the Negative Control at 1 count in 1 replicate; VAF <1/10,000), and (4) precision (passed, <2-fold variation among Positive Control replicates for VAF >1/500). Importantly, the validation analysis on fresh frozen (FF):FFPE paired tissues from 21 CRC patients shows: (1) The 6-gene DS assay performed on FFPE samples faithfully reproduces assay results on FF samples; (2) The ultrasensitive DS assay can accurately detect additional "new" mutations at low allelic frequencies compared to a standard NGS method. TwinStrand DS identified 17 mutations not identified by standard NGS; 13 of these new mutations had < 10% VAF. Furthermore, preliminary Kaplan-Meier analysis of the third-line EGFRi data shows that while the statistical significance was not achieved due to the small simple size (n=28), patients harboring combined *APC* and *TP53* mutations(AP) (vs non-AP patients) tended to have longer progression free survival (6.65 vs 3.95 months, P=0.064) and overall survival (17.80 vs 10.65 months, P=0.14). Additional data acquisition and analysis is ongoing. Thus, there is an opportunity to change clinical practice and standards of care to ultimately improve CRC outcomes if this new, robust, sensitive test is clinically-validated.

Consensus genomic subtypes of gastric adenocarcinoma and their therapeutic implication

Yun Seong Jeong[1], Young-Gyu Eun[2], Sung Hwan Lee[3], Sang-Hee Kang[4], Sun Young Yim[5], Eui Hyun Kim[6], Joo Kyung Noh[2], Bo Hwa Sohn[1], Ju-Seog Lee[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Kyung Hee University, Seoul, Korea, Republic of,[3]CHA Bundang Medical Center, Seongnam, Korea, Republic of,[4]Korea University Guro Hospital, Seoulg, Korea, Republic of,[5]Korea University College of Medicine, Seoul, Korea, Republic of,[6]Yonsei University College of Medicine, Seoul, Korea, Republic of*

Background**:** Gastric adenocarcinoma (GAC) is heterogeneous lethal disease in genomic and clinical level. Although the clinical relevance of genomic and molecular subtypes of GAC has been demonstrated, their translation to the clinic has been hindered by discrepancies in classification methods. We aim to examine a consensus of genomic subtypes and correlate them with clinical outcomes.

Method: We collected genomic data from 2527 GAC tumors and divided the data into discovery (n = 1427) and validation sets (n = 1100). By integrating 8 previously established genomic subtype algorithms, we identified 6 clinically and molecularly distinct genomic consensus subtypes (CGSs) in discovery set. For validation of clinical significance of new subtypes, we constructed GAC predictor of integrated consensus subtype with 120 genes (GPICS120) and applied it to validation data set. In systematic analysis of genomic and proteomic data, we estimated potential response rate of each subtype to standard and experimental treatments such as radiation therapy, target therapy, and immunotherapy and further validated their functional significance in cell line models.

Results: Among identified 6 subtypes. CGS1 is characterized by poorest prognosis, very high stem cell characteristics, and high IGF1 expression, but low genomic alterations. CGS2 showed canonical

epithelial gene expression patterns. CGS3 and CGS4 are characterized by high copy number alterations and low immune activity. However, CGS3 and CGS4 are different in high HER2 activation (CGS3) and SALL4 and KRAS activation (CSG4). CGS5 has highest mutation burden and moderately high immune activity that is characteristics of MSI-high tumors. Most of CGS6 tumors are EBV-positive and shows extremely high methylation and high immune activity. Most interestingly, CSG1 is most responsive to immunotherapy while CGS3 is significantly associated with benefit of chemoradiation therapy due to high basal level ferroptosis. In addition, we also identified potential therapeutic targets for each subtype.
Conclusion: Consensus subtype is robust classification system and can be the basis for pre-clinical investigation of subtype-based targeted interventions and future clinical trials.

Molecular pathology studies reveal PD1+ CD8 T cell density correlates with response to supraphysiological testosterone treatment in pre-treatment biopsies and MYC mRNA and protein correlate with response after treatment

Carolina Gomes Alexandre[1], Jessica Hicks[1], Tracy Jones[2], John T Isaacs[1], Kiara Bowers[1], Alyza Skist[1], Laura Sena[1], Jennifer Meyers[2], Emmanuel Antonarakis[1], David Sanin[1], Hanfei Qi[1], Samuel Denmeade[1], Mark Markowski[1], Srinivasan Yegnasubramanian[1], Angelo De Marzo[1]. *[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Pathology, Johns Hopkins University School of Medicine, Baltimore, MD*

While most patients with metastatic prostatic adenocarcinoma respond initially, nearly all develop resistance to multiple lines of androgen deprivation therapies. This is related to overexpression of the androgen receptor (AR), which is frequently driven by AR amplification. In some patients, increased AR renders tumor cells sensitive to high dose androgens which paradoxically inhibits their growth. Bipolar Androgen Therapy (BAT) was introduced in which patients with castration resistant prostate cancer (CRPC) are treated intermittently with high dose testosterone. This produces biochemical and objective responses, and may re-sensitize prostate cancer to subsequent second generation AR inhibitors. This study utilizes samples from a recently performed clinical trial for patients with CRPC that included sequential biopsies of soft tissue metastases before BAT and after 3 cycles of BAT and before patients were treated with nivolumab.Tumor cells were present in FFPE blocks for both the pretreatment and C4D1 time points for 24 of the patients. These FFPE samples were stained using a recently validated iterative multiplex IHC assay containing 6 antibodies including: CD3 (T cells), CD4 (Helper T Cells), CD8 (Cytotoxic T Cells), PD1 (T Cell Checkpoint), FOXP3 (T-Reg cells), and Keratin 8 (epithelial cell marker). Biopsy slides were scanned after each round of staining and whole slide scans were imported into the HALO image analysis where they underwent color deconvolution, image registration and fusion. Regions of tumor were demarcated manually, and computerized automated image analysis was used to determine cell densities for 8 cell phenotypes (total CD3+, CD3+CD4+, CD3+CD8+, CD3+CD4+Foxp3+, CD3+CD4+PD1+, CD3+CD8+PD1+, CD3+CD4+PD1-, CD3+CD8+PD1-). There was a higher density of CD3+CD8+PD1+ cells in the pretreatment biopsies of men who responded (R) (to BAT) as compared with those who did not respond (NR)(p=0.015 Wilcoxon rank-sum test; mean 92.7 [R] vs 13.9 [NR]). The difference in R vs. NR was less and not significant in the CD3+CD8+PD1- population. There was a trend towards a higher density of CD3+CD4+PD1+ cells in the pretreatment samples in responders, but less so in the CD3+CD4+PD1- population. In the C4D1 biopsies, only CD3+ total cells were significantly higher in the R vs. NR (P=0.02), but the other phenotypes were not. We conclude that increased density of CD3+C8+PD1+, but not CD3+CD8+PD1- cells was present in pre-treatment biopsies in responders as compared with non-responders to BAT. These results indicate that men who are likely to respond to high dose testosterone treatment harbor tumors that are immunologically distinct prior to treatment

than those men unlikely to respond. Additional spatial analysis and comparisons with RNAseq data will be presented.

TFF1 and TFF3 predict response to CDK4/6 inhibitors in breast cancer patients

Linjie Luo[1], Yan Wang[2], Sophia Mastoraki[2], Akshara Singareeka Raghavendra[3], Juliana Navarro-Yepes[2], Nicole M. Kettner[1], Serena Kim[4], Debasish Tripathy[5], Kelly Hunt[6], Khandan Keyomarsi[1].
[1]Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]2School of Social Sciences, Rice University, Houston, TX,[5]Breast Cancer Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Breast Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background**:** Cyclin-dependent kinase 4/6 inhibitors (CDK4/6is) in combination with endocrine therapy (ET) have become the mainstay treatment for patients with hormone receptor (ER)-positive, HER2-negative metastatic breast cancer (BC). However, one-third of patients do not respond to the treatment (intrinsic resistance), leading to early tumor progression and treatment failure, and most patients eventually acquire resistance to therapy. The exact mechanisms of resistance to CDK4/6i are yet to be elucidated, and due to subsequent early (intrinsic) or late progression on CDK4/6i, long-term cures are not achieved.
Methods: Transcriptomic profiles of BC cell lines that were sensitive or resistant to approved CDK4/6i, independent of subtype, were downloaded from the Cancer Cell Line Encyclopedia database. Bioinformatics analysis was performed by integrated Differential Expression and Pathway (iDEP) workflow. In parallel, transcriptomic profiles of metastatic biopsies from pre-CDK4/6i-treated BC patients (n = 54) were generated using RNA-Access technology. Key common biomarkers identified from the BC cell lines and patient tumor samples were validated by immunohistochemistry in formalin-fixed paraffin-embedded (FFPE) metastatic specimens from 73 patients prior to CDK4/6i therapy.
Results: Transcriptomic profile comparisons of BC cell lines (n = 35) that were sensitive versus resistant to CDK4/6is identified Trefoil Factor 1 and 3 (TFF1 and TFF3) secretory proteins as top predictors of response. Correlation analysis showed a strong negative correlation between TFF1 and TFF3 levels to IC50 values of palbociclib and abemaciclib. Knockdown of TFF3 in CDK4/6i-sensitive BT20 cells with shRNA induced drug resistance in the cells. Transcriptomic data from 54 BC patients pre-treated with CDK4/6i showed the expression levels of TFF1 and TFF1/3 receptors (CCR4 and CCR7) were significantly increased in patients who developed late progression (> 6 months) compared to early progressors (< 3 months). In addition, IHC analysis of TFF1 and TFF3 expressions in 73 pre-treated BC patient samples showed significantly higher protein expression levels in late progressors than in early progressors.
Conclusions: Our results identified and validated the common biomarkers, TFF1 and TFF3, as predictors of CDK4/6i response efficacy in ER-positive, HER2-negative BC patients. These findings provide a predictive tool capable of selecting *de novo* metastatic BC patients who will have the greatest benefit from the combination of CDK4/6i with endocrine treatment. Furthermore, our discovery of biomarkers in early versus late progression on CDK4/6i therapy will enable new therapeutic avenues and provide the rationale for future large-scale clinical trials.

A pivotal clinical trial of cResponse, a functional assay for cancer precision medicine

Seth Salpeter[1], Vered Bar[1], Guy Neev[1], Adi Zundelevich[1], Gil Rosen[1], Sandra Hanks[2], Naoise Costelloe[3], Jonathan Krell[4], Ravid Straussman[5]. *[1]Curesponse Ltd, Rehovot, Israel,[2]Curesponse UK Ltd, Sutton, United Kingdom,[3]Curesponse UK, Sutton, United Kingdom,[4]Imperial College, London, United Kingdom,[5]Weizmann Institute, Rehovot, Israel*

Precision cancer therapy has the potential to revolutionize treatment outcome. While genomic analysis has become central to cancer personalized medicine, recent studies have not shown that it drastically improves the patient's survival as compared to standard drug selection. Additionally, genomic mutations may suggest several treatment protocols without elucidating which approach will yield the best clinical response. To advance cancer precision guidance, we have developed cResponse, a combined genomic-functional drug sensitivity platform to determine individualized patient treatment regimens. Fresh patient cancer samples are taken by biopsy or resection and sectioned into 250uM slices which when cultured in cResponse platform demonstrate similar architecture and tissue proliferation to those found in vivo. An initial clinical study showed that cResponse can preserve human cancer tissue in 3D culture together with its microenvironment, including endothelial and immune cells, at a high viability (>90%) with continued cell division for more than 7 days. On a cohort of 34 patients treated with neoadjuvant therapy or systemic therapy for metastatic disease, the assay was able to predict patient response to drug treatment with a sensitivity of 96% and a specificity of 77.7%. To further validate the capacity of the cResponse platform to predict patient response to cancer therapy, a follow up pivotal clinical study was established at 7 major cancer centers located in the UK with the goal of recruiting a total of 170 patients to provide a large statistical validation of the previous results. Here we report on the outcome of the first 50 patients recruited to the pivotal trial and describe the predictive results correlated to patient response.

#4348

Validation of an integrative pan-solid tumor predictor of pembrolizumab monotherapy benefit

Benjamin J. Bulen, Nickolay A. Khazanov, Laura E. Lamb, Daniel H. Hovelson, Kat Kwiatkowski, D. Bryan Johnson, Daniel R. Rhodes, Scott A. Tomlins. *Strata Oncology, Ann Arbor, MI*

Background: We previously reported the development and validation of an integrative Immunotherapy Response Score (IRS) algorithm, which integrates tumor mutation burden (TMB) and quantitative gene expression of PD-L1, PD-1, ADAM12 and TOP2A, to predict PD-1 or PD-L1 (together PD-[L]1) monotherapy (mono) benefit across solid tumors from routine formalin fixed paraffin embedded samples. Herein, we evaluated IRS performance for predicting pembrolizumab (pembro) mono benefit in a second, independent validation cohort.
Methods: We identified patients from an ongoing observational trial (NCT03061305) integrating molecular profiling with real world treatment data who were 1) treated with systemic pembro mono, 2) not included in the original IRS cohort, and 3) had valid molecular profiling data to generate IRS. IRS status (IRS-High [H] vs. -Low [L] by the previously validated threshold; -H with increased benefit) association with pembro real world progression free survival (rwPFS) by time-to-next therapy was determined by Cox proportional hazard modeling (adjusting for age, gender, line of systemic therapy, and PD-(L)1 mono indicated (microsatellite instable high [MSI-H], TMB-H, or approved tumor type) vs. not indicated. The predictive nature of the IRS biomarker was assessed in the subset of >= 2nd line patients through a case cross-over analysis (pembro rwPFS vs. immediately preceding therapy line rwPFS) as assessed by likelihood ratio test (LRT).
Results: Of the 176 patients in this independent validation cohort (from 25 tumor types), 78 (44%) patients were IRS-H, while 40 (23%) were TMB-H. Pembro mono rwPFS was significantly longer in IRS-H vs. IRS-L patients (median rwPFS 18.7 vs. 6.4 months, adjusted hazard ratio [aHR] 0.46,

p=0.007), while PD-(L)1 mono indicated status was not associated with pembro mono rwPFS (indicated vs. not indicated aHR 1.47, p=0.26). In the case cross-over analysis of 55 (31%) patients treated with systemic therapy prior to pembro mono, pembro rwPFS was significantly longer than preceding therapy in IRS-H patients (median 18.7 vs. 5.5 months) but not IRS-L patients (median 4.9 vs. 5.4 months); the LRT for interaction between IRS status and pembro/prior therapy was significant (p=0.046); results in the TMB-L/non-MSI-H subset (n=45) of patients was similar (LRT p=0.025).
Conclusion: These results confirm the pan-solid tumor PD-(L)1 monotherapy predictive nature of the IRS biomarker.

#4349

C-C chemokine receptor 2-positive monocytic myeloid-derived suppressor cells predicts chemotherapeutic responses of the metastatic lesions in breast cancer patients

Ju Won Kim[1], Jason K. Sa[2], Seung Pil Jung[3], Kyong Hwa Park[1], Serk In Park[4]. *[1]Department of Internal Medicine, Korea University Anam Hospital, Seoul, Korea, Republic of,[2]Biomedical Sciences, Korea University College of Medicine, Seoul, Korea, Republic of,[3]Department of Surgery, Korea University Anam Hospital, Seoul, Korea, Republic of,[4]Biochemistry and Molecular Biology, Korea University College of Medicine, Seoul, Korea, Republic of*

Anti-tumoral T cell immunity is counterbalanced by several types of immunosuppressive cells such as Myeloid-Derived Suppressor Cells (MDSC). Circulating MDSC levels correlate with poor prognosis and metastatic progression of breast cancer patients. However, the value of MDSC in predicting chemotherapeutic treatment responses in the metastatic lesions is not clearly understood. We performed a prospective cohort clinical study to measure MDSC before and after chemotherapy in metastatic breast cancer patients (*N*=64). Multicolor flow cytometry was used to quantitate two major subtypes, i.e. monocytic (M-) and polymorphonuclear (PMN-) MDSC, and one additional subtype, C-C chemokine receptor 2 (CCR2)-positive M-MDSC in the fresh peripheral blood mononuclear cells. M-MDSC were defined as HLA-DR$^{low/-}$CD45^{+}CD11b^{+}CD15^{-}CD14^{+} PBMC, and PMN-MDSC were defined as CD45^{+}CD11b^{+}CD33^{+}CD15^{+} CD14^{-} PBMC. PMN-MDSC and CCR2^{+} M-MDSC, but not M-MDSC, were significantly increased after chemotherapy. Subsequently, we divided the patients by two groups (therapy-sensitive *vs*. -resistant groups) by treatment responses. Treatment-resistant patients had significantly increased CCR2^{+} M-MDSC. Unsupervised clustering of patients based on MDSCs populations dichotomized patients PMN-MDSC high or M-MDSC high groups. M-MDSC high patients had increased bone and lymph node metastasis. In addition, CCR2^{+} M-MDSC levels correlated with the progression-free survival (P<0.05). Altogether, our results showed that CCR2^{+} M-MDSC levels potentially predict the therapeutic responses in the metastatic lesions of breast cancer patients.

Pharmacodynamic biomarkers: Evaluation of oncology drug target engagement in human plucked scalp and beard hair

Greg Tudor, Frida Ponthan, Adam Boanas, Aude-Marine Bonavita, Catherine Booth. *Epistem Ltd, Manchester, United Kingdom*

We have developed a method to assess target expression changes following exposure of plucked hairs to chemotherapeutic agents and other potential therapeutics. Successful *ex vivo* responses provide proof of concept data prior to clinical studies. Plucked hair is a valuable surrogate biomarker tissue to monitor pharmacodynamic (PD) responses in a clinical trial. The collection of hairs is

minimally invasive, simple and is amenable to frequent sampling. Since hairs are epithelial appendages, many signaling pathways active in other epithelial tissues, including cancers, are also present in hairs. Highly proliferative plucked human scalp hair can be utilized as a surrogate tissue to measure proliferation, phosphorylation and DNA damage responses after treatment. Furthermore, hairs are highly vascularized, suggesting that administered Test Articles may be delivered efficiently to the hair in a similar manner to other highly vascularized tissues, including many tumor types. Human plucked hair (either from the scalp or beard) was placed in maintenance media in the presence of conventional or targeted chemotherapeutic agents, known for their different mechanisms of action (e.g. Gemcitabine, Carboplatin, Tarceva), for a range of time points. Hairs were then fixed post-exposure and longitudinal sections immunohistochemically labelled for various markers including p-ERK1/2, p-AKT, p-Chk1, g-H2AX, Ki67 and androgen receptor. Quantitative image analysis to measure the level of labelling was performed using an Aperio ScanScope. The relative number of positively labelled cell nuclei, or relative tissue area (depending on the labelling pattern of the target), of the hair outer root sheath labelled was analyzed, along with label intensity. In subsequent trial patients, formaldehyde fixed plucked hairs were returned to the lab, similarly sectioned, labelled and quantified. In addition, where antibody labelling is not possible or more detailed information on the modulation of a pathway may be useful, drug treated plucked hairs can be subjected to Next Generation Sequencing (NGS) gene expression analysis. The expected changes in labelling were observed. For example, Gemcitabine, which is linked to DNA polymerase inhibition, increased p-Chk1 labelling 4-fold after 4-8 hours and strongly induced p53 by 24 hours. Tarceva, an inhibitor of the EGF pathway, decreased levels of both p-ERK1/2 and p-AKT 3-fold after only 10 minutes. The alkylating agent carboplatin increased g-H2AX labelling up to 12-fold after 24 hours. We have demonstrated that plucked hair is a valuable PD biomarker tissue for various chemotherapy agents. Proof of concept studies performed *ex vivo* can inform the design of clinical validation studies by indicating optimum markers and timepoints. Further, each hair is an independent unit thereby allowing independent replicate tissues (hairs) to be sampled.

Multiplex detection of G12/G13 KRAS mutations with an electrochemiluminescent hybridization assay

Annamaria Szabolcs[1], Timothy J. Break[1], Isaac H. Shin[1], Seth B. Harkins[1], Jacob N. Wohlstadter[2].
[1]Assay Development, Meso Scale Discovery, Rockville, MD,[2]Meso Scale Discovery, Rockville, MD

Purpose: Oncogenic Kirsten rat sarcoma virus (KRAS) mutations are the most prevalent cancer mutations in all human tumors. Also, genotyping the KRAS gene has become increasingly important with the emergence of new evidence highlighting differences in downstream signaling pathways, tumor microenvironment composition, treatment responses and prognoses linked to specific single nucleotide polymorphisms (SNPs) in the G12 or G13 codons. FDA approval of G12C-specific anti-KRAS drugs highlights the importance of the development of reliable SNP assays to interrogate the mutation status in a tumor sample. Currently available genotyping assays are based on NGS, PCR, or ddPCR. These methods can be time-consuming, costly, suffer from amplification bias, or require follow-up testing or bioinformatics skills to analyze. Building on Meso Scale Discovery's (MSD) existing technology, we aimed to develop a method for the identification of eight KRAS SNPs located on the G12-G13 codons in a single reaction.
Methods: Ten-spot, 96-well N-PLEX plates were used for the study. SNP-specific upstream probes carrying unique 5′ leader sequences complementary to spot-specific captures on the N-PLEX plates were designed for eight KRAS genotypes (WT, G12R, G12C, G12S, G12A, G12D, G12V, G13D). Locus-specific downstream probes were 5' phosphorylated for ligation and 3' biotinylated for detection. Synthetic DNA targets were used as assay calibrators, and commercially available FFPE

reference samples were tested for validation. DNA (10 ng) was PCR amplified with primers flanking the KRAS mutation sites. A multiplexed mixture of upstream and downstream probes was hybridized to the amplicons, and 30 cycles of ligation was performed using DNA ligase in a thermal cycler. Samples were subsequently hybridized to spot-specific capture oligonucleotides on the surface of the assay plates and detected with SULFO-TAG labeled streptavidin. Electrochemiluminescence readout was collected on an MSD imager.
Results: Optimization of probe concentrations and ligation temperature was performed to maximize signal-to-background ratios and assay specificity. Spike recovery experiments using artificial target DNA showed successful identification of KRAS mutant genotypes at spike levels as low as 0.1% over wild-type background. Validation experiments with gDNA extracted from FFPE reference samples confirmed that the multiplex SNP assay can accurately differentiate eight KRAS genotypes in samples with >0.4% tumor burden.
Conclusion: These data highlight a novel approach to simultaneously identify eight KRAS genotypes from 10 ng of DNA input in a single reaction within 4-5 hours. The assay is capable of identifying double mutants and can provide a semiquantitative assessment of tumor burden without the need for follow-up testing.

#4352

Leveraging deep proteome profiling of plasma- and serum-derived extracellular vesicles for melanoma biomarker discovery and disease dissection

Evelyn Lattmann[1], Luca Räss[2], Marco Tognetti[2], Julia Martinez Gomez[1], Valérie Lapaire[1], Roland Bruderer[2], Lukas Reiter[2], Yuehan Feng[2], Lars M. Steinmetz[3], Mitchell P. Levesque[1]. *[1]Department of Dermatology, University of Zurich, University Hospital Zurich, Schlieren, Switzerland,[2]Biognosys AG, Schlieren, Switzerland,[3]Department of Genetics, Stanford University School of Medicine, Palo Alto, CA*

Extracellular vesicles (EV) play an important role in melanoma progression but their potential as clinical biomarkers has yet to be realized. EVs can be found in most liquid biopsies (e.g., blood, urine, CSF) and exosomes are the most prominent subcategory of EVs. Exosomes are 50-200 nm lipid-bilayer enclosed particles secreted by all body cells, including tumor cells, and serve as mediators of metastasis formation and typically contain several classes of bioactive molecules such as RNA, proteins, lipids, and metabolites.
Blood and its liquid components plasma/serum are the most frequently used matrix for biomarker discovery due to the ease of collection. However, most proteomic platforms for plasma/serum profiling are unable to profile EV proteins due to the high dynamic range of protein concentrations in EV preparations. This is due to 1) EV isolation methods that vary in their potential to separate EVs from free proteins, and 2) the presence of a natural corona of high-abundant blood proteins attached to the EV surface. To tackle this challenge, we developed SEC-DIA-MS an integrated workflow combining size-exclusion chromatography, EV concentration, and optimized mass spectrometry to enable deep profiling of the proteome content of the enriched vesicles.
From 200 µl of plasma or serum from a test melanoma patient cohort (6 patients and 3 matched controls), we quantified 2,242 exosome-associated proteins, achieving a 2.5-fold increase in depth compared to previous melanoma studies. To gain a better understanding of the exosome enrichment efficiency, we extensively characterized the plasma/serum proteome by analyzing native, depleted, and EV-enriched blood from the same donors. We successfully validated well-known exosome markers such as CD9, CD63, CD81, PDCD6IP, and TSG101, and found that EV samples are significantly enriched in intact membrane proteins and those related to T cell biology, further underlining the uniqueness of the EV proteome composition. We further assessed the differences between plasma and serum EVs and suggest the use of plasma samples for future studies due to

better separation of healthy and melanoma samples. Furthermore, known melanoma markers such as MCAM, TNC, and TGFBI were upregulated in melanoma plasma-derived EV but not depleted plasma samples, highlighting the specific information contained in EVs.
Taken together, we demonstrated the applicability and potential of an EV-based proteomic workflow for biomarker discovery in plasma and serum. The ease of automating and scaling up such an approach enables a broader application to other indications and biological matrices.

Utilizing scRNA sequencing to understand biomarkers of response and resistance to Sacitizumab Govetican in localized TNBC

Nicole Peiris[1], Simona Cristea[2], Mengran Zhang[2], Siang Koh[1], James Coates[1], Ilze Smidt[1], Veerle Bossuyt[1], Laura Spring[1], Aditya Bardia[1], Leif Ellisen[1]. *[1]Harvard Medical School, Massachusetts General Hospital, Boston, MA,[2]Harvard Medical School, Dana Farber Cancer Institute, Boston, MA*

Triple-Negative Breast Cancer (TNBC) is an aggressive breast cancer subset, which lacks expression of estrogen receptors, progesterone receptors, and human epidermal growth factor receptor-2. This subset of breast cancer disproportionately affects Black and African American women and improving TNBC treatment options is vital to reducing breast cancer mortality. The novel antibody-drug conjugate, Sacitizumab Govetican (SG), which targets TROP2 at the cell surface, has shown promising clinical results from the NeoSTAR trial (NCT04230109), a phase II study evaluating neoadjuvant SG therapy in a localized TNBC setting. As part of the NeoSTAR clinical trial, we have collected and processed pre- and post- SG treatment patient samples, with the aim of understanding response to this monotherapy. Herein, we identify biomarkers of response and resistance to SG monotherapy through the use of single cell RNA sequencing of matched pre- and post-treatment patient biopsies combined with exome sequencing these patient samples. Pre-treatment core needle biopsy samples, and if applicable, post-treatment residual disease biopsies were dissociated into single cell suspensions and subjected to single cell RNA sequencing. Additionally, fixed patient tissue samples were processed accordingly for exome sequencing analyses. Overall, we analyzed over 144,000 cells from 37 total scRNA seq libraries with an average of 3800 cells per biopsy sample, demonstrating the feasibility of this method. From these analyses, we observed several cell-type differences between patients who achieved a pathological complete response (pCR) and patients who had residual disease (RD). Specifically, our data shows that tumor infiltrating lymphocytes are a potential prognostic biomarker of response to SG. Furthermore, we detected alterations in among stromal and immune cell subsets, among non-responders, indicating that these cell types maybe indicative of SG resistance. Taken together, we outline biomarkers of response to SG treatment for an improved understanding of resistance mechanisms in the neoadjuvant setting to improve TNBC outcomes among patients.

An exosome-based *ESR1* monitoring RT-qPCR technology that rapidly and accurately detects circulating tumor acquired resistance variants at ≤0.1% frequency in liquid biopsy samples

Sarah Statt[1], Julie Thibert[1], Kurt Franzen[2], Aquiles Sanchez[2], Liangjing Chen[1], Megan Yociss[1], Elliot Hallmark[1], Melissa Church[1], Stela Filipovic-Sadic[1], Gary Latham[1], Johan Skog[2]. *[1]Asuragen, a bio-techne brand, Austin, TX,[2]ExosomeDx, a bio-techne brand, Austin, TX*

Introduction: Hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-) breast cancer is the most common type of breast cancer. Patients with HR+/HER2- metastatic breast cancer (mBC) often become resistant to aromatase inhibitors commonly used in endocrine therapy (ET). Estrogen receptor (*ESR1*) ligand binding domain mutations are frequently

detected in HR+ mBC and have been reported to be associated with ET resistance, noting up to 60% patients with mBC will develop resistance to treatment via acquired resistance in ESR1. Recent studies have shown that monitoring of *ESR1* mutations in plasma may serve as a predictive biomarker of acquired resistance to ET, showcasing a strong need for sensitive nucleic acid-based assays. We describe a comprehensive methodology for targeted clinical RT-qPCR monitoring of *ESR1* mutations in plasma that utilizes both exosomal nucleic acids and cfDNA to report multiple mutations, provide a streamlined workflow, and accommodate a range of inputs from clinically relevant samples.
Methods: Exosomal nucleic acids (exosomal DNA and RNA) and circulating cell-free DNA (cfDNA) were co-isolated using the ExoLution Plus Isolation Kit (Exosome Diagnostics). RT-qPCR-based target enrichment was performed using modified QuantideX reagents (Asuragen) and mutations were confirmed on the QuantStudio qPCR Platform (ThermoFisher). Bioinformatic analyses were conducted using custom software.
Results: We developed novel technologies and tested greater than samples across key ET resistance mutations, utilizing contrived samples as needed due to availability. Preliminary studies demonstrated that ESR1 exosomal RNA + cfDNA ranged from approximately 9,500 copies to 64,000 copies in a set of 2mL female presumed normal plasma samples; these results suggest that even 2mL plasma could provide sufficient exosomal RNA/DNA + cfDNA for mutation detection at variant frequencies less than or equal to 0.01%. The *ESR1* RT-qPCR showed greater than 90% analytical sensitivity (at less than or equal to 1% mutant allele frequency) and greater than90% analytical specificity. Further, the technology detected less than 10 mutant copies for most tested mutants, showing an LOD of at least 0.1% (5 mutant copies in a background of 5,000 WT copies).
Conclusion: A fast, efficient, and sensitive *ESR1* RT-qPCR panel approach was developed and evaluated, demonstrating the reliable and specific detection of rare variants in liquid biopsy specimens. Importantly, this prototype technology has potential to address several challenges associated with mutation monitoring in liquid biopsies by expanding detection of mutant analytes (exosomal RNA and DNA), improving analytical sensitivity (novel reagents and software), and increasing accessibility (qPCR instrument install base).

#4355

Prediction of cancer treatment response from histopathology images for a broad set of treatments and indications

Danh-Tai Hoang[1], Gal Dinstag[2], Leandro C. Hermida[3], Doreen S. Ben-Zvi[2], Efrat Elis[2], Katherine Caley[1], Sanju Sinha[3], Neelam Sinha[3], Christopher H. Dampier[3], Tuvik Beker[2], Kenneth Aldape[3], Ranit Aharonov[2], Eric A. Stone[1], Eytan Ruppin[3]. *[1]The Australian National University, Canberra, Australia,[2]Pangea Biomed, Tel Aviv, Israel,[3]National Cancer Institute, Bathesda, MD*

Background: Advances in artificial intelligence have paved the way for predicting cancer patients' survival and response to treatment from hematoxylin and eosin (H&E)-stained tumor slides. Extant approaches do so either via prediction of actionable mutations and gene fusions, or directly from the H&E images by training a task-specific model using large treatment outcome data.
Methods: Here we present the first approach for predicting patient response to multiple targeted treatments and immunotherapies directly from H&E slides. It is founded on two conceptual steps: (1) First, we developed DeepPT, a deep-learning framework that trains on formalin-fixed, paraffin-embedded (FFPE) TCGA whole slide images and their corresponding gene expression profiles to predict wide-scale tumor gene expression from the slides. (2) Second, we apply ENLIGHT, a published approach that predicts individual responses to a wide range of targeted and immunotherapies based on the tumor biopsy measured transcriptomics. Here we apply ENLIGHT to

predict patient treatment response from the DeepPT predicted expression values instead of those measured directly from the tumor, notably, without any further training or adaptation of ENLIGHT. Results: First, we find that DeepPT generalizes well to predicting gene expression in all 13 TCGA cohorts tested in cross-validation and importantly, in two independent unseen breast and brain cancer datasets. DeepPT outperforms HE2RNA, a state-of-the-art algorithm for the same task. Second, we demonstrate that the combined DeepPT/ENLIGHT pipeline (termed ENLIGHT-DeepPT) successfully predicts true responders using the original ENLIGHT decision threshold with odds ratios of 1.5 - 4.5, increasing the baseline response rates by 15-85% among predicted responders in five independent unseen cohorts of diverse cancer types and treatments. Remarkably, in one dataset where matched data was available, ENLIGHT-DeepPT has similar performance to that obtained by a supervised learning algorithm that was recently published in Nature, trained on the same cohort. Conclusions: We present for the first time a general framework for predicting patient response to a broad array of targeted and checkpoint therapies from histopathological images, without reliance on treatment outcome data, which are yet scarce and challenging to obtain. Importantly, ENLIGHT-DeepPT offers clinicians real-time treatment recommendations when one cannot wait for sequencing results. Also, and due to its very low cost, we very much hope that it will facilitate the advent of precision oncology in developing countries.

Biomarkers of Therapeutic Benefit 5

Multiplex immunofluorescence for cancer research
Patrick Savickas, Sharwari Phanse. *R&D, HistoWiz, New York, NY*

Multiplex Immunofluorescence (M-IF) is a technique where multiple antibodies are visualized using unique fluorophores on the same slide. Thus, instead of employing panels of separately stained IHC slides that only reveal regional localization, it enables direct visualization of numerous proteins of interest on the same cell. This enables researchers and clinicians to comprehend precise interactions taking place at the cellular level in their tissue. The challenge of figuring out how to individually link markers with fluorophores without incurring cross contamination has hindered the development of M-IF assays. The first traditional approach was to ensure each marker was generated from a unique host species, and then use secondary antibodies against those host species conjugated to unique fluorophores. As a result, the unique host species that an antibody could be generated in were exhausted forcing the researchers to reach into exotic species. The second generation of technologies attempted to temporally solve this problem by sequentially staining the markers and then stripping off the antibody in between steps; preserving the fluorophores. This system leveraged the interaction of tyramide attached to a fluorophore and its affinity for tyrosine residues in tissue to form a stronger bond then the antibody to the tissue to endure the harsh striping step. This allowed the usage of multiple antibodies from the same host species but added antigen sheltering as the confounding variable due to crowding and exhaustion of antigenic sites. The latest generation technology we are using attempts to solve this linkage problem with DNA barcoding. A lock and key mechanism wherein the primary antibody is pre-conjugated with a unique barcode and the fluorophore with a corresponding inverse barcode. In this technique the primary antibodies can be applied as a cocktail in parallel to the tissue with the dna based linkage easily and gently broken when necessary. We then took this novel technique and applied it in a shotgun approach using Tissue Microarrays (TMAs) to screen against dozens of cores from breast, endometrial, carcinoma and melanoma cases. We then use Inform software to algorithmically categorize each cell and R-Studio to statically prove a significant coefficient of variation. This creates the ability to build panels for signatures that answer key research questions like “Where are the immune cells in the tissue microenvironment” and “is the

tumor hot or cold? Activated, exhausted or proliferating?". This abstract contrasts the operation of the new technology with the earlier approaches and will demonstrate how artificial intelligence-assisted algorithms can analyze and produce statistically significant datasets for cancer researchers.

Complimentary use of DNA- and RNA-based NGS assays optimizes detection of clinically relevant translocations for comprehensive genomic profiling

Rongqin Ren[1], Jennifer Jackson[2], Jacob Kames[2], David Riles[2], Christopher Coldren[1], Scott Wheeler[1], Pranil Chandra[1], Michelle Shiller[1]. *[1]PathGroup, Nashville, TN,[2]Personal Genome Diagnostics, Baltimore, MD*

Introduction: Detection of gene translocations is a key component of clinical diagnostics to enable precision medicine in oncology. Several methods such as fluorescence in situ hybridization or RT-PCR have historically been employed, however, next-generation sequencing (NGS)-based comprehensive genomic profiling (CGP) including DNA and RNA sequencing approaches have been validated for this purpose. Here we explore the complimentary nature of these methods to enable detection of clinically relevant translocations to guide patient care.
Methods: We utilized Endeavor, a 505 gene DNA-based CGP assay developed by Personal Genome Diagnostics, to assess single nucleotide variants, insertion/deletions, amplifications, translocations, microsatellite instability, and tumor mutation burden as well as a 53 gene RNA-based Invitae NGS FusionPlex Solid Tumor v1 assay. 151 patients with advanced or metastatic solid tumors, including lung, colorectal, esophageal, breast, brain, bladder, and prostate cancers, were consecutively enrolled and only overlapping target regions were evaluated to compare performance.
Results: Of the 151 cases selected for the study, failure rates were 2.0% and 9.9% for Endeavor and FusionPlex, respectively. Translocations were detected in 21/151 (13.9%) cases by Endeavor and 17/105 (11.3%) cases by FusionPlex. For the 133 cases where data was available from both assays, 12 (9.0%) concordant translocation positive cases were detected involving *ALK*, *RET*, *NTRK1*, *NTRK3*, *MET* exon 14 skipping, *EGFR*vIII, and *EWSR1* with 109 (82.0%) cases translocation negative by both assays achieving a concordance rate of 91%. For 7 (5.3%) cases, Endeavor detected translocations events in *FGFR1*, *FGFR2*, *ETV4*, *ETV6*, *MYC*, and *NTRK3* that were not detected by FusionPlex. Conversely, FusionPlex identified 5 (3.8%) cases with translocations in *ROS1*, *NTRK2*, and *EGFR*vIII that were not detected by Endeavor (Table 1). Discrepancies in translocation detection were attributed to variability in assay failure rates, panel design, and underlying biological differences in detectability associated with DNA- and RNA-based methods.
Conclusions: In this study, comparison of translocation detection using DNA and RNA-based NGS approaches revealed a high concordance between the two assays and were equally valuable for identifying actionable targets. These findings provide confirmatory support for the complimentary use of DNA- and RNA-based NGS approaches to most accurately identify clinically relevant translocations thereby providing more comprehensive results to help guide cancer treatment strategies.

Individualized risk stratification in newly diagnosed multiple myeloma

Arjun Raj Rajanna[1], Francesco Maura[1], Andriy Derkach[2], Bachisio Ziccheddu[1], Niels Weinhold[3], Kylee Maclachlan[2], Benjamin Diamond[1], Faith Davies[4], Eileen Boyle[4], Brian Walker[5], Alexandra Pos[3], Malin Hulcrantz[2], Ariosto Silva[6], Oliver Hampton[7], Jamie K. Teer[6], Niccolò Bolli[8], Graham Jackson[9], Martin Kaiser[10], Charlotte Pawlyn[10], Gordon Cook[11], Dennis Verducci[1], Dickran Kazandjian[1], Fritz Van Rhee[12], Saad Usmani[2], Kenneth H. Shain[6], Marc S. Raab[3], Gareth Morgan[4],

Ola Landgren[1]. *[1]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]University Hospital, Heidelberg, Germany,[4]NYU Langone, Perlmutter Cancer Center, New York, NY,[5]Indiana University, Indianapolis, IN,[6]Moffitt Cancer Center, Tampa, FL,[7]M2GEN, Tampa, FL,[8]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,[9]The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle, United Kingdom,[10]The Institute of Cancer Research, London, United Kingdom,[11]University of Leeds, Leeds, United Kingdom,[12]University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Clinical outcomes for newly diagnosed multiple myeloma (NDMM) patients are heterogenous with survival ranging from months to > 10 years. Though several clinical and genomic features predict outcomes, the “one-size-fits-all” treatment paradigm remains dominant for NDMM.
Hypothesis: By integrating clinical, genomic and therapeutic data, using artificial intelligence, an individualized risk-prediction model for NDMM (IRM) can facilitate individually-tailored therapeutic decisions.
Methods: We included 1933 patients with clinical and genomic data from 5 cohorts: MMRF CoMMpass (n=1062), MGP (n=492), Moffit AVATAR (n=177), UAMS (n=93), and MSKCC (n=109). The median follow-up was 43 months. Overall, we considered 160 clinical (e.g., age, ECOG, race), therapeutics, and genomic variables. To correct for time-dependent variables such as autologous stem cell transplant (ASCT) and continuous treatment, a multi-state model was designed across two phases: induction (phase 1), and post-induction (phase 2). Neural Cox Non-proportional-hazards (NCNPH) was used to integrate the data and build the model.
Results: Overall, the 5-year overall survival (OS) c-index for IRM was 0.73, significantly higher than all existing prognostic models: R2-ISS (0.62), ISS (0.61) and R-ISS (0.56). The overall model accuracy was significantly improved by the inclusion of 12 genomic features, including 1q21 gain/amp, *TP53* loss, t(4;14)(*NSD2*;*IGH*), complex copy number signatures, APOBEC mutational signature contribution, and del1p. Prescribed therapy emerged as a key determinant of risk, suggesting that effective combinations may have a different impact in the context of individual patient features, with the potential to significantly change clinical outcomes despite poor historical prognostication (i.e., treatment variance). Leveraging these concepts, we interrogated the clinical impact of ASCT and continuous treatment in the context of NDMM treated with bortezomib, lenalidomide and dexamethasone (VRd). Integrating predicted outcomes and treatment variance for all 4 possible treatment combinations (i.e., VRd +/- ASCT +/- continuous treatment) we identified 3 patient groups. In the first group (n=632), patients were characterized by complex genomic features, older age, high ISS, poor outcomes and limited treatment variance, reflecting aggressive and refractory myeloma. The second group (n=571) was characterized by high treatment variance, with favorable outcomes if ASCT and continuous treatment are provided. The last group (n=730) included patients with favorable clinical and genomic profiles, achieving good outcomes, with minimal advantage from ASCT.
Conclusion: Integrating historical and emerging genomic features with clinical and therapeutic data, we developed the first individualized risk-prediction model for personally-tailored therapeutic decisions in NDMM.

#5454

Peripheral blood biomarkers in Phase II study of pembrolizumab in combination with oral binimetinib in patients with unresectable locally advanced or metastatic triple-negative breast cancer

Saranya Chumsri[1], Joseph J. Larson[2], Daniel L. Adams[3], Kathleen S. Tenner[2], Cha-Mei Tang[3], Morgan T. Weidner[1], Amanda N. Arnold[1], Dana L. Haley[1], Pooja Advani[1], Kostandinos Sideras[1], Alvaro Moreno-aspitia[1], Edith A. Perez[1], Keith L. Knutson[1]. *[1]Mayo Clinic Florida, Jacksonville, FL,[2]Mayo Clinic, Rochester, MN,[3]Creatv Microtech Inc., Potomac, MD*

Background: Activation of the RAS/MAPK pathway is associated with reduced tumor-infiltrating lymphocytes and poor outcomes in triple-negative breast cancer (TNBC). This trial evaluated the efficacy of pembrolizumab and MEK inhibitor, binimetinib. Here we evaluated potential biomarkers in peripheral blood to predict response.

Methods: Patients with unresectable locally advanced or metastatic TNBC with ≤ 3 prior lines of therapy were enrolled. Treatment includes a 2-week run-in with binimetinib followed by pembrolizumab. There were 2 dose levels (DL) with binimetinib at 45 mg at DL 0 and 30 mg at DL -1. A standard 3+3 design was used in phase I, and Simon's two-stage Optimal design was used in phase II. Circulating tumor cells (CTC) and circulating cancer-associated macrophage-like cells (CAML) were isolated using CellSieve microfilters and immunofluorescently labeled with PD-L1 and p-ERK. Wilcoxon rank sum test and Cox regression model were used for analysis.

Results: A total of 22 patients were enrolled, with a median age of 58 years old. Dose-limiting toxicity (DLT) was observed in 2 out of 4 patients in DL 0, with grade 3 ALT abnormality, flank pain, and nausea. In the next 6 patients in DL -1, there was 1 DLT with grade 3 AST/ALT abnormality. There were 17 patients treated with DL -1 and were evaluable for response. The objective response rate (ORR) was 29.41% (95% CI: 10.31-55.9) with 1 complete response (CR) and 4 partial responses (PR). The clinical benefit rate (CBR ≥ 24 weeks) was 35.29% (95% CI: 14.21-61.67). ORR in patients without liver metastases was 55.56% (95% CI: 21.20 - 86.30), and CBR was 66.67% (95% CI: 29.93-92.51). There was no response observed in all 5 patients with liver metastases. Baseline mean CTC count was 1.3 cells, and CAML count was 8.9 cells/7.5 mL. Baseline PD-L1 in CAML (p 0.04) and

decline in CAML size (p 0.02) after 1 cycle were significantly associated with CBR. However, baseline CTC count, CAML count (p 0.64), CAML size (p 0.46), p-ERK in CAML (p 0.23), and changes in CTC count, CAML count (p 0.83), p-ERK (p 0.07), and PD-L1 (p 0.08) in CAML were not significantly associated with responses. Using Cox regression analysis, a reduction in CAML count (p 0.02), CAML size (p 0.01), and PD-L1 in CAML (p 0.03) were associated with significant improvement in overall survival but not the reduction in p-ERK (p 0.6).
Conclusions: Pembrolizumab and binimetinib at 30 mg are safe with manageable toxicities. Promising activity was observed in patients without liver metastases. Baseline PD-L1 expression, early reduction in CAML count, size, and PD-L1 expression were significantly associated with subsequent responses, providing potential noninvasive biomarkers to predict response to this combination. Future larger clinical trials are warranted to further evaluate the efficacy of this combination.

#5455

Large-scale cancer genomic analysis reveals significant disparities between microsatellite instability and tumor mutational burden

Jungyoon Choi[1], Jung Sun Kim[1], Kyong Hwa Park[2], Xingyi Guo[3], Yeul Hong Kim[2]. *[1]Korea University Ansan Hospital, Ansan, Korea, Republic of,[2]Korea University Anam Hospital, Seoul, Korea, Republic of,[3]Vanderbilt University Medical Center, Nashville, TN*

Microsatellite instability (MSI) and tumor mutational burden (TMB) are efficacy biomarkers for cancer immunotherapies, with both MSI-high and TMB-high considered hypermutator phenotypes that predict better drug responses. However, the inter-relationship between these biomarkers has not been well-investigated. Herein, we conducted a large-scale cancer genomic analysis to characterize patterns of distribution between MSI-high and TMB-high across 22 human cancer types, and identify mutated genes that may contribute to MSI-high cancers.We analyzed somatic mutation data from the Genomics Evidence Neoplasia Information Exchange (GENIE; n=49,496) to characterize gene mutations and patterns of distribution between MSI and TMB for each cancer. Associations between TMB and MSI were evaluated using multivariable linear regression models adjusted for age at sequencing report, sex, race, sequencing center, and histological

subtype. Associations between MSI and gene mutations were evaluated using multivariable logistic regression models adjusted for the above mentioned covariates and TMB.Our analysis revealed that considerable differences in the prevalence of MSI-high and TMB-high by cancer types. The moderate differences were observed in cancers with the top prevalence of MSI-high/TMB-high, such as 31.1%/28.7% in endometrial cancer, 18.4%/17.7% in colorectal cancer, and 17.2%/12.2% in stomach cancer, while most other cancers showed high differences of prevalence (>10%). Notably, MSI-high patients were observed to have a substantial proportion of TMB-low phenotypes ranging from 31% to 89% among these cancer types, likely indicating distinct drug responses compared to TMB-high phenotypes. Association analyses between TMB and MSI for these cancers showed the strongest associations in colorectal cancer (P=4.0x10-255) and stomach cancer (P=6.2x10-60), while marginal or no associations were observed in several cancers including head and neck cancer (P=0.08) and hepatocellular carcinoma (P=0.15). In addition, we identified several mutated genes associated with MSI-high phenotypes, including known mismatch repair genes (e.g., MSH3, POLD1, MLH1, and MSH6) and novel mutated genes (e.g., RNF43, ARID1A, ARID1B, NOTCH3, SMARCA4, KMT2C, and CREBBP), in endometrial cancer (n=32 genes), in colorectal cancer (n=29 genes) and in stomach cancer (n=18 genes), at a Bonferroni-corrected $P < 0.05$.Our study revealed large discrepancies in prevalence between MSI-high and TMB-high in many cancer types,, highlighting the need to consider distinct or combined biomarkers for immunotherapies. Our study also identified novel mutated genes associated with MSI-high cancers, providing additional insights into MSI-high carcinogenesis and candidate genetic biomarkers to screen patients for potential immunotherapy.

Application of a multiplex urinalysis test for predicting treatment response in patients with BCG unresponsive bladder cancer: a pilot study

Hideki Furuya[1], Kaoru Murakami[1], Ian Pagano[2], Runpu Chen[3], Yijun Sun[3], Nari Kim[1], Edward E. Kadel[4], Cheryl V. Wong[4], Nicole Davarpanah[4], Charles J. Rosser[1]. *[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]University of Hawaii Cancer Center, Honolulu, HI,[3]The State*

University of New York at Buffalo, Buffalo, NY,[4]Genentech, San Francisco, CA

Introduction and Objective: Recently, we reported that Oncuria™, a multiplex urinalysis test, could be predictive of BCG treatment response. Furthermore, high-grade BCG unresponsive bladder cancer have limited treatment options. Such patients are offered either radical cystectomy or systemic therapy. One of the systemic therapies include immune-oncology agents, e.g., PD-1 or PD-L1 inhibitors. In this study, we tested the performance of Oncuria™ in a BCG unresponsive cohort to determine if it could predict response to a PDL1 inhibitor.
Methods: Oncuria™ data was evaluated in voided urine samples obtained from a prospectively collected cohort of 18 subjects who have BCG-unresponsive NMIBC with treatment of atezolizumab monotherapy or atezolizumab BCG combination (provided by Genentech, NCT02792192). The urine samples were collected prior to treatment in both arms. The Oncuria™ test, which measures 10 cancer-associated biomarkers was performed in an independent clinical laboratory. Predictive models were previously developed using supervised learning and cross-validation analyses. Model performance was validated using ROC curves.
Results: Pre-treatment urinary concentrations of MMP9, VEGFA, CA9, SDC1, PAI1, APOE, A1AT, ANG and MMP10 were increased in patients who developed disease recurrence. A combinatorial predictive model of treatment outcome achieved sensitivity and specificity of >90%.
Conclusion: Previous pilot study found that monitoring the urinary levels of a cancer-associated biomarker panel enabled the discrimination of patients who did not respond to intravesical BCG therapy. In this study, we noted the performance of Oncuria™ for the prediction of systemic PDL1 inhibitor treatment response. A limitation of this study includes its small sample size. With further study, the multiplex Oncuria™ test may be applicable for the clinical evaluation of bladder cancer patients who have not previously responded to intravesical BCG treatment and is considering systemic immune-oncology options.

#5457
Prevalence of “low” HER2 expression is frequent in breast cancer but also in cancers of other origin: A tissue microarray study on 131 tumor

types

Maximilian Lennartz[1], Florian Viehweger[1], David Dum[1], Ria Uhlig[1], Andrea Hinsch[1], Doris Hoeflmayer[1], Christoph Fraune[1], Christian Bernreuther[1], Patrick Lebok[1], Soeren Weidemann[1], Guido Sauter[1], Till Sebastian Clauditz[1], Frank Jacobsen[1], Till Krech[1], Andreas H Marx[2], Sarah Minner[1], Ronald Simon[1], Natalia Gorbokon[1], Stefan Steurer[1], Eike Burandt[1]. *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Academic Hospital Fuerth, Fuerth, Germany*

HER2 is a receptor tyrosine-protein kinase coded by the ERBB2 gene. The HER2 status is routinely assessed to select patients eligible for targeted therapy with anti-HER2 drugs. HER2 positivity was restricted to cancers with a 3+ score at immunohistochemistry (IHC) and/or gene amplification. The successful use of HER2 antibody-drug conjugates in tumors with IHC scores of 1+ (HER2 low) or 0 with incomplete and faint staining in ≤10% of tumor cells (HER2 ultralow) is currently changing the traditional dichotomy of HER2 testing in breast cancer. To determine HER2 expression in neoplastic tissues, a tissue microarray containing one 0.6mm tissue spot each from 7,505 tumor samples from 131 different tumor types and subtypes was analyzed by immunohistochemistry. IHC scoring included 3+, 2+, 1+, and a category "+" (faintly positive in less than 10% of tumor cells; ultralow). The cohort included 310 breast cancers for which the HER2 amplification was also assessed by fluorescence in situ hybridization. Among 555 evaluable breast cancers, HER2 IHC was 3+ in 7.6%, 2+ in 3.2%, 1+ in 14.6%, "+" in 15.9% and 0 in 58.7%. The HER2 amplification rate was in 95.8% of 3+, 61.5% of 2+, 18.2% of 1+, but 0% in "+" and HER2 0 breast cancers. Among 4,912 non-breast cancers, the HER2 status was 3 in 0.6%, 2 in 0.7%, 1 in 3.3%, "+" in 2.3%, and 0 in 93.2%. In these tumors, 3+ positivity was largely restricted to gastric/esophageal adenocarcinoma, urothelial carcinoma, ovarian cancer as well as adenocarcinomas of the lung, colon, and pancreas. A 2+ positivity was mostly seen in tumor entities that had also 3+ cases. A 1+ or "+" HER2 positivity was found in 50 of 147 analyzed non-breast cancer categories. HER2 low and ultralow (1+ or "+") was most commonly seen in basal cell carcinoma of the skin (52.2%), clear cell carcinoma of the ovary (33.3%), urothelial carcinoma of the renal pelvis (33.3%), gallbladder adenocarcinoma (26.7%), muscle-invasive urothelial carcinoma of the

bladder (24.5%), prostatic adenocarcinoma, Gleason 4+4 (23.3%), endometrial serous carcinoma (22.7%), prostatic adenocarcinoma, Gleason 5+5 (19.2%), carcinosarcoma of the ovary (18.8%), renal oncocytoma (17.9%), serous carcinoma of the ovary (17.8%), gastric adenocarcinoma, intestinal type (13.2%), neuroendocrine tumor (NET) of the lung (11.1%), carcinosarcoma of the uterus (11.1%), endometrioid carcinoma of the ovary (11.1%), squamous cell carcinoma of the larynx (10.7%), parathyroid gland adenoma (10%), endometrioid endometrial carcinoma (9.7%), adenocarcinoma of the esophagus (9.5%), cholangiocarcinoma of the liver (9.3%), and pancreatic/ampullary adenocarcinoma (8.6%). While 3+ IHC is limited to only few cancer types, there is a much broader range of tumor entities that can show HER2 low and ultralow expression. HER2 antibody-drug conjugates may therefore be successful drugs in a large variety of different tumor entities.

TONSL is an immortalizing oncogene of the chromosome 8q24.3 amplicon and new therapeutic target in breast cancer

Aditi S. Khatpe[1], Rebecca Dirks[2], Poornima Bhat-Nakshatri[2], Henry Mang[2], Katie Batic[2], Sarah Swiezy[2], Jacob Olson[3], Xi Rao[4], Yue Wang[4], Hiromi Tanaka[4], Sheng Liu[4], Jun Wan[4], Duojiao Chen[4], Yunlong Liu[4], Fang Fang[5], Sandra Althouse[6], Emily Hilsey[7], Maggie M. Granatir[7], Rebekah Addison[7], Constance J. Temm[7], George Sandusky[7], Audrey Lee-Gosselin[8], Kenneth Nephew Nephew[5], Kathy D. Miller[9], Harikrishna Nakshatri[1]. *[1]Indiana University School of Medicine, Indianapolis, IN,[2]Department of Surgery, Indiana University School of Medicine, Indianapolis, IN,[3]Decatur Central High School, Indianapolis, IN,[4]Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN,[5]Medical Science Program, Indiana University School of Medicine, Bloomington, IN,[6]Department of Biostatistics and Health Data Science, Indiana University School of Medicine, Indianapolis, IN,[7]Department of Pathology and Laboratory Medicine, Indiana University School of Medicine, Indianapolis, IN,[8]Stark Neurosciences Research Institute, Indiana University School of Medicine, Indianapolis, IN,[9]Department of Medicine, Indiana University School of Medicine, Indianapolis, IN*

Study of genomic aberrations leading to immortalization of epithelial cells has been technically challenging due to lack of an appropriate isogenic model system. To address this technical challenge, we utilized primary breast luminal epithelial cells propagated from healthy donors of different genetic ancestry and their hTERT-immortalized counterparts to identify functional gene expression changes associated with immortalization. We identified elevated expression of TONSL (Tonsoku Like, DNA Repair Protein) as one of the earliest events during immortalization. TONSL is located on chromosome 8q24.3 and amplified in ~20% of breast cancers with significantly higher amplification in metastatic tumors. TONSL forms a complex with FACT and MMS22L1 to modulate multiple cellular pathways including DNA replication, repair through homologous recombination (HR) and functions as a post replicative histone/chromatin reader. TONSL alone immortalized primary breast epithelial cells and increased telomerase activity. While TONSL overexpression alone was insufficient for neoplastic transformation, TONSL-immortalized primary cells modified to overexpress defined oncogenes generated estrogen receptor-positive adenocarcinomas in NSG mice. Analysis of breast tumor microarray with ~500 tumors revealed poor overall and progression free survival of patients with TONSL-overexpressing tumors. TONSL increased chromatin accessibility to pro-oncogenic transcription factors including NF-κB and limited access to the tumor suppressor p53. Most importantly, TONSL overexpression resulted in significant changes in the expression of genes associated with DNA repair hubs, including upregulation of several genes in HR and Fanconi Anemia pathways. Consistent with the effects of TONSL on HR-associated genes, TONSL overexpressing primary cells exhibited upregulated DNA repair via HR. Moreover, TONSL was an essential gene for growth of TONSL-amplified breast cancer cell lines *in vivo*. Breast cancer cell lines with TONSL/chr8q24.3 amplification were sensitive to TONSL-FACT complex inhibitor CBL0137, both *in vitro* and *in vivo*. To our knowledge, TONSL is the only gene other than telomerase with immortalizing function and represents a new therapeutic target for breast cancer with chr8q24.3 amplification.

Association between stomatitis and treatment efficacy with novel TROP2-directed antibody drug conjugate (ADC), datopotamab

deruxtecan, in patients with metastatic cancer

Rachel O. Abelman[1], Laura M. Spring[1], Phoebe K. Ryan[1], Geoffrey Fell[2], Dejan Juric[1], Rebecca S. Heist[1], Aditya Bardia[1]. *[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA,[2]Harvard Medical School/Dana Farber Cancer Institute, Boston, MA*

Background**:** Incidence of toxicity with immunotherapy has been correlated with likelihood of treatment response (Hussaini, Cancer Treat Rev 2021; Schuell, Br J Cancer 2005). However, this phenomenon has not yet been demonstrated with antibody-drug conjugates. Datopotamab deruxtecan (Dato-DXd) is a novel ADC composed of an anti-Trop2 monoclonal antibody, a stable tetrapeptide-based cleavable linker, and a topoisomerase-I inhibitor payload (Bardia, Annals of Onc 2021). Early phase studies have demonstrated significant activity in heavily pretreated patients with metastatic non-small cell lung cancer (NSCLC) and metastatic breast cancer (MBC). Stomatitis was a common treatment-emergent adverse event (TEAE) observed in clinical trials. We conducted a study to evaluate the association between incidence of stomatitis and treatment response with Dato-DXd and evaluate the impact of steroid mouthwash. We hypothesized that presence and grade of mucositis would correlate with observed treatment efficacy.

Methods: We included all patients treated at one academic institution (Massachusetts General Hospital) with Dato-DXd. Stomatitis was assessed by NCI-CTCAE V5.0. Objective Response Rate (ORR) was assessed by RECIST criteria with independent radiology review. Use of mouthwash was evaluated by secondary review and categorized as primary or secondary prophylaxis. A time-to-event analysis was performed to evaluate the time to onset of stomatitis.

Results: 60 patients, including 19 with MBC and 41 with NSCLC, were treated with Dato-DXd between June 2018-September 2022. The median age of patients was 64 and 41/60 patients were female. The median time to onset of mucositis was 14 days (95% CI 12-42 days). There was no significant difference in incidence of stomatitis between the MBC and NSCLC cohorts. Compared to patients who had progressive disease (PD), patients who had a partial response (PR) or stable disease (SD) were 11 times more likely to have stomatitis (OR 11.0, 95% CI 3.61-44.01, $p<0.001$). Later in the trial (January 2020 onward), 28 patients received

primary steroid prophylaxis - excluding these patients, those who were found to have PR/SD were 8.8 times more likely to develop stomatitis compared to patients who had PD (OR 8.8, 95% CI 1.5-73.3, p=0.023). **Conclusion:** The development of stomatitis may be associated with higher likelihood of therapeutic efficacy. Given that these findings are a hypothesis-generating post-hoc exploratory analysis from a single institution, this requires validation in larger studies before drawing strong conclusions and impacting clinical decision making. Further research is also needed evaluate the relationship between TEAEs and therapeutic efficacy with other ADCs.

#5460

Novel immunohistochemistry-based predictive and prognostic tests for hormone receptor-positive breast cancer

Danira Jaksic[1], Amandeep Kaur[1], Dean Reddick[1], David David Datzkiw[1], Shailly Varma Shrivastav[2], Vijayakrishna Gadi[3], Leigh Murphy[4], Anuraag Shrivastav[1]. *[1]The University of Winnipeg, Winnipeg, MB, Canada,[2]Oncodrex Inc, Winnipeg, MB, Canada,[3]University of Illinois Cancer Center, Chicago, IL,[4]CancerCare Manitoba, Winnipeg, MB, Canada*

Background: Breast cancer (BC) is the most diagnosed cancer worldwide and the most common cancer diagnosed in American women. Despite successes of adjuvant endocrine therapies in treating the most common subtype of hormone receptor-positive (HR+) BC, de novo and emergent resistance to these therapies, i.e., endocrine resistance, remains a significant concern with patients experiencing recurrences during and after adjuvant treatment. We report here unique patterns of expression (UPE) of N-myristoyltransferase 1 (NMT1) protein that are prognostic and predictive markers for HR+ BC. We have discovered that the expression and localization of NMT1 are predictive markers for the endocrine therapy response in HR+ BC. The data from many observational studies suggest that after five years of adjuvant endocrine treatment, the likelihood of distant recurrence continues for the subsequent twenty years. We have developed simple immunohistochemical (IHC)-based tests that could become part of routine first line prognostic and predictive tests and have the potential to be incorporated as necessary tests in the panel of BC tests for designing treatment regimens of BC.

Methods: Expression patterns of NMT1 were determined using IHC analyses on formalin fixed paraffin embedded primary tumor samples from treatment naïve BC patients. The tumor tissues in duplicates were stained with NMT1 monoclonal/polyclonal antibodies on an autostainer (Leica Bond). Stained slides were scored in a blinded manner to outcomes and scored with an "H" index representing the intensity and percent positive cells within each section. The relationship of UPE was correlated with clinical outcomes of RFS (RFS = endpoint recurrence and/or death due to BC) and OS (OS = endpoint death due to breast cancer).
Results: The final cohort was composed of 448 BC cases of primary HR+ tumors from patients who received adjuvant tamoxifen therapy after surgery. UPE2 (defined by > median H score 100) was significantly associated with better clinical outcomes represented by both RFS (HR = 0.70, *P* = 0.0304, 95% CI 0.510 to 0.97, n = 440) and OS (HR = 0.71, *P* = 0.0306, 95% CI 0.530 to 0.97, n = 440), whereas UPE4 strongly predicted worse treatment response for both RFS (HR= 1.49, P = 0.0014, 95% CI 1.08 to 2.04, n=440) and OS (HR = 1.54, P = 0.0055, 95% CI = 1.54 to 2.08, n=440).
Conclusions: We observed that the expression and localization patterns of NMT1 constitute four unique patterns of expression signatures (UPE:1-4) and serve as prognostic and potentially predictive markers for HR+ BC. This assay provides a novel method to stratify cancers that may better enable endocrine treatment and duration optimization in the adjuvant setting for HR+ breast cancer. Moreover, in distinction to genomic assays, fewer logistic and financial barriers to implementation would exist for the UPE:1-4 IHC assay in resource-poor settings.

Gain early insights from single cell RNA-sequencing of clinical trial needle biopsy cores

Thomas Gallup[1], Sang Yun[1], Dave Gallup[1], Kyuson Yun[2]. *[1]EMPIRI Inc, Houston, TX,[2]Department of Neurology, Houston Methodist Research Institute, Houston, TX*

Single cell RNA-sequencing (scRNA-seq) yields valuable insights into the molecular heterogeneity of multiple cell types in normal and cancer tissues. scRNA-seq approach has the potential to not only answer basic research questions but also enhance clinical studies and clinical trials and accelerate

drug development and testing. However, a consistent and reproducible method for isolating viable single cells and generating high quality single cell data from needle biopsy cores has been challenging to develop. Based on our experience isolating single cells from a large number of surgical tumor tissues, we set out to optimize a dissociation and processing protocol to generate viable single cell suspensions in adequate quantity for scRNA-seq from needle biopsy cores. A total of 17 de-identified 18-gauge needle biopsy samples were collected in collaboration with MD Anderson Cancer Center investigators. Samples were from liver, lymph node, pelvis, abdominal, neck, and lung tissues and included matched pre- and post-treatment samples. Patient biopsies were kept in RPMI medium on ice and transferred to EMPIRI (time to capture ranged from 3 to 6.5 hours after biopsy collection). Samples were dissociated using mechanical and enzymatic methods to achieve a single cell suspension. Cells were washed and viability and cell counts were verified before capture via 10x Chromium Connect. Captured cells were processed through the 10x Genomics Chromium Next GEM Single Cell workflow before sequencing on Illumina NovaSeq 6000 sequencer. Raw sequencing data were processed through EMPIRI's computational pipeline that includes QC steps, doublet removal, and Seurat and other downstream analyses. Recovery of viable cells from individual 18-gauge biopsy cores ranged from 2,000-300,000 cells per core, depending on the tissue type and cellularity. Cell viability was strictly monitored and was maintained above 80% for 16 of 17 samples (most samples >90%). Cell counts after sequencing and pipeline analysis averaged 6,466 cells per sample. The median number of UMI counts per cell was 5,580, and an average of 1,699 genes were identified per cell. Average sequencing saturation was 73%. Here, we demonstrate the feasibility of integrating scRNA-seq analysis into clinical trials or clinical studies to obtain rapid insights into on-target drug effects and anticipated cellular responses to therapies, including immunotherapies, within 3 weeks of biopsy collection. We have established a method for isolating high quality single cells for scRNA-seq from tissue biopsy core, as small as a single 18-gauge needle core. We tested our protocol on 17 human samples and showed successful isolation of highly viable cells from lung, lymph node, pelvis, abdominal, neck, and lung tissues. We were able to generate scRNA-seq data sets from all samples for analysis.

Acknowledgements: We thank our MDACC collaborators, particularly Drs. Scott Kopetz and Van Morris.

Elevated creatine phosphokinase (CPK) as a strong predictor of aumolertinib (Au) treatment response in patients (pts) with advanced non-small cell lung cancer (NSCLC): post-hoc analysis of AENEAS

Shun Lu[1], Chuan Li[2], Hong Jian[1], Xiaorong Dong[3], Jianhua Chen[4], Gongyan Chen[5], Yuping Sun[6], Yinghua Ji[7], Jiawei Wei[2], Si Sun[2], Zhenzhong Su[2], Qiu Sun[2], Hongying Wei[2], Qiong Wu[2]. *[1]Department of Medical Oncology, Shanghai Chest Hospital, Shanghai JiaoTong University, Shanghai, China,[2]Hansoh Pharmaceutical Group Co. Ltd., Shanghai, China,[3]Cancer Center, Union Hospital Tongji Medical College Huazhong University of Science and Technology, Wuhan, China,[4]Department of Medical Oncology-Chest, Hunan Cancer Hospital & The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China,[5]Thoracic Oncology Medicine, Harbin Medical University Cancer Hospital, Harbin, China,[6]Department of Oncology, Jinan Central Hospital, Jinan, China,[7]Department of Oncology, First Affiliated Hospital of Xinxiang Medical University, Xinxiang, China*

Background: In AENEAS trial (NCT03849768), first-line Au for EGFR-mutated, advanced NSCLC showed robust improvement in PFS over gefitinib (G). CPK elevation was the most common AE during Au treatment which may pose safety concerns. To evaluate the relationship between CPK elevation and Au efficacy, we performed a post-hoc analysis of AENEAS.
Methods: AENEAS is a double-blind, randomized controlled phase III trial. Untreated advanced NSCLC pts with EGFR sensitizing mutations were assigned 1:1 to receive Au (110 mg QD) or G (250 mg QD). The primary endpoint was PFS. Secondary endpoints included ORR, DCR, DoR and DepOR. Data cutoff: Aug 1, 2021.
Results: 37.9% (81/214) of pts receiving Au had CPK elevation, among whom the mPFS was 26.3 mos and was significantly longer (HR=0.45; 95% CI: 0.31-0.67; P<.0001) than that of the CPK-normal pts (133/214) at 13.9 mos. PFS benefits remained consistent across all prespecified subgroups. Also for all the secondary endpoints, CPK-elevated pts demonstrated significant benefits over CPK-normal pts (TABLE). Multivariable

regression analysis revealed that CPK elevation was an independent predictor of prolonged PFS for pts receiving Au, with 54% reduced risk of progression or death for CPK-elevated pts compared with CPK-normal pts (HR=0.46; 95%CI: 0.31-0.68; P=.0001). Au demonstrated PFS benefits over G in both CPK-elevated pts (HR=0.40; 95% CI: 0.21-0.79; P=.0059) and CPK-normal pts (HR=0.63; 95% CI: 0.48-0.83; P=.0010), and the benefit was magnified in CPK-elevated pts. Further supported by post-hoc analysis of a phase 1/2 study (NCT02981108), PFS was also significantly prolonged in CPK-elevated pts receiving second or later line Au (17.7 vs 10.9 mos; HR=0.63; 95% CI: 0.46-0.87; P=.0049).
Conclusion: Our study first revealed the predictive value of CPK elevation on improved treatment response of Au, which is of great significance to help guide medical care.

Summary of Endpoints

	Elevated CPK(N=81)	**Normal CPK(N=133)**

The PD-L1 protein expression in Chinese patients with recurrent or metastatic head and neck squamous cell carcinoma: A multi-center retrospective study

Haizhen Lu[1], Dong Kuang[2], Lili Jiang[3], Jingping Yun[4], Qingxin Xia[5], Jian Wang[6], Pei Duan[2], Ping Zhou[3], Shengbing Zang[4], Yiping Jin[5], Xiangnan Jiang[6], Jielin Li[7], Wenmin Tang[7], Jiansong Zhou[7], Jihua Chen[7], Jianming Ying[1]. *[1]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]Tongji Hospital, Tongji Medical College, Huazhong University of Science & Technology, Wuhan, China,[3]West China Hospital, Sichuan University, Chengdu, China,[4]Sun Yat-Sen University Cancer Center, Guangzhou, China,[5]Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China,[6]Fudan University Shanghai Cancer Center, Shanghai, China,[7]MSD China, Shanghai, China*

Programmed death-ligand 1 (PD-L1) is a trans-membrane protein and co-inhibitory factor of the immune response. PD-L1 can combine with its receptor (PD-1) to reduce the proliferation of PD-1-positive cells and induce apoptosis. Therefore, PD-L1 was employed as a prognostic marker and a target for anti-cancer immunotherapy in blocking the PD-1 and PD-L1 checkpoints. PD-L1 is highly expressed in various malignancies, including head and neck squamous cell carcinoma (HNSCC). HNSCC is the sixth most common cancer worldwide, with high incidence and mortality rates in China. Although PD-L1 expression has been widely investigated, the PD-L1 expression status in Chinese HNSCC patients (pts) is largely unrevealed. The primary objective of this study was to determine the prevalence of PD-L1 expression with the Combined Positive Score (CPS) ≥20 in Chinese pts

with recurrent or metastatic (R/M) HNSCC. The secondary objectives were to determine the prevalence of CPS≥1 in pts with R/M HNSCC and to study the difference in the demographic characteristics, clinicopathological parameters, treatment status, and other available biomarkers between the PD-L1 CPS≥20 group and the PD-L1 CPS<20 group. This study was a multi-center retrospective analysis of data from six centers in China from August 9, 2021, to February 28, 2022. Pts with histologically/cytologically confirmed diagnoses of R/M HNSCC were included. PD-L1 expression was assessed by IHC using the 22C3 PharmDx assay (Agilent, Santa Clara, CA, USA) and was determined using a CPS. The Chi-square test, Fisher's exact test, or Wilcoxon rank sum test would be used to compare the prevalence of these variables among pts between the PD-L1 CPS≥20 group and the PD-L1 CPS<20 group. Out of 406 enrolled pts with R/M HNSCC, 402 testing pts were included in the final analysis. For all testing R/M HNSCC pts, 168 pts (41.8% [95% CI 36.92-46.78]) had PD-L1 expression with CPS ≥20. In addition, 337 pts (83.8% [95% CI 79.86-87.29]) had PD-L1 expression (CPS≥1). For the testing pts, there were statistically significant differences in variables of gender (P < 0.001), smoking habit (P = 0.0138 for non-smokers versus current smokers), and primary tumor site (P < 0.001 for hypopharynx versus oral cavity and P = 0.0304 for larynx versus oral cavity) between the PD-L1 CPS≥20 group and the PD-L1 CPS<20 group. In summary, in Chinese R/M HNSCC pts, most pts (83.8%) had PD-L1 expression, and two-fifths (41.8%) had PD-L1 expression with CPS ≥20. Prevalence of PD-L1 among Chinese pts with R/M HNSCC was consistent with that reported in the global KEYNOTE-048 study. PD-L1 expression was significantly associated with gender, smoking history and primary tumor site. Our findings of the variables related to the PD-L1 expression levels can supply adjuvant evidence for clinical practice and are a solid basis for future research on immunotherapy.

Predictive biomarkers for PD-1 and PD-L1 checkpoint inhibitor response in NSCLC: An analysis of clinical trial and real-world data

WeiQing Venus So[1], David Dejardin[2], Eva Rossmann[3], Jehad Charo[4].
[1]Roche Innovation Center New York, F. Hoffmann-La Roche Ltd., New York, NY,[2]Department of Biostatistics, F. Hoffmann-La Roche Ltd., Basel, Switzerland,[3]Roche Innovation Center Basel, Basel, F. Hoffmann-La Roche

Ltd., Basel, Switzerland,[4]Roche Glycart AG, F. Hoffmann-La Roche Ltd., Schlieren, Switzerland

Importance**:** Largest analysis combining clinical trial and real-world data (RWD) to assess the clinical utility of biomarkers for anti-PD-1/PD-L1 checkpoint inhibitors (CPI) in NSCLC patients.
Objective: To assess the association between tumor PD-L1, TMB and blood analytes with clinical outcomes in patients with advanced NSCLC following CPI therapy.
Design: Retrospective cohort study with patients stratified into high and low biomarker groups. Correlation with treatment outcome in the different biomarker groups was investigated and compared between patients treated with CPI versus chemotherapy.
Setting: Data derived from electronic health records mostly from community oncology settings were combined with clinical trial data.
Participants: Starting with 71850 patients with advanced NSCLC who received CPI or chemotherapy, we selected 24152 patients from an electronic health record-derived de-identified NSCLC clinicogenomic database (CGDB) from a real-world cohort and nine Roche atezolizumab trials. Patients were diagnosed between January 2011 and February 2020 (data collection cut-off date).
Main Outcomes and Measures: Drug response was assessed by RECIST criteria for clinical trials and real-world response for RWD. Durable response was defined as having CR/PR without progression during the study period of 270 days. Associations of biomarker levels with treatment outcomes were analyzed using Fisher's exact test.
Results: High expression of PD-L1 on tumors (≥50%) were associated with lower risk of resistance to CPI (odds ratio [OR] 0.21; 95% CI = 0.14, 0.32; P< .001). The association was stronger in patients who had prior chemotherapy than first line CPI, with non-squamous than squamous histology, and smokers than non-smokers. Higher TMB (≥9.57 mut/Mb) was also associated with durable response (OR = 0.41; CI = 0.30, 0.55; P< .001). The combination of high TMB and PD-L1 expression was the strongest predictor of durable response (OR = 0.04; CI = 0.00, 0.20; P< .001). There was no evidence of an association between PD-L1/TMB and response to chemotherapy, suggesting a CPI-specific predictive effect. In contrast, blood

analytes were prognostic, having correlation with clinical outcome irrespective of treatment type.
Conclusion: This study supports the predictive utility of PD-L1 expression and TMB for NSCLC patients receiving CPI therapy and further elucidates their utility in patient sub-populations.

Immune cell dynamics of patients and mice with hepatocellular carcinoma treated with anti-PD-L1 plus anti-CTLA-4 combination therapy
Yuta Myojin, Benjamin Ruf, Mohamed-Reda Benmebarek, Kylynda Bauer, Rajiv Trehan, Kelley Coffman, Chi Ma, Cecilia B. Monge, Changqing Xie, Tim Greten. *National Cancer Institute Center for Cancer Research, Bethesda, MD*

Background: Hepatocellular carcinoma (HCC) is one of the major causes for cancer-related death. Single agent immunotherapy or combined immunotherapy have become the standard of care in advanced HCC. Recently, the combination of durvalumab (dur) plus a single dose of 300 mg tremelimumab (trem) (STRIDE regimen) have received FDA approval based on results from the HIMALAYA trial. However, immune responses have not been studied in detail. We tested the combination of 4x 75 mg trem plus dur and locoregional therapies in HCC at and conducted correlative studies.
Methods: We enrolled 28 patients with biopsy proven advanced HCC in an open-labeled phase 2 trial using dur and trem combined with ablative therapies (NCT02821754). Patients received four doses of 75mg trem every 4 weeks and 1500mg dur every 4 weeks until progression. Patients underwent an interventional radiologic procedure (RFA/TACE) on day 36. Peripheral blood mononuclear cells (PBMC) and serum from patients enrolled were collected at baseline and after 1 cycle (day 28). PBMC was analyzed by multicolor spectral cytometry using a 17 antibody pan immune cell panel and a 25 antibody T cell panel. Serum samples from patients were collected at baseline and on day 28. Serum samples were analyzed with a 34-plex cytokine/chemokine array. Mice with orthotopically injected HCC (RIL-175 and Hep55.1C) were treated with anti-PD-L1 plus anti-CTLA4 and followed for tumor responses. Hepatic lymphocytes, tumor infiltrating

lymphocytes (TILs), and splenocytes were analyzed by spectral cytometry from mice treated with immune checkpoint inhibitors.
Results: 28 patients with advanced HCC were enrolled in this study. The best clinical response for treatment was the following, partial response (PR, n=5), stable disease (SD, n=12), progressive disease (PD, n=8), and not evaluable (n=3). Median PFS and OS were 4.5 and 20.8 months respectively. Patient PBMC analysis demonstrated an increase of regulatory T cells 1.65 times from baseline after 28 days in all patients. The frequency of $Tbet^{+}CD4^{+}$ T cells showed a non-significant increase in patients demonstrating a PR. Serum cytokine analysis revealed the levels of IL-18, IL-10, CCL-2, and VEGF-a increased in responders after treatment. in contrast, an increase of IL-6 and TNF-alpha after treatment was found only in patients with PD. In animal experiments, the size of liver tumors treated with anti-PDL1 and anti-CTLA4 were significantly smaller than that with isotype controls. The lymphocytes in the adjacent livers and tumor-infiltrating lymphocytes (TILs) were analyzed. $PD1^{+}CD8^{+}$ T cells and $Tbet^{+}CD4^{+}$ T cells in the liver and TILs increased with combination treatment.
Conclusion: Anti-PD-L1 and anti-CTLA4 combination therapy have an anti-tumor effect on HCC. We observed an expansion of $PD1^{+}$ $CD8^{+}$ T cells and $Tbet^{+}$ $CD4^{+}$ T cells.

Functional status of tumor-associated macrophages impacts clinical outcome of durvalumab in patients with advanced NSCLC as revealed by proteomics mass spectrometry
Anna Margaret Hansen, Vivian Ying Wang, Andrew Chambers, David Chain, Jaime Rodriguez Canales, Jorge Blando, Steve Sweet, Zachary A. Cooper, Ashok Gupta, Carl Barrett, Yeoun Jin Kim, Ikbel Achour.
AstraZeneca US, Gaithersburg, MD

Introduction: Predictive biomarkers of anti–PD-(L)1 therapies have largely focused on the tumor-T cell axis where tumor cell PD-L1 expression has demonstrated its clinical utility in predicting overall survival (OS) in patients with advanced NSCLC. In prior work using computational image analysis of multiplex immunofluorescence (mIF), we have shown the positive impact of CD68+ PD-L1+ macrophages in combination with CD8+

T cells in predicting long-term OS benefit in NSCLC patients treated with durvalumab (anti-PD-L1), highlighting the impact of the myeloid compartment on IO responses. In part, using proteomics mass spectrometry we sought to investigate further the functional impact of myeloid cells on the IO response and in particular, suppressive (M2) tumor associated macrophages (TAMs).
Methods: Pre-treatment tumor samples from 66 patients with advanced NSCLC patients enrolled in durvalumab nonrandomized phase 1/2 trial (10 mg/kg Q2W, CP1108/NCT01693562) were processed for global and targeted proteomics. A pathologist determined the tumor area and a single FFPE tumor tissue section was used for laser-capture macrodissection and protein extraction followed by mass spectrometry analysis using label-free, data-independent and parallel reaction monitoring.
Results: Among the immune associated proteins detected by proteomics mass spectrometry, we evaluated CD163 protein expression, a well-described marker of suppressive (M2) macrophages, and its impact on durvalumab clinical outcomes, alone and in relationship with PD-L1 and immune infiltration. While proteomics-based biomarker evaluable population (BEP) shows shorter median (m) OS compared to intended to treat population, we validated that high expression of PD-L1 as measured by IHC or proteomics associates with greater OS benefit as expected when treating with durvalumab. Building on this, the evaluation of protein associated with suppressive M2 macrophages, revealed that approximately 30% of NSCLC patients with high CD163 protein expression show poor OS benefit (5 months mOS) following durvalumab treatment. In contrast, patients with PD-L1 TC $\geq$50% and low CD163 expression derive greater OS benefit (13.4 months mOS) than those with high CD163 expression (5 months mOS) or with PD-L1 TC <50% regardless of level of CD163 expression (4.1-7.4 months mOS). Moreover, patients with poorer outcome have significantly higher baseline CD163 protein expression as a proportion of total CD45 protein expression.
Conclusion: This analysis further confirms the importance of myeloid cell function within the tumor microenvironment (TME) in determining the outcome to T cell-directed IO therapy and highlights the utility of proteomics mass spectrometry in assessing more broadly and quantitatively the TME complementing findings based on RNAseq and IHC/mIF assays.

Single-cell analysis of CD34-enriched blood cells reveals early prognostic markers of myelodysplastic syndromes

Zohar Shipony[1], Nimrod Rappoport[2], Gila Lithwick-Yanai[1], Eti Meiri[1].
[1]Ultima Genomics, Newark, CA,[2]Weizmann Institute of Science, Rehovot, Israel

Myelodysplastic Syndromes (MDS) are a group of blood malignancies characterized by aberrant differentiation of hematopoietic stem and progenitor cells (HSPC) in the bone marrow that results in inefficient hematopoiesis and high risk of transformation to acute myeloid leukemia. In order to detect aberrant HSC differentiation in blood samples sensitively and accurately, we explored the use of scRNA-seq of CD34-enriched cells from peripheral blood in identifying differentiation trajectories that are abnormal in patient samples versus expected normal development.
A total of 685,000 CD34-enriched PBMCs from 93 samples were analyzed using 10X 3' v3 scRNA-seq library preparation. For increased efficiency, the samples were multiplexed in groups of 5 individuals and were later identified based on individual natural genetic variation using a custom genotyping assay or low-pass WGS. We then sequenced these 24 libraries on a UG100 sequencer to yield an average of 20,000 reads per cell. Six of these libraries were also sequenced on a NovaSeq. Comparison between scRNA profiles generated on the two different sequencers yielded highly similar results, including a similar ability to demultiplex the patient samples using genetic markers, accurately quantify gene modules and determine cell populations.To analyze the scRNA data, we used a novel computational framework, Metacell, to reconstruct metacell modules for both healthy and disease samples allowing us to find variability in the differentiation process between the disease samples and the normal baseline state. Two patients with MDS which had transformed to acute myelogenous leukemia (AML) demonstrated unique and distinct metacell clusters that were significantly separate from normal HSPC differentiation patterns, demonstrating distinct clusters with elevated levels of BCL2 which is an existing therapy target in secondary AML. Our results demonstrate that scRNA-seq analysis of peripheral blood HSPCs samples can be used to detect aberrations in HSC development in MDS patients and serve as a prognostic tool for stratification of patients with aggressive disease and drug response. Given

the cost-efficiency of the entire process, we believe this is one of the first examples of the potential practical utility of single-cell analysis in a clinical setting.

Which are the clinicopathological characteristics useful to define the metastatic breast cancer patients that will respond to CDK4/6 inhibitors and hormone therapy? An Italian real-world experience

Sara Bravaccini, Andrea Roncadori, William Balzi, Giovanni Martinelli, Maria Teresa Montella, Michela Palleschi, Roberta Maltoni. *IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy*

The development of CDK4/6 inhibitors has changed the therapeutic management of hormone receptor positive (HR+) metastatic breast cancer (mBC) by targeting the cell cycle machinery and overcoming endocrine resistance. However, a high proportion of patients will present disease progression due to the resistance of cancer cells to CDK4/6 inhibitors. Loss of retinoblastoma function, dysregulation of several signaling pathways and overexpression of CDK6, CDK7 and cyclin E have been described as main actors in the development of resistance to CDK4/6 inhibitors. Despite these findings on the role of new emerging biomarkers, we wondered if the clinicopathological characteristics could be useful to identify the patients that will respond to CDK4/6 inhibitors by the analysis of a retrospective case series of patients with HR+ mBC treated with hormone therapy plus CDK4/6 inhibitors (ribociclib, palbociclib, abemaciclib) at IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori" (Meldola, Italy). 177 mBC patients 66 of whom were treated with CD4/6 inhibitors plus letrozole and 111 treated with CDK4/6 inhibitors and fulvestrant were enrolled in the study. The median age was 63 years (range 38-92), of whom 103 younger than 65 years. 152 were in postmenopausal status. Among the clinical characteristics, neutropenia was developed in 80 patients. ki67 was low (<20%) in 85 patients. 21 (23.3%) patients had bone metastases, 36 visceral metastases (23.3%) and 33 (36.7%) in other organs. The multivariable Cox PH model showed that having received a prior adjuvant treatment and the number of metastases were the only factors associated with the progression-free survival (PFS). Furthermore, when introducing the

presence of neutropenia as a potential predictor of PFS in the Cox PH model, it resulted to be a risk predictor of progression. To better describe the mechanism linking PFS and neutropenia a multistate model was developed. Low body surface area and older age were associated with an increased risk of developing neutropenia. High Ki67, the presence of visceral metastases and the absence of a prior adjuvant chemotherapy were prognostic factors of progression/death. As expected, among neutropenic patients, those with multiple previous lines of treatment were at higher risk of disease progression/death. Finally, the neutropenia status was associated with a more than double risk of progression/death with respect to patients without neutropenia (HR=2.311; p=0.025). Given that we identified a set of factors associated with the probability to develop neutropenia and considering that neutropenia itself is associated with an increased risk of progression, these baseline characteristics should be taken into account in order to reduce the occurrence of both neutropenia and disease progression.

#5469

Characterization of *CCNE1* amplifications and associated genomic features in ovarian and uterine cancers

Sunantha Sethuraman[1], Dominik Glodzik[1], Pier Selenica[2], Adrienne Johnson[1], Jorge S. Reis-Filho[2], Artur Veloso[1], Ian M. Silverman[1]. *[1]Repare Therapeutics Inc., Cambridge, MA,[2]Memorial Sloan Kettering Cancer Center, New York, NY*

Amplification of the Cyclin E1 gene (*CCNE1*) is a recurrent genetic alteration in ovarian and uterine cancers. Therapeutic approaches to target cancers harboring *CCNE1* amplification are being developed (e.g. PKMYT1, WEE1, and CDK2 inhibitors). In this study, we report the genomic landscape and architecture of *CCNE1* amplifications using a combination of whole-exome (WES) and whole-genome sequencing (WGS) approaches. WES data from 361 ovarian and 580 uterine cancers was retrieved from TCGA. WGS data from 113 ovarian and 51 uterine cancers was retrieved from PCAWG. For both WES and WGS, amplification was defined as CN minus ploidy (CN-ploidy) >= 4. *CCNE1* amplification was detected in up to 21.2% of ovarian and 13.7% of uterine cancers from both methods. A review of the co-alteration landscape using WES revealed that *TP53* alterations frequently co-occurred with *CCNE1* amplifications in both

ovarian and uterine cancers (ovarian: 95.8% vs 87.6%, OR = 3.24, p=0.1; uterine: 89.6% vs 36.0%, OR = 15.2, p =2.14e-13) and *BRCA1* alterations were mutually exclusive with *CCNE1* amplifications in ovarian cancer (2.1% vs 17.9%, OR=0.2, p = 3.1e-3). In addition, alterations in *ARID1A* (0% vs 40.5%, OR = 0, p = 1.3e-10) and *PTEN* (4.2% vs 60.1%, OR = 0.03, p =2.7e-15) were mutually exclusive with *CCNE1* amplifications in uterine cancer. The number of *CCNE1* copies ranged widely, with median CN-ploidy values of 9.3 (range: 4.0 -35.0) in ovarian and 7.7 (range: 4.0 -40.3) in uterine cancers from the WES cohort, and 7.4 (range: 4.1 -34.3) in ovarian and 11.0 (range: 4.6 - 81.9) in uterine cancers from WGS. We also observed a broad range of *CCNE1* amplicon sizes, from highly focal to chromosome arm-level amplifications. WGS data showed frequent loss of heterozygosity (LOH) of chromosome 19 arms and an enrichment of fold-back inversions proximal to the *CCNE1* amplicon implicating breakage-fusion-bridge in formation of *CCNE1* amplicons. Whole genome duplication (WGD) was detected significantly more frequently in ovarian and uterine cancers with *CCNE1* amplification than the wild-type group (ovarian: 90.9% vs 48.3%, p = 6.4e-10; uterine: 78.7% vs 21.9%, p = 7.1e-15). As compared to *CCNE1* wild-type cancers, *CCNE1*-amplified cancers were found to display an enrichment for certain structural variant signatures: RS1, dominated by 100Kb-1Mb duplications (median = 30, p=0.08); RS2, dominated by translocations (median = 16, p=0.001); and RS7, dominated by 100Kb-1Mb deletions (median=23, p=0.0002). In conclusion, *CCNE1*-amplified ovarian and uterine cancers are enriched for *TP53* alterations and display a high degree of genome instability manifested as WGD and characteristic structural variants. Fold-back inversions and LOH were frequently observed at the *CCNE1* locus in tumors with *CCNE1* amplification, suggesting a potential breakage-fusion-bridge mechanism in the genesis of this amplicon.

Identification of gene amplification based signature as predictors for chemotherapy in squamous cell carcinoma of the lung

Yuan Tang[1], Yuli Li[1], Ting Hou[2], Lili Jiang[1], Hongjie Liu[2], Chunxiao Pan[2], Weiya Wang[1], Li Qiu[1], Yajing Zhang[1], Guiping Zhang[1], Ke Zheng[1].
[1]Department of Pathology, West China Hospital, Chengdu, China,[2]Burning Rock Biotech, Guangzhou, China

Background: Lung squamous cell carcinoma (LUSC) is the second most popular histologic subtype accounting for 25%~30% of lung cancer. Due to the lack of targeted therapies for LUSC, the prognosis is poor and chemotherapy still plays a full role in the treatment of LUSC patients currently. However, a significant proportion of patients showed a bad response to chemotherapy. The development of predictive biomarkers is urgent. We aimed to identify new chemotherapy biomarkers based on genomic alterations.
Methods: We retrospectively analyzed DNA sequencing data of 317 LUSC patients (pts) at West China hospital. We collected the clinical features and progression-free survival (PFS) of 35 pts with chemotherapy only. Pts were assigned to different subgroups based on genomic alterations using non-negative matrix factorization (NMF) clustering. Based on the characteristics of the cluster, we then explored clear gene signatures to predict the prognosis of chemotherapy. The clinical information and sequencing data of TCGA LUSC with chemotherapy were used to validate the prognostic value of the signature.
Results: The 317 LUSC pts were grouped into 4 clusters characterized by different genomic alterations. Cluster 1 (C1) had 129 pts and was characterized by *TP53* alterations. There were 116 pts in cluster 2 (C2) characterized by *PIK3CA* amplification (amp). Cluster 3 (C3) had 33 pts and was characterized by gene amp of *CCND1*, *FGF3*, *FGF4*, and *FGF19*. Cluster 4 (C4) was characterized by gene amp of *FGFR1*, *KDR*, *KIT*, and PDGFRA. The 35 pts treated with chemotherapy only were also classified into 4 clusters. C1 was associated with the shortest PFS (hazard ratio (HR), 2.87; 95% confidence interval (CI), 1.15-7.13; p = 0.018) independently of the clinical stage, but C2, C3, and C4 showed no significant difference. In addition, we also found that pts with *TP53* loss of function (LOF) alteration had significantly shorter PFS than those without
TP53 LOF (wildtype or not LOF, p = 0.029). So we further modified the clustering by *TP53* alteration from C1 and gene amp from C2, C3, and C4. Therefore, 35 pts were then grouped into 3 subtypes based on *TP53* LOF and gene amp characteristics, and the PFS was significantly different. Pts (n = 8, 23%) with at least one amp of 9 genes (*PIK3CA, CCND1, FGF3, FGF4, FGF19, FGFR1, KDR, KIT,* and *PDGFRA*) but no *TP53* LOF had the longest PFS (HR, 0.12; 95% CI, 0.02-0.66; p = 0.011). Pts (n = 6) with

TP53 LOF but no 9-gene amp had poor survival compared with pts in other subtypes. This gene signature was validated in TCGA pts. The signature of 9-gene amp without TP53 LOF also indicated the best PFS and *TP53* LOF without 9-gene amp indicated the worst PFS ($p = 0.081$).
Conclusion: We develop a biomarker signature that consists of 9-gene amp and *TP53* LOF to indicate the prognosis of chemotherapy. Our results suggest that 9-gene amp without *TP53* LOF in LUSC is a favorable prognostic marker for patients taking chemotherapy.

Integrating tumor-intrinsic and immunological factors to identify immunogenic breast cancers from a low-risk cohort; results from the randomized SweBCG91RT trial

Axel Stenmark Tullberg[1], Martin Sjöström[2], Emma Niméus[3], Fredrik Killander[3], Laura Chang[4], Felix Y. Feng[2], Corey W. Speers[5], Lori J. Pierce[5], Anokó Kovács[6], Dan Lundstedt[7], Erik Holmberg[7], Per Karlsson[7].
[1]University of Gothenburg, Gothenburg, Sweden,[2]Department of Radiation Oncology, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA,[3]Lund University, Lund, Sweden,[4]Exact Sciences, Redwood City, CA,[5]Department of Radiation Oncology, University of Michigan, Ann Arbor, MI,[6]Department of Pathology, University of Gothenburg, Gothenburg, Sweden,[7]Department of Oncology, University of Gothenburg, Gothenburg, Sweden

Purpose: The local immune infiltrate's influence on tumor progression may be linked to tumor-intrinsic factors. This study aimed to investigate whether integrating immunological and tumor-intrinsic factors could identify patients who may be candidates for de-escalation of radiotherapy (RT).Experimental Design: The practice-changing SweBCG91RT trial included 1178 patients with stage I-IIA breast cancer, randomized to breast-conserving surgery with or without adjuvant RT with sparse use of systemic therapy (95% without systemic therapy) and followed for a median time of 15.2 years. We developed two gene expression models to capture immunological activity and immunomodulatory tumor-intrinsic qualities, respectively. We then analyzed if combining these two variables could identify a subgroup where RT de-escalation is feasible.

Results: The immunomodulatory model correlated with proliferation and was named Proliferative Index. The immunological model was enriched for T cell signatures and was named Immunescore. Increased Proliferative Index predicted an increased prognostic benefit from Immunescore ($p_{interaction}$=0.01). Combining the two models stratified patients who may be recommended an escalated RT (RT boost) by RT benefit and prognosis. Patients with a low predicted risk benefited from standard RT (HR: 0.28, CI 95% 0.09-0.85, p=0.025) and had a 5.4% 10-year incidence of ipsilateral breast tumor recurrence (IBTR) after radiation. In contrast, the group with a high predicted risk, characterized by rapidly proliferating tumors without an immune infiltrate, had a clinically meaningful high 10-year incidence of IBTR despite RT treatment (19.5% (CI 95% 12.2-30.3)).
Conclusions: Integrating tumor-intrinsic and immunological factors may identify immunogenic tumors in early-stage breast cancer populations and identify patients for whom de-escalated RT may be appropriate. Patients with rapidly proliferating tumors and an immune infiltrate may be candidates for RT de-escalation.

Utilizing response in immune checkpoint inhibitor treated cohorts improves clinical applicability of neoantigen immunogenicity predictions

Hima Anbunathan, Neeraja Ravi, Rachel Marty Pyke, Steven Dea, Richard O. Chen, Sean Michael Boyle. *Personalis, Inc., Menlo Park, CA*

Introduction: Neoantigen-based biomarkers have improved predictions of response to immune checkpoint blockade (ICB) therapy, highlighting the importance of accurate prediction of immunogenic neoantigen candidates. A challenge in developing robust immunogenicity prediction models is limited availability of sequencing-associated immunogenicity data for evaluating methods due to the complexity of generating such datasets. We propose a novel approach to optimize prediction models of immunogenic neoantigens using a meta-analysis framework based on multiple ICB cohorts.
Methods: To build on the 110 mono-allelic immunopeptidomics-derived SHERPA® MHC binding prediction framework, we engineered T-cell recognition features on two datasets: peptide-centric data aggregated by Schmidt et al. and patient-specific exome and transcriptome sequencing data

from the TESLA consortium. We developed two-tiered models based on the feature landscapes of both datasets to predict peptide-MHC (pMHC) immunogenicity, incorporating features with significant performance gains. We systematically re-processed publicly available DNA and RNA sequencing data from over 500 ICB treated patients spanning 12 different cohorts across five different cancer types with a harmonized bioinformatics pipeline. We then evaluated the performance of each model consisting of a unique combination of immunogenic features across the ICB training (N=7) and validation (N=5) cohorts using a meta-analysis framework.
Results: We evaluated iterations of SHERPA-Immunogenicity (SI) models using the Schmidt et al. and TESLA datasets, resulting in a range of performance metrics (area under the precision recall curves of 0.74-0.84 and positive predictive values of 0.32-0.54). After aggregating pMHC predictions into patient-specific scores based on the most immunogenic peptide present (SHERPA-Immunogenicity Maximum - SIM) or the quantity of immunogenic peptides identified (SHERPA-Immunogenicity Burden - SIB), we observed that responders had higher SIM and SIB scores compared to non-responders across the melanoma training cohorts. We found SIM scores outperformed SIB scores, suggesting the degree of epitope immunogenicity may be a critical factor in predicting response. The model with the most significant meta p-value for ICB response in melanoma cohorts (OR=2.43, p=0.006) also predicted overall survival in 3/5 melanoma cohorts ($p<0.05$).
Conclusions: We developed a novel framework to predict neoantigen immunogenicity utilizing meta-analysis of ICB cohorts to overcome dataset limitations and gain prediction performance confidence. We look forward to supporting personalized cancer vaccine development with our pMHC immunogenicity predictions and applying our predictive biomarker on additional ICB cohorts.

Genomic profiling of chemotherapy-related clonal hematopoiesis in patients with high-grade serous ovarian cancer
Sara Corvigno, jun yao, Li Zhao, amma asare, Joseph celestino, richard hajek, Ency Arboleda Goette, Elaine Stur, Emine Bayraktar, Mark S Kim, ping song, Qingxiu Zhang, xingzhi song, Mohammad Mohammad, kenna

Shaw, Jianhua zhang, karen lu, amir jazaeri, shannon westin, Sanghoon Lee, anil sood. *UT MD Anderson Cancer Center, Houston, TX*

Background: Clonal hematopoiesis (CH) is identified as the presence of clonal populations of hematopoietic stem cells (HSC). Hematopoietic lineage differentiation is subjected to genetic mutations that, due to fitness advantages, might give rise to clonally expanded populations. Clonal hematopoiesis of indeterminate potential (CHIP) is defined as the outgrowth of a single clone driven by acquired somatic mutation(s) in HSCs, in the absence of hematological abnormalities. Previous studies have been shown the association of CH with aging and a higher risk of developing secondary hematologic malignancies in cancer patients treated with chemotherapy agents. It is therefore of great interest to study CH incidence prior to and post chemotherapy exposure and its association with the evolution of hematologic malignancies. We aimed to characterize CHIP variants of a highly selected group of patients with high-grade serous ovarian cancer (HGSC) who underwent neoadjuvant chemotherapy; moreover, while previous CHIP studies are largely knowledge based and are limited to known hematologic genes or target gene panels, our study discovers novel CHIP mutations.
Methods: Comprehensive ultra-high-depth whole exome sequencing using unique molecular barcode technologies was performed using plasma-derived cell-free DNA and matched white blood cells DNA and tumor DNA from pre-NACT (n=12) and post-NACT (n=12) samples of patients with HGSC who have excellent or poor response to NACT. Using spike-in mutated DNAs as positive controls, we detected variant alleles at 1% variant allele frequency.
Results: We identified on average about 3,000 candidate CHIP variants in one patient. Among these, 1,977 variants affecting 1,375 genes were recurrently found in more than one patient. These CHIP genes include not only previous reported CHIP genes (e.g. DNMT3A, JAK2, TET2, and KMT2D) but also many novel CHIP candidates (such as RPTN, MTCH2, FAM186A, CACNA1A, FCGBP, and MUC3A). A number of CHIP mutations were uniquely found enriched in post-chemotherapy samples (e.g. ARID1A T290P, TP53 G245D, SMARCA4 G495D, and CIC T2456P). Interestingly, there is a strong enrichment of COSMIC cancer census genes in CHIP genes identified in every patient.

Conclusions: Our findings corroborate the notion that CHIP mutations are present in nonmalignant blood cells of patients with HGSC, and some are enriched after chemotherapy. Moreover, our innovative sequencing approach allowed discovery of novel candidate CHIP genes. The systematic identification of CHIP in patients with HGSC might be an important new clinical consideration when establishing chemotherapy protocols.

Combined use of MRI and TAM analysis in GB monitoring

Carolina Giordano[1], Giuseppe Maria Della Pepa[1], Simona Romano[2], Laura Marrone[2], Carlo Maria Donzelli[1], Maria Fiammetta Romano[2], Simona Gaudino[1]. *[1]Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy,[2]University of Naples Federico II, Napoli, Italy*

Glioblastoma (GB) is the most frequent and aggressive primary brain tumor. It is a highly infiltrating tumor. Complete eradication by surgery is difficult. The probability of survival beyond two years is very low. Magnetic resonance imaging (MRI) is a routine procedure for diagnosing gliomas. However, morphological MRI often fails to identify and quantify the presence of infiltration in peritumoral non-enhanced areas, resulting in inaccuracy in the assessment of invasive margins. Up to 50% of the patients show pseudo-progression. Morphological MRI fails to distinguish the marked enhancement in the tumor bed caused by radionecrosis from actual tumor progression. Diagnosis of GB recurrence through MR morphological sequences has a sensitivity and specificity of about 68% and 77%. Such percentages rise thanks to the use of non-morphological sequences (PWI, DWI, MRS), which are used in routine tumor protocols only in large centers and interpreted by expert neuroradiologists. Biomarkers in conjunction with MRI may help improve the classification, prognosis, and treatment choice. GB is highly infiltrated with monocytic cells, tumor-associated macrophages (TAMs), that invade the peripheral blood. Our group has recently identified a splice isoform of FK506-binding protein 51 (FKBP51) as a reliable TAM marker. We found an expansion in circulating CD163/FKBP51s monocytes in a cohort of GB patients. In patients with an MRI diagnosis of complete surgical tumor removal, these monocytes dramatically decreased. In patients with an MRI diagnosis of residual tumor, most of the peripheral CD163

monocytes that in the preoperative stage were FKBP51s- had turned into FKBP51s+. CD163/FKBP51s+ monocytes helped to distinguish between radionecrosis and actual tumor progression. These results suggest that circulating CD163/FKBP51s+ monocytes are associated with GB and can be helpful in monitoring GB patients.

Improved prediction of immunotherapy responses by constitutive neoantigen load and LINE-1 methylation

Hyoeun Bang[1], Jeong Yeon Kim[2], Cheolyong Joe[3], Kyeonghui Kim[2], Younghak Bang[3], Hyemin Kim[4], Honghi Cha[4], Eunjoo Oh[4], Naeun Lee[3], Inkyung Shin[1], Seung-Jae Noh[1], Dae-Yeon Cho[1], Se-Hoon Lee[4], Jung Kyoon Choi[2]. *[1]PentaMedix Co., Ltd., Seongnam, Korea, Republic of,[2]Bio and Brain Engineering, KAIST, Daejeon, Korea, Republic of,[3]Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea, Republic of,[4]Medicine, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of*

Previous biomarkers such as PD-L1 expression, tumor mutation burden (TMB), and neoantigen load have limited accuracy in predicting responses to immune checkpoint inhibitor (ICI) therapy. In this work, we propose an improved predictor of ICI responses on the basis of our previous findings on the role of neoantigen functionality and genomic hypomethylation in tumor immunity. Specifically, we developed a metric of constitutive neoantigen load given the association of constitutive neoantigens derived from genes indispensable for cancer growth with favorable clinical responses to ICI (Clin. Transl. Med. 12:e714). A panel that captures somatic mutations on the 300 most essential genes identified by genome-wide screening in ~1,800 pan-cancer cell lines was used. Our DeepNeo algorithm (Nat. Commun. 11:951; Nat. Genet. 2023) was employed to identify T cell-reactive neoantigens from somatic mutations binding patient-matched HLA proteins. Also, considering the role of genomic hypomethylation in inducing resistance of tumors to ICI therapy (Nat. Commun. 10:4278), we developed an assay that estimates genomic hypomethylation by targeted sequencing of LINE-1 elements. Constitutive neoantigen load and LINE-1 methylation status were evaluated in our cohort consisting of 335 lung cancer patients treated with ICIs. As a result, constitutive neoantigen load (HR=0.671; p-

value=3.13E-03) and LINE-1 methylation (HR=0.597; p-value=0.012) outperformed PD-L1 (HR=0.74; p-value=0.199), TMB (HR=0.917; p-value=0.511), and the combination of PD-L1 and TMB (HR=0.707; p-value=0.218). The combination of constitutive neoantigen load and LINE-1 methylation (HR=0.245; p-value=1.11E-05) showed even better predictive power. In conclusion, our approach can be used as new companion diagnostics for ICI-based immune-oncology.

Veracyte Biopharma Atlas for colorectal cancer: Combining multi-parameter approach and machine learning to capture the complexity of the tumor immune contexture

laurent vanhille, Alboukadel Kassambara, Chafik Hamdad, Margaux Mercadal, Alexia Papadopoulos, Pernelle Outters, Théo Vasse, Vanina Leca, Jérôme Galon, Jacques Fieschi. *Veracyte, Inc., Marseille, France*

(a) Understanding the immune contribution has deeply modified the standard of care of patients, especially with the advent of immunotherapies (ITs). However, ITs are still efficient only on a minority of the patients, especially for colorectal cancer (CRC), a high-incidence cancer. One hypothesis to explain the heterogeneity of the response to IT is that the presence or absence of immune factors within the tumor micro-environment (TME) may critically impact the efficacy of treatments. In this context, a deeper molecular understanding of the TME could be key to stratify patients. Here, we describe a proof of concept of the Veracyte Biopharma Atlas for CRC based on a multi-omics approach which integrates a unique range of assays allowing to decipher the immune contexture of tumors and offer a personalized and dynamic “fingerprint” of the interactions between the tumor and the immune system.
(b) Veracyte Biopharma Atlas characterizes the tumor microenvironment by analyzing information from 3 different modalities: (i) proteomics (Brightplex® multiplex immunohistochemistry panels), (ii) transcriptomics (RNA sequencing) and (iii) genomics (somatic mutations by exome sequencing). This deep characterization of the tumor and its micro-environment requires the integration of thousands of features. The innovative Veracyte Biopharma Atlas approach relies on linear (multimodal factor analysis) and non-linear (self-organizing map) approaches with

graphical representation of the data to integrate this multi-omics information.
(c) Gene expression profiling, genomics analysis and proteomics by multiplex spatial technology were performed on 47 CRC FFPE samples to characterize the immune contexture of this disease. Multimodal analysis was used to derive a unique atlas map highlighting clusters distinguished by complex features and their immune tumor contexture. Indeed, as examples, the atlas map allows the identification of a group of patients displaying high immune cell infiltration, including T cell and macrophages. They are also characterized by an immune genes signature. By contrast, another group of patients is poorly infiltrated by immune cells but exhibits an elevated M2/M1 ratio, favorable to tumor development.
(d) This proof of concept lays the foundations of an atlas for CRC that will be extended to samples associated with clinical data to build a map of the disease. Later-on, by projecting data from new specimens onto this referential map, it will become possible to establish an Immunogram of the tumor microenvironment of individual patients to define the most appropriate treatment but also facilitate the development of new therapies.

An investigation to study differential gene expression of lung cancer cells, tumor associated macrophages, and bone marrow derived mesenchymal stems cells in the tumor microenvironment

Hirendra N. Banerjee[1], Joseph Hedley[1], Cheslsey Aurelus[1], Narendra Banerjee[1], Kuldeep Rawat[1], Quentin Reaves[1], Shennel Brown, Darla Gilmartin[1], Makieyah Liverman[1], Jazmine Cuffee[1], Elizabeth Cagle[1], Erik Armstrong[1], Brent lake[1], Santosh Mandal[2], Somiranjan Ghosh[3], Stephen Beebe[4], Kamal Asadipour[4], Christopher Krauss[5], Santanu Bhattacharya[6], Tanmay Kulkarni[7], Zahidur Abedin[8]. *[1]Natural, Pharmacy and Health, Elizabeth City State University, Elizabeth City, NC,[2]Chemistry, Morgan State University, Baltimore, MD,[3]Pediatrics, Howard University Medical School, DC, DC,[4]Bioelectrics, Old Dominion University, Norfolk, VA,[5]IBBR, University of Maryland, Gaithersburg, MD,[6]Biochemistry and Molecular Biology, Mayo Clinic, Jacksonville, FL,[7]Biomedical Engineering and Pathology, Mayo Clinic, Jacksonville, FL,[8]Molecular Biology, Primbio Research, Garnet Valley, PA*

Cancer is a public health crisis affecting approximately 19.3 million globally, annually. Lung cancer has the highest percentage of incidence and is responsible for 27% of cancer-related deaths. The prevalence of lung cancer worldwide led us to investigate differential gene expression in lung adenocarcinoma and small cell lung cancer cell lines in comparison to a healthy lung cell line. We also investigated the effect of lung tumor microenvironment to bone marrow derived pluripotent mesenchymal stem cells (PMSC) and tumor associated macrophages. This research involved cancer and healthy cell line culture with appropriate medium. Whole transcriptomic and small non-coding RNA sequencing and analysis by Ingenuity Pathway Analysis (Qiagen, USA), Quantitative RT-PCR and ELISA assays. We further studied morphological changes and differential gene expression in extracellular vesicles(exosomes) isolated from the TAM and TME exposed PMCs by atomic force microscopy and RNA sequencing techniques. The results of our investigation showed differential gene expression and novel core canonical pathways in the lung cancer cells, TME exposed TAM, and PMSC. We also observed morphological changes in TME derived exosomes from TAM and PMSC. RNA sequencing results showed differential gene expression of both coding and non-coding RNAs including tRNA fragments. Thus, our findings of this investigation led to identification of multiple cancer related genes and small non-coding microRNA, long non-coding RNA, and tRNA fragments which will have potential diagnostic and therapeutic target value that demands further future research. Medical Research Institute (CMRI), Sydney, Australia,[2]Melanoma Institute Australia, Sydney, Australia,[3]QIMR Berghofer Medical Research Institute, Sydney, Australia,[4]Faculty of Medicine and Health, The University of Sydney, Sydney, Australia,[5]The John Curtin School of Medical Research, Canberra, Australia

Introduction: Cutaneous melanoma (CM) is one of the most aggressive types of skin cancer, with a poor prognosis for advanced stages. Despite the advances in immunotherapy (IO) treatment, robust predictive biomarkers are still required. The aim of this study was to identify a prognostic and predictive protein-based signature for advanced CM.
Methods: A training cohort of 142 pretreatment tumor samples from 71 patients with metastatic CM treated with IO (anti-PD-1) and an independent validation cohort from 67 patients with stage III treatment-naïve CM were analyzed by data-independent acquisition mass spectrometry (DIA-MS). Survival analysis based initially on univariate regression and subsequently on 100 runs of 20-fold cross-validation of multivariate Cox regression with Least Absolute Shrinkage and Selection Operator (LASSO) was performed to obtain a reduced list of candidate proteins associated with melanoma-specific survival. A risk score was built from the final six proteins. The prognostic ability of this 6-protein signature for melanoma-specific survival was demonstrated by a time-dependent receiver operating characteristic curve (AUROC) and validated by four independent datasets. The predictive ability of the 6-protein signature was also explored in the training dataset using response to IO as the outcome of interest. Finally, differential expression analyses were conducted on the training data to identify the top proteins associated with response to IO. Proteins that were highly correlated (Pearson R^2 >0.9) with the 6-protein signature were identified and subjected to pathway enrichment analysis (PEA).
Results: Proteomic analyses identified 4298 and 4577 proteins in the training and validation cohorts respectively, with 81.1% overlap between the two sets. Using LASSO multivariate Cox modeling, six proteins were identified in the training cohort, from which a risk score was calculated that dichotomized patients into high- and low-risk groups (Hazard ratio (HR) 2.7, 95% confidence interval (CI) 1.9-3.9, and, AUROC 0.86). The 6-protein signature's prognostic performance was validated using the RNAseq dataset from the same training cohort (HR 2.7, p<0.001), a second RNASeq dataset

from The Cancer Genome Atlas (HR 1.7, p<0.001), a single-cell RNASeq dataset from patients treated with IO (HR 1.2, p<0.001) and finally a proteomic dataset in an independent cohort (stage III treatment-naïve CM) (HR 2.4, p<0.001). The 6-protein signature was also associated with response to IO (HR 2.3, p=0.005). PEA showed that the highly correlated proteins were mostly related to DNA repair and DNA metabolic pathways. PEA revealed activation of immune-related pathways in patients who achieved a good response to IO.
Conclusion: A 6-protein signature identified a sub-group of patients with advanced CM who are at higher risk of progression on IO and death from melanoma.

Glucagon-like peptide 1 agonist use and the progression of monoclonal gammopathy of undetermined significance to multiple myeloma in US veterans with diabetes mellitus

Nikhil Grandhi[1], Lawrence Liu[2], Mei Wang[3], Theodore Thomas[3], Akhil Kumar[3], Kristin Vargo[3], Kristen Sanfilippo[1], Grahm Colditz[1], Su-Hsin Chang[3]. *[1]Washington University In St. Louis, St. Louis, MO,[2]City of Hope Comprehensive Cancer Center, Duarte, CA,[3]St. Louis Veterans Affairs Medical Center, St. Louis, MO*

Background: Glucagon-like peptide 1 (GLP-1) agonists are increasingly used in diabetics due to their cardiac and renal benefits along with their actions as antihyperglycemics. They also showed inhibitory effects in ovarian, breast, prostate, and pancreatic cancers in preclinical studies. However, to our knowledge, no studies have examined whether GLP-1 agonists have a similar effect in multiple myeloma. Using a population-based study design, we aimed to assess the association of GLP-1 agonist use in the progression of MGUS to MM in patients with diabetes mellitus (DM).
Methods: Patients diagnosed with MGUS from 1999-2021 in the Veterans Health Administration were identified via ICD codes and further confirmed by a natural language processing (NLP)-based algorithm. Progression to smoldering MM (sMM) or MM was also confirmed by another NLP-based algorithm. Only patients with DM, IgG, IgA, or light chain MGUS, and

black and white patients were included. We excluded patients who experienced progression within 1 year of MGUS diagnosis or within 2 years of DM diagnosis, and patients diagnosed with MGUS before DM diagnosis. We performed 1:2 matching for patients with and without GLP-1 agonist exposure based on their follow-up time. Gray's test was performed to detect the difference between the two cumulative incidence functions (CIF) for progression stratified by GLP-1 agonist use status. The association between GLP-1 agonist use and progression was estimated by multivariable-adjusted hazard ratio (aHR) using Fine-Gray distribution hazard model with death as a competing event and time-varying GLP-1 agonist use. The covariates included age, BMI, monoclonal protein (M-spike) level (≥1.5g/dL), creatinine (>1.5 mg/dL), glycated hemoglobin (HbA1c; < 7%, 7% - 9%, and > 9%) at MGUS diagnosis, metformin and sodium-glucose co-transporter 2 inhibitor (SLGT2i) use, as well as sex, race, MGUS heavy chain subtype, light-chain MGUS, Charlson Comorbidity Index, and months from diagnoses of DM to MGUS.
Results: Our NLP algorithm confirmed 19,551 patients with DM and MGUS. After applying our inclusion and exclusion criteria, we had 14,832 patients, of which 1,303 had GLP-1 agonist use. After matching, our analytic cohort included 1,303 patients with exposure, and 2,606 patients without. There is no evidence to show that CIFs were different between the exposed and unexposed groups. However, the multivariable analysis showed that GLP-1 agonist use was associated with decreased progression to MM: aHR 0.35, 95% confidence interval 0.14-0.90, $p = 0.03$.
Conclusions: For DM patients with MGUS, GLP-1 agonist use is associated with a 65% reduction in risk of progression from MGUS to sMM/MM. Prospective studies examining whether GLP-1 agonists can be used as possible chemoprevention in MGUS patients with DM should be explored.

Ray[1], Carrie Fehnel[2], Olawale Akinbobola[2], Andrea Saulsberry[2], Kourtney Dortch[2], Anberitha Matthews[2], Amal Anga[3], Christopher Giampapa[4], Elizabeth Sales[5], Sherry Okun[6], Edward T. Robbins[7], Bradley Wolf[8], Paul Levy[9], Horace L. Wiggins[10], Thomas Ng[11], Vishal Sachdev[12], Ganpat Valaulikar[3], Hetal D. Patel[13], Nicholas R. Faris[2],

Matthew Smeltzer[14], Raymond U. Osarogiagbon[2]. *[1]University of Memphis, Memphis, Memphis, TN,[2]Baptist Cancer Center, Memphis, TN,[3]Veterans Affair Medical Center, Memphis, TN,[4]Jackson-Madison County General Hospital, Jackson, TN,[5]Doctors Anatomic Pathology, Jonesboro, AR,[6]Tupelo Pathology Group, Tupelo, MS,[7]Baptist Memorial Hospital - Memphis, Memphis, TN,[8]Baptist Memorial Hospital - DeSoto, Southaven, MS,[9]Baptist Memorial Hospital - North Mississippi, Oxford, MS,[10]St. Bernard's Regional Medical Center, Jonesboro, AR,[11]Methodist University Hospital, Memphis, TN,[12]North Mississippi Medical Center, Tupelo, MS,[13]Jackson-Madison County General Hospital, Jackson, MS,[14]University of Memphis, Memphis, TN*

Introduction. Despite its importance, pathologic nodal (pN) staging of lung cancer remains poor. We evaluated the quality and survival impact of two interventions to improve pN staging.
Methods. Using a non-randomized stepped-wedge design, we implemented use of a lymph node (LN) specimen collection kit to improve intraoperative LN collection (surgical intervention) and a novel gross dissection method for intrapulmonary LN retrieval (pathology intervention) in 12 hospitals in five contiguous Hospital Referral Regions in AR, MS and TN (2009-2021). With appropriate statistical methods we compared surgical quality and survival of patients among: neither (Group 1), pathology only (Group 2), surgical only (Group 3), and both (Group 4) interventions.
Results. Of 4,019 patients, 50%, 5%, 21% and 24%, were in Groups 1-4 respectively. Rates of non-examination of LNs and non-examination of mediastinal LNs: 11%, 9%, 0% and 0%; 29%, 35%, 2% and 2% respectively in Groups 1-4 ($p<0.0001$). Attainment of American College of Surgeons Operative Standard 5.8: 22%, 29%, 72%, 85%; International Association for the Study of Lung Cancer's stringent definition of 'complete resection': 14%, 21%, 53%, 61% ($p<0.0001$). Compared to Group 1, adjusted hazard ratios, aHR (95% CI), were: Group 2, 0.93 (0.76-1.15); Group 3, 0.91 (0.78-1.03); Group 4, 0.75 (0.64-0.87). Compared to Group 2, Group 4 aHR- 0.72 (0.57-0.91); compared to Group 3, was 0.83 (0.69-0.99). These relationships remained after excluding wedge resections.
Discussion. Combining a LN collection kit and novel gross dissection method significantly improved pN evaluation and survival in a population-

based cohort.

Opioid, non-opioid, and non-pharmacological pain management in patients with a history of cancer

Oyomoare L. Osazuwa-Peters[1], Justin M. Barnes[2], Eric Adjei Boakye[3], Trinitia Y. Cannon[1], Tammara L. Watts[1], Tomi Akinyemiju[1], Nosayaba Osazuwa-Peters[1]. *[1]Duke University School of Medicine, Durham, NC,[2]Washington University in St. Louis School of Medicine, St. Louis, MO,[3]Henry Ford Health System, Detroit, MI*

Background Pain is highly prevalent among individuals with cancer. Consequently, adequate and equitable pain management are hallmarks of quality cancer care. Unfortunately, up to one-third of patients with cancer consider their pain symptoms poorly managed. Objective To characterize clinical and sociodemographic factors associated with opioid, non-opioid, and non-pharmacological pain management among individuals with a history of cancer. Methods We used the 2018 to 2020 full-year consolidated data files of the Medical Expenditure Panel Survey (MEPS), linked to the medical conditions, prescribed medicines, outpatient visits and office-based medical provider visits files. We estimated adjusted relative risk (aRR) of receipt of opioid, non-opioid, and non-pharmacological pain management (acupuncture, chiropractor, and massage/occupational/physical therapy), based on clinical (cancer site, comorbidities, depression status) and sociodemographic (race, sex, age, marital status, education, insurance, income, English speaking ability) factors, accounting for complex survey design in quasi-Poisson regression models. Results The study cohort was composed of 7,035 individuals with cancer, with 19.2% (0.65%; weighted proportions (standard error) receiving opioids, 51.09% (0.9%) receiving non-opioids, and 20.56% (0.75%) receiving non-pharmacological pain management. In our final models, compared to Other cancers, patients with bladder cancer were more likely to receive opioids (aRR 1.52; 95% CI 1.06, 2.17), while those with lung cancer were less likely to receive non-pharmacological pain management (aRR 0.46; 95% CI 0.25, 0.84). Also, depression was associated with increased risk of both opioid (aRR 1.26; 95% CI 1.09, 1.46) and non-opioid (aRR 1.26; 95% CI 1.18, 1.34) , but not non-pharmacological pain management. There were no statistically

significant differences in risk of opioid prescription between Black vs. White patients with cancer; however, Asian patients were significantly less likely to receive opioids (aRR 0.18; 95% CI 0.05, 0.67) as were patients who did not speak English well (aRR 0.22; 95% CI 0.11, 0.43). Female patients with cancer were significantly more likely to receive non-opioids (aRR 1.21; 95% CI 1.12, 2.31) and non-pharmacological pain management (aRR 1.49; 95% CI 1.27, 1.75) than males. Conclusions There are clinical and sociodemographic factors associated with opioid, non-opioid, and non-pharmacological pain management among individuals with cancer, and those who are depressed are at highest risk for opioid prescription, while those who cannot speak English well are less likely to receive opioids. For equitable pain care in patients with cancer, it is important that barriers associated with pain management are eliminated.

#4361

The plasma proteome as a cardiovascular disease risk assessment tool in cancer survivors

Emma V. Troth[1], Matthew Ayala[1], Jessica Chadwick[1], Erin Hales[1], Michael Hinterberg[1], Jessica N. Kuzma[1], Clare Paterson[1], Rachel Ostroff[1], Joan E. Walter[2], Christian Mueller[2], Josef Coresh[3]. *[1]SomaLogic, Inc., Boulder, CO,[2]Cardiovascular Research Institute, University of Basel, Basel, Switzerland,[3]Johns Hopkins University, Baltimore, MD*

Cardiovascular disease (CVD) is the most common non-cancer cause of death in cancer survivors and there is an unmet clinical need for easy, accurate, and safe CVD prognostic risk-stratification in adult cancer survivors. This study investigated whether a previously validated 27-plasma protein prognostic model for four-year cardiovascular (CV) events could have such a utility. We used the 27-plasma protein model to predict the four-year risk of a CV event (myocardial infarction, stroke, transient ischemic attack, heart failure hospitalization, death) in 906 participants with a prior history or active malignancy of any type of cancer and compared predictive results to follow-up CV outcome data. The participants were from the BASEL VIII or ARIC (visit 3) studies with a medically adjudicated prior diagnosis of cancer. BASEL VIII is an observational cohort study in patients with suspected coronary artery disease. ARIC is a multi-site cohort study funded by the NHLBI, NCI, and NPCR investigating risk factors for CV

health. A subset analysis was conducted to assess model performance in participants with no prior history of CVD and those with stable CVD. The 27-plasma protein model accurately stratified participants into 4 distinct and non-overlapping (95% CI) risk bins. The median time to event for all cancer survivors who had an event in this study was 1.3 years. Observed 4-year event rates across the 4 risk bins (low, medium-low, medium-high, and high) were 10.4%, 16.8%,31.5% and 58.2%, respectively, which were higher than stratified event rates from our previously published metacohort analyses (5.6%, 11.2%, 20.0% and 43.4%, respectively) in participants with elevated CVD risk factors (e.g., prior events, diabetes, kidney disease and suspected coronary artery disease). The plasma protein model accurately predicted 4-year CVD risk with a C-index of 0.71 (0.68, 0.74) and 4-year AUC of 0.74 (0.69, 0.79). Performance of the protein model was comparable between participants with no prior history of CVD (C-Index: 0.69; AUC: 0.71) and stable CVD (C-Index: 0.69; AUC: 0.72), demonstrating the model accurately predicts CV event risk in cancer survivors regardless of cardiovascular history. Cancer survivors in this cohort can be distinguished with 4-year CV event rates as high as 58.2%, underscoring the urgent need for an easy and accurate risk stratification tool for this population. Prognostic protein testing may provide a novel tool for CVD risk assessment in adult cancer survivors.

#4363

Monocyte-specific epigenetic age acceleration and cardiomyopathy risk among survivors of childhood cancer

Cheng Chen[1], Qian Dong[2], Qin Na[3], Nan Song[4], John Easton[2], Heather L. Mulder[2], Emily Walker[2], Geoffrey Neale[2], Emily R. Finch[2], Qian Li[2], Yutaka Yasui[2], Daniel A. Mulrooney[2], Melissa M. Hudson[2], Kirsten K. Ness[2], Jinghui Zhang[2], Xiang Chen[2], Hui Wang[1], Leslie L. Robison[2], Zhaoming Wang[2]. *[1]Shanghai Jiao Tong Univ., School of Med., Shanghai, China,[2]St. Jude Children's Research Hospital, Memphis, TN,[3]Nanjing Medical University, Nanjing, China,[4]College of Pharmacy, Chungbuk National University, Cheongju, Korea, Republic of*

Our assessment of epigenetic age acceleration (EAA), calculated with DNA methylation (DNAm) data generated from bulk DNA derived from peripheral blood mononuclear cells (PBMC), supports accelerated aging in

childhood cancer survivors (CCS). It is challenging to disentangle variation of DNAm at cell-type specific levels from the effects of age-dependent cell type composition, and bulk measurements may obfuscate the links between EAA and age-related outcomes (e.g., cardiomyopathy). Methylation profiling was generated using Infinium EPIC BeadChips on PBMC-derived DNA from CCS in the St. Jude Lifetime Cohort. Tensor composition analysis was employed to deconvolute bulk DNAm and infer DNAm at each leukocyte subtype level, i.e., a single n (individuals) by m (DNAm sites) matrix of observed DNAm data was deconvoluted into multiple n by m matrices of DNAm data. Epigenetic age (EA, using Levine's clock) and EAA (residuals from the fit of a simple linear regression of EA on chronological age at blood draw) were calculated for bulk PBMCs and each cell subtype (CD4T, CD8T, B, natural killer, and monocyte). Cardiomyopathy (CMP) was assessed by echocardiography, and severity graded (2 = moderate, 3 = severe/disabling, 4 = life-threatening and 5 = fatal) using a modified version of the National Cancer Institute Common Terminology Criteria for Adverse Events. Cumulative doses of anthracyclines and mean heart radiation doses (heart-RT) calculated through radiation dosimetry were abstracted from medical records. Associations between EAA and CMP were evaluated by multivariable Cox regression. Cell-type specific EA was highly correlated with bulk EA with Pearson r2 between 0.63 (CD8T) and 0.79 (CD4T), but the linear regression lines of cell-type specific EA against bulk EA differed in both intercept and slope, suggesting heterogeneity across leukocyte subtypes. Cell-type specific EAA was moderately correlated with bulk EAA with Pearson r2 between 0.23 (monocyte) and 0.29 (CD8T). Among 2,044 CCS (median age = 33.7 years), 104 (5.1%) developed CMP (≥grade 3). Among bulk EAA and five cell-type specific EAAs, monocyte EAA was the only one significantly associated with CMP (hazard ratio per standard deviation increase in EAA = 1.25, 95% CI = 1.04-1.50, P = 0.018). Cell sorting of PBMC followed by DNAm is currently underway for further validation. We showed an in-depth view of the variability of EAA across leukocyte subtypes, and more importantly, demonstrated that monocyte EAA was associated with CMP risk. Our novel finding is plausible and consistent with the literature implicating monocyte-derived cardiac macrophages in cardiac remodeling, which can be induced by cardiotoxic cancer treatment exposures in CCS. Therapeutic strategies that prevent deleterious effects of monocytes contributing to adverse cardiac

remodeling, while sparing their essential immune functions, may prevent or ameliorate CMP among CCS.

#4364

Cost-effectiveness analysis of abemaciclib and endocrine therapy combination for the adjuvant treatment of HR+/HER2-, node-positive, high-risk, early breast cancer

Ashna Talwar[1], Ashish Deshmukh[2], Meghana Trivedi[1], Rajender R. Aparasu[1]. *[1]University of Houston, College of Pharmacy, Houston, TX,[2]Medical University of South Carolina, Charleston, SC*

Background**:** Abemaciclib is the only approved cyclin-dependent kinase 4/6 (CDK4/6) inhibitor approved for adjuvant treatment of hormone receptor-positive, human epidermal growth factor receptor-2-negative (HR+/HER2-), node-positive, high-risk early breast cancer (EBC) patients. However, the addition of abemaciclib to the standard of care endocrine therapy (ET, such as tamoxifen or aromatase inhibitors) results in a drastic increase to the overall healthcare costs.

Objective: In this study, we aimed to evaluate the cost-effectiveness of abemaciclib and ET combination versus ET monotherapy for the adjuvant treatment of HR+/HER2-, EBC from the U.S. third-party payer perspective.

Methods: A Markov-based decision analytic model using TreeAge Software was developed. The model simulated lifetime costs and health outcomes over a lifetime. The model incorporated the disease course of the progression-free disease, progressive disease, death due to disease, and mortality due to other causes. All clinical data and utilities were derived from the literature and clinical trial: monarchE. Notable adverse events such as neutropenia, leucopenia, anemia, and diarrhea were included. Age-specific mortality risk was calculated from the U.S. life tables. The outcomes were measured by costs, quality-adjusted life-years (QALYs), and incremental cost-effectiveness ratio (ICER). The willingness-to-pay threshold was set at $100,000 per QALY gained.

Results: We simulated our analysis on patients assigned to either abemaciclib + ET or ET alone groups as per the monarchE trial. The median age of the patients was 51 years. In base case analysis, the total costs for abemaciclib plus ET and ET alone treatment, were USD 122,052.11 and USD 40,344.87, respectively. Abemaciclib plus ET treatment produced 4.5

QALYs, while the ET treatment alone produced 4.31 QALYs. Overall, abemaciclib plus ET was marginally more effective than ET with an additional 0.20 QALYs but much costlier with an ICER of $417,780.18/QALY. For utilities ranging from 0.41 to 0.69, the ICERs ranged from USD 36,5950 to USD 4,463,866.59 per QALY, which exceeded the WTP threshold. Using probabilistic sensitivity analysis, we estimated that the combination of abemaciclib plus ET was a cost-effective strategy at the willingness-to-pay threshold of $500,000 per QALY or higher for the base case population.
Conclusion: At current costs, abemaciclib plus ET is not cost-effective as compared to ET monotherapy for patients with node-positive, high-risk, HR+/HER2- EBC in the US healthcare system from the third-party payer perspective.

#4365
Comorbidities at diagnosis are associated with poor outcomes among pediatric acute lymphoblastic leukemia and lymphoblastic lymphoma patients
Maua Mosha[1], Jennifer Mayer[1], Ernest K. Amankwah[2]. *[1]Johns Hopkins All Children's Hospital, St. Petersburg, FL,[2]Johns Hopkins University School of Medicine, St. Petersburg, FL*

The influence of comorbidities at index diagnosis on outcomes of pediatric leukemia and lymphoma is not well established. We evaluated the association between medical comorbidities and pediatric acute lymphoblastic leukemia (ALL) and lymphoblastic lymphoma (LL) outcomes in a retrospective cohort study using electronic health records from the TriNetX Research Network Database, a global de-identified federated health research network. Study participants included pediatric (≤21 years) patients newly diagnosed with ALL or LL from July 2009-June 2019 and followed through June 2022. The main outcomes included progression/relapse, toxicity, overall mortality and cancer-specific mortality. Comorbidities included chronic lung disease; congenital heart disease; neurologic, immune, hematologic, vascular and genetic disorders; renal disease; gastrointestinal disease; prematurity and hepatobiliary disease. Patients with any comorbidity were matched with patients with no comorbidity on age at diagnosis, gender, race/ethnicity, and treatment using

propensity score matching. We identified 5,375 patients diagnosed with ALL/LL with comorbidities and 5,375 without comorbidities after propensity score matching. The mean age at diagnosis was 9.7 years (standard deviation=6.2). A higher proportion of the patients were male (56.9%), White (63.6%) and Not Hispanic or Latino (63.4%). Patients diagnosed with comorbidities had a higher risk for progression/relapse (73% vs 51%; Relative Risk, RR=1.42, 95% confidence interval (CI)=1.38-1.47) and treatment related toxicity (80% vs 50%; RR=1.59, 95% CI=1.54-1.64), compared to patients diagnosed with no comorbidities. Similarly, overall mortality (Hazard ratio, HR=1.62, 95% CI=1.37-1.91) and cancer-specific mortality (HR=4.39, 95% CI=2.28-8.46) were higher among patients diagnosed with comorbidities than those without comorbidities. Comorbidities among patients diagnosed with ALL/LL is associated with poor outcomes independent of treatment and thus targeted interventions for the proper management of these patients are needed to improve outcomes.

#4367

The MD Anderson Symptom Inventory (MDASI) survey discloses persistent moderate to high-level symptoms in cancer survivors

Katherine Gilmore, Patricia Chapman, Johnny Rollins, Soo-Hyun Lee-Kim, Justine Robinson, Ellen Mullen, Haleigh Mistry, Prachee Singh, Robin Coyne, Ana Nelson, William Osai, Karen Stolar, Susan Knippel, Danielle Fournier, Tamera Plair, Whittney Thoman, Angela Peek, Loretta Williams, Maria A. Rodriguez. *UT MD Anderson Cancer Center, Houston, TX*

Background: We implemented the integration of the MD Anderson Symptom Inventory (MDASI) survey into patient visits in our Survivorship Clinics to help manage long and late effects of cancer and its therapy. Patients are transitioned to Survivorship if they have completed treatment with curative intent, are in remission, and past the period of highest relapse risk, as determined by disease experts [average ~ 3 years past treatment]. Methods: The MD Anderson Symptom Inventory (MDASI) is a validated cancer specific symptom burden questionnaire. It was integrated into the electronic health record (EHR), and sent via the patient portal to patients 7 days prior to their clinic visit. High alerts (>= 7) were set for four key symptoms (pain, distress, sadness, and shortness of breath). Alerts triggered

an automated message to the provider. From November 2019 to October 2022, 4322 patients completed PRO surveys.
Results: Table 1 summarizes the frequency of moderate (4-6) and high (7-10) level responses. Categories with more than 5% of respondents endorsing a moderate symptom value are bolded with those more than 10% bold and italic. There is significant variation of severity for the four key symptoms amongst patients with different disease types. Lymphoma and thyroid cancer patients have higher symptom severity, while prostate cancer patients report relatively low symptom severity. Overall, for this cohort of responders, the totals of moderate and high levels symptoms are: distress =12.5 %; pain = 9.5 %; sadness = 8.7 %; and shortness of breath = 8 %.
Conclusion: A subset of cancer survivors still experience moderate to high level symptoms, as measured by the MDASI survey, even years after treatment. There are notable differences across patient populations. Further study can identify at-risk patient groups who may require additional intervention.

Table 1. Moderate and High Values for Four Symptoms from the Survivorship MDASIs

Symptom network identification from anxious and depressive groups in colorectal cancer patients

Jinah Sim[1], Ji Won Yu[1], Nan Song[2], Ae Sun Shin[3], Ji Won Park[4], Seung Yong Jeong[4]. *[1]Hallym University, Chuncheon, Korea, Republic of,[2]College of Pharmacy,, Chungbuk National University, Chungbuk, Korea, Republic of,[3]Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]Seoul National University Hospital, Seoul, Korea, Republic of*

Backgrounds: Colorectal cancer (CRC) is one of the most common cancers in the world, and recently in South Korea, the incidence rates are increasing. CRC patients have a high prevalence of depression and experience various symptoms such as bowel problems. However, previous studies analyzing network analysis has not yet been conducted to understand the association between symptoms with chronic anxiety and depression.
Methods: In this study, symptom network and centrality analysis were conducted to confirm the interaction between symptoms and functioning (e.g., pain, fatigue, physical functioning, etc.) of patients diagnosed with CRC according to the higher risk of anxiety and depressive groups ahead of surgical treatment. In this study, symptom and functioning variables in a total of 939 CRC patients were measured using EORTC QLQ-C30 and EORTC QLQ-CR29. Network analysis, visualization, and centrality analysis were performed to determine the connectivity between anxiety, depression, and other correlated symptoms amongst CRC patients using the qgraph R package.
Results: As a result of confirming the difference in anxiety and depression according to socio-demographic characteristics, there was a significant difference in the education level in the group with anxiety($Ps<0.05$). The group with depression showed significant differences in Fasting blood sugar and education level($Ps<0.05$). There were significant differences in symptoms according to anxiety and depression, the group with high risk of anxiety showed significant differences in 30 symptoms such as urological frequency and physical function. The group having depression showed significant differences in 26 symptoms such as fatigue and physical function. In the result of performing symptom network analysis and centrality analysis without any stratification of anxiety or depression, fatigue was found to be a central symptom in all patients. In both the anxious and depressed groups, pain was estimated as the central symptom.
Conclusion: In conclusion, the study compared and analyzed symptom networks to confirm the interaction between symptoms of CRC patients

according to anxiety and depression. The symptom network of CRC patients showed different patterns according to anxiety and depression. Pain appeared as a central symptom in both the anxious and depressed groups. This indicates that pain is a key role because it is related to other symptoms and affects the flow of the symptom network the most. Therefore, intensive pain management is expected to be important in treating CRC patients with anxiety and depression. It is expected that the basis for the management of colorectal cancer patients and survivors can be prepared toward the long term of cancer treatment and survival.

The effects of primary hepatocellular carcinoma surgical resection on five year survival rates among different races

Jingwei Song[1], Eric Song[2], Daniel Gharavi[2]. *[1]School of Medicine, Virginia Commonwealth University, Richmond, VA,[2]Honors College, Virginia Commonwealth University, Richmond, VA*

Background: Hepatic surgical resection is the treatment of choice for noncirrhotic HCC patients. Previous studies indicate that Asian patients were proportionally more likely to be treated surgically. However, studies on the outcome of this preference are very limited.
Methods:We examined data from the Surveillance, Epidemiology and End Results (SEER)-Medicare database to identify patients diagnosed with HCC between 2004 and 2017.The disease specific and relative five year survival rates as well as 95% Cl were calculated.
Results:Among the total of 6,716 Asian or Pacific Islander (A/P) patients diagnosed with localized HCC, 45.9% of them received surgical resection. The localized HCC surgical resection rates for White (27,360 total cases) and Black (4,546 total cases) were 35.6% and 33.1% respectively. This pattern remained the same for patients with regional and distant site involved HCC: Highest percentage of A/P patients received surgical resections. For patients with localized HCC, five year cause specific survival rate was statistically higher for A/P patients than White and Black ($P<0.05$) 24 months after the surgery. These trends continued until the end of the study. For patients with regional HCC, surgical resection played no significant role for the five year cause specific survival rate among the different races. However, for patients with distant involved HCC, five year

cause specific survival gap between White and A/P gradually increased after surgery and reached a statistically significant level on month 48 (23.9% with 95% CI 18.6% to 29.6% for White and 9.7% with 95% CI 4.4% to 17.5% for A/P). The pattern remained the same between Black and A/P patients without statistical significance, most likely due to the limited sample size for both.. Our research also indicated that surgical resection may play a similar role for the five year relative survival rate. After localized HCC surgical resection, A/P patients had the highest five year relative survival rate compared to White and Black patients ($P<0.05$). For the patients with regional HCC, surgical resection played no significant role on five year relative survival rate among different races. However, for the patients diagnosed with distant involved HCC, five year relative survival gap between White and A/P gradually increased after surgery and reached a statistically significant level on month 48 (23.7% with 95% CI 18.3% to 29.4% for White and 10.5% with 95% CI 5.2% to 18.0% for A/P). The pattern remained the same between Black and A/P patients without statistical significance due to the limited sample size in both categories. Conclusion: A/P primary HCC patients were more likely to be treated surgically. However, the benefits of surgical resection for A/P patients can only be appreciated for those with localized HCC. For A/P patients diagnosed with distant site node involved HCC, surgical resection may cause more harm than good.

How much time is needed to complete quality of life assessments in oncology trials? - Metadata analysis

Jowita Marszewska, Lindsay Hughes. *Individual, Philadelphia, PA*

Introduction: Digitalization in clinical trials introduced electronic data collection. Participants in diverse environments can use electronic devices to report their experiences with the drug by completing patient reported outcome assessments (ePROs). Quality of life (QOL) reports describe how a patient feels or functions during a treatment with a new drug. For oncology trials, QOL data is needed to prove the treatment effect and support a labeling claim.
Methods: The literature search in the Web of Science for articles containing QOL keyword found ten articles with the highest number of citations. QOL

instruments relevant to cancer research were identified based on the literature search. Form completion times corresponding to the cancer-specific instruments were identified and analyzed using a metadata of 948 instruments and 17,234,458 assessment submissions.
Results: Three general QOL measures in oncology trials were identified: the EORTC Quality of Life Questionnaire - Core Questionnaire (EORTC QLQ-C30), Functional Assessment of Chronic Illness Therapy - Fatigue (FACIT-F), and SF-36 Health Survey (SF-36). Median times of form completion in seconds (s) increased in the following order: FACIT-F < EORTC QLQ-C30 < SF-36v2 and were equal to 105 s < 213 s < 386 s. Metadata analysis showed that participants spent less than two minutes on completion of the FACIT-F assessment, which is only 18% of the estimated completion time of 10 minutes. Metadata analysis showed that it took participants three and a half minutes to complete the EORTC QLQ-C30 assessment, which is roughly one third of the estimated completion time of 11 minutes. The completion time for SF-36v2 fell within the estimated range of 5 to 10 minutes.
Conclusions: Properly selected QOL instruments facilitate collection of the right data for demonstration of a treatment benefit. It is recommended to include a general oncology and a disease specific QOL instrument to show the treatment's success of improving patient's QOL. At the same time, the completion of the instruments should not be burdensome considering disease progression characteristic for oncology studies.

iCCaRe: Social determinants of health navigation, psycho-oncology, and emotional support for Black prostate cancer survivors: Review of current practices

Dottington Fullwood[1], AJ Merriweather[1], Che Ngufor[1], Deidre Pereira[2], KC Balaji[3], Roxana Dronca[4], Gerardo Colon-Otero[5], Jennifer Crook[1], Parisa Fathi[1], Emelina Asto-Flores[1], Shannon Pressey[1], Folakemi Odedina[1]. *[1]Mayo Clinic Cancer Center Florida, Jacksonville, FL,[2]Clinical and Health Psychology, University of Florida, Gainesville, FL,[3]Urology, University of Florida - Jacksonville, Jacksonville, FL,[4]Oncology, Mayo Clinic Cancer Center Florida, Jacksonville, FL,[5]Internal Medicine, Mayo Clinic Cancer Center Florida, Jacksonville, FL*

Background: Black men continue to be disproportionately affected by prostate cancer incidence and mortality as compared to their White counterparts, despite worldwide declining prostate cancer diagnosis rates. This complex phenomenon remains poorly understood, especially at the point of a prostate cancer diagnosis. Newly diagnosed Black men report initial feelings ranging from being “shocked,” to “receiving a death sentence,” and both an ineptness of asking questions and a reliance on physicians for treatment options due to lack of knowledge. The psychological distress from prostate cancer uncertainties affects health management and treatment decisions, though it is unclear to what extent the role of social determinants of health factor in making informed healthcare decisions.
Aim: In this scoping review, we examined the influence of the social determinants of health at point of prostate cancer diagnosis among Black men seeking to make an informed decision about their treatment plans.
Methods: We followed the methodological framework: the Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR). Five electronic databases, Emabase, Pubmed, PsycInfo, Scopus, and Web of Science were searched for quantitative and qualitative primary studies from the period 2005 until March 2022. Two authors independently screened titles and abstracts, and full texts, against predefined criteria: empirical research, post 2000, in English-language peer-reviewed journals; participants included Black prostate cancer survivors and research explored social determinants of health at point of prostate cancer diagnosis. Studies were quality assessed for data charting.
Results: The search yielded 283 studies, with 45 included studies for synthesis. Traditional social determinants of health were frequent. However, identification of themes such as social support, masculinity and stigma, fear of abandonment by medical staff, and cost of diagnostic procedures were prominent determinants. Notably, sub-themes emerged that included coping factors such as emotional distress, perceptions of normalcy, and poor prostate cancer knowledge.
Conclusion: Understanding the social determinants of health impact on Black men, especially at point of prostate cancer diagnosis will allow survivors, physicians, and researchers to work at solving these health disparities.

Hierarchy of prognostic quality markers after curative-intent resection of stage IA non-small cell lung cancer

Huibo Shao[1], Yu-Sheng Lee[2], Carrie Fehnel[1], Olawale Akinbobola[1], Andrea Saulsberry[1], Kourtney Dortch[1], Anberitha T. Matthews[1], Nicholas R. Faris[1], Meredith A. Ray[3], Matthew Smeltzer[3], Raymond U. Osarogiagbon[1].
[1]Baptist Cancer Center, Memphis, TN,[2]University of Memphis, Memphis, TN,[3]School of Public Health, University of Memphis, Memphis, TN

Introduction**.** 5-year disease-free survival after curative-intent resection of stage IA NSCLC approximates 65%. The quality of resection and differences in cancer biology probably account for most curative-intent treatment failure. We evaluated the hazard associated with markers of surgical quality.

Methods. Using the population-based Mid-South Quality of Surgical Resection cohort, we compared outcomes of pathologic IA NSCLC resections from 2009 to 2021. With the stringent International Association for the Study of Lung Cancer complete (R0) resection for reference, we evaluated eight quality benchmarks: wedge resection; resections with positive margins; non-examination of lymph nodes (LN) from anywhere (pNX), mediastinal (pNXmed), intrapulmonary, hilar, low paratracheal and subcarinal stations. We evaluated hazard ratios (HR), adjusted for age, sex, insurance, histology, comorbidity, preoperative staging and technique of resection (95% CI) from Proportional Hazards models.

Results. Of 2,243 resections, 906 (41%) were R0; 1,333 were non-R0, including 3% R1/R2, 13% pNX, 15% wedge resections, 15% pNXmed, 45% without subcarinal, 41% without hilar, 47% without low paratracheal, and 36% without intrapulmonary LNs.Compared to IASLC-R0, adjusted HRs were: 2.04 (1.21-3.44) for R1/R2; 1.75 (1.33-2.31) for pNX; 1.64 (1.26-2.14) for wedge resections; 1.35 (1.12-1.63) for non-examination of intrapulmonary LN; 1.33 (1.03-1.72), pNXmed; 1.25 (1.02-1.53), non-examination of hilar LN; 1.15 (0.95 - 1.39) missing station 4; and 1.11 (0.90-1.37) missing station 7 LNs.

Conclusion. Surgical quality, indicated by markers of LN evaluation, have significant impact on long-term survival and should be required selection criteria or stratification factors in lung cancer surgery trials.

Venetoclax-based therapy in treatment-naïve and relapsed/refractory acute myeloid leukemia

Aditya Ravindra, Luna Acharya, Bradley Loeffler, Sarah L. Bell, Grerk Sutamtewagul, Prajwal Dhakal. *University of Iowa Hospitals & Clinics, Iowa City, IA*

Background**:** Clinical trials in acute myeloid leukemia (AML) report complete remission (CR) in ~60% of newly diagnosed (ND) pts treated with venetoclax (VEN)-based therapy with hypomethylating agents (HMA, azacitidine [AZA] and decitabine [DEC]) or low-dose cytarabine. However, results from prospective studies in relapsed refractory (R/R) AML remain scarce. Here, we compare the outcomes in ND and R/R pts treated with VEN-based therapy.

Methods: We performed a retrospective analysis of ND and R/R pts with AML diagnosed between 2016 and 2021 who were treated with VEN-based therapy at the University of Iowa. We used ANOVA and chi-square test to compare variables between ND and R/R pts. Logistic regression analyses and Cox regression models evaluated the effects of ND vs. R/R AML on objective response rate (ORR defined as complete remission (CR) + complete remission with incomplete count recovery [CRi]) and overall survival (OS), respectively. OS was estimated using the Kaplan-Meier method.

Results: Of 53 pts, 31 pts had ND AML, and 22 pts had R/R AML. Median age was 67 years (range 26-85). Among total pts, 52% were treated with VEN + AZA, 48% were treated with VEN+ DEC, 25% had prior exposure to HMA, and 19% had an allogeneic transplant before treatment with VEN-based therapy. Eleven pts had *TP53* mutation (7 pts in ND, 4 in R/R group), 13 had *NPM1* mutation (ND- 8, R/R-5), and 7 had *FLT3* mutation (ND-5, R/R-2). ORR was 53% in total pts (CR- 34%, CRi- 19%), of which 11% did not have minimal residual disease. There was no statistically significant difference in ORR between ND and R/R pts (Odds ratio [OR] 2.04, 95% confidence interval [CI] 0.6-6.4, p=0.2). Treatment with VEN + DEC conferred a similar ORR compared to VEN + AZA (OR 0.37, 95% CI 0.1-1.2, p=0.1). Prior HMA use did not affect ORR (OR 0.4, 95% CI 0.08-2.2, p=0.3). ND pts had longer 6-month OS than R/R pts (82% vs. 55%), but 12-

month OS was similar (59% vs. 55%). ND or R/R status did not affect OS (Hazard ratio [HR] 0.7, 95% CI 0.3-1.6, p=0.4). Treatment with VEN + DEC conferred similar OS compared to VEN + AZA (HR 1.6, 95% CI 0.7-3.7, p=0.2). Age, *TP53*, *NPM1,* and *FLT3* mutations, and adverse cytogenetics, did not affect ORR or OS.
Conclusions: Our real-world analysis shows no significant difference in ORR or OS among pts with ND or R/R AML indicating effective response to VEN-based therapy regardless of treatment status. We report similar 12-month OS for ND and R/R pts despite a higher 6-month OS for ND group. Treatment combination with either AZA or DEC had comparable outcomes, and prior HMA use did not predict worse outcomes in our study. These results are important clinically as AZA and DEC are often used interchangeably, and a significant proportion of pts with prior myelodysplastic syndrome are treated with HMA. Subsequent studies are required to understand the similarities and differences in factors predicting response to VEN-based therapy in ND and R/R AML.

#4374
Patient provider communication about the use of medical cannabis for cancer symptoms
Kea Turner[1], Jessica Y. Islam[1], Yessica C. Martinez[1], Omar Garcia Rodriguez[1], Diane Rodriguez Irlanda[2], Oliver T. Nguyen[1], Heather S.L. Jim[1], Kathleen M. Egan[1]. *[1]Moffitt Cancer Center, Tampa, FL,[2]University of South Florida, Tampa, FL*

There has been limited study of patient-provider communication regarding medical cannabis for cancer symptoms. To address this gap, this study assesses the prevalence of patient-provider communication about the use of medical cannabis for cancer symptoms. Three types of communication are examined: 1) patient-provider discussions; 2) provider recommendations; and 3) provider instructions for how to use medical cannabis. We administered a survey from August to November 2021 with adult cancer patients who completed treatment from July 2017 to December 2019 at a National Cancer Institute designated Comprehensive Cancer Center; 1,592 individuals participated (response rate: 17.6%). About half of participants were female (52.1%). The age distribution of participants included 18-44 (9.4%), 45-54 (12.8%), 55-64 (25.3%), 65-74 (35.4%), and 75 and above

(17.3%). Participant's racial and ethnic background included Hispanic/Latinx (6.5%), African American/Black (4.0%), Asian American (1.0%), additional or multiple racial categories (3.5%), and White (91.5%). About a third (33.5%) of participants (530/1584) reported discussing medical cannabis for cancer symptoms with a healthcare provider. Participants who had discussed cannabis with a provider reported discussions with multiple providers including their oncology physician (62.3%), primary care provider (45.7%), oncology advanced practice provider (APP) (34.3%), dietician (7.4%), pharmacist (2.8%), and other healthcare provider (34.3%). Fewer (15.6%) participants (248/1592) reported receiving a recommendation for medical cannabis from a healthcare provider for their cancer symptoms. Participants who had received a recommendation reported recommendations from their oncology physician (32.7%), primary care provider (26.6%), oncology APP (13.7%), dietician (4.8%), pharmacist (1.6%), and other healthcare provider (56.9%). About a third (33.7%) of participants (537/1592) reported using medical cannabis during their cancer treatment and most often reported receiving instructions on how to use cannabis from no one (36.9%) or from a cannabis store or dispensary worker (23.8%). Less commonly, participants reported receiving instructions from their healthcare provider including their primary care provider (3.7%), oncology APP (2.0%), oncology physician (1.5%), pharmacist (<1%), or dietician (<1%). Based on this survey, about a third of cancer patients discuss medical cannabis with a healthcare provider but fewer receive a recommendation and/or instructions for how to use medical cannabis from a healthcare provider. Additional interventions may be needed to ensure that cancer patients interested in or currently using medical cannabis receive guidance from oncology care providers.

#4375

A bootstrapping method to optimize go/no-go decisions from single-arm, signal-finding studies in oncology

Aparna Mohan[1], Raunak Dutta[1], Jacqueline Buros-Novik[2], Omobolaji Akala[3], Brian Gregory Topp[3]. *[1]Vantage Research, Chennai, India,[2]Generable, New York, NY,[3]Merck, Rahway, NJ*

Background: Phase Ib, single-arm trials are common in oncology development. Since these trials are not powered for statistical significance,

Go/No-Go decisions are largely driven by observed trends in ORR relative to historic control. Here we develop a bootstrapping method to systematically compare secondary endponts, such as the waterfall plot, to historic control data. In addition, we identify an actionable Go threshold and estimate the expected false positive and false negative rates associated with that threshold.
Method: A proprietary mathematical model was used to simulate thousands of single-arm trials (n = 30) with a combination of pembrolizumab and a novel agent with miserable (Rx0), modest (Rx1), moderate (Rx2) or magnificent (Rx3) efficacy. A bootstrapping method was used to compare waterfall plots from these trials to a simulated Phase III pembrolizumab monotherapy control arm (n = 511).
Results: The bootstrapping method provides a visualization of the observed waterfall plot for the single-arm combination trial relative to the range of possible outcomes from historic control data (5^{th}, median, 95^{th} percentile). The method also provides a score reflecting the probability that the observed data is different from the historic control. An ROC analysis showed a strong ability to separate drugs with modest (AUROC = 83%), moderate (AUROC = 96%) and magnificent combination efficacy (AUROC = 99%) from drugs with miserable efficacy. The method was shown to effectively move drugs with a range of efficacy through an *in-silico* pipeline while rejecting drugs without combination efficacy.
Conclusion: This bootstrapping method allows comparisons of secondary endpoints from early clinical trials to historic control data. The visualization is intuitive, and the quantification provides an actionable Go-threshold. The method also provides an estimate of the risk associated with that recommendation. We suggest incorporation of this as a component of Go/No-Go decision making in early oncology trials.

#4376

A correlation of soluble HLA serum levels with clinical data and survival in patients with invasive breast cancer after neoadjuvant treatment

Christian M. Tegeler[1], Jonas Rieth[2], André Koch[3], Dominik Dannehl[4], Léa L. Volmer[4], Sabine Matovina[4], Markus Hahn[4], Tobias Engler[4], Andreas D. Hartkopf[5], Sara Y. Brucker[4], Juliane S. Walz[6], Jonas S. Heitmann[7], Annika Nelde[8]. *[1]Department of Obstetrics and Gynecology; Department of Peptide-*

based Immunotherapy, University Hospital and University of Tübingen, Tübingen, Germany,[2]Department of Peptide-based Immunotherapy; Department of Immunology, University Hospital and University of Tübingen; Institute for Cell Biology, Tübingen, Germany,[3]Department of Obstetrics and Gynecology, University Hospital of Tübingen; Research Institute for Women's Health, University of Tübingen, Tübingen, Germany,[4]Department of Obstetrics and Gynecology, University Hospital of Tübingen, Tübingen, Germany,[5]Department of Obstetrics and Gynecology, University Hospital of Ulm; University Hospital of Tübingen, Tübingen, Germany,[6]Department of Peptide-based Immunotherapy; Department of Immunology, University Hospital and University of Tübingen; Institute for Cell Biology; Clinical Collaboration Unit Translational Immunology, German Cancer Consortium (DKTK), Tübingen, Germany,[7]Department of Internal Medicine, Clinical Collaboration Unit Translational Immunology, German Cancer Consortium (DKTK); University Hospital of Tübingen; Cluster of Excellence iFIT (EXC2180), Tübingen, Germany,[8]Department of Peptide-based Immunotherapy; Department of Immunology, University Hospital and University of Tübingen; Institute for Cell Biology; Cluster of Excellence iFIT (EXC2180), Tübingen, Germany

Invasive breast cancer (IBC) is the most common malignant disease in women worldwide. In recent years, the landscape of treatment options has rapidly evolved. With the success of checkpoint inhibitors in triple negative IBC, immunotherapy has become standard of care highlighting the strength of T cell-based strategies for anti-tumor therapy. Naturally, the targets of T cell-mediated immune responses are represented by short peptides presented on human leukocyte antigen (HLA) molecules. For several years, huge effort has been made to analyze and characterize HLA-presented tumor antigens to further understand anti-tumor immunity and to identify suitable targets for novel immunotherapy approaches. Aside from membrane-bound HLA molecules, soluble HLA-peptide complexes (sHLA) can be found in a variety of body fluids. These molecules are suggested to impact cellular immune responses, but it is still a matter of debate, whether shifts in sHLA levels contribute to disease outcome or are observed as a consequence of disease. Whereas the role of the non-classical sHLA-G in IBC has been studied showing elevated levels in patients compared to a healthy cohort, data on classical sHLA class I molecules is not yet available. Here, we

report on sHLA class I serum levels in patients with IBC after neoadjuvant chemotherapy or combined chemotherapy with antibody treatment (n = 52). We observed higher serum levels of sHLA in neoadjuvant-treated IBC patients without histopathological complete response after neoadjuvant therapy (n = 36) compared to healthy volunteers (n = 84). Patients with locally advanced tumors, according to TNM classification, had a tendency towards lower sHLA levels than patients with small size tumors. Furthermore, sHLA levels were decreased in patients with sentinel node or disseminated axillary lymph node metastases compared to non-metastatic patients. Of note, sHLA levels tended to be elevated in patients with Her2-overexpression (based on immunohistochemistry staining and fluorescence in situ hybridization), whereas for histological hormone receptor expression a tendency towards lower sHLA levels in patients with high expression was observed. Furthermore, sHLA levels were reduced in patients with disseminated tumor cells in bone marrow aspiration. No significant difference in sHLA levels were seen in terms of grading of tumor, prevalence of distant metastasis, menopausal status and elevated tumor markers. Interestingly, we observed a tendency to prolonged progression-free survival in patients with high serum concentrations of sHLA, which will be updated with data from additional patients at the AACR meeting. Taken together, these data provides first insights about sHLA class I in patients with IBC after neoadjuvant treatment suggesting an impact of sHLA and T cell-mediated immune surveillance on survival in patients with IBC.

#4377

Economic burden of lung cancer patients in the emergency department

Jayla Hsiung[1], Kamil Taneja[2], Bill Hum[2], Karan Patel[3], Michael Diaz[4], Shreyas Chandragiri[5], Eric M. Toloza[6]. *[1]Highland Park High School, Highland Park, NJ,[2]Renaissance School of Medicine, Stony Brook, NY,[3]Cooper Medical School, Camden, NJ,[4]University of Florida College of Medicine, Gainesville, FL,[5]Sidney Kimmel Medical School, Philadelphia, PA,[6]Thoracic Oncology, Moffitt Cancer Center, Tampa, FL*

Introducti**on:** In 2022, the National Cancer Institute estimated that more than 240,000 individuals will be diagnosed with lung or bronchus cancer. Many patients present to the emergency department (ED) for septicemia and pneumonia, which leads to long hospital stays. However, there is little data

on the annual trends of hospital charges and risk factors for a high charge for these patients.

Methods: We utilized the 2006-2012 Nationwide Emergency Department Sample to analyze the charges of lung cancer patients. Multivariate linear regressions were used to identify factors associated with higher ED and inpatient (IP) costs. The 20 most common primary diagnoses of these patients were included in the analysis to take into account the reason for the ED visit. Charges were corrected for inflation by normalizing to 2012 US Dollars.

Results: During this time period, 1,344,817 lung cancer patients presented to the ED. Lung cancer patients were charged a cumulative of $3.06 billion in the ED and $38.6 billion in the IP setting. Annual cumulative ED charges increased by a factor of 2.5 from $575 million in 2006 to $1.42 billion in 2012 ($p<0.001$). Annual cumulative IP charges increased by a factor of 1.4 from $10.8 billion in 2006 to $14.6 billion in 2012 ($p<0.001$). Furthermore, annual per-patient ED and IP charges increased significantly during this time period. Per-patient annual ED charges increased by a factor of 1.6 from $2,169 in 2006 to $3,522 in 2012 ($p<0.001$). Per-patient annual IP charges increased by a factor of 1.2 from $41,835 in 2006 to $49,051 in 2012 ($p<0.001$). Table 1 shows the top 5 factors associated with higher ED and with higher IP charges, respectively.

Conclusion: The ED and IP charges associated with lung cancer patients are drastically increasing. ED charges have increased by a factor of 2.5 and IP charges have increased by a factor of 1.4 from 2006 to 2012. Furthermore, hospitals in the West and Midwest are associated with higher charges.

Factors Associated with High Emergency Department and Inpatient Charges for Lung Cancer Patients

	Emergency Department			Inpatient	
Factor	Beta (95% Confidence Interval)	p-value	Factor	Beta (95% Confidence Interval)	p-value
Chest Pain	2868 (2628-3109)	<0.001	Septicemia	22251 (19960-24541)	<0.001
Abdominal Pain	2274 (2041-2509)	<0.001	West Hospital	22155 (16220-28090)	<0.001

West Hospital	1434 (1007-1862)	<0.001	Respiratory Failure	19331 (16798-11557)	<0.001
Midwest Hospital	933 (662-1205)	<0.001	Secondary Malignancy	10283 (9009-11557)	<0.001
Lower Respiratory Disease	882 (756-1007	<0.001	Age 30-39	9057 (349-17755)	<0.001

Risk factors for death in the emergency department for melanoma patients

Jayla Hsiung[1], Kamil Taneja[2], Karan Patel[3], Michael Diaz[4], Jared Wolfe[3], Eric M. Toloza[5]. *[1]Highland Park High School, Highland Park, NJ,[2]Renaissance School of Medicine, Stony Brook, NY,[3]Cooper Medical School, Camden, NJ,[4]University of Florida College of Medicine, Gainesville, FL,[5]Moffitt Cancer Center, Tampa, FL*

Introduction**:** Many cancer deaths are related to melanoma. While there have been many studies that have identified risk factors for death in these patients, very few of them have analyzed the risk factors for death in melanoma patients in the emergency department (ED).
Methods: We utilized the 2006-2012 Nationwide Emergency Department Sample to characterize melanoma patients who die in the ED. Multivariate logistic regression was used to identify patient and hospital characteristics that were significantly associated with a higher chance of death. A p-value ≤0.05 was considered significant.
Results: From 2006 to 2012, 239,956 melanoma patients presented to the ED, and 2.1% of these melanoma patients died. Most melanoma patients who died in the ED were over the age of 70 years (60.0%), male (63.8%), Medicare beneficiaries (65.6%), of the highest income quartile (31.0%), presenting to a hospital in the South (35.3%), presenting to non-trauma hospitals (48.3%), and presenting to metropolitan non-teaching hospitals (43.4%). The most common reasons for patients who died upon presentation to the ED were a secondary malignancy (20.7%), septicemia (10.8%), acute cerebrovascular disease (7.5%), pneumonia (5.2%), and congestive heart

failure (2.6%). The top 3 factors associated with high risk of death were septicemia (odds ratio (OR)=7.39, 95% confidence interval (CI)=5.79-9.43; p<0.001), acute cerebrovascular disease (OR=3.44, 95%CI=2.62-4.51; p<0.001), and age >70 years (OR=2.50, 95%CI=1.24-5.03; p=0.010). Table 1 lists all risk factors associated with a higher risk of death.

Conclusion: Melanoma patients over the age of 70, with septicemia, acute cerebrovascular disease, or pneumonia, and of male sex are at higher risk for death in the ED. Clinicians should be aware of these risk factors when melanoma patients present to the ED.

Risk Factors Associated with Death for Melanoma Patients in the Emergency Department

Risk Factor	Odds Ratio (95% Confidence Interval)	p-value
Septicemia	7.39 (5.79-9.43)	<0.001
Acute Cerebrovascular Disease	3.44 (2.62-4.51)	<0.001
Age >70	2.50 (1.24-5.03)	0.010
Charlson Comorbidity Index of 3 or More	2.32 (1.89-2.84)	<0.001
Pneumonia	1.76 (1.27-2.45)	0.001
Charlson Comorbidity Index of 1	1.64 (1.40-1.93)	<0.001

Charlson Comorbidity Index of 2	1.63 (1.31-2.03)	<0.001
Medicaid	1.63 (1.19-2.23)	0.002
Metropolitan Teaching Hospital	1.33 (1.05-1.68)	0.017

Survival among adults diagnosed with secondary acute myeloid leukemia

Ephrem Sedeta[1], Ahmedin Jemal[2], Lauren Nisotel[2], Hyuna Sung[2]. *[1]Internal Medicine, Brookdale University Hospital and Medical Center, Brooklyn, NY,[2]Surveillance & Health Equity Science, American Cancer Society, Atlanta, GA*

Background**:** The burden of second primary cancers including secondary acute myeloid leukemia (sAML) is increasing in the United States; however, limited data exist regarding survival among individuals with sAML. This study aims to examine survival differences between sAML and AML arising de novo (dnAML) in relation to antecedent cancer types and the receipt of prior cancer treatment.

Methods: Individuals aged ≥20 years and diagnosed with sAML or dnAML between 2001 and 2018 and followed for vital status through 2019 were identified from Surveillance, Epidemiology, and End Results 17 database, covering 27% of the US population. The differences in AML-specific survival between individuals with sAML and dnAML were examined using multivariable Cox proportional hazards regression. Trends in five-year age-standardized relative survival from 2001-2014 were assessed using Joinpoint survival model for sAML and dnAML, separately.

Results: A total of 7,306 individuals diagnosed with sAML and 40,398 individuals with dnAML were included. During a median follow-up of 6 months, 78% of individuals with sAML died from AML compared to 71% of those with dnAML. In multivariable models, the risk of AML-specific mortality was 8% higher in individuals diagnosed with sAML than in those diagnosed with dnAML (hazard ratio [HR]=1.08, 95%CI=1.05-1.11), with the elevated risk more pronounced among those with younger ages at diagnosis ($HR_{20\text{-}54\ years}$=1.60, 95%CI=1.46-1.75 versus $HR_{65+\ years}$=0.99, 95%CI=0.96-1.03; $P_{interaction}$<0.0001) and those who received chemotherapy ($HR_{chemotherapy\ yes}$=1.14, 95%CI=1.10-1.19 versus $HR_{chemotherapy\ no/unknown}$=0.95, 95%CI=0.90-0.99; $P_{interaction}$=0.0004). Subgroup analysis by antecedent cancer types showed that HRs substantially varied ranging from 0.74 (95%CI=0.57-0.95) for

individuals with a history of thyroid cancer to 1.78 (95%CI=1.04-3.07) for those with a history of soft tissue sarcomas. Further subgroup analysis by the receipt of chemotherapy for antecedent cancers showed that the elevated risk was generally restricted to individuals with a history of chemotherapy receipt with some variations by cancer types. Five-year relative survival significantly increased from 2001 to 2014 for both sAML and dnAML; though the increase was slower for sAML (annual percent change [APC]=0.30%, 95% CI 0.20-0.40) compared with dnAML (APC=0.77%, 95%CI=0.69-0.84). Likewise, five-year survival for the most contemporary period (2010-2018) was substantially lower for sAML (9.8%, 95%CI=9.3-10.3) than for dnAML (22.8%, 95%CI=22.3-23.2).
Conclusion: Individuals with sAML had in general worse AML cause-specific survival compared with their dnAML counterparts, with the differences most pronounced among those diagnosed at younger ages and who received chemotherapy. The findings may inform targeted treatment and survivorship recommendations for cancer survivors who develop sAML.

Pre- and postoperative fecal microbiota and its association with complications after surgery in colon cancer patients
Dieuwertje E. Kok[1], Jannigje G. Kers[2], Hendriek C. Boshuizen[2], Niels Klaassen[2], Henk K. van Halteren[3], Flip M. Kruyt[4], Marjolein L. Smidt[5], Johannes H. W. De Wilt[6], Annemarie Boleij[6], Ellen Kampman[2], Erwin G. Zoetendal[2]. *[1]Division of Human Nutrition and Health, Wageningen University & Research, Wageningen, Netherlands,[2]Wageningen University & Research, Wageningen, Netherlands,[3]Division of Human Nutrition and Health, Admiraal de Ruyter Hospital, Goes, Netherlands,[4]Division of Human Nutrition and Health, Hospital Gelderse Vallei, Ede, Netherlands,[5]Maastricht University Medical Center & GROW School for Oncology, Maastricht, Netherlands,[6]Radboudumc, Nijmegen, Netherlands*

Introduction: Postoperative complications impact morbidity and mortality of colon cancer patients. Emerging evidence suggests that intestinal microbiota might play a critical role in the development of postoperative complications after gastrointestinal surgery. Here, we studied changes in fecal microbiota composition comparing samples collected before and after colon cancer surgery. Moreover, we examined whether the microbiota composition before surgery was associated with postoperative complications, and we explored potential determinants of the preoperative microbiota in colon cancer patients.

Methods: For this study, two fecal samples were provided by 78 patients with colon cancer. The first (preoperative) sample was collected shortly after diagnosis and before (median and interquartile (IQR) range of 4 (2-6) days) colon cancer surgery. The second (postoperative) sample was collected approximately 6 weeks (median and IQR of 42 (37-47) days) after surgery and before start of adjuvant chemotherapy (whenever applicable). Based on 16S ribosomal RNA gene amplicon sequencing, the fecal microbiota diversity and composition were determined. Preoperative microbiota composition of patients who developed postoperative complications in the 30 days following surgery (n=18, 23%) was compared to those who did not (n=60, 77%) using univariate and multivariate analyses. Explorative random forest analyses were conducted to identify predictors of complication status, with relative abundance of the core genera, sex, age, fecal calprotectin levels, dietary fiber intake, body mass index, smoking status, ASA classification, cancer stage and tumor location being considered as potential predictors.
Results: After surgery, microbial alpha diversity was reduced compared to the preoperative situation, whereas compositional changes over time only reached statistical significance for *Lachnospiraceae NK4A136* and *Coprococcus 1*, which both decreased in relative abundance after surgery. Already before the start of surgery, relative abundance of the genera *Bacteroides* (10% vs 6%) and *Lachnoclostridium* (0.6% vs 0.2%) appeared to be higher in patients with complications versus those with uncomplicated recovery. In a prediction analysis, current smoking and relative abundance of *Lachnoclostridium* were identified as most profound predictors of complication status. Fecal calprotectin levels and current smoking status explained most (together 6%) of the overall variation in microbiota composition before surgery.
Conclusion: In this study, higher relative abundances of the genera *Bacteroides* and *Lachnoclostridium* before surgery were associated with postoperative complications in patients with colon cancer. Future studies should expand on the potential causal and pathogenic routes underlying these observations.

Predictive risk factors for cancer thrombosis in gastric cancer patients

Song Ee Park[1], Moon Ki Jung[2], In Gyu Hwang[1]. *[1]Division of Hemato-oncology, Department of Internal Medicine, Chung-Ang University, Seoul, Korea, Republic of,[2]Division of Cardiology, Department of Internal Medicine, Chung-Ang University, Seoul, Korea, Republic of*

Background Gastric cancer is strongly associated cancer thromboembolism. We aimed to identify the Khorana risk score (KRS) and other risk factors for cancer thromboembolism in patients with gastric cancer after gastrectomy.
Methods We reviewed 610 gastric patients, who had undergone D2 radical gastrectomy between January 2005 and December 2017. Kaplan-Meier survival analysis and Cox regression models were used to evaluate for independent predictor of cumulative incidence of cancer thromboembolism and survival.
Results The median follow up was 67.0 months. There were 35 (5.7%) caner thromboembolism. The cumulative incidences of thromboembolism were 6.1%, 3.1%, 3.3%, and 20.7% in stages I, II, III, IV. 181 (29.7%) patients were relapsed cancer and 159 (26.1%) patients were died. A high KRS (cumulative incidence 5.8%) was not associated with cancer thromboembolism compared to an intermediate KRS (cumulative 5.7%) (HR=1.005, 95% CI = 0.540-2.061, P= 0.876). After gastrectomy, recurrent cancer (cumulative incidence 9.9%) was associated with cancer thromboembolism compared to no recurrence (cumulative incidence 4.0%) (HR 3.713, 95% CI 1.879-7.335, P < 0.001).
Conclusions Recurrent gastric cancer patients after gastrectomy were significantly increased cancer thromboembolism risk compared to no recurrent cancer patients. Among patients with gastric cancer after gastrectomy, KRS did not stratify the patients at high risk of cancer thromboembolism.

Evolution of curative-intent lung cancer surgery in a 4 eras in the population-based mid-south quality of surgical resection (MS-QSR) cohort
Olawale Akinbobola[1], Meredith A. Ray[2], Carrie Fehnel[1], Andrea Saulsberry[1], Kourtney Dortch[1], Anberitha T. Matthews[1], Nicholas R. Faris[1], Caroline M. Godfrey[3], Matthew Smeltzer[2], Raymond U. Osarogiagbon[1]. *[1]Baptist Cancer Center, Memphis, TN,[2]University of Memphis, Memphis, TN,[3]Vanderbilt University Medical Center, Nashville, TN*

Background**.** Most patients die within 5 years of curative-intent lung cancer surgery. Differences in surgical quality and cancer biology drive long-term overall survival (OS) differences after curative-intent resection. From 2009 onward, we implemented a sequence of interventions to improve surgical quality and pathologic evaluation in a regional population. We evaluated population-level surgical quality and OS in the MS-QSR cohort.
Methods. We categorized the MS-QSR into 4 (approximately) 5-year eras: 1) 2004-08, baseline; 2) 2009-13 (quality feedback and pilot intervention studies); 3) 2014-18 (surgical intervention with a lymph node collection kit); 4) 2019-22

(dual surgical and pathology intervention with novel gross dissection method). We compared surgical quality and OS across eras using standard statistical methods.
Results. Of 6,701 resections, 15%, 33%, 32%, and 20% were in Eras 1-4, respectively. American College of Surgeons Operative Standard 5.8 quality was attained in 4%, 22%, 45%, and 65% of resections in Eras 1-4, respectively; the International Association for the Study of Lung Cancer's stringent definition of 'complete resection' was achieved in 0%, 9%, 20%, and 31%, respectively; 120-Day mortality rates were 10%, 9%, 7%, and 4%; 3-year OS rates were 49%, 64%, 71%, and 84%; 5-year OS, 34%, 52%, and 61%, in Eras 1-3 (too early for Era 4); $p<0.0001$ for all comparisons.
Conclusion. Population-level surgical quality and OS have improved sequentially in parallel with implementation of interventions to surgical and pathology practices. The higher OS threshold in the MS-QSR creates a platform to interrogate the biologic drivers of surgical outcomes differences.

#4383
Development and validation of the Lung Cancer-Health Index (LC-HI), a clinically-relevant, disease-specific patient-reported outcome measure
Anika Varma[1], Spencer Rosero[1], Jamison Seabury[1], Jennifer Weinstein[1], Charlotte Engebrecht[1], Christine Zizzi[1], Nuran Dilek[2], John Heatwole[3], Megan Baumgart[4], Deborah Mulford[4], Ronald Maggiore[5], Lainie Conrow[6], Jennifer King[7], Jacinta Wiens[7], Chad Heatwole[1]. *[1]Center for Health + Technology, University of Rochester, Rochester, NY,[2]Department of Neurology, University of Rochester, Rochester, NY,[3]Pittsford Sutherland High School, Rochester, NY,[4]Department of Medicine, University of Rochester, Rochester, NY,[5]Hospice of Michigan, Ann Arbor, MI,[6]Wilmot Cancer Institute, University of Rochester Medical Center, Rochester, NY,[7]Go2 Foundation for Lung Cancer, Washington DC, DC*

Study Aim: The goal of this research is to develop and validate a novel, disease-specific patient-reported outcome measure (PRO) for use in clinical monitoring and therapeutic trials in Lung Cancer (LC).
Methods: LC currently accounts for the greatest number of cancer deaths worldwide, driving an increased need for novel therapeutic development in LC. To bolster clinical trial infrastructure, it is critical to have a comprehensive, sensitive and reliable PRO that accurately tracks LC multifactorial disease burden. This research describes the development and validation of the Lung Cancer-Health Index (LC-HI) as an efficient mechanism for assessing how

patients with LC feel and function in response to therapeutic treatment. We conducted semi-structured, qualitative interviews with 15 individuals diagnosed with LC and collected 653 direct participant quotes to determine the most frequent and important symptoms in LC. Based upon participant responses, we designed a survey that inquired about 162 symptoms from 14 symptomatic themes. This survey was implemented in a cross-sectional study with 139 participants with LC. The collected data was used to generate the first version of the LC-HI, which contained symptom questions showing the highest impact to the population and the potential to respond to therapeutic intervention. Symptom questions were grouped into distinct subscales using factor analysis. We beta-tested the LC-HI with 15 patients with LC to evaluate its usability, clarity, and applicability. Based on patient feedback, we modified the instrument and evaluated its test-retest reliability with 22 individuals with LC. Known groups testing was performed with the final instrument.
Results: The final version of the LC-HI contains 45 symptom questions grouped into 10 subscales that measure the following areas of LC health: 1) fatigue, 2) physical function, 3) emotional health, 4) sleep and daytime sleepiness, 5) activity participation, 6) breathing function, 7) gastrointestinal function, 8) cognitive function, 9) social performance, and 10) pain. Total LC disease burden is measured using a weighted composite of these subscale scores. During beta interviews, individuals with LC deemed the instrument to be easy to use, clear, relevant, and comprehensive. Statistical and psychometric analyses confirmed that the LC-HI is reliable, valid, sensitive, specific, of high internal consistency, and able to differentiate between groups with known varying levels of disease burden (based on disability status and smoking history).
Conclusions: Our research demonstrates the validity of the LC-HI as a marker of the multifaceted disease burden in LC. This disease-specific PRO provides researchers and clinicians with a reliable tool to use in patient monitoring, clinical trials, and to support FDA drug labeling claims.

Does progressive disease justify pembrolizumab discontinuation: a simulation analysis

Kannan Thiagarajan[1], Madhav Channavazzala[1], Brian Gregory Topp[2]. *[1]Vantage Research, Chennai, India,[2]Merck, Rahway, NJ*

Background: With checkpoint inhibition becoming first line therapy in several cancer indications, there is a growing number of patients that are refractory to PD1 therapy. It is unclear if these patients should remain on PD1 inhibitors while

new therapies are added on top or if PD1 should be discontinued when new therapies are initiated. Here we simulate a randomized controlled study comparing pembrolizumab + a checkpoint inhibitor (P+C) to a checkpoint inhibitor (C) in virtual patients that are refractory to PD1 therapy.
Methods: An IO QSP model was developed that includes intra-patient heterogeneity in tumor dynamics (target, non-target, and new metastatic lesions). The model was calibrated to individual lesion data from a large multicentre, open-label phase III study (Keynote-001) in patients with metastatic melanoma. A two year phase III study comparing P+C to C was simulated with 310 virtual patients in each group. Virtual patients were removed from the trial at the time of RECISTv1.1 progression or dropout due to AE or loss to follow-up.
Results: Virtual patients in the P+C arm displayed deeper (-11.5% vs 24.5%) and longer response (186.4 days vs 96.5 days) than virtual patients in the CPI arm. The percent of virtual patients displaying low prevalence progression (< 50% of the target lesions with PD) was 86% vs 52% for P+C vs. C. Median progression free survival was also longer in the P+C arm (3.8 vs 2.1 months). Difference in progression free survival were driven mainly by virtual patients that displayed oligoprogression during the pembrolizumab monotherapy run-in period.
Conclusions: Simulations presented here show that virtual patients that continued pembrolizumab treatment beyond RECISTv1.1 progression (as part of a combination) did better than virtual patients that discontinue pembrolizumab (and switch to a new therapy).

Unprecedented tumor: immune interaction--clinical and drug-development implications

Farah Mazahreh[1], Liyan Mazahreh[2], Brad Fugere[2], Ahmad Mazin Safar[3].
[1]Medicine, UAMS, Little Rock, AR,[2]CAVHS, Little Rock, AR,[3]UAMS Winthrop P. Rockefeller Cancer Institute, Little Rock, AR

Background: Classic therapeutic (RX) oncology principles demand radiographic response or durable stable disease as surrogates of overall survival (OS) prolongation, the ultimate metric of Rx benefit. Progressive disease (PD), however, is an undisputed indication of treatment failure. Immune Oncology (IO) trials reporting individual patient outcomes using swimmers' plot (SP) suggest substantial OS subsequent to PD, unprecedented pre-IO.
Hypothesis: Unrecognized phenomenon of OS benefit in the setting of radiographic PD, is tissue-agnostic and prevalent (>15%).

Methods: We conducted a retrospective review of IO monotherapy trials in 3 cancers if SP were reported. Percentage of PD patients (Pts) surviving beyond defined time landmarks is reported (Table).
Results: Realizing that 3rd or subsequent Rx lines rarely provide > 6 months OS duration in most cancers, our results indicate that 2/3rd of IO-treated pts, regardless of histology, or line of therapy are performing significantly better than expected; 1/3rd surviving > 1 year beyond PD.
Discussion: In IO, radiographic bulk may increase despite undeniable OS benefit (in years). We likely underestimated this phenomenon since pts with PD at 1st assessment aren't included in the SP, and with longer follow up, OS of PD pts is likely to improve with longer time to manifest it. This phenomenon--we term 'Disguised Responders' (DRs)--challenges an oncology principal. DRs needs to be considered by clinicians and future drug developers to accurately identify putative novel drugs. A plausible mechanism of DRs posits that 'virulence' of a given subclone, regardless of size or bulk, dictates Rx outcome. Virulence may operate through cachexia-induction, propensity to metastasize or metabolic adaptability, to name a few. Novel experimental approaches are desperately awaited to probe and measure virulence of different tumor subclones in future drug evaluations.

Comparison of cytotoxicity of anthracycline based antineoplastic drugs in breast cancer

Mitali Singhal[1], Jacobo Elies Gomez[1], Sanjit Nayak[2], Kirsten Riches Suman[2], Amalia Ruiz Estrada[1]. *[1]School of Pharmacy and Medical Science, University of Bradford, Bradford, United Kingdom,[2]School of Chemistry and Biosciences, University of Bradford, Bradford, United Kingdom*

Mitoxantrone (MTX) is used for the chemotherapeutic treatment of breast cancer, but it has a dose-limiting cardiotoxicity. One of the mechanisms of MTX cytotoxicity is by inhibiting the topoisomerase II enzyme, which is crucial for maintaining cellular processes like replication. The aim of the study is to investigate if an alternative analog of MTX, named KP71 would be a suitable antineoplastic drug with reduced cardiovascular side effects. Cytotoxicity of both drugs in breast cancer cell lines MDA-MB-468, MDA-MB-231, MCF7, the non-neoplastic breast cell line MCF10, cardiac human fibroblasts (HFB), and human umbilical vein endothelial cells (HUVEC) was assessed by MTT at 96h. The IC_{50} values (nM) for MTX/KP71 were as shown in table below. DNA decatenation assay demonstrated topoisomerase II inhibition with values of IC_{50}

= 2.9/12.3 μM for topoisomerase IIα, and 2.1/7.0 μM for topoisomerase IIβ for MTX/ KP71 respectively. Western blotting showed DNA damage by the gradation in γH2AX expression at different concentrations of MTX and KP71 at 6 h and 24 h treatment. KP71 was found to retain the ability to inhibit the proliferation of neoplastic cell lines in vitro with a slower profile of cytotoxicity on non-neoplastic cell lines as compared to MTX. KP71 partly exerted cytotoxicity by damaging DNA and inhibiting topoisomerase II enzyme activity. Organotypic HFB-HUVEC co-cultures were used to investigate the effects of anthracycline drugs in angiogenesis. Although both drugs reduced the number of tubules (and branches) compared to control (absence of drug), there were not significant differences between MTX and KP71.

MTT IC50 (nM)		
	MTX	KP71
MDA-MB-468	27	50
MDA-MB231	38	169
MCF7	63	150
MCF10	35	90
HFB	160	1177
HUVEC	56	93

#4387

Total toxicity burden of FDA approved immune checkpoint inhibitors in USA

Fan Yang, Chloe Shay, Zhaohui Qin, Nabil Saba, Yong Teng. *Emory University, Atlanta, GA*

Immune checkpoint inhibitors (ICIs) have revolutionized the treatment landscape for multiple cancers, demonstrating effective and durable responses and becoming the standard of care for a variety of malignancies. However, ICI-based treatment has resulted in the rise of unique immune-related adverse events (irAEs). To date, very little information is available on the frequency, significance, and management of single-organ or multiorgan irAEs in clinic. In this study, the irAEs associated with the treatment of seven FDA-approved ICIs, including three PD-1 inhibitors (cemiplimab, nivolumab and pembrolizumab), three PD-L1 inhibitors (atezolizumab, avelumab and durvalumab), and one CTLA4 inhibitor (ipilimumab), were analyzed based on the data of 149,303 report cases (January 1, 2015 - June 30, 2022) collected from FDA Adverse

Events Reporting System (FAERS) public dashboard. Our data reveal that irAEs associated with the treatment of anti-PD-1 ICIs (e.g., pembrolizumab) require less hospital care resources compared with anti-PD-L1 and anti-CTLA4 ICIs. Tissue and organ toxicity of ICIs are age and gender specific. 'Cardiac disorders' is the main disorder caused by these ICIs in cancer patients aged 65-85, while 'reproductive system and breast disease' is the main disorder in cancer patients aged 18-64. There are risks of respiratory and urinary system toxicity in male patients and reproductive system toxicity in female patients when they receive the treatment of ICIs. Studies such as this one provide the statistical data for understanding patients at risk of developing irAEs, which will underscore the importance of further exploring research strategies to predict, detect, and mitigate toxicities from ICIs.

Real world data and multi-genomic analysis of non-common mutations in the EGFR mutation-positive non-small cell lung cancer

Seoree Kim[1], Yeoun Eun Sung[2], Joo Ri Kim[2], Chan Kwon Jung[2], Jeong-Oh Kim[2], Jeong-yeon Shin[2], Guk Jin Lee[1], Sang hoon Chun[1], Young Ho Lee[3], Jin Hyoung Kang[2]. *[1]Bucheon St. Mary's Hospital, Bucheon, Korea, Republic of,[2]Seoul St. Mary's Hospital, Seoul, Korea, Republic of,[3]Research Center for Bioconvergence Analysis, Korea Basic Science Institute (KBSI), Daejeon, Korea, Republic of*

Introduction: There are similar and different properties between the epidermal growth factor receptor mutations (mEGFR), which are classified into common, uncommon, and compound mutation subtypes depending on their location and pattern on the EGFR gene. We investigated the RWD and RNA expression profile of non-common mutations (uncommon and compound mutations) in the mEGFR+ NSCLC patients.
Method: We analyzed the NGS data extracted from the Foundation Medicine (FMI) SRC. And, we collected the medical information for stage I-IIIA mEGFR+ NSCLC patients receiving curative surgical resection. In Böehringer Ingelheim (BI) open data access (ODA), we analyzed treatment results in stage IV mEGFR+ NSCLC patients treated with EGFR TKI. We explored the RNA expression profile by High-Plex Digital Spatial Profiling. A total of 18,676 DEG libraries were constructed, and 419 significance genes with > 2-fold changes, 3-log 2 normalized read counts, and p-value = 0.05 (up and down) were identified.

Result: In FMI-SRC cohort, 10,059 mEGFR+ cases of total 78,656 cases consist of common, 6,994 (69.5%), uncommon, 1,966 (19.6%), and compound, 1,099 (10.9%). In hospital cohort, 941 mEGFR+ cases consist of common, 860 (91.4%), uncommon, 60 (7.4%), and compound, 21 (2.2%). Median relapse-free survival (mRFS) in non-common mutations (31.4M and 33.7M) was shorter than common mutations (40.1M, p=0.877). CNS recurrence in the non-common mutations (40.0% and 35.3%) tended to be higher than that of common mutations (27.4%, p=0.361). In BI-ODA, median time on treatment (mTOT) in 163 uncommon mutations (10.0M) and 139 compound mutations (11.5M) were shorter than historical data of common mutations (17.3M). Spatial RNA-seq data of the ratio of deconvolution individual cells showed that genes involved in inflammatory and immune response were relatively lower in non-common mutations. Gene ontology string analysis revealed RNA expression of genes in compound mutations was functionally associated with chemokine production (23.4%), electron transfer activity (14.9%) and T cell selection (8.5%), and, in uncommon mutations, was associated with regulation of oligopeptide transport (26.1%), hypermethylation of CpG island (21.7%), and CD4+ CD25+ regulatory T cell lineage commitment (13.0%), compared to common mutations. Based on the GSEA, relatively highly clustered genes in compound mutations were the protein modification process, G-protein coupled receptor, regulation of cytosolic calcium ion concentration, and IL-5 production pathways, and lower ES levels in oxidative phosphorylation and RNA processing pathways, when compared to common mutations.
Conclusion: Taken together, our results suggest that uncommon and compound mEGFR subtypes exhibiting shorter mRFS and mTOT, and distinguishing RNA expression profile of functional signaling pathways be not same disease entity as common mEGFR subtype

#4392

Expression landscape of trophoblast cell surface antigen 2 (Trop-2) in breast cancer

Kai Song, Oh Kyu Yoon, Luting Zhuo, Emon Elboudwarej, Biao Li, Jillian Boice, Yang Pan, See Phan, Monica Motwani. *Gilead Sciences Inc., Foster City, CA*

Background**:** Antibody-drug conjugates (ADCs) are novel agents linking potent payloads to antibodies targeting antigen-expressing tumors. Sacituzumab govitecan (SG), a Trop-2-directed ADC, is approved for patients with metastatic triple-negative breast cancer (mTNBC) with ≥2 prior therapies (≥1 in metastatic

setting). SG is also being investigated in other breast cancer subtypes, including hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2-) metastatic breast cancer and in earlier lines of treatment. To understand the landscape of Trop-2 expression and potential clinical actionability of Trop-2 and other antigens, we evaluated RNA expression data in breast cancer from The Cancer Genome Atlas (TCGA) and Molecular Taxonomy of Breast Cancer International Consortium (METABRIC).
Methods: TCGA and METABRIC datasets were assessed for Trop-2, HER2, and programmed death ligand 1 (PD-L1) expression via processed RNA sequencing (RNA-seq) and microarray data of the corresponding genes *TACSTD2*, *ERBB2*, and *CD274*. Gene expression across clinical parameters was assessed via one-way ANOVA, t-test, or Spearman correlation. HER2 status was classified as HER2 immunohistochemistry (IHC) 0 or HER2-low (IHC1+, or IHC2+ and in situ hybridization-negative). Survival was estimated via Kaplan-Meier method. Neoadjuvant therapy datasets were assessed for effects of aromatase inhibitors on Trop-2 expression.
Results: RNA-Seq data was available from 1030 and 2136 breast cancer patients in TCGA and METABRIC datasets, respectively. Most patients (96%) had high *TACSTD2* expression (>100 transcripts per million [TPM]). *TACSTD2* expression was comparable by breast cancer histology (median log2TPM 6.8-7.5), by disease stages I-IV (median log2TPM 7.0-7.5), or by subtypes (median log2TPM 7.1-7.3). *TACSTD2* expression was not correlated with *ERBB2* (Spearman rho=0.06) or *CD274* (Spearman rho=-0.13) expression. No difference in *TACSTD2* expression was noted between HER2 IHC0 or HER2-low subtypes. *TACSTD2* expression was not associated with survival, though low tertile *TACSTD2* groups had better prognosis in the basal subtype; treatments were heterogeneous. Changes in *TACSTD2* gene expression were not observed post-aromatase inhibitors.
Conclusions: While SG is approved for use in mTNBC, *TACSTD2* is stably expressed across all breast cancer stages and subtypes, including HER2 IHC0 and HER2-low, and across all ranges of PD-L1 expression, suggesting a broad patient population may benefit from Trop-2-directed ADCs.

Tumor volumetric analysis to correlate disease burden with response to dual immune checkpoint blockade in metastatic NSCLC
Muhammad Aminu, Natalie I. Vokes, Maliazurina B. Saad, Hui Li, Lingzhi Hong, Mohamed S. Mohamed, John Boom, Pingjun Chen, Mehmet Altan, Saumil Gandhi, Stephen Swisher, Mara B. Antonoff, Jenny V. Pozadzides,

George Blumenschein Jr, Don L. Gibbons, Tina Cascone, Yasir Y. Elamin, Xiuning Le, Marcelo V. Negrao, Ferdinandos Skoulidis, Anne S. Tsao, Janet Tu, J.Jack Lee, Jianjun Zhang, John V. Heymach, Jia Wu. *The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Compared to other well-studied biomarkers, the relationship between overall tumor burden and immune-checkpoint inhibitor (ICI) efficacy is poorly understood.
Methods: We identified patients with stage IV NSCLC without EGFR, ALK or ROS1 alterations treated on the LONESTAR protocol with nivolumab + ipilimumab with formal 3-month radiographic response evaluation. Response was annotated using RECIST 1.1. Manual segmentation of primary and measurable metastatic lesions on pre-treatment CT scans was performed, and tumor volume was calculated from these measurements. Tumor burden was defined as the involvement status, volume, or lesion counts within specific organs (lungs, pleura, lymph nodes, liver, adrenals, bone, and soft tissue) and across whole body. We explored the impact of baseline tumor burden on ICI response and its association with other clinical features.
Results:152 patients were included; patients with progressive disease (PD; n=50) at 3 months were compared to all others (n=102). Overall disease volume correlated to tumor volume at the primary lesion (spearman rho=0.69), lymph node (rho=0.45), soft tissue (rho=0.23), lung metastases (rho=0.22), and pleura (rho=0.20); overall lesion counts correlated to lesion counts in lymph nodes (rho=0.61), lung metastases (rho=0.45), and bone (rho=0.16). On univariate analysis, overall tumor volume (P=2e-53) and lesion counts (P=2e-51) had the strongest association with PD, outperforming PD-L1 (P=0.02), ECOG performance status (PS, P=7e-16), and clinical variables including prior treatment and smoking status. PD correlated with higher disease burden in all individual organs except bone; adrenal metastases inversely correlated with PD. Volumetric features complemented PD-L1 and other clinical risk factors to predict PD; in a composite model (ClinVol) AUC=0.82, sensitivity=66%, specificity=93%, while PD-L1 alone yielded an AUC=0.62, sensitivity=94%, specificity=28%. Similar trends were observed for subgroup analyses stratified by brain metastasis status or smoking history, in which volumetric measures increased the power of PD-L1 to predict PD by a consistent AUC increase of ~0.2. Upon subgroup analysis stratified by PD-L1, volumetric models showed robust stratification of PD, with AUC of 0.97, 0.81, 0.81 respectively for PD-L1 <1%, 1-49%, and ≥50%.

Conclusion: Higher baseline tumor burden was associated with increased likelihood of disease progression on combination ICI therapy. ClinVol modeling improves predictive accuracy of 3-month progression.

Feasibility analysis of querying EHR databases for cancer clinical trial criteria

Dylan J. Cooper[1], Joseph Herman[1], Nalan Yurtsever[2], Sergio Garza[3], Daniel A. King[4], Yonah Ziemba[2]. *[1]Northwell Health Cancer Institute, Lake Success, NY,[2]Department of Anatomic and Clinical Pathology, Northwell Health, New Hyde Park, NY,[3]Cancer Informatics, Northwell Health Cancer Institute, Lake Success, NY,[4]Medical Oncology, Northwell Health, Lake Success, NY*

Background: In order to enroll patients for clinical trials (CT), it is common to run queries in clinical databases using CT eligibility criteria as filters and specifications. However, CT eligibility criteria are often unavailable as discrete data fields, which can interfere with CT recruitment. The purpose of this study was to identify the most commonly needed eligibility criteria that are specified in cancer CT to investigate whether and how they could be found in clinical databases.
Design: We examined the data elements needed for the trial eligibility criteria that would be used in queries for all the Breast, Gastrointestinal, Genitourinary, Head and Neck, and Cutaneous Cancer treatment trials open for enrollment across our health system. We then performed a sort-rank exercise for these eligibility criteria terms.
Results: The analysis included 33 trials and 12 data elements. Table 1 shows the number of times each eligibility criterion appeared in the 33 CTs and its feasibility for an EHR query. The data elements that appeared most frequently were Organ/Cancer Site (100%), Tumor Morphology (66.7%), Presence of Metastases (51.5%), TN Staging (39.4%), and Days Since Diagnosis (24.2%). Of these, only Organ/Cancer Site and Days Since Diagnosis were accessible as structured datapoints in our clinical databases.
Conclusions: The lack of feasibility for EHR query is likely due to the fact that healthcare information is generally stored in a discrete, structured form as a means of completing care transactions (drug orders or laboratory values) and ensuring billing compliance (ICD and outpatient CPT codes). This presents a critical challenge when data are required for CT enrollment, quality assurance metrics, and prospective and retrospective clinical research. Health systems—and by extension, their patients—would benefit from investing in structured data

schemas involving AJCC staging, tumor morphology, and presence of metastases.

Eligibility criteria with corresponding number of appearances in CTs and feasibility for EHR query		
Eligibility criterion	Number of trials with each criterion	Feasibility for EHR query
Organ/Cancer Site	33 (100%)	Accessible (ICD codes very detailed for site and used consistently for purpose of billing)
Tumor Morphology	22 (66.7%)	Not accessible (Code have not been created in ICD system, SNOMED is not widely adopted, not needed for billing)
Presence of Metastases	17 (51.5%)	Not accessible (Not coded consistently, coded in ICD as a “secondary” malignancy but generally does not affect billing)
TN Staging	13 (39.4%)	Not accessible (Not coded in ICD system)
Days Since Diagnosis	8 (24.2%)	Accessible (Structured data captured for purpose of initial transaction)
Tumor Markers and Other Lab Results	4 (12.1%)	Accessible (Structured data captured by laboratory instrument for purpose of initial transaction)
Immunohistochemical Biomarkers	4 (12.1%)	Not accessible (Pathologist assessment documented as narrative text)
History of Systemic Therapy	3 (9.1%)	Accessible (NDC drug code captured with initial order in order to complete the initial transaction)
Feasibility of Resection	3 (9.1%)	Not accessible (Surgeon assessment documented as narrative text)
Disease progression	3 (9.1%)	Not accessible (Radiologist assessment documented as narrative text)
Surgical Procedure	2 (6.1%)	Accessible as CPT codes for outpatient surgeries as needed for billing. Not accessible for inpatient surgeries where billing is capitated

		as a single fee for entire hospitalization based on disease related groups
Margins	2 (6.1%)	Not accessible (Pathologist assessment documented as narrative text)

#4396

TROP2 expression in non-small cell lung cancer

Peiwen Kuo[1], Emon Elboudwarej[1], Lauri Diehl[1], Jilpa Patel[1], Sabeen Mekan[2], Juliane M. Jürgensmeier[1]. *[1]Gilead Sciences Inc., Foster City, CA,[2]Gilead Sciences Inc., Morris Plains, NJ*

Introduction: Non-small cell lung cancer (NSCLC) is a major cause of cancer-related deaths globally with high unmet need. A variety of novel therapeutic strategies are being explored to improve patient outcomes including the use of antibody drug conjugates (ADCs) to deliver highly potent, cytotoxic payloads to tumors. Trophoblast cell-surface antigen 2 (TROP2), also known as tumor-associated calcium signal transducer 2 (TACSTD2), has emerged as an attractive target for ADCs. Sacituzumab govitecan-hziy is a novel ADC composed of a TROP2 antibody coupled to SN-38 and is being evaluated in NSCLC. High TROP2 mRNA expression is observed in many tumor types, however, TROP2 protein expression in NSCLC is not well-established. Here we characterized TROP2 expression across three independent datasets to explore the TROP2 relationship to baseline characteristics, molecular features of interest, and its prognostic value in NSCLC.
Methods: We analyzed three independent datasets: (1) The Cancer Genome Atlas (TCGA) NSCLC adenocarcinoma (LUAD, N=660) and squamous cell carcinoma (LUSC, N=484) mRNA expression data, (2) a NSCLC adenocarcinoma FFPE tumor sample set (“Translational data set”; N=107), (3) an independent clinical NSCLC adenocarcinoma (N=103) and squamous cell carcinoma (N=37) data set. TROP2 IHC was performed on tumor sample sets (2) and (3) using the SP295 antibody (Robust Prototype Assay, Ventana) with H-Score and assessment of the percentage of membrane-positive tumor cells as readouts. Wilcoxon rank-sum and Kruskal-Wallis tests (continuous variables), Kaplan-Meier method (survival probability curves) and log-rank test (time to event outcome) were used (GraphPad Prism 8.1.2 and R version 4.0.5).
Results: TROP2 mRNA was highly expressed in NSCLC and expression was similar in adenocarcinoma and squamous cell carcinoma in the TCGA data set. TROP2 expression did not vary with patient’s age, gender, race or tumor stage.

Furthermore, TROP2 expression was not associated with TP53, KRAS or driver mutation status (including EGFR, ALK, ROS, RET, MET). TROP2 expression in the Translational sample set was consistent with the findings from the TCGA data analysis: TROP2 mRNA and protein expression were high and independent of patient baseline demographics, tumor stage and TP53 and KRAS mutation status. Finally, in an independent clinical NSCLC dataset, TROP2 protein was highly expressed and there was no relationship between TROP2 and baseline demographics including gender and age. TROP2 membrane H-scores and percentage of membrane-positive tumor cells also highly correlated in the two independent datasets.
Conclusions: Three large independent datasets confirmed high expression of TROP2 in NSCLC both, as mRNA and protein. TROP2 expression in tumors did not differ between histological subtypes, baseline characteristics or clinically relevant driver alterations. Based on the TCGA data set, TROP2 expression was not prognostic for survival.

Chemotherapy-induced peripheral neuropathy and falls in cancer survivors relate to digital balance and gait impairments

Vrutangkumar Shah[1], Daniel Muzyka[1], Carolyn Guidarelli[2], Kristen Sowalsky[1], Kerri M. Winters-Stone[2], Fay B. Horak[2]. *[1]Clario, Portland, OR,[2]OHSU, Portland, OR*

Background and Aim: Standing postural sway and gait tests with body-worn inertial sensors provide a multitude of objective, digital balance, and gait measures that represent several different domains controlling mobility. However, it is not clear which domains of balance or gait best reflect the impact of treatment-induced peripheral neuropathy on mobility or differentiate fall risk in cancer survivors. This study aimed to determine which domains of balance and gait differed between cancer survivors who reported 1) symptoms of peripheral neuropathy versus asymptomatic survivors and 2) falls in the previous six months versus non-fallers.
Methods: Both postural sway during 30 seconds of quiet stance and gait characteristics from the Instrumented Time-Up-and-Go test (ITUG) were recorded with six synchronous inertial sensors (Opals by APDM Wearable Technology, a Clario company). The sensors were placed on both shanks and wrists, and one on the lumbar spine and sternum in 425 female cancer survivors (age: 62 ± 6 years). A principal component analysis (PCA) approach was used

first to identify independent domains of mobility from 14 balance and gait measures for subsequent analysis.
Results: PCA analysis revealed 5 independent domains (PC1: Sway amplitude, PC2: Gait pace; PC3: Sway frequency; PC4: Gait spatial-temporal and PC5: Turning) that accounted for 81% of the variance of performance across the participants. Cancer survivors who reported neuropathy showed a significantly higher sway frequency (PC3) than asymptomatic survivors. Cancer survivors who reported falls showed a significantly larger sway area (PC1) and slower gait pace (PC2) than non-fallers.
Conclusions: Wearable sensor instrumentation from short balance and gait tests capture objective digital gait and balance outcomes reflective of treatment-related neuropathy and fall risk in women treated with chemotherapy for cancer. Wearable sensors could be used for oncology clinical trials to assess the impact of cancer treatment and symptom mitigation strategies to limit changes in mobility that might lead to excess falls in people with cancer.

Validation of an updated algorithm to identify non-small cell lung cancer (NSCLC) patients in administrative claims databases

Sandip Pravin Patel[1], Rongrong Wang[2], Summera Qiheng Zhou[3], Daniel Sheinson[2], Ann Johnson[2], Janet Lee[2]. *[1]University of California, San Diego, CA,[2]Genentech Inc, South San Francisco, CA,[3]Genesis Research, Hoboken, NJ*

Purpose: Administrative claims data using the ICD-9-CM or ICD-10-CM coding systems are not detailed enough to distinguish between lung cancer subtypes, which presents challenges for real-world research. This study updated and validated a previous treatment-based algorithm that uses claims data to identify NSCLC vs small-cell lung cancer (SCLC) (Turner RM, et al. Front Pharmacol 2017;8:883).
Methods: This study used Optum's de-identified Market Clarity Data (2007-2021) which deterministically links medical and pharmacy claims with electronic health record (EHR) data from providers across the continuum of care. Included patients had lung cancer diagnosis and histology information available in the EHR, which is the gold standard for validation. Patients were required to have ≥3 months of continuous health plan enrollment before and after the diagnosis date. First, to replicate the Turner algorithm, patients were identified between Jun 2014 and Oct 2015 with any first-line NSCLC treatment and no SCLC treatment (Step 1). Next, the Turner algorithm was applied from Nov 2015 to Dec 2020 to evaluate if performance decreased given the approval

of immunotherapies since 2015 (Step 2). Finally, the Turner algorithm was updated with NSCLC treatments approved since 2015 in concordance with the latest US treatment guidelines. Algorithm performance at each step was measured using sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV).
Results: Sample sizes and performance statistics for each step are presented in the Table. From Step 1 to Step 2, specificity and PPV decreased while sensitivity and NPV increased. Algorithm performance improved slightly for all measures from Step 2 to Step 3.
Conclusions: This updated treatment-based algorithm improves validity and accuracy in identifying NSCLC patients in claims databases and supports its use in real-world research using claims databases when histology data is unavailable.

	Step 1: Turner replication	**Step 2: Turner 2015-2020**	**Step 3: Updated Turner 2015-2020**
Date range	Jun 2014-Oct 2015	Nov 2015-Dec 2020	Nov 2015-Dec 2020
Sample size	406	2573	2744
Sensitivity	0.873	0.920	0.932
Specificity	0.933	0.865	0.923
PPV	0.987	0.976	0.988
NPV	0.560	0.640	0.673

Can technology improve the quality and efficiency of multidisciplinary cancer conferences?

Opuruiche Ibekwe, Carmelo Gaudioso, Kristopher M. Attwood, Ellis G. Levine, Stephen B. Edge, Chukwumere E. Nwogu. *Thoracic Surgery, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: The use of multidisciplinary cancer conferences (MCCs) in cancer patient management is known to lead to improved quality of care and patient outcomes. Applying technology to MCCs may serve to optimize the process and enhance its contribution to patient care. The purpose of this study is to evaluate the impact of a tumor board technology platform on the quality of MCCs.
Methods: Data was collected prospectively from Thoracic, Gynecology (GYN) and Breast Cancer MCCs, September 2020 to February 2022, at a

comprehensive cancer center using an MCC performance assessment tool and a self-administered survey. The Mann Whitney U and X^2 tests were used as appropriate, to compare the quality of information presented and discussed, time per case reviewed, and consensus before and after implementation of the NAVIFY® Tumor Board Solution. Weighted composite scores of 11 of the variables were calculated and averaged between observers. Higher mean scores reflect higher quality and vice versa.

Results: Pre and post NAVIFY® data were collected from 249 and 289 cases, respectively. The overall quality of information presented increased after NAVIFY® implementation (Table 1). This increase was maintained within the Thoracic, Breast and GYN MCC subgroups (mean composite scores: 63.9 vs 82.9; $p < .001$, 63.4 vs 72.3; $p < .001$, and 59.8% vs 63.5%; $p = 0.009$ respectively). Increased participation by surgical, medical and radiation oncologists was also documented for the MCCs (mean score: 3.9 vs 4.1; $p < .001$, 3.4 vs 3.9; $p < .001$, and 3.5 vs 3.6; $p = 0.035$ respectively) as well as increased frequency of consensus (85.9% to 95.5%; $p = 0.001$). No change in discussion time was seen. Pathologists/radiologists surveyed reported greater ease of finding information they needed to prepare for the MCC (76.1% vs 96.7%; $p = 0.048$).

Conclusions: Using technology to organize and convey data at MCCs improves quality of information presented and discussed, clinician participation and the ability to reach a consensus.

Table 1. Comparison of Observational Measures Before and After NAVIFY® Platform Introduction

		Baseline Period	**Post Period**	**P-value**
Total Observed Cases	N	250 (46.4%)	289 (43.6%)	
Observed Cases By MCC	Thoracic	156 (62.4%)	177 (61.2%)	0.963
	Breast	42 (16.8%)	50 (17.3%)	
	GYN	52 (20.8%)	62 (21.5%)

Machine learning (ML) on real-world data (RWD) of front-line (1L) metastatic castration resistance prostate cancer (mCRPC) patients for dynamic prediction of time to tx discontinuation (TTD)

Prerna Jain, Deep K. Hathi, Hossein Honarvar, Rahul K. Das. *ConcertAI, Cambridge, MA*

Background: Abiraterone (abi) and enzalutamide (enza) are two novel androgen therapies (NAT) for 1L treatment (tx) for mCRPC. As there is no head-to-head randomized controlled clinical trial (RCT) between Abi and Enza, predicting 1L comparative effectiveness of these two drugs for mCRPC, especially in patient groups under-represented in RCTs is critical. ML was performed on electronic health records (EHR) to evaluate risk factors of TTD in 1L mCRPC patients and identify predictive markers of patient subgroups with differential outcomes from enza vs. abi.
Methods: Patients with curated mCRPC diagnosis and 1L tx between Jan 2012-May 2022 were identified in a ConcertAI® oncology EHR database. For dynamic prediction of TTD, survival XGBoost models were built with four different timepoints as index: 1L start, and 30, 60, and 90 days from 1L start. A 60:20:20 split was used for train, validation, and test sets. TTD was defined as either tx end or death. Risk factors and interaction terms were identified using SHapley Additive exPlanations (SHAP) and marginal hazard ratios.
Results: The sample size ranged between 1580-1636 patients (Table 1). Holdout testset cumulative dynamic AUROC for the models ranged between 0.65-0.75. PSA rise from 1L start, elevated PSA, liver enzymes, and platelets to lymphocytes ratio, low hemoglobin and albumin, prior NAT tx, intake of pain

medications, lower BMI, and high comorbidity were risk factors for TTD across all models. Tx with enza or abi was predictive of lower risk of TTD. While enza was better than abi in the overall population, SHAP interaction terms revealed that enza had worse TTD than abi in patients with higher ALP and NATs did not have any TTD benefit over chemo for patients with lower HGB.
Conclusions: ML on RWD identified prognostic markers for 1L mCRPC tx discontinuation and predictive markers of patient subpopulations with different outcomes from enza vs. abi.

Table 1: Summary of TTD Models: Cohort characteristics, model performance, risk factors: Mean HR (95% CI)

	Index of models			
	1L Tx-start	**1L Tx start + 30 days**	**1L Tx start + 60 days**	**1L Tx start + 90 days**
N patients (event prevalence)	1636 (89 %)	1611 (89.8%)	1585 (91.3)	1570 (92.2)

The precision chemotherapy to improve the epithelial ovarian cancer prognosis

Seongeun Pak, Youn Jin Choi. *Catholic University of Korea, Seoul, Korea, Republic of*

Purpose: Recurrence is common in ovarian cancer patients, even in those patients who show complete response after first-line chemotherapy, 80% of the patients experience a recurrence. So gynecologic oncologists often have to consider several factors when choosing next chemotherapy regimen. Therefore, this study aimed to find serial chemotherapy regimen choice to anticipate patients' better prognosis.

Materials and Methods: We reviewed 656 patients diagnosed ovary cancer in one tertiary institutional hospital between 2006 and 2020. Patents' clinic-

pathologic characteristics, primary treatment, chemotherapy regimens, survival outcomes were collected. We divided patients into several groups according to their chemotherapy regimen by mechanism of action and compared them. 1st line chemotherapy(CTx) type 1: carboplatin-paclitaxel, carboplatin-docetaxol, cisplatin-paclitaxel, cisplatin-docetaxol2nd line CTx type 1 : carboplatin-paclitaxel, carboplatin-docetaxol, cisplatin-paclitaxel, cisplatin-docetaxol2nd line CTx type 4 : carboplatin-gemcitabine2nd maintenance CTx type 2 : PARP inhibitor(PARPi)2nd line CTx Type 5: Platinum + topoisomerase inhibitor 2nd line CTx Type 6(cisplatin-vinorelbine)2nd line CTx Type 8(topoisomerase inhibitor only) 2nd line CTx Type12 (single taxol) The survival rate of ovary cancer patients decreased from stage 1 to stage 4.Among 1st line CTx type 1 and 2nd line CTx type(1 or 4) patients, those who used PARPi in 2nd line maintenance CTx(n=14) had a higher death rate than those who did not receive maintenance CTx or received that other than PARPi(hazard ratio 1.44). In the 1st line CTx 1~4 group, we divided patients according to 2nd line CTx type. We compare 2nd line CTx type 5 group(n=30) with type 6+8+12 group(n=26). The death rate was of type 5 group was higher than type 6+8+12 group. And Overall survival of 2nd line CTx type 5 group was 22 months, that of 2nd line CTx type 6+8+12 group was 26 months.
Conclusion: When changing the chemotherapy regimen in the recurrence of ovarian cancer, the survival rate or overall survival may vary depending on the order in which the regimen is used. If we collect patients data more broadly, the predictive power will be better.

#4402

Survival impact of post-operative immunotherapy in resected stage III cutaneous melanomas in the checkpoint era

Garo G. Hagopian[1], Christopher Grant[1], Danielle Brazel[1], Priyanka Kumar[1], Maki Yamamoto[2], James Jakowatz[2], Warren Chow[3], Thuy Tran[2], Justin Moyers[3]. *[1]Internal Medicine, UCI Medical Center, Orange, CA,[2]Surgical Oncology, UCI Medical Center, Orange, CA,[3]Hematology and Oncology, UCI Medical Center, Orange, CA*

Introduction: Since 2015, immune checkpoint inhibitors have been approved as post-operative therapy for resected stage 3 cutaneous melanoma. This approval was a result of studies which demonstrated improved recurrence free survival. However, overall survival (OS) benefit has yet to be observed. We examine the

OS of postoperative immunotherapy in stage 3 melanoma using real world data from the National Cancer Database (NCDB).
Methods: Data was collected from the 2020 NCDB Participant Use File (October 2022 release). Patients were staged by both the 7th and 8th version of American Joint Committee on Cancers (AJCC). Those who underwent definitive surgery since 2016 and had sufficient pathologic data for staging were included. Patients who received systemic therapy prior to surgery were excluded. Patients were then sorted by the type of postoperative therapy started within 12 weeks from definitive surgery and classified into the no post-operative systemic therapy (NP) or postoperative immunotherapy (PI) groups. Survival time was calculated from the time of definitive surgery to last contact or death. OS was estimated by Kaplan-Meier method and compared by log-rank method.
Results: 18,167 patients underwent surgery for stage 3 disease between 2016-2020. By AJCC v8 staging, 4,256 had Stage 3A disease, 3,752 stage 3B disease, 9,251 stage 3C disease, and 908 stage 3D disease. Median OS was not met in any stage 3 PI groups. The 36 - month landmark survival of all stage 3 subgroups is shown in Table 1. Only 13.3% of patient received PI in 2016. PI use increased to 24.8% in 2017, 43.8% in 2018, 46.8% in 2019, and 50.8% in 2020.
Discussion: Using a large real-world database, we found that patients receiving post-operative immunotherapy in the checkpoint era have a significant survival benefit compared to those who did not. The benefit was significant in stage IIIB-C in AJCC v7 and Stage IIIC-D in AJCC v8. However, the benefit was not significant in stage 3A melanoma.

Table 1: 36-month Landmark survival reported with 95% confidence interval for both AJCC versions

		No Post-Operative Immunotherapy		**Post-Operative Immunotherapy Given**

The Efficacy of Immune Checkpoint Inhibitors in Advanced Biliary Tract Cancer with KRAS Mutation

Sun Young Jeong, Jaeyeon Jang, Youngkyung Jeon, Ye Ji Jung, Daeho Choi, Joohyun Hong, Seung Tae Kim, Jung Yong Hong, Joon Oh Park, Young Suk Park, Ho Yeong Lim. *Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of*

BackgroundWith a 15% of incidence, KRAS is one of the most common mutations in biliary tract cancer (BTC) and a poor prognostic factor. In BTC, the immune checkpoint inhibitor (ICI) as salvage therapy has modest activity. There was little data on the efficacy of ICIs according to the status of KRAS mutation in BTC.

MethodWe conducted molecular profiling in BTC patients who received the ICIs as salvage therapy. Programmed death ligand 1 (PD-L1) expression on tumor cells and tumor-infiltrating lymphocytes (TIL) was also assessed. We analyzed overall survival (OS) and progression-free survival (PFS) of ICI in BTC patients according to the status of PD-L1 expression and KRAS mutation.

ResultA total of 62 patients were included in this analysis. The median age was 68.0. 47 patients (75.8%) received pembrolizumab and 15 (24.2%) received

nivolumab as salvage therapy. All patients received gemcitabine plus cisplatin as the frontline therapy, and 53.2% had fluoropyrimidine plus oxaliplatin (FOLFOX) before ICIs. The median lines of prior chemotherapy were 2.5. KRAS mutation was found in 14 patients (22.6%). 28 patients (45.2%) were positive for PD-L1 CPS. There was no statistical correlation between the status of KRAS mutation and PD-L1 expression. The median OS and PFS to ICI were 5.6 (IQR; 3.3 - 8.0) and 3.8 (IQR; 3.0 - 4.5) months, respectively. There were no statistically significant differences in PFS to ICIs according to the status of KRAS mutation (Mutant type vs. Wild type) and PD-L1 expression (Positive vs Negative). In subgroup analysis, patients with both KRAS mutation and PD-L1 positivity had longer PFS as compared to patients with KRAS mutation and PD-L1 negativity (6.5 vs 2.6 months, p=0.047). This finding was not shown in patients with a wild type of KRAS.
ConclusionThis analysis showed that PD-L1 expression might be a novel biomarker for ICIs in BTC patients with KRAS mutation but not the wild type of KRAS.

#4404

Survival impact and trends of immunotherapy use in metastatic merkel cell carcinoma in the checkpoint era: analysis of a large database

Christopher R. Grant[1], Garo Hagopian[1], Danielle Brazel[1], Priyanka Kumar[1], Justin Moyers[2]. *[1]Department of Medicine, University of California Irvine Medical Center, Orange, CA,[2]Division of Hematology and Oncology, Department of Medicine, University of California Irvine Medical Center, Orange, CA*

Introduction: Merkel Cell Carcinoma (MCC) is an aggressive skin cancer that has typically been treated with conventional chemotherapy in the metastatic setting. In 2017, metastatic MCC treatment options expanded when the FDA approved immune checkpoint inhibitors based on single-arm uncontrolled studies. We utilized data from the National Cancer Database (NCDB) to examine the survival benefit of first line immunotherapy (IO) or chemotherapy (CT) in metastatic MCC.
Methods: The NCDB was analyzed to identify patients with metastatic MCC from 2017-2020. Patients who did not have data available on AJCC version 8 staging group, survival status, and treatment details (surgery, radiation therapy, CT, IO) were excluded from the analysis. Patients were divided into cohorts based on first line systemic therapy; those who received chemotherapy and those who received immunotherapy. Survival time was calculated from the time of

initiation of systemic treatment to last contact or death. Overall survival (OS) was estimated by Kaplan-Meier method and compared by log-ranked method. Results: We identified 648 patients with stage IV MCC between 2017-2020. Of those, 15.3% (n=99) received CT, 51.7% (n=335) received IO, and 32.9% (n=213) did not receive systemic therapy. Median OS was 13.2 (95% CI: 10.1-16.2) months for those receiving any systemic therapy. Median OS was 13.8 (95% CI: 7.9-19.7) months for CT and 12.9 (95% CI: 9.6-16.2) months for immunotherapy (p=0.379). In the first year of IO approval in 2017, only 37.4% of patients received IO which increased to 54.5% in 2018, 59.6% in 2019, and 54.9% in 2020. Chemotherapy use decreased throughout the same time period from 23.9% in 2017 to 12.4% in 2020. There was a notable difference in the number of patients less than 65 years old who received IO (66%) relative to the number of patients 65 years and older who received IO (80%) (p=0.006). Discussion: Immunotherapy has supplanted chemotherapy as the first line treatment of choice in MCC, particularly in those 65 and older. However, we did not find first line use of immunotherapy to provide a statistically significant survival advantage over chemotherapy in stage IV Merkel cell carcinoma. Clinical equipoise exists, and a randomized clinical trial is needed.

#4405

Tumor mutational burden, as a potential predictive marker for the efficacy of immunotherapy in advanced gastric cancer

Jaeyeon Jang, Youngkyung Jeon, Sun Young Jeong, Ye Ji Jung, Daeho Choi, Joohyun Hong, Jeeyun Lee, Won Ki Kang, Seung Tae Kim. *Samsung Medical Center, Seoul, Korea, Republic of*

Background: The optimal value of tumor mutational burden (TMB) for predicting treatment response of immunotherapy in advanced gastric cancer (AGC) is still unclear. We aimed to establish the optimal cut-off value of TMB, and evaluate the efficacy of immunotherapy in AGC according to TMB and other markers.
Method: From October 1, 2020, to July 27, 2021, at Samsung medical center in Korea, patients with AGC, who received pembrolizumab or nivolumab were included. TMB was measured by next-generation sequencing (NGS)-based assays, and PD-L1 is tested using immune-histochemical assay 22C3 pharmDx. Based on receiver operating characteristic analysis, the cut-point value of TMB was determined as the point where the Youden's index is maximum.
Result: A total of 53 patients were analyzed. The cut-off value of TMB for predicting the overall response of immune checkpoint inhibitors was defined as

13.31 mutations/megabase (mt/mb), with 56% of sensitivity and 95% of specificity. Under this definition of TMB, 7 patients were TMB-high group (≥13.31 mt/mb), while 46 patients were TMB-low group (<13.31 mt/mb). The overall response rate (ORR) had a statistically significant difference between TMB-low (8.7%, n=4/46) and TMB-high patients (71.4%, n=5/7; *p*=0.001). The progression-free survival (PFS) and overall survival (OS) for 53 patients were 1.93 months (95% CI, 1.600-2.268) and 4.26 months (95% CI, 2.992-5.532). The OS was longer in the TMB-high group with the median of 20.8 months (95% CI, 2.292-39.281) compared to the TMB-low group with the median of 3.31 months (95% CI, 1.604-5.019; *p*=0.049). The ORR of the patients whose PD-L1 CPS was 1 or above was not different from the patients whose PD-L1 CPS was lower than 1.
Conclusion: In this study, the optimal value of TMB for predicting the objective response rate of immunotherapy in AGC was determined as 13.31 mt/mb. TMB-high (≥13.31 mt/mb) was associated with a better objective response rate, and TMB-high patients exhibited better overall survival. TMB has the potential for predicting therapeutic response to immunotherapy in advanced gastric cancer.

#4406

Impact of site of metastases on response to immunotherapy in microsatellite stable (MSS) metastatic colorectal cancer (mCRC)

Marwan Fakih, Jaideep Sandhu, Xiaochen Li, Chongkai Wang. *City of Hope National Medical Center, Duarte, CA*

Background: We have noted that responses to the combinations of regorafenib and nivolumab (REGONIVO) or regorafenib ipilimumab nivolumab (RIN) were limited to MSS mCRC without liver involvement. We sought to delineate the impact of non-liver metastatic sites on the response to these combinations.
Methods: We performed a single center retrospective analysis of MSS mCRC receiving REGONIVO or RIN. To isolate the impact of immunotherapy on metastatic disease sites, we performed a 2-month (mo) analysis of organ specific response using organ specific RECIST assessment.
Results: 96 patients (Pts) (39 RIN and 57 REGONIVO) were evaluated. Overall response rate (ORR), median progression free survival (PFS), and median overall survival (OS) were 0%, 2 mo, and 7 mo in pts with liver metastatic (LM) disease (n = 33). We focused on the impact of other metastatic disease site on OS and PFS within the non-LM group to exclude liver as a confounding variable (n=63). Pts with lung-only mCRC had the best prognosis with an ORR, median PFS, and median OS of 56%, 13 mo, and unreached at 24 mo. Pts with

peritoneal mCRC fared poorly (ORR 0%, median PFS= 1.5 mo, median OS =12 mo). A high ORR (75%) was noted in a small cohort of 4 pts with lymph node only disease. However, concurrent LN with lung only mCRC diminished efficacy outcomes. Differences in PFS and OS by organ involvement were independent of treatment (REGONIVO or RIN) based on estimates from Cox proportional hazard model. 2-mo response rates by metastatic sites are shown in Table 1. Responses at the 2-mo mark in the 96 pt cohort occurred in lung, LN, and soft tissue metastases but were most robust in lung only metastatic disease. Conclusions: Responses to the combination REGONIVO or RIN are most robust in lung-only metastatic disease and appear to be modest in the setting of LN and soft tissue involvement. Liver and peritoneal disease was associated with lack of benefit from these combinations.

Table 1 2-month Response Rates by Site of Metastatic Disease

Sites of mCRC	Number of Pts	PD	SD	PR+CR
Lung	72	33 (45.8%)	21 (29.2%)	18 (25.0%)
Lung response in the setting of liver mets	*27*	*18 (66.7%)*	*7 (25.9%)*	*2 (7.4%)*
Lung response without liver mets	*45*	*15 (33.3%)*	*14 (31.1%)*	*16 (35.6%)*
Lung response in lung only metastatic disease	*16*	*3 (18.8%)*	*4 (25.0%)*	*9 (56.2)*
Liver	33	31 (93.9%)	2 (6.1%)	0 (0%)
Lymph Node (LN)	49	32 (65.3%)	12 (24.5%)	5 (10.2%)
LN in the setting of liver mets	*22*	*20 (90.9%)*	*2 (9.1%)*	*0 (0%)*
LN in the setting of no liver	*30*	*14 (46.7%)*	*11 (36.7%)*	*5 (16.6%)*
LN only	*4*	*1 (25%)*	*0 (0%)*	*3 (75%)*
Peritoneal	15	14 (93.3%)	1 (6.7%)	0 (0%)
Soft tissue	30	11 (39.3%)	15 (53.6%)	2 (7.1%)
Bone	8	4 (50%)	4 (50%)	0 (0%)

Brain	1	1 (100%)	0 (0%)	0 (0%)
Spleen + Adrenal	5	4 (80%)	1 (20%)	0 (0%)

#4407

Clinicopathologic characteristics and mutational analysis of MYC amplified head and neck squamous cell carcinoma (HNSCC)

Thomas Cyberski[1], Alka Singh[2], Mark Lingen[3], Alexander Pearson[2], Nishant Agrawal[4], Evgeny Izumchenko[2], Ari Rosenberg[2]. *[1]The University of Chicago Pritzker School of Medicine, Chicago, IL,[2]Medicine, Section Hematology/Oncology, University of Chicago, Chicago, IL,[3]Pathology, Medicine, University of Chicago, Chicago, IL,[4]Surgery, Section Otolaryngology, University of Chicago, Chicago, IL*

Amplification of MYC proto-oncogene is commonly found in many types of cancer, and frequently associated with poor clinical outcomes. Analysis of the TCGA-HNSCC dataset indicates that MYC amplification is estimated to be present in ~12% of HNSCC cases, and has a significant impact on patients' median survival (32.2 vs 56.9 months for patients with wild-type MYC). While the association between MYC amplification and HNSCC progression was previously reported, its role in regulating mechanisms of acquired resistance to therapy remain under investigated. In this study, we seek to further characterize the clinicopathological features associated with MYC amplified HNSCC, and highlight the molecular changes that may contribute to acquired resistance to treatment.

Seven HNSCC patients with MYC amplification were identified by searching the Oncoplus database at the University of Chicago. A retrospective chart review was conducted to collect demographic and clinical data for each patient, and mutational landscape was characterized. In a single patient, MYC amplification was acquired following treatment with chemoimmunotherapy (nivolumab, carboplatin, paclitaxel), chemoradiation, and maintenance nivolumab resulting in rapidly progressive disease despite an initial response to therapy. RNA sequencing and immunohistochemical staining was performed to compare specimens collected before and after progression.

Seven patients were diagnosed with HNSCC and were found to have MYC amplification on molecular testing of their cancer between 2018 and 2021. Four were male, median age 61 (range 46-71), stage T2-4 (n=6), N2-3 (n=6), p16+ (n=2). All patients (n=7) developed recurrent and/or metastatic disease following

primary therapy with locoregional recurrence (n=3), metastatic recurrence (n=2), or both (n=2). Median survival for the cohort was 3.1 years. Previous therapy included surgery (n=4), radiotherapy (n=7), chemotherapy (n=7), targeted therapy (n=4), and immunotherapy (n=4). The most common mutations co-occurring with MYC amplification were CDKN2A loss (n=5), TP53 loss (n=5), CCND1 amplification (n=2) and KDM6A loss (n=2). Acquisition of MYC amplification and acquired resistance to chemoimmunotherapy was associated with upregulation of glycolysis pathway, WNT/beta-catenin signaling, and significant changes to tumor microenvironment (TME) such as tumor infiltrating lymphocytes repertoire and PD1/PD-L1 expression levels.
Alongside the data from TCGA, the cases described in this study highlight the poor prognosis associated with MYC amplified HNSCC. While loss of function mutations in CDKN2A and TP53, upregulation of glycolysis pathway, and TME reprogramming may contribute to treatment resistance and secondary immune evasion, further studies in larger cohorts are warranted to develop therapies that target MYC mediated mechanisms of resistance in HNSCC.

Provisional prognostic score for monomorphic epitheliotropic T-Cell lymphoma

Philip A. Haddad, Dinesh Keerty, Neelakanta Dadi. *LSUHSC-S, Feist-Weiller Cancer Center/Overton Brooks VAMC, Shreveport, LA*

Background: Monomorphic Epitheliotropic Intestinal T-cell Lymphoma (MEITL) is a rare extranodal intestinal PTCL. It is an aggressive disease with an overall poor prognosis. However, the disease presents a diverse spectrum of survival outcomes. We conducted this study to develop a provisional MEITL prognostic score (MPS) for this rare disease.
Methods: We used our updated MEITL database, which contains retrospective data on 218 cases. Such data included demographics such as sex, age, and race. It also included disease presentation symptoms, duration of symptoms before diagnosis, site(s) of the disease, stage, blood counts, disease immune and molecular phenotype, types of treatment, quality of response, and survival outcomes. Out of the 218 cases, only 140 cases had complete survival and outcomes data, the sample chosen for this study. Cox proportional-hazards model and Log-rank tests were used to assess the influence of clinicopathologic factors on overall survival (OS). Due to the relatively small training cohort, we included factors that statistically impacted OS as well as factors that numerically trended that way.

Results: The median OS of the cohort was 11 months. The following dichotomous variables were identified as impactful prognostic factors in this cohort: Bone marrow involvement (9 vs. 14 months), Non-biclonal TCR status (10 vs. 17.5 months), CD56+ (10 vs. 26 months), Ki67≥70% (4 vs. 8 months), cMyc expression >15% (7 vs. 12 months). A prognostic model was devised using these variables to identify different levels of risk. Each variable was assigned a score of 1 when present, except for cMyc, which was assigned 2 points for having the highest hazard ratio among all the variables. In this exploratory cohort, low risk was assigned a score of 0, intermediate risk a score of 1-2, and high risk a score of 3-6. This prognostic score system led to our cohort's most optimal risk discriminatory model, where low, intermediate, and high risk had a median OS of 26, 12, and 4 months, respectively (p=0.002). Conclusion: This MPS is a promising new tool for risk-stratifying patients with MEITL. However, it still needs prospective validation.

#4409

Survival determinants of aggressive adult T-cell leukemia/lymphoma (ATLL): analysis of a pooled database

Supriya Gupta, Christopher Graham, Philip A. Haddad. *LSUHSC-S, Feist-Weiller Cancer Center/Overton Brooks VAMC, Shreveport, LA*

Background: Adult T-cell leukemia/lymphoma (ATLL) is a rare Peripheral T-cell Lymphoma subtype caused by Human T-Lymphotropic Virus 1 (HTLV-1). The disease encompasses a vast phenotype ranging from the smoldering and chronic indolent subtypes to the lymphoma and acute aggressive subtypes. Aggressive ATLL which comprise acute/leukemic, lymphoma, and other indolent subtypes with aggressive transformation tend to have poor outcome with conventional chemotherapy rarely achieving durable lasting remission. We conducted this pooled database analysis to identify key factors that affect the clinical outcomes of aggressive ATLL subtypes.
Methods: To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 462 ATLL cases. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on the overall survival (OS).
Results: Three hundred and forty-seven aggressive ATLL patients with survival data were included in this analysis. The median OS of the whole group was 14 months, with a median OS of 12.8, 16, and 12 months for acute, lymphoma, and

transformed subtypes. The median age was 54 years, with a M:F ratio of 1.1. SCT demonstrated superior OS compared to chemotherapy (28 vs. 10 months, $p<0.0001$). Similarly, LSG15 regimens were superior to no chemotherapy and other combinations (29 vs. 1 vs. 15 months, $p<0.0001$). Asians and Afro-Caribbeans lived longer than Whites, Indians, and Hispanics (15.7, 15, 10, 3, 1 months, $p<0.0001$, respectively). The presence of hypercalcemia (Ca>11 mg/dl, Anemia (Hgb<12 g/dl), elevated LDH ($\geq$1000 U/L), and effusions adversely effected OS. Moreover, visceral involvement generally and specifically GI, kidney, lung, and heart were significantly detrimental to OS. However, age, sex and the presence of constitutional symptoms or HAM/TSP did not impact the OS.
Conclusions: This study explored a wide array of clinical factors and their impact on the OS of aggressive ATLL. It identified race, types of treatment, the presence of hypercalcemia, anemia, elevated LDH, effusion and visceral metastases as significant determinants of OS in aggressive ATLL.

#4410
Determinants of progression-free and overall survival of angioimmunoblastic T-Cell lymphoma (AITL): a pooled analysis
Philip A. Haddad, Frankie Powell. *LSUHSC-S, Feist-Weiller Cancer Center/Overton Brooks VAMC, Shreveport, LA*

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a major subtype of peripheral T-cell lymphoma with a T-cell follicular helper phenotype. It accounts for approximately 1-2% of non-Hodgkin's lymphoma and 15-20% of peripheral T-cell lymphoma. AITL has unique clinical features with an aggressive course and poor prognosis. Therefore, it is essential to uncover the clinically significant prognostic factors to chart an optimal treatment strategy for AITL. Currently, AITL prognostic factors are not well established. Several retrospective AITL series with limited numbers reported varying prognostic factors and occasionally discordant results. Consequently, such studies lacked the power to validate factors that influence long-term clinical outcomes. We conducted this meta-analysis to evaluate the pooled impact of selected clinicopathologic factors on progression-free (PFS) and overall survival (OS) in patients with AITL.
Methods: A review of the medical literature was conducted using online databases. Inclusion criteria comprised AITL diagnosis, English language, and studies reporting factors impacting PFS and OS with hazard ratios (HR). A meta-analysis was conducted using an inverse variance method. The pooled

value for the estimate, with 95% CI, was calculated using the Fixed effects model and the Random effects model.
Results: Eight retrospective series with 944 patients were included and analyzed. Factors that impacted both PFS and OS included: Bone marrow involvement (HR 1.51, 95%CI:1.01-2.25; HR 1.58, 95%CI:1.02-2.44), mediastinal involvement (HR 1.44, 95%CI:1.10-1.88; HR 1.48, 95%CI:1.09-2.02), B-symptoms (HR 1.40, 95%CI:1.14-1.71; HR 1.55, 95%CI:1.22-1.96), stage >II (HR 1.50, 95%CI:1.05-2.13; HR 1.74, 95%CI:1.15-2.61), ECOG $\geq$2 (HR 1.74, 95%CI:1.42-2.13; HR 2.39, 95%CI:1.65-3.44), ↑LDH (HR 1.47, 95%CI:1.12-1.94; HR 1.39, 95%CI:1.01-1.91), Albumin<3.5g/dl (HR 1.43, 95%CI:1.10-1.85; HR 1.57, 95%CI:1.01-2.45), sIL2R >530U/ml (HR 1.72, 95%CI:1.12-2.65; HR 1.90, 95%CI:1.29-2.80), and extra-nodal involvement >1 site (HR 1.92, 95%CI:1.53-2.41; HR 2.01, 95%CI:1.48-2.72). Factors that impacted OS only are: effusion (HR 2.60, 95%CI:1.32-5.14), leukocytosis (HR 1.11, 95%CI:1.02-1.22), and PIT >1 (HR 1.83, 95%CI:1.22-2.73). Factors that impacted PFS only are: Age (HR 1.37, 95%CI:1.18-1.59), Anemia (HR 1.63, 95%CI:1.34-1.97), and ↑β2-microglobulin (HR 1.73, 95%CI:1.19-2.52). However, sex, thrombocytopenia, ↓total protein, ↑IgG, ↑IgA, ↑IgM, ↑CRP, and IPI >2 did not significantly impact PFS or OS.
Conclusions: This is the first meta-analysis to explore the impact of clinicopathologic factors on AITL PFS and OS. It delineates factors that impact PFS and OS and those that do not influence either.

#4411
Clinicopathologic determinants of survival in enteropathy-associated T-cell lymphoma (EATL): analysis of a pooled database
Philip A. Haddad, Sai Malireddy. *LSUHSC-S, Feist-Weiller Cancer Center/Overton Brooks VAMC, Shreveport, LA*

Background: EATL is a rare and rapidly progressive extranodal T-cell lymphoma which arises from the intestinal intraepithelial T lymphocytes. It often occurs in the context of untreated or long-standing Celiac disease (CD) or the development of refractory sprue. EATL tends to be less responsive to conventional chemotherapy, often with poor clinical outcomes. We conducted this analysis to explore the clinicopathologic determinants of survival in this rare extranodal T-cell entity.
Methods: To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 220 cases. Kaplan-Meier

survival curves were constructed. Cox proportional-hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS).
Results: A total of 220 patients with confirmed EATL were identified. The median age was 60, with a peak incidence between 64 and 75. There was a slight female predominance with F:M ratio of 1.1. The jejunum was the most involved site (47%). The median OS of the whole group was 10 months. The most common presentations were abdominal pain, followed by perforation, diarrhea, obstruction, and gastrointestinal bleeding. The majority presented at stage I&II (53%). The median duration of symptoms before diagnosis was 2 months. Younger patients (p=0.02) and HLH (p=0.006) had worse OS. The time interval between diagnosing CD and EATL impacted OS, with <1 yr and >20yrs having worse outcomes (p=0.04). Combination chemotherapy and stem cell transplant (SCT) were statistically superior to no treatment, with a median OS of 11, 22, and 0.75 months respectively (p=0.002). Further analysis revealed that surgical resection imparted a survival advantage in combination with chemotherapy and SCT. When surgical resection was incorporated into the analysis, median OS amounted to 0.75, 9, 16, 8, 69 months for surgery alone, chemotherapy, surgery+chemotherapy, SCT, and surgery+SCT, respectively (p=0.003). Combinations that used anthracyclines (p=0.02) and etoposide (p=0.05) had better OS. The quality of response to treatment also seemed to impact the outcome (p=0.0001) with median OS of 9, 9, and 69 months for <PR, PR, and CR, respectively. OS was not impacted by stage, constitutional symptoms, presentation with obstruction or perforation, or CD30+. While male sex, colon and visceral involvement, and null TCR type seemed to impact OS negatively, they did not reach statistical significance.
Conclusions: This study presents updated clinicopathologic data from a pooled cohort of patients with EATL. It identifies age, CD duration, HLH, treatment modalities, and quality of response as major determinants of OS in this rare disease.

Combination Therapies for Cancer

Combined inhibition of CDK4/6 and AKT is highly active against the luminal androgen receptor (LAR) subtype of triple negative breast cancer (TNBC)
Maria del Rosario Chica-Parrado, Gun Min Kin, Chang-Ching Lin, Kyung-min Lee, Fabiana Napolitano, Dan Ye, Emmanuel Bikorimana, Saurabh Mendirata,

Ariella Hanker, Carlos L. Arteaga. *UT Southwestern Harold C. Simmons Comprehensive Cancer Center, Dallas, TX*

The LAR subtype of TNBC is enriched for targetable biomarkers, including androgen receptor (AR) expression, *PIK3CA* mutations, and intact Rb. The purpose of this study was to investigate the most effective combinations of inhibitors of CDK4/6 (palbociclib), AR (enzalutamide), and PI3K-AKT (alpelisib/capivasertib) against preclinical models of LAR TNBC. MDA-MB-453 and MFM-223 (both AR positive/Rb-intact/*PIK3CA*-mutant) LAR TNBC cells were treated with each inhibitor alone or in different combinations. Drug sensitivity was measured as growth in 2D, colony formation, and CellTiterGlo viability. Synergistic drug effects were expressed as the combination index (CI) calculated by CompuSyn methods. Activation of cell cycle and PI3K-AKT signaling molecules in response to different inhibitors or siRNAs was measured by immunoblot analysis. An androgen response element (ARE) luciferase reporter assay was used to evaluate AR transcriptional activity. MDA-MB-453 and MFM-223 cells were sensitive to single-agent palbociclib, alpelisib, or capivasertib (IC_{50} ~500 nM) but not enzalutamide (IC_{50} 15-25 μM). Palbociclib combined with either the PI3Kαi alpelisib or the AKTi capivasertib synergistically inhibited growth of both cell lines (CI values, 0.07-0.86). AR transcriptional reporter activity was not altered by any of these treatments. Treatment with palbociclib monotherapy (24 h) suppressed p-Rb and increased phosphorylation of AKT^{S473} and its substrates FOXO3A, GSK3β, and PRAS40, suggesting PI3K/AKT signaling mediates an adaptive response to CDK4/6 blockade. In MDA-MB-453 cells, palbociclib-induced phosphorylation of AKT substrates was suppressed by treatment with capivasertib but not with alpelisib alone or with the PI3Kβ/δ inhibitor AZD8186, suggesting that the compensatory activation of AKT was due to a mechanism independent of the PI3K isozymes. We next used RICTOR siRNAs to block mTORC2-mediated phosphorylation AKT^{S473} after palbociclib treatment. Gene silencing of RICTOR reduced levels of the mTORC2 substrate p-$SGK1^{S422}$ but did not block phosphorylation of AKT^{S473} and its substrates in palbociclib-treated cells, suggesting that this adaptative response was mTORC2-independent. Mean CI values showed that the combination of palbociclib/capivasertib was clearly more synergistic than palbociclib/alpelisib in both cells lines (mean CI, 0.29 vs. 0.78). Currently, we are comparing both combinations in mice bearing established MDA-MB-453 xenografts. Further investigation of the mechanisms of adaptive activation of AKT upon blockade of CDK4/6 in TNBC cells are in progress. In sum, addition of an AKT inhibitor, but not PI3K inhibitors, to palbociclib suppressed the

rebound activation of AKT following treatment with the CDK4/6i, supporting a testable therapeutic strategy in LAR TNBC with intact Rb.

Synergistic antitumor activity of *nab*-sirolimus in combination with *KRAS* inhibitors (KRASis) sotorasib and adagrasib in *KRAS G12C* NSCLC and bladder cancer xenografts

Shihe Hou[1], Andrew Kwon[1], Jorge Nieva[2], Neil Desai[1]. *[1]Aadi Bioscience, Inc., Pacific Palisades, CA,[2]University of Southern California, Los Angeles, CA*

KRAS is frequently mutated in non-small cell lung cancer (NSCLC) and other tumor types, with *KRAS G12C* mutation representing ~12% of patients with NSCLC. Sotorasib (sot) is approved and adagrasib (ada) is under review for the treatment of *KRAS G12C* NSCLC. Mutations in *KRAS* may lead to mTORC1 activation, and mTOR may contribute to adaptive resistance to KRASis. *nab*-Sirolimus (*nab*-S) is a novel albumin-bound nanoparticle form of the mTOR inhibitor sirolimus approved for the treatment of locally advanced unresectable or metastatic malignant perivascular epithelioid cell tumors. This study investigated the antitumor activity of *nab*-s in combination with KRASis in *KRAS G12C* NSCLC and bladder xenograft models. Athymic mice bearing subcutaneous *KRAS G12C*- and *STK11*-mutant NCI-H2030 and NCI-H2122 NSCLC and *KRAS G12C* and *PTEN*-null UMUC3 bladder cancer were treated for 6 weeks with *nab*-s IV at 15 mg/kg/wk, sot or ada (for NCI-H2122 and UMUC3) orally at 30 mg/kg/d alone or in combination. Tumor samples were harvested for analysis of tumor drug levels and biomarkers. In all 3 models tested, single-agent (SA) *nab*-s or KRASis overall showed modest tumor growth suppression. In contrast, *nab*-s in combination with either sot or ada showed greater tumor growth inhibition and a higher meaningful tumor regression rate vs SA (**Table**). There was no significant difference in antitumor activity between combinations of *nab*-s with either sot or ada. High trough intertumoral sirolimus levels were observed in groups treated with *nab*-s alone or in combination with KRASis, indicating sustained presence of sirolimus in the tumor. *nab*-S in combination with either sot or ada showed synergistic antitumor activity compared to the SA. A multicenter, single-arm, open-label Phase 1/2 clinical study is planned to determine the recommended Phase 2 dose, safety, tolerability, and efficacy for the combination of ada and *nab*-s in patients with *KRAS G12C* tumors.

Clinical evaluation of a functional combinatorial precision medicine platform reveals combination-specific sub-populations in t-cell lymphoma

Edward Kai-Hua Chow[1], Masturah Rashid[2], Sanjay Prasad De Mel[3], Jasmine Goh[1], Anand Jeyasekharan[4]. *[1]Cancer Science Institute, National University of Singapore, Singapore, Singapore,[2]KYAN Therapeutics, Singapore, Singapore,[3]2NUS Center for Cancer Research (N2CR), Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore,[4]Cancer Science Institute, National University Singapore, Singapore, Singapore*

T-cell lymphoma (TCL) is a heterogenous subgroup of non-Hodgkin's lymphoma with poor prognosis. Approved targeted monotherapies have seen limited success due to lack of effective combinations or identification of sensitive patient populations. Hence, there is a need to develop alternative strategies to identify effective combinations for individual patients and specific TCL sub-populations. We interrogated the potential for an ex vivo combinatorial drug sensitivity platform, Quadratic Phenotypic Optimization Platform (QPOP), in a clinical study for relapsed/refractory Non-Hodgkin Lymphoma (RR-NHL) to identify effective subtype-specific combinations through a functional combinatorial precision medicine approach.

We analyzed 37 primary samples from patients with RR-NHL of both T- and NK-cell origin in Singapore, with disease amenable to biopsy or blood/ marrow aspiration. Single cell suspensions from tumor samples were treated with a panel of 12 drugs with known preclinical or clinical efficacy against TCL. Post-drug treatment cell viability was used as a phenotypic input for QPOP analysis, which maps experimental data points to a second-order quadratic function to predict cell killing efficacies for all possible permutations of drug combinations. Romidepsin-based combinations appeared among the top ranked QPOP-derived 2-drug combinations with predicted output cutoff < 0.55 in 91.8% of samples treated with similar QPOP drug panel. Among these combinations, combinations with copanlisib, ifosfamide and venetoclax were the most frequently occurring doublet, appearing in 24, 14 and 8 samples, respectively. A total of 10 patients received QPOP-derived romidepsin-based combinations at physicians' discretion. We noted outcomes of stable disease or better in 7/10 (70%) patients, with clinical benefit seen in 2 complete responses and 2 partial responses (40%). Thus, romidepsin-based combinations showed improved outcomes for TCL patients compared to the prior reported overall response rate of 25% that led to romidepsin's approval as monotherapy. This study showed the clinical utility of QPOP in identifying combination therapy-specific sub-populations in TCL. Targeted agents, such as romidepsin, copanlisib and venetoclax, that have previously been explored as single agents in TCL were predicted by QPOP to be more effective in the proper combination for the proper patient. This study demonstrates that functional combinatorial precision medicine platforms, such as QPOP, may improve clinical outcomes through identification of more appropriate combination therapies. This work, as well as additional studies in other cancer types, provide evidence towards the need for optimal combination therapy design and the potential of functional precision medicine to improve precision and personalized cancer treatment.

Combining bromodomain and extraterminal (BET) protein inhibitor treatment with standard MAPK inhibitors improved MAPK signaling inhibition in colorectal cancer

Hey Min Lee[1], Alexey Sorokin[1], Preeti Kanikarla Marie[1], Saikat Chowdhury[1], Anand Singh[2], Amanda Anderson[1], Jumanah Yousef Alshenaifi[1], Funda Meric-Bernstam[3], Kunal Rai[2], Scott Kopetz[1]. *[1]GI Medical Oncology Department, UT MD Anderson Cancer Center, Houston, TX,[2]Genomic Medicine Department, UT MD Anderson Cancer Center, Houston, TX,[3]Investigational Cancer Therapeutics Department, UT MD Anderson Cancer Center, Houston, TX*

Background: Overexpression and activation of the MAPK signaling pathway is known to play a key role in colorectal cancer (CRC) progression. Substantial efforts have been made to target MAPK signaling pathways in CRC, particularly blocking oncogenic mutations in KRAS or BRAF. However, standard treatments targeting MAPK signaling have demonstrated limited activities in CRC patients and are in strong need of improved efficacies. Thus, we investigated how the combination of BET inhibitor treatment could affect MAPK signaling activation.
Methods: We performed a wide-scale drug combination study testing 15 drug combinations using CRC patient-derived xenograft (PDX) models. PDX models were treated for 21 days, and tumor volume and body weight changes were measured for assessment of treatment responses and toxicities. For the BET inhibitor (iBET-151) plus MEK inhibitor (binimetinib or trametinib) combination, RNA-seq and RPPA was performed on PDX tumor tissues collected after 7 days of treatment for pharmacodynamics study (n=3 per treatment condition). Tumors collected on day 21 were sequenced for H3K27Ac ChIP-seq and IHCs for understanding epigenomic changes in active enhancers and target validations.
Results: Our preliminary screening of 15 drug combinations in CRC PDX models have shown the most promising and active responses in a combination of BETi with MEKi (5 out of 20 PDXs obtained tumor regression). Preclinical H3K27ac ChIP-seq data has shown lost enhancer peaks after BET inhibition were significantly associated with RAS signaling pathways ($q<0.05$). Gene set enrichment analysis on preclinical transcriptomic data also demonstrated downregulation of KRAS-signaling in BETi plus MEKi combination treatment compared to MEKi as monotherapy ($p<0.05$). MAPK activation scores (MPAS) were also significantly downregulated in transcriptomic and enhancer levels under BETi plus MEKi combinations compared to MEKi. Downstream transcription factors of MAPK signaling pathways, such as MYC and FOSL1,

were synergistically downregulated in combination with BETi. Also, we found downregulation of EREG, a member of the epidermal growth factor (EGF) family, under BET inhibition which may play a role in MAPK downregulation together with standard therapy.
Conclusions: Some studies have shown MAPK signaling activation as a resistance mechanism of BET inhibition in multiple cancer types. However, the understanding of the crosstalk between the activity of BET inhibition in a combination with MAPK signaling inhibition is limited in CRC. We found BET inhibition induces deeper inhibition of MAPK pathway activation together with standard targeted therapies. Our data demonstrated transcriptomic and epigenetic levels of the mechanism of BETi activity together with MAPK inhibition in CRC.

Synergy between FAK and PI3K inhibitors in cervical and pancreatic cancer cells

Chao-Cheng Chen[1], Suyang Wang[1], Jr-Ming Yang[1], Chuan-Hsiang Huang[2].
[1]Pathology, Johns Hopkins Medicine, Baltimore, MD,[2]Johns Hopkins Medicine, Baltimore, MD

The Ras/PI3K/ERK signaling network is frequently mutated in many cancer types including cervical cancer and pancreatic cancer. Our previous study suggested that PI3K and FAK form a positive feedback loop to modulate ERK activation. We tested combined inhibition of FAK and PI3K on the growth of cervical and pancreatic cancer in vitro. We found that FAK and PI3K inhibitors synergistically inhibited the growth of some cervical cancer and pancreatic cancer cell lines. The synergy was due to both increased apoptosis and decreased cell proliferation. Molecularly, FAK inhibition caused downregulation of PI3K and ERK signaling in cervical cancer but not pancreatic cancer cells. Interestingly, PI3K inhibitors induced activation of several RTK including insulin R and IGF-1R in cervical cancer cells, as well as EGFR, Her2, Her3, Axl, and EphA2 in pancreatic cancer cells. Together, our results show the promise of combining FAK and PI3K inhibition for cervical cancer and pancreatic cancer treatment, but biomarkers for sensitivity to the combination are needed, and concomitant RTK inhibition may be required to combat potential resistance to the combination.

Synergistic activity of SCD1 blockade in combination with tyrosine kinase inhibitors lenvatinib and cabozantinib in hepatocellular carcinoma (HCC)

Justyna J. Gleba[1], Aylin Alasonyalilar-Demirer[1], Matthew L. Pawlush[1], Ahmet Bilgili[1], Peyton G. Hickman[1], Kabir Mody[2], Lewis R. Roberts[3], Steven R. Alberts[4], Mark J. Truty[5], Tushar C. Patel[3], Han W. Tun[6], John A. Copland[1].

[1]Cancer Biology, Mayo Clinic Cancer Center Florida, Jacksonville, FL,[2]IMV Inc, Dartmouth, NS, Canada,[3]Gastroenterology and Hepatology, Mayo Clinic Cancer Center Florida, Jacksonville, FL,[4]Medical Oncology, Mayo Clinic Cancer Center Florida, Jacksonville, FL,[5]General and GI Surgery, Mayo Clinic Cancer Center Florida, Jacksonville, FL,[6]Hematology/Oncology, Mayo Clinic Cancer Center Florida, Jacksonville, FL

Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer. Tyrosine kinase inhibitors (TKIs) are approved as a first-line treatment for unresectable HCC. Lenvatinib and cabozantinib are two of the most used TKIs, but the therapeutic duration is limited due to the development of drug resistance. Therefore, understanding the mechanisms of resistance and combining TKIs with other drugs antagonizing resistance should lead to antitumor synergy, eliminating drug resistance. It turns out that the simultaneous use of TKIs together with an inhibitor of stearoyl-CoA desaturase 1 (SCD1) prevents the development of drug resistance, leading to a durable response. SCD1 is the enzyme responsible for *de novo* fatty acid (FAs) synthesis, converting saturated fatty acids (SFAs) into monounsaturated fatty acids (MUFAs). MUFAs are an alternative energy source to glucose, integral to cellular membranes, and prevent endoplasmic reticulum (ER) stress and other signaling pathways. In our laboratory, we developed a novel, highly specific SCD1 inhibitor - SSI-4. We have tested the biological activity of SSI-4 against different HCC cell lines and patient-derived xenografts (PDX) mouse models. Of the twelve tested HCC cell lines, four were highly sensitive to SSI-4 (IC_{50} 1-50 nM). Other cell lines showed moderate or no sensitivity to SSI-4. We tested the concomitant use of SSI-4 with lenvatinib and cabozantinib, tyrosine kinase inhibitors (TKIs) FDA-approved for HCC, in HCC cell lines *in vitro* and using HCC PDX *in vivo* mouse models. Our studies showed that the combination of the SCD1 inhibitor with both lenvatinib and cabozantinib showed a highly synergistic effect and no development of drug resistance i.e. durable response versus single TKI therapy. Ongoing mechanistic studies are examining whether known molecular targets of tested TKI's such as VEGFR1, 2, and 3, PDGFRα, FGFR, KIT, and RET dominate in HCC drug resistance to lenvatinib and

cabozantinib, and how the use of SSI-4 overcomes the phenomenon of resistance.

#5490

Combination of the PI3k inhibitor Paxalisib with the nucleoside analog Gemcitabine over-activates the integrated stress response and induces atypical teratoid/rhabdoid tumor cell death

Tyler Findlay, Kristen Malebranche, Anupa Geethadevi, Eric Raabe, Charles Eberhart, Jeffrey Rubens. *Johns Hopkins University School of Medicine, Baltimore, MD*

We have previously identified high activation of both mTORC1 and mTORC2 in the aggressive infantile brain tumor, atypical teratoid/rhabdoid tumor (AT/RT). Paxalisib is a highly brain penetrant PI3k inhibitor which acts upstream of mTOR to simultaneously inhibit mTORC1/2. Paxalisib is well-tolerated in ongoing pediatric clinical trials. In murine orthotopic xenograft models of AT/RT, Paxalisib significantly extended survival (CHLA-06: 40 to 54 days, p=0.001; BT12: 21 to 35 days, p=0.02). However, to improve the durability of this single agent therapy, we evaluated the efficacy of rational therapeutic partners. Analysis of RNAseq following mTOR inhibition (mTORi) of 4 cell lines representative of AT/RT showed an upregulation of genes associated with the integrated stress response (ISR), (*ATF4*: CHLA-06, *t*-test $p<0.05$; *CHOP*: CHLA-02, CHLA-06 *t*-test $p<0.001$). The activation of the ISR is further suggested through induction of *PPP1R15A*, a gene whose activation is closely associated with stress events and leads to downstream cell growth arrest and apoptosis (BT37 *t*-test $p<0.001$, CHLA-02, CHLA-06, CHLA-266, *t*-test $p<0.01$). Gemcitabine is a pyrimidine nucleoside prodrug, which inhibits DNA synthesis and induces DNA damage. As a result, Gemcitabine also induces phosphorylation of eIF2α and the activation of the ISR. While the ISR can be protective, intense or prolonged activation leads to cell death. We therefore hypothesized that Paxalisib would combine with Gemcitabine to hyper-activate the ISR and drive AT/RT cell death. Through Western blot analysis, we demonstrate that combination therapy increases phospho-eIF2α, ATF4, and CHOP compared to DMSO control. Furthermore, we demonstrate that combination therapy increases apoptosis (Western blot cPARP, MUSE Annexin V Assay) and synergizes to decrease AT/RT cell growth (SynergyFinder BLISS score CHLA-06: 16.8, BT12: 14.3, CHLA-266: 13.9, BT37: 11.4, CHLA-05: 10.4). Ongoing treatment of mice bearing CHLA06 orthotopic tumors demonstrate that combination therapy further extends median survival. Our

studies suggest that pharmacologically activating the ISR may be an effective strategy to target AT/RT and combination of Paxalisib and Gemcitabine may be an effective treatment to help extend survival in this deadly disease.

Determining effects of the CD206 positive M2 macrophage depleting engineered exosome in combination with anti PD1 therapy in breast tumor

Mahrima Parvin[1], Mohammad H. Rashid[2], Ahmet Alptekin[2], Ali S. Arbab[3].
[1]Biochemistry and Cancer Biology, Augusta University, Augusta, GA,[2]Georgia Cancer Center, Augusta University, Augusta, GA,[3]Medical College of Georgia, Augusta University, Augusta, GA

Introducti**on:** Triple negative breast cancer (TNBC) subtype of breast cancer, which lacks molecular markers such as HER2 and estrogen/progesterone receptors, has limited treatment options. Exosomes are nano-sized (30-150 nm) spherical vesicles, derived from the endosomal system for intercellular communications, can be engineered to express targeting peptides to target specifically CD206 positive M2 macrophage. Investigators have used either synthetic nanoparticles or fusion protein to deliver Fc-IgG2b to initiate Antibody dependent cellular cytotoxicity (ADCC) but reports are showing a lack of ADCC following tagging with gold nanoparticles. To overcome this, in our lab, we developed engineered exosomes in non-tumorous cells, HEK293, to carry therapeutic Fc-mIgG2b to enhance ADCC and to carry peptide to deplete CD206+ M2 macrophages. We investigated the effectiveness of engineered therapeutic exosomes to target and deplete immunosuppressive CD206+ M2 macrophages in TNBC in combination with anti PD-1.
Methods: In this study, we developed syngeneic metastatic TBNC model (luciferase + 4T1 cells in Balb/c) by implantation of 50K 4T1-luci cells in fat pad. On day 1 of tumor implantation, animals were treated with vehicle, engineered exosomes, anti-PD1 plus engineered exosomes, 2 dose/week for 3 weeks. They were euthanized 1 day after the last dose of treatment. Single-cell suspension was made from the primary TME, lung, and spleen. Using flow cytometry surfaces markers were investigated to determine different T-cell and myeloid cell populations.
Results: We observed very surprising results following three weeks of therapies. Although the number of cytotoxic T-cells was significantly higher in the primary and metastatic TME in exosome-treated animals, there was also an increased number of proliferative T reg cells. The number of CD8+ cells was decreased following concurrent therapy with an anti-PD1 antibody. Most interestingly, lung

tissue macrophages (CD11c) showed significantly increased PD-L1 expression following exosomes and anti PD1 with engineered exosomes therapies.
Conclusion: This study demonstrates that treatment with engineered therapeutic exosome targeting M2 macrophages with anti PD-1 could be utilized effectively. This study will also make a greater impact in exosome engineering based targeted therapy and will open new arena to target and deplete pathogenic cell in different tumors using engineered exosome.

Novel strategy to make KRAS targeted therapies more effective for PDAC treatment

Ana I. Martinez Bulnes[1], Orlando Garcia[1], poornima Shaji[2], Swathi Holla[3], Nirnoy Dan[4], Anupam Dhasmana[1], Shabnam Malik[1], Murali Yallapu[5], Stephen Behrman[6], Subhash Chauhan[1], Sheema S. Khan[5]. *[1]Immunology and Microbiology, University of Texas Rio Grande Valley, McAllen, TX,[2]UT Southwestern Medical Center, Dallas, TX,[3]Immunology and Microbiology, Baylor College of Medicine, Houston, TX,[4]University of Connecticut, Connecticut, NY,[5]Immunology and Microbiology, University of Texas Rio Grande Valley, edinburg, TX,[6]Medicine, University of Tennessee Health Science Center, Memphis, TN*

Introduction**:** Pancreatic Ductal Adenocarcinoma (PDAC) patients exhibit extremely poor prognosis. KRAS mutation on codon-12 is present in 70-95% of PDAC cases and it drives PDAC growth and progression. Galectin-1 (Gal-1) is present in both PDAC and stromal cells, being involved in tumor microenvironment, immune cell activation and metastasis. Therefore, this study discusses the efficiency of combined inhibition of mutated $KRAS^{G12D}$ and Gal-1 inhibition to effectively suppress PDAC growth and progression. For this we have delivered $KRAS^{G12D}$ inhibiting siRNA ($siKRAS^{G12D}$) using a superparamagnetic iron oxide nanoparticle (SPION) and a galectin inhibitor.
Methods: SPION nano-formulation was used to deliver $siKRAS^{G12D}$ and investigate in conjunction with Gal-1 inhibitor for its anticancer efficacy. Particles were investigated for size, physico-chemical characterization (Dynamic light scattering), hemocompatibility (hemolysis assay) and the complexation of siKRAS (gel retardation assay). Cellular internalization and uptake of the particles were investigated. Anti-cancer efficacy was determined using *in vitro* functional assays for cell viability (MTT), migration (Boyden chambers),

invasion (Matrigel), clonogenicity, tumor spheroid formation, and in a *KrasG12D;LSL-Trp53R172H* syngeneic mouse model.
Results: Our results demonstrate that SP-siKRAS efficiently internalized in PDAC cells and suppressed $KRAS^{G12D}$ as well as its downstream targets, YAP and PDL-1. Combined targeting of siKRAS and Gal-1 inhibited cell proliferation, clonogenicity, migration, and invasion of PDAC cells and tumor spheroid growth in 3D cell models, which recapitulate the heterogeneity and pathophysiology of PDAC. We have used -*KrasG12D;LSL-Trp53R172H* syngeneic mouse model of PDAC for investigating efficacy of combined SP-siKRAS formulation and galectin-1 inhibitor. Our results showed that the combination treatment inhibited the fibrotic tumor growth and increased survival rate. The combined treatment increased infiltration of total T cell population and CD8+T cells, reduced the population of myeloid-derived suppressor cells (MDSCs) by 50%
(CD45+, CD3-, CD11b+, Ly6C high, Ly6G-) and T-Regulatory cells (Treg) by 57% (FoxP3+CD25+CD45+CD3+) and increased memory T cells by 34% in mice.
Conclusion: This gene therapy targeting KRAS G12D mutation with a Gal-1 inhibition has a potential to modulate the oncogenic network and tumor microenvironment resulting in the repression of growth, metastasis, chemoresistance, and improvement in patient survival. This study will develop a novel sustainable therapeutic approach to target PDAC growth and improve patient survivability.

#5494
Preclinical combination of ONC201 with radiotherapy and Temozolomide in a GBM mouse orthotopic model results in reduced tumor burden and prolonged survival
Lanlan Zhou, Laura Jinxuan Wu, Jun Zhang, Andrew George, Marina Hahn, Leiqing Zhang, Attila A. Seyhan, Wafik S. El-Deiry. *Pathology and Laboratory Medicine, Legorreta Cancer Center at Brown University, Providence, RI*

Glioblastoma (GBM) is the most common and lethal primary malignancy of the central nervous system. It is estimated that more than 13,000 new cases of GBM will be diagnosed this year in the United States. Despite multidisciplinary treatments such as surgery, chemotherapy, and radiotherapy, the five-year survival rate for GBM patients is only 6.8 percent and has shown no notable improvement in the last three decades. There have only been five drugs and one device ever approved by the FDA for the treatment of GBM since it was first

identified in the scientific literature in the 1920's. Our *in vitro* studies suggested that first-in-class small-molecule imipridone TIC10/ONC201 can inactivate ERK/AKT, induce the integrated stress response (ISR), upregulate pro-apoptotic TRAIL receptor DR5, deplete cancer stem cells, and induce mitochondrial dysfunction, growth arrest or cell death in GBM cells. Knockdown of ClpP protects GBM cells from ONC201 but not TMZ. ONC201 crosses the blood-brain barrier and has induced durable tumor regressions in adult and pediatric H3K27M-mutant diffuse midline glioma patients. We hypothesized that ONC201 may synergize with radiotherapy and temozolomide in GBM. GBM mouse orthotopic models were established through intracranial injection of luciferase expressing U251 GBM cells with a KOPF model 940 small animal stereotaxic frame and a Stoelting Quintessential Stereotaxic Injector. Tumor formation and growth was confirmed with bioluminescence imaging. Randomized treatment group mice received weekly treatment of ONC201 (100 mg/kg p.o.) and/or radiotherapy (2 Gy local irradiation) and/or TMZ (20 mg/kg i.p.) for four weeks for long term survival and tumor monitoring or one week for short term biomarker studies. We observed that the triple combination of ONC201, radiotherapy and TMZ significantly prolongs survival and reduces tumor burden compared to single treatment and dual combinations. Short term biomarker studies demonstrated that triple combination treatment decreases tumor cell proliferation, induces more apoptosis and inhibits ClpX to unleash mitochondrial ClpP. Our data support further development of the triple combination regimen of ONC201, TMZ and radiation therapy for GBM first-line treatment.

#5495

Combination therapy with poly (ADP-ribose) polymerase inhibitor in endometrial cancer

Conway Xu, Xiaonan Hou, Erik Jessen, Chen Wang, S. John Weroha. *Mayo Clinic, Rochester, MN*

Objective: Endometrial cancer (EC) is the most common gynecologic malignancy and serous histology is the second most common subtype. It is associated with poorer outcomes as recurrent disease tends to be resistant to chemotherapy. Given the dearth of proven targeted therapies in this setting and the tendency for serous ECs to have homologous recombination deficiency (HRD), this study aimed to test the synergy between poly (ADP-ribose) polymerase inhibitors (PARPis) and SN38, an active metabolite of DNA topoisomerase I, irinotecan. PARPis are currently FDA approved in ovarian

cancer and have their greatest efficacy in tumors with HRD while topoisomerase inhibitors are a standard chemotherapy option for recurrent cancer.
Methods: A genomic instability score (GIS) was derived from low-pass whole genome sequencing-based bioinformatics analysis according to three previously reported HRD metrics: telomeric allelic imbalance, large state transitions, and loss of heterozygosity. GIS was calculated for 34 patient derived xenograft (PDX) tumors, of which eight had serous histology. PARPi, rucaparib, and SN38 were used to treat EC PDX tumors in e*x vivo* 3D cell culture experiments using RealTime Glo for viability after 4-5 days of drug exposure. Synergy was assessed by calculating the combination index (CI) using Chou-Talalay method.
Results: GIS ≥ 42 was noted in 62.5% (5/8) of serous EC PDX tumors and only 19.2% (5/26) of non-serous EC PDX tumors. Synergy (CI < 1.0) between rucaparib and SN38 was demonstrated in 85.7% (6/7) of serous EC PDX *ex vivo* 3D cell culture experiments, but only 62.5% (10/16) of non-serous EC PDX tumors.
Conclusions: Most serous EC PDX tumors had a high GIS, consistent with HRD, when compared to a minority of non-serous histologies. Furthermore, combination therapy of rucaparib and SN38 had a synergistic effect in almost all serous EC PDX models, while still being effective in a majority of non-serous models. Additional PDX tumors need to be assessed to establish the predictive value of a GIS on synergy between rucaparib and SN38. Further *in vivo* studies are also needed to confirm these *ex vivo* findings of synergy. Ultimately, the hope is to generate preclinical data which justifies the use of PARPis in serous ECs as monotherapy or in combination with other anticancer therapies.

Glutaminase inhibition induces replication stress in ovarian cancer cells and inhibition of replication checkpoint causes synthetic lethality

Pamela Luna, Ganesh Acharya, Damieanus Ochola, Swetha Peddibhotla, Chinnadurai Mani, Mark B. Reedy, Komaraiah Palle. *Texas Tech University Health Sciences Center, Lubbock, TX*

Ovarian cancer (OC) is a highly aggressive disease and the most lethal gynecologic malignancy in women. Although the majority of OC patients respond to chemotherapeutic drugs, more than 70% of the patients relapse and die as a result of chemoresistance. Therefore, novel therapeutics are warranted to prevent chemoresistance and treat the relapsed disease to improve prognosis. Many cancer cells depend on Glutamine as major carbon source and these cells have high Glutaminase (GLS) expression, an enzyme that converts Glutamine to

Glutamate. Chemo-resistant OC cells have elevated levels of GLS, which confirms their increased dependency on glutamine metabolism. Based on these observations, we postulated that GLS inhibition may attenuate the aggressive growth of GLS ^{high} OC cells and may sensitize to the agents that can further potentiate these effects. Interestingly, GLS inhibition using a clinical-stage drug CB839 caused replication stress and activated DNA damage checkpoint protein 1 (CHK1) mediated cell cycle arrest. These novel findings suggested a role for CHK1 in protecting GLS inhibition-induced DNA damage by facilitating the timely repair of DNA breaks. Based on these observations, we hypothesized that GLS inhibition in combination with CHK1 inhibition may cause synergistic lethality in chemo-resistant and GLS^{high} OC cells. We evaluated the combination of GLS inhibitor CB839 and CHK1 inhibitor Prexasertib. Our results demonstrate that GLS inhibition-induced CHK1 phosphorylation is significantly attenuated by Prexasertib treatment. Similarly, combined treatment of CB839 and Prexasertib showed significantly elevated levels of DNA damage as measured by COMET assays, replication stress-mediated DNA damage responses, and synergistic OC cell lethality compared to individual drug treatments. Furthermore, CB839 and Prexasertib combination was more synergistic in cells that expressed high GLS compared to low GLS-expressing OC cells indicating the specificity of the combination of these drugs. Together, our studies identified a novel connection between metabolic and DNA damage checkpoint pathways in OC and propose a novel synergistic lethality-based combination therapy to treat chemo-resistant and aggressive OC.

Venetoclax and dinaciclib elicit synergisticpreclinicalefficacy against high-risk B-cell leukemia

Ernesto Diaz-Flores, Holly Pariury, Mignon Loh. *UCSF - University of California San Francisco, San Francisco, CA*

Hypodiploid acute lymphoblastic leukemia (ALL) is an aggressive blood cancer with a poor prognosis despite intensive chemotherapy or stem cell transplant. Children and adolescents with positive end-of-induction minimal residual disease (MRD) have an overall survival lower than 30%. However, data regarding therapeutic alternatives for this disease is nearly non-existent, emphasizing the critical need for new or adjunctive therapies that can improve outcomes. We previously reported on the therapeutic efficacy of venetoclax (ABT-199) in hypodiploid B-ALL but with limitations as monotherapy *(Diaz-Flores, Cancer Research, 2019)*. Accordingly, hypodiploid B-ALL patient

derived xenografts treated with Venetoclax developed therapeutic resistance over time. To better understand the mechanism of resistance that arises following inhibition of BCL-2, we first generated a hypodiploid cell line (NALM-16) deficient in BCL-2. Given that BCL-2 plays an essential role in B-cell function standard CRISPR/Cas9 knockout strategies greatly impaired survival. We overcame this limitation by using a magnetic levitation system (the LeviCell by LevitasBio). Analysis of the surviving clones identified an increase in MCL1 (**Fig. 1A**). We then harnessed unbiased drug screen (>1800 bioactive compounds) followed by selection of synergistic drug combinations identified Dinaciclib as an efficient drug combination with Venetoclax in eliminating leukemic cells in vitro. Interestingly, mechanistic studies identified that Dinaciclib, through transcription regulation (RNApol II) significantly modulates MCL-1. Data using knock-outs and knock-ins of MCL-1 indicated how MCL-1 only becomes essential for survival when Venetoclax is present. Preclinical studies using patient derived xenografts indicated that, while none of the drug monotherapies achieved complete blast elimination, venetoclax + dinaciblib led to complete resolution of the leukemic burden within all solid organs analyzed (**Fig. 1B**). This combination therapy was relatively well tolerated. This study also indicates that high BCL-2 and MCL-1 levels with concomitant BIM, BAD and/or PUMA levels, represent biomarkers for response to this combination. In summary, our study identified a highly synergistic drug combination, venetoclax and dinaciclib, for the treatment of hypodiploid B ALL, an aggressive leukemia with few effective current therapies. Finally, the promising results presented in this study may prompt further studies to support the inclusion of hypodiploid and other B-ALL patients to clinical trials combining phase I/II drugs against BCL-2 (mainly venetoclax) and CDK9 (dinaciclib, alvocidib, flavopiridol, SNS-032) or MCL-1 (MIK-665).

SHP2 inhibition enhances antitumor effect of mirdametinib in a pediatric brain tumor model bearing CDC42SE2BRAF fusion by rewiring the proteome and phosphoproteome landscape

Nur P. Damayanti[1], Anthony Alfonso[2], Josue D. Ordaz[1], Erika Dobrota[3], M. Reza Saadatzadeh[3], Pankita Pandya[2], Barbara J. Bailey[1], Khadijeh Bijangi-Vishehsaraei[2], Harlan E. Shannon[2], Kathy Coy[2], Melissa Trowbridge[2], Anthony L. Sinn[2], Rosa Gallager[4], Julia Wulfkuhle[4], Emanuel Petricoin[4], amber mosley[2], Mark S. Marshall[2], Alex Lion[2], Michael J. Fergusson[2], karl balsara[5], Karen E. Pollok[2]. *[1]Neurological Surgery, Indiana University School of Medicine, Indianapolis, IN,[2]Indiana University School of Medicine, Indianapolis,*

IN,[3]Pediatric, Indiana University School of Medicine, Indianapolis, IN,[4]George Mason University, Manassas, VA,[5]Neurological Surgery, University of Oklahoma School of Medicine, Oklahoma, OK

Pediatric gliomas are the most common type of pediatric brain tumors representing wide range of molecularly and clinically heterogenous subtypes. The hyperactivity of mitogen-activated protein kinases (MAPK) pathway has been identified in the majority of pediatric glioma suggesting its therapeutic potential. However, pharmacologic targeting single MAPK pathway's component is limited due to the development of drug resistance and differential response associated with tumor molecular landscape. Therefore, effective combination strategy in the framework of precision medicine is needed. Here we report combination benefit and molecular underpinning therapeutic response of brain penetrant MEK inhibitor (mirdametinib) and SHP2 inhibitor (SHP099) in a pediatric patient derived xenograft (PDX) and xenoline developed at our institution. Our model was derived from a pediatric patient who was diagnosed with rare high-grade subtype of glioma, anaplastic pleomorphic xanthoastrocytoma, and did not respond to MEK inhibitor, trametinib. Integrative multi-omics revealed molecular fidelity between our model and its patient tumor counterpart including the presence of 7q35 fusion, *CDC52SE2-BRAF*, *CDKN2A/B* loss, and MAPK pathway hyperactivation. *In vitro* studies using our xenoline IU-X128 demonstrated synergy between SHP099 and mirdametinib to curtail cell proliferation ($p<0.05$). Moreover, this combination was well tolerated in our PDX, IU-RHT128, and potentiated anti-tumor effect of the single agent within clinically achievable doses. Reverse Phase Proteome Array (RPPA) identified MAPK reactivation via Mushasi RNA binding protein-PI3K-AKT crosstalk as a potential innate resistance mechanism to single agent MEK inhibitor in the PDX tumor. Further, tandem mass tags (TMT)-LC-MS/MS profiling on tumor treated with single agent SHP099 or mirdametinib and their combination revealed that combination therapy does not only revert certain proteome and phosphoproteome reprogramming from single agent treatment but also created a novel landscape which can be associated with anti-tumor effect. In this case, kinase network reprograming leading to MAPK reactivation was identified in mirdametinib treated tumor which was attenuated in the combination treatment. In summary, our results demonstrated that combination SHP099 and mirdametinib is superior to single agent alone in the pediatric A-PXA brain tumor model with proteome and phosphoproteome reprogramming of multiple networks as potential molecular mechanisms underlying therapeutic benefit of combination therapy. Ultimately, clinical translation of this finding

will potentially benefit patient of this malignant rare pediatric glioma subset which currently does not have standard therapy.

Synergistic effects of the combination of ERK1/2 with EGFR, KRAS^{G12C}, CDK4/6, and PD-L1 inhibition for cancer treatment

Ya Kong[1], Peng Chen[1], Lulu Jiang[1], Bin Jiang[2], Jay Mei[3], Bo Shan[3], Bing Hou[3].
[1]Shanghai Antengene Corporation Limited, Shanghai, China,[2]Antengene Biotech LLC, Shanghai, PA,[3]Antengene Corporation, Shaoxing, China

Background: Mitogen-activated protein kinase (MAPK) cascade is a key pathway that regulates a wide variety of cellular processes, which is frequently activated in cancers. Many nods of the MAPK pathway are considered as promising anti-tumor drug targets, such as RTKs, KRAS^{G12C}, RAF, MEK1/2, and ERK1/2. Multiple inhibitors targeting proteins on MAPK pathway have been developed for cancer treatment. However, the effectiveness of these inhibitors is often limited due to acquired drug resistance via pathway feedback activation, indicating the necessity of combination strategies to help block reactivation or bypass activation of MAPK pathway. ATG-017 is an oral, potent, and highly selective inhibitor of ERK1/2, which is under Phase 1 clinical investigation. This study tested the *in vivo* antitumor effects induced by the combination of ATG-017, with EGFR inhibitor (Osimertinib), KRAS^{G12C} inhibitor (ATG-012), CDK4/6 inhibitor (Abemaciclib) or PD-L1 inhibitor (Atezolizumab), in preclinical tumor models.
Methods: The *in vivo* combinations of the drugs were tested in NCI-H1975, NCI-H358 (non-small cell lung cancer) or EL4 (T cell Lymphoma) CDX mouse models. The tumor bearing mouse were treated with vehicle control, ATG-017 (15 or 25 mg/kg, QD), Osimertinib (1mg/kg, QD), ATG-012 (10mg/kg, QD), Abemaciclib (25mg/kg, QD), Atezolizumab (10mg/kg, BIW) or the combination for 9 to 21 days. The tumor size was measured twice a week and tumor growth inhibition (TGI) was evaluated compared with vehicle group. Tumor tissues were collected for tumor infiltrating lymphocyte (TIL) analysis using Flow cytometry or multiplex IHC.
Results: In the NCI-H1975 CDX *in vivo* study, the monotherapy of ATG-017 and Osimertinib induced TGIs of 61.95% and 79.18%, respectively on day 17 after grouping. The combination of ATG-017 and Osimertinib showed 101.85% TGI. In the NCI-H358 CDX *in vivo* study, the monotherapy of ATG-017, ATG-012, and combination induced TGI of 44.29% ,73.71% and 97.13%, respectively on day 8 after grouping. The monotherapy of ATG-017, Abemaciclib, and the

combination induced TGIs of 91.40% ,63.10% and 108.15%, respectively on day 20 after grouping. In the EL4 syngeneic T cell lymphoma model, neither ATG-017 nor Atezolizumab showed single agent activity, while the combination induced a significant TGI of 21.86% on day 9 after grouping. The percentage of infiltrating CD8+ T cells, CD8:CD4 ratio and M1:M2 macrophage ratio were found increased in the combination group, suggesting the potential role of ATG-017 plus PD-L1 inhibitor in changing a "cold" tumor towards a "hot" phenotype. Conclusion: Strong synergism has been observed for the combination of ATG-017 with EGFR, $KRAS^{G12C}$, CDK4/6, and PD-L1 inhibition, suggesting promising therapeutic strategies for cancer patients that warrants further investigation.

Patient-derived organotypic cultures (PDOCs) from melanoma metastases as a precision medicine test to improve patient management

Antonella Bresin[1], Fiorenza Lotti[2], Lauretta Levati[1], Pier F. Ferrucci[2], Francesca Ricci[1], Francesco Scicchitano[1], Zorika C. Di Rocco[1], Giandomenico Russo[1], Luisa Lanfrancone[2]. *[1]IDI-IRCCS, Rome, Italy,[2]European Institute of Oncology, Milan, Italy*

INTRODUCTION Despite significant improvements in advanced melanoma therapy, there is still a pressing need for innovative therapies. Here, we optimized a method for testing the drug sensitivity of PDOCs and evaluated whether this preclinical model could be a valid tool for rapidly determining the patient's tumor response profile to approved and alternative therapies.
METHODS PDOCs were generated from melanoma metastases (> 60 specimens) after mechanical or enzymatic dissociation. Tissue fragments (<70um) were harvested, embedded in 3D collagen beads (1.5 mg/mL type I collagen), and cultured in a 96-well plate for 6 days, maintaining tumor and stromal viability. More than 20 primary cell lines from the same samples were also stabilized. The melanoma cells or the PDOCs were left untreated or treated with the patient's own therapy or with alternative drugs, and the efficacy of treatments was evaluated by MTT assay and flow cytometry. CD8+ T cell infiltration and cytokine secretion were also investigated.
RESULTS The first experiments were set up to validate PDOCs as predictive preclinical models of patient response to therapy. We tested approved melanoma therapies (i.e., the combination of BRAF and MEK inhibitors, or anti-PD-1 antibodies) on the same melanoma specimens at the IDI and IEO institutes. More than 10 different samples were compared, finding reproducible results

between the two Institutions. Furthermore, drug response in PDOCs was comparable to the clinical response of matched patients undergoing the tested therapy, demonstrating PDOCs are reliable predictive tools. Then, we used primary cell lines to screen a pool of ten different targeted agents selected through functional screening of a bioactive library of 512 compounds on patient-derived xenografts, and based on known drug resistance mechanisms in melanoma. The three best-performing compounds were subsequently studied in PDOCs as single agents or in combination with immunotherapy. We found high heterogeneity of drug efficacy in different melanoma samples with no obvious correlation to BRAF or NRAS mutations, metastasis type, or patients' prior therapies. Of note, in some cases, the combination with an anti-PD-1 inhibitor significantly improved the efficacy of one or more of the three drugs. CONCLUSIONS We optimized and validated PDOCs as personalized preclinical models suitable for assessing the drug sensitivity/resistance profile of individual patient-derived melanomas. By retaining tumor stromal components and heterogeneity, PDOCs could be used to predict patients' clinical response to currently approved agents, helping oncologists expedite decision-making when several treatment options are possible. Furthermore, the model could be used to evaluate the effectiveness of alternative treatments on tumors resistant to approved therapies, and to explore new drug combinations.

Vertical inhibition of the MAPK pathway with D3S-002, a potent and selective ERK1/2 inhibitor, to improve anti-tumor activity of and overcome resistance to KRAS G12C inhibitors

Jing Zhang, Jingtao Lu, Zhiqiang Zheng, Jiang Lu, Allison Wang, Jia Wang, Janet Chen, Haopeng Rui, Cheng Chen, Zhi Jian Chen. *D3 Bio (Wuxi) Co. Ltd., Shanghai, China*

While covalent KRAS G12C inhibitors have demonstrated encouraging clinical efficacy in patients with KRAS G12C mutation, the overall response rate and progression-free survival appear to be suboptimal. Achieving deeper and more durable responses in these patients remain as major challenges. Preclinical and clinical translation research highlights adaptive feedback reactivation of the RAS-RAF-MEK-ERK signaling cascade as key molecular mechanisms driving primary and acquired resistance to KRAS G12C inhibitors. Concurrent inhibition of KRAS G12C and downstream MAPK pathway is thus an attractive combination strategy to improve clinical outcomes for KRAS G12C-mutant population.

D3S-002 is a potent and selective kinase inhibitor targeting ERK1/2, the final node of the RAS-MAPK pathway and the central mediator of the feedback activation loop. To investigate the combination effect of D3S-002 with KRAS G12C inhibitor D3S-001, this study utilized multiple preclinical in vivo models including cancer cell line-derived xenograft (CDX) tumors that are sensitive to, or primarily resistant to KRAS G12C inhibitors, and patient-derived xenograft (PDX) tumors that have progressed on KRAS G12C inhibitor treatment in the clinic. In NCI-H358 NSCLC and SW837 CRC models that are sensitive to KRAS G12C inhibitor monotherapy, adding D3S-002 to D3S-001 or to D3S-001 and cetuximab doublet regimen led to faster, deeper, and more durable anti-tumor responses at dose levels that are well tolerated in mice with no body weight loss observed. In NCI-H2122 NSCLC model that is primarily resistant to KRAS G12C inhibitor alone, the addition of D3S-002 resulted in near complete tumor growth inhibition.
Furthermore, CR9537 PDX model was established from tumor biopsy of a CRC patient who had progressed on combination treatment of KRAS G12C inhibitor MRTX849 and a SHP2 inhibitor in a clinical trial. Next generation sequencing (NGS) analysis identified secondary KRAS Q61H mutation as an acquired resistance mechanism. In this PDX model, KRAS G12C inhibitor, D3S-001 or MRTX849, monotherapy only achieved approximately 50% tumor growth inhibition, highlighting the acquired resistant phenotype. Adding D3S-002 to D3S-001 or MRTX849 resulted in over 80% tumor growth inhibition and significantly prolonged survival, suggesting the combination treatment can be beneficial for KRAS G12C inhibitor pre-treated patient population.
Collectively, vertical inhibition by concurrently targeting KRAS G12C and ERK1/2 with respective inhibitor D3S-001 and D3S-002 demonstrated enhanced anti-tumor activity in NSCLC and CRC models with different sensitivity to KRAS G12C inhibitor monotherapy. These results provide a strong rationale for further investigation of the combination strategy of D3S-001 and D3S-002 in KRAS G12C-mutant solid tumors in the clinic.

Androgen blockade confers sensitivity to PIKfyve inhibition in prostate cancer

Yuanyuan Qiao, Sarah Nicole Yee, Caleb Cheng, Yang Zheng, Jie Luo, Yi Bao, Xia Jiang, Xuhong Cao, Yuping Zhang, Arul M. Chinnaiyan. *University of Michigan Medical School, Ann Arbor, MI*

In 2022, 268,490 American men will be diagnosed with prostate cancer and 34,500 men will succumb to its complications. Despite significant advances in prostate cancer treatment over the past few decades, resistance inevitably develops with certain therapies, including second-generation anti-androgens; new case numbers also keep climbing each year, leading to one in every eight men being diagnosed with prostate cancer during his lifetime. Therapies targeting the androgen receptor (AR) as the main driver of prostate cancer lead to various mechanisms of resistance and promote disease progression to castration-resistant prostate cancer (CRPC), which has a median survival of only 9-36 months. Amongst recurrent CRPC, 17%-30% of patients develop neuroendocrine prostate cancer which is characterized by it's unique histopathology and loss of AR signaling. Our previous study demonstrated that autophagy blockade via PIKfyve inhibition has preferential cytotoxicity in neuroendocrine prostate cancer over prostatic adenocarcinoma leading us to further validate the role of AR signaling in PIKfyve blockade sensitivity. Thus, we postulate that androgen signaling attenuates the dependency of prostate cancer on PIKfyve, while on the other hand, AR antagonist may sensitize prostatic adenocarcinoma to PIKfyve inhibition.

Method

Several AR positive prostate cancer cell lines were examined for combinational effect of AR antagonists and PIKfyve inhibitors *in vitro* with synergistic scores calculated. A pair of isogenic LNCaP cells with proficient AR signaling (LNCaP-parental) and deficient AR signaling (LNCaP AR-null) were used for PIKfyve inhibitor sensitivity. Additionally, two AR positive cell line-derived xenografts (LNCaP and VCaP) were established *in vivo* for combinational assessment of AR antagonist Enzalutamide and PIKfyve inhibitor ESK981. Tumor growth inhibition were monitored pre- and post- treatments. On target assessment were examined for downstream targets of AR antagonist, as well as LC3-lipidation for PIKfyve inhibition. *In situ* cell death events of treated tumors *in vivo* were evaluated by TUNEL assay.

Conclusion

We have discovered that inhibition of AR signaling by Enzalutamide demonstrated strong synergistic anti-proliferative effects with PIKfyve inhibition by ESK981. Similarly, using a pair of isogenic LNCaP cells with proficient (LNCaP-parental) and deficient AR signaling (LNCaP AR-null), we showed that loss of AR signaling notably increased the sensitivity of LNCaP cells to PIKfyve inhibition. Concurrent treatment with Enzalutamide and ESK981 *in vivo* triggered greater tumor inhibition and more robust *in situ* cell death events than either agent alone. Collectively, PIKfyve may have a context-dependent role in

AR signaling-dependent and -independent prostate cancer, so that by co-targeting AR signaling and PIKfyve, therapeutic outcome of prostate adenocarcinoma can be improved.

#5503

Targeting CDK12-mediated DNA damage response to overcome cisplatin resistance in human urothelial carcinoma

Po-Ming Chow[1], Jun-Ren Dong[1], Chung-Sheng Shi[2], Kuo-How Huang[1].
[1]Department of Urology, National Taiwan University College of Medicine, Taipei City, Taiwan,[2]Graduate Institute of Clinical Medical Sciences, Chang Gung University, Tao-Yuan City, Taiwan

Urothelial carcinoma (UC) accounts for more than 90% of bladder cancer. According to the 2019 Surveillance, Epidemiology and End Results (SEER) Program database, the 5-year survival rates of regional and metastatic bladder cancer are 36.3% and 4.6%, respectively. Patients who received radical cystectomy suffer from a high recurrence rate of up to 30%. As for metastatic UC, only half of the patients respond to standard platinum-based chemotherapy, with 20% of 5-year overall survival. CDK12 shows transcription regulatory effects via regulating RNA polymerase II CTD phosphorylation. In our research, we used CDK12 selective inhibitor SR-4835 to treat the UC cell lines including T24, BFTC905, RT4, and cisplatin-resistant T24/R. MTT assay result has demonstrated the cytotoxicity of SR-4835 against UC cells. Using q-RT-PCR and immunoblotting, we have confirmed the reduction of ATM mRNA and protein expression after the treatment of SR-4835. The expression of DNA damage marker gamma-H2AX was also elevated. Flow cytometry data indicated an increase in apoptotic population after treatment. According to these findings, we presume SR-4835 can lead to a DNA damage-induced apoptosis process. Furthermore, we also observed the inhibition of AKT pathway, which is related to cell survival and proliferation. Due to the effects of DNA-repair inhibition, we aim to combine SR-4835 to enhance the anti-cancer effects of cisplatin. The results of UC mice xenograft have confirmed that SR-4835 and cisplatin display a synergistic effect against UC tumor growth *in vivo*. We will further dissect the mechanisms of the *in vitro* synergistic effects between SR-4835 and cisplatin using immunoblotting, RNA-sequencing, comet assay, and various functional assays. Conclusively, our study aims to explore the role of CDK12 in urothelial carcinoma and the therapeutic effects of SR-4835, especially its potential to overcome cisplatin resistance and manage metastatic disease.

A tumor-promoting senescent secretome triggered by platinum chemotherapy exploits a targetable TGFβR1/Akt-mTOR axis in lung cancer

Estela González-Gualda[1], David Macias[1], Samir Morsli[1], José Ezequiel Martín[1], Hui-Ling Ou[1], Mary Denholm[1], Ioana Olan[2], Reuben Hoffmann[3], Mark Dane[3], Dimitris Veroutis[4], Guillermo Medrano[5], Francisca Mulero[5], Carla P. Martins[6], Mariano Barbacid[5], Vassilis Gorgoulis[7], James E. Korkola[3], Doris M. Rassl[8], Gary J. Doherty[9], Robert C. Rintoul[10], Masashi Narita[2], Daniel Muñoz-Espín[1].
[1]Oncology, University of Cambridge UK, Cambridge, United Kingdom,[2]CRUK Cambridge Institute, Cambridge, United Kingdom,[3]Oregon Health & Science University, Portland, OR,[4]University of Athens, Athens, Greece,[5]Spanish National Cancer Research Centre, Madrid, Spain,[6]AstraZeneca, Cambridge, United Kingdom,[7]University of Athens, Athens, Greece,[8]Royal Papworth Hospital NHS Foundation Trust, Cambridge, United Kingdom,[9]University of Cambridge, Cambridge, United Kingdom,[10]Oncology, Royal Papworth Hospital NHS Foundation Trust, Cambridge, United Kingdom

Background Platinum-based chemotherapy is commonly used for the treatment of non-small cell lung cancer (NSCLC), yet clinical outcomes and survival rates remain very poor and continues to be a cancer of unmet need. Recent evidence points to cellular senescence, a response to oncogenic- and therapy-induced genotoxic stress, and its associated proinflammatroy secretory phenotype (SASP) as an emerging hallmark of cancer. Hence, targeting senescence and its associated tumor-promoting activities is emerging as a novel and promising therapeutic strategy but largely unexplored in lung cancer.
Experimental Procedures Our study includes a variety of methodologies, including: - Functional in vitro analyses: proliferation, colony formation, tumor spheres, migration assays. High throughput unbiased analyses: RNAseq, proteomics and microenvironment microarrays (MEMA). - In vivo models of lung cancer: xenografts, orthotopic and genetically engineered mouse models. Longitudinal tumor burden by IVIS and microCT and mouse survival. - Clinical samples: Histological and in silico analyses.
Results Here we show that cisplatin-derived SASP enhances the malignant phenotype of lung cancer cells. Using xenograft, orthotopic and KrasG12V-driven murine NSCLC models, we demonstrate that cisplatin-induced senescent cells strongly promote tumor progression. Mechanistically, we find that a TGF-β-enriched SASP drives pro-proliferative effects through TGFβR1 and Akt/mTOR pathway activation. We validate the translational relevance of

chemotherapy-induced SASP using clinical NSCLC samples from a trial with patients who received neoadjuvant platinum-based chemotherapy. Importantly, TGFβR1 inhibition with galunisertib or senolytic treatment significantly reduces tumor promotion driven by cisplatin-induced senescence. Finally, we demonstrate, using distinct murine NSCLC models, that addition of TGFBR1 inhibitors to platinum-based chemotherapy reduces tumor burden and improves survival, providing pre-clinical proof-of-concept for future trial designs on combination therapies.

Conclusions and Impact We regard this work as a major conceptual dissection of tumor-promoting activities of therapy-induced senescence, and a preclinical advance in the management of lung cancer with potential wide therapeutic applications in precision medicine. Of note, we expect our findings to have implications for multiple cancer types, including ovarian, breast, mesothelioma, oesophageal, head and neck, bladder and brain cancers, where platinum-based therapies remain important standard-of-care treatments.

#5505

Combination nitazoxanide and auranofin treatment has synergistic anticancer activity in anaplastic thyroid cancer and act by enhanced activation of multiple cell death pathways

Chandrayee Ghosh[1], Viswanath Gunda[1], Jiangnan Hu[1], Lisa Zhang[2], Ya-Qin Zhang[3], Min Shen[4], Electron Kebebew[1]. *[1]General Surgery, Stanford University School of Medicine, Stanford, CA,[2]National Institute of Child Health and Development, National Institutes of Health,, Bethesda, MD,[3]3National Center for Advancing Translational Sciences, National Institute of Health, Bethesda, MD,[4]National Center for Advancing Translational Sciences, National Institute of Health, Bethesda, MD*

Purpose: Anaplastic thyroid cancer (ATC) is one of the most aggressive human cancers, with a median survival time of 6 months and with no current curative treatment. We have used quantitative high-throughput screening (qHTS) of clinically approved or investigational agents to identify candidate compounds for ATC therapy. As monotherapy for most cancers is not effective, we used combination drug matrix screening of highly active compounds from our single agent qHTS to identify compound combinations that may show synergistic effect. In this study, we evaluated the anticancer activity of nitazoxanide and auranofin combination treatment and its mechanism of action and biomarkers of treatment response in *in vitro* and *in vivo* models of ATC.

Experimental Design: We used four (8505C, C643, SW1736, THJ16T) ATC cell lines in *in vitro* and *in vivo* ATC models to evaluate the safety and efficacy of this combination treatment compared to single agent and vehicle control.
Results: Combination nitazoxanide and auranofin treatment synergistically inhibited cellular proliferation ($p<0.001$) and inhibited colony formation and migration ($p<0.001$) in ATC cell lines. We observed cellular oxidative stress with significant increase in ROS levels in the combination treatment group ($p<0.001$). Nitazoxanide treatment alone and in combination with auranofin caused G1/G0 arrest in cell cycle, induced autophagy (increased LC3BII expression) and later apoptosis. Auranofin treatment alone and in combination with nitazoxanide induced ferroptosis (decreased GPX4 expression and intracellular GSH/GSSG ratios). RNA-Seq analysis, to identify biomarkers of response, showed >7-fold increase in HMOX-1 (heme oxygenase 1) with combination treatment which was validated by western blot. Combination treatment significantly inhibited tumor growth as compared to single agents ($p<0.01$) and had no significant treatment-related toxicity *in vivo*. Analysis of tumor samples showed significantly increased LC3BII expression by immunohistochemistry and reduced GPX4 mRNA expression ($p<0.0001$) with combination treatment compared to control *in vivo*.
Conclusions: Combination nitazoxanide and auranofin treatment has synergistic anticancer activity in both *in vitro* and *in vivo* ATC models. The synergistic activity of the combination is due to enhanced G1/G0 arrest, greater activation of autophagy, apoptosis and ferroptosis than single drug treatment. LC3BII, HMOX-1 and GPX4 levels could be useful biomarkers of treatment response to combination nitazoxanide and auranofin.

#5506

Circulating immature neutrophils early detect hyperprogressive disease upon first-line PD-1/PD-L1 inhibitors in non-small cell lung cancer patients selecting best candidates for platinum-based chemotherapy and PD-1/PD-L1 inhibitors combinations

Roberto Ferrara, Giuseppe Lo Russo, Chiara Maura Ciniselli, Annamaria Piva, Barbara Bassani, Elena Jachetti, Giuseppina Calareso, Valeria Duroni, Settimio Di Gregorio, Claudia Proto, Arsela Prelaj, Alessandro De Toma, Mario Occhipinti, Marta Brambilla, Sara Manglaviti, Laura Mazzeo, Arturo Rinaldi, Teresa Beninato, Monica Ganzinelli, Filippo De Braud, Marina Chiara Garassino, Paolo Verderio, Mario Paolo Colombo, Sabina Sangaletti.
Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Hyperprogressive disease (HPD) has been described in ≃14-25% of pretreated non-small cell lung cancer (NSCLC) patients upon single-agent (SA) PD-1/PD-L1 inhibitors (ICI) and has not been reported upon platinum-based chemotherapy (PCT) and ICI combinations. So far, no predictive biomarkers are available for HPD early detection.
Methods: NSCLC patients treated with 1st line SA-ICI or PCT-ICI were assessed for HPD and circulating neutrophils. HPD was defined as delta tumor growth rate (TGR) >50% and/or TGR ratio ≥2. Circulating low density neutrophils (LDNs) were assessed by flow cytometry on peripheral blood mononuclear cells (PMBCs). LDNs were defined as $CD66b^{+}CD15^{+}$ cells among $CD11b^{+}$ PBMCs and immature subtypes as $CD10^{-}$ LDNs. The LDNs predictive role was assessed by penalized model-based tests.
Results: 144 NSCLC patients were included: 75 treated with SA-ICI, 69 with PCT-ICI. In the SA-ICI cohort, HPD occurred in 8 (11%) patients, while progressive disease (PD) and response or stable disease (PR/SD) occurred in 33 (44%) and 34 (45%) of patients respectively. Immature circulating $CD10^{-}$ LDNs were significantly higher in baseline blood samples of HPD patients [median (ME): 39.3, interquartile range (IQR): 28.7] compared to PD [ME: 7.4, IQR: 14.9, $p<0.01$] or PR/SD patients [ME: 3.7, IQR: 12.6, $p<0.01$]. Circulating $CD10^{-}$ LDNs were associated with HPD [odds ratio (OR): 1.17, 95% CI: 1.06; 1.29], with a good prediction capability [cross-validated AUC 0.97 (95%CI: 0.94;1.00)]. A 30.5% cut-off value for $CD10^{-}$ LDNs circulating neutrophils was identified by Younden index to discriminate HPD from others. In the PCT-ICI cohort, 14 patients had circulating $CD10^{-}$ LDNs ≥30.5%, being at high risk of HPD. However, no HPD was observed in PCT-ICI cohort and dynamic LDNs evaluation in high HPD risk patients showed 52.3% (IQR: 28.4) median reduction in $CD10^{-}$ LDNs upon PCT-ICI, versus only 8.9% (IQR: 34.6) reduction in HPD patients upon SA-ICI, suggesting that PCT prevents HPD by reducing selectively immature LDNs.
Conclusions: Baseline circulating immature neutrophils characterize HPD upon 1st line SA-ICI and a 30.5% cut-off of immature neutrophils could select NSCLC patients to be addressed to PCT-ICI combinations.

A potential combinatorial treatment strategy to overcome olaparib resistance in high-grade ovarian cancer

Jie Bao[1], Eva Daniela Mendoza Ortiz[2], Jessica Agudelo[3], Roman Filimonov[3], Anniina Färkkilä[1], Jing Tang[1]. *[1]Faculty of Medicine, University of Helsinki, Helsinki, Finland,[2]Institute of Molecular Medicine Finland, University of Helsinki, Helsinki, Finland,[3]Puissan Biotech Oy, Helsinki, Finland*

PARP1 inhibitors have evolved the treatment of *BRCA*1/2-mutated high-grade serous ovarian cancer. However, its resistance is frequently observed. In our initial combinatorial drug screening, OSU-03012 (AR-12) appeared as a promising drug to be combined with PARP inhibitor Olaparib in multiple ovarian cancer cell lines, regardless of *BRCA* mutation status. OSU-03012 is designed as an orphan drug with anti-microbial activity. It has also shown cell-context-dependent anti-cancer activity. Using imaging-based high-throughput drug sensitivity analysis, we found that OSU-03012 and BX-912, while both classified as 3-Phosphoinositide Dependent Protein Kinase 1 (PDK-1) inhibitors, not only differed in their synergistic effect together with Olaparib, also caused distinct phenotypic changes in ovarian cancer cells. Cell senescence was observed in BX-912 but not OSU-03012 treatment, alone or together with Olaparib. Recently, dihydroorotate dehydrogenase (DHODH) has been identified as a secondary target of OSU-03012, which explains its anti-cancer activity by regulating nucleotide metabolism and thus affecting DNA repair. However, in our study, OSU-03012 did not similarly affect cell viability and phenotype on ovarian cancer cell lines as a DHODH inhibitor BAY2402234. Interestingly, compared to BX-912 and BAY2402234, OSU-03012 showed higher selectivity on ovarian cancer cell lines over normal epithelial carrying *BRCA* and *TP53* mutations; it also exhibited reduced toxicity on a human fibroblast cell line. We are further clarifying the putative targets of OSU-03012 using thermal proteome profiling. To investigate the molecular evidence of OSU-03012 for treating ovarian cancer, we performed a differential gene expression analysis using Genomics of Drug Sensitivity in Cancer (GDSC) database. All ovarian cancer cell lines included in GDSC drug screening are classified as Olaparib- or OSU-03012-sensitive/insensitive, based on the respective IC50 threshold. We found that OSU-03012 sensitivity is positively associated with several known genes regulating ovarian cancer progression, such as *LUM* and *COL3A1,* as well as genes (e.g., *PTPRZ1*) that are associated with Olaparib insensitivity in this analysis. Interestingly, angiogenesis signatures were found to be enriched in both Olaparib and OSU-03012-sensitive cancer cell lines. We are currently establishing a cancer-vascular cell system in a microfluidic setting to study how such combinatorial

drug treatment would connect to tumor microenvironment remodeling. Altogether, we identified a potential non-cancer drug for ovarian cancer treatment and to overcome Olaparib resistance. A multidisciplinary approach highlights the importance of drug target profiling and sensitivity signatures scoring to improve treatment stratification.

Artesunate increases enzalutamide efficacy in advanced prostate cancer

Xinyi Wang, Fengyi Mao, Jinghui Liu, Yifan Kong, Daheng He, Chi Wang, Zhiguo Li, Xiaoqi Liu. *University of Kentucky, Lexington, KY*

Prostate cancer (PCa) is the most diagnosed worldwide. PCa development and progression require androgen receptor (AR) signaling, which stimulates its downstream gene expressions and cancer progression. While second-generation anti-androgen drugs plus androgen deprivation therapy (ADT) remains the first-line treatment for advanced prostate cancer patients, around one-third of patients will relapse in a short period. Advanced prostate cancer results in more mortalities than primary PCa patients. Evidence shows that the recurrence is caused by AR overexpression, AR variants, AR mutations, and signaling crosstalk. Thus, it is urgently needed to discover a novel therapeutic strategy for treating advanced prostate cancer. The heat shock protein family (HSP), including HSP90 and HSP70, play important roles in refolding aggregated protein for cancer cell proteomic equilibrium. HSP is induced primarily by heat shock factor (HSF1). As AR's chaperone protein, HSP70 and HSP90 increase AR transcription activity. Inhibiting HSP70 and HSP90 promotes STUB1, an E3 ligase, binding to AR and AR - V7, and ubiquitination. Artesunate (ART) is a semi-synthetic ingredient from Artemisia annua and is the most common treatment for malaria throughout the world. It was approved for medical use by the FDA (Food and Drug Administration) (Food and Drug Administration). Recently ART has been unveiled for its anticancer properties. However, the efficacy of ART treatment in advanced prostate cancer and the direct target of ART have not been investigated yet. Herein, we have examined the efficacy of combining Enzalutamide (Enza) and ART in advanced prostate cancer cell lines. We also performed unbiased bioinformatics analysis using RNA seq results in enzalutamide-resistant cell line C4-2R cells and 22RV1 cells to investigate the cell response toward ART treatment. We identified ART could downregulate of AR signaling pathway. Moreover, we determined that ART treatment

induces AR degradation in proteasome dependent manner. Interestingly, we found HSP70 and HSP90 are also decreased in RNA seq results. Taking these together suggests that ART may target HSF1 directly. Our results suggest ART induced AR degradation could be a promising clinical strategy for advanced prostate cancer.

#5509

The PI3K inhibitor Paxalisib combines synergistically with the MEK inhibitor Mirdametinib to target atypical teratoid/rhabdoid tumors

Kristen J. Malebranche, Tyler Findlay, Anupa Geethadevi, Charles Eberhart, Eric Raabe, Jeffrey Rubens. *Johns Hopkins University School of Medicine, Baltimore, MD*

Atypical teratoid/rhabdoid tumors (AT/RT) are aggressive pediatric brain tumors and the most common malignant brain tumors of infancy. The four-year event-free survival rate is only 37%. For patients with relapsed AT/RT there are limited treatment options, but precision therapies may help improve survival for patients with this deadly disease. We have previously identified strong activation of the PI3K-AKT-mTOR (mTOR) signaling pathways in AT/RT. Paxalisib is a highly brain-penetrant PI3K inhibitor acting upstream of mTOR. We find that Paxalisib slows tumor growth in orthotopic xenograft models of AT/RT and extends median survival from 40 to 54 days ($p=0.001$, log-rank test). RNASeq after mTOR pathway inhibition identifies reflexive activation of the RAS-RAF-MEK-ERK (MAPK) pathway as a possible mechanism of therapy resistance (KEGG pathway analysis). The RAS-RAF-MEK-ERK (MAPK) pathway plays a pivotal role in regulating cell growth and survival and activation of the pathway contributes to the aggressive growth of numerous cancers. Mirdametinib is a small, allosteric MEK inhibitor currently used in clinical trials for both pediatric low- and high-grade gliomas (PD0325901). We find that dual inhibition of both the mTOR and MAPK pathways by Paxalisib and Mirdametinib synergize to reduce AT/RT growth and viability (Bliss synergy score 16.77). Paxalisib also combines with Mirdametinib to induce high levels of apoptosis and cell senescence (as determined by western blot: cPARP, pRB, P21, P16). Naïve treatments in mice bearing AT/RT orthotopic tumors suggests the combination therapy decrease mTOR and MAPK pathway activation (as determined by western blot). These data support the use of Paxalisib and Mirdametinib combination therapy as a promising novel combination therapy to treat relapsed AT/RT.

#5510

TAS102 synergizes with regorafenib against colorectal and gastric cancer cells

Jun Zhang, Lanlan Zhou, Shuai Zhao, Wafik S. El-Deiry. *Brown University, Providence, RI*

TAS-102 is an oral formulation consisting of trifluridine (FTD) and thymidine phosphorylase inhibitor tipiracil hydrochloride (TPI). Regorafenib is a multi-targeted tyrosine kinase inhibitor, it inhibits the activities of VEGFR2 and 3, Ret, Kit, PDGFR and Raf kinases and results in the inhibition of tumor angiogenesis and cell proliferation. TAS102 or regorafenib monotherapy can lead to an overall survival benefit in metastatic colorectal cancer (mCRC) patient previously treated with conventional chemotherapy and target therapy (Arnold et al., 2018). TAS102 in combination with bevacizumab, a monoclonal antibody against vascular endothelial growth factor A (VEGF-A), is associated with a significant and clinically relevant improvement in progression-free survival in colorectal cancer (C-TASK FORCE)(Kuboki et al., 2017; Pfeiffer et al., 2020). FTD can synergize with nintedanib to inhibit the growth of colorectal cancer xenografts(Suzuki, Nakagawa, Matsuoka, & Takechi, 2016). We previously reported that regorafenib combined with a fluoropyrimidine can delay disease progression in case reports of multidrug-resistant mCRC patients(Marks et al., 2015). Therefore, we hypothesized that the combination of TAS102 and regorafenib may be active in CRC and other gastrointestinal (GI) cancers, and may in the future provide a treatment option for patients with advanced GI cancer. We investigated the therapeutic effect of TAS102 in combination with regorafenib in preclinical studies employing cell culture, colonosphere assays that enrich for cancer stem cells, and in vivo. We found that TAS102 in combination with regorafenib has synergistic activity against multiple GI cancers in vitro including colorectal and gastric cancer, but not liver cancer cells. TAS102 inhibits colonosphere formation and this effect is potentiated by regorafenib. In vivo anti-tumor effects of TAS102 plus regorafenib appear to be due to anti-proliferative effects, necrosis and angiogenesis inhibition. Growth inhibition by TAS102 plus regorafenib occurs in xenografted tumors regardless of p53, KRAS or BRAF mutations, although more potent tumor suppression was observed with wild-type p53. Regorafenib significantly inhibits TAS102-induced angiogenesis and microvessel density in xenografted tumors, and inhibits TAS102-induced ERK1/2 activation

regardless of RAS or BRAF status in vivo. Collectively, TAS102 plus regorafenib is a
synergistic drug combination in preclinical models of GI cancer, with regorafenib suppressing TAS102-induced increase in microvessel density and p-ERK as contributing mechanisms. The drug combination may be further tested in gastric and other GI cancers.

#5511

Investigating Wee1 and Myt1 combined inhibition as a potential cancer therapeutic strategy

Sargun Sokhi, Joanne D. Hadfield, Jeremy Fung, Gordon K. Chan. *Oncology, University of Alberta, Edmonton, AB, Canada*

Introduction: Cell cycle is under the surveillance of checkpoints to repair any damage before the cell transits between phases. Wee1 and Myt1 kinases prevent premature entry into mitosis by monitoring the G2/M checkpoint by adding an inhibitory phosphorylation on Cdk1. Wee1 is overexpressed in various tumors and MK-1775, a Wee1 small molecule inhibitor, is currently in phase I/II cancer clinical trials. Although MK-1775 was shown to potentiate the effect of other genotoxic therapies, yet clinical resistance has emerged towards it. In examining the mechanism of MK-1775-mediated cytotoxicity, we identified Myt1 as a resistant factor. Emerging evidence suggests that Myt1 is an important cancer therapeutic target. Hence, we are examining a novel Myt1 kinase small molecule inhibitor, RP-6306 in combination with MK-1775 as a potential synthetic lethal cancer therapy. We hypothesize that a combination of MK-1775 and RP-6306, inhibitors against two partially redundant kinases important for adaptation to genotoxic stress, will achieve synthetic lethality while circumventing the issue of resistance development following monotherapies.
Model Systems Used: 1) a cervical cancer cell line that is tetracycline inducible for Myt1 expression; 2) cancer cell lines (breast and cervical) that are resistant to MK-1775 through upregulation of Myt1.
Methods: We established the IC50 of RP-6306 in a panel of tumorigenic and non-tumorigenic cell lines using standard crystal violet viability assay. Following that, we tested the combination effect of MK-1775 and RP-6306 in model cell lines listed above using zero potency model of synergy. The effect of the combination treatment on the clonogenicity was evaluated using clonogenic assay. Timelapse microscopy on a High Content Imaging system

was used to determine the effect of RP-6306 and MK-1775 on mitotic duration and cell fates.
Results: We found that MK-1775 and RP-6306 combination treatment shows synergistic cell killing in a panel of cancer cell lines. Wee1 inhibition shows synergistic cell killing with Myt1 inhibition especially in inducible Myt1 overexpressing cells. Wee1 and Myt1 combined inhibition resists the increase in clonogenic potential of the cancer cells transiently overexpressing Myt1. RP-6306 and MK-1775 combination treatment promotes mitotic arrest leading to cell death in Myt1 overexpressing cells. We also found that the mechanism of cell death in the cells treated with the combination treatment is centromere fragmentation leading to mitotic catastrophe.
Conclusions: The combined Wee1 and Myt1 inhibition leads to synthetic lethality. Hence, our findings strongly suggest that the combined MK-1775 and RP-6306 treatment has promising potential to mitigate MK-1775 resistance. Our research contributes to the development of novel potential combination therapy while optimizing and improving the efficacy of MK-1775 treatment for potential clinical use.

TIC10/ONC201 in combination with ceralasertib exhibits potent synergy in high grade serous ovarian cancer cells

Maryam Ghandali[1], Kadir Mert Selvi[2], Kelsey E. Huntington[1], Andrew George[1], Anna Ochsner[1], Benedito A. Carneiro[1], Donn S. Dizon[1], wafik S. El-Deiry[1]. *[1]Legorreta Cancer Center at Brown University, Providence, RI,[2]hacettepe University, Ankara, Turkey*

High-grade serous ovarian cancer (HGSOC) is the most common and malignant form of ovarian cancer. Although patients with HGSOC are likely to respond to treatment, it is common for the cancer to recur and become resistant to treatment, therefore there is a need to develop new targets and novel combinations to increase patient survival rates. ATRi's (Ataxia telangiectasia and Rad3 related inhibitors) have shown efficacy in HGSOC. Considering ATRi's have shown moderate efficacy as a single treatment in HGSOC patients, we hypothesized that combining ATRi's with ONC201 would enhance efficacy. ONC201 is a pro-apoptotic TRAIL-inducing compound that activates the integrated stress response and inactivates the Akt pathway which is upregulated in over 70% of HGSOC. Inactivation of the Akt pathway may result in a synergistic effect that could be translated for use in

patients with HGSOC. Three HGSOC cell lines were treated with the novel drug combination of ceralasertib (ATRi) and ONC201 and CellTiterGLO viability assays were performed after 72 hours to evaluate the synergistic effect of combination treatment. Western blots were performed to investigate the synergistic effect of combination treatment on the Akt pathway as well as expression of the cellular metabolic stress protein ATF4. Cytokine profiling using the Luminex 200 technology was performed to study treatment-induced changes in the tumor microenvironment. Cell viability after ceralasertib and ONC201 combination treatment showed synergy in HGSOC cell lines (OVCAR3, KURAMOCHI, TOV21G) . In TOV21G cell line, combination studies of ONC201 and ceralasertib calculated by compusyn software demonstrated a synergistic effect of both drugs, Combination indexes below one were observed at concentration of 0.008-2 μM of ceralasertib with 0.31-5 μM of ONC201 with the best combination index of 0.65. We similarly observed synergy in the two other cell line between ONC201 and ceralasertib. Western blotting showed reduction in total Akt and Erk expression and an increase in ATF4, consistent with the observed synergetic effect of ceralasertib and ONC201 combination. Our ongoing studies are exploring potential mechanisms of synergy between ceralasertib and ONC201 and effects on immune–mediated killing of HGSOC cells. Our results suggest a rational and potentially effective novel therapy combination of ATRi ceralasertib and ONC201 that maybe further developed for HGSOC.

Identifying DNA methylation biomarkers in Brazilian women of African descent

Lissette Delgado-Cruzata[1], Diego J. Gomes de Paula[2], Jennifer Vieira Gomes[3], Tatiana A. Simão[4], Leonor Gusmão[3], Luis Felipe Ribeiro Pinto[2], Sheila C. Soares-Lima[2]. *[1]The City University of New York, John Jay College, Bronx, NY,[2]National Cancer Institute, Rio de Janeiro, Brazil,[3]Rio de Janeiro State University (UERJ), Rio de Janeiro, Brazil,[4]Biochemistry Department, Rio de Janeiro State University (UERJ), Rio de Janeiro, Brazil*

Breast cancer is the most common cancer, and the leading cause of cancer-related deaths in Brazilian women. Studies have shown that in Brazil while breast cancer mortality has increased in the last decade for all women,

mortality in women of African descent has doubled. A recent study showed that Afro-Brazilian women suffer from higher excess breast cancer mortality even after adjusting for extent of disease, year of diagnosis, age and socioeconomic status, which suggests biological factors also contribute to the differences in the clinicopathological make-up of the disease in women in this group. DNA methylation biomarkers, representing a combination of genetic and non-genetic factors, have the potential to be especially valuable when considering the combined contribution of the environment and genetics in breast cancer etiology. Several groups have found differences in DNA methylation levels associated with race and ethnicity in breast cancer. In addition, research has shown that women of different races/ethnicities with similar breast cancer tumor subtypes have distinct DNA methylation patterns. To explore further the association between race, ancestry and DNA methylation, we conducted a study in paired tumor and non-tumor tissue samples of forty-eight Brazilian women who self-identified as Black or Brown and were treated at National Cancer Institute Breast Cancer Hospital in Rio de Janeiro, Brazil. We carried out a DNA methylation profiling analysis using Illumina EPIC (850k) arrays in bisulfite converted DNA originally extracted from frozen tissue samples. A total of 739,883 differentially methylated probes (DMP) were identified, of which a large proportion 6,241 (78.4%) were hypomethylated. Lower DNA methylation was more common on intragenic regions and gene bodies, while hypermethylation was more commonly found on the promoter regions. DNA methylation was often higher in non-tumor than tumor samples. Among our top hits we found genes previously associated with estrogen receptor negative tumor types, CDH4, CERK, PROX1 and ADHFE1, and with high risk of breast cancer mortality (ST6GAL1, LYN, TFF1 and BMP3). A DPM enrichment pathway analysis predicted effects in known signaling pathways and transcriptional misregulation. We are currently analyzing the associations between the top differentially methylated regions with ancestry informative markers, and the clinicopathological characteristics of disease, to gain a better understanding of the role of DNA methylation marks in this population. This study adds to our current knowledge on epigenetics marks that will ultimately help us address mortality due to this disease in this population.

Pegaspargase is a viable option in elderly adults with acute lymphoblastic leukemia

Yosef Joseph Rene Amel Riazat-Kesh[1], Hannah Levavi[2], Sangeetha Venugopal[3], Carli Beall[4], Ronald Hoffman[2], Marina Kremyanskaya[2], John Mascarenhas[2], Sara Kim[5], Michal Bar-Natan[2]. *[1]Internal Medicine, Mt. Sinai Morningside and West, New York, NY,[2]Hematology/Oncology, Mt. Sinai Hospital, New York, NY,[3]Sylvester Cancer Center, University of Miami, Miami, FL,[4]Oncology Pharmacy, Northwestern Medicine, Chicago, IL,[5]Oncology Pharmacy, Northwell Health, New York, NY*

Pegaspargase (peg-asp) is a pegylated form of asparaginase with a longer half-life used in pediatric-inspired chemotherapy for treatment of adult acute lymphocytic leukemia (ALL). Peg-asp appears to confer a survival advantage, but use in older adults is limited by concern for toxicity, though incidence and associated factors are poorly characterized. Our primary objective was to compare peg-asp tolerability in different age groups; secondary objectives were assessment of patient- (pt) and disease-dependent factors associated with toxicity. We retrospectively reviewed 58 ALL pts treated with at least 1 dose of peg-asp (500-2500IU/m2) at our institution between 2016-2021. We used χ-squared- and Fisher's test, and multivariable regression analysis to assess relationships between pt-factors and toxicities. Median doses received was 2 (range 1-7). 38 pts were 40 years or older, 20 were >60 years. 18 received PEG during induction only, 8 in consolidation only, 27 in both, and 5 during salvage therapy post-relapse. 17 had Philadelphia (Ph) positive B-ALL; 32 Ph negative B-ALL; 7 T-ALL; and 2 had mixed phenotype acute leukemia. Pts were 19-78 years old (median 48.5). Grade 3 or 4 toxicities observed in >10% of cases included hepatotoxicity (81%, 47/58); antithrombin 3 depletion (72.4%, 42/58); hypofibrinogenemia <100 (58.6%, 34/58); hypertriglyceridemia (20.8%, 10/48); venous thromboembolism (12.1%, 7/58) and hemorrhage (12.1%, 7/58). Acute pancreatitis (8.6%, 5/58) and hypersensitivity (2/58, 3.4%) were less common. On univariate analysis, grade 3 liver injury was significantly associated with younger age groups (18-40 and 40-60 vs >60 years; p=0.025), likely due to older age strongly correlating (p <0.01) with receipt of <2000IU/m2 pegaspargase. No other toxicity was significantly associated with age. Hypofibrinogenemia and hepatotoxicity were significantly associated with initial receipt of pegaspargase during induction vs consolidation (p=0.042, p=0.013, respectively) but age was not. Pts receiving a max dose PEG of <2000IU/m2 had significantly lower odds of developing hepatotoxicity and hypertriglyceridemia than those receiving 2000 IU/m2 or more (p=0.008,

p=0.003, respectively). On multivariate analysis, higher max dose of PEG received (2000 IU/m2 or over) correlated with greater odds of hepatotoxicity, hypertriglyceridemia and acute pancreatitis (OR 1.72, CI 1.23-2.38; OR 1.31, CI 2.18, CI 1.59-3.03; and OR 1.46, CI 1.13-1.88, respectively). Hypertriglyceridemia was also associated with older age and BMI >30 (OR 1.31, CI 1.05-1.62, and OR 1.31, CI 1.09-1.59, respectively). In summary, low dose pegaspargase is a viable option in ALL in adults over 60, with only hypertriglyceridemia associated with older age. Future work might correlate serum pegaspargase activity to intolerance and outcomes, and examine whether prophylactic treatment e.g. with levocarnitine might prevent toxicity.

Use of antihypertensive drugs and the risk of cancer, findings of a population-based cohort study in Shanghai

Suna Wang[1], Li Xie[1], Ying Qian[1], Jie Wang[1], Guanglu Zhang[1], Lei Li[1], Weituo Zhang[1], Herbert Yu[2], Wensui Zhao[3], Biyun Qian[1]. *[1]School of Public Health and Hongqiao International Institute of Medicine, Shanghai Tongren Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China,[2]Cancer Epidemiology Program, University of Hawaii Cancer Center, Honolulu, HI,[3]Shanghai Changning District Center for Disease Control and Prevention, Shanghai, China*

Background: The widespread use of antihypertensive drugs has raised concerns on whether the use increases the risk of cancer. Although multiple studies have addressed this issue, it remains unclear if hypertension patients who are on antihypertensive medications are at higher risk for cancer.
Methods: Between 2013 and 2017, we enrolled 101,370 individuals with hypertension from community healthcare centers in Changning Shanghai, followed through December 31, 2019. Drug administration was defined as the class and number of ever use the major antihypertensives. The main outcomes included the incidences of all cancer and major types of cancer in Shanghai (lung, colorectum, thyroid, and stomach).
Results: During a mean follow-up of 5.1 (SD 1.3) years, 4970 cancer cases were newly diagnosed in the cohort. CCBs were the most frequently used antihypertensives which were associated with a moderately increased risk of all cancer (hazard ratio, HR: 1.11, 95% CI: 1.05-1.18). The second commonly used drug ARBs were also associated with increased risk of all cancer (HR: 1.10, 95%CI: 1.03-1.17) as well as lung and thyroid cancers (HR: 1.21,

95%CI: 1.05-1.39; HR: 1.66, 95%CI: 1.22-2.27, respectively). No cancer association was found with other antihypertensives. Individuals who use more than one class of antihypertensives had a higher risk of all cancer, and a possible dose-response relationship was suggested.
Conclusions: Use of ARBs or CCBs may be associated with an increased risk of cancer. Taking more than one class of antihypertensives appeared to have a higher risk for cancer.

#5519

Biobanking of gastric organoid models from a racially diverse cohort for gastric cancer interception

Priya Alagesan[1], Paula Scotland[2], HannahSofia Brown[1], Shannon J. McCall[3], Meira Epplein[4], Katherine S. Garman[2]. *[1]Duke University School of Medicine, Durham, NC,[2]Department of Medicine – Division of Gastroenterology, Duke University Medical Center, Durham, NC,[3]Duke BioRepository & Precision Pathology Center, Department of Pathology, Duke University School of Medicine, Durham, NC,[4]Department of Population Health Sciences, Duke University School of Medicine, Durham, NC*

Purpose: In the United States, significant disparities exist in gastric cancer incidence and mortality between Black Americans and non-Hispanic White Americans. *Helicobacter pylori* (*HP*) infection is the most important risk factor for developing non-cardia gastric adenocarcinoma (GAC), the most common type of gastric cancer. Non-cardia GAC is thought to occur via progression from *HP*-induced atrophic gastritis to gastric intestinal metaplasia (GIM), dysplasia, and cancer. The purpose of this study was to enroll racially diverse (~50% self-identified as Black) patients from the endoscopy suite across the spectrum of *HP*-associated disease (gastritis, GIM, GAC) in a prospective observational cohort to biobank blood and tissue samples with patient-reported survey data and clinical history from the electronic health record.
Methods: In an ongoing prospective study funded by an NIH P20 disparities project, we enrolled a diverse, racially balanced cohort of research participants undergoing upper endoscopy. We tracked and optimized screening, enrollment, and collection of blood, tissue, and survey data. Organoids were generated from fresh and/or cryopreserved biopsies of normal gastric tissue, gastritis, GIM, or GAC. Gene expression, immunohistochemistry and DNA mutational profiling were performed in a subset of organoids.

Results: To date, 563 patients were identified in screening (47% Black patients) and 250 were successfully included with a 44% enrollment rate (46% Black participants). Rates of successful sample and data collection were: 86% blood, 87% tissue collection, and 89% survey collection. The proportion of Black participants was greater in the *HP*-positive group (65%) vs. known *HP*-negative (46%) (p=0.03). Gastric organoids were generated with >90% success from 49 patients, including paired organoid lines from incomplete, complete, and/or extensive GIM, matched tumor and non-tumor and gastric antrum and body samples. 20 organoid lines were derived from cryopreserved endoscopic biopsies. Ongoing characterization of tumor organoids reflects expected heterogeneity among gastric cancer patients and provides a functional measure of cytokine expression.
Conclusions: To address health disparities related to gastric cancer, diverse patient cohorts must be established with successful biobanking from groups most affected by the disease. Patient-derived gastric organoids can be generated from diverse populations and across different clinical conditions as one approach to understanding and addressing gastric cancer health disparities.

#5520

Research Ready graphic-style story to support future research participation among adolescents

Lauren Bates[1], Susan Gertz[2], Susan Hershberger[2], Melinda Butsch Kovacic[3], We Engage 4 Health Community-Academic Partnership. *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH,[2]Miami University, Oxford, OH,[3]University of Cincinnati, Cincinnati, OH*

Historically, marginalized adults are more likely to be mistrustful of health research worrying both about its invasiveness and their own safety. As a result, many decline to participate. Adolescents have a much lower perception of risk compared to adults and are also susceptible to peer pressure and socialized trust or mistrust from their parents and family members, which can influence risk perception. As encouraging equitable participation in research becomes an important tool in the fight against cancer disparities, We Engage 4 Health created a graphic-style story “Research Ready” to help community members learn the 3 P’s: the purpose of cancer research, how they are kept safe while participating, and why people from diverse backgrounds are needed to participate. An accompanying Research Review Activity was also included

to further support participants' decision-making regarding research participation. Two groups of diverse adolescents were asked to read the story aloud together in small groups and then discuss an active research study targeting adolescents using the review activity with a scientist to consider whether the first the teen story character (Vito) and ultimately themselves, should consider participation in the study and to identify what information was needed from study staff to better be able to make a decision based on their values and accurate information provided by study staff. Group 1 included 45 adolescents that were 68% African American and 10% European American. Group 2 included 73 high schoolers that were 78% Asian, 15% European American, and 5% African American. Post-discussion surveys indicated that only 9% and 3% in group 1 and group 2 respectively had previously participated in health research. However, after the story discussion, 83% and 89% indicated they thought it would be safe to participate in research and 76% and 89% indicated a willingness to participate in research in the future. Finally, 60% collectively enjoyed the story's graphic-style format. These data suggest Research Ready to be potentially useful in promoting future research participation and may be especially useful in engaging ethnic/racial groups commonly underrepresented in cancer research.

Racial and ethnic disparities for intravascular large B-cell lymphoma: A Surveillance, Epidemiology, and End Results (SEER) database analysis with emphasis on Hispanics.

Daniela Urueta Portillo[1], Daniel Rosas[1], Joel E. Michalek[1], Qianqian Liu[1], Adolfo E. Diaz Duque[2]. *[1]UT Health and Sciencer Center San Antonio, San Antonio, TX,[2]Mays Cancer Center UT Health San Antonio MD Anderson, San Antonio, TX*

Background: Intravascular large b-cell lymphoma (IVLBCL) is a rare but highly aggressive subtype of non-Hodgkin lymphoma (NHL). IVLBCL is a clonal proliferation with selective growth within the blood vessel. It has been primarily described in Asian and European populations, and a median age presentation is in the sixth to seventh decades without a sex predilection. The US incidence is 0.95 in 1 million, but is thought to be higher, as the diagnosis is mainly done postmortem. Meanwhile, the incidence rate of IVBCL in Hispanics (HI) remained unknown. This study looks at demographics,

treatment patterns, and outcomes of patients with IVLBCL in the US, examining disparities by HI vs Non-Hispanic (NH).
Methods: Data were analyzed on IVLBCL patients reported to the SEER 18 database between 2000 and 2018. SEER 18 contains the most comprehensive population-based cancer information in the US, covering approximately 27% of the US population and 36% of HI alone. The racial groups analyzed were NH whites, HI whites, blacks, and Asians/PIs (Pacific Islanders). Patient characteristics, age-adjusted incidence rate, and survival rate were compared across ethnic groups. Kaplan-Meier and Cox regression analyses compared overall survival (OS) between HI and NH. Multivariate analysis and propensity score matching were performed, with adjustment for age, stage and B-symptoms.
Results: We identified 164 patients with IVLBCL, of which 10% were HI. 41% of HI were male vs 44% of NH. HI were diagnosed at an older age, 72. vs 69 y.o., compared to NHI (p=0.907). Most of NH and HI were diagnosed between 60-80 y.o. (p=0.322), 53.1% and 47.1%, respectively. Regarding race, HI and NH were mainly identified as whites (88% vs 78%), followed by Asians (6% vs 17%) (p=0.013). For HI, 53% presented B symptoms compared to 16% of NH (p=<0.001). On survival analysis, the survival probability at 2, 5 and 10 years of HI vs NH was (0.540 vs 0.505), (0.432 vs 0.425), and (0.443 vs 0.237), respectively. The median survival time was 0.8 years for HI and 1.9 years for NH. The 10 year OS probability was not significantly different for HI vs NH (p=0.66).On multivariate analysis, when adjusted for age, those patients who were 60 to 80 y.o. had worse OS compared to those younger than 60 y.o., with HR 1.4 (95% CI: 0.7 - 2.1).
Conclusion: In our study, despite a lower percentage of patients identified as Asian in our HI population, there is a significant difference in the presence of B-symptoms between HI and NH, going against the traditional description of an Asian variant with increased systemic symptoms. Despite this finding, it demonstrated similar outcomes in the 10 years survival analysis for HI and NH. Standardized treatment may explain why no variation was reported in OS. Our analysis shows that ethnic variations do not seem to affect oncological outcomes in IVLBCL for HI in the US.

#5522

Does physician-patient language concordance increase clinical trial enrollment in breast cancer patients?: A real-life study in a majority-minority population

Daniela Urueta Portillo[1], Ana M. Mendoza Sanchez[2], Nitzia E. Quilantan[3], Lisa Maria Mendoza Sanchez[4], Marcela Mazo Canola[1], Jonathan Gelfond[1], Julio A. Peguero[2]. *[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Oncology Consultants, Houston, TX,[3]Oncology Consulants, Houston, TX,[4]Universidad Autonoma de Chihuahua, Chihuahua, Mexico*

Introduction: Clinical trial accrual and enrollment are essential to break disparities seen in minority populations affected by cancer. Despite Hispanics (HI) being 18.9% of the US population and the fastest-growing minority in the US, they only represent 4% of the patients enrolled in clinical trials. These disparities are often explained by different social determinants of health, but could also be due to decreased perceived interest by oncologists in their participation simply due to lack of English proficiency. Effective doctor-patient communication is vital in establishing a healthy doctor-patient relationship, and is vital in delivering high-quality health care. In this study, we explore whether physician-patient language concordance affects clinical trial enrollment.
Methods: We evaluated 233 patients diagnosed with breast cancer who consented to experimental clinical trials in a private Oncology practice in Houston, Texas, from 2008-2022. All trials had approved consent in English and Spanish. We used logistic regression to model the probability of treatment, while adjusting for the effects of cancer type, gender, race, ethnicity, and language concordance.
Results: Of the 233 patients with breast cancer, 191(82%) were enrolled in a clinical trial, and 96% of these patients spoke the same language as their providers. 42 patients were not enrolled, with 95% of patients speaking the same language as their provider. There were 209 (90%) patients who spoke English, 22 (9%) were Spanish speakers and 2 (1%) were Arabic speakers. Of the Spanish speakers, 18 were enrolled, with 13 (72%) having language concordance with their provider. The ethnicity was evaluated, resulting in 72 (31%) patients being Hispanics, 55 (24%) African American, 94 (40%) Caucasian, 7 (3%) Asian, 4 (2%) Middle Eastern and 1 (0.4%) American Indian. It also evaluated the rate of consent withdrawal, showing only 6 (3%) patients. After evaluating the results, it was noted that there was no statistically significant association of physician-patient language concordance with enrollment rate ($p=0.776$). There was also no significant difference in consent withdrawal ($p=0.626$), and no change associated with gender ($p=0.344$) or ethnicity when evaluated ($p=0.13$).

Conclusion: In conclusion, our analysis confirms no significant difference in breast cancer patients' enrollment in clinical trials if there is language concordance between physician and patient. The efforts of the medical workforce to use translators and translated versions of informed consents, surveys or outcome assessments, when available, seem enough for our patients to agree to continue enrollment.

#5523

Impact of COVID-19 on longitudinal breast cancer research studies involving TNBC patients

Cherie Bates[1], Esther Kong[1], Elena Zaikova[1], Samuel Aparicio[1], Karen Gelmon[2]. *[1]Molecular Oncology, BC Cancer Research Institute, Vancouver, BC, Canada,[2]Medical Oncology, BC Cancer, Vancouver, BC, Canada*

Background Triple-negative breast cancer (TNBC) accounts for ~15% of breast cancer diagnoses but is linked to worse outcomes and comprises a disproportionate number of breast cancer deaths. The TNBC pilot study is a prospective longitudinal study to provide a critical resource for understanding TNBC disease. However, the pandemic impacted the collection of samples.
Objective To highlight the impacts of COVID-19 on this longitudinal cancer translational research study including the patient's perspective and to develop recommendations to avoid future disruptions.
Methods 389 participants were enrolled in the prospective longitudinal cohort, which collected serial blood samples for up to 5 years. Due to the pandemic, research was curtailed for 6 months due to concerns about patient safety, halting the collection of blood samples. Missed samples and data gaps were documented. To complement this, we initiated a survey capturing the patient perspective on their experience of the study disruption due to COVID.
Results 217 enrolled participants missed a blood draw or had a collection outside the study window. 158 patients missed 1 time-point collection, and 59 patients missed ≥ 2 collections. Of the 217 participants who missed a collection, 6 disease recurrence diagnoses and 3 deaths occurred during research curtailment. The collection of survey responses from participants is ongoing and will be presented at the AACR Annual Meeting.
Conclusion Missed samples resulted in irreplaceable data gaps critical to monitoring patient outcomes, and reduced cohort sampling during the pandemic. Our current knowledge of the risks suggests that with proper informed consent, collections could have continued. To mitigate disruption in

future clinical studies, clear plans should be part of study design to provide continuity. The participants' experience to be reported will also help researchers understand their issues and help develop policies.

Missed collections and clinical events during COVID-19 research curtailment

	Number of patients
Total with missed or late blood draws	217
Missed 1 collection	158
Missed ≥ 2 collections	59
Diagnosed with disease recurrence	6
Deaths	3

Persistent patient barriers to genomic testing in ambulatory oncology

Ellana K. Haakenstad[1], Jane Roberts[1], Anna C. Revette[1], Wendy Loeser[1], Joseph Grider[1], Andrea Kruse[1], Alissa Gentile[1], Rachel Freedman[1], Neal I. Lindeman[2], Olga Kozyreva[1], Pedro Sanz-Altamira[1], Christopher S. Lathan[1], Michael Hassett[1], Ethan Cerami[1], Annette S. Kim[2], Danielle K. Manning[2], Jonathan Nowak[2], Marios Giannakis[1], R. Coleman Lindsley[1], William C. Hahn[1], Barrett J. Rollins[1], Levi Garraway[3], Bruce E. Johnson[1], Nadine Jackson McCleary[1]. *[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA,[3]Roche and Genentech, San Fransisco, CA*

Purpose: Tumor genomic testing and cancer clinical trial enrollment provide key access to precision cancer therapeutics and supportive care options to enhance the patient experience. However, physician and patient barriers limit participation of patients who are historically underrepresented in genomic studies and clinical trials [historically underrepresented patients (HUP)], thereby decreasing generalizability for those most negatively affected by cancer diagnosis. We interviewed patients to identify factors impacting genomic testing uptake and clinical trial enrollment.

Methods: From 09/2021 - 12/2021 we interviewed 16 patients diagnosed with cancer seen at an ambulatory oncology center. Patients were HUP (Black, American Indian or Alaska Native, Native Hawaiian or other Pacific Islander,

Hispanic/Latinx, or older adult [70 years or older], or from a low-income zip code). From non-inclusive groups, patients identified as: 3 primarily spoke a language other than English, 9 Black, 3 other race, 6 Hispanic, and 3 aged 70 years or older. One-on-one interviews utilized a structured interview guide and lasted approximately 45 minutes. Participants were recruited until thematic saturation was reached then transcripts coded for major patterns and themes.
Results: Regarding tumor genomic testing, many patients were unsure if they received testing or if testing was recommended (citing possible confusion with medical terminology or overwhelm with information). Cited barriers included education (not understanding the benefit of participating, investigational drug/device identity, the procedures and processes involved), mistrust of research (specifically concerns over data privacy); and logistical accessibility (cost, time away from work, transportation). Those tested found it to be an easy process. Several cited that a patient advocate or social worker would be beneficial to navigate the process. Barriers around clinical trial enrollment included education (the risks of participating/side effects, size of the study, investigational drug/device identity), mistrust of research (data privacy, inclusion of HUP in trial, loss of autonomy in decision making), and logistical accessibility (time commitment). HUP who participated in a clinical trial appreciated the additional psychosocial support and clinical monitoring. Patients were emphatically interested in participating in genomic testing and cancer clinical trials when presented as the best course of care, though concerns about side effects from clinical trials persisted.
Conclusion: Patient barriers to tumor genomic testing and cancer clinical trials center around education, mistrust in research, and logistical accessibility. Patients who participated in genomic testing and clinical trials did have a positive experience. Barriers may be addressed with personalized education and coaching, including supportive resources referral.

Community cancer research advocates: Helping underrepresented minority groups become research ready

Sarah Been[1], Susan Gertz[2], Susan Hershberger[2], Melinda Butsch Kovacic[3], We Engage 4 Health Community-Academic Partnership. *[1]University of Cincinnati, Cincinnati, OH,[2]Miami University, Oxford, OH,[3]University of Cincinnati Cancer Center, University of Cincinnati, Cincinnati, OH*

Even though certain racial/ethnic minority groups get cancer more often, are diagnosed at younger ages, and are at risk for earlier death, clinical trials fail to include adequate proportions of representatives from these groups. Encouraging equitable participation in research becomes an important tool in the fight against cancer disparities. Therefore, we co-created with community representatives a graphic-style story entitled "Research Ready" that is used by trained Community Research Advocates (including some survivors or family of survivors themselves) to hold brief discussions to help eligible hesitant participants to learn the 3 P's: the purpose of cancer research, how they are kept safe while participating, and why people from diverse backgrounds are needed to participate. Importantly, advocates use a Research Review activity to discuss factors that influence their willingness to participate as well as identify questions they have for the research study's staff. Focus group and survey-based evaluation data show these discussions to be useful in increasing hesitant patients' willingness to consider participation in research and increase perception of safety. Advocates too appreciate the opportunity to serve. While this pilot is small, additional partnerships within the University of Cincinnati Cancer Center to expand the program will be developed. Future partnership with a community patient navigator program will also enable additional support and transportation to research appointments. Collectively, we anticipate that this program will ultimately support hesitant patients' decision-making and improve cancer research participation particularly among racial/ethnic minorities.

State-of-the-art biobanking of gastroesophageal adenocarcinoma samples: Integrating non-viable biospecimens with 3D and 2D cell models and their characterization, validation, and utilization of cell models for precision oncology

Mingyang Iris Kong, Sanjima Pal, Julie Berube, France Bourdeau, Betty Giannias, Nicholas Bertos, Veena Sangwan, Lorenzo Ferri. *McGill University Health Centre Research Institute, Montreal, QC, Canada*

Traditionally, biobanking platforms have collected and stored non-viable biological specimens such as serum, plasma, and fresh-frozen or formalin-fixed paraffin-embedded (FFPE) tissues. These constitute key resources for clinical and contemporary genomics, transcriptomics, and proteomics studies. However, such specimens cannot be used for studies involving drug testing,

high throughput target validation, and implementation for personalized medicine. Next-generation biobanking strategies rectify this issue by combining the collection of non-viable samples from patients with the propagation of viable tissue fractions as *in vitro* 2D and 3D cell models or *in vivo* xenograft models. Such cutting-edge biobanking strategies enable downstream cell-based high-throughput functional assays promoting the discovery of therapeutic targets or assessing treatment responses and resistance to treatment. Here, we provide comprehensive details of our establishment of a state-of-the-art biobanking platform for gastroesophageal adenocarcinoma (GEA) samples (n=389). Our approach opens new directions for understanding disease biology and conducting translational cancer studies. Patient-derived 2D cells (n=376), organoids (PDOs) (n=185), and xenografts (PDXs) (n= 99) included in our pipeline retain crucial features of the original human tumors, serving as valuable tools for clinical and experimental analyses in the context of precision oncology. We also discuss the entire approach of next-generation biobanking and emphasize the importance of integrating the propagation of PDOs and PDXs simultaneously. In addition, we explain each protocol optimized to propagate patient tissue-derived cell models. We validate that these models recapitulate tissue heterogeneity and are relevant preclinical models. Taken together, we described each approach used to develop one of the largest next-level biobanks for GEA.

Undergraduate cancer research scholars' community field experiences encourage community engagement to curb future disparities in the cancer workforce

Melinda Butsch Kovacic, Rachael D. Nolan, Melissa Loyd, Sharon Sauter, Karen Ramos, John R. Kues. *University of Cincinnati Cancer Center, University of Cincinnati, Cincinnati, OH*

Lack of access to cancer prevention, early screening, and treatment, particularly in low socioeconomic, underserved communities, are cited as substantial barriers to improving survivorship. Overcoming the complexity of this problem will require a larger, diverse, and dedicated workforce. Community engagement can lead to greater awareness of and both access and accrual to research. Encouraging trainees understanding of and participation in community engagement early on is one approach to curb cancer research related disparities. The current pipeline of cancer-focused healthcare

professionals and researchers that understand, appropriately engage, and connect with their target communities and patient populations is dangerously inadequate. To expand our future culturally competent, cancer-focused workforce, the University of Cincinnati Cancer Center has established the Cancer Research Scholars Program which is supported in part by a National Cancer Institute R25. The program offers to 20-23 undergraduate scholars each year, unique and inspiring paid research opportunities across the cancer continuum and educational experiences that included cancer topics, professional development, team science, and both cultural humility and microaggression training. Importantly, all scholars prepare for and participate in one of three community-engaged, cancer-focused summer field experiences offered with our community partners to encourage the supporting of and//or active participation in community-engaged research, education, and outreach in their future cancer careers. Twelve of the 23 summer 2022 Scholars were also invited to continue their research into the academic year either in-person or virtually. After year 1, Scholars and mentors completed surveys and on-camera interviews about the program highlighting the program's successes as well as areas for improvement. Nearly all Scholars appreciated the community engagement opportunities offered and understood their value to their potential careers. Annual tracking of these Scholars will determine the program's longer-term impact on the cancer workforce.

#5528

Palliative and end of life care utilization in Asian and White patients with stage IV lung cancer

Xiao Hu[1], John W. Melson[1], Stacey Pan[2], Yana Salei[2], Yu Cao[1]. *[1]Division of Hematology-Oncology, Department of Medicine, Tufts Medical Center, Boston, MA,[2]Department of Medicine, Tufts Medical Center, Boston, MA*

Background**:** Lung cancer (LC) is the leading cause of cancer death in Asian Americans, the fastest growing racial/ethnic group in the US. Early palliative care (PC) is recommended for patients with stage IV LC. Research on PC and end of life care (EOLC) for Asian patients (AP) with stage IV LC in the US is limited. This retrospective study examines racial influences on PC and EOLC in patients with stage IV LC at an urban academic medical center serving a large proportion of AP.

Methods: Patients newly diagnosed with stage IV LC from 01/01/2014 to 12/31/2019 were identified from Tufts Medical Center cancer registry.

Baseline demographics, disease characteristics, treatment history, PC and hospice use, and EOLC were compared between AP and White patients (WP) by Mann-Whitney U test and Chi-square/Fisher's exact tests for continuous and categorical variables, respectively. Time to palliative care (TTPC) in AP and WP was compared via log-rank test.
Results: Of 89 AP and 197 WP (similar median age: 71 and 68 years old, respectively), AP had significantly more male representation (71.9% vs 48.2%), never-smokers (36.0% vs 7.1%), non-small cell histology (85.4% vs 72.6%), linguistic diversity (non-English languages: 6 vs 2), and interpreter use (43.8% vs 0.5%), with less preference for English (12% vs 99%). No difference in brain metastasis at diagnosis was noted. PC use was similar in AP and WP (38.2% vs 37.6%); relatively more first encounters occurred inpatient vs outpatient in both groups. Median TTPC tended to be longer in AP (15.7 vs 12.4 months, p=0.120). PC evaluation occurred within 12 months after diagnosis in 27 (30.3%) AP and 63 (32.0%) WP. Of those seen by PC, only 7 (20.6%) AP and 16 (21.3%) WP had more than one PC encounter. Of 22 AP and 74 WP with confirmed death, relatively more AP patients died in hospital (68.2% vs 32.4%, p=0.004), more often in ICU (40.9% vs 24.3%); no differences were found in use of mechanical ventilation (18.2% vs 16.2%) or cardiopulmonary resuscitation (0% vs 1.4%) preceding death. Within 6 months of death, outpatient oncologists and AP patients had fewer code status (0% vs 24.3%, p=0.010) but similar rates of health care proxy (18.2% vs 32.4%, p=0.110) and hospice care (18.2% vs 28.4%, p=0.411) discussions. Hospice enrollment (29.2% vs 32.0%, p=0.722), median time from entering hospice to death (16.5 vs 12.5 days, p=0.795) and from last systemic treatment to death (39 vs 55.5 days, p=0.844) were similar in AP and WP.
Conclusion: PC utilization was similarly sub-optimal in AP and WP with newly diagnosed stage IV LC in this study, though TTPC tended to be longer in AP. While hospice utilization was also similar in AP and WP, AP had a higher rate of in-hospital death and fewer code status discussions with their outpatient oncologists in the 6 months preceding death. Whether these findings reflect racial disparities, cultural preferences, or other factors influencing PC and EOLC for AP with advanced LC warrants further study.

#5529

Lung cancer clinical trials in Latin America: A 20-year analysis

Thomas M. Knapp[1], Joseph Nygaard[1], Joshua Cassinat[1], Priya Gopalan[2].
[1]University of Central Florida, Orlando, FL,[2]Orlando VA Medical Center,

Orlando, FL

Background Several multinational cancer research collaborative organizations have been formed recently in Latin America in an effort to increase clinical research and the enrollment of patients in clinical trials, including the Latin American Cooperative Oncology Group (LACOG), established in 2012, and the Latin American Consortium for Lung Cancer Research (CLICaP), established in 2010. The aim of this study is to characterize changes in lung cancer clinical trial participation in Latin America before and after 2012.
Methods Clinical trials were identified in clinicaltrials.gov using the search terms "lung cancer," country filters for 21 Latin American countries, and study start dates 01/01/2001-12/31/2011 and 01/01/2012-12/31/2021. Clinical trials were categorized as either originating in Latin America (LA) or outside Latin America with participation of Latin American countries (non-LA). The number of trials, trial phase, driver mutation studied, and types of intervention were collected for each country. Descriptive statistics and chi-square analysis with 95% confidence intervals were calculated.
Result: Our analysis included 426 clinical trials involving Latin American countries, of which 74% (317/426) were phase 3 trials. Only 6% (26/426) of the trials from 2001-2021 were LA trials. Comparing the period 2001-2011 to 2012-2021, there was a marked increase in total clinical trials (101 v. 325, $p<0.001$), predominantly due to an increase in non-LA trials (87 v. 313, $p<0.001$). The number of LA trials was unchanged between the two periods (14 v. 12, $p=0.69$). There was an increase in the percentage of phase 3 trials (60% v. 79%, $p<0.001$) between the two periods. There was also an 83% increase in studies for patients with specific driver mutations (EGFR, KRAS, ALK, and RET) (53 v. 97, $p<0.001$). The countries with the highest rates of open clinical trials were Brazil, Mexico, and Argentina. In all three countries, the total number of clinical trials increased between the period 2001-2011 and 2012-2021: Mexico (40 v. 88, $p<0.001$, 120% increase), Brazil (61 v. 108, $p=0.003$, 77% increase), and Argentina (50 v. 78, $p=0.013$, 56% increase).
Conclusion Overall, there was a significant (>3-fold) increase in clinical trial participation by Latin American countries, specifically in non-LA trials, from 2012-2021. This increase may correspond to the organization of CLICaP and LACOG, which are multinational cancer research organizations in Latin America. However, there were few LA trials. More LA studies are therefore needed to confidently extrapolate the results of global clinical trials to patients in Latin America.

#5530

A community led approach to addressing disparities in pancreatic cancer care for Native Americans in Oregon

Claymore Kills First, Grace A. McCarthy, Charles D. Lopez, Brett C. Sheppard, Jackilen Shannon, Jonathan R. Brody. *OHSU, Portland, OR*

Pancreatic adenocarcinoma (PDAC) is the third leading cause of cancer-related deaths in the United States (US). Due to unique barriers facing Native Americans (NA) patients, this underrepresented population has worse outcomes and increased mortality. In Oregon, NAs have nearly double the PDAC incidence rate compared to the general US population. Oregon Health & Science University (OHSU) is a leader in PDAC care and research, yet NAs remain underrepresented in pancreatic cancer research at OHSU, and across the country. This highlights the need for a focused and comprehensive research program that collaborates with local tribal communities to identify specific issues and barriers that can be addressed to improve patient care in the NA population. We hypothesize that if we establish a workflow that strengthens existing relationships with tribal communities and leverages established OHSU infrastructure and expertise, we can directly address the unmet need of understanding, preventing and treating PDAC for NA individuals in our local communities. This includes increasing enrollment of NAs in PDAC clinical trials and developing a genetic registry that could help both depict genetic underpinnings that predispose NA individuals to PDAC and potentially guide therapeutic approaches. To build trust within NA communities, we initiated collaborations with Oregon tribes to develop culturally appropriate programs guided by NA community members. Through OHSU's Northwest Native American Center of Excellence, we developed a close relationship with the Confederated Tribes of Warm Springs. Together with our institution's Community Outreach, Research, and Engagement (CORE) team, we are working with the Confederated Tribes of Warm Springs to better understand provider and NA community member attitudes towards and barriers to clinical trial participation. We will incorporate these perceptions into a tribe-specific program that describes the multi-faceted facilitators and barriers that inform decision-making. Moreover, we are implementing a patient navigator program to help NA patients overcome clinical trial barriers by providing culturally appropriate patient education, reimbursement for travel-associated expenses, local administration of

chemotherapy, and telehealth capabilities. Future work includes co-implementing strategies for tribes to review incoming research requests with the goal of implementing a system to promote awareness and enrollment of NAs in PDAC clinical research. This system will be then be utilized to establish the first NA PDAC tissue registry to identifying gene-environment interactions and unique genetic alterations that may predispose NA individuals to PDAC. Overall, this collaborative work will create a roadmap for engagement and a conscientious process to provide awareness and the best in class treatment for NA individuals with PDAC.

Early detection of cancer disparity and treatment resistance in TNBC

Amy H. Tang[1], Richard A. Hoefer[2], Dasom Lee[3], Emily L. Breeding[4], Mary L. Guye[5], Janet S. Winston[6], Billur Samli[6], Jennifer Koblinski[7], Valentina Robila[8], Michael O. Idowu[9], Rick J. Jansen[10], Harry D. Bear[11]. *[1]Microbiology and Molecular Cell Biology, Leroy T. Canoles Jr. Cancer Center, Eastern Virginia Medical School, Norfolk, VA,[2]Sentara Cancer Network, and George Mason University, Sentara Healthcare Systems, Norfolk, VA,[3]Department of Medicine, Division of Oncology, Stanford University School of Medicine, Stanford,, CA,[4]VUMC Department of General Surgery, Vanderbilt University Medical Center, Nashville, TN,[5]Sentara Surgery Specialists - Surgical Oncology, Sentara CarePlex Hospital, and Sentara Cancer Network, Newport News, VA,[6]Sentara Pathology, and Pathology Sciences Medical Group, Sentara Norfolk General Hospital, Norfolk, VA,[7]Massey Cancer Center, Virginia Commonwealth University, Richmond, VA,[8]Department of Pathology, Division of Anatomic Pathology, Virginia Commonwealth University, Richmond, VA,[9]Department of Pathology, Division of Anatomic Pathology, Virginia Commonwealth University (VCU) Medical Center, Richmond, VA,[10]Department of Public Health, Genomics, Phenomics, and Bioinformatics Program, North Dakota State University, Fargo, ND,[11]Departments of Surgery and Microbiology & Immunology, Division of Surgical Oncology, Virginia Commonwealth University, Richmond, VA*

Triple-negative breast cancer (TNBC) is the most aggressive breast cancer subtype and disproportionately affects BRCA1 mutation carriers and young black women. Black/African American (AA) patients with TNBC have the highest mortality rate and the shortest survival of any racial/ethnic group in

the United States. TNBC challenges our ability to personalize effective therapy. Neoadjuvant chemotherapy (NACT) is the standard-of-care (SOC) to treat T2 or LN+ TNBC. The addition of immune checkpoint blockade (ICB) has revolutionized treatment for these high-risk patients. Pembrolizumab plus chemotherapy is the new SOC for neoadjuvant systemic therapy (NST) in TNBC. Pathologic complete response (pCR) is a reliable indicator that correlates with improved long-term survival. However, clinical uncertainties remain in those who have an incomplete pathologic response (pIR) since many similarly treated TNBC patients with identical stage and comparable residual cancer burden (RCB) demonstrate disparate clinical outcomes. Current methods fall short in predicting tumor recurrence and treatment resistance in the clinic.

Supported by ample evidence in developmental, evolutionary, and cancer biology, we proposed that EGFR-K-RAS-SIAH pathway activation is a major driving force in TNBC and that its most downstream gatekeeper, SIAH, is a tumor-specific, therapy-responsive, and prognostic biomarker for patient risk stratification in TNBC. The persistent high expression of SIAH in residual tumors after neoadjuvant therapy reflects EGFR/K-RAS pathway activation (ON) and resistance to treatment. The loss of expression of SIAH in residual tumors reflects EGFR/K-RAS pathway inactivation (OFF) and response to treatment (i.e. treatment efficacy). Here we propose to establish the power of SIAH as a prognostic biomarker to differentiate high-risk from low-risk tumors and predict “real-time” therapy response, in both pre- and post-neoadjuvant (NACT/NST) setting.

Breast cancer mortality rates in Hampton Roads Virginia and Richmond Virginia are among the worst in the U.S. and demonstrate a major cancer health disparity. Black patients in our region have a 60-70% higher mortality rate than white patients according to CDC/SEER databases. Using a large cohort of 525 racially diverse TNBC patients (246 black and 279 white patients) at Sentara Cancer Network, we conducted Kaplan-Meier survival analyses and detected a major racial disparity, with significantly lower survival among the Black/AA TNBC cohort, compared to national databases. We will expand this TNBC disparity study by using 2 large racially-diverse cohorts of 981 TNBC patients (459 Black and 493 white patients) from the Sentara Cancer Network and VCU Massey Cancer Center to analyze the prognosis of SIAH expression. By focusing on this tumor-driving EGFR-K-RAS-SIAH pathway, we aim to delineate the underlying molecular basis of treatment resistance and racial disparity in high-risk TNBC.

Increasing racial and ethnic diversity of phase 1 solid tumor clinical trials through enrollment at a safety net hospital

Varun Roy[1], Esther Lee[2], Ming Li[1], Xiomara Menendez[1], Elena Nieves[1], Rebecca Umayam[1], Nicole Jensen[1], Lorraine Martinez[1], Diana Hanna[1], Jorge Nieva[1], Anthony El-Khoueiry[1], Jacob Thomas[1]. *[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Georgetown University School of Medicine, Washington DC, DC*

Background: Racial minorities are under-represented in oncology clinical trials. African Americans and Hispanic/Latinos account for 13% and 18% of the US population, respectively, but in 2018 these groups combined were only 8% of oncology trial subjects. Disproportionate enrollment can limit how generalizable trial outcomes may be and can perpetuate healthcare disparities. The majority of clinical trial enrollment occurs at large academic cancer centers that may not reflect the diverse general cancer patient population in the US. Los Angeles County/University of Southern California Medical Center (LAC+USC) is a large safety net hospital that serves a racially and ethnically diverse patient population.

Methods: We developed a database of all adult patients (pts) enrolled in phase I solid tumor trials at LAC+USC from 2015 - 2022. The data collected includes baseline demographics (age, gender, race, ethnicity, primary language, tumor histology), type of therapeutic intervention, radiologic response per RECIST 1.1, duration of treatment, and survival. Progression-free survival was defined as time from enrollment in the study until progression, discontinuation of treatment, or death. Disease control rate (DCR) was defined as pts with best response of CR, PR, or SD.

Results: 120 pts with solid tumors were enrolled in phase 1 trials at LAC+USC from 2015-2022. Median age was 58 (range 26-78); 58% female; ECOG 0-1 (99%), 2 (1%). 73 patients (61%) were Hispanic, 27 (23%) Asian/Pacific Islander, 9 (8%) non-Hispanic (NH) White, 5 (4%) were NH Black, and 6 (5%) were unknown. 70% of pts had a primary language other than English: 56% Spanish. The most common tumor types were colorectal (16%), hepatocellular (13%), non-small cell lung (12%), head and neck (11%), and ovarian (11%). Trial interventions included chemotherapy (19%), immunotherapy (35%), targeted therapy (54%), and 10% required biomarker selection. The disease control rate (DCR) was 58/120 (48%): 2 pts had CR, 9

pts had PR, and 47 pts had SD. 4-month progression-free survival (PFS) was 42/120 (35%), and 6-month PFS was 27/120 (23%). 90-day survival was confirmed in 101/120 (84%) of patients.
Discussion: A racially diverse population can be successfully enrolled in early phase oncology trials at a safety net hospital. Patient populations that are underrepresented nationally in clinical trials had robust enrollment and comprised the majority of participation (88%) in this setting. Almost half of patients derived clinical benefit (48% DCR) from trial participation. Creating an infrastructure to enroll patients to phase 1 clinical trials at a safety net hospital may be a successful strategy to improve racial and ethnic diversity.

Providing culturally responsible health care to Pacific Islander communities: The creation of a cultural competency training for healthcare professionals

Mark Lee Willingham Jr.[1], Kevin Cassel[2], Angela Sy[3], Munirih Taafaki[4], Tressa P. Diaz[5], Angelina G. Mummert[6]. *[1]Population Sciences in the Pacific - Cancer Prevention, University of Hawai'i Cancer Center, Honolulu, HI,[2]Population Sciences in the Pacific Program, University of Hawai'i Cancer Center, Honolulu, HI,[3]Department of Tropical Medicine, Medical Microbiology & Pharmacology, John A. Burns School of Medicine, Honolulu, HI,[4]Department of Quantitative Health Sciences, John A. Burns School of Medicine, Honolulu, HI,[5]School of Health, University of Guam, Mangilao, Guam,[6]Office of Research & Sponsored Programs, University of Guam, Mangilao, Guam*

Cultural competency is the ability to respectfully engage, understand, and communicate through conscientious interaction, enabling effective work and meaningful relationships in cross-cultural situations. Cultural competency recognizes the importance for organizations of participants' diverse social and cultural values, beliefs, and behaviors, and has gained attention because it can bridge health perspectives, understanding, and respect between health professionals and patients. There remains a need for cultural competency in healthcare as disparities persist across the U.S. in racial and ethnic minority groups who experience worse health outcomes and lower healthcare quality than the general public. Therefore, a cultural competency training curriculum was created using various resources to improve interactions between Pacific Islander patients and healthcare professionals. This training helps to reduce

racial/ethnic disparities in healthcare by encouraging mutual understanding and improving patient satisfaction, adherence to medical instructions, and overall health outcomes by highlighting patient-centered care as a result of utilizing components of cultural competency. To improve patient experiences in Hawai'i, healthcare professionals need the tools to better interact with patients from different cultures, such as Pacific Islanders. This training provides healthcare professionals with culturally-based content for improving cultural competence techniques for interacting with Pacific Island patients. This training was pilot tested with key stakeholders from community organizations and Cancer Center faculty/staff. Local health clinics, providers, and practices will have the opportunity to participate in this training through a Zoom-based electronic training format and be provided with three continuing medical education credits. The initial delivery of the training was intended for in-person sessions; however, a virtual format was adapted due to the COVID-19 pandemic and subsequent social distancing regulations. Healthcare providers are provided pre-training resources, a pre- and post-test, and a course evaluation to determine the validity of training objectives. To date, two Federally Qualified Health Centers have been provided the training , n=60, as well as one Cancer Health Equity Partnerships' Scientific Workshop, n=40. For attendees, the analysis of correct responses from the pretest to post-test showed a significant improvement on 6 of the 12 questions. Respondents also agreed that the training resources aligned with the course objectives. Improved patient interactions from this training can help support better patient outcomes, adherence to medical advice regarding cancer screenings, and many other aspects of improving health equity for Pacific Islanders.

"Simply ask and explain": perspectives from Black patients with lung cancer on strategies to address racial disparities in biospecimen research participation

Jeenn A. Barreiro-Rosa[1], Oluwatumilara Akeke[1], Annabella Opoku[2], Alison Hilton[3], Jessica Carda-Auten[3], Randall Teal[3], Aaron Carpenter[1], Hayley N. Morris[3], Lauren Matthews[3], Ashley Rankin Collins[3], Marjory Charlot[3]. *[1]UNC School of Global Public Health, Chapel Hill, NC,[2]University of Alabama, Tuscaloosa, AL,[3]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

Background: Participation of racially diverse populations in research is necessary to advance cancer care. However, representation of Black individuals in biospecimen cancer research remains low and requires being asked to engage in research. We sought to understand the experiences, beliefs, and knowledge about biospecimen research among Black patients with lung cancer.
Methods: Semi-structured interviews with a purposive sample of 15 Black patients diagnosed with lung cancer were conducted between January and August 2022 at a large academic center in North Carolina. Interviews were digitally recorded and transcribed and analyzed using thematic analysis.
Results: Themes related to who should initiate discussions about biospecimen donation, what should be considered before donation, and communication strategies to increase participation of Black patients with cancer in biospecimen research emerged from the interviews. Most participants indicated that discussions about biospecimen donation should be initiated by trusted and knowledgeable members of the medical team and most expressed trusting their providers. Some also expressed the importance of including family members in discussions about medical and research decisions. Some participants felt it was important to consider if donating specimens would cause pain or would require additional procedures. Recommended communication strategies to facilitate participation included use of simple and easily understood language in addition to messaging related to how biospecimen donation would benefit others. Participants also felt cultural humility, respect, and empathy during research recruitment would help enhance enrollment of Black participants in biospecimen research. Of note, all participants reported never being asked to participate in biospecimen research and felt that underrepresentation of Black participants may be due to not being asked.
Conclusion: Black participants in this study have not been asked to participate in biospecimen research but are willing to be engaged in conversations about research from their medical team. Simply being asked, trusting their medical provider, cultural humility, and framing the message on how the research will benefit others are some of the recommended strategies to enhance research participation among Black patients. Future research should incorporate these strategies into an intervention to assess the impact on recruiting Black individuals in biomedical research.

Research team perspectives on engaging Black patients with cancer in biospecimen research

Aaron Carpenter[1], Hayley N. Morris[2], Annabella Opoku[3], Alison Hilton[2], Jessica Carda-Auten[2], Randall Teal[2], Jeenn A. Barreiro-Rosado[4], Lauren Matthews[2], Oluwatumilara Akeke[2], Ashley Rankin Collins[2], Marjory Charlot[2]. *[1]UNC Gillings School of Global Public Health, Chapel Hill, NC,[2]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[3]University of Alabama, Tuscaloosa, AL,[4]UNC School of Global Public Health, Chapel Hill, NC*

Background**:** Representation of Black individuals with cancer in biospecimen research remains disproportionately low compared to white counterparts. Clinicians and research staff are responsible for informing, inviting, and consenting patients to participate in such research. We sought to understand clinician and research staff perspectives on engaging Black patients in biospecimen research.

Methods: We conducted 10 in-depth interviews with purposively sampled clinicians and research staff at a large academic cancer center in North Carolina between January and August 2022. Participants underwent semi-structured interviews (duration 45-60 minutes) and were asked open ended questions about biospecimen research barriers in general, barriers specific to people who identify as Black or African American, and considerations when discussing biospecimen research with Black patients. Interview transcripts were analyzed using thematic analysis.

Results: Perceived patient related barriers to biospecimen donation included pain from sample collection, invasive sample collection, lack of to time or transportation, medical research mistrust, health literacy, and limited knowledge of opportunities for involvement. Many felt that these barriers were faced by both Black and non-Black patients. However, some felt for Black patients, these barriers existed within the context of historical injustices in medicine, current bias in health care and socioeconomic inequities, while others felt socioeconomic status not race was more of a concern. Clinician and research staff identified barriers to discussing biospecimen research included lack of time given busy clinical practice and concern with patients' physical and emotional state. Patients' race was not considered a barrier. When asked about considerations for discussing biospecimen research specifically with

Black patients, participants felt time to establish rapport and trust, readiness to discuss historical injustices in biomedical research, reminding participants research is voluntary, and having in person discussions were important. Few felt that patient race was not relevant to these discussions.
Conclusion: Some clinicians and research staff acknowledge that historical injustices and current racial bias in biomedical research and health care contribute to low representation of Black individuals in biospecimen research, while others did not. Further research is needed to assess whether race and/or racism agnostic approaches versus acknowledgement of structural racism's influence on biomedical research and health care have an impact on fair representation of Black individuals in biospecimen research.

Landscape and analysis of ERBB2 amplification and short variant mutations in large-scale Chinese patients with colorectal cancer

Zhiqin Chen[1], Shijun Yu[1], Yin Wu[1], Bei Zhang[2], Ding Zhang[2], Yong Gao[1], Ming Quan[1]. *[1]Department of Oncology, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China,[2]The Medical Department, 3D Medicines Inc, Shanghai, China*

Background**:** Human epidermal growth factor receptor 2 (ERBB2) amplification is a rapidly emerging therapeutic target in CRC, in spite of a relatively low incidence. While ERBB2 amplification has been considered as a critical biomarker to predict the efficacy and safety of anti-ERBB2 therapy of CRC, its point mutation status is largely ambiguous.**Methods:** Blood or tissues samples from 2454 Chinese patients with CRC were collected, and the genomic landscape, clinical characteristics and genetic features of ERBB2 in these samples were retrospectively investigated using next-generation sequencing (NGS) analysis. **Results:** Of the 2454 colorectal cancer patients, 3.46% (85) carried ERBB2 amplification, 2.24% (55) carried ERBB2 mutation, and some patients harbored both ERBB2 amplification and point mutation at the same time. Microsatellite instability high (MSI-H) was found in approximately 32.7% (18/55) of patients with ERBB2-mutated CRC, but almost negative in ERBB2-amplified CRC. The median fold change of ERBB2 amplification was 30 (Range 4 to 245). Among the 16 mutation sites detected from 55 patients with ERBB2 point mutations, p.R678Q was the

most common mutation site (28%), followed by p.V842I (24%) and p.S310F/Y (12%), which appeared to be slightly different from previous reports. ERBB2
mutation was more frequently found in CRC patients aged < 50 years. 50.9% of CRC patients with wild-type ERBB2 carried KRAS mutation, which was significantly higher than those with mutated ERBB2 (25.6%). A higher incidence of BRAF mutation was observed in patients with mutated-ERBB2 (8.5% vs. 2.3%). In addition, CRC patients with ERBB2 CNV showed a higher prevalence of TP53 mutation comparing with those with ERBB2 SNV (92.3% vs. 58.3%), while KRAS mutation exhibited a contrary trend (14.1% vs. 45.8%)**Conclusions:** The overall variation rate of ERBB2 is 5.4% in Chinese patients with CRC, which is accompanied by significantly different molecular pathological characteristics compared to patients with wild-type ERBB2, and different mutation types (CNV or SNV) display different molecular pathological characteristics.

Prognostic impact of sarcopenia in patients with metastatic castration sensitive prostate cancer

Hiroaki Iwamoto, Kouji Izumi, Atsushi Mizokami. *Department of Integrative Cancer Therapy and Urology, Kanazawa University Graduate School of Medical Science, Kanazawa, Japan*

Background/Aim: Recently, sarcopenia has been reported to be a useful prognostic factor in cancer patients, including prostate cancer patients. Gleason score, the presence or absence of visceral metastases, and the number of bone metastases, which were used in the LATITUDE and CHAARTED trials, are known prognostic factors for metastatic castration-sensitive prostate cancer (mCSPC). Although a large proportion of patients with mCSPC are elderly, the significance of sarcopenia in metastatic castration-sensitive prostate cancer is unknown.
Patients and Methods: Of 193 patients with mCSPC treated at Kanazawa University Hospital between 2000 and 2019, 150 patients with confirmed CT at diagnosis were included. Sarcopenia was determined based on the definition of Martin et al. Overall survival and prognostic factors were retrospectively evaluated.
Results: The median age was 72 years, median PSA 241 ng/mL, Gleason score (GS) ≥ 9 in 91 patients, visceral metastases in 23 patients, and

sarcopenia in 106 patients. 109 patients (72.7%) were diagnosed as high risk by Latitude risk classification and 105 patients (70%) were diagnosed as high volume by Charted risk classification. All cause death was 64 patients, and the median follow-up period was 38.2 months. The median overall survival was 69.6 months. On multivariate analysis, GS ≥9 (P <0.0001, hazard risk =3.78), LDH ≥ 300 U/L (P <0.0001, hazard risk =2.88), and sarcopenia (P=0.04, hazard risk=2.07) were significant independent poor prognostic factors predicting shorter OS. The prognosis could be significantly stratified into a high risk group if two or more of these three factors were met and a low risk group if one or less was met (44 months vs. 106.4 months, P=0.0001, hazard risk=2.91). This classification more clearly stratified prognosis than the LATITUD classification (55.1 months vs. 135 months, P =0.027, hazard risk =1.8) or the CHAARTED trial classification (52.9 months vs. 135 months, P =0.009, hazard risk =1.98).
Conclusion: Sarcopenia that can assess general status was considered useful in the prognostic evaluation of patients with mCSPC.

#5538

Prevalence of factors serving as common cancer clinical trial eligibility criteria by race and ethnicity

Yayi Zhao[1], Rossybelle P. Amorrortu[1], Rachel Howard[2], Kedar S. Kirtane[3], Susan T. Vadaparampil[4], Dana E. Rollison[1]. *[1]Department of Cancer Epidemiology, Moffitt Cancer Center, Tampa, FL,[2]Department of Health Informatics, Moffitt Cancer Center, Tampa, FL,[3]Department of Head and Neck-Endocrine Oncology, Moffitt Cancer Center, Tampa, FL,[4]Office of Community Outreach, Engagement, and Equity; Department of Health Outcomes & Behavior, Moffitt Cancer Center, Tampa, FL*

Background: Racial/ethnic minority patients remain underrepresented in clinical trials potentially due to restrictive trial eligibility criteria that disproportionally affect minority cancer patients.
Objective: To examine the prevalence of existing medical conditions and abnormal lab values that commonly serve as clinical trial eligibility criteria among cancer patients by race and ethnicity.
Methods: A cross-sectional analysis was conducted among patients new to Moffitt Cancer Center in 2011-2021 with multiple myeloma (n=3,967), breast (n=14,348), lung (n=10,492), and prostate (n=7,823) cancers. Demographics, existing medical conditions, and lab values were obtained from the Electronic

Health Record, whereas history of cancer and metastatic disease at diagnosis were obtained from the Cancer Registry. Prevalence of medical conditions and abnormal lab values were reported among all patients and compared by race groups (White, Black, Hispanic, and other races) using age-adjusted logistic regression. For factors with prevalence higher than 5%, stratified analysis was conducted with respect to cancer type and adjusted for multiple comparisons.
Results: Compared to White patients, Black (B) and Hispanic (H) patients were found to have higher prevalence of diabetes (OR [odds ratio] = 2.26 [B]/1.40 [H]), organ transplantation (OR=1.58 [B]/1.77 [H]), hepatitis (OR=1.74 [B]/1.48 [H]), HIV (OR=4.25 [B]/1.92 [H]), and abnormal creatinine value (OR=1.77 [B]/1.23 [H]). In addition, Black patients were more likely to have hypertension (OR=1.41) while patients of other races were more likely to be diabetic (OR=1.36). Similar patterns were observed across cancer types.
Conclusion: Restrictive cancer clinical trial eligibility criteria may post a structural barrier that disproportionately impact racial/ethnic minority patients. Investigators should consider leveraging real-world data to define and design appropriate trial eligibility criteria.

Prevalence of factors commonly included as clinical trial eligibility by race/ethnicity.

Factors	**All**	**White**	**Black**		**Hispanic**		**Other**	
	Prevalence (%)	**%**	**%**	**OR (95% CI)**	**%**	**OR (95% CI)**	**%**	**OR (95% CI)**

Assessing knowledge, vaccine hesitancy, and completion rates of free HPV vaccination in uninsured/underinsured low-income patients

Hiram Diaz[1], Gerardo Colon-Otero[2], Laura M. Pacheco-Spann[3], Christopher C. DeStephano[4], Sandra Casanova-Leyva[5]. *[1]University of Puerto Rico, San Juan, PR,[2]Department of Hematology/Oncology, Mayo Clinic, Jacksonville, FL,[3]Quantitative Health Sciences, Mayo Clinic, Jacksonville, FL,[4]Department of Medical and Surgical Gynecology, Mayo Clinic, Jacksonville, FL,[5]Mayo Clinic, Jacksonville, FL*

Background: Human Papillomavirus (HPV) vaccination rates remain low in the U.S., particularly among minorities and low-income patients. In 2014, a Mayo Clinic study of uninsured, low-income, working, Volunteer in Medicine (VIM) Clinic patients in Jacksonville, Florida found a statistically significant lower awareness of HPV (50.3% vs 63.6%) and the HPV vaccine (32.1% vs 62.7%) than the national population. As a result, our team collaborated with Merck to develop a free HPV vaccination program and video education campaign for VIM patients.

Methods: We assessed VIM patients HPV vaccination knowledge, awareness, and prevalence of hesitancy towards receiving the vaccine. VIM patients (ages 18-45) with no previous history of HPV vaccination were invited to participate in this study. The Parents Attitudes about Childhood Vaccines (PACV) survey was used to evaluate vaccine hesitancy. Patients who declined the HPV vaccine were shown an educational video to assess effectiveness in persuading patients' opinion. Each participant received a vaccine hesitancy PACV score, which was compared with their vaccine disposition. Mayo Clinic IRB approval of the study was obtained.

Results: Our analysis included 43 patients (34 females, 9 males) with a median age of 40 (age range 27- 45). Patients had overall knowledge of HPV of 88.4%, with 69.8% having heard of the HPV vaccine. 85.7% PACV survey respondents were deemed non-hesitant (PACV scores 0-49), and 80.6% of the non-hesitant subset (29/36) agreed to undergo vaccination. The average PACV score of vaccine-interested participants was lower (25.2) than the average of participants not interested in the vaccine (36.7). Black participants had a statistically significant higher PACV score than White participants. The PACV scores of individuals who were already familiar with the HPV vaccine were significantly lower than those of participants who were unfamiliar with the HPV vaccine. Only 20% (2/10) of individuals, who had previously declined vaccination, agreed to receive the HPV vaccine after viewing the HPV

educational video. Of the 33 participants who agreed to receive the free HPV vaccine, only 9 (27.3%) completed all three doses.
Conclusions: HPV vaccine awareness and knowledge at VIM increased compared to the 2014 cohort. Vaccine hesitancy was not observed in most patients, yet video education was effective in only a small portion of patients with vaccine hesitancy. Additionally, a minority of patients who agreed to receive the free HPV vaccine series completed all three doses. Our results suggests that free HPV vaccination and video education is not sufficient to achieve adequate vaccination rates among low-income uninsured young adults, nor overcoming vaccine hesitancy. Innovative measures are warranted to improve vaccination rates in this population.

Spouse caregivers of patients with glioblastoma report unmet needs throughout the disease trajectory

Diana L. Coman[1], Megan Chard[1], Lisa Desautels[2], Barbara J. Lutz[1], Laurie Minns[1]. *[1]University of North Carolina, Wilmington, NC,[2]The Glioblastoma Support Network, Overton, NV*

Glioblastoma (GBM) is a devastating and terminal cancer that results in memory loss, cognitive declines, personality changes, neuropsychiatric symptoms, and physical impairments that greatly affect quality of life of both the patient with GBM and their primary caregiver, who is often a spouse or partner. These caregivers describe feeling unsupported and unprepared to assume the responsibilities associated with addressing the progressive physical, emotional, and psychological support needs of their loved ones with GBM. In this qualitative study, female spouse primary caregivers were recruited through a private Facebook support group to write letters describing their experiences in caring for their loved ones with GBM. Using a reflexive thematic analysis, 101 letters from caregivers were analyzed for unmet needs, challenges, and opportunities for better care and support. Caregivers expressed feeling unsupported and poorly prepared, and described different levels and types of needs and challenges throughout the GBM disease trajectory. The 4 phases of the trajectory included the acute phase (first 2-4 months post diagnosis), living with disease progression, end of life stage, and the bereavement stage. Challenges included difficulties adapting to sudden life changes, the need for more education on what to expect, feelings of sudden loss, relationship strain, and not having enough knowledge about GBM.

Associated emotional responses included feelings of fear, lack of control, agony, disappointment, and exhaustion. These challenges and emotional impact were greatest during the acute and living with disease progression phases. Caregivers also described relying heavily on friends, community supports (such as faith groups), peer-support through the Facebook group during this living with disease progression phase, but still experienced high levels of relationship strain and other unmet needs. These findings on the primary caregivers' experiences provide opportunities to guide more timely and tailored interventions to provide support and improve care for patient/caregiver dyads to help mitigate the burden of this progressive disease and improve quality of life for caregivers.

Diagnostic and Prognostic Biomarkers 4

Association of circulating markers of gut barrier damage and inflammation with colorectal neoplasia stage

Flavia Genua[1], Petr Holý[2], Pavel Souček[3], Václav Liška[4], David J. Hughes[1].
[1]Cancer Biology and Therapeutics Laboratory, Conway Institute, School of Biomedical and Biomolecular Sciences, University College Dublin, Dublin, Ireland,[2]Faculty of Medicine in Pilsen and Third Faculty of Medicine Charles University, Prague, Czech Republic,[3]Laboratory of Pharmacogenomics, Biomedical Center, Faculty of Medicine in Pilsen, Charles University, Pilsen, Czech Republic,[4]Department of Surgery, Biomedical Center, Faculty of Medicine in Pilsen, Charles University and University Hospital Pilsen, Pilsen, Czech Republic

A disturbance in the microbiome facilitated by gut barrier dysfunction and inflammation can influence the progression of colorectal neoplasia. One of the most studied indicators of gut barrier status is lipopolysaccharide (LPS). Increased permeability of the gut barrier leads to extensive translocation of microbes into the lamina propria, which is associated with higher circulating levels of LPS. Additionally, increased serum concentrations of inflammatory cytokines including IFNy, IL6, IL10, and TNFα have been associated with impaired gut integrity and its progressive dysfunction.
We investigated the role of gut barrier permeability and inflammation in colorectal cancer (CRC) development by assessing markers of intestinal barrier dysfunction and inflammation in two different patient cohorts; Irish

(discovery) and Czech (validation). ELISA assays were used to assess circulating concentrations of lipopolysaccharide binding protein (LBP) and C-reactive protein (CRP) in serum from patients with CRC (n=30), colorectal adenoma (n=40), and negative after colonoscopy/blood donor controls (n=35). Circulating levels of inflammatory cytokines and calprotectin were assessed using an MSD MultiSPOT platform and an MSD R-plex assay (Mesocale Discovery, Rockville, Md, United States), respectively. Differences between pathology groups were assessed using the Kruskal Wallis or Mann-Whitney U test. Receiver operating curve (ROC) analysis was implemented to identify single and combinations of biomarkers capable of discriminating between CRC patients and controls with maximum sensitivity (SE) and specificity (SP) (RStudio, PBC, Boston, MA URL http://www.rstudio.com/).
In the discovery cohort, levels of LBP, TNFα, IL6, calprotectin and CRP were significantly higher in CRC patients than in controls after false discovery rate correction (p=0.02, p=0.03, p=0.006, p=0.01, p=0.006, respectively). The area under the ROC curve (AUC) was 0.76 (95% CI: 0.64-0.87, p = 0.003) for LBP,
0.69 (95% CI: 0.55-0.82, p = 0.007) for calprotectin and 0.87(95% CI: 0.74-1.00, p = 0.003) for CRP. The optimal biomarker combination for discriminating between CRC and controls was the combination of the three markers (SP= 0.75, SE = 0.75). In the validation cohort, levels of calprotectin and TNFα, were significantly higher in cancer compared to control (p=0.05, p=0.02, respectively). Furthermore, IFNγ and IL10 were also significantly elevated in cancer compared to control (p= 0.02, p=0.003, respectively).These results support the hypothesis that a dysfunctional gut barrier and attendant inflammation may influence CRC development and progression. Additionally, LBP, CRP and calprotectin may have potential as diagnostic biomarkers for CRC or for risk stratification. Gut bacterial and barrier wall modulation and stabilization has potential for preventing colorectal adenomas and hence colorectal cancer.

Assessing LGR5 expression levels on colorectal cancer tissue samples for use in LGR5-targeting CAR-T cell therapy clinical trial

Emma J. Thompson[1], Veronika Bandara[2], Batjargal Gundsambuu[2], Silvana Napoli[2], Stuart Mills[3], Jade Foeng[4], Dylan McPeake[4], Timona Tyllis[4], Caitlin Abbott[4], Allison Cowin[3], Timothy Sadlon[5], Shaun McColl[4], Carmela Ricciardelli[6], Simon C. Barry[5], Claudine S. Bonder[1]. *[1]Centre for Cancer*

Biology, University of South Australia, Adelaide, Australia,[2]Carina Biotech, Adelaide, Australia,[3]Future Industries Institute, University of South Australia, Adelaide, Australia,[4]Chemokine Biology Laboratory, University of Adelaide, Adelaide, Australia,[5]Molecular Immunology, Robinson Research Institute, University of Adelaide, Adelaide, Australia,[6]Adelaide Medical School, University of Adelaide, Adelaide, Australia

Leucine-rich repeat containing G-protein coupled receptor (LGR5) is stem cell marker that potentiates canonical signaling in the Wnt/β-catenin signaling pathway (Barker *et al.* 2007). LGR5 is known to be expressed on several tissues; particularly the stem cells within intestinal crypts and the stem cell niche at the base of hair follicles (Barker *et al.* 2007 and Jaks *et al.* 2008). The plasticity and stem phenotype of LGR5+ cells has led to their identification as a cancer stem cell marker for some solid tumors including colorectal cancer (CRC) (Barker *et al.* 2009). This presents LGR5 as a potential target molecule for CAR-T cell directed specific tumor cell killing. For treatment of CRC with LGR5-directed CAR-T cells, it is critical to gain an understanding of the level of LGR5 expression on normal tissue compared with cancerous tissue. The aim of this study was to develop a screening technique for patient selection, and importantly identify potential responders to LGR5-targeting CAR-T cell therapy.Utilizing commercially purchased tissue microarrays a cohort of patient primary tumor biopsies (n=472) were assessed for LGR5 expression; ~60% displayed moderate to high level LGR5 positivity, with a trend toward higher grade, later stage tumors having higher levels of LGR5. LGR5 expression levels on lymph node metastases showed a positive correlation to LGR5 expression on patient-matched primary tumor tissue. Seven out of ten liver biopsies from metastatic colon cancer lesions showed a medium to high level LGR5 staining, indicating this may be used as a screening tool for metastatic CRC patients. We also observed restricted expression of LGR5 across the many normal tissues, suggesting limited off-target effects of LGR5-targeting CAR-T cells.The data obtained in this study provides evidence that LGR5 IHC of biopsies could be used as a diagnostic screening tool of CRC patients for inclusion into a Phase1a/2 clinical trial.

Urine metabolomic biomarkers discovery for bladder cancer diagnostics

Andrew J. Schwab, Matthew W. Mitchell, Edward D. Karoly, Rangaprasad Sarangarajan. *Metabolon, Inc., Morrisville, NC*

Current estimates in the United States for 2022 are about 81,180 new cases of bladder cancer diagnosis with about 17,100 deaths from the disease (American Cancer Society). Urothelial carcinoma, also known as transitional cell carcinoma (TCC), is the most common type of bladder cancer, approximately 70% of newly diagnosed TCC patients have non-muscle invasive bladder cancer (NMIBC) tumors. The gold standards for initial diagnosis and recurrence of TCC, cystoscopy and cytology, are both limited by their inability to visualize certain areas within the bladder or detect low grade tumors. Moreover, these tests are associated with false positive profiles, with potential for abnormal readouts even in individuals with no obvious signs of cancer. High recurrence rate predicates the need for constant monitoring of signs and symptoms associated with bladder disease following initial diagnosis, and non-invasive diagnostic modalities to detect both recurrent and primary early-stage tumors are a critical unmet need. In this study, comprehensive metabolomic profiling from human urine samples was used to identify and validate a panel of metabolites as potential biomarkers of bladder cancer. Urine samples from 439 total subjects (comprised of 66 bladder cancer, 119 history of bladder cancer but no bladder cancer at time of urine sampling, 58 hematuria subjects, 48 renal cell carcinoma, 58 prostate cancer, and 89 healthy subjects) were analyzed using a proprietary global untargeted metabolomic platform. A follow-up study to determine the reproducibility of the initial data set was conducted with 162 urine samples from subjects with bladder cancer that were either recurrent or primary, or with a negative diagnosis for bladder cancer with a previous history of bladder cancer or had hematuria or urinary voiding issues. Utilizing both data sets, eight biochemicals (lactate, gluconate, palmitoyl sphingomyelin, acetylcarnitine, choline phosphate, succinate, and adenosine) were identified as potential urine biomarkers for bladder cancer. In addition, 3-hydroxybutyrate (BHBA), 2-hydroxybutyrate (AHB), and adipate were identified as potential urine biomarkers for urological cancers. In total, 37 biochemicals have now been identified with having the potential to serve as urine bladder cancer biomarkers, and the majority of the biochemicals identified as biomarkers

were associated with biochemical pathways previously shown to be perturbed in bladder tumors. The performance characteristics of the identified biochemicals in the detection of bladder cancer will be reported.

#5547

Evaluation of two clinically focused targeted NGS systems for liquid biopsy testing shows a high level of concordance in resulting actionable mutations

Sarah Kreston, Claire Gould, Kylie Blair, Leisa Jackson, Janice Riley, Gary A. Pestano. *Biodesix, Inc., Boulder, CO*

Introduct**ion:** The use of blood-based molecular diagnostics is increasingly becoming routine in clinical oncology practice. The purpose of this study was to evaluate variant resulting concordance for the four major somatic variant classes using two clinical next-generation sequencing (NGS) systems for conducting highly sensitive blood-based analyses. All donor specimens were de-identified remnants from patients previously diagnosed with advanced NSCLC. We utilized two independent panels, systems and bioinformatic pipelines that are focused on clinical testing for key actionable variants. The fifty-gene panel Oncomine Precision Assay (OPA) GX was performed on the Genexus Integrated Sequencer and the 52 gene GeneStrat NGS (GSNGS) test was run as a reference on the Ion GeneStudio S5 PRIME system. The four major classes of mutations evaluated included Single Nucleotide Variants (SNV), Insertions and Deletions (INDEL), copy number amplifications (CNAs) and gene fusions.

Methods: For this study, de-identified reference GSNGS cell-free nucleic acid (cfNA) remnant specimens (n=33 variants) that passed all validated QC bioinformatics thresholds were blinded and tested on the Genexus. DNA concentration was measured by fluorometry, and specimens were diluted to an input of 6.6 ng to 53.4 ng for library preparation. The Genexus system is pre-programmed to process specimens to result generation. Variant calls for all mutation classes were conducted using the on-board bioinformatics pipelines, and results were compared to those generated by the GeneStrat NGS Test. We included specimens harboring somatic variant mutations in KRAS, NRAS, BRAF, EGFR, ERBB2, and FGFR; CNAs; EML4-ALK fusions; and MET exon 14 skipping.

Results: All samples passed the OPA (Genexus) bioinformatic quality control criteria and mapped reads were highly consistent, demonstrating accuracy of

calls between both the Ion Torrent platforms, informatic pipelines and panels. We observed 100% concordance in variant calls for SNVs, INDELs and fusions between the two platforms. There was one CNA variant observed on the S5 that was not called by the Genexus workflow, yielding overall concordance of 97% (32 of 33). Of note, 44 additional somatic variants (SNV and INDELs) and 1 additional fusion were detected using the Genexus workflow. This was due to the lower threshold for variant calling on this system.

Conclusion: The high concordance of the independent workflows for the detection of nucleic acid variants in circulation demonstrates the capability of both systems to be used for testing of clinical specimens. Specifically, actionable variants in the four major mutation classes were successfully detected in the reference and test specimen set. As a part of clinical validation, orthogonal testing of variants will need to be conducted.

Clinical management and decision making in early ER-positive breast cancers through improved prognosis and pathway directed molecular profiling

John M. S. Bartlett[1], Cheryl Crozier[2], Vinay K. Mittal[3], Dan Dion[2], Angela De Luca[2], Adam E. Sundby[2], Elizabeth Woroszchuk[2], Bradley d'Souza[2], Louis Gasparini[2], Mary Anne Quintayo[2], Mehar Chahal[2], Anna Y. Lee[2], Mathieu Larivière[3], Kyusung S. Park[3], Anupma Sharma[3], Jeffrey M. Smith[3], Seth Sadis[3], Daniel W. Rea[4], Melanie Spears[2], Jane Bayani[2]. *[1]Cancer Research UK Edinburgh Centre, The University of Edinburgh, Edinburgh, United Kingdom,[2]Diagnostic Development, Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Thermo Fisher Scientific, Carlsbad, CA,[4]Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, United Kingdom*

Hormone receptor positive (HR+ve) breast cancer (BCa) comprises over 80% of all newly diagnosed BCas. While there is an initial good response to anti-hormone therapies, many patients will experience a recurrence. Validated prognostic tests are used to guide chemotherapy decisions, but the goal of precision medicine has yet to be achieved. We developed and validated a 95-gene prognostic signature (Bayani et al 2017) from the TEAM trial (van de Velde et al, 2011), demonstrating this risk classifier performed as well as the 21-gene, 50-gene and 70-gene tests and can be used in HER2+/-ve cases

including only nodal status. RNA profiling has improved decisions regarding adjuvant chemotherapy but is insufficient for stratification to targeted therapies increasingly available in the early setting. The genomic landscape of BCas has identified recurrent patterns of mutation and copy-number changes. Except for HER2, there are few genes for whom mutational or gene dosage are reliable for stratification to targeted therapies. It is increasingly evident that a multi-omic approach to precision medicine is needed to encompass the biological complexity of cancer. Here we present the findings from the RNA profiling of patients from the TEAM trial using a custom diagnostic-grade NGS panel of the 95-gene risk classifier and DNA sequencing using a large (500 gene) comprehensive genomic profiling panel (OCAPlus, Thermo Fisher Scientific). 95-gene prognostic results of 1,182 patients showed prognostic utility using the custom panel with 265 (22%) low-risk patients experiencing >90% relapse free survival (DRFS)(HR=4.47 (95% CI 2.46-8.02, p=5.54e-07)) at 10 years. In 857 cases profiled with OCAPlus, the genes most frequently mutated included PIK3CA (53%), MAPK31 (25%), TP53(17%), CDH1 (17%) and GATA3 (10%). Frequent copy number changes were identified in CCND1 (18%), FGFR1 (12%), and MDM2 (5%). To investigate the potential for stratification to targeted therapies, a pathway approach was taken to identify aberrations in targetable signaling pathways. Among the 788 cases with both OCAPlus and the 95-gene results, the most frequently impacted pathways were PI3K/AKT (67%), HHR Pathway (55%), Chromatin regulation (50%), RAS/RAF/MEK/ERK (40%) and Cell Cycle (37%). To address the clinical need for those patients deemed at risk for recurrence, the consequence of aberrations in those pathways were investigated. Among 95-gene high-risk patients (n=604), those with mutations in genes of the Cell Cycle pathway experienced poorer DRFS (HR=1.95 (95%, CI 1.29-2.95, p= 0.0159), suggesting these patients might benefit cell cycle-targeting therapies. With no reliable biomarkers to predict response, and with associated side effects/ toxicities of these agents, this offers a rational pathway-directed method of decision making for those identified as high-risk of recurrence.

Normalized platelet splicing junction count is a novel biomarker for diagnosis of ovarian tumors

Eunyong Ahn[1], Se Ik Kim[2], Sungmin Park[1], Sarah Kim[1], Seung Jin Yang[3], Yeochan Kim[3], Dong Won Hwang[2], Heeyeon Kim[4], HyunA Jo[4], Untack Cho[4], Juwon Lee[4], Yong-Sang Song[2], TaeJin Ahn[5]. *[1]Foretell My Health,*

Pohang, Korea, Republic of,[2]Department of Obstetrics and Gynecology, Seoul National University Hospital, Seoul, Korea, Republic of,[3]School of Life Science, Handong Global University, Pohang, Korea, Republic of,[4]Cancer Research Institute, College of Medicine, Seoul National University, Seoul, Korea, Republic of,[5]Handong Global University, Pohang, Korea, Republic of

Owing to a lack of disease-specific symptoms and effective screening tools, most ovarian cancers are diagnosed at an advanced stage, resulting in high recurrence and mortality rates. Recently, there has been an effort to diagnose ovarian cancer utilizing platelets, which are crucial in the immunology of oncogenesis. These transcriptome-wise techniques, however, had two significant drawbacks: utilizing a normalization method that can be altered depending on the content of the samples in the dataset and using an excessive number of features. We, therefore, present a method for assessing the existence of ovarian cancer or benign tumors by utilizing a fewer features with a sampling invariant normalization technique.
First, we downloaded platelet transcriptome data of patients with ovarian cancer (n=28), benign ovarian tumor (n=17), and their healthy counterparts (n=204) from GEO (GSE158508 and GSE89843 - PRJNA353588 and PRJNA353588). Second, for external validation, we prospectively enrolled patients with ovarian cancer (n=4) and benign ovarian tumors (n=9), and healthy women (n=14) at Seoul National University Hospital (SNUH), collected their blood samples, and obtained platelet transcriptome data. The normalization was performed using commonly and invariantly existing 20 splice junctions in the isolated platelet of tumor and normal samples. Herein, 319 splice junctions were selected as features for the SVM model diagnosing the existence of an ovarian tumor. Feature selection and model development were conducted using a training set (n=152) and model performance was assessed from a separate test set (n=97).
SVM classifier that utilized our splice junction-based biomarkers (20 for normalization, 319 for tumor classification) demonstrated 93.8% (71.7 - 98.9%) sensitivity, 100.0% (95.5 - 100.0%) specificity, and 1.0 of AUC in the test data set with a predetermined 0.5 cut-off value. Considering the difference of sequencing raw data between the open source and newly collected sample in terms of read length and read types (single-end vs paired-end), the SVM model from the open source was not suitable to the independent validation set. Thus, we train new SVM models using the same splice junctions with LOOCV in SNUH dataset. As the results, the model showed its diagnostic

performance with 92.3% (66.7 - 98.6%) sensitivity and 92.9% (68.6 - 98.7%) specificity.
We found novel splice junction-based biomarkers for the early detection or diagnosis of ovarian tumors. Although possible confounding factors such as ethnic variance may affect the performance of the models using these biomarkers, since the data preprocessing procedure is sampling invariant, the inclusion of samples from the same population would not affect our classification results. Furthermore, suggested biomarkers can be utilized during medical checkups of women without any symptoms to find women with ovarian tumors, whether benign or malignant.

Sociodemographic disparities in access to biomarker testing in patients with advanced colorectal cancer

Saad Sabbagh[1], Iktej Jabbal[2], Barbara Dominguez[1], Mira Itani[1], Mohamed Mohanna[1], Arun Nagarajan[1]. *[1]Cleveland Clinic Florida Foundation, Weston, FL,[2]AdventHealth Sebring, Sebring, FL*

Introducti**on** All patients with newly diagnosed colorectal cancer are recommended to undergo microsatellite instability (MSI) testing. In addition, mutational testing using biomarkers such as KRAS, NRAS, and BRAF is recommended for patients with metastatic cancers. Testing for these markers is vital as they guide therapeutic decision-making and serve as prognostic indicators. Our study aims to analyze disparities in testing for MSI and KRAS biomarkers based on sociodemographic factors in patients with metastatic colorectal cancer. Furthermore, we explored the survival characteristics in these patients based on sociodemographic factors and on access to biomarker testing.
Methods The National Cancer Database (NCDB) was queried for patients diagnosed with metastatic colorectal cancer (MCC). At the bivariate level, we performed chi-squared statistics and multivariate logistic regression modeling to explore variables associated with patients undergoing MSI and KRAS testing. In addition, Multivariate Cox regression and Kaplan-Meier analyses were performed for survival analysis.
Results N = 51,913 patients with MCC diagnosed between 2010 to 2017 were included. The median age for Whites was 68.0 years versus 64.0 years for Blacks. Blacks had a lower probability of undergoing MSI testing (OR 0.90, [0.84-0.96] $p< 0.0009$). Factors associated with a lower likelihood for MSI

testing included treatment at a Community Cancer Program (OR 0.61, [0.55-0.66] p<0.0001), residing in areas with people having lower education (OR 0.68, [0.62-0.74] p<0.0001) and in rural areas (OR 0.74, [0.61-0.90] p-value 0024), and a median household income of < $38,000 (OR 0.88, [0.80-0.96] p 0.0040). Patients with no insurance and Medicaid/governmental insurance were also less likely to undergo both MSI and KRAS testing. Blacks had a decreased likelihood of having high MSI levels among patients who underwent testing compared to Whites (OR 0.67, [0.50-0.91] p-value 0.0107). After controlling for confounding variables, survival analysis showed poor survival in patients who did not undergo testing for MSI and KRAS (HR 1.20, [1.17-1.23] p<0.0001 and HR 1.04, [1.01-1.06] p-value 0.0016 respectively). **Conclusion** Our analysis reveals that sociodemographic factors such as being from a minority race, having no insurance, residing in areas with lower education and rural settings were associated with a lower probability of undergoing MSI testing in patients with metastatic colorectal cancer. This is of concern as our study also reveals that not undergoing biomarker testing is associated with poorer survival. Addressing such sociodemographic discrepancies among racial groups is essential in achieving equitable care and narrowing gaps in outcomes.

#5551

Cancer associated PSA-glycoforms as prostate cancer markers

Hannu Koistinen[1], Ruusu-Maaria Kovanen[1], Timo-Pekka Lehto[2], Antti Rannikko[3], Tuomas Mirtti[2]. *[1]Department of Clinical Chemistry, University of Helsinki, Helsinki, Finland,[2]University of Helsinki, Helsinki, Finland,[3]Helsinki University Hospital, Helsinki, Finland*

Changes in protein glycosylation have been observed in several cancers, where they affect cellular growth behavior, invasiveness and acquisition of metastatic potential. Such changes are not random and have been found to associate with cancer aggressiveness. Thus, detection of protein glycosylation may offer novel opportunities for cancer biomarker development. Since prostate-specific antigen (PSA) is glycosylated, assessing different PSA-glycoforms may provide valuable diagnostic and prognostic information. We recently established a novel in situ proximity ligation-based method for the detection of different protein-glycoforms in tissue sections. This method utilizes protein-specific antibody and glycan-binding lectins. We have optimized this method for the detection of different PSA-glycoforms in

formalin-fixed paraffin-embedded prostatic tumor samples. We found that PSA is, indeed, differently glycosylated in prostate cancer (n=23) compared to benign prostate tissue (n=4). Two of the 25 studied lectins showed prominent staining only in cancer tissues ($p<0.0001$ for both), although the total PSA staining was stronger in benign tissues ($p=0.006$). We are currently validating these results in large, well-curated clinical cohorts, with intention to test whether PSA-glycoforms in tissue offer improved detection of clinically significant prostate cancer. These studies facilitate development of tools for identification of cancer-specific PSA-isoforms in serum samples. Detection of such isoforms is likely to provide independent diagnostic and prognostic information.

#5552

MAGE-A3 and MAGE-A4 protein show co-expression in tumor of lung, bladder, and colon cancer

Rachel Gonzalez. *OriGene Technologies, Inc., Rockville, MD*

Melanoma Antigen Gene Family (MAGE-A) are part of the cancer-testis antigens whose limited expression in normal tissues and high expression in cancer make them excellent targets for immunotherapy. Clinical trials have already begun targeting MAGE-A3 and MAGE-A4 proteins in tumors. Should these trials lead to new treatment protocols, it is important to develop a diagnostic immunohistochemistry (IHC) tool for pre-screening patients who would benefit. The MAGE-A family consists of 12 members that share up to 85% sequence homology presenting a challenge for finding highly specific antibodies for IHC. Using CytoSections, a new screening control tool for IHC, ICC, IF, and in-situ hybridization, highly specific IHC MAGE-A3 and MAGE-A4 antibodies were developed and screened. The MAGE-A3 and MAGE-A4 antibodies were assessed on twenty-two lung cancers, twenty-one colon cancer, and more than thirty bladder cancers which resulted in cases that co-express MAGE-A3 and MAGE-A4 proteins in all three types of tumors. Using immunofluorescence, tumors positive for both proteins were double stained for MAGE-A3 and MAGE-A4 to show the proteins were co-expressed in the same tumor cells. Immunohistochemistry continues to be a rapid and reproducible method for the detection of proteins in tumors. Antibodies specific to MAGE-A3 and A4 proteins for IHC may be a useful tool in predicting outcomes or benefits for patients.

Diagnostic aqueous humor proteome predicts metastatic potential in uveal melanoma

Chen-Ching Peng, Liya Xu, Jesse Berry. *The Vision Center, Children's Hospital Los Angeles, Los Angeles, CA*

Introduction: Approximately half of patients with uveal melanoma (UM), a primary eye cancer, will develop metastatic disease. Gene expression profiling (GEP) is clinically validated to stratify risk of metastasis by assigning UM patients to two highly prognostic molecular classes: class 1 (low metastatic risk) and class 2 (high metastatic risk). However, GEP requires intraocular tumor biopsy which are limited by small tumor size and tumor heterogeneity; furthermore, there are small risks of retinal hemorrhage, bleeding or tumor dissemination. Thus, liquid biopsy has emerged as a significantly less invasive alternative. Blood biopsy has largely been unsuccessful for clinical use in UM due to low detection rates in the setting disease limited to the eye, however eye-specific aqueous humor (AH) liquid biopsy may be a better alternative. In this study, we seek to determine the AH proteome related to the advanced GEP class 2 using the diagnostic AH specimens.

Method: Twenty UM treatment naive AH were collected before plaque brachytherapy. Patients were sub-grouped by GEP classes into GEP 1 (n=12) and GEP 2 (n=5). Three patients were classified as GEP unknown (GEP NA, n=3) due to the unavailability of tumor biopsy. Ten microliters of AH samples were analyzed by proximity extension assay-derived multiplexed Olink platform. Protein expression levels of 1472 targets were analyzed, compared between GEP classes and correlated with clinical features. Significant differentially expressed proteins (DEPs, fold-change (FC) > 2 or FC < 0.5, $P < 0.01$) were subjected to Qiagen ingenuity pathway analysis for cellular pathway and upstream regulator identification.

Results: GEP 2 class was correlated with AJCC stages ($P = 0.012$), advanced clinical tumor stages ($P = 0.007$) and mutated BAP1 ($P = 0.018$). 45 DEPs were identified when comparing GEP classes. Among them, 31 are up-regulated DEPs [fold-change (FC) >2, $P < 0.01$] and 14 are down-regulated DEPs (FC < 0.5, $P < 0.01$) in GEP 2 compared to GEP1. The unsupervised clustering analysis showed that the 45 DEPs well-differentiate AH samples by GEP classes, and the 3 GEP NA samples were clustered with GEP1 class. Pathway analysis showed that 45 DEPs contribute to metastatic-related pathways including cellular movement, cellular proliferation and epithelial to

mesenchymal transition. Two upstream regulators, IL1 receptor and SPRY2, were predicted to regulate 8 out of the 45 DEPs. IL1R2 (FC = 3.4, P = 0.021) and SPRY2 (FC = 0.6, P = 0.052) protein expression levels were found matched as prediction in our Olink dataset.
Conclusions: 45 AH DEPs could differentiate GEP class 1 and 2 at the diagnostic stage and could be detected even when the tumor was too small to biopsy. IL1R and SPRY2 are potential upstream regulators for the 8/45 DEPs that contribute to metastasis-related pathways. AH liquid biopsy offers a new opportunity to determine metastatic potential for patients in the absence of tumor biopsy.

Mammaglobin-A expression in highly specific for tumors derived from the breast, the female genital tract and salivary gland tumors

Natalia Gorbokon, Patrick Timm, David Dum, Anne Menz, Franziska Büscheck, Cosima Völkel, Andrea Hinsch, Maximilian Lennartz, Andreas Luebke, Claudia Hube-Magg, Christoph Fraune, Christian Bernreuther, Patrick Lebok, Till Clauditz, Frank Jacobsen, Guido Sauter, Ria Uhlig, Stefan Steurer, Sarah Minner, Andreas Marx, Ronald Simon, Eike Burandt, Till Krech. *University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Human mammaglobin-A (SCGB2A2) is a small epithelial secretory protein with unknown function. Because of its frequent expression in breast epithelial cells, it is used as a diagnostic marker for breast cancer and represents an attractive target for novel therapies involving adaptive T cell transfer and antitumor vaccines for breast cancer patients. However, there is growing evidence that mammaglobin-A expression is not limited to breast cancers.
Methods: In order to comprehensively determine mammaglobin-A expression in normal and neoplastic tissues, a tissue microarray containing 16,328 samples from 128 different tumor types and subtypes as well as 608 samples of 76 different normal tissue types was analyzed by immunohistochemistry.
Results: Mammaglobin-A positivity was found in 37 of 128 tumor categories, 32 of which were derived of one of four organs: breast (6 tumor categories), endometrium (5 tumor categories), ovary (5 tumor categories), and salivary glands (16 tumor categories). Only 5 additional tumor types showed occasional mammaglobin positivity. These tumors mostly exhibited a weak mammaglobin-A staining and included medullary thyroid cancer, teratoma of

the testis, squamous cell carcinoma of skin and the pharynx, and prostatic adenocarcinoma (Gleason 5+5=10). Among 1,139 evaluable invasive breast carcinomas of no special type (NST), low mammaglobin-A immunostaining was linked to high BRE grade ($p=0.0011$), a loss of estrogen and progesterone receptor expression ($p<0.0001$ each), and triple negative status ($p<0.0001$) but not to patient survival. In endometrial cancer, low mammaglobin-A immunostaining was linked to advanced tumor stage ($p=0.0198$). Although a similar trend was seen for endometrioid and serous high-grade carcinomas of the ovary, these associations did not reach statistical significance. Conclusions: Our data characterize mammaglobin-A as a highly specific marker for tumors derived from either female organs or the salivary gland. The potential use of anti-Mammaglobin therapies should be studied also in other mammaglobin-positive tumor types.

Altered p53/p16 expression is linked to urothelial carcinoma progression but is unrelated to prognosis in muscle-invasive tumors

Simon Schallenberg[1], Henning Plage[2], Sebastian Hofbauer[2], Kira Kornienko[2], Sarah Weinberger[2], Paul G. Bruch[2], Florian Roßner[1], Sefer Elezkurtaj[1], Martina Kluth[3], Maximilian Lennartz[3], Tim Mandelkow[4], Elena Bady[4], Niclas C. Blessin[3], Andreas H. Marx[5], Henrik Samtleben[5], Margit Fisch[6], Michael Rink[6], Marcin Slojewski[7], Krystian Kaczmarek[7], Thorsten Ecke[8], Steffen Hallmann[8], Stefan Koch[9], Nico Adamini[10], Sarah Minner[4], Ronald Simon[4], Guido Sauter[4], David Horst[1], Tobias Klatte[2], Thorsten Schlomm[2], Henrik Zecha[10]. *[1]Institute of Pathology, Charité Berlin, Berlin, Germany,[2]Department of Urology, Charité Berlin, Berlin, Germany,[3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[4]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[5]Department of Pathology, Academic Hospital Fuerth, Fuerth, Germany,[6]Department of Urology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[7]Department of Urology, University Hospital Stettin, Stettin, Poland,[8]Department of Urology, Helios Hospital Bad Saarow, Bad Saarow, Germany,[9]Department of Pathology, Helios Hospital Bad Saarow, Bad Saarow, Germany,[10]Department of Urology, Albertinen Hospital, Hamburg, Germany*

Background**:** Most inactivating p53 mutations result in a nuclear accumulation of the defective p53 protein. However, p53 alterations that result in a complete lack of cellular p53 and complete absence of p53 immunostaining do also occur. As p16 is upregulated in p53 inactivated cells, p16 immunohistochemistry may be a surrogate marker for p53 inactivation.

Design: In this study, we investigated p53 and p16 immunostaining on more than 2,500 urothelial bladder carcinomas in a tissue microarray format to better understand their impact in relation to clinicopathological parameters of disease progression and patient outcome.

Results: p16 immunostaining was not observed in normal urothelium but occurred in 1,576 (63.5%) of cancers including 755 (30.4%) with a strong staining. The fraction of p16 positive cases increased markedly from pTaG2

low grade (9.6%) to pTaG3 high grade tumors (46.5% strongly positive, p<0.0001 for pTaG2 low vs. pTaG3) but continuously decreased from pTaG3 to pT2 (41.3% strongly positive), pT3 (36.5%) and pT4 (33.3%; p=0.0030). Within pT2-4 carcinomas, p16 positivity was also linked to high grade (p=0.0005) but unrelated to overall survival. p53 staining has been recorded as negative in 203 (8.4%), very weak in 373 (15.4%), weak in 1,341 (55.3%), strong in 115 (4.7%), and very strong in 393 (16.2%) cancers. The fraction of tumors with negative (potentially p53 null phenotype), strong, and very strong p53 positivity increased markedly from pTaG2 low grade to pTaG3 high grade tumors (p<0.0001) and from pTaG3 to muscle-invasive pT2-4 cancers (p=0.0007). p53 staining pattern was unrelated to histopathological parameters of malignancy or patient prognosis within pT2-4 carcinomas, however. There was a significant overall association between p53 and p16 expression but strong p16 expression predominated in tumors with very strong, strong, and negative p53 staining. Subset analyses showed that the combination of p53 negative/p16 strongly positive cancers was particularly linked to features of tumor aggressiveness.
Conclusion: Our data show that altered function of p53 and p16 immunostaining increases during grade and stage progression although these alterations lack prognostic significance in pT2-4 carcinomas. That high level p16 expression is limited to neoplastic urothelium and that the p53 null phenotype is largely limited to grade 3 and invasive urothelial carcinomas are features with potential diagnostic utility.

#5556
Lemur tyrosine kinase 3 serves as a predictor of patient outcome and a target for the treatment of ovarian cancer
Thea K. Kirsch-Mangu[1], Axel S. Tullberg[2], Anna Portela[3], Khalil Helou[2], Ghassan M. Saed[1]. *[1]Wayne State University School of Medicine, Detroit, MI,[2]University of Gothenburg, Gothenburg, Sweden,[3]Xenopat, Barcelona, Spain*

The objective of these in vitro and in vivo studies was to validate Lemur Tyrosine Kinase 3 (LMTK3) as a specific target and predictor of clinical outcome in ovarian cancer. LMTK3 belongs to a family of regulated tyrosine kinases with three structurally related isoforms, LMTK1, LMTK2,

and LMTK3. Both nuclear and cytoplasmic LMTK3 expressions correlated with tumor grade and patient survival in cancers such as breast and colorectal cancer. We tested the clinical significance of the LMTK3 gene by immunohistochemistry (IHC) using LMTK3 monoclonal antibody on formalin-fixed paraffin-embedded sections (FFPE) collected from 204 early-stage (stage I-II) ovarian cancer patients. Results from this IHC LMTK3 study revealed a higher cytoplasmic to nuclear localization of LMTK3 correlated with worse overall survival ($P<0.01$). Further investigation of LMTK3's prognostic value by screening LMTK3 signaling in 270 stage III-IV ovarian cancer patients is ongoing. We utilized the MTT ((3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay for testing the killing efficacy of targeting LMTK3 by a monoclonal antibody, siRNA, and specific LMTK3 binding peptides (LMTK3BP) in ovarian cancer cell lines SKOV3, MDAH-2774, A2780, and TOV-21G. Treatment with LMTK3 specific monoclonal antibody, siRNA, and LMTK3BP significantly induced killing of both chemosensitive and chemoresistant ovarian cancer cells without affecting normal cells in vitro. Moreover, we observed this killing as synergistic with both Cisplatin and Taxotere treatment in vitro. Lastly, we used an A2780 cell line derived orthotopic xenograft mouse model of ovarian cancer to test the efficacy of specific LMTK3BP in vivo. Strikingly, LMTK3BP 20 mg/kg IV dose given three times a week for three weeks showed a 35% tumor reduction. Furthermore, in vivo safety studies showed no signs of toxicity of the LMTK3BP, even at a very high dose of 40 mg/kg. Thus, with dose optimization in ongoing experiments, we could expect a higher efficacy. In conclusion, this study highlighted the importance of LMTK3 as a predictor of patient clinical outcome and potential target for treatment in ovarian cancer.

Background: Cancers often overexpress multiple clinically relevant oncogenes.
However, it is not known if multiple oncogenes within a cancer combineuniquely in specific cellular sub-populations to influence clinical outcome.We studied this phenomenon using the prognostically relevantoncogenes MYC, BCL2 and BCL6 in Diffuse Large B-Cell Lymphoma(DLBCL).
Methods: Quantitative multispectral imaging simultaneously measured oncogene co-expression at single-cell resolution in reactive lymphoid tissue

(n=12)and four independent cohorts (*n*=409) of DLBCL. Mathematically derived co-expression phenotypes were evaluated in DLBCLs with immunohistochemistry (*n*=316) and nine DLBCL cohorts with gene expression data (*n*=3974). Bulk and single-cell RNA sequencing was performed on patient-derived B-cells with induced co-expression of MYC,BCL2 and BCL6.
Results: Unlike in non-malignant lymphoid tissue where the co-expression of MYC, BCL2 and BCL6 in a B-cell is limited, DLBCLs show multiple permutations of oncogenic co-expression in malignant B-cells. The percentage of cells with a unique combination MYC+BCL2+BCL6- (M+2+6-) consistently predicts survival in contrast to that of other combinations (including M+2+6+). An estimated percentage of M+2+6- cells can be derived from any quantitative measurement of the component individual oncogenes, and correlates with survival in immunohistochemistry and gene expression datasets. Comparative transcriptomic analysis of DLBCLs and transformed patient-derived B-cells identifies cyclin D2 (CCND2) as a potential BCL6-repressedregulator of proliferation in the M+2+6- population.
Conclusions: Unique patterns of oncogene co-expression at single-cell resolution affect clinical outcomes in DLBCL. Similar analyses evaluating oncogenic combinations at the cellular level may impact diagnostics and target discovery in other cancers.

Understanding the molecular mechanism of tumor budding and its relationship with tumor microenvironment in colorectal cancer

Phimmada Hatthakarnkul[1], Holly Leslie[2], Hester Van Wyk[3], Leah Officer-Jones[4], Silvia Cusumano[4], Aula Ammar[5], Kathryn A.F. Pennel[5], Jean A. Quinn[5], Jennifer Hay[6], James Park[3], Noori Maka[3], John Le Quesne[2], Chanitra Thuwajit[7], Nigel Jamieson[5], Joanne Edwards[5]. *[1]Biomedical Science, Mahidol University, Bangkok, Thailand,[2]University of Glasgow, Glasgow, United Kingdom,[3]School of Medicine, University of Glasgow, Glasgow, United Kingdom,[4]Beatson Institute, Glasgow, United Kingdom,[5]School of Cancer Science, University of Glasgow, Glasgow, United Kingdom,[6]Glasgow Tissue Research Facility, University of Glasgow,*

Glasgow, United Kingdom,[7]Immunology, Mahidol University, Bangkok, Thailand

Background: Tumor budding (TB), a single or cluster of up to 4 cells at the tumor-invasive front, is a well-established prognostic marker and an independent predictor of metastasis in colorectal cancer (CRC). Despite that, the underlying molecular mechanism that drives this phenotype and its relationship with the tumor microenvironment (TME) remains unclear.
Methods: The relationship between TME and TB was investigated using multiplex immunofluorescence (mIF) in tissue microarrays (TMAs) of the tumor core and full sections. GeoMx^{TM} digital spatial profiling (DSP) was employed to identify the mechanism underlying TB and its surrounding TME, using the GeoMx Immune-oncology pathway panel in full CRC sections.
Results: In the current study, TB was independently associated with decreased cancer-specific survival (OR 1.856, 95% CI 1.360-2.533, P<0.001) in a cohort of 650 CRC patients. Additionally, TB was significantly associated with the Glasgow microenvironment score (GMS) (P=0.017). mIF performed in TMAs of the tumor core (n=650) showed that high CD3+ (OR0.374, 95% CI0.263-0.533, P<0.001) associated with good prognosis, whereas high CD68+ (OR2.902, 95% CI1.728-4.873, P<0.001) associated with poor prognosis. In addition, eighteen full sections were stained with an immune-related multiplex panel. Interestingly, in the invasive area, CD3+CD8+ was less frequent, while CD3+FOXP3+ was significantly higher compared to the stromal area in a patient with high TB (P=0.06, P<0.01, respectively). Moreover, though no significant difference was found, tumors with high buds showed an increase in neutrophil marker (CD66b) compared to low buds. No association is also found with a myeloid marker (CD68, CD163). The proliferation index of the tumor in the invasive area showed that the tumor with low buds is likely to be more proliferative. Besides, we found that a small subpopulation of budding is KI67+, suggesting the heterogeneity among TB. Furthermore, the mechanism underlying TB was observed using GeoMx^{TM}. Twelve cases, selected from mIF stained, with low (n=6) or high buds (n=6) were utilized, and 96 areas of interest (AOI) were identified from the tumor core, invasive front, and stroma. The results showed the differential expression of genes between the tumor core and the invasive front in patients with high TB. A

significant decrease in immune-related genes (e.g., CD3, NKG7, IL6, CXCR6, CD47, IFNAR1 and VSIR) compared to the stromal area at the invasive front was also observed (P<0.001).
Conclusion: TB is associated with poor prognosis and showed a distinct gene expression characteristic compared to the tumor mass. It may also affect the inflammatory response at the invasive tumor. The underlying mechanism of TB and its relationship with TME warrants future studies to confirm this finding.

#5559

Exploratory analysis of hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) *PIK3CA* mutated (mut) advanced breast cancer (aBC) treated with taselisib (TAS) and/or fulvestrant (FUL) reveals increased *CCNE2* expression with poor outcome to placebo (PBO) + FUL but not TAS + FUL in SANDPIPER

Radia M. Johnson[1], Bonnie Liu[1], Javier Cortés[2], Susan Dent[3], Nadia Harbeck[4], Ian E. Krop[5], William Jacot[6], Robert L. Yauch[7], Thomas J. Stout[7], Frauke Schimmoller[7], Steven Gendreau[7], Timothy R. Wilson[7].
[1]Genentech, Inc., South San Francisco, CA,[2]International Breast Cancer Center (IBCC), Pangaea Oncology, Quironsalud Group, Madrid Barcelona; Universidad Europea de Madrid, Madrid, Spain,[3]Duke Cancer Institute, Duke University, Durham, NC,[4]Department Gynecology and Obstetrics, Breast Center and Cancer Center (CCC) Munich, Ludwig-Maximilians-University (LMU) Hospital, Munich, Germany,[5]Yale Cancer Center, New Haven, CT,[6]Institut du Cancer de Montpellier (ICM) Val d'Aurelle, Montpellier University, Montpellier, France,[7]Genentech, Inc., San Francisco, CA

PIK3CA mutations occur in ~40% of patients (pts) with HR+/HER2- aBC. TAS is a potent and selective β-sparing PI3K inhibitor that has shown modest clinical benefit when combined with FUL endocrine therapy in patients (pts) with *PIK3CA*mut aBC. To better understand the molecular features associated with response to TAS and/or FUL, we examined the gene expression profiles of archival tissue from pts enrolled in SANDPIPER (NCT02340221). Most patients did not have prior treatment with a CDK4/6i. RNA sequencing was performed on baseline tissue

samples from 456 pts with *PIK3CA*mut tumors. Exploratory biomarker analyses revealed 28 genes associated with worse outcome. Of these, *CCNE2* [HR=1.11 (1.04-1.19), p=0.002], *RRM2* [HR=1.14 (1.07-1.22), p<0.0001] and *TUB4A* [HR=1.15 (1.05-1.26), p=0.004] are involved in the regulation of mitotic cell cycle. *CCNE2* encodes CYCLIN E2, a G1 cyclin that binds and activates CDK2. Elevated expression of *CCNE2* has been associated with poor outcome in ER-positive breast cancer, and has been identified as part of gene signatures that predict disease progression in tamoxifen-resistant breast cancer or advanced breast cancer. Since *CCNE2* expression may be a marker of more proliferative tumors, we assessed whether the inclusion of *CCNE2* gene expression would add value to a prognostic model that already includes cell cycle as a factor. Analysis of deviance after sequential addition of variables into Coxph models with stratification factors showed that elevated *CCNE2* expression is significant, in addition to cell cycle signature scores, for association with worse PFS (*likelihood ratio test p* = 0.001). When we grouped patients based on *CCNE2* expression split by quartile with the highest values (Q4) grouped as *CCNE2* high vs lower values (Q1-Q3), we found that the *CCNE2* high group does worse in the PBO + FUL treatment arm. Median PFS for *CCNE2*-high group in the placebo arm was 3.75 months compared to the other groups (log-rank $p < 0.0001$; PBO, *CCNE2*-low 7.3 months, TAS, *CCNE2*-high 7.6 months; TAS, *CCNE2*-low 7.3 months). A significant statistical interaction was observed between high *CCNE2* gene expression and PBO + FUL treatment arm HR=1.51 (1.03-2.20), p=0.04], suggesting that CCNE2 expression may be associated with poor PFS to in 2L ER+/HER2- *PIK3CA*mut aBC patients that receive PBO + FUL. Our analysis revealed an association between high *CCNE2* expression and worse PFS in patients that received PBO + FUL. Further, this association was not observed in the patients that received the combination of TAS+FUL, which may inform future rational combination strategies for the clinical development of PI3K inhibitors in ER+/HER2- *PIK3CA*mut aBC.

Prognostic effect of co-mutations on patients with *NPM1*+ acute myeloid leukemia (AML) enrolled in the Connect® Myeloid registry

Jaroslaw P. Maciejewski[1], Daniel A. Pollyea[2], Gail J. Roboz[3], Karen Seiter[4], Bart L. Scott[5], Irene S. DeGutis[6], Pavel Kiselev[6], Edward Yu[6], Ali

McBride[6], Willem Heydendael[6], Harry P. Erba[7]. *[1]Cleveland Clinic, Taussig Cancer Center, Cleveland, OH,[2]University of Colorado, Aurora, CO,[3]Weill Cornell Medicine and NY Presbyterian Hospital, New York, NY,[4]New York Medical College, Valhalla, NY,[5]Fred Hutchinson Cancer Research Center, Seattle, WA,[6]Bristol Myers Squibb, Princeton, NJ,[7]Duke University, Durham, NC*

Introduction: The 2017 World Health Organization classification of myeloid neoplasms and acute myeloid leukemia (AML) recognizes AML with mutated *NPM1* as a distinct entity with favorable prognosis. However, as mutations other than *NPM1* may further influence disease prognosis, here we assess the prognostic effect of *NPM1* co-mutations in patients (pts) with AML enrolled in the Connect® Myeloid Registry (NCT01688011).
Methods: The Registry is a large, US, multicenter, prospective observational cohort study of pts with newly diagnosed AML, myelodysplastic syndromes, idiopathic cytopenia of undetermined significance, or myelofibrosis. In this analysis, pts with AML ≥55 years of age were grouped by known *NPM1* status (*NPM1*+ vs *NPM1*–). The frequency of gene mutations was analyzed among patients with *NPM1*+ AML and *NPM1*– AML. Overall survival (OS) was evaluated using the Cox model adjusted for age and mutations in *TP53* and *RUNX1*.
Results: Overall, 123 pts with *NPM1*+ AML and 360 pts with *NPM1*– AML were included. Most pts were male (*NPM1*+, 61.5%; *NPM1*−, 60.7%) and White (*NPM1*+, 78.0%; *NPM1*−, 85.6%); median (range) age was 67 (55-87) and 71 (55-97) years for the *NPM1*+ and *NPM1*− groups, respectively. After adjusting for age, pts with *NPM1*+ AML had significantly longer median OS than pts with *NPM1*– AML (26 vs 15 months; HR [95% CI]: 0.58 [0.44-0.76]; $P < 0.01$; Table). Pts with *NPM1*+ vs *NPM1*– AML had a lower frequency of certain key mutations such as *TP53* (1.6% vs 18.6%) and *RUNX1* (0.8% vs 14.8%). The significant survival benefit with *NPM1*+ vs *NPM1*– initially observed after adjusting for age was not observed after further adjusting for presence of *TP53* and *RUNX1* mutations (*NPM1*+ vs *NPM1*–; 23 vs 19 months; HR [95% CI]: 0.75 [0.48-1.17]; $P = 0.21$).
Conclusions: *TP53* plus *RUNX1* mutation was identified as a pattern of co-mutational burden that were observed less frequently and potentially contributed to the improved OS of pts with *NPM1*+ AML and poorer OS of pts with *NPM1*– AML.

Molecular imaging of calcification and soft tissue defines prognosis of DCIS to invasive breast cancer

Jayakrupakar Nallala[1], Doriana Calabrese[1], Sarah Gosling[2], Esther Lips[3], Rachel Factor[4], Allison Hall[4], Sarah Pinder[5], Ihssane Bouybayoune[5], Elinor Sawyer[5], Lorraine King[4], Jeffrey Marks[4], Thomas Lynch[4], Donna Pinto[6], Jelle Wesseling[3], Shelley Hwang[4], Keith Rogers[2], Nick Stone[1], Grand Challenge PRECISION consortium. *[1]University of Exeter, Exeter, United Kingdom,[2]Cranfield University, Cranfield, United Kingdom,[3]The Netherlands Cancer Institute, Amsterdam, Netherlands,[4]Duke University School of Medicine, Durham, NC,[5]Kings College London, London, United Kingdom,[6]DCIS411, San Diego, CA*

Introduction: Ductal carcinoma in situ (DCIS) is a non-obligatory precursor to invasive breast cancer (IBC). Currently there are no reliable markers to indicate if DCIS will progress IBC after an initial treatment, or if it will remain as DCIS. Because of this uncertainty, standard treatment for DCIS includes surgery with or without radiotherapy. Breast microcalcifications are a common feature in the mammographic detection of DCIS and occur in around 80% of DCIS and 50% of IBC. Despite this, their potential role in the development of DCIS and with progression to IBC remains largely unexplored. The main aim of the study is to identify novel biomarkers for DCIS prognosis, based on chemical and molecular compositional changes of calcifications and their surrounding soft tissue in DCIS.
Methods: Consecutive tissue section from 422 patients were analyzed using mid-infrared and Raman hyperspectral imaging and X-ray diffraction (XRD) and included (i) ‘DCIS controls’ (DCIS without recurrence) (n=193), (ii) ‘DCIS cases’ (DCIS which subsequently recurred as an invasive disease) (n=123), (iii) ‘synchronous DCIS with invasive cancer’ (n=44) and ‘benign’ (n=62) groups. Both parametrized and data mining approaches including cluster analysis, unsupervised and supervised multivariate statistical analysis and biomodelling based on leave-one-sample-out cross-validation were used to classify the data and develop DCIS prediction models.
Results: Prediction modelling of 314 calcification and soft tissue spectral images from 170 patients (‘DCIS controls’=118 versus ‘DCIS cases’=52) showed an AUROC mean value of 0.85 in distinguishing DCIS that did not recur from DCIS that recurred as IBC. Prediction modelling of XRD data from 124 patients (‘DCIS controls’=67 versus ‘DCIS cases’=57) showed an

AUROC mean value of 0.80. The calcification spectral features showed pathology specific changes in phosphate to carbonate ratio as well as changes in magnesium whitlockite content. The epithelial features showed changes in protein secondary structure and content indicating structural remodeling between the two groups. XRD parametrized data analysis corroborated these observations in terms of difference in whitlockite, as well as crystallinity/unit axis of the measured calcifications. The prediction models are currently being tested independently on the remaining sample data.
Conclusion: Complementary chemical and molecular analysis of breast calcifications and soft tissue using spectroscopy and XRD imaging predicts the likely progression of DCIS to IBC. Subject to the ongoing validation of biomarkers, these approaches appear as promising DCIS risk assessment tools that can inform diagnosis, prognosis and treatment options.

Prevalence and prognostic significance of malnutrition in patients with brain metastasis

Zheran Liu[1], Yu Zhang[2], Yiyan Pei[1], Yan He[1], Jiayi Yu[3], Renjie Zhang[1], Jingjing Wang[1], Weelic Chong[4], Yang Hai[4], Xingchen Peng[1], Fang Fang[1].
[1]West China Hospital of Sichuan University, Chengdu, China,[2]Affiliated Hospital of Chengdu University, Chengdu, China,[3]Chengdu University of Traditional Chinese Medicine, Chengdu, China,[4]Thomas Jefferson University, Philadelphia, PA

Background: Malnutrition is a severe but modifiable risk factor for cancers. However, the relationship between malnutrition and the survival of patients with brain metastases has not been fully revealed. We aimed to evaluate the prevalence of malnutrition and assess its prognostic value on patients with brain metastases.
Method: We retrospectively recruited 2633 patients with brain metastases between January 2014 and September 2020. Three malnutrition scores were used to evaluate patients' malnutrition status at their first admission, including controlling nutritional status (CONUT), the nutritional risk index (NRI), and the prognostic nutritional index (PNI). The association between malnutrition and overall survival was estimated.

Results: A total of 1984 (75.4%) of patients were assessed as any degree malnourished and 963 (36.6%) of patients were assessed as moderate to severe malnutrition by at least one malnutrition score. The three malnutrition scores were associated with each other and with BMI. Malnutrition assessed by any of the three scores was significantly associated with poor overall survival (adjust hazard ratio [HR] and 95% confidence interval [CI] for CONUT: 1.12 [1.10-1.16]; for NRI: 0.97 [0.97-0.98]; for PNI: 0.96 [0.95-0.97], all p values <0.001). Furthermore, malnutrition was a better indicator than BMI, and adding malnutrition to the Graded Prognostic Assessment scoring system could significantly improve the accuracy of prognosis prediction.
Conclusion: Malnutrition was prevalent in patients with brain metastases and was significantly associated with overall survival. Malnutrition monitoring on patients' first admission could improve the survival prediction ability for brain metastasis.

Androgen receptor (AR) is frequently found in human cancers and inversely linked to patient outcome in breast and renal cell carcinomas

Florian Viehweger[1], David Dum[1], Anne Menz[1], Ria Uhlig[1], Andrea Hinsch[1], Doris Höflmayer[1], Tim Mandelkow[1], Christoph Fraune[1], Christian Bernreuther[1], Patrick Lebok[1], Sören Weidemann[1], Guido Sauter[1], Maximilian Lennartz[1], Frank Jacobsen[1], Till S. Clauditz[1], Till Krech[1], Andreas H. Marx[2], Ronald Simon[1], Stefan Steurer[1], Eike Burandt[1], Sarah Minner[1]. *[1]Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Pathology, Klinikum Fürth, Fürth, Germany*

Background**:** Androgen receptor (AR) is a nuclear transcription regulator which mediates the growths stimulating effect of androgens. Inhibition of AR signaling is the most important first line therapy in prostate cancer. Clinical trials are ongoing for molecularly defined subsets of breast cancers expressing AR. In surgical pathology, AR immunohistochemistry is used as a marker for prostate cancer.
Design: To comprehensively determine AR expression in normal and neoplastic tissues, a tissue microarray containing 18,234 samples from 141

different tumor types and subtypes as well as 608 samples of 76 different normal tissue types was analyzed by immunohistochemistry.
Results: AR positivity was found in 116 of 141 tumor categories, and 66 of these tumor categories contained at least one case with strong AR staining. AR positivity was most seen in different categories of prostate cancer (87.8-100%), various subtypes of breast cancer (34.3-94.9%) and ovarian cancers (48.7-97.1%), in endometrial cancers (53-61.1%), salivary duct carcinomas (70%), teratomas (60%), renal cell carcinomas (41.8-62.7%), urinary bladder cancers (43.2-48.7%), granular cell tumors (40.7%), leiomyosarcomas (33.3%), gastrointestinal stroma tumors (31.1%) and urothelial carcinomas of the kidney pelvis (30.4%). Seventy-seven additional tumor types showed AR expression in up to 30% of the analyzed samples, but AR expression was typically only weak in these tumors. Among 1,430 evaluable invasive breast carcinomas of no special type (NST), absent or low AR immunostaining was significantly linked to high BRE grade ($p<0.0001$), advanced pT stage ($p<0.0001$), presence of nodal and distant metastasis ($p<0.0001$ each), HER2 overexpression ($p=0.005$), reduced estrogen and progesterone receptor expression ($p<0.0001$ each), triple negative status ($p<0.0001$) and shortened patient survival ($p=0.0024$). Among 1,149 clear cell renal cell cancers (RCC), low AR immunostaining was linked to high ISUP, Fuhrman and Thoenes grades ($p<0.0001$ each), high UICC and pT stage ($p<0.0001$ each), presence of distant metastases ($p=0.0075$), and reduced time to recurrence ($p=0.0007$), overall survival ($p=0.0097$) and tumor-specific survival ($p=0.0129$). In 297 papillary RCC, low AR staining was associated with high ISUP grade ($p=0.0179$), advanced pT stage ($p=0.0055$) and nodal metastasis ($p=0.0044$). Low AR expression was linked to invasive growth ($p<0.0001$) and nodal metastasis in urothelial carcinoma ($p=0.0052$).
Conclusion: The results of our study demonstrate AR expression in a wide range of cancers. AR expression occurs most frequent in cancers of the prostate, breast, and ovary, but can be found in many types of non-prostate and non-gynecological neoplasms. The poor prognosis of breast and kidney cancers with reduced AR expression argues against a tumor promoting role of AR in these tumor types.

#5564
SerpinE2: A potential biomarker for urological cancers

Ruusu-Maaria Kovanen, Netta Koskinen, Timo-Pekka Lehto, Antti Rannikko, Tuomas Mirtti, Hannu Koistinen. *University of Helsinki, Helsinki, Finland*

SerpinE2, also known as protease nexin-1, is an extracellular serine protease inhibitor modulating the activity of serine proteases such as thrombin, plasmin, urokinase-type plasminogen activator and trypsin. Dysregulation between extracellular serine proteases and their cognate inhibitors has been implicated in malignant progression, making serpins promising biomarkers for tumor progression and prognosis. SerpinE2 is upregulated in many cancers and promotes tumor invasion and metastasis. In this study, we analyzed serpinE2 expression by immunohistochemistry on tissue microarrays comprising of samples from prostate, bladder and kidney cancers. The studied samples were clinically hard-to-risk stratify and thus relevant for biomarker studies. We aimed to study the association of serpinE2 expression with survival and clinicopathological features in all three cancers, and evaluate its potential as an immunohistochemical biomarker. In the case of bladder cancer, association of serpinE2 expression with response to neoadjuvant chemotherapy was also assessed. We found that although the strong expression of serpinE2 was related to more aggressive prostate cancers ($p = 0.017$) and high grade bladder cancers ($p = 0.034$), it was not associated with relapse, treatment response or survival of prostate and bladder cancer patients. In renal cancer, on the contrary, serpinE2 expression was significantly lower in patients with tumor relapse ($p = 0.048$) and high expression predicted favorable disease-specific survival ($p = 0.013$). Our findings help understanding the functional role of serpinE2 in cancer progression and guide the prognostic biomarker research of serpinE2, particularly for prediction of renal cancer-specific survival.

Circulating bacterial DNA is a non-invasive biomarker for early recurrence of NSCLC patients

Haiming Chen[1], Yiming Lu[2], Mantang Qiu[1]. *[1]Peking University People's Hospital, Beijing, China,[2]Beijing Institute of Radiation Medicine, Beijing, China*

Background: Alteration of human microbiota has been implicated in non-small cell lung cancer (NSCLC). However, most metagenomics studies utilized fecal samples, circulating bacteria DNA in patients with respectable NSCLC remain unexplored. This study aimed to characterize bacteria DNA in plasma of respectable NSCLC patients and build a machine-learning model to detect early recurrence of NSCLC.
Methods: We performed whole genome sequencing of plasma from 101 NSCLC patients with (n = 36, R) or without (n = 65, NR) tumor recurrence within three years after surgery. Microbial DNA was obtained by removing the host genome and relative abundance was measured by mapping reads into microbial genomes. Significant microbial features were identified in the discovery set and built into a random forest model, which was tested in the validation set.
Results: We enrolled 22 R and 39 NR patients with matching demographic features in the discovery set. The remaining 14 R and 26 NR patients were included in the validation set. PCoA analysis using Bray-Curtis distance showed significant differences between R and NR patients at genus level and species level in the discovery set. Notably, in the discovery set, 4 genera and 13 species showed significantly lower abundance in R patients, whereas 11 genera and 21 species were conversely enriched. Based on these significant microbial features, the random-forest model obtained the maximal AUC value of 0.9044 (95% CI, 0.8203-0.9886) when 11 features were selected. In the validation set, this model distinguished R from NR patients with an AUC of 0. 8434 (95% CI, 0.7189-0.9679).
Conclusions: This pioneer study characterized alteration of circulating bacterial DNA in NSCLC patients with early recurrence, and illustrated significant difference in microbial composition between R and NR patients. The predictive model constructed with selected circulating microbial features was an accurate and non-invasive tool for prediction in early NSCLC recurrence.

Quantification of tumor-associated vasculature as an imaging biomarker for monitoring the response of triple-negative breast cancer to neoadjuvant chemotherapy

Chengyue Wu[1], Casey E. Stowers[1], Zhan Xu[2], Ernesto A. B. F. Lima[1], Clinton Yam[3], Jong Bum Son[2], Jingfei Ma[2], Gaiane M. Rauch[4], Thomas E.

Yankeelov[1]. *[1]Oden Institute for Computational Engineering and Sciences, University of Texas at Austin, Austin, TX,[2]Department of Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Department of Breast Imaging, The University of Texas MD Anderson Cancer Center, Houston, TX*

Introduction: Patients with locally advanced, triple-negative breast cancer (TNBC) typically receive neoadjuvant systemic therapy (NAST). However, the response of TNBC to NAST is varied and a prognostic marker is still lacking. Since angiogenesis plays an important role in cancer progression, the quantification of changes in the tumor vasculature during treatment has the potential to provide useful information for characterizing the treatment response. We have recently developed a method to quantify changes in tumor-associated vasculature through a novel analysis of dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI). In this study, we investigated its ability to monitor the response of TNBC to NAST.
Methods: Dynamic contrast-enhanced (DCE) MRI was acquired in TNBC patients (N = 50; 25 pathological complete response (pCR), 25 non-pCR) before, after 2 and 4 cycles of Adriamycin/Cyclophosphamide (A/C), as part of the ARTEMIS trial (NCT02276433). Using DCE-MRI, we identified the tumor-associated vessels *via* a breast vasculature analysis. Specifically, the difference between pre- and post-contrast DCE-MRI images was enhanced by a histogram-based intensity transfer function. The 3D vasculature in the breast was then segmented by applying a Hessian filter. Given the vasculature segmented by the algorithms and the tumor masks segmented by radiologists, a lowest-cost tracking algorithm was used to automatically detect the vessels that are most likely to contact the tumor. These vessels are defined as tumor-associated vessels (TAV). The number of TAVs per patient was tabulated and the Wilcoxon rank sum test compared the TAV values before (V1), after 2 cycles (V2), and after 4 cycles of NAST (V3). Additionally, we compared the percent change of TAV from V1 to V3 between the pCR patients and non-pCR patients. Statistical significance was defined as $P < 0.05$.
Results: A significant decrease in the number of TAVs was observed during the NAST. In particular, the number of TAVs has a median (interquartile range) of 15 (7 - 24), 7 (3 - 14), and 2 (0 - 8) at V1, V2, V3, respectively,

which are (pair-wise) significantly different ($P < 0.01$). Moreover, pCR patients showed a significantly greater decrease in the number of TAVs as compared to non-pCR patients. The percent changes in the number of TAVs from V1 to V3 have a median (range) of -88.89% (-100.00% - -60.00%) and -66.67% (-87.85% - -40.88%) in the pCR and non-pCR patients, respectively ($P < 0.05$).
Conclusion: These preliminary results demonstrate that tumor-associated vasculature may be a valuable imaging biomarker for monitoring the response of TNBC to NAST. Ongoing efforts include additional investigation of the TAVs beyond their number, as well as applying the analysis to more patients.

Development of prognostic index based on twenty-three genes for predicting superficial-to-invasive progression of non-muscle invasive bladder cancer patients

Jae-Yoon Kim[1], Seong-Hwan Park[1], Seon-Young Kim[1], Seok Joong Yoon[2], Seon-Kyu Kim[1]. *[1]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of,[2]Chungbuk National University College of Medicine, Cheongju, Korea, Republic of*

Background: Although recent advances in high-throughput technology and data-driven approach have provided many insights into non-muscle invasive bladder cancer (NMIBC), previous studies are still limited in their ability to predict the clinical behavior of NMIBC. Here, using deep learning method with long term follow-up data, we identified a prognostic gene set consisting of a small gene group for precisely predicting NMIBC heterogeneity.
Methods: We sought to identify progression-associated genes in patients with NMIBC using Cox regression analysis and verified their predictive values using a fully connected neural network (FNN) algorithm in five independent cohorts comprising more than 800 NMIBC patients. Based on these genes, a prognostic index (PI) in NMIBC progression was also developed. The association between the PI and prognosis of NMIBC patients was evaluated using Kaplan-Meier plots and log-rank tests.
Results: Gene expression profiling in NMIBC patients identified a prognostic gene set consisting of 1,789 genes for predicting NMIBC

progression in a patient cohort (training set, n = 103). Their prognostic significances were validated based on FNN algorithm in other four independent cohorts (validation sets, n = 722). Pathway enrichment analysis revealed a twenty-three gene signature including known prognostic transcription factors such as FOXM1 and E2F1 along with novel genes. We incorporated these genes into the PI system, which was a significant prognostic indicator of NMIBC progression. The PI system was shown to be an independent risk factor by a multivariate analysis and subset stratification according to stage and grade (each $P < 0.001$). The subset analysis also revealed that the PI system could identify patients who would benefit from BCG immunotherapy.
Conclusions: The twenty-three gene-based PI represents a promising diagnostic tool for the identification of high-risk NMIBC patients who would display different clinical behaviours as well as response to BCG immunotherapy.

#5571
FoxP3 absolute quantification to build an effective risk model for cancer patient survival
Adele Ponzoni, Sandra Delebecq, Melodie Boute, Corinne Ramos, Jonathan Stauber. *ImaBiotech, Loos, France*

Background: Forkhead box protein P3 (FOXP3), belonging to the forkhead/winged-helix family, is of great importance in modulating the differentiation and development of T-regulatory cells (Tregs). The numbers of $FOXP3^+$ Tregs as well as exhaustive subsets of $CD4^+$ and $CD8^+$ T cells have been observed increased in solid tumor tissues of patients with colorectal and breast cancers, which helps to create an immunosuppressive environment and promotes tumor progression. However, the correlation between the presence of $FOXP3^+$ Tregs and patients' survival has been extensively studied in many cancer types, which remains conflicting. The approach presented here aims to absolutely quantify the level of FOXP3 in single cells and constructed effective immune risk models to predict tumor prognosis.
Method: Imaging mass cytometry (IMC) was used to quantify FOXP3 inside each single cell. The indirect quantification used a free-metal titration curve in order to match the level of intensity of the metal-tagged antibodies

to the level of expression of the antigen. Deep learning (StarDist QuPath extension) was used for cell segmentation and expression quantification. FOXP3 quantification in tissue or at the single cell level was validated against ELISA assay that measure FOXP3 in tissue lysate.
Results: Linearity of the metal signals with an average %CV of 17% was observed emphasizing the linear correlation between free metal concentration and intensity. With the IMC technique, the minimum amount of FoxP3 detectable is 0.09 femtogram and its absolute quantification in the different cells in tumor tissues was confronted to disease prognosis in order to start building an effective immune risk model.
Conclusion: With the introduction of new biologics in cancer therapy, it is imperative to follow real quantitative change in the expression of biological marker that are indicator of tumor prognosis. Indeed, although the FOXP3 distribution was already seen to be heterogenous in tumors, its absolute level of expression indicative of disease progression can be directly correlated to gain better understanding of the patient response stratification to biologics.

A COX-2-based pro-tumourigenic inflammatory signature predicts poor outcome in early-stage non-small cell lung cancer

Victoria Fife[1], Matthew Roberts[1], Christian P. Bromley[2], Derrick Morgan[1], Sophie Atkinson[1], Cong Zhou[1], Anshuman Chaturvedi[3], Steven Bagley[4], Garry Ashton[4], Lisa M. Coussens[5], Philip A. J. Crosbie[6], Caroline Dive[1], Elaine Kilgour[1], Santiago Zelenay[2]. *[1]Cancer Biomarker Centre, Cancer Research UK Manchester Institute (Alderley Park), Manchester, United Kingdom,[2]Cancer Inflammation and Immunity, Cancer Research UK Manchester Institute (Alderley Park), Manchester, United Kingdom,[3]Histopathology, The Christie Hospital, Manchester, United Kingdom,[4]Core Facilities, Cancer Research UK Manchester Institute (Alderley Park), Manchester, United Kingdom,[5]Department of Cell, Developmental & Cancer Biology, Knight Cancer Institute, Oregon Health and Science University, Portland, OR,[6]Division of Infection, Immunity and Respiratory Medicine, University of Manchester, Manchester, United Kingdom*

Lung cancer is the most common cause of cancer-related deaths with Non-Small Cell Lung Cancer (NSCLC) accounting for ~85% of cases. Patients with early-stage NSCLC (stages I-IIIA) undergo surgery with curative intent but up to 30% relapse. Identification of biomarkers that predict outcome at the point of surgery could inform patient management. Here, we explored whether a COX-2-based pro-tumourigenic inflammatory gene signature (PTI), measured in surgically resected samples from early-stage NSCLC patients, can predict patient outcome. Gene expression analysis was performed on 30 formalin fixed paraffin embedded surgical tumour samples from early-stage NSCLC patients with 36-63 months follow-up, using a custom code-set on the NanoString nCounter® platform. Additionally, *in silico* analysis of early-stage NSCLC data from The Cancer Genome Atlas (TCGA) was undertaken. The PTI gene signature and a published signature associated with T cell-inflamed tumours measuring IFNγ activity (IFNG)[1] were assessed in both datasets and correlated with patient outcome. NanoString gene expression data was robust, displaying good correlations with immunohistochemistry (IHC) expression for key proteins such as CD8 and COX-2, $R=0.88$, $p<1x10^{-6}$ and $R=0.83$, $p<1x10^{-6}$, respectively. The IFNG signature score, widely reported to associate with response to checkpoint inhibitors[2], did not correlate with outcome and consistent with this observation neither did CD8 protein expression (by IHC). In contrast, patients with LUSC (n=16) with the highest (upper quartile) PTI score showed significantly worse overall survival ($p<0.01$). Median overall survival for these PTI^{high} patients was <6 months vs 4.5 years for LUSC patients with PTI^{low} scores. Analysis of TCGA data from stage I-IIIA LUAD/LUSC cases confirmed these contrasting findings for the PTI compared with the IFNG signature. A multiplexed IHC panel for immune contexture analysis was successfully transferred from the Coussens Laboratory Oregon to CRUK Manchester[3] and with inclusion of COX-2 in this panel and adaptation of the pipeline for use with the HALO image analysis platform, analysis of the immune contexture in PTI high versus low tumours is underway. Transcriptional profiling of early-stage NSCLC samples revealed that COX-2-associated inflammation predicts patient outcome following surgery. These data highlight the importance of pro-tumourigenic inflammation in early-stage NSCLC. Findings are under validation in a larger cohort, including early-stage NSCLC samples from Manchester's early-detection screening studies and mapping of the immune

contexture of PTI high versus low tumours is underway. 1: Ayers, M., et al., J Clin Invest., 2017 2: Danaher, P., et al., J Immunother Cancer., 2018 3: Banik, G., et al., Methods Enzymol., 2020

Use of circulating tumor DNA (ctDNA) for early assessment of treatment response in patients with non-small cell lung cancer (NSCLC): A real-world (RW) analysis incorporating baseline ctDNA level and molecular response

Sean Gordon, Bojan Losic, Katie Quinn, Kyle Chang, Jiemin Liao, Han-Yu Chuang. *Guardant Health, Redwood City, CA*

Background: Data suggests that changes in ctDNA quantity correlate with response to therapy in patients with advanced solid malignancies. Furthermore, absolute baseline (pre-treatment) ctDNA level has been shown to be associated with patient prognosis. However, there is little information on how these variables can be combined to better interpret ctDNA results and enhance predictive power of treatment response. Here, we develop a model that incorporates the effects of both baseline ctDNA level as well as linear and nonlinear relative ctDNA change.
Methods: We queried the Guardant INFORM database, which comprises aggregated commercial payer health claims and de-identified records from over 225,000 individuals with comprehensive ctDNA testing via Guardant360 (G360). From September 2018-March 2022, patients with NSCLC treated with immune checkpoint inhibitors (ICI) (monotherapy or in combination) who received a ctDNA test within 15 weeks prior to treatment initiation and a second test 3-15 weeks after treatment initiation were retrospectively evaluated. Cox proportional hazards (CPH) were used for RW time to next treatment (TTNT) and time to treatment discontinuation (TTD) analyses. Gender, age, line of therapy (LOT) and comorbidities were included as covariates. ctDNA change from baseline to on-treatment (using the Guardant360 Response algorithm) was modeled as a continuous variable using a regularized cubic spline and baseline ctDNA level (using maximum variant allele fraction) was modeled as an interaction effect. Model validation and calibration were carried out via bootstrap resampling, ANOVA was used for multiple design hypothesis testing.

Results: 82 patients met the study criteria. 31 patients with large ctDNA decrease (e.g. >=50% decrease), also known as molecular responders, had significantly longer TTNT and TTD compared to other patients, regardless of baseline ctDNA level. 51 patients with small ctDNA decrease or ctDNA increase showed ctDNA level dependent trends in TTNT and TTD, with decreased risk for shorter TTNT and TTD for lower baseline ctDNA level. We found that the interaction between baseline ctDNA level and ctDNA change was significant (TTNT: p = .0069, TTD: p = .0236), and that ctDNA change had a nonlinear effect on both TTNT and TTD (TTNT: p = .0014, TTD: p = .0349). TTNT (TTD) bootstrap-adjusted concordance indices were 0.69 (0.65) and hazard ratios [95% CI] were 5.36 [1.79, 16.10] (2.37 [1.13, 4.98]).
Conclusions: These data demonstrate a statistically significant interaction between baseline ctDNA level and treatment-induced ctDNA level change in association with RW clinical outcomes. This facilitates the development of patient-based models incorporating baseline ctDNA level with ctDNA molecular response for association with RW clinical outcomes.

Immune-based Biomarkers for Prognostic and Predictive Benefit

#5701
Predictive biomarker models of immunotherapy response in patients with metastatic melanoma: genomic, transcriptomic, and immune profiles from the Personalised Immunotherapy Program (PIP)
Tuba N. Gide[1], Nurudeen A. Adegoke[1], Yizhe Mao[1], Monica Lennox[1], Saurab Raj[1], Camelia Quek[1], Ismael A. Vergara[1], Nigel Maher[1], Alison Potter[2], Robyn P. M. Saw[3], John F. Thompson[4], Andrew J. Spillane[1], Kerwin F. Shannon[1], Matteo S. Carlino[1], Maria Gonzalez[1], Serigne N. Lo[1], Alexander M. Menzies[1], Inês Pires da Silva[1], Richard A. Scolyer[1], Georgina V. Long[1], James S. Wilmott[1]. *[1]Melanoma Institute Australia, The University of Sydney, Camperdown, Australia,[2]Royal Prince Alfred Hospital and NSW Health Pathology, Camperdown, Australia,[3]Royal North Shore Hospital, Camperdown, Australia,[4]Royal Prince Alfred Hospital, Camperdown, Australia*

Background: While immune checkpoint inhibitors (ICI) have become the standard-of-care for advanced melanoma patients, only half of treated patients will survive beyond 5-years and many develop significant toxicity. The PIP study is combining pre-treatment clinical, molecular, and immunological profiles of melanoma patients to provide accurate prediction of response to ICI therapies.
Methods: 504 patients with advanced melanoma who received anti-PD-1±CTLA-4 ICI were studied to develop predictive models of resistance to ICI. Resistance was defined as patients with progressive disease as best response, or partial response/stable disease with <6 months progression-free survival (RECIST 1.1). Machine learning models were developed using clinicopathological characteristics, tumor mutation burden (TMB, Qiaseq TMB IO), gene expression profiling ((GEP), Nanostring Pancancer 360 IO) and spatial quantitative pathology immune profiling (multiplex immunofluorescence, (MIF)) of baseline melanoma biopsies. Models were developed in a discovery cohort (n=247), validated in an independent cohort (n=97), with an accruing prospective cohort (n=160). Model predictive performance was assessed using the area under the curve (AUC).
Results: Models were developed and validated using sequential addition of omics features to relevant clinical factors. Baseline clinical data alone achieved an AUC of 68%. Clinical plus three-tier TMB (<10, 10-20, >20 mut/mb) achieved an AUC of 78%. Clinical data plus GEP achieved 79% AUC, inclusive of tumor inflammation, antigen presentation and T-cell related signatures. Clinical and MIF spatial pathology achieved an 82% AUC including the distances between T-cells, CD16+ cells and melanoma cells as features in the model. Finally, the combination of TMB and GEP achieved an 83% AUC. Prospective validation of the models is awaiting follow-up milestones.
Conclusion: Multi-omic models using pre-treatment tissue and clinicopathology can significantly improve the accuracy of predicting patient outcomes to ICI treatments compared to baseline clinical data alone. Several models may be required based on different omic combinations to account for the reality of biopsy suitability and assay failures. These findings prove personalized precision treatment of patients with immunotherapies is possible in the clinical setting and such approaches should become routine care.

Background: Tumor biomarkers such as CD8 density and location (i.e., immune inflamed phenotype) and immune rich molecular subtype have been linked to immune checkpoint blockade (ICB) overall survival (OS) in

different cancers. The IMagyn050 trial (NCT03038100), which evaluated the efficacy of Atezo vs placebo (Pla) with carboplatin, paclitaxel and bevacizumab (CPB) in front line ovarian cancer patient (pts), did not meet its co-primary endpoints of PFS in ITT or PD-L1+ (Moore et al. JCO 2021). In the current IMagyn050 substudy we assessed potential predictive tumor immune biomarkers for Atezo clinical benefit.
Methods: FFPE tumors from the biomarker evaluable population were tested for PD-L1 IHC, CD8/PanCK IHC (total CD8 T cells and immune location phenotypes [inflamed, excluded, desert]) and RNA-seq (to derive molecular subtypes, biological pathways and cellular components [xCELL]) in tissue from baseline (n=860), on-treatment (OT, 9 weeks, n=233), intra- (n=8) and inter-lesion (n=12) matched samples. Hazard ratio (HR) interaction test from multivariate adjusted Cox-regression analysis for PFS and OS was performed to test predictive biomarkers.
Results: While tumors with CD8 T cells, immunoreactive molecular subtypes or immune inflamed phenotype were enriched for PD-L1+, only pts with immune inflamed tumors showed improved OS Atezo benefit (HR 0.67). Improved Atezo PFS/OS benefit was also observed in pts with whose tumors had high oxidative phosphorylation (OXPHOS, HR: 0.72/0.65) and UV Response (UV, HR: 0.64/0.58) but not IFNγ response. Plasma B cells were linked to improved OS Atezo benefit vs Pla (HR 0.53). We leveraged OT samples from pts in the neoadjuvant cohort to assess treatment effect on the tumor microenvironment. Analyses showed that CPB reduced tumor proliferation and increased tumor immune inflammation (CD8 T cells, PD-L1 and IFNα/IFNγ response), further increased by Atezo. Immune inflammation is challenging in ovarian cancer due to extensive tumor heterogeneity. Prevalence of tumor biomarkers varied by anatomic locations: total CD8, CD8 localization and molecular subtypes. Inter- and intra-lesion biomarker status within the same pt showed PD-L1 and plasma B cells as most consistent. Molecular subtypes and immune phenotypes had moderate intra-lesion agreement but discordant between lesions. PD-L1 and OXPHOS were the only biomarkers linked to Atezo benefit regardless of anatomical location.
Conclusion: This comprehensive exploratory study suggests that DNA damage, OXPHOS, plasma B cells and immune inflamed tumors, but not molecular subtypes or total CD8 T cells, may predict Atezo + CPB OS. This treatment promotes immune inflammation in OC tumors. Notably, we

found that several biomarkers are highly heterogeneous. Our findings highlight the challenges of achieving durable clinical benefit from targeted immunotherapy in ovarian cancer pts.

The immune cell state atlas analysis predicts therapeutic benefits with immune checkpoint inhibitors

Tingyi Li[1], Vineeth Sukrithan[2], Aakrosh Ratan[3], Martin McCarter[4], John Carpten[5], Howard Colman[6], Alexandra P. Ikeguchi[7], Xuefeng Wang[1], Igor Puzanov[8], Susanne Dalton[9], Michelle Churchman[10], Patrick Hwu[1], Paulo C. Rodriguez[1], William S. Dalton[10], George J. Weiner[11], Ahmad Tarhini[1].
[1]Moffitt Cancer Center & Research Inst, Tampa, FL,[2]The Ohio State University, Columbus, OH,[3]University of Virginia, Charlottesville, VA,[4]University of Colorado Cancer Center, Aurora, CO,[5]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[6]Huntsman Cancer Institute, Salt Lake City, UT,[7]Stephenson Cancer Center, Oklahoma City, OK,[8]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[9]Markey Cancer Center, Lexington, KY,[10]M2GEN, ORIEN, Hudson, FL,[11]University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA

Introducti**on:** In this study, we investigated the prognostic role of the immune cell state atlas in predicting therapeutic benefits of patients treated with immune checkpoint inhibitors (ICI) within the ORIEN network of 18 collaborating cancer centers under the Total Cancer Care protocol.
Methods: We utilized RNA-seq data of 926 samples generated from 875 individuals. Gene expression data were deconvoluted for immune cell states using the Carcinoma EcoTyper software. We then conducted a series of survival analyses to test the association between survival outcomes and predicted cell types and states in five malignant tumors: Genitourinary (GU), Gastrointestinal (GI), Thoracic (THO), Cutaneous (CUT), Head & Neck (H&N). The regularized Cox regression model in R package 'glmnet' was then applied to select the complementary pathway signatures (including gene ontology and KEGG pathways) to the immune cell states in predicting survival outcomes. We also explored the immune-related long non-coding RNAs (lncRNA) as potential biomarkers for cell states and patient outcomes.

Results: EcoTyper analysis revealed that 692 (~80%) of patients were assigned to the 10 pre-identified Carcinoma Ecotypes (CE1 to CE10) or cell state atlas group. Overall, two immune deficiency ecotype patient groups (CE1 and CE2) pre-identified based on the independent training data were linked to worse survival, while two proinflammatory ecotype groups (CE9 and CE10) were associated with favorable surxvival. Those ecotype groups showed strong prognostic significance in predicting OS in melanoma and H&N. Meanwhile, CE6, a non-neoplastic tissue enriched cell subtype, was also found to be highly associated with longer OS in H&N and GU. CE7, an age-related mutation patient subgroup, contributed to shorter survival in both melanoma and GI. We also found that a subset of activated B cell state and the exhausted/effector CD4 T cell state were significantly associated with patient survival in melanoma and GU, respectively. The penalized Cox regression model revealed that β-catenin signaling pathway, P53 pathway and heme metabolism in the MSigDB Hallmark gene sets are the most complementary pathways to the ecotype scores in multiple cancer types. In additional, multiple pathways in KEGG such as endocytosis were found to jointly contribute to the ecotype-pathway composite prognostic model. In anazlying immune-related lncRNA biomarkers, we highlighted the prognostic role of NKILA in our dataset, which has been studied to promote tumor immune evasion.
Conclusion: Our analysis has successfully established the utility of immune cell state atlas in predicting therapeutic benefits with ICIs. We expect that the discovered complementary signatures in the cancer-cell compartment will also lead to a novel spectrum of tumor-based biomarkers to ICI.

An integrated immune signature predictive of adjuvant immunotherapeutic benefits for high-risk melanoma
Alyssa N. Obermayer[1], Timothy I. Shaw[1], Sandra J. Lee[2], F. Stephen Hodi[3], William A. LaFramboise[4], Walter Storkus[5], Arivarasan D. Karunamurthy[6], Patrick Hwu[7], Howard Streicher[8], Dung-Tsa Chen[1], John M. Kirkwood[9], Ahmad A. Tarhini[10]. *[1]Biostatistics and Bioinformatics, H Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[2]Biostatistics, Dana Farber Cancer Institute, Boston, MA,[3]Dana Farber Cancer Institute, Boston, MA,[4]Pathology, Allegheny Health Network Cancer Institute,*

Pittsburgh, PA,[5]Immunology, University of Pittsburgh, Pittsburgh, PA,[6]Pathology, University of Pittsburgh, Pittsburgh, PA,[7]Administration, H Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[8]National Cancer Institute, Rockville, MD,[9]UPMC Hillman Cancer Center, Pittsburgh, PA,[10]Cutaneous Oncology and Immunology, H Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Introduction CTLA4 blockade with ipilimumab was more favorable than interferon-α2b (IFN) in high-risk melanoma in phase adjuvant III trial E1609. Characterization of the pretreatment tumor immune biomarkers and clinical covariates may inform the likelihood of response to ipilimumab and other immune checkpoint inhibitors (ICI), and guide future development of this and other modalities in this patient population.
Methods We utilized PATH-SURVEIOR, a bioinformatics framework developed in-house for associating genes and pathway signatures with clinical endpoints, to perform survival analysis of gene expression levels of 31 candidate immune-related biomarkers based on previous preliminary data. We analyzed microarray gene expression data from 471 melanoma patients treated with ipilimumab (ipi) and 248 melanoma patients treated with IFN as part of E1609. We then developed a LASSO Cox regression model and validated our model in 22 patients treated with neoadjuvant ipi in a separate clinical trial.
Results Using PATH-SURVEIOR, we evaluated 31 candidate immune biomarkers and their association with patient outcome by including treatment group (ipi and IFN) as a multiplicative covariate interaction in the Cox hazard model. Our analysis identified CXCL9, CD8A, CXCL10, and INPP5D as Tier 1 biomarkers (HR > 1 and $P < 0.05$) and IDO1, IGKC, and IL2RB as Tier 2 biomarkers (HR > 1 and $P < 0.1$). Next, we developed an ipilimumab immune-based risk score using LASSO Cox regression (L-IPI7) based on these 7 aggregate biomarkers. We then split our 471 ipi-treated cohort into training (310, 66%) and testing (161, 33%) cohorts and assessed our model for its ability to predict overall survival (OS) and relapse-free survival (RFS). Our risk score was capable of stratifying ipi-treated patients into High-Risk and Low-Risk populations, which correlated with OS. As a negative control, we assessed our risk score in 248 IFN-treated patients and found no significant association with OS. As validation, we applied our L-IPI7 score to a cohort of 22 patients treated with

neoadjuvant ipi and determined that the score was able to predict patients with a high risk of relapse. Interestingly, when we developed an interactive Cox-regression model with colitis status (grade 0-1 vs grade 2+), we found that neoadjuvant ipi patients with low-grade colitis were associated with a higher L-IPI7 risk score for disease relapse. In addition, we determined that: i) higher age and higher L-IPI7 risk score identified patients with the worst OS and RFS And ii) female patients with a low L-IPI7 risk scores had a better OS and RFS.
Conclusions We developed a broadly applicable model based on LASSO Cox Regression predictive of adjuvant ipi treatment outcomes in melanoma. Our L-IPI7 score based on expression of CXCL9, CD8A, CXCL10, INPP5D, IDO1, IGKC, IL2RB effectively predicts survival, with interactions with age, gender and on-treatment development of colitis.

[1]Hoffmann-La Roche Limited, Mississauga, ON, Canada,[2]Genentech, Inc., South San Francisco, CA,[3]PathAI, Boston, MA

Background: In recent years, a relationship between the tumor microenvironment (TME) and patient response to targeted cancer immunotherapy has been suggested. We applied machine-learning algorithms on H&E stained tissue to study the TME in metastatic non-small cell lung cancer (NSCLC) patients. Our goal was to identify digital pathology (DP) features associated with outcome under combination treatment or monotherapy with atezolizumab (atezo), an anti-PD-L1 therapy, and relate those features to other data modalities. We analyzed patient data from two phase 3 clinical trials, OAK (docetaxel versus atezo in 2L+ NSCLC) and IMpower150 (bevacizumab, carboplatin, and

paclitaxel (BCP) versus BCP+atezo (ABCP) in advanced 1L non-squamous NSCLC).
Methods: As part of our effort to build a DP-based tumor-immune microenvironment atlas, digitized H&E images were registered onto the PathAI research platform. Over 200K annotations from 90 pathologists were used to train convolutional neural networks (CNNs) that classify slide-level human-interpretable features (HIFs) of cells and tissue structures from images and deployed on images from OAK and IMpower150. HIFs and PD-L1 status were associated with outcome in all samples in each arm in OAK and results were validated in IMpower150, using Cox proportional hazard models. Bulk RNAseq was run using samples extracted from the same area as the H&E slide.
Results: We identified a composite feature capturing the ratio of immune cells to fibroblasts in the stroma predictive of both overall survival (OS) (HR=0.74 p=0.0046) and progression-free survival (PFS) (HR=0.87 p=0.14). While patients primarily benefit from atezo if they are PD-L1 high, we found that even PD-L1 negative patients benefited from atezo when enriched for this feature (22C3 PD-L1 assay: OS HR=0.59 p=0.015, PFS HR=0.8 p=0.25; SP142 PD-L1 assay: OS HR=0.74 p=0.12, PFS HR=0.88 p=0.45). We thus recognized a DP feature that was predictive for positive outcome with atezo treatment, independent of PD-L1 levels. This association was then validated in IMpower150 comparing ABCP to BCP, both overall (OS HR=0.69 p=0.012) and in PD-L1 negative patients (SP263 assay OS HR=0.56 p=0.034). Integrating with RNAseq, patients enriched for this DP feature showed similar enrichment for B and T gene signatures and depletion in CAF-related gene signatures, thus showing the harmonization of TME between different data modalities.
Conclusions: Using a deep learning-based assay for quantifying pathology features of the TME from H&E images in two NSCLC trials, we identified a novel biomarker predictive of outcome to PD-L1 targeting therapy, even in PD-L1 low & negative patients. Importantly, our work shows how different data modalities (DP, gene expression) can be integrated to further our understanding of the TME.

ImmunoPROFILE: A prospective implementation of clinically validated, quantitative immune cell profiling test identifies tumor-

infiltrating CD8$^+$ and PD-1$^+$ cell densities as prognostic biomarkers across a 2,023 patient pan-cancer cohort treated with different therapies

James Lindsay[1], Bijaya Sharma[2], Kristen D. Felt[2], Anita Giobbie-Hurder[1], Ian Dryg[1], Jason L. Weirather[1], Jennifer Altreuter[1], Tali Mazor[1], Priti Kumari[1], Joao V. Alessi[3], Ajit J. Nirmal[4], Michael P. Manos[5], Ananth R. Kumar[1], William Lotter[1], Ethan Cerami[1], Burce E. Johnson[4], Neil I. Lindeman[6], Lynette M. Sholl[7], Jonathan A. Nowak[8], Scott J. Rodig[7]. *[1]Data Science, Dana-Farber Cancer Institute, Boston, MA,[2]ImmunoProfile, Brigham and Women's Hospital, Boston, MA,[3]Data Science, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA,[4]Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA,[5]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[6]Harvard Medical School, Brigham and Women's Hospital, Boston, MA,[7]Department of Pathology, Brigham and Women's Hospital, Boston, MA,[8]Brigham and Women's Hospital, Harvard Medical School, Boston, MA*

Tumor-infiltrating lymphocyte (TIL) density has been identified as a prognostic and predictive biomarker in select tumors treated with defined therapies. These observations suggest that TILs may be general markers of patient outcomes, but evidence in support of this hypothesis has been limited by small cohorts.

We validated ImmunoPROFILE, a multiplexed immunofluorescence (MIF)-based assay coupled with machine-learning-based image analysis, to identify and quantify tumor cells (cytokeratin, PAX5, PAX8, SOX10), T cells (CD8), T-regulatory cells (FOXP3), exhausted cells (PD-1) and immunosuppressive tumor and immune cells (PD-L1). We applied the MIF panel to specimens from patients collected prospectively over three years and analyzed 2,023 cases across 27 tumor types. The association between biomarkers and overall survival (OS) was investigated using Cox models controlling for patient risk factors such as cancer type, metastatic vs. primary disease, age, and gender. Multivariable biomarker selection was based on likelihood ratios.

The assay was highly robust (success rate 97%), reproducible (inter-scanning and intra-staining density controls within 1 SD, inter-staining PD-

L1 scores ≤11% CV), and operator-independent (R^2 >0.7 to >0.9 for each biomarker and 95% concordance in PD-L1 score-based interpretation between technicians). From whole slide images, a total of 11,932 individual regions of interest were analyzed across the cohort, resulting in >50 million spatially-resolved single cells which were summarized into cell population densities and PD-L1 scores.

High densities of $CD8^+$ (>64/mm^2, p<0.0001), PD-1^+ (>50/mm^2, p<0.0001), and $FOXP3^+$ (>30/mm^2, p<0.0001) T cells were associated with longer overall survival (OS) irrespective of therapy and across all cancer types. PD-L1 metrics were not associated with OS (p=0.43). Compared to patients with low densities of $CD8^+$ and PD-1^+ cells, high densities of at least one of these cell types had better OS (Both high, HR: 0.49, 95% CI: 0.41 - 0.59; $CD8^+$ high, HR: 0.63, (0.48 - 0.82); PD-1^+ high, HR: 0.71, (0.54 - 0.93)). The results were consistent in the subset of patients (N=1572) who did not receive immunotherapy (IO). In patients who received IO therapy (N=451), only PD-1^+ T-cell density associated with OS (HR: 0.48, (0.36 - 0.65)).

To our knowledge, this is the first enterprise-level immune biomarker assay using multiplexed staining, digital imaging, and machine learning to be applied in a prospective manner to clinical specimens at scale. We found that select immune cell densities are prognostic across cancer types and therapies and demonstrated that quantification of multiple cell populations yields better prognostic power than single marker analyses.

Tumor and immune determinants of response to anti-BCMA CAR T-cell therapy in multiple myeloma using cell-free DNA

Mia Carleton[1], Hitomi Hosoya[2], Kailee L. Tanaka[1], Brian Sworder[1], Vanna Hovanky[2], Bita Sahaf[2], Matthew J. Frank[2], George E. Duran[1], Tian Y. Zhang[3], Sally Arai[2], David Iberri[1], Michaela Liedtke[1], David B. Miklos[2], Michael S. Khodadoust[1], Surbhi Sidana[2], David M. Kurtz[1]. *[1]Department of Medicine, Division of Oncology, Stanford University School of Medicine, Stanford, CA,[2]Division of BMT and Cellular Therapy, Stanford University School of Medicine, Stanford, CA,[3]Department of Medicine, Division of Hematology, Stanford University School of Medicine, Stanford, CA*

Background: Multiple myeloma (MM) is an incurable disease with a heterogenous clinical course and genomic landscape. Autologous anti-BCMA chimeric antigen receptor (CAR) T-cells are a promising new therapy, but determinants of response and resistance are not well known. Cell-free DNA (cfDNA) is a useful tool to study MM as it allows for repeated, non-invasive tumor assessment. We apply a novel method for simultaneously tracking tumor mutations and CAR T-cells from cfDNA using Cancer Personalized Profiling by Deep Sequencing (CAPP-Seq).
Methods: We designed a 480kb CAPP-Seq hybrid capture panel to identify mutations, track tumor burden and minimal residual disease, and detect cfDNA derived from the CAR transgene (CAR-cfDNA) in patients receiving idecabtagene vicleucel (ide-cel). Flow cytometry (FC) for enumeration of CAR T-cells was performed from peripheral blood mononuclear cells (PBMCs) when available.
Results: We profiled 153 biologic samples, including plasma, PBMCs, and bone marrow mononuclear cells, from 15 patients receiving ide-cel and 18 healthy controls. We observed a median of 84 SNVs (range 30-277) prior to therapy. Patients with prolonged responses (>90 days) had significantly lower circulating tumor DNA (ctDNA) at day 28 post-infusion than patients with early progression (<90 days) (0.6 vs. 4.6 log haploid genome equivalents (hGE)/mL; p=0.002). Additionally, higher ctDNA at D28 was prognostic for time to progression (TTP) (HR=1.67, p=0.019). We validated CAR-cfDNA detection by comparison with FC from PBMCs at matched timepoints (n=38), finding a significant correlation (rho=0.79, p=3E-09). CAR-cfDNA typically reached its peak level around D14 (median 332 hGE/mL), with ctDNA declining at the same time-point. Thus, CAR-cfDNA levels and ctDNA burden were inversely correlated (rho= -0.3, p=0.019). Surprisingly, peak CAR expansion was not associated with TTP (HR=1, p=0.463). However, lower CAR-cfDNA at D28 was prognostic for inferior TTP (HR=2.68, p=0.011). This suggests CAR persistence may play a more important role in clinical outcomes. Furthermore, among progressors, time until loss of detectable CAR-cfDNA correlated with TTP (rho=0.81, p=0.02). Patients who progressed before day 90 had a median CAR persistence of 28 days. In contrast, patients who progressed after day 90 had a median of 137 days and often had emergent copy number alterations in ctDNA at relapse. This included one case with emergent loss of chr16, where *TNFRSF17* (*BCMA*), resides. This event was detected 36

days prior to clinical relapse; BCMA loss was validated via whole-genome sequencing and immunohistochemistry staining of the tumor.
Conclusions: Cell-free DNA is a promising biomarker for mutational genotyping, disease monitoring, and tracking CAR T-cells in MM. The persistence of CAR-cfDNA has particular prognostic importance and novel strategies to increase CAR persistence should be explored.

Immunomodulatory Agents and Interventions

IL-1 blockade prevents cardiac toxicity and improves immunotherapy efficacy

Nilesh P. Talele[1], Heena Kumra[1], Igor L. Gomes-Santos[1], Sylvie Roberge[1], William W. Ho[1], Patrik Andersson[1], Sampurna Chatterjee[1], Marie Siwicki[2], Dan G. Duda[1], Mikael J. Pittet[3], Dai Fukumura[1], Rakesh K. Jain[1]. *[1]Harvard Medical School/Massachusetts General Hospital, Norwood, MA,[2]Center for Systems Biology, Massachusetts General Hospital Research Institute and Harvard Medical School, Boston, MA,[3]Department of Pathology and Immunology, University of Geneva, Geneva, Switzerland*

Background: Immune checkpoint blockers (ICBs) have revolutionized cancer treatment, but they are often associated with severe immune related adverse events (irAEs). These severe irAEs are more often seen in patients with obesity or concomitantly treated with cytotoxic therapies.
Methods: We aimed to understand the mechanisms of ICB-induced irAEs, in the context of obesity and ICB/chemotherapy combinations. We developed a mouse model of cardiac irAEs, which is the most fatal type of irAE in ICB-treated cancer patients, with clinically relevant features: (i) an ICB-resistant cancer (pancreatic ductal adenocarcinoma or PDAC), (ii) obesity induced with high-fat diets, and (iii) a combination treatment of ICB (α-PD1 + α-CTLA4) and chemotherapy (FOLFIRINOX).
Results: Our FDA and single institution retrospective analyses indicate that patients treated with ICB had greater relative risk of developing myocarditis as compared to other anti-cancer therapies. Mice with orthotopic PDAC and obesity developed irAEs after treatment with ICB and chemotherapy as compared to chow diet. These irAEs recapitulated those observed in patients with cancer and obesity, including cardiac dysfunction consistent

with myocarditis, cardiac fibrosis, and increased circulating levels of interleukin-1 beta (IL-1b). IL-1β blockade prevented myocarditis and reduced cardiac fibrosis after immunotherapy. Importantly, IL-1β blockade also enhanced the anti-tumor effects of ICB + FOLFIRINOX combination therapy, and increased mouse survival.
Conclusions: We developed a translationally relevant 'triple hit' mouse model and discovered that IL-1β mediates ICB-induced cardiotoxicity. In addition, we found that IL-1β blockers, which are already used in the clinic for cardiology indications, both reduce adverse events and simultaneously enhance the antitumor effects triggered by immunotherapy.

Activity of novel RNA therapeutics to overcome resistance to immune checkpoint blockade

Marvin O'Ketch, Jeffrey A. Kiefer, Dnyanesh Rasale, Warren S. Weiner, Lizette A. Castaño, Nathalie A. Azorsa, David W. Lee, Kerry M. Barnhart, Spyro Mousses, David O. Azorsa. *Oligon, Scottsdale, AZ*

T-cells in the tumor microenvironment can often become exhausted and dysfunctional due to chronic and prolonged exposure to antigen. The resulting condition of T cell exhaustion represents an important mechanism of clinical resistance to immune checkpoint blockade. The transcription factor NR4A1 is known to be upregulated in tumor-specific T-cells and is a mediator of T cell dysfunction including driving exhaustion during chronic antigen stimulation of T-cells. Pro-oncogenic activities of NR4A1 have been observed in various solid tumors, including colorectal and breast cancers, and co-expression of NR4A1 with known immune checkpoint markers such as PD-L1 and B7 family members has also been observed in various cancer cell lines. These findings have identified NR4A1 as an important target for overcoming resistance to cancer immunotherapy. We hypothesize that targeted silencing of the NR4A1 and other immunomodulatory genes can reverse T-cell exhaustion and expand the clinical benefit of immune checkpoint blockade in solid tumors resistant to immune therapy. To reverse T-cell exhaustion with a targeted approach, we developed T cell targeting SeekRs^{TM}, which are chimeric RNA therapeutics containing dual-flanking aptamer binders connected by a double-stranded bridge containing siRNA silencers that can target multiple

immunomodulatory genes. First-generation aptamer-siRNA chimeras designed with a CTLA-4 targeting aptamer containing a STAT3 siRNA demonstrated effectiveness in silencing its target. Modifications to the structure included the addition of chemically modified nucleotides to improve serum stability. Additionally, dimerization of the structure to form a SeekR dimer molecule greatly improved internalization and target silencing compared to the monomeric chimera. Newly developed SeekRs targeting T cells and designed to silence NR4A1 have effectively downregulated NR4A1 in model cell lines and activated T cells. These results demonstrate that dual targeting SeekRs can be used to specifically deliver siRNA to T cells for targeted silencing that can reverse exhaustion and potentially overcome resistance to cancer immunotherapy in the clinic.

Heterogeneity of IFN-γ responsiveness in myeloid malignancies-implication for the possible impact on IFN-γ immunotherapy

Kedwin Ventura, Iuliia Kovalenko, Jui-En Ray Lee, Biswas Neupane, Daniel Stapor, Sawa Ito. *University of Pittsburgh School of Medicine, Pittsburgh, PA*

Introduction: Allogeneic stem cell transplantation (alloSCT) can potentially cure hematologic malignancies through graft-versus-leukemia effect (GVL). Several studies have suggested that IFN-γ pathway is critical for GVL sensitivity or resistance in leukemia cells. In mouse model, acute myeloid leukemia (AML) generated in IFN-γ receptor-deficient mice acquired resistance to GVL (Matte-Martone, Shlomchik WD, J Clin Invest. 2017). Other groups have reported that IFN-γ restores HLA expression on myeloid blasts from patients who relapsed AMLs after alloSCT. These data support the clinical application of IFN-γ to augment GVL in subjects with post-transplant relapse. However, AML is molecularly heterogeneous, and the IFN-γ responsiveness may vary by AML subtypes. We analyzed IFN-γ responsiveness of primary AML cells and investigated the role of IFN-γ on cell death and T-cell recognition of AML cell lines.
Methods: Primary AML cells collected at diagnosis (n=60), at relapse after chemotherapy (n=4), and at post-transplant relapse (n=8) were stimulated with IFN-γ at 1 ng/ml or 50 ng/mL *in vitro*, and IFN-γ responsiveness was analyzed by measuring phosphorylation of STAT1 (pSTAT) after 15

minutes and upregulation of HLA-DR after 48 hours by flow cytometry. U937 and THP-1 cell lines were used to investigate IFN-γ induced cell death and the impact of IFN-γ priming of leukemia cells on the activation of alloreactive T cells. For this, Jurkat cells transduced with anti-HA1 T cell receptor (αHA1-TCR-T) were used, and the activation was analyzed through CD69 upregulation by flow cytometry.
Results: IFN-γ responsiveness was heterogeneous in both pSTAT1 and HLA-DR upregulation of primary AML blasts. IFN-γ responsiveness also varied within the subpopulation of leukemic blasts within the sample at diagnosis and relapse, implying clonal evolution. Compared to THP-1, U937 cells fail to upregulate HLA-DR with IFN-γ despite appropriate pSTAT1 response to IFN-γ, suggesting silencing of downstream IFN-γ activation site (GAS) and transcription of IFN-stimulated genes (ISGs). IFN-γ directly induced cell death in THP-1 *in vitro*, while U937 was resistant to IFN-γ induced cell death. Priming of THP-1 with IFN-γ significantly improved the affinity of αHA1-TCR-T to peptide-stimulated THP-1.
Conclusion: IFN-γ responsiveness of AML blasts was heterogeneous, and cell line data suggest an impact of IFN-γ sensitivity on IFN-γ mediated cell death and alloreactive T cell recognition. Future studies aim to understand the mechanisms underlying IFN-γ sensitivity or resistance in AML, which would help to design clinical trials by selecting the patients who would obtain maximal benefit from IFN-γ therapy in post-transplant relapse (NCT04628338).

Use of luciferase-labeled target cells to explore immune cell killing in high throughput format in 2D and 3D co-cultures

Carla Castro, Philipp Metzger, Daniel Feger, Sarah Ulrich, Oliver Siedentopf, Jan E. Ehlert, Holger Weber. *Reaction Biology Europe GmbH, Freiburg, Germany*

With the development and approval of cutting-edge immune-based approaches for cancer treatment in recent years, the global immune-oncological (IO) pipelines have dramatically increased. To overcome the challenges of rising treatment resistance, new strategies are being developed pointing towards enhancing and sustaining T cell-mediated

cytotoxicity, exploiting NK, monocytes and γδT cell killing capacity, and combinatorial therapies, among others.

Examples of such strategies are the bispecific antibodies, which are mainly T-cell (BiTE) engagers, but also NK-cell engagers. In addition to the FDA approved immune checkpoint inhibitors, monoclonal antibodies against tumor antigens are being developed to enhance the cytotoxic response of NK and macrophages/monocytes through antibody-induced cell cytotoxicity (ADCC)

To facilitate the efficacy analysis of BiTEs, we developed a 384-well format assay system based on luciferase-labeled tumor cells (advantages: high-throughput capability, non-radioactive, non-toxic, relatively low cost, and easily adaptable to automation). As only the tumor cells are labeled, the specific detection of luciferase exclusively correlates to the number of viable tumor cells, allowing for co-cultures with high excess of effector cells without the effector cells causing interference. Due to high sensitivity, few tumor cells are required for a sufficient signal/noise ratio, keeping the overall need for primary effector cells to a minimum, even at high effector/target cell ratios. This is of great advantage when working with rare cytotoxic subpopulations (e.g. NK cells), precious samples from patients, or simply saves resources when performing large exploratory studies. In addition, combination of low 384-well format volumes with nanodrop agent dispensing technology minimizes the amounts of expensive antibodies and other agents.

Applying this technology, we evaluated the combinatorial effects of Blinatumomab with other clinically relevant agents on the luciferase-labeled GCB-like DLBCL cell line OCI-LY1. Depending on compound combination, we observe synergistic (e.g. Lenalidomide) but also antagonistic effects (e.g. MEK-inhibitor, Selumetinib, and MCL-1-inhibitor, S63845). We also developed CD3-stimulated T cell killer assays either using target cells grown in monolayer or spheroids, with the intent to study checkpoint inhibitors or other T cell activation modulators. In contrast to target cells grown in monolayers, immune cytotoxicity of spheroids by anti-CD3 stimulated T cells was incomplete, showing the additional challenge for effector cells when using 3D cultures as targets. Moreover, we show an ADCC example using NK as cytotoxic cells. Our data supports the outstanding usefulness of this methodological approach for the exploration

of the overall efficiency of a therapy to enhance tumor cell killing by immune effector cells.

#4420

Carbohydrate-CD11b engagement enhances differentiation of tumor-associated myeloid cells in immunotherapy of solid cancers

Mei Zhang. *Biomedical Engineering, Case Western Reserve University School of Medicine, Cleveland, OH*

Background: Methods to perturb tumor-associated myeloid cell function are being actively pursued to overcome these challenges in immunotherapy and search for a cure. CD11b is a potential therapeutic target to modulate suppressive myeloid derived cells and induce tumor-reactive T-cell responses. However, CD11b can bind to multiple carbohydrate ligands that trigger a variety of myeloid cell functions like adhesion, migration, and even phagocytosis and proliferation. This has created a major challenge to understand the molecular basis by which CD11b converts differences in receptor-ligand binding into subsequent immune signaling responses, and to use this knowledge for therapeutic development.

Methods: This study investigated a previously reported carbohydrate ligand, BG34-200, that showed anti-tumor effect through modulating $CD11b^+$ cells. Applying modern approaches of peptide microarray, multi-parameter FACS analysis, cellular/molecular immunological technology, advanced microscopic imaging, and transgenic mouse models of solid cancers, we studied the BG34-200-CD11b carbohydrate-protein engagement and immunological changes it triggered in the context of solid cancers including osteosarcoma, melanoma and pancreatic cancer.

Results: Our results show that BG34-200 can mediate direct, specific, multi-site and multivalent binding to integrin CD11b to trigger cellular differentiation in a suppressive tumor-associated myeloid cell subset. In melanoma, osteosarcoma, and pancreatic cancer, we detected this rare myeloid cell subset in blood, which displayed an inflammatory monocyte phenotype and exhibited immunosuppressive behavior. BG34-200-CD11b engagement could induce differentiation of these tumor-associated inflammatory monocytes into dendritic cells by inducing phagocytosis that effectively trigger F-actin cytoskeletal rearrangement and intrinsic ICAM-1 clustering important for antigen presentation and effector T cell stimulation.

Conclusions: Our findings improve understanding of molecular basis by which CD11b converts difference in carbohydrate ligands into subsequent immune signaling responses, may lead to development of safe and novel therapies modulating myeloid derived cell function for immunotherapy of solid cancers.

#4421

Targeting myeloid-derived suppressor cells with actinium-225 lintuzumab, a CD33 antibody radioconjugate to enhance antitumor immunity

Amanda Chin, Mary Chen, Jason Li, Megan McCloskey, Caroline Jennings, Le-Cun Xu, Monideepa Roy, Denis Beckford, Helen Kotanides. *Actinium Pharmaceuticals, Inc., New York, NY*

Introduction: Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of myeloid lineage cells with potent immunosuppressive activity found enriched in cancer patients. Crosstalk between MDSCs and the tumor microenvironment can promote tumor immune evasion and thus there is growing interest in developing therapeutic approaches to intervene in the MDSC suppressive function. Both monocytic-MDSC (M-MDSC) and granulocytic-MDSC (G-MDSC) subpopulations express the cell surface CD33 myeloid marker. For well-defined cell surface markers like CD33, there is considerable interest in the use of radionuclides as therapeutic payloads, particularly α-particle emitters such as actinium-225 (^{225}Ac) since they deliver substantially higher decay energies over a much shorter distance than β-emitters, rendering them more suitable for precise, potent, and efficient target cell killing while minimizing toxicity to surrounding bystander cells. Actimab A, the anti-CD33 antibody lintuzumab armed with the ^{225}Ac radioisotope (CD33 ARC), is currently being evaluated in R/R AML and has demonstrated significant anti-leukemic activity in Phase 1/2 clinical trials. We therefore hypothesized that MDSCs can be directly targeted by the CD33 ARC. Hence, we evaluated the therapeutic potential of the CD33 ARC to deplete MDSCs through preclinical studies in vitro and in vivo with humanized mouse model. Methods: CD33 ARC was generated by conjugating lintuzumab with *p*-SCN-Bn-DOTA and subsequently radiolabeled with ^{225}Ac. Primary MDSCs were isolated from cancer patient peripheral blood or healthy donor

PBMCs. The specific binding of CD33 ARC to CD33 positive MDSCs and the decreased viability of MDSCs in response to treatment in vitro was characterized by immunophenotyping using flow cytometry. The therapeutic efficacy of CD33 ARC to deplete MDSC in vivo was evaluated in human CD34 reconstituted humanized NOG-EXL mice.
Results: CD33 positive MDSCs (M-MDSCs and G-MDSCs) were identified in human cancer peripheral blood samples, including colorectal and lung. Significantly more MDSCs were found in the peripheral blood of cancer patients in comparison to healthy donors. CD33 ARC treatment of human cancer MDSCs induced a potent dose-dependent reduction in MDSC viability leading to increased depletion of MDSCs. Furthermore, in the humanized NOG-EXL mouse model, CD33 ARC therapy demonstrated in vivo activity of CD33 ARC to deplete human MDSCs.
Conclusions: In this study, we demonstrate CD33 ARC alpha targeted radiotherapy depletes human CD33 positive immune suppressing MDSCs present in multiple cancer types, to enhance antitumor immunity. These findings present a translatable strategy that supports further evaluation of ^{225}Ac lintuzumab as a MDSC targeting agent to improve the efficacy of antitumor therapies.

#4422

Evaluation of immune response to tumor associated antigens in patients with high grade serous ovarian cancer vaccinated intra-dermally with DCP-001, an allogeneic, cancer cell-based vaccine

Marco De Bruyn[1], Annegé Vledder[1], Rob ten Pas[2], Anneke Eerkens[1], Koen Brummel[1], Hester van Zeeburg[2], Jeroen Rovers[2], Hans Nijman[1].
[1]University Medical Center Groningen, Groningen, Netherlands,[2]Mendus, Leiden, Netherlands

Treatment of high grade serous ovarian cancer (HGSOC) after debulking and chemotherapy remains challenging. This phase 1 trial (NCT04739527) evaluates the use of a cell-based relapse vaccine, DCP-001, to prevent disease recurrence after primary treatment. Previous data in acute myeloid leukemia, has shown that DCP-001 induces an immune responses to tumor associated antigens, like WT1 and PRAME, frequently upregulated in HGSOC. In NCT04739527, DCP-001 is given four times biweekly (week 0, 2, 4 and 6) at a dose of 25 million cells/vaccination (vc), followed by 2

monthly boosters (week 14 and 18) of 10 million cells/vc, after primary debulking and chemotherapy. IFNγ ELISpot is performed on peripheral blood mononuclear cells after restimulation with WT1, PRAME, MAGEA3/4 and NY-ESO1. Vaccine induced T-cell response (VIR) at any point after week 0 are calculated as at least a 2-fold increase of the mock-corrected baseline response. Sustained VIR are counted if a VIR to the same antigen is observed in at least 2 timepoints after start of DCP-001. Flow cytometry is performed using a 40-marker panel to evaluate the immune profiles of innate and adaptive immune system, as well as activation and exhaustion markers and memory profiles. At present, a total of 7 patients have been included and 6 have completed the full vaccination schedule (week 22). DCP-001 is well-tolerated, with only mild to moderate adverse events, mainly related to local injection side reactions, or systemic discomfort with fatigue, diarrhea, temperature elevation and headache. Immune responses have been evaluated in 5 patients by IFNy ELISPOT. VIR were detected in a range of 0-8, and all but 1 patient had at least one sustained VIR to either of the 4 antigens. One patient had no VIR, however this patient had already high baseline responses to all 4 antigens. Flow cytometry showed changes during the vaccination in the immune profiles of these patients, with in general an activation of the innate and adaptive immune system. Detailed analysis is currently ongoing. Finally, at the week 22 visit, 2 patients had progressed during the treatment and 4 had no clinical signs of progressive disease. Taken together, initial data from the phase I trial demonstrate that DCP-001 is safe and well-tolerated and induces durable T-cell responses to tumor associated antigens in OC patients. The study will continue to enroll new patients, follow-up for progression and overall survival and will further analyze the immune responses induced by DCP-001.

#4423

XMT-2056, a HER2-targeted STING agonist antibody-drug conjugate, exhibits ADCC function that synergizes with STING pathway activation and contributes to anti-tumor responses

Jahna Soomer-James, Marc Damelin, Naniye Malli. *Mersana Therapeutics, Inc., Cambridge, MA*

XMT-2056 is a systemically administered Immunosynthen STING agonist antibody-drug conjugate (ADC) that targets a novel HER2 epitope and induces complete tumor regressions with a single dose in multiple tumor models. We have previously shown that XMT-2056 delivers its STING agonist payload into tumor cells and FcγRI (CD64)-expressing myeloid cells, activating STING signaling in both cell types, leading to type I interferon (IFN) and anti-tumor innate immune responses. Here, we demonstrate that XMT-2056 exhibits ADCC (antibody-dependent cell-mediated cytotoxicity) function, which synergizes with STING pathway activation and induces potent cancer cell-killing activity in co-cultures of HER2-expressing cancer cells and FcγRIII$^+$ (CD16$^+$) immune cells. We show that both XMT-2056 and HT-19 (the unconjugated parental antibody) retain significant cancer cell-killing activity in an Fc-dependent manner in PBMC co-cultures depleted of FcγRI-expressing myeloid cells. This activity is abrogated by co-depletion of FcγRIII$^+$ immune cells, illustrating the ADCC function of XMT-2056. In this setting, XMT-2056 cancer cell-killing activity was significantly increased compared to HT-19, suggesting that the STING payload contributes to the differential activity observed with XMT-2056 treatment. Indeed, co-treatment of cancer cell and immune cell co-cultures with HT-19 and free STING agonist payload enhanced the anti-tumor responses, although to a lesser extent than XMT-2056, suggesting a synergy between the ADCC function and STING pathway activation. Consistently, XMT-2056 treatment of HER2-expressing cancer cells co-cultured with unstimulated CD56$^+$/FcγRIII$^+$ NK cells induced granzyme b and IFN-γ cytokine production, expression of NK cell activation markers, and cancer cell-killing activity. The ADCC activity of HT-19 was comparable to that of trastuzumab in NK cell co-cultures. Finally, we found that depletion of FcγRI$^+$ cells inhibited the cancer cell-killing activity of XMT-2056 in cancer cell and PBMC co-cultures more substantially compared to depletion of FcγRIII$^+$ cells or CD56$^+$ NK cells, indicating a greater contribution of myeloid cells to the XMT-2056 mechanism of action in this setting. Notably, XMT-2056 was capable of engaging both FcγRI$^+$ myeloid cells and FcγRIII$^+$ NK cells, activating both STING-mediated innate immune responses and ADCC function in triple cultures with HER2-expressing cancer cells. Collectively, our data reveal a synergy between ADCC function and STING pathway induction both mediated by XMT-2056, which enhances the cancer cell-killing activity of

FcγRIII$^+$ cells. This additional mechanism of action of XMT-2056 can potentially impact the overall anti-tumor immune responses in tumors infiltrated by FcγRIII$^+$ cells.

Immunoregulatory role of club cell secretory proteins in non-small cell lung cancer

Aakanksha Rajiv Kapoor, Vivek Mittal. *Cardiothoracic Surgery, Weill Cornell Medicine, New York, NY*

Introducti**on.** Immune checkpoint inhibitors (ICI) particularly those targeting the PD-1/PD-L1 axis are approved for NSCLC patients. However, most patients experience little clinical benefit due to immunosuppressive barriers in the tumor microenvironment. Our goal to identify immunomodulatory agents that may overcome these barriers, led to the finding that low dose stereotactic body radiation therapy (SBRT) in combination with ICI resulted in marked tumor regression and improved survival by generating durable anti-tumor immunity (Ban et al., Nature Cancer, 2021). Unexpectedly, we uncovered that the immune-modulating functions of SBRT was acutely dependent on the secretory function of lung resident *Scgb1a1*$^+$ club cells that protect the bronchioles from xenobiotic agents. Blocking club cell secretome *in vivo* blunted the efficacy of the combination treatment and altered myeloid cell phenotypes. These findings led to the hypothesis that radiation-induced club cell factors may synergize with ICI to attenuate immunosuppressive barriers by reducing myeloid suppressive cells.

Methods and Data. Expression of 8 highest expressed club cells secretory factors (CC10, SP-A, SP-B, SP-D, Hp, Secretoglobin 3A1, 3A 2, and 1C 1) in combination with PD-1 blockade elicited significant tumor control and improved survival of NSCLC mice. Mechanistically, the 8 club cell factors inhibit myeloid suppressor cell phenotypes as determined by reduced pSTAT3, pERK and concomitant inhibition of immunosuppressive mediators Arg1, iNOS, etc. Further screening of individual club cell factors showed that CC10 alone effectively blunted myeloid suppression activity as determined by flow cytometry for Arg1 and iNOS. Hence, CC10 can functionally alter the immunosuppressive nature of myeloid suppressor

cells. The ability of CC10 in improving the efficacy of ICI in impairing tumor growth and improving survival is currently being examined.
Conclusions. Myeloid suppressor cells inhibit immune cells like T cells or NK cells leading to poor prognosis in cancer treatment. Increase in their numbers has been linked to tumor aggressiveness and low efficacy of immunotherapy. Hence, there is an unmet clinical need to specifically target these cells. Agents targeting myeloid suppressor cell accumulation and differentiation (e.g., ATRA, Vitamin D, Sunitinib, Gemcitabine, Bevacizumab, Tadalafil), are being tested in human clinical trials. However, these agents lack specificity and selectivity for myeloid suppressor cells *in vivo*. Therefore, our work provides the rationale for the development of CC10 as selective inhibitor of myeloid suppressor cells and has the potential for achieving a robust and durable anti-tumor immunity in NSCLC.

GlycoConnect™ immune cell engagers (GC™-ICEs). A non-genetic approach to targeted IL-15 immunotherapy
Remon van Geel, Floris van Delft. *Synaffix BV, Oss, Netherlands*

Engagement of T cell or NK cells to harness a patient's immune system is a promising approach in immuno-oncology. An immunocytokine, *i.e.* a tumor-targeting antibody (fragment) genetically fused to an immunostimulatory cytokine, is specifically designed for this purpose. Fusion antibody-IL-15 immunocytokines, based on a variety of molecular architectures, are currently finding their way to the clinic with promising results.
Here we demonstrate how GlycoConnect™, a site-specific conjugation technology anchoring on the native antibody glycan, can be applied for attachment of IL-15 without prior antibody engineering. Moreover, the immunostimulatory activity of these GlycoConnect™ immune cell engagers (GC™-ICEs) can be modulated by tailoring linker design and payload stoichiometry. In particular, we demonstrate how a protease-cleavable mAb-IL-15 conjugate can be used to prevent systemic activation of the immune system, leading to a significantly improved therapeutic index in rodent models. In vitro and in vivo studies will be presented to showcase

the biological activity of these GC™-ICEs in comparison to conventional immunocytokines obtained via genetic engineering.

Removal of soluble TNF receptors as a novel form of immunotherapy for patients with advanced solid tumors

Piotr J. Wysocki[1], Piotr Tomczak[2], Tomasz Jankowski[3], Tomasz Nowikiewicz[4], Gal Markel[5], Ronnie Shapira[5], Gokhan Demir[6], Mustafa Bozkurt[6], Sameera Bilgrami[7], Annette Marleau[7], Adam Ostrowski[8], Lawrence Florin[9], Victoria Manax[10], Robert Segal[11]. *[1]Szpital Uniwersytecki w Krakowie Oddzial Kliniczny Onkologii, Krakow, Poland,[2]Centrum Medyczne Pratia Poznan, Skorzewo, Poland,[3]Samodzielny Publiczny Szpital Kliniczny nr 4 w Lublinie Klinika Pneumonologii, Onkologii i Alergologii, Lublin, Poland,[4]Centrum Medyczne INTERCOR Sp. z o.o., Bydgoszcz, Poland,[5]Sheba Medical Center, Tel Hashomer, Israel,[6]Acibadem Universitesi Klinik Arastirmalar Etik Kurul, Kayisdagi Caddesi, Kayisdagi Caddesi, Turkey,[7]Research and Development, Immunicom, Inc., San Diego, CA,[8]Clinical Operations, Immunicom, Inc., Krakow, Poland,[9]Clinical Operations, Immunicom, Inc., Philadelphia, PA,[10]Medical Affairs, Immunicom, Inc., Houston, TX,[11]Medical Affairs, Immunicom, Inc., Philadelphia, PA*

Immunicom, Inc. has developed a novel subtractive immunotherapeutic apheresis method (Immunopheresis®) to selectively remove soluble tumor necrosis factor receptors, sTNF-R1 and sTNF-R2 (sTNF-Rs) generated by tumors. sTNF-Rs block the tumoricidal activities, hence their removal restores the anticancer immunotherapeutic activity of native TNF-α. Past use of systemic administration of TNF-α to treat solid tumors resulted in unacceptable toxicities. Immunicom's LW-02 Column contains a bead matrix covalently bonded to a single-chain, TNF-α capture ligand (scTNF) with high affinity and selectivity to remove sTNF-Rs from plasma. Three clinical trials (NCT04004910, NCT04142931, NCT04690686) have been conducted in patients with various advanced-stage breast cancers (BC), melanoma (M), renal cell carcinoma (RCC) and non-small cell lung cancers (NSCLC). Patients were assigned to receive LW-02 Column Immunopheresis® monotherapy or combined with various chemo- or

immunotherapies. Immunopheresis® was administered 3x/week for each trial's 12 or 16-week Primary Treatment period with each procedure processing 2 plasma volumes (2PV). Patients with (at least) clinical stability and/or tumor responses could receive additional treatment. Compared to healthy persons, patients in all 3 trials were noted as having significantly elevated baseline blood concentrations of sTNF-R1 and sTNF-R2. For instance, sTNF-R1 plasma levels were 3.5 ng/mL, 3.5 ng/mL, 2.2 ng/mL and 2.1 ng/mL for BC, M, RCC and NSCLC, respectively, which were 5-8-fold higher than normal values. Likewise, sTNF-R2 plasma concentrations (which can be 4-fold, or more, greater than sTNF-R1) were 4-9-fold higher for BC (16.5 ng/mL), M (19.1), RCC (22.7) or NSCLC (11.1 ng/mL) than normal values. Through the data cutoff, >1,600 LW-02 Column Immunopheresis® procedures were performed. On average, 95% of sTNF-R1 and 80% of sTNF-R2 are removed from plasma at the 30-minute procedure timepoint. At the 2PV timepoint, overall mean reductions of sTNF-R1 and sTNF-R2 in whole blood were 51 and 52%. Further, minimal leaching (mean of 113 ng per procedure), of the scTNF capture ligand was detected, a quantity that is insufficient to cause any meaningful clinical effects. *In vitro* testing determined that the LW-02 Column has no discernable evidence of unintended or "off-target" removal of other cytokines or blood constituents or any non-specific binding. Moreover, the trial results demonstrate Immunopheresis® is safe with minimal side effects determined to be related to treatment with the column. Results from 3 trials indicate that cancer patients with advanced solid tumors present with significantly upregulated levels of immune inhibitory sTNF-Rs. LW-02 Column Immunopheresis® can safely and selectively remove sTNF-Rs thus allowing endogenous TNF-α to instigate its multiple anticancer pathways.

Cucurbitacin B: A promising drug candidate for targeting tumor immunosuppressive cells

Emmanuel B. Anning[1], Mudassier Ahmad[2], Sahir Alvi[2], Carlos Parez[3], Mehdi Chaib[4], Divyam Bansal[2], Dae Kim[5], Subhash Chauhan[6], Taha Merghoub[7], Bilal Hafeez[2]. *[1]Graduate School of Biomedical Sciences, Baylor School of Medicine, Houston, TX,[2]Immunology and Microbiology, University of Texas Rio Grande Valley, Edinburg, TX,[3]Graduate School of Biomedical Sciences, University of Texas Rio Grande Valley, Edinburg,*

TX,[4]Graduate School of Biomedical Sciences, MD Anderson Cancer Center, Houston, TX,[5]Immunology and Microbiology, University of Texas Rio Grande Valley, Houston, TX,[6]Immunology and Microbiology, University of Texas Rio Grande Valley, McAllen, TX,[7]Memorial Sloan Kettering Cancer Center, New York, NY

Immunotherapy has emerged as a major breakthrough in cancer treatment. However, it showed only a marginal response in pancreatic and liver cancers. Thus, novel strategies are highly desirable to take full advantage of immunotherapy in the treatment of these cancers. One of the critical factors that influence the efficacy of immunotherapy is the increased infiltration of myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAM) into tumors that alter the immune landscape and serve as facilitators of tumor proliferation, metastatic growth, and immunotherapy resistance. Thus, we believe that selecting a potent molecule that has the ability to suppress the function or revert the phenotypes of TAM and MDSCs will have a more significant impact in enhancing tumor immunotherapy response. Cucurbitacin B (Cuc B) is a potent inhibitor of Stat3, CSF-1R, and PI3Kγ and has shown its chemopreventive and therapeutic effects against various cancers but is limitedly explored for its application in modulating tumor immune response. In this study, we investigated the molecular effects and underlying molecular mechanisms of Cuc B on TAM and MDSCs. Cuc B significantly ($P<0.01$) decreased the expression of M2 markers (Arginase I, YM1 FIZZ1, PPARγ and TGFβ in M2 polarized BMDMs and increased M1 markers (NOS2, IL-6, and CD11C) compared to IL-4 alone treatment group**.** It has been demonstrated that TAMs secrete PDL-1 which neutralizes the function of T-cells. Cuc B treatment significantly ($P<0.001$) decreased PDL-1 expression in IL-4-treated RAW264.7 cells. Surprisingly, we observed that Cuc B treatment abolished the protein levels of PI3Kγ in IL-4 treated macrophages as determined by confocal microscopy and Western blot analysis. Cuc B treatment of bone marrow-derived MDSCs significantly ($P<0.01$) decreased the expression of Arginase-1, IL-10, PDL-1, and Stat3. We observed that IL-4-treated BMDMs inhibited phagocytic capacity which was significantly restored upon Cuc B treatment. We observed that Cuc B is a more potent molecule than a pharmacological inhibitor of PI3Kγ (IPI-549) in suppressing key signaling components of TAM and MDSCs. We are

performing *in vivo* study to investigate Cuc B potential to enhance checkpoint blockade immunotherapy response in clinically relevant mouse models of cancer. These results suggest that Cuc B is a novel therapeutic agent which has the potential to suppress or revert TAMs and MDSCs phenotypes. Cuc B may be used as an adjuvant drug molecule in combination with PD1 or CTLA-4 antibodies for improving immunotherapy response against less responsive tumors.

'Free' ISG15 acts as an immunoadjuvant to enhance $CD8^+$ T cell-mediated anti-tumor immunity

Mariam Oladejo, Laurence Wood. *Immunotherapeutics and Biotechnology, Texas Tech University Health Sciences Center, Abilene, TX*

Interferon-stimulated gene 15 (ISG15) is a ubiquitin-like molecule that is primarily involved in antiviral responses. ISG15 can either exist in the conjugated form, where it is covalently bound to proteins in a process termed ISGylation or can be released extracellularly in the cytokine-like "free" form. Although conjugated ISG15 often indicates poor prognosis in cancers, 'free' ISG15 is suggested to have immunostimulatory properties, owing to its ability to stimulate the production of IFN-gamma from lymphocytes and natural killer (NK) cells. While the immunomodulatory properties of free ISG15 are known, its ability to improve the antigen-specific T-cell response mediated by tumor immunotherapies has not been fully elucidated. The need for $CD8^+$ T cell-based immunoadjuvant in cancer immunotherapy is underscored by the current failure in the generation of optimum $CD8^+$ T cell response by the multitude of cancer vaccines in clinical trials. In this study, we demonstrated that ISG15 is vital for the generation of antigen-specific adaptive immunity; we showed that ISG15 deficient (ISG15-/-) mice do not develop effective systemic $CD8^+$ T cell response after ovalbumin protein vaccination in non-tumor bearing mice. Upon tumor challenge of ISG15-/- mice and wild type C57/BL6 mice with B16-OVA melanoma tumors, effective OVA-specific $CD8^+$ T cell-mediated anti-tumor immunity was not elicited, and the tumors progressed at a faster rate in the ISG15-/- mice. We then utilized a clinically relevant model to evaluate the therapeutic benefits of 'free' ISG15. We used a synergistic therapeutic approach that involved the concomitant administration of a

DNA-construct encoding ‘free’ ISG15(mutISG15) and a *Listeria-monocytogenes*(Lm)-based cancer vaccine directed against the tumor vasculature (Lm-LLO-CD105A) to intervene in murine models of renal cell carcinoma (Renca) and breast cancer (4T1-Luc). The combination of Lm-LLO-CD105A and mutISG15 led to a significant reduction in tumor burden in both syngeneic models. This tumor control was mediated by the expansion of a population of highly polyfunctional $CD8^+$ T cells in the combinatorial therapy group. These $CD8^+$ T cells were characterized by the robust production of multiple cytokines, including IFN-gamma, IL-2, and TNF-alpha.Moreover, we confirmed that mutISG15 significantly increased the antigen (CD105)-specific anti-tumor response generated by Lm-LLO-CD105A. Not surprisingly, *in-vitro* studies demonstrated that mutISG15 probably potentiates the induction of maturation, activation, and antigen-presentation of dendritic cells to facilitate the activation and effective functionality of tumor-specific T cells. Conclusively, our results positions ‘free’ ISG15 as a powerful T-cell stimulant that may provide a suitable therapeutic option for improving the effectiveness of therapeutic cancer vaccines.

Sacituzumab-Interferon beta mutein fusion protein, ABN202 (anti Trop2-interferon beta mutein), is a potent therapeutics for Trop-2-positive urothelial cancer

Jiyang Lee[1], Myeung-Ryun Seo[1], Heegeon Park[2], YeongMun Kim[1], Saehyung Lee[2], Na Young Kim[2], Chan Gyu Lee[3], Hae Min Jeong[3], Jun Young Choi[2], Young kee Shin[1]. *[1]Seoul National University, Seoul, Korea, Republic of,[2]ABION INC., Seoul, Korea, Republic of,[3]Genopharm Inc., Seoul, Korea, Republic of*

Background : Trop2, trophoblast cell-surface antigen 2, is a type 1 transmembrane glycoprotein overexpressed in many solid tumors such as breast, lung, pancreatic, gastric, colon, urothelial cancer. Overexpression of Trop2 is associated with aggressive disease progression and poor prognosis. Recently, Trop2 targeting antibody-drug conjugate such as sacituzumab-govitecan (Trodelvy®) was approved for the treatment of triple-negative breast cancer and urothelial cancer (UC) patients. Interferon-beta (IFN-beta), a pleiotropic cytokine, can induce direct/in-direct tumor killing and

activate anti-tumor immune response in tumor microenvironments. However, it is challenging to develop IFN-beta as an anti-cancer agent due to its low biophysical properties, short half-life, and the systemic toxicity. Previously, we developed IFN-beta mutein (ABN102), which showed improved stability and biophysical properties compared to wild-type IFN-beta. We hypothesis to reduce any toxicity of ABN102 by fusing with tumor targeting antibody. In this study, we generated antibody cytokine fusion protein (ABN202), anti Trop2-interferon-beta mutein, and evaluated the efficacy of ABN202 against Trop2-positive UC cell line models. Method & Result : We aimed to determine the direct anti-cancer efficacy of ABN202 using Trop2-positive UC cell lines and the indirect immune cell mediated effect of ABN202 using Trop2-positive UC cell lines co-cultured with human peripheral blood mononuclear cell (PBMC). The in vivo efficacy of ABN202 was further confirmed in Trop2 positive tumor mouse model. Our results revealed that ABN202 directly inhibited proliferation and activates the apoptosis-related signaling mechanisms via Type 1 IFN signaling, showing better efficacy than either anti Trop2 antibody (sacituzumab) or ABN102 alone. ABN202 induces the activation of PBMC subsets and enhanced immune cell-mediated cancer cell killing when UC cell lines were co-cultured with PBMC. The anti-cancer efficacy of ABN202 were confirmed in Trop2-positive tumor mouse model. Conclusion : We evaluated the direct and indirect anti-cancer efficacy of ABN202 (anti Trop2-interferon-beta mutein) in Trop2-positive urothelial cancer. Our results support that ABN202 is a potent drug candidate in Trop2-positive urothelial cancer by directly inhibiting tumor growth and activating anti-cancer immune responses through type 1 IFN signaling.

A highly differentiated A2AR inhibitor for potential use in cancer therapy

Chandregowda Venkateshappa, Kishore Narayanan, Rashmi Nair, Aravind AB, Ramakishore VP Putta, Jwala Nagaraj, Megha Goyal, Vijay Kamal Ahuja, Amith A Dhudashiya, Samiulla DS, Girish Daginakatte, Thomas Antony, Kavitha Nellore, Susanta Samajdar, Murali Ramachandra.
Aurigene Discovery Technologies Limited, Bangalore, India

As a potent immunosuppressor adenosine is essential for maintaining tissue homeostasis and preventing an overzealous immune response during inflammation and infection. However, adenosine generated within the tumor microenvironment by the action of ectonucleotides hinders the immune reaction towards cancer cells by signaling through adenosine receptors such as high affinity A2AR expressed on immune cells. Tumors evade the immune response by usurping pathways that negatively regulate normal immune responses. Resistance to inhibition of immune checkpoint targets arises because of an upregulation in the expression of the CD39-CD73 axis and the resulting increase in production of adenosine in the tumor microenvironment. Inhibition of either adenosine generation or signaling by inhibition of A2AR along with other immune activation strategies have been shown to be effective therapeutic approaches.
In view of this, we sought to discover and develop novel small molecule inhibitors that dually target A2AR and an immuno-suppressive ligand expressed in the tumor microenvironment. Aurigene's dual inhibitors exhibit potent inhibition of both A2AR and an immuno-suppressive target of relevance in respective biochemical assays. Potent biochemical activity translated into rescue of chemokines and IL-2 in human PBMCs. Lead compounds exhibited desirable drug-like properties and excellent pharmacokinetic exposure in rodents. In a syngeneic tumor model, lead compounds demonstrated significant tumor growth inhibition. Anti-tumor efficacy correlated well with tumor drug levels and modulation of pharmacodynamic markers. In summary, we have identified first-in-class dual inhibitors with good drug like properties, which showed significant antitumor efficacy. Evaluation of these lead compounds in additional tumor models and in vivo toxicity studies will be presented.

Galectin-3 synergizes with CD47 to suppress phagocytosis and T cell immunity in peritoneal metastases of gastric adenocarcinoma

Yibo Fan, Shumei Song, Yuan Li, Shilpa Dhar, Jiankang Jin, Xiaodao Yao, Ruiping Wang, Ailing Wang, Melissa Pool Pizzi, Jingjing Wu, Katsuhiro Yoshimura, Lang Ma, Samir Hanash, George Calin, Linghua Wang, Michael Curran, Jaffer Ajani. *UT MD Anderson Cancer Center, Houston, TX*

Peritoneal metastasis (PC), the common sites of gastric adenocarcinoma (GAC) metastasis, remains resistant to therapies available in the clinics and new target is strived to be found. CD47 is one of the major players in conveying the “don’t eat me” signal upon binding its receptor SIRPα on myeloid cells which evade innate immune responses. Previously clinical studies on the blockade of CD47 alone resulted in limited clinical benefits suggesting that other target(s) must be inhibited simultaneously with CD47 for gaining advantage. Here, we found that CD47 was highly expressed on peritoneal malignant cells and its overexpression was a poor prognosticator. Additionally, we observed that Galectin-3 (Gal-3) was highly enriched in tumor cluster and was positively correlated with CD47 expression in short survival of patients revealed by scRNA-seq and metastatic GAC samples. Moreover, we found double positive of Gal-3 and CD47 significantly associated with diffuse type, poor differentiation, and tumor relapse. Mechanistically, Depletion of Gal-3 in mouse tumor and human tumor cells reduced the levels of CD47 through inhibition c-Myc expression and its binding to the promoter of CD47. Additionally, tumor-derived Gal-3 were found critical for tumor progression accompanied with protected GAC cells from phagocytosis by macrophages. Gal-3 deficiency resulted in a marked reduction in M2 macrophages and elevated T cell effector activity. Dual blockade of Gal-3 and CD47 significantly decreased tumor growth by promoted phagocytosis, repolarization of macrophage and boosted T cell immune responses in the tumor microenvironment. Our data uncover that Gal-3 synergizes with CD47 to suppress phagocytosis and orchestrates immunosuppressed milieu in the tumor microenvironment warrants combination therapeutic strategy in GAC patients with peritoneal metastases.

#4434

A PD-1-targeted, receptor-masked IL-2 immunocytokine with maintained potential to engage endogenous IL-2Ra drives selective stimulation of PD-1^{+} T cells and robust anti-tumor efficacy

Jiaxi Wu, Nicolin Bloch, Aaron Chang, Ramandeep Bhavsar, Supriya Patel, Qingqing Wang, Hassan Shakil Ahmed, Vidur Garg, Michael Amatulli, Yuetian Yan, Shunhai Wang, Drew Dudgeon, Willy Ramos, Pamela Krueger, Ashique Rafique, Tammy Huang, Erica Ullman, Aynur Hermann,

William Olson, John Lin, Eric Smith, Tong Zhang. *Regeneron Pharmaceuticals, Inc., Tarrytown, NY*

Interleukin-2 (IL-2) is a key cytokine for T cell proliferation, differentiation, and effector function. Recombinant IL-2 has been used for the treatment of metastatic melanoma and renal cell carcinoma, and induced complete, durable tumor regression in some patients. However, its broader use in cancer immunotherapy has been limited by severe toxicity. A new generation of IL-2 therapies with decreased binding to IL-2 receptor α-chain (IL-2Rα) is being developed to reduce toxicity and Tregs expansion yet with limited clinical success so far. Here, we show that the ability to engage IL-2Rα is critical for maximal anti-tumor activity of a systemic IL-2 therapy, and an alternative approach to circumvent systemic toxicity is to deliver IL-2 specifically to tumor-reactive T cells. We developed REGN10597, a PD-1-targeted, receptor-masked IL-2 immunocytokine with attenuated systemic IL-2 activity but maintained capacity to engage endogenous IL-2Rα on PD-1^+ T cells. Compared to WT IL-2, receptor masked IL-2 shows improved PK and diminished systemic toxicity in mice. REGN10597 shows PD1-targeting-dependent IL-2 activity in vitro and drives selective expansion of tumor-infiltrating PD-1^+ CD8 T cells with vigorous effector functions in vivo. In preclinical syngeneic tumor models in PD-1 humanized mice, REGN10597 demonstrates robust anti-tumor efficacy both as a single agent and in combination with PD-1 or PD-L1 blocking antibodies. These findings highlight the therapeutic potential of REGN10597 as a novel targeted and receptor masked WT IL-2 therapy, supporting its clinical development for the treatment of cancer.

A causal modeling platform for testing lifestyle interventions on the microbiome and response to immunotherapy

Aaditya Pallerla[1], Bailey Conrad[2], Amna Bibi[2], Nyelia Williams[2], Caroline Wheeler[2], Rebecca Hoyd[2], Shankar Suman[2], Joseph Amann[2], Yangyang Liu[2], Marisa Bittoni[2], Shiqi Zhang[3], Madison Grogan[2], Alvin Anand[2], Najma Afrah[2], Carolyn Presley[2], Fred K. Tabung[2], Lang Li[4], Yael Vodovotz[5], Jiangjiang Zhu[3], David P. Carbone[2], Steven K. Clinton[2], Daniel Spakowicz[1]. *[1]Pelotonia Institute for Immuno-Oncology, The Ohio State*

University Comprehensive Cancer Center – James Cancer Hospital and Solove Research Institute, Columbus, OH,[2]Department of Internal Medicine, The Ohio State University College of Medicine, Columbus, OH,[3]Department of Human Sciences, The Ohio State University College of Education and Human Ecology, Columbus, OH,[4]Department of Biomedical Informatics, The Ohio State University College of Medicine, Columbus, OH,[5]Department of Food Science and Technology, The Ohio State University College of Food, Agriculture, and Environmental Sciences, Columbus, OH

Rational manipulation of the gut microbiome by diet or other interventions is a promising approach to improving the efficacy and safety of cancer immunotherapy. However, linking lifestyle variables to specific microbial populations and the host immune response to cancer therapies is challenging due to their complexity. We established an experimental system to examine such complexity by linking a human dietary intervention and fecal biospecimens to mouse models to test the response to immunotherapy. Longitudinal human microbiome samples collected before and after a specific dietary or other intervention allow us to test the hypothesis that an intervention alters the response to immunotherapy via impact on the host microbiome. One set of samples was taken from the BEWELL study, which examined the impact of 2 x 80 mL black raspberry (BRB) drink boxes per day for 4 weeks in people at high risk for lung cancer. Participant samples were chosen based on enrichment of specific taxa. Pre- and post-BRB intervention samples were gavaged into mice. Mouse mc38 cells were injected subcutaneously and treated with anti-PD1 Ab or isotype control. Tumor size was monitored, and at the end of the study, tumor immune cell composition data were collected. Tumor growth over time was modeled using a linear mixed-effects model with tumor volume as the outcome variable and the predictor variables of time and treatment (PD1 vs. IgG) interacting with gavage and quadratic time to accommodate non-linear tumor growth and including random effects by mouse. For sample 68, enriched for *Roseburia* CAG 309, the interaction between time, gavage post-BRB, and Anti-PD1 treatment significantly affected tumor volume ($p < 0.05$) relative control. The same significant effect ($p < 0.05$) was also seen for sample 79, enriched for *Lachnospira pectinoschiza*, and samples 84 and 85, enriched for *Blautia obeum*. To determine the mechanism by which this

might occur, we analyzed the tumor's immune cell composition. Post-BRB mice treated with Anti-PD1 showed a significant increase in tumor-infiltrating CD8+ immune cells relative control, as compared to mice gavaged with pre-BRB stool. Modeling results showed samples whose response was improved slightly after the BRB dietary intervention. These samples were associated with the enrichment of the taxon *Roseburia* CAG 309. A black-raspberry dietary intervention in humans modified the microbiomes of several participants in a way that is hypothesized to improve response to PD1 treatment. Future directions include supplementing individual microbes into pre-intervention gavages to confirm which taxa improve response. These results suggest that this modeling platform is an effective system for testing microbiome modification on tumor growth and assessing mechanisms by which this might occur and is extendable to other lifestyle-based interventions where pre- and post-intervention specimens are collected.

#4436

A novel antibody-enabled dual precision targeted protein stabilization (TPS^2) that augments anti-tumor immune response by targeting CBL-B inhibitor to exhausted T cells while blocking checkpoint molecule, PD-1

Joanne Lim[1], Anna Skaletskaya[1], Uttapol Permpoon[2], Yeonjoon Kim[2], Shikha Saini[1], Khuloud Takrouri[1], Zinaida Ribkovskaia[1], Palash Bhar[1], Nathan Fishkin[1], Dong-Ki Choi[2], Ji Hyun Park[2], James Palacino[1], Peter U. Park[1]. *[1]Orum Therapeutics, Cambridge, MA,[2]Orum Therapeutics, Daejeon, Korea, Republic of*

It is well-established that T cells play a key role in the success of cancer immunotherapies. The goals of T cell-targeting therapies have been to restore the effector function of tumor-specific T cells that are either dysfunctional due to the immunosuppressive mechanisms in the tumor microenvironment, the lack of co-stimulatory signals, or negative regulation by expression of checkpoint molecules such as PD-1. E3 ligase Casitas B-Lineage Lymphoma Proto-Oncogene B (CBL-B) has recently gained attention as a master regulator of multiple immune-activation mechanisms. Inhibition of CBL-B enables the activation of antigen-specific T cells, and has been shown in syngeneic mouse tumor models to be efficacious as a

cancer immunotherapy agent. CBL-B inhibition has also been shown to enhance and prolong the effects of anti-PD-1 antibody (Ab) therapy. However, genetic knockout of CBL-B in mice led to spontaneous autoimmunity characterized by auto-antibody production and infiltration of activated T cells and B cells into multiple organs that could result in tissue damage. In order to mitigate safety issues that could result from systemic CBL-B inhibition, we developed novel antibody-drug conjugates (ADCs) that target CBL-B inhibitors (CBL-Bi) to T cells via binding to PD-1. Using PD-1-expressing Jurkat NFAT reporter cells and mixed lymphocyte reaction assay, we demonstrated that our TPS^2 approach enhanced the activation of T cells *in vitro* compared to treatment with anti-PD-1 Ab alone. Evaluation of pathways downstream of TCR activation in primary exhausted T cells showed increased Notch1, phospho-PLCγ2, and ZAP-70 accumulation following anti-PD-1/CBL-Bi treatment and is correlated with IFNγ induction. When autologous mature dendritic cells were co-cultured with dissociated tumor cells from melanoma patients, the highest magnitude of tumor-infiltrating lymphocyte activation was observed using delivery of CBL-Bi by anti-PD-1 ADC, compared to CBL-Bi alone, anti-PD-1 Ab alone, or combination treatment. The potential of anti-PD-1/CBL-Bi ADC for activation effector T cell function is also evident by increased intratumoral transcript levels of Granzyme B and Perforin following treatment in a humanized mouse model. In conclusion, we validated that the biological activity of CBL-Bi is retained after conjugation with an anti-PD-1 antibody. The use of anti-PD-1 Ab for developing the ADC not only targets the CBL-Bi payload to exhausted T cells but also blocks negative regulation of T cells via PD-1. Together, anti-PD-1/CBL-Bi ADC enhanced T cell activation *in vitro* as well as *in vivo*. Evaluation of safety and efficacy in animal tumor models is ongoing, to support further development of the TPS^2 approach.

BXQ-350: A novel biologic with an innovative mechanism of action targeting sphingolipid metabolism that induces cancer cell death and repolarizes the tumor microenvironment

Gilles H. Tapolsky, Tim Stephens, Nikhil Wilkins, Robin Furnish, Charlie Cruze, Ray Takigiku. *Bexion Pharmaceuticals, Inc, Covington, KY*

Background: Antineoplastic agents seem to affect tumors by targeting cancer cells via cytotoxic mechanism (traditional cytotoxic agents), an oncogenic pathway that promotes cancer cells proliferation (targeted agents), or immune pathways that are dysregulated in the tumor microenvironment (immune checkpoint inhibitors -ICI-). Clinical results have demonstrated that ICIs led to significant clinical benefits and durable responses in patients that previously had no or limited therapeutic options. Clinical results also demonstrated that combining ICIs or ICI with cytotoxic / targeted agents improved response rate and duration of response. BXQ-350 is a novel biologic simultaneously leading to cancer cells death and rebalancing the tumor microenvironment by targeting sphingolipid metabolism that is dysregulated in cancer cells. Sphingosine-1-phosphate (S1P) is a signaling metabolite known to promote cancer cell survival and proliferation and to favor an immunosuppressor environment; ceramide is a metabolite known to induce cancer cell apoptosis, mitophagy or necrosis and to favor an immunoeffector environment.
Methods: BXQ-350 was investigated preclinically in different *in vitro* and *in vivo* models and clinically in a first-in-human Phase 1 safety and dose escalation study in cancer patients with recurrent advanced solid tumors.
Results: Preclinical results demonstrated that BXQ-350 targets sphingolipid metabolism, decreases S1P levels while it simultaneously increases ceramide levels, leading to cancer cells death across multiple cancer cell lines. By impacting S1P and ceramide, BXQ-350 is additive or synergistic with different classes of antineoplastic agents. In addition, *ex vivo* experiments demonstrated BXQ-350 modulates many of immune-effector / suppressor cells as it repolarizes macrophages towards the antitumoral M1 phenotype, inhibits differentiation and activity of immunosuppressor of MDSCs, and promotes the proliferation of CD4+ and CD8+ Tcells as well as their activity. Clinical results revealed that BXQ-350 was well tolerated in cancer patients and showed signs of single agent activity. Analyses of biomarker samples showed that in patients experiencing a clinical benefit, systemic S1P plasma levels decreased significantly, and ceramide levels increased. Analysis of circulating cytokines revealed that BXQ-350 seemed to induce an increase of antitumoral cytokines (IFNg, TNFa, IL-2) and a decrease in protumoral ones (IL-6, IL-8, IL-10).
Conclusions: Preclinical and clinical results demonstrated that BXQ-350 modulates sphingolipid metabolism leading to cancer cell death and

stimulating the tumor microenvironment. Additional studies are ongoing to further understand BXQ-350's MOA.

#4438

Bypassing immune evasion in colorectal cancer by integrin inhibition-mediated downregulation of PD-L1

William J. MacDonald, Brooke Verschleiser, Lindsey Carlsen, Kelsey E. Huntington, Wafik S. El-Deiry. *Legorreta Cancer Center at Brown University, Providence, RI*

Integrin receptors have long posed a potentially attractive target for disrupting cancer hallmarks. Promising preliminary findings with integrin inhibition as an adjuvant to chemotherapy have not translated to clinical success. However, the effect of integrin inhibition on tumor-immune cell interactions remains largely unexplored. Further investigation could shed light on a connection between integrin signaling and immune checkpoint expression, opening the path for using integrin inhibitors to sensitize otherwise resistant tumors to immunotherapy. Fluorescently labeled wild-type HCT-116 colorectal cancer cells and TALL-104 T-cells were co-cultured and treated with GLPG0187, a small molecule integrin inhibitor, at various doses. Co-cultures were observed at different time points using fluorescence microscopy and cell counts were quantified using ImageJ software. The co-culture included the cell viability marker ethidium homodimer so the number of viable cells of each type could be determined using colocalization. This assay revealed synergistic cancer cell killing, indicating that integrin inhibition may be sensitizing cancer cells to immune cells. The hypothesized mechanism involves TGF-beta-mediated PD-L1 expression in cancer cells. GLPG0187 has been shown to inhibit the αvβ6 integrin receptor, which is responsible for the activation of latent-TGFβ into the active form. By blocking this receptor, there would potentially be a reduction of TGFβ signaling and therefore a reduced expression of PD-L1 leading to an enhanced immune response. To investigate this mechanism, both WT and p53-/- HCT-116 cells were pre-treated with GLPG0187 and subsequently with latent-TGFβ. Western blot analysis demonstrated that the addition of latent-TGFβ increased the expression of PD-L1 in cancer cells. Additionally, a low dose of integrin inhibitor rescued these effects, returning PD-L1 expression back to control levels. However, the higher

dose of the drug did not reduce PD-L1 expression. This could potentially be due to off-target effects conflicting with the proposed pathway, however, these findings are still under active investigation. Ongoing proteomic experiments include a larger range of both drug and latent-TGFβ doses. Probing for additional downstream markers of TGFβ and up-stream markers of PD-L1 will help to further elucidate the mechanism. Further co-culture experiments include anti-PD-L1 and anti-PD-1 therapy to investigate the viability of integrin inhibition as an adjuvant to immune checkpoint blockade.

Negative impact of the GABA pathway on aPD(L)1 immunotherapy

Svetlana Lyalina[1], Guadalupe Ortiz-Munoz[1], Kobe Yuen[1], Ira Mellman[1], Sanjeev Mariathasan[1], Matthew Albert[2], Deepti Nagarkar[3], Christine Moussion[1]. *[1]Genentech, South San Francisco, CA,[2]HiBio, South San Francisco, CA,[3]Nagarkar (Individual), South San Francisco, CA*

Although gamma-amino butyric acid (GABA) is well characterized as the primary inhibitory neurotransmitter of the central nervous system, its role in the periphery as an immunomodulatory agent is not well understood. Given the widespread use of GABA-A receptor agonists as palliative care in clinical practice, we examined here the impact of GABA on response to immunotherapy in preclinical tumor models and the association of GABA-A receptor agonist usage with outcomes in patients receiving immunotherapy.We show that important genes controlling the GABA pathway are enriched in human tumors versus normal tissue across indications, and tumor cells themselves are able to produce GABA. We found that several key genes of the GABA pathway are upregulated in non-responders to atezolizumab and we derived a 5-gene signature associated with poor outcomes in 2L urothelial cancer patients receiving atezolizumab. Preclinical models further indicated that GABA at the tumor site promotes tumor growth and dampens adaptive immunity preventing response to immunotherapy. Finally, we noted that 45% of urothelial cancer patients received concomitant GABA-A positive allosteric modulators, given as palliative therapy in atezolizumab trials IMvigor-210 and -211. This group exhibited significantly lower OS and PFS as compared to atezolizumab treated patients who did not receive GABA-A positive modulators. A

similar negative impact was seen in patients receiving standard of care anti-PD(L)1 immunotherapy in 2L NSCLC using EHR derived deidentified Flatiron Health - Komodo Health claims linked data. These findings highlight the need for further evaluation of concomitant GABA modulators to understand potential risk associated with palliative care in the setting of cancer immunotherapy.

Efficacy of Gen-1, an interleukin-12 immune gene therapy, at different dose frequencies

Subeena Sood[1], Jean D. Boyer[2], Jessica Kim[2], Majed M. Matar[2], Olivia Signer[2], Jennifer S. Rice[2], Alanna M. Smith[2], Nicholas Borys[2], Khursheed Anwer[2]. *[1]Research and Development, Imunon Inc, Lawrenceville, NJ,[2]Imunon Inc, Lawrenceville, NJ*

Introduction: The purpose of this study was to investigate the effect of dosing frequency on the antitumor activity of intraperitoneal GEN-1, an interleukin-12 (IL-12) immune gene therapy in a mouse model of peritoneally disseminated ovarian cancer.
Procedures: Three GEN-1 dosing regimens were examined for efficacy in ID-8 tumor-bearing mice: weekly, every 2 weeks and every 3 weeks. 2.5 million cancer cells were bolus injected into 4 groups (B, C, and D) of 10 mice each. A control group (A) of 6 mice had PBS injected IP without tumor and an untreated control (E) of 15 mice were injected with 2.5 million cancer cells. Groups B, C, and D were injected with GEN-1 IP weekly, every 2 weeks, and every 3 weeks respectively. Six animals from each group B, C, and D were harvested for translational research (TR) after 5 weekly, 3 every 2-week and 2 every 3-week treatments respectively. The remaining 4 animals in each group were followed for weight change (tumor burden) and survival. Additionally, TR evaluated change in ascites T-cell, B-cell and myeloid cell populations.
Results: There was a gradual rise in tumor burden and mortality in all treatment groups with comparable rate between once every week and once every 2-week regimens. Once every 3-week regimen had relatively higher

mortality rate and higher tumor burden. There were similar or higher increases in T-cell and B-cells with reduced treatment frequency with lesser increases in myeloid cell density with reduced treatment frequency. Conclusions: Once every 2-week dosing of GEN-1 in human studies is warranted. Future combination studies of Gen-1 with immune checkpoint inhibitors will evaluate the safety and efficacy of this regimen.

Bifunctional immunotherapeutic HCW9218 facilitates recruitment of immune cells from tumor draining lymph nodes to promote antitumor activity and enhance checkpoint blockade efficacy in solid tumors

Varghese George, Pallavi Chaturvedi, Niraj Shrestha, Leah Kanakraj, Crystal Gilkes, Nicole Encalada, Meng Wang, Xiaoyun Zhu, Bai Liu, Peter Rhode, Hing C. Wong. *HCW Biologics, Inc., Miramar, FL*

Immunotherapeutics that aid in boosting natural immune defenses against cancers have revolutionized cancer treatment. Previously, we reported a novel heterodimeric bifunctional fusion molecule, HCW9218, designed using soluble tissue factor (TF)-based scaffold technology comprising extracellular domains of the human transforming growth factor-β (TGF-β) receptor II and a human interleukin (IL)-15/IL-15 receptor α complex which exhibited both immune cell stimulatory and TGF-β neutralizing properties. Herein, we showed in two different syngeneic murine tumor models (B16F10, 4T1) that subcutaneous treatment with HCW9218 induces a proliferative burst of $CD8^+$ T cells and NK cells in blood and a subsequent infiltration of these cells into established tumors. In vivo imaging of 4T1 tumor-bearing mice after treatment showed that HCW9218 was present both in lymph nodes and established tumors up to 24hr following treatment. Comprehensive analysis of tumor infiltrating lymphocytes (TILs) showed that HCW9218 mediated antitumor activity by expanding TCF^+TIM3^- 'progenitor exhausted' (Tpex) $CD8^+$ T cells in tumors. Sphingosine-1-phosphate receptor blockade resulted in decreased tumor infiltration of $CD8^+$ Tpex in B16F10 and 4T1 tumor-bearing mice indicating that these cells originate from tumor draining lymph nodes (TdLN). Increased 'terminally exhausted' $TCF\text{-}1^-TIM3^+$ (Tex) $CD8^+$ TILs were also observed in tumors of HCW9218-treated mice indicating increased antitumor activity. Tumor transplantation experiments further

confirmed the mechanism of HCW9218 antitumor activity by increasing influx of CD45.1$^+$ CD8$^+$ T cells into transplanted tumors from CD45.2$^+$ mice. Additionally, HCW9218 enhanced the therapeutic efficacy of PD-L1 treatment by increasing the infiltration of activated/memory CD8$^+$ T cells into B16F10 tumors in mice leading to significant reduction in tumor volume. Collectively, the results of this study
demonstrated that HCW9218 treatment of mice bearing solid tumors resulted in modulating the TdLN immune landscape and invigorating T cells for enhanced checkpoint blockade therapy. HCW9218 are currently in two clinical trials (clinicaltrials.org: NCT05322408, NCT05304936) against chemo-resistant/refractory solid tumors.

Dual benefit of MALT1 blockade in glioblastoma

Juliana Hofstatter Azambuja[1], Saigopalakrishna S. Yerneni[2], Gabriela N. Debom[1], Lisa M. Maurer[1], Hannah E. Butterfield[1], Linda R. Klei[1], Gary Kohanbash[1], Peter C. Lucas[1], Linda M. McAllister-Lucas[1]. *[1]University of Pittsburgh, Pittsburgh, PA,[2]Carnegie Mellon University, Pittsburgh, PA*

Background**:** Glioblastoma multiforme (GBM) is the most common and aggressive malignant primary brain tumor. Despite advances in treatment modalities, GBM remains largely incurable and new treatment approaches are desperately needed. An innovative strategy for cancer therapy is to combine the inhibition of cancer cell-intrinsic oncogenic signaling with cancer cell-extrinsic immunological activation of the tumor microenvironment (TME). MALT1 represents a candidate target whose inhibition may provide this dual benefit. Originally identified as a proto-oncoprotein in lymphoma, MALT1 has recently also been implicated in multiple solid tumors, including GBM, and significant effort has been made to develop MALT1 protease inhibitors as anti-cancer agents. Interestingly, blockade of MALT1 protease has also been shown to selectively reprogram tumor infiltrating Treg cells into antitumor effector cells. Based on these observations, we hypothesized that in GBM, MALT1 acts both within tumor cells and within cells of the TME to promote tumorigenesis and MALT1 inhibitor treatment could thus have dual benefit.
Methods/Results: We assembled a panel of mouse and human GBM cell lines and performed western-blot analysis to show that these cells

demonstrate constitutive MALT1 expression and proteolytic activity. MALT1 blockade in GBM cells, using siRNA or MALT1 protease inhibitors, reduces viability and clonogenic potential, suggesting that inhibition of MALT1 could impair tumor cell survival. Single-cell RNAseq data from public datasets demonstrated that myeloid cells have the highest MALT1 expression in the GBM TME. Our data indicate that co-culture of macrophages with GBM cells induces MALT1-NF-κB activation within the macrophages and this is associated with polarization towards an M2-like immunosuppressive phenotype. Additionally, treating primary human or mouse macrophages with MALT1-protease inhibitor prevents GBM-induced M2-polarization, increases M1-polarization and enhances GBM cell killing. In a syngeneic orthotopic mouse model, GBM tumor growth is impaired, and survival is extended when tumor cells are implanted into MALT1-protease dead (PD) host mice (mice which harbor a point mutation in the MALT1-protease catalytic cysteine) as compared to when implanted into wild-type host mice. MALT1-PD mice demonstrate a less immunosuppressive GBM TME with increased M1-macrophages and decreased M2-macrophages, MDSCs and Tregs. Taken together, our findings suggest that inhibiting MALT1 protease in TME cells promotes anti-tumor immunity against brain tumors.
Conclusions: Our studies suggest MALT1 protease as a new therapeutic target in GBM whose inhibition could have dual benefit via both direct effect on tumor cells and by reversing the immunosuppressive TME.

Targeting PI3K isoforms to improve the effectiveness of T cell mediated immunotherapy

Ritu Bohat[1], Xiaofang Liang[1], Chunyu Xu[1], Yitao Tang[2], Jiakai Hou[1], Nicholas A. Egan[1], Leilei Shi[3], Ashley Guerrero[1], Roshni Jaffery[1], Elizabeth M. Burton[4], Han Liang[5], Hussein Tawbi[2], Michael A. Davies[2], Weiyi Peng[1]. *[1]Biology and Biochemistry, University of Houston, Houston, TX,[2]Department of Melanoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Epigenetics and Molecular Carcinogenesis, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[5]Bioinformatics and Computational*

Biology, Systems Biology, The University of Texas MD Anderson Cancer Center, Houston, TX

Hyperactivation of the PI3K pathway has been reported to correlate with resistance to immune checkpoint blockade therapy (ICB) in melanoma, highlighting the therapeutic potential of combining PI3K inhibition (PI3Ki) with ICB. To maximize the clinical benefit of PI3Ki-based immune oncology (IO) combination, we characterized the role of PI3K isoforms in tumor and T cells and determined the immunological impacts of PI3Ki alone or in combination with ICB. Inhibitions of PI3K were achieved by either genetic knockdown (KD) or the bioactive compound in PTEN-present (B16/MC38), PTEN-absent (BP/D4M) tumor cell lines, and CD8+ T cells (Pmel-1). Following PI3Ki, we determined the activation status of the PI3K pathway (p-AKT level), transcriptional profile, and cellular function of these cells. We found both *in vitro* KD and pharmacological inhibition of either PI3Kα or PI3Kβ displayed a dramatic reduction of the PI3K pathway in tumor cells but moderate or no reduction in T cells, whereas the PI3K pathway significantly decreased in T cells with PI3Kγ or PI3Kδ inhibition. KD of PI3Kα or β isoforms drastically sensitized both D4M and MC38 tumors to αPD1 *in vivo*. We also observed that only PI3Kγ or PI3Kδ inhibition profoundly suppressed cytokine production and cytotoxicity of CD8+ T cell, suggesting that PI3Kα or PI3Kβ isoform inhibition can achieve tumor specific PI3Ki with limited impacts on T cell function. Furthermore, we used multiple syngeneic melanoma models to determine whether PI3K isoform inhibition can synergize the antitumor activity of ICB *in vivo*. In PTEN-present tumors, BYL719 (BYL, a PI3Kα inhibitor) synergized with αPD1 to delay tumor growth and extend survival (median survival of MC38-bearing mice in control (Ctrl), BYL, αPD1, and combination (Comb) groups: 30, 36, 33, and >45 respectively; $p<0.05$: Ctrl/BYL/αPD1 vs Comb). However, a limited combinatorial effect between GSK2636771(a PI3Kβ inhibitor) and αPD1 was observed in PTEN-present tumor models. Moreover, the combination of BYL and αPD1 exhibits superior antitumor activity in a spontaneous Braf-mutant, PTEN-loss melanoma model when compared with either reagent. Mechanistically, the combination of BYL and αPD1 improved CD8+ T cells tumor infiltration (14 days treatment, mean CD8+ number/mg of the tumor, Ctrl:1392.9, BYL:2073.9, αPD1:1545.2, Comb:4691.8; $p<0.01$: Ctrl/BYL/

αPD1 vs Comb) and reduced MDSCs in MC38 tumors ($p<0.05$: Ctrl vs Comb). Multi-omics profiling of tumor cells with *in vitro* and in *vivo* PI3K isoform inhibition is ongoing. Collectively, our results demonstrate that PI3Kα inhibitor can potentiate T cell-mediated antitumor immune responses regardless of PTEN status, providing a strong rationale for the clinical development of the BYL-based IO combination. In collaboration with Novartis, MD Anderson Cancer Center will launch a Phase I/II trial of the FDA-approved BYL in combination with αPD1 in advanced melanoma and breast cancer patients.

Increasing the Clinical Utility of Cell-Free DNA Testing

Whole genome error-corrected sequencing for sensitive circulating tumor DNA cancer monitoring

Alexandre P. Cheng[1], Adam J. Widman[2], Anushri Arora[3], Itai Rusinek[4], William F. Hooper[1], Rebecca Murray[1], Daniel Halmos[1], Theophile Langanay[1], Giorgio Inghirami[1], Soren Germer[3], Melissa Marton[3], Adrienne Helland[3], Rob Furatero[3], Jaime McClintock[3], Lara Winterkorn[3], Zoe Steinsnyder[3], Yohyoh Wang[1], Srinivas Rajagopalan[1], Asrar I. Alimohamed[5], Murtaza S. Malbari[1], Ashish Saxena[1], Margaret K. Callahan[2], Dennie T. Frederick[6], Lavinia Spain[7], Ariel Jaimovich[4], Doron Lipson[4], Samra Turajlic[7], Michael C. Zody[3], Nasser K. Altorki[1], Jedd D. Wolchok[1], Michael A. Postow[2], Nicolas Robine[3], Genevieve Boland[6], Dan A. Landau[1]. *[1]Weill Cornell Medical College, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]New York Genome Center, New York, NY,[4]Ultima Genomics, Newark, CA,[5]Dana Farber Cancer Institute, Boston, MA,[6]Massachusetts General Hospital, Boston, MA,[7]The Francis Crick Institute, London, United Kingdom*

In many areas of oncology, we lack sensitive tumor-burden monitoring to guide critical decision making. While circulating tumor DNA (ctDNA) promises to enable disease monitoring, this approach is limited by the sparsity of ctDNA in the plasma. To overcome this challenge, error-corrected deep targeted sequencing has been proposed.

Nonetheless, this framework is limited by the low number of genomic equivalents (GEs, ~10^3 /mL of plasma), imposing a ceiling on effective sequencing depth. We have previously shown that genome-wide mutational integration through plasma whole genome sequencing (WGS) can sever the dependency between available GEs and assay sensitivity (Zviran *et al*, 2020). In this approach, tumor-informed mutational profiles are applied to plasma WGS, allowing detection of tumor fractions as low as 10^{-5}. However, the higher cost of WGS limits practical depth of coverage (20-30X) and may limit broad adoption. Lower costs may thus allow for enhanced ctDNA cancer monitoring via WGS. We therefore applied emerging lower-cost WGS (1USD/Gb, Almogy *et al*, 2022) to plasma from 7 patients with metastatic cancer at ~115x coverage depth. Read depth profiling and error rates were comparable between matched Ultima and standard platform datasets. Integration of deep learning architectures for signal to noise enrichment (Widman *et al*, biorxiv, 2022) with deeper WGS coverage enabled ctDNA detection at the parts per million range.
We reasoned that lower sequencing cost can be harnessed for duplex error-corrected WGS. Proof-of-concept experiments in mouse PDX samples showed ~1,500x decrease in errors. Applied to the plasma of stage IV melanoma patients (n=5), we obtained error rates ~10^{-7}. We used this approach to tackle the challenging context of cancer monitoring in early-stage melanoma without matched tumor sequencing. While in uncorrected WGS, *de novo* mutation calling yielded limited ability to detect melanoma specific mutations, duplex-corrected WGS allowed us to harness melanoma mutational signatures for disease monitoring without matched tumor profiling. Analytic validation of our assay showed sensitive and specific cancer detection when the concentration of ctDNA was at 10^{-4} concentrations. Applied to a cohort of stage III melanoma patients with negative ctDNA detection using previously described methods, we detected ctDNA in all cases (n=4), demonstrating enhanced sensitivity using duplex WGS. These data demonstrate the exciting potential of low cost WGS for ultra-sensitive ctDNA cancer monitoring. In the tumor-informed setting, deeper sequencing increased sensitivity for mutational profile detection. Moreover, the application of duplex error-correction at genome scale allowed for sensitive cancer monitoring without matched tumor profiles. We envision that the era of low-cost sequencing will empower ultra-

sensitive cancer monitoring via WGS, with transformative impact on cancer care.

Detection and monitoring of t(11;14) in liquid biopsies from patients with relapsed/refractory multiple myeloma treated with venetoclax-based regimens

Xiaotong Li[1], Lao H. Saal[2], Christian Brueffer[2], Yilun Chen[2], Johanna Asklin[2], Saman Alvi[1], Srinivas Venkatram[1], Jeremy A. Ross[1]. *[1]AbbVie Inc., North Chicago, IL,[2]SAGA Diagnostics, Lund, Sweden*

Venetoclax (Ven) is a selective B-cell lymphoma 2 inhibitor being studied in t(11;14)+ relapsed/refractory multiple myeloma (MM) Detection of t(11;14) in MM requires bone marrow (BM) aspiration and evaluation of CD138+ plasma cells by fluorescence in situ hybridization (FISH) Innovative techniques may provide less invasive detection of t(11;14) in liquid biopsies Here we present results of the SAGAsign® integrated approach combining low-coverage whole-genome sequencing (WGS) to characterize t(11;14) breakpoints together with personalized digital polymerase chain reaction (dPCR) assays to efficiently detect and monitor the genomic rearrangements in circulating tumor DNA (ctDNA) Baseline BM aspirates were collected from 270 patients (pts) from Ven clinical trials (NCT02755597, NCT01794520, NCT03314181, NCT02899052) Previously generated WGS to an average coverage ~22× was used Paired samples of peripheral blood mononuclear cell (PBMC) DNA and plasma circulating cell-free DNA (cfDNA) were analyzed by dPCR at timepoints after Ven-based treatment Of the 90 t(11;14)+ pts by FISH, 160 t(11;14) breakpoints were identified by WGS in 74 pts (concordance in Table) At the time of data cutoff, dPCR assays were designed and evaluated in 8 t(11;14)+ pts; 7/8 (88%) and 6/8 (75%) pts had detectable t(11;14) in cfDNA or PBMCs, respectively Higher levels of t(11;14) mutant allele frequency (MAF) were observed in cfDNA compared with PBMCs After Ven-based treatment, t(11;14) MAF in cfDNA became undetectable in pts with a complete response In conclusion, this approach has the capability to reconstruct t(11;14) breakpoints from WGS data that is highly concordant with FISH; translocations appear more readily detectable in cfDNA than PBMC samples from pts with MM SAGAsign assays detected and

monitored t(11;14) in liquid biopsies thus highlighting its potential utility for identifying pts with t(11;14) for targeted therapies

Concordance between WGS and FISH testing for t(11;14)

Blood-based early detection of non-small cell lung cancer using orphan noncoding RNAs

Mehran Karimzadeh, Jeffrey Wang, Aiden Sababi, Oluwadamilare I. Afolabi, Dung Ngoc Lam, Alice Huang, Diana R. Corti, Kristle C. Garcia, Seda Kilinc, Xuan Zhao, Jieyang Wang, Taylor B. Cavazos, Patrick Arensdorf, Kimberly H. Chau, Helen Li, Hani Goodarzi, Lisa Fish, Fereydoun Hormozdiari, Babak Alipanahi. *Exai Bio Inc., Palo Alto, CA*

Background: Orphan non-coding RNAs (oncRNAs) are a novel category of small non-coding RNAs that are present in the tumor tissue and blood of people with cancer and largely absent in people without cancer. To examine the potential of using oncRNAs for early cancer detection via liquid biopsy, we assessed the oncRNA content of serum from people with and without non-small cell lung cancer (NSCLC) and developed a prediction model for NSCLC.

Methods: A total of 540 serum samples were obtained from Indivumed (Hamburg, Germany) and MT Group (Los Angeles, CA) and divided into cohort A for training (150 NSCLC cases, 219 controls; female: 30.7%/36.1%; mean age: 67.9 ± 8.9/62.4 ± 9.2; ever-smoker: 95.3%/26.9%, respectively) and cohort B for internal validation (88 NSCLC cases, 83 controls; female: 40.9%/54.2%; mean age: 62.7 ± 9.2/54.1 ± 12.4; ever-

smoker: 89.8%/6.0%, respectively). We used RNA isolated from 0.5 mL of serum to generate and sequence libraries at an average depth of 18.5 ± 6.5 million 50-bp single-end reads using next-generation sequencing. Previously, we created a large catalog of NSCLC oncRNAs found in 999 NSCLC tumor tissues and largely absent in 679 normal samples from The Cancer Genome Atlas (TCGA) smRNA-seq database. This catalog was distilled by removing smRNA species found in the serum of an independent cohort of 31 non-cancer donors to yield a final NSCLC oncRNA catalog of 81,004 distinct oncRNA species. This distilled catalog was the reference for identifying NSCLC oncRNAs in the present study. Using oncRNA data we generated by sequencing samples from cohort A, we trained a logistic regression model for predicting NSCLC presence. The model was then validated in cohort B.
Results: From the 540 samples sequenced, we detected 64,379 oncRNAs from the distilled TCGA oncRNA catalog in at least one sample across both cohorts (A: 55,650, B: 47,539).Using 5-fold cross-validation, the AUC of the logistic regression model was 0.95 (95% CI: 0.93-0.97) for the training cohort, and was 0.98 (0.97-0.99) for the validation cohort. Sensitivities for detecting NSCLC at 95% specificity were 0.78 (0.69-0.86) for early stage (I/II) cancer and 0.75 (0.60-0.87) for late stage (III/IV) cancer in the training cohort, and 0.92 (0.83-0.98) and 1.0 (0.85-1.0), respectively, in the validation cohort.
Conclusion: These results demonstrate the potential for accurate, sensitive, and early detection of NSCLC through sequencing the oncRNA content of a routine blood draw. The performance of the model trained on one cohort and internally validated in a separate cohort supports the generalizability of this approach in detecting NSCLC.

Shames[1]. *[1]Genentech Inc., South San Francisco, CA,[2]Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN,[3]Hospital Universitario Insular de Gran Canaria, Las Palmas, Spain,[4]Yonsei Cancer Centre, Yonsei University College of Medicine, Seoul, CA,[5]Institut Bergonie CLCC Bordeaux, Bordeaux, France,[6]Clínica Universidad de Navarra, CIMA Universidad de Navarra Pamplona, Pamplona, Spain,[7]Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: TIGIT is a co-inhibitory receptor and immune checkpoint associated with T cell and natural killer (NK) cell dysfunction in cancer. Tiragolumab is an anti-TIGIT antibody with an active IgG1/kappa Fc. In a randomized double-blind phase 2 clinical trial in non-small cell lung cancer (NSCLC), tiragolumab + atezolizumab (anti-PD-L1) combination treatment demonstrated significant improvement relative to atezolizumab alone. However, the mechanisms underlying the efficacy of this combination are not well understood.
Methods: In CITYSCAPE (phase 2, NCT03563716), chemotherapy-naïve patients with locally advanced/metastatic NSCLC received either placebo + 1200 mg atezolizumab or 600 mg tiragolumab + 1200 mg atezolizumab q3w IV. We collected tumor pretreatment samples and serum samples (baseline and on-treatment) from patients enrolled in the trial, which were subject to bulk RNA-seq and proteomics, respectively. In the mouse tumor model, BALB/c mice were implanted with syngeneic CT26 tumors. After tumor establishment, mice were randomized by tumor volume and then treated with control IgG2a, anti-PD-L1, anti-TIGIT IgG2a-LALAPG (Fc-inactive) ± anti-PD-L1, anti-TIGIT IgG2b ± anti-PD-L1, or anti-TIGIT IgG2a ± anti-PD-L1. Three days after treatment, CD45+ immune cells were collected from the peripheral blood and tumor from selected treatment groups and underwent single cell RNA sequencing or flow cytometry profiling. Tumor growth was also monitored to determine efficacy.
Results: Here, we show that tiragolumab functions as both a conventional checkpoint inhibitor and, via Fc gamma receptor engagement, as a modulator of immunosuppressive myeloid cells and T regulatory (Treg) cells. Gene expression analysis of patient tumor samples revealed high levels of these cell subsets, were instead associated with treatment benefit

in the tiragolumab + atezolizumab arm but not atezolizumab arm. Analysis of patient serum proteins suggested an association of myeloid cell activation with clinical benefit mediated by the combination therapy. In mouse tumor models, treatment with anti-PD-L1 + anti-TIGIT IgG2a (but not anti-TIGIT IgG2b or Fc-silent anti-TIGIT) led to effective tumor control in mice, suggesting a pivotal role for activating Fc receptors. Phenotypic profiling by single cell RNAseq and flow cytometry revealed that Fc-active anti-TIGIT remodels the tumor microenvironment, most prominently by inducing antigen presentation machinery in myeloid cells, counteracting of anti-PDL1-enforced CD8+ T cell exhaustion, and reducing Treg suppressive capacity.
Conclusions: These findings reveal that FcR engagement is one of several distinct mechanisms by which tiragolumab unleashes antitumor immune responses, and inform further clinical development of anti-TIGIT therapies.

Assessing the real-world utility of cell-free microbial DNA in diagnosing early-stage lung cancer

Serena Fraraccio[1], Stephen Wandro[1], Akanksha Singh-Taylor[1], Sandrine Miller-Montgomery[1], Eddie Adams[1], Rob Knight[2], Leopoldo N. Segal[3], Harvey I. Pass[4], Gregory D. Sepich-Poore[1]. *[1]Research & Development, Micronoma, Inc., San Diego, CA,[2]Department of Bioengineering, Department of Pediatrics, Department of Computer Science and Eng., University of California San Diego, San Diego, CA,[3]Division of Pulmonary and Critical Care Medicine, New York University School of Medicine, New York, NY,[4]Department of Cardiothoracic Surgery, New York University School of Medicine, New York, NY*

Introduction: Links between cancer and microbes date back four millennia (Sepich-Poore et al. 2021. *Science*). Recently, we found that microbial DNA is detectable in tumor tissues and patient blood from many human cancer types (Poore et al. 2020. *Nature*). These intratumoral and bloodborne microbiomes were distinct between cancer types, between normal and malignant tissues, and present in cell-free plasma samples. However, the practical utility of cell-free microbial DNA (cf-mbDNA) as a bona fide liquid biopsy diagnostic, including its applicability in early-stage disease in treatment-naïve individuals, distinguishing histological subtypes, and

discriminating against non-cancer-but-diseased patients remains unknown. Thus, we constructed an age and sex-matched cohort of >1000 individuals with lung cancer, lung disease, and no disease (healthy) to evaluate the utility of a cf-mbDNA-driven liquid biopsy diagnostic.
Methods: Shallow shotgun metagenomic sequencing with gold-standard positive and negative controls was performed using 400 μL of patient plasma. Direct genome alignments separated human and microbial reads, and generated genome-wide binned and species-level abundances, respectively. Novel taxonomic diversity was captured by additionally performing *de novo* co-assemblies in tandem with tumor and blood samples from The Cancer Genome Atlas (TCGA). Multi-modal, stacked machine learning classifiers then evaluated the diagnostic performance of microbial-only and multi-species (microbial + human) information.
Results: Cf-mbDNA provides strong diagnostic performance in treatment-naïve, cancer-bearing individuals versus age and sex-matched healthy controls, as early as stage I disease (AUROCs≥0.90). Furthermore, cf-mbDNA outperforms histological classification compared to human genomic information. Multi-species models paired with routinely-available clinicodemographic information provided robust discrimination of lung cancer versus lung diseases (AUROC≥0.80). Importantly, the addition of cell-free microbial information produced an integrated model surpassing the diagnostic performance of PET-CT and clinical risk models for lung nodule malignancy determination in a blinded validation cohort of Stage I lung cancer and non-cancer lung disease samples.
Conclusion: Cf-mbDNA features comprise a novel class of biomarkers that are combinable with host analytes, and show promise for real-world, early-stage, lung cancer diagnosis.

Cell-free DNA fragmentation profiling for monitoring therapeutic response in metastatic colorectal cancer

Bahar Alipanahi[1], Iris van 't Erve[2], Keith Lumbard[1], Laurel K. Millberg[1], Zach Skidmore[1], Lorenzo Rinaldi[1], Jacob Carey[1], Jennifer Tom[1], Cornelis J. A. Punt[3], Nicholas C. Dracopoli[1], Gerrit A. Meijer[2], Robert B. Scharpf[1], Victor E. Velculescu[4], Remond Fijneman[2], Alessandro Leal[1]. *[1]Delfi Diagnostics, Baltimore, MD,[2]Netherlands Cancer Institute, Amsterdam, Netherlands,[3]University Medical Center Utrecht, Utrecht, Netherlands,[4]The*

Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD

BACKGROUND: Cell-free circulating tumor DNA (ctDNA) assays have been adopted to monitor therapeutic response in both early- and late-stage cancer. However, tests currently available require deep-targeted sequencing to detect cancer-specific mutations at low mutant allele frequency (MAF) levels in the circulation. Recently, we developed a tumor-agnostic approach called DELFI Tumor Fraction (DELFI-TF), a Bayesian probabilistic model designed to predict plasma tumor fractions based on genome-wide fragmentation-related features.
METHODS: Overall, 692 longitudinal plasma samples collected from 153 patients with initially unresectable colorectal cancer (CRC) liver-only metastases participating in the phase III study CAIRO5 (NCT02162563) were split across a training (RAS/BRAF mutant) and a validation cohort (RAS/BRAF wildtype). For all cell-free DNA (cfDNA) samples of patients within the training cohort (n=312), the tumor burden was quantified as the MAF of the tumor-tissue-proven RAS/BRAF variant measured by digital droplet PCR (ddPCR). Using cfDNA fragment-sequencing statistics from low-coverage WGS data, a Bayesian regression model was trained against the MAF of the tumor-specific driver RAS/BRAF variant in all longitudinal timepoints in the training cohort. Changes in DELFI-TF scores during first-line FOLFOX/FOLFIRI and bevacizumab therapy were assessed to predict disease response. A tissue-informed approach was applied to detect minimal residual disease in the subgroup of patients treated with curative intent (complete resection of the primary tumor and liver metastases).
RESULTS: In the training cohort, DELFI-TF scores strongly correlated with RAS/BRAF MAF measured by ddPCR ($r=0.85$, $p<0.001$). DELFI-TF captured plasma tumor fractions associated with copy number changes when ddPCR failed to detect RAS/BRAF mutations. Before treatment initiation, DELFI-TF correlated with the sum of the largest diameters on CT scans according to RECIST1.1 ($r=0.49$, $p<0.001$). Patients with negative and positive changes in DELFI-TF more often exhibited response and progressive disease based on consecutive RECIST assessments, respectively. Median progression-free survival was 9.9 and 12.8 months for patients with DELFI-TF low versus DELFI-TF high, respectively ($p=0.007$). Overall survival was 28.8 and 58.9 months for patients with

DELFI-TF low versus DELFI-TF high, respectively (p=0.001). In patients treated with curative intent, tissue-informed focal and arm-level copy number changes were detected 4-12 weeks after metastasectomy. Most patients presenting molecular relapse were later diagnosed with clinical recurrence by conventional CT imaging.
CONCLUSIONS: DELFI-TF demonstrates the ability to use cfDNA fragmentomes to estimate cfDNA tumor burden with a performance comparable to standard approaches for treatment response monitoring and clinical outcome prediction.

Circulating tumor DNA in colorectal cancer patients with resectable liver metastases: Preliminary results of the MIRACLE study

Lissa Wullaert[1], Maurice P. H.M. Jansen[2], Jaco Kraan[2], Jan M. van Rees[1], Corine M. Beaufort[2], Yannick M. Meyer[1], Boris Galjart[1], Pieter M. H. Nierop[1], Florian E. Buisman[1], Diederik J. Höppener[3], Erik P. van der Stok[1], Gianmarco Motta[2], Dirk J. Grünhagen[1], Henk M. W. Verheul[2], Stefan Sleijfer[1], Saskia M. Wilting[2], Cornelis Verhoef[1], John W. M. Martens[2].
[1]Surgical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands,[2]Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands,[3]Oncological Surgery, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Introducti**on:** Recurrence risk after curative surgery for colorectal liver metastases (CRLM) remains high, underlining the need for novel prognostic markers. Liquid biopsies provide promising biomarkers to detect minimal residual disease (MRD) after local treatment. The aim of this study was to determine and compare the characteristics of cell-free DNA (cfDNA) and circulating tumor DNA (ctDNA) in liquid biopsies taken before and after surgical treatment of CRLM.
Materials & Methods: Patients with isolated CRLM were recruited before undergoing potentially curative hepatic resection. Only patients who did not receive per-operative chemotherapy were selected. Peripheral blood samples were collected in CellSave preservative tubes at four different time points and processed into plasma within 96 hours after withdrawal. Subsequently, cfDNA was isolated from 4mL plasma, in which the total

cfDNA concentration was measured. Mutations characterizing ctDNA were determined before surgery by next generation sequencing (NGS) using a colon-specific targeted panel (Oncomine Colon cfDNA assay, 14 genes). Samples were sequenced at >20.000 average reads depth and variants were called mutations when the variant allele frequency was above their predefined limit of detection. Longitudinal blood samples of ctDNA-positive patients were evaluated by digital PCR (dPCR) using mutation-specific assays, in which samples were considered ctDNA positive when >5 mutant copies were detected.
Results: Blood samples of 231 patients were collected one day before surgery (T0), and were repeated one day (T1), one week (T2), and three weeks (T3) after surgery. The cfDNA yields per mL plasma were higher at T1 and T2 (median 93 ng and 64 ng, respectively) compared to T0 (6 ng, $p<0.001$) and T3 (12 ng, $p<0.001$). NGS at T0 was performed for 196 patients and detected ctDNA in 129 patients (66%). Mutations had a median allele frequency of 6.3% (ranging from 0.28 to 86.4%), and were observed in 12 genes, predominantly in *TP53 (n=69), KRAS (n=57), APC (n=40), and PIK3CA (n=23)*. dPCR analyses were performed for 87 patients out of the 129 patients with ctDNA at T0, and confirmed *TP53, KRAS, PIK3CA,* and *BRAF* mutations in 75 patients, with average ctDNA loads of 9%, 8%, 18% and 4% for these genes. Longitudinal dPCR analyses were performed in 58 patients of whom subsequent post-surgical samples were available, and revealed that ctDNA was detectable in 22 patients (40%) at T1/T2, and in 21 patients (36%) at T3. Nine patients (16%) had detectable ctDNA at both T1/T2 and T3. Average mutation loads were 0.97% at T1/T2 and 1.79% at T3 ($p=0.36$).
Discussion/Conclusion: ctDNA is a potential biomarker to detect MRD after curative treatment for CRLM. Our results demonstrate that out of all patients with detectable ctDNA at baseline (before surgery), ctDNA is still present in 36% of patients three weeks after resection.

Chemokine (C-X-C motif) ligand 17 promotes cutaneous squamous cell carcinoma via modulating tumor-immune evasion

Alok R. Khandelwal, Rema Anisha Kandula, Emily Daniel, Md Maksudul Alam, Henry Craighead, Tara Moore-Medlin, Cherie-Ann O. Nathan. *LSU Health Shreveport, Shreveport, LA*

Cutaneous squamous cell carcinoma (cSCC) is a keratinocyte-derived invasive and metastatic tumor of the skin. It is the second-most commonly diagnosed form of skin cancer, striking 200,000 Americans annually. Further, organ transplant patients are at significantly increased risk of cSCC compared to the general population. Excision of cSCC of the head and neck area results in significant facial disfigurement. An increased understanding of the mechanisms involved in the pathogenesis of cSCC could identify means to prevent, inhibit, and reverse this process. Chemokine (C-X-C motif) ligand 17 (CXCL17) is the latest chemokine family member, and an increased CXCL17 protein expression was observed in both mouse and human cSCC cell lines. Further, deletion of CXCL17 was associated with significant inhibition of tumor cell-intrinsic properties such as proliferation, migration, and motility. CXCL17 is identified as a potent chemoattractant for macrophages, dendritic cells and myeloid-derived suppressive cells. Accordingly, utilizing a syngeneic, tumor-cell xenograft cSCC mouse model, we evaluated the effect of CXCL17 deletion on cSCC tumor-immune evasion and elucidated the underlying mechanism. Deletion of CXCL17 was associated with a significant reduction in tumor volume compared to the wild-type counterparts. Further, CXCL17 deleted cSCC tumor cell xenografts exhibited a significant increase in CD8+, cytotoxic T cells in the tumor microenvironment, suggesting an important role of CXCL17 in mediating tumor-immune evasion. Interestingly, treatment with CXCL17 induced macrophage M2 polarization and promoted macrophage efferocytosis *via* modulating efferocytotic machinery proteins such as MERTK, TIM4, GAS6 and AXL. Our studies have established substantial evidence for the role of CXCL17 in modulating tumor-cell extrinsic properties to affect the progression of cSCC.

The expression and immune regulation of thymic stromal lymphopoietin in non-small cell lung cancer development and progression

Chung-Yu Chen[1], Ying-Yin Chen[1], Hung-Chueh Peng[1], Yi-Ling Ye[2]. *[1]National Taiwan University Hospital Yunlin Branch, Douliu, Taiwan,[2]National Formosa University, Huwei Township, Taiwan*

Purpose: Previous studies have shown thymic stromal lymphopoietin (TSLP) to be an important driver of type 2 inflammation. A new and unexpected function for TSLP has been found in the induction and progression of a variety of tumors. This study conducted TSLP performance in lung cancer patients and the correlation of the clinical pathological data.
Materials and Methods: The patients with pathological diagnosis of lung cancer were enrolled. The percentage of CD19 + B cells was determined in the lymphocyte gate and counted via flow cytometry. Relevant serum cytokines including TSLP were analyzed using LEGENDplex software. In vitro study was conducted by A549 cell line and the mRNA expression change of TSLP was extracted by Reverse Transcriptase PCR (RT-PCR).
Results: When comparing the frequencies of B cell subsets between early-stage (N = 31) and late-stage lung cancer group (N = 29), the frequency of memory B cell (17.3±6.1% vs 23.4±15.1%, p=0.042), CD27+IgM+ B cell (1.8±1.3% vs 2.9±2.3%, p=0.030), class-switched B cell (15.5±5.5% vs 22.2±14.9%, p=0.023), class-switched memory B cell (69.9±11.3% vs 59.9±19.7%, p=0.017) and plasmablast (8.5±7.3% vs 18.0±20.8%, p=0.019) were significantly different between groups. The patients with higher frequency of class-switched B cell had significantly worse prognosis than low frequency (HR 3.054, 95% CI 1.007-9.262, p=0.049). The level of IL-1B, IL-6, IL-10, IL-12, IL-13, and TSLP were significantly higher in the late-stage cancer patients. Simulation in vitro test with human lung A549 cell line was performed, the expression of short-form TSLP (sfTSLP) level decreased with the higher anti-cancer drug as Pemetrexed concentration.
Conclusions: The increase proportion of CD27+CD38- (class-switched) B cell could be an independent, poor prognostic factor for NSCLC patients. TSLP signaling is addressed to the anti-cancer therapeutic response. Therefore, TSLP and relevant cytokines may be involved directly and indirectly in shaping the inflammatory status of the tumor microenvironment.

SOX4 promotes tumor development and immune evasion via disruption of zinc homeostasis between nasopharyngeal carcinoma cells and T cells

Yuma Yang[1], Lanqi Gong[1], Jie Luo[1], Xiaona Fang[1], Jiao Huang[1], Lu Bai[1], Qin Liu[1], Beilei Liu[1], Shan Liu[1], Jinlin Huang[1], Ching Ngar Wong[1], Baifeng Zhang[1], Danyang Zheng[1], Yu Zhang[2], Wei Dai[1], Xinyuan Guan[1]. *[1]Clinical Oncology, The University of Hong Kong, Hong Kong, Hong Kong,[2]State Key Laboratory of Oncology in Southern China, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Nasopharyngeal carcinoma (NPC) is a highly undifferentiated squamous malignancy with dense infiltration of dysfunctional T cells that is endemic in East and Southeast Asia. Based on multicentral single-cell RNA sequencing (scRNA-seq) analysis, we have identified SRY-Box Transcription Factor 4 (SOX4), an essential developmental transcription factor, is specifically and highly expressed by NPC cells and contributes to tumor growth and distant metastasis. SOX4 upregulation also promotes ZIP14-mediated intracellular zinc uptake, leading to competitive deprivation of free zinc in the tumor microenvironment (TME), which inhibits zinc-dependent T cell receptor (TCR) activation. Thus, our study provides experimental insights into how NPC develops and evades immune surveillance.
Methods: scRNA-seq data and bulk RNA-Seq data from our lab and GEO database were integrated and analyzed on a bioinformatic basis. Immunohistochemistry staining was performed to validate the SOX4 protein level in an independent clinical cohort. Cell lines, patient-derived xenografts, and humanized mouse models were generated to evaluate the *in vitro* and *in vivo* function of SOX4. Flow cytometry was used for T-cell immunophenotyping. Immunoprecipitation was used to study protein-DNA interaction. The dual-luciferase reporter assay was utilized to demonstrate the transcriptional regulation of SOX4 on the ZIP14 promoter. qRT-PCR, immunoblotting, and immunofluorescence staining were also employed for functional studies.
Result: Our transcriptome analysis showed SOX4 was frequently overexpressed by NPC cells, compared to infiltrating immune and stromal cells. Increasing SOX4 expression in normal nasopharyngeal epithelial cells enhanced proliferation, stemness, migration, and invasion. SOX4 also transcriptionally upregulated ZIP14 in NPC

cells which promoted the uptake of free zinc from the TME. Thus, competitive deprivation of zinc between NPC cells and T cells in the TME inhibited TCR signaling and T-cell cytotoxicity, leading to NPC immune evasion. Conclusion: This study reveals the SOX4-ZIP14-Zinc axis as a vital mechanism for simultaneously inducing tumor development and immunosuppression in the NPC microenvironment. Therapeutic inhibition of SOX4 or ZIP14 is a new strategy for NPC patients and potentially synergizes with PD-1/PD-L1 blockades to overcome immunosuppressive signals in the TME.

Developing a PROTAC-based NR4A1 degrader for melanoma cancer therapy

Rohan Master[1], Yuewan Luo[2], Yufeng Xiao[3], Daohong Zhou[4], Lei Wang[5], Guangrong Zheng[6], Weizhou Zhang[5].
[1]University of Florida, Gainesville, FL,[2]Biotech Research and Innovation Centre, University of Florida, Copenhagen, Denmark,[3]Department of Medicinal Chemistry, University of Florida, Gainesville, FL,[4]Department of Biochemistry & Structural Biology, Joe R. Teresa Lozano Long School of Medicine, San Antonio, TX,[5]Pathology, Immunology, and Laboratory Medicine, University of Florida, Gainesville, FL,[6]Medicinal Chemistry, University of Florida, Gainesville, FL

Introduct**ion:** Melanoma originates from melanocytes within the epidermis and is one of the most common cancers, with nearly 100,000 new cases yearly. Despite numerous advancements in therapies to treat melanoma, a prevalent population of patients still do not respond to currently approved therapies. Recent studies have highlighted the role of transcription factor nuclear receptor subfamily 4 group A member 1 (NR4A1) in melanoma for cancer survival, invasion, and metastasis. NR4A1 is also involved in glucose metabolism. Our project aims to identify an effective degrader of NR4A1 using a PROTAC strategy and then validate its effectiveness in reducing the growth of melanoma. PROTACs consists of three domains: a warhead that binds to the protein of interest, a ligand to an E3 ligase, and a linker that brings both domains in proximity to one another. The PROTAC can recruit an E3 ligase to ubiquitinate NR4A1 and degrade it via the ubiquitin-proteasome system (UPS).
Results: Our first goal was to identify valid PROTAC candidates that can effectively degrade NR4A1. We identified NR-V04, which demonstrated a dose-dependent degradation of NR4A1 in various melanoma cell lines. We further investigated time-dependent degradation, and NR-V04 was able to achieve *in vitro* degradation of NR4A1 16 hours after treatment. Additionally, we validated the mechanism of degradation via the UPS through various models. NR-V04 treatment of cells with a VHL knockout, which removes the E3 ligase recruited, experienced no degradation of NR4A1, and treatment of cells treated with MG132, a proteasome inhibitor, also showed no degradation. We observed degradation *in vitro* of numerous mouse and human cell lines. To investigate the cancer-killing effects of NR-V04, we completed MTS assays on the human melanoma cell lines CHL1 and A375, which showed an EC50 of 0.723 μM and 1.025 μM, respectively. When comparing NR-V04 treated and untreated CHL1 cells, NR-V04 was able to significantly decrease melanoma cell viability. NR4A1 knockout in CHL1 also showed decreased melanoma cell viability, and when comparing NR-V04 treated and untreated in NR4A1 knockout, there was no further decrease in melanoma cell viability. As for *in vivo* models, NR4A1 knockout in CHL1 and A375 exhibited slower tumor growth compared to the wild type. Furthermore, NR-V04 showed suppression of CHL1 and A375 tumor-bearing NSG mice melanoma growth at low dose concentrations of 1 mg/kg after seven days compared to vehicle and warhead treatment. Western blot analysis of tumor tissue provides support for the ability of NR-V04 to degrade tumor-intrinsic NR4A1.
Conclusion: NR-V04 can selectively degrade NR4A1, *in vitro* and *in vivo*, to decrease melanoma cancer cell viability via the UPS. NR-V04 holds promising therapeutic potential as a cancer therapy for patients with melanoma.

#4452

FASN inhibition overcomes immune evasion by upregulating MHC-I in hepatocellular carcinoma

Jiao Huang[1], Wai Ying Tsang[1], Xiaona Fang[1], Yu Zhang[2], Jie Luo[1], Lanqi Gong[1], Baifeng Zhang[1], Ching Ngar Wong[1], Beilei Liu[1], Jinlin Huang[1], Yuma Yang[1], Shan Liu[1], Zhihong Li[1], Xinyuan Guan[1]. *[1]The University of Hong Kong, Hong Kong, China,[2]Sun Yat-sen University Cancer Center, Guang Zhou, China*

Immune evasion is one of the important factors leading to the progression of hepatocellular carcinoma(HCC). Restricted antigen presentation by decrease of MHC-I remains a huge barrier to triggering an immune attack. However, knowledge is limited on how to enhance antigen presentation of cancer cells. Here we identify that FASN inhibition by shRNA and inhibitors could boost MHC-I level on HCC cell surface. FASN deficiency also

promotes antigen presentation and augments $CD8^+$ T cell cytotoxicity. Mechanistically, FASN knock-down decreases the degradation of MHC-I in lysosomes. Moreover, ZDHHC3-mediated palmitoylation participates in this process. In vivo, orthotopic HCC mouse model shows that Fasn knock-down greatly improves the cytotoxicity of tumor-infiltrating $CD8^+$ T cells and suppresses HCC tumor growth, indicating that inhibiting FASN is a promising way to enhance the efficiency of immunotherapy in HCC.

#4453

Neutrophil-to-lymphocyte ratio associates with intratumoral myeloid predominance and clinical outcomes of pembrolizumab in head and neck squamous cell carcinoma

Hiroki Morimoto[1], Takahiro Tsujikawa[1], Aya Miyagawa-Hayashino[2], Alisa Kimura[1], Sumiyo Saburi[1], Junichi Mitsuda[1], Kanako Yoshimura[1], Gaku Ohmura[1], Shigeyuki Mukudai[1], Hikaru Nagao[1], Yoichiro Sugiyama[1], Shibata Saya[3], Hiroshi Ogi[4], Eiichi Konishi[2], Kyoko Itoh[4], Shigeru Hirano[1]. *[1]Otolaryngology–Head and Neck Surgery, Kyoto Prefectural University of Medicine, Kyoto, Japan,[2]Surgical Pathology, Kyoto Prefectural University of Medicine, Kyoto, Japan,[3]SCREEN Holdings Co., Kyoto, Japan,[4]Pathology and Applied Neurobiology, Kyoto Prefectural University of Medicine, Kyoto, Japan*

Neutrophil-to-lymphocyte ratio (NLR) in peripheral blood is an emerging biomarker candidate of immunotherapy in a wide range of cancers. However, little is known about the potential relationships between the tumor immune microenvironment and systemic inflammatory markers including NLR. Here we have explored systemic and tumor-immune microenvironmental characteristics related to treatment outcomes of immune checkpoint inhibition, based on 29 consecutive patients with recurrent/metastatic head and neck squamous cell carcinoma who received pembrolizumab between 2020 and 2021. NLR greater than 4.5 at pretreatment status significantly correlated with short overall survival (OS). Although NLR did not show a significant association with tumor volumes, high NLR exhibited significant correlations with malnutrition status characterized by CONUT (controlling nutritional status), and GNRI (geriatric nutrition risk index). Among the patients whose NLR was greater than 4.5 at pretreatment status, those whose NLR decreased to less than 4.5 at day 21 had a better OS than those whose NLR did not decrease, indicating that longitudinal changes in NLR correlate with prognosis. To investigate association with tumor-immune microenvironment, 14-marker multiplex immunohistochemistry was performed to quantitatively evaluate intratumoral $CD8^+$ T cells, helper T cells, regulatory T cells, B cells, natural killer cells, macrophages, dendritic cells, mast cells, and granulocytes. Notably, NLR at pretreatment status significantly correlated with intratumoral immune cell densities, where high NLR correlated with low lymphoid cells and high tumor associated macrophages in tissue. NLR in peripheral blood significantly correlated with myeloid to lymphoid cell ratios in tissue, suggesting the presence of association between circulating and intratumoral immune complexity profiles. This study highlights that the association between intratumoral myeloid predominance and systemic nutritional and inflammatory status might be a possible factor for resistance to immunotherapy. Understanding immune dynamics in tissue and blood during immunotherapy potentially contributes to the establishment of predictive biomarkers and monitoring for immunotherapy.

Loss of CX3CL1 expression mediates immune evasion in *STK11* mutated lung adenocarcinomas

Eria Eksioglu[1], Gabriela M. Wright[1], Trent R. Percy[2], Kenneth L. Wright[1], W. Douglas Cress[1]. *[1]Moffitt Cancer Center, Tampa, FL,[2]Arkansas College of Osteopathic Medicine, Fort Smith, AR*

Immunotherapy has improved survival for many cancer patients, especially for immunogenic malignancies such as lung cancer. However, even in lung cancer, the response rate for anti-PD1 therapy (for example) does not exceed 20%. Thus, it is critical to identify mechanisms that block the response to immune checkpoint therapies. STK11 (also known as LKB1) is encoded by the serine threonine kinase 11 gene (*STK11*). Patients harboring tumors with *STK11* mutations have reduced infiltrates of cytotoxic T-cells and clinical studies have shown that they respond poorly to anti-PD1 or anti-PDL-1 therapies regardless of PDL-1 status, which otherwise predicts benefit. Herein, we have used gene expression data from a cohort of 442 lung adenocarcinoma patients to identify CX3CL1 (fractalkine) as a gene silenced in *STK11* mutant tumors with potential to be a key direct modulator of the immune system relevant to STK11 loss. To further explore this hypothesis, we have edited the *STK11* gene in A549 cells back to wild type (*STK11* corrected). As predicted, restoration of STK11 function resulted in modest expression of CX3CL1 as measured by Western blotting. Unexpectedly, exposure of *STK11* corrected cells to human immune cells isolated from the blood of healthy donors resulted in a 5 to 10-fold increase in CX3CL1 suggesting

interactive signaling between tumor and immune cells. Using transwell assays and *STK11* corrected A549 cells we find that restoration of functional STK11 increases immune cell migration, adhesion and invasion in vitro. Finally, cytotoxicity assays demonstrate that *STK11* corrected A549 cells are 3 to 5-fold more sensitive to immune cell killing. Taken together these results suggest the hypothesis that CX3CL1 loss mediates immune evasion in *STK11* mutant lung adenocarcinomas. Future work will further explore the mechanisms underlying this pathway in preclinical models.

#4455

Protein phosphatase 4 inhibition stimulates anti-tumor immunity in ovarian cancer

Remya Raja[1], Christopher Wu[1], Esen Y. Bassoy[1], Thomas Rubino[1], Emma Utagawa[1], Paul Magtibay[2], Kristina Butler[2], Marion Curtis[1]. *[1]Immunology, Mayo Clinic, Scottsdale, AZ,[2]Gynecology, Mayo Clinic, Phoenix, AZ*

Background**:** Increased infiltration of T cells into ovarian tumors has been repeatedly shown to be predictive of enhanced patient survival. However, despite the evidence of an active immune response in OC, immune checkpoint blockade therapy has been ineffective. Recently studies have shown that deficiencies in the DNA damage response (DDR) can drive increased genomic instability and tumor immunogenicity. One target involved in the DDR that has the potential to be of therapeutic value is protein phosphatase 4 (PP4); however, the effect of PP4 deficiency on anti-tumor immunity remain unknown.
Results: Our results show that PP4 inhibition combined with carboplatin leads to increased carboplatin sensitivity, DNA damage, and micronuclei formation. Using a panel of ovarian cancer cells, we show that PP4 inhibition triggers inflammatory signaling via NF-κB and STAT1 activation resulting in increased expression of pro-inflammatory cytokines including IFNβ1, CCL5, CXCL10, and IL-6. Moreover, conditioned media from OC cells treated with the combination of PP4 inhibitor and carboplatin significantly increased migration of both CD8 T cell and NK cells over carboplatin treatment alone. Knockdown of STING in OC cells significantly abrogated the increase in CD8 T cell migration induced by PP4 inhibition. *PPP4C* or *PPP4R3B* knockdown resulted in strong induction of NK cell IFN-γ, increased degranulation, and increased NK cell-mediated cytotoxicity against OC cells. Stable knockdown of PP4C in a syngeneic, immunocompetent mouse model of ovarian cancer resulted in significant reduction of tumor growth *in vivo*. PP4C low tumors had increased infiltration of CD161+ NK cells and CD4+ T cells. Addition of low dose carboplatin treatment in vivo led to increased CD8+ T cell infiltration in PP4C low tumors when compared to the untreated groups.
Conclusions: Our work has identified a role for PP4 inhibition in promoting anti-tumor immune activation. These findings provide the rationale for combining PP4 inhibitors with immunotherapy as a new approach in ovarian cancer treatment.

Inducible nitric oxide synthase (iNOS) and cycloxygenase-2 (COX2) inhibition reprogram the tumor microenvironment and suppress tumor growth in hepatocellular carcinoma

Ronghua Wang, Christof Kaltenmeier, Ruiqi Yang, Tony Haykal, Hamza Yazdani, Celine Tohme, David Geller, Samer Tohme, Timothy Billiar. *Surgery, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Hepatocellular carcinoma is a common cancer worldwide and a leading cause of cancer-related death. Chronic inflammation, accumulation of genetic changes and alternations of the liver microenvironment are critical during the process of carcinogenesis and development of HCC. Inducible nitric oxide synthase (iNOS or NOS2)-derived NO and cyclooxygenase-2 (COX2) are important parts of the neoplastic inflammatory environment. Continuous exposure to moderate to high concentrations of NO, produced by inducible NO synthase (iNOS) and COX2, promotes neoplastic transformation, chemotherapeutic resistance, enhanced cell proliferation, increased inflammation and immune resistance. Our previous study reported that iNOS promoted stem-like characteristics and activation of liver cancer stem cells through Notch signaling pathway. iNOS activity in both the liver cancer stem cells and the microenvironment contributes to tumor progression in mice, suggesting that targeting iNOS in the entire tumor could have therapeutic benefit in HCC. iNOS-derived NO and COX2-derived prostaglandin E2 (PGE2) were shown to promote feed-forward iNOS/COX2 crosstalk because NO induced COX2 and PGE2 induced NOS2. Our research showed that iNOS inhibition with the iNOS inhibitor (1400W) and COX2 inhibitor (Celebrex) diminished HCC tumor growth. The cytokine analysis revealed considerably lower levels of inflammatory cytokines including, IL-6, tissue inhibitor of matrix metalloproteinase-1 (TIMP1), macrophage inflammatory protein-3alpha (MIP-3alpha), IL-1B, CC chemokine subfamily of eosinophil chemotactic proteins eotaxins (CCL11), M-CSF, thymus and activation-regulated chemokine (TARC, CCL17) and leukemia inhibitory

factor (LIF) in HCC with iNOS/COX2 inhibition. iNOS/COX2 levels influence the polarization and spatial location of lymphoid cells including CD8+ T cells. Targeting iNOS/COX2 blockade improved CD8+ T cell penetration into the tumor core. We also found that iNOS/COX2 blockade result in more CD4+ T helper cells and CD8+ tumor infiltrating lymphocyte (TIL), but reduce the number of exhausted CD4+ T cells and CD8+ T cells (PD1-high, Lag3+, CD39+ Tex). The results suggesting that iNOS/COX2 inhibitor therapy may alleviate HCC growth by promoting a anti-tumorigenic TME, modifying lymphoid spatial localization and gene expression phenotypes and decreasing T-cell exhaustion.

Post exposure suppression of radiation pneumonitis by TRAIL pathway agonists TLY012 and ONC201

Jillian R. Strandberg[1], Anna Louie[1], Marina Hahn[1], Praveen Srinivasan[1], Andrew George[1], Arielle De La Cruz[1], Leiqing Zhang[1], Liz Hernandez Borrero[1], Kelsey Huntington[1], Christopher Azzoli[2], Abbas E. Abbas[2], Lanlan Zhou[1], Seulki Lee[3], Wafik S. El-Deiry[1]. *[1]Legorreta Cancer Center at Brown University, Providence, RI,[2]Lifespan Cancer Institute, Providence, RI,[3]D&D Pharmatech, Rockville, MD*

Thoracic therapeutic ionizing radiation is limited by toxicities such as pneumonitis and fibrosis of the lungs. Such limitation restricts therapeutic doses and adversely affects patient quality of life while undergoing and following treatment. ONC201/TIC10 is a small-molecule anti-cancer drug that activates the integrated stress response (ISR) and drives the tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) pathway. Pegylated recombinant long-acting TRAIL (TLY012) has been shown in preclinical models to induce the reversal of fibrosis and currently has orphan drug status for systemic sclerosis and chronic pancreatitis. We show a similar effect of both TLY012 and ONC201 in vivo in protecting from radiation pneumonitis and fibrosis of the lungs. WT and TRAIL-/- C57Bl/6 mice receiving a single 20 Gy thoracic radiation dose with shielding of other organs and treated with 10 mg/kg of TLY012 twice a week showed a significantly reduced alveolar wall thickness and lessened inflammation compared to controls and DR5-/- mice receiving the same treatment upon histological analysis of the lungs conducted 13 days post-irradiation. WT and TRAIL-/- C57Bl/6 mice treated with 100 mg/kg of ONC201 once a week showed similar effect to a lesser extent. Further analysis in C57Bl/6 WT mice bearing orthotopic mammary fat pad e0771 TNBC tumors similarly receiving a single 20 Gy thoracic radiation dose revealed the same pattern of protection from radiation pneumonitis upon TRAIL-pathway agonism through treatment with TLY012 and ONC201 both in combination and alone, while also showing a significant reduction in tumor burden at the experimental endpoint (day 9 post-irradiation) in the combination treated mice. Further, pulse oximetry readings of the hind paw revealed a notable reduction in oxygen saturation in all mice except those treated with TLY012. Cytokinomic profiling of mouse serum upon sacrifice revealed a significant reduction in CCL22/MDC levels in the TLY012 cohort. Additional post-hoc analysis including immunophenotyping, immunostaining, and bulk RNA analysis through Nanostring nCounter technologies is underway. Altogether, these findings suggest a role for TLY012, ONC201, or broader modulation of the TRAIL/DR5 pathway in mitigating adverse effects and outcomes of therapeutic radiation, and may serve as a foundation for safer use of radiation in the clinic.

Single cell landscape of multicentric Castleman disease in identical twins

Jason Yongsheng Chan[1], Jui Wan Loh[1], Jing Quan Lim[1], Herty Liany[1], Elizabeth Chun Yong Lee[1], Jing Yi Lee[1], Bavani Kannan[1], Boon Yee Lim[1], Kerry Lim[1], Jeslin Chian Hung Ha[1], Cedric Chuan-Young Ng[1], Tun Kiat Ko[1], Dachuan Huang[1], Dominique Yuan Bin Seow[2], Chee Leong Cheng[2], Sock Hoai Chan[1], Joanne Ngeow[1], Bin Tean Teh[1], Soon Thye Lim[1], Choon Kiat Ong[1]. *[1]National Cancer Centre Singapore, Singapore, Singapore,[2]Singapore General Hospital, Singapore, Singapore*

Idiopathic Multicentric Castleman Disease (iMCD) is a rare IL-6-driven hematological disorder characterized by systemic lymphadenopathy, elevated immunoglobulin levels, and prominent plasmacytosis in the bone marrow and lymph nodes. An unusual occurrence of iMCD in identical twins provided a unique opportunity to answer genetic and molecular features of this disease, including the cell-of-origin of IL-6 signals, and the immune milieu within affected lymphoid organs and in circulation. Germline whole genome sequencing of the affected twins identified pathogenic homozygous mutations of *NCOA4* c.G1322A and monoallelic mutations of *TRAF3* c.G1504A - both genes recently implicated in IL-6 signaling and B-cell regulation. Their unaffected sister was heterozygous mutant for *NCOA4* and homozygous wildtype for *TRAF3* loci. Via single cell sequencing of 63,519 cells from bone marrow, lymph node, and peripheral blood mononuclear cells, we identified nodal endothelial cells and fibroblastic

reticular cells (FRC) as the source of IL-6 signals. The latter are composed of mainly T-cell zone FRCs (CCL19+/CCL21+/IL7+/PDPN+/MADCAM1-) and a minor population of follicular dendritic cells (FDCs) (CD21+/CD35+/CXCL13+). An “inflammatory” peripheral monocytosis enriched for the expression of S100A family genes was evident in both twins, as well as a group of monocytes expressing cytotoxic gene signatures in the affected twin with milder clinical manifestations. Their unaffected sister mainly carried monocytes enriched for expression of major histocompatibility complex (MHC) class II genes. In conclusion, we provided evidence of a genetic cause of iMCD, identified the putative cell-of-origin of IL-6 signals in this rare disease, and described a distinct monocytic immune response phenotype.

Spatial profiling of the inflamed tumor microenvironment identifies novel prognostic subclasses in non-metastatic clear cell renal carcinoma patients

Teijo Pellinen[1], Lassi Luomala[1], Kalle Mattila[2], Jenni Säilä[1], Annabrita Hemmes[1], Katja Välimäki[1], Oscar Bruck[1], Lassi Paavolainen[1], Harry Nisen[1], Petrus Järvinen[1], Olli Kallioniemi[1], Paula Vainio[3], Panu Jaakkola[3], Tuomas Mirtti[1]. *[1]University of Helsinki, Helsinki, Finland,[2]University of Turku, Turklu, Finland,[3]University of Turku, Turku, Finland*

INTRODUCTION: Clear cell renal cell carcinoma (ccRCC) is highly vascularized and inflamed, and RNA signatures of angiogenesis/inflammation have been suggested as biomarkers for predicting progression and therapy benefit. Here, we explored as to how the spatial localization of endothelial cells and leukocytes and their mutual interactions contribute to disease progression.
EXPERIMENTAL PROCEDURES: We applied multiplexed fluorescence IHC (mfIHC) to quantify CD45+ leukocytes, CD31+ endothelial cells, D2-40+ lymphatic cells, CD11b+ myeloid cells, CD3+ and CD20+ lymphocytes, as well as PDGFRB+ fibroblasts and epithelial cells (CK+/Ecadherin+/CAIX+) in two cohorts of non-metastatic primary ccRCC. Both the Helsinki (N=178) and Turku cohorts (N=241) contained TMA cores from tumor center, tumor border, and benign areas of each patient. mfIHC data were compared with clinical parameters, such as tumor stage (pT), Fuhrman grade, necrosis, and patient outcome (RFS, recurrence-free survival).
RESULTS: CD31+ endothelial cells were associated with favorable ($p<0.001$) and CD45+ leukocytes with poor prognosis ($p<0.001$), high pT ($p<0.05$), high Fuhrman grade ($p<0.05$), and high necrosis ($p<0.05$) in TMA cores representing the tumor center and tumor border areas. CD45+ cells varied spatially with regards to CD31+ cells and EpiStain+ cells. For example, in tumor center cores, CD45+ cells co-localized with EpiStain+ cells ranging from 0.1 to 97% (median for both cohorts, 70.6% and 72.5%). The association of CD45+ leukocytes with poor prognosis was significant when counting the fraction of CD45+ cells not interacting with CD31+ or EpiStain+ cells, but not when including only the interacting cells. We then categorized patients into three classes based on the quantity of the cell types: 1) $CD45^{+High}/CD31^{+Low}$, 2) $CD45^{+Low}/CD31^{+High}$, and 3) Other. $CD45^{+High}/CD31^{+Low}$ phenotype patients had a significantly lower 5-year RFS rate compared to that of $CD45^{+Low}/CD31^{+High}$ patients (Helsinki: 37.9% vs. 92.0%; Turku: 50.0% vs. 93.5%; $p<0.001$, Log-rank test).
CONCLUSIONS: In ccRCC, both the quantity and spatial localization of inflammatory cells with respect to vascular endothelial cells and tumor cells dictates its association with patient prognosis. Our results suggest that although CD45+ leukocyte infiltration associates with recurrent disease, the higher risk is only observed when CD45+ cells are not in contact with vasculature or tumor cells. This suggests how analysis of well-known prognostic biomarkers by IHC can be refined by using mfIHC and considering the spatial configurations of cells in the TME in ccRCC. Ongoing work is aimed to add further profiling of additional TME cell subset associations with inflammation, prognosis, and therapy response.

Spatial profiling of immune biomarkers in resected treatment-naïve early stage lung adenocarcinoma

Sharia D. V. Hernandez[1], Wei Lu[1], Alejandra G. Serrano[1], Claudio J. Arrechedera[1], Beatriz Sanchez-Espiridion[1], Nejla Ozirmak[2], Max Molina[1], Larisa Kostousov[1], Sean Barnes[1], Khaja Khan[1], Ximing Tang[1], Junya Fujimoto[1], Edwin R. Parra[1], Gabriela Raso[1], Stephanie T. Schmidt[3], Carmen Behrens[4], John Heymach[4], Jianjun Zhang[4], Ken Chen[2], Boris Sepesi[5], Tina Cascone[4], Don Gibbons[1], Ignacio I. Wistuba[1], Cara Haymaker[1], Luisa M. Solis[1]. *[1]Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, MD Anderson Cancer Center, TX,[2]Bioinformatics & Computational Biology, The University of Texas MD Anderson Cancer Center, MD Anderson Cancer Center, TX,[3]Genomic Medicine, The University of Texas MD Anderson Cancer Center, MD Anderson Cancer Center, TX,[4]Thoracic-Head & Neck Med Onc, The University of Texas MD Anderson Cancer*

Center, MD Anderson Cancer Center, TX,[5]Thoracic and Cardiovascular Surgery, The University of Texas MD Anderson Cancer Center, MD Anderson Cancer Center, TX

Background**:** Recently, neoadjuvant immunotherapy plus chemotherapy has been approved for treatment of resectable non-small cell lung carcinoma (NSCLC). Defining the immune landscape of these tumors and its spatial distribution will help to understand lung cancer biology. Here, we analyzed the distribution of immune-related biomarkers in tumor-defined regions and its associations with clinicopathological variables in resected lung adenocarcinomas using high-plex profiling approaches.
Methodology: Thirty-three FFPE tumor tissues from surgically resected treatment-naïve lung adenocarcinoma stage I/II were used to construct a tissue microarray from the MD Anderson ICON cohort. We used three 1-mm core per patient [2 from central tumor (CT), and 1 from invasive margin (IM)] and performed the GeoMx Digital Spatial Profiling protein protocol to assess 49 immune biomarkers. Pancytokeratin (panCK; epithelial), CD45 (immune) and SYTO 13 (nuclear) were utilized as morphology biomarkers. Regions of interests were placed in cores containing tumor, and segmented in '"Tumor (Tu)" (PanCK+) and the "tumor microenvironment (TME)" (PanCK-). Digital counts were normalized using background correction. Statistical analysis was performed using linear mixed model. A p value equal or less than 0.05 was considered significant.
Results: We first compared the relative counts of immune biomarkers in the TME in CT and IM. IM had higher CD3, CD8, CD45RO, as well as CD163 and STING (P ranges 0.006 to 0.035), while CT had higher PD1 (P 0.025). Then we analyzed differential biomarker expression by sex and smoking status. Females had higher counts of Immune related biomarkers: CD45, CD3, CD20, immune checkpoints: PD-L1, VISTA, CTLA4, LAG3, and ICOS, and myeloid: CD68, CD11c, CD163, and B2M (P ranges 0.0005 to 0.046). Smokers had higher counts of CD66b (P 0.007) and B2M (P 0.039) while never smokers had higher counts of HLA-DR, CD34, FoxP3, OX40L, Tim-3, and B7-H3 (P ranges 0.001 to 0.049). Finally, we analyzed Tu segments. IM had higher CD66b, VISTA, CD163, OX40L, HLA-DR, GZMB, STING, and CD8 (P ranges 0.007 to 0.045) than CT. Female patients had higher CD45, CD68, CD11c and CD163 (P ranges 0.008 to 0.045) , and males had higher SMA (P 0.005). Smokers had higher CD66b (P 0.007), B2-microglobulin (P 0.043), and never smokers had higher HLA-DR, STING, CD34, CD44, FoxP3 and CD25 (P ranges 0.006 to 0.043).
Conclusions: In this study, biomarker analysis of treatment-naïve adenocarcinoma in CT areas and IM indicates a higher immune response in the IM and presence of inhibitory signaling inside the tumor. Our data also showed that tumors from females have higher immune response than tumors from males, which is concordant with previous studies. Distinct profiling by smoking status was also observed. Further analysis of gene expression analysis of this set is ongoing.

Optimized human immunophenotyping panels enhance the flexibility for high-dimensional flow cytometry analysis with CyTOF

Lauren J. Tracey, Michael Cohen, Christina Loh. *Standard BioTools Inc, Markham, ON, Canada*

The immune system plays a pivotal role in the pathogenesis of cancer. Beyond its importance in leukemia and lymphoma, scientists now understand that the immune system is involved in virtually all malignancies. Heterogeneity of cell phenotypes within a tumor microenvironment, including blood cell phenotypes, is a hallmark of cancer that is poorly understood. Resolution of these phenotypes is essential to direct therapeutic development. CyTOF® technology has pioneered the field of high-dimensional flow cytometry through the use of isotopically pure metal-tagged antibodies and a highly sensitive mass cytometer to enable 50-plus-parameter analysis. Easy panel design without the need for compensation controls or issues of autofluorescence allows for comprehensive single-cell analysis in complex biological samples and is particularly well suited for revealing the intricacies of oncogenesis. Maxpar® OnDemand reagents were recently introduced for CyTOF to increase flexibility and facilitate larger panel design in a short period of time. To this end, lineage markers that have strong, reliable expression were reassigned to optimal metal isotopes to reserve the high-sensitivity lanthanide channels for more difficult-to-detect markers with low endogenous expression, common in immuno-oncology studies. In this study, we aimed to test the newly released Maxpar OnDemand™ Antibodies to create an optimized immune phenotyping panel and maximize further customization for CyTOF. Individual antibody performance was compared between the new and existing antibodies with different metal tags. Human peripheral blood mononuclear cells (PBMC) and fresh whole blood (WB) were stained to confirm equivalent capabilities for population gating. Importantly, we demonstrated the power of these antibodies to generate reproducible, impactful data by creating functional human immunophenotyping panels. A 20-marker human phenotyping panel was tested in PBMC and WB. We identified

major immune cell populations including T cells, B cells, granulocytes, natural killer (NK) cells, and monocytes. Furthermore, the addition of CD45RO to the panel enhanced the delineation of naive, memory and effector T cell subsets. Additional myeloid markers were included to resolve the complexity within this compartment. With the updated placement of key lineage markers, the optimized phenotyping panel is ideal for future immuno-oncology studies as it can be easily expanded to interrogate cell cycle proteins, cytokines, cell signaling proteins, and oncogenic transcription factors. This work demonstrates the capability of CyTOF for robust, high-parameter immunophenotyping and a high degree of flexibility to expand our understanding of the complex processes underlying carcinogenesis and response to therapy. For Research Use Only. Not for use in diagnostic procedures.

Immunoregulatory effects of NNMT-expressing cancer-associated fibroblasts

Janna Heide[1], Andras Piffko[2], Agnes J. Bilecz[1], Ethan A. Teich[1], Lisa Schweizer[3], Sayed R. Alhunayan[1], Kaiting Yang[2], Ernst Lengyel[1]. *[1]Department of Obstetrics and Gynecology, University of Chicago, Chicago, IL,[2]Department of Radiation and Cellular Oncology, University of Chicago, Chicago, IL,[3]Max Planck Institute of Biochemistry, Muenchen, Germany*

Nicotinamide N-methyltransferase (NNMT) is highly expressed in the stroma of several malignancies and has been shown to drive the transformation of resting fibroblasts into cancer-associated fibroblasts (CAFs) through epigenetic changes. Given that CAFs can promote immunosuppression in cancer, the aim of our study was to investigate the effect of NNMT-expressing CAFs on the tumor-immune environment.
Using a co-culture system of normal fibroblasts and activated PBMCs, we found that IFN-γ produced by PBMCs upregulates NNMT expression in fibroblasts. We confirmed this mechanism *in vivo* in IFN-γ knockout mice and identified T cells as the main source of IFN-γ in the tumor. Gene expression and protein analysis showed that upregulation of NNMT in CAFs induces the secretion of the chemokine CXCL1, a critical chemoattractant for immunosuppressive myeloid-derived suppressor cells (MDSCs). Upregulation of NNMT induces CXCL1 secretion directly through promoter hypomethylation, and *in vitro* migration assays show that NNMT-expressing CAFs recruit high numbers of MDSCs. Using spectral flow cytometry, we analyzed the tumor-immune cell infiltration in whole-body NNMT-knockout mice and discovered that NNMT knockout of the stroma significantly reduced the abundance of MDSCs and increased the number of functional CD8+ T cells. Increased T cell cytotoxicity was associated with a significant reduction in tumor burden in the syngeneic ID8 ovarian and MC38 colon cancer models. These findings were confirmed after adoptive transfer of NNMT-wildtype immune cells into irradiated whole-body NNMT-knockout mice. Moreover, in scRNA-seq data of various human malignancies, we found a strong correlation between NNMT and CXCL1 expression in CAFs.
In summary, our results support a model in which cancer cells induce IFN-γ secretion by T-cells, thereby upregulating NNMT expression in fibroblasts, leading to CXCL1 secretion. CXCL1 secreted by CAFs recruits MDSCs to the tumor, which in turn suppress the anti-tumor T cell response.

Prognostic significance of systemic inflammatory markers in recurrent or metastatic head and neck cancer patients treated with nivolumab

Hiroe Tada, Kazuaki Chikamatsu. *Gunma University School of Medicine, Maebashi, Japan*

Treatment strategies for head and neck cancer has been improved with the contribution of immunotherapy. In spite of the fact, the mechanisms underlying the response to immune checkpoint inhibitors (ICIs) remain unclear, and discovery of the biomarker predicting therapeutic efficacy of ICIs is urgently required. Our previous study indicated that in patients with recurrent or metastatic head and neck squamous cell carcinoma treated with nivolumab, circulating T cells showed dynamic alterations depending on treatment efficacy using flow cytometry and mass cytometry. However, these analyses are somewhat complicated to apply each patient in clinical setting. In this study, we focused on systemic inflammatory markers, including inflammatory makers such as blood cell fractions and C-reactive protein(CRP) in peripheral blood. Firstly, we assessed the pretreatment systemic inflammatory markers in 61 recurrent or metastatic head and neck cancer patients treated with nivolumab, and determined whether these markers were associated with treatment responses by Kaplan-Meier method, multivariate analysis, regression analysis and classification and regression trees(CART). Next, we investigated circulating T cell subsets in 36 recurrent or metastatic head and neck cancer patients using flow cytometry. High neutrophil to lymphocyte ratio(NLR), platelet to lymphocyte ratio(PLR), and systemic immune-inflammation index(SII) significantly associated with poor prognosis in overall survival (NLR: p=0.0047, PLR: p=0.0357, SII:

p=0.0011). Furthermore, high albumin, lymphocyte to monocyte ratio(LMR), and prognostic nutritional index(PNI) were significant good prognostic markers of overall survival (albumin: p=0.0037, LMR: p=0.0088, PNI: p=0.037). Overall survival time were estimated the values that were defined systemic inflammatory markers by multivariate analysis. These systemic inflammatory markers were assigned importance by each coefficient. Notably, the number of monocyte and lymphocyte have a strong influence on overall survival time. In addition, the index that were depending on the number of white blood cells and monocyte, the percentage of lymphocyte, platelet count, albumin, and PNI were useful prognostic tools in analyzing regression analysis. Furthermore, the evaluation of PNI were contributed to the predict treatment efficacy in analyzing CART. Moreover, NLR, PLR, and SII were positively correlated with the proportion of Treg (NLR: R^2=0.3622/p=0.0001, PLR: R^2=0.4198/p<0.0001, SII: R^2=0.3654/p<0.0001). We concluded that in recurrent or metastatic head and neck cancer patients treated with nivolumab, systemic inflammatory markers could provide new insight into rational therapeutic strategies in cancer immunotherapy for head and neck cancer.

Comparison of two DTH models for T cell-mediated immunity in preclinical screen

Yingying Cai. *Yingying Cai (Individual), Shanghai, China*

Introduction: Delayed-type hypersensitivity (DTH) involves the recruitment of T cells into tissues and the activation by antigen-presenting cells to produce cytokines, which further activates local endothelial cells and recruits macrophages, resulting in tissue erythema, swelling and inflammation. DTH models in mice are classical *in-vivo* T cell-mediated immunity screening models for atopic dermatitis, asthma and autoimmune diseases. Different antigens and haptens have been used to establish DTH models with different Th1/Th2 profiles. More immunity characterization of the most widely used DTH models need to be revealed.
Results: We established DNFB, Oxazolone induced DTH models in both BALB/c and C57BL/6 mice with ear thickness as the readout. At the termination, we measured Th1 (ie, IFN-γ) / Th2 (ie, IL-4) profile, pro-inflammatory cytokines including IL-13, TNF, and IL-17 as well as myeloperoxidase (MPO) activity from mice ears as indices to score the degree of inflammation. Oxazolone in BALB/c exhibited more repeatable and robust window in Th1/Th2 balance and cytokines profiles. The comparison of two DTH models were further validated by the pathological analysis for cell infiltration in mouse ears and immune-phenotyping in spleen by FACS.
Conclusion: The comparison of DNFB and Oxazolone induced DTH models characterized the disease progression and established a more comprehensive preclinical DTH model with well-defined Th1/Th2 profile for the drug efficacy evaluation in the T cell-mediated immune response.
Key words: Delayed-type hypersensitivity, mice model, T cell-mediated

Evaluation of tumor draining lymph nodes in dogs with spontaneously arising osteosarcoma using single-cell sequencing

Samuel A. Brill, Dylan T. Ammons, Anne C. Avery, Douglas H. Thamm. *Colorado State University, College of Veterinary Medicine & Biomedical Sciences, Fort Collins, CO*

Tumor draining lymph nodes (TDLNs) function as an anatomic niche which primes immune cells to generate anti-cancer responses. While tumors are frequently staged based on the presence or absence of TDLN metastasis, mechanisms for how tumors impact the TDLN microenvironment and immunologic responses are incompletely understood. Dogs with spontaneously arising tumors provide an opportune model to study immuno-oncology, sharing many similarities to human patients with their environment, clinical care, and pathobiology. To evaluate how tumors impact TDLN responses, we conducted single cell RNA sequencing (scSeq) on cryopreserved TDLNs of dogs with osteosarcoma (n=4) and healthy controls (n=2). We obtained an average of 3,984 cells per sample (range 1,603-5,259) with a total of 4,780 cells from healthy samples and 19,121 cells from TDLN samples. All samples were integrated into one dataset, then unsupervised clustering was completed. Each unique cell cluster was assigned an identity using canonical markers and reference mapping to human datasets. Following cell classification, we observed notable changes in gene expression across all cells isolated from the LNs, with most differences arising from changes to the transcriptome of myeloid cells. Although still preliminary, the data also demonstrate differences in the abundance of T, B, and myeloid cells between healthy and tumor draining LNs. Taken together, this dataset provides indications of the changes TDLNs undergo in dogs with osteosarcoma.

Inhibition of ERO1a and IDO1 improves dendritic cell infiltration into pancreatic ductal adenocarcinoma

Apple Tay[1], Andreas Lundqvist[1], Siu Kwan Sze[2]. *[1]Oncology-pathology, Karolinska Institutet, Stockholm, Sweden,[2]School of Biological Science, Nanyang Technological University of Singapore, Singapore, Singapore*

Pancreatic ductal adenocarcinoma (PDAC) is one of the most hypoxic, lethal, and treatment resistant cancers. Due to its desmoplasias along with the hypoxic state and scarce infiltration of T cells, PDAC is considered a cold tumor. Using a proteomic approach, we previously identified that the expression of endoplasmic reticulum oxidoreductase 1 alpha (ERO1α) is induced by hypoxia and correlates with reduced survival in PDAC. Furthermore, we observed an increased kynurenine formation under hypoxia, suggesting a role of indoleamine 2,3-dioxygenases (IDO1) in PDAC. Since ERO1α and IDO are involved in driving immune suppression through influencing the generation of immature myeloid cells, we sought to investigate whether inhibition of these pathways modulates the myeloid cell composition in PDAC. Using MiaPaCa2 as a PDAC spheroid model with hypoxic core grown in serum-free defined media and immune cell infiltration, we assessed the functional role of ERO1a with IDO1 in modulating monocyte infiltration and differentiation into pro- and anti-inflammatory phenotypes, followed by characterizing the immunomodulatory factors secreted using tandem mass spectrometry. Inhibition of ERO1a and IDO1 significantly improved U937 monocyte infiltration (p-value = ****) and differentiation into dendritic cells (p-value = ****). Secretome analysis of proteins identified with high false discovery rate (q-value<0.01) revealed a downregulation of hypoxia and pancreatic cancer pathways in PDAC spheroids. In the presence of monocytes, upregulation of immune-related pathways for antigen presentation (15-fold) and myeloid cell maintenance signaling (2-fold) were observed. Moreover, specific immune-modulatory factors involved in immune infiltration and migration including interleukin 8, lymphocyte cytosolic protein 1 and transgelin-2 were upregulated at 27-, 20-, and 14-fold respectively. Taken together, these results indicate that inhibition of ERO1a and IDO1 drives an inflamed tumor microenvironment associated with improved monocyte infiltration and differentiation into dendritic cells to potentially enable T cell infiltration and killing of PDAC tumors.

Plasmacytoid dendritic cells, prevalent in the TME of smokers, is associated with a good prognosis and treatment response of LUAD.

Eun Young Kim, Yoon Jin Cha, Yong Jun Choi, Min Kyung Park, Yoon Soo Chang. *Yonsei University College of Medicine, Seoul, Korea, Republic of*

Background: Attempts to find therapeutic biomarkers through investigation of subgroup showing good responses to certain drugs in cancer often yielded meaningful results. Smoker's lung adenocarcinoma has consistently shown a favorable response to immune checkpoint inhibitors (ICIs) than non-smoker's lung adenocarcinoma. Comparing the macrophages (Mϕ) and dendritic cells (DC) constituting the innate immune tumor microenvironment (TME) in lung cancer of smokers and nonsmokers, we tried to figure out the difference in TME and biomarkers that predict the therapeutic response to ICIs.

Methods: The inflammatory TME of current and never smokers' lung cancer was explored by tumor and adjacent normal appearing lung tissues (Tu and NL hereafter) scRNA sequencing and verified by IF, IHC, and open-source dataset.

Results: Compared to lungs of nonsmokers, smokers' lung have an increased proportion of cell populations involved in innate immunity, and the increased cell population was mostly Mϕ, which were enriched in NL. When the number of Mϕ present in the NL of the corresponding individual were taken as the denominator, Tu of smokers has a lower proportion of Mϕ than that of non-smokers. Further sub-clustering of Mϕ and DCs showed that FCN1-mono and CD163-LGMN Mϕ, which correspond to the initial differentiation into the resident cell population within the tissue, and mo-DC, cDC2, and pDC were significantly enriched in the Tu. Among them, pDC is a functionally differentiated tissue resident cell that showed a different tissue distribution pattern between smokers and non-smokers, so it was estimated as one of the causes of the different treatment response to ICIs between the two patient groups. The difference of pDC's distribution was further verified through IHC staining using anti-LILRA4 and anti-TLR9 antibody, showing pDC was significantly enriched in the smokers' TME. A significant increase in TLR9 expression was observed in or around lung cancer immediately after ionizing radiation or cisplatin treatment in LSL-Kras G12D mouse model. The survival analysis of TCGA-LUAD dataset showed that the patients' overexpressing pDC markers such as IRF4 and TLR9 was superior clinical outcomes to the age, gender and smoking matched control group. Comparing the difference in TMB between the top 25% and bottom

25% groups according to the expression of TLR9, it was 5.81/Mb in the upper group and 4.36/Mb in the subgroup, showing a significant difference.
Conclusions: pDC is an innate immune cell population that showed a prominent increase in smokers' TME compared to that of non-smokers, suggesting that its increase may be one the factors that smokers' lung cancer show favorable responses to ICI than that of non-smokers. These findings suggest that the pDC signature can be developed as a biomarker predicting the response to ICIs and increasing the number of pDCs or its activity may improve treatment outcome of ICIs.

Tumor-derived extracellular vesicles transmit retroelement and pericentromeric RNAs to drive proinflammatory and DNA damage responses in stromal fibroblasts and immune cells

Valentina Evdokimova[1], Peter Ruzanov[1], Hendrik Gassmann[2], Lincoln D. Stein[1], Poul H. Sorensen[3], Stefan Burdach[2], Laszlo Radvanyi[1]. *[1]Ontario Institute for Cancer Research, Toronto, ON, Canada,[2]Technical University of Munich, Munich, Germany,[3]University of British Columbia, Vancouver, BC, Canada*

Chronic cancer-associated inflammation and immunosuppression are common features in most patients with solid malignancies. The causes of this chronic inflammatory-immunosuppressive state are still largely undefined. We hypothesized that selective RNAs can be secreted by cancer cells in extracellular vesicles (EVs) and may trigger proinflammatory responses in target cells, leading to chronic inflammation linked to immune cell dysfunction and immunosuppression. We found that tumor cell lines from pancreatic ductal adenocarcinoma (PDAC), prostate cancer (PCa) and from pediatric cancer such as Ewing sarcoma (EwS) continuously secrete large numbers of small (40-200 nm) EVs. In contrast to non-transformed fibroblasts, cancer cell-derived EVs are enriched with large subsets of retroelement and pericentromeric transcripts, including *LINE*, *SINE* and *HERV* retroelements, and human satellite 2 and 3 (HSAT2,3) RNAs. These virus-like RNAs were highly elevated in plasma EVs from EwS patients but not in healthy donors. Some of them, including *HERV-K* and *HSAT2*, were detected in peripheral blood myeloid cells with $CD33^{+}HLA\text{-}DR^{-}$ immunosuppressive phenotypes, and these cell populations were expanded in EwS patients compared to healthy donors. Using mouse xenografts and *in vitro* models, we also found that at least some of these RNAs, such as *HSAT2*, are transmitted to stromal fibroblasts and immune cells in the tumor microenvironment. They also accumulated in fibroblasts after treatment with EwS EVs, coincident with the induction of proinflammatory and DNA damage responses. Prolonged exposure of fibroblasts to EwS EVs also led to mitotic defects and senescence. Expression and dissemination of these highly immunogenic virus-like RNAs in EVs may thus be a common feature of multiple human malignancies, potentially affecting host cells in the local and systemic tumor environment. This, in turn, may induce chronic inflammation contributing to an overall immunosuppressed state in patients.

Disruption of ATG9A-dependent basal autophagy sensitizes cancer cells to innate inflammatory signaling

Dasun N. Jayatunge, Tsz-Ming Tsang, Colten M. McEwan, Joshua L. Andersen. *Department of Chemistry and Biochemistry, Brigham Young University, Provo, UT*

Pathogen-derived nucleic acids are recognized by pattern recognition receptors (PRRs), including cGAS and RIG-I, which trigger the innate immune response by activating IRF3-mediated interferon gene expression. In tumors, high levels of chromosomal instability can also lead to DNA fragments leaking into the cytosol to trigger PRR-mediated interferon response, resulting in pro-inflammatory cytokine secretion from the tumor. This could potentially expose tumor cells to immune attack. However, through mechanisms that are not completely understood, tumor cells dampen the interferon response to escape immune recognition. Previous work demonstrated that loss of ATG9A, but not ATG5, increased inflammatory signaling through the STING-IRF3 cascade, suggesting that perhaps an autophagy-independent function of ATG9A regulates inflammation. Here we found that loss of ATG9A or other upstream regulators of basal autophagy (e.g., ATG101), but not core LC3 lipidation machinery (ATG5 or ATG7), sensitizes cells to dsDNA-induced IRF3 activation and interferon gene expression. We also found that loss of ATG9A or ATG101, but not ATG5 or ATG7, increases the basal activity of the ubiquitin-sensing, IRF3-targeted kinase TBK1, which increases further upon dsDNA treatment. In these ATG9A and ATG101 deficient cells, TBK1 is clustered around large p62-positive condensates that previously been shown to contain large accumulations of LC3. Our preliminary data suggest a model in which ATG9A deletion causes the accumulation of LC3-positive membrane at p62 condensates, which may act as a platform for inflammatory signaling. Our current work focuses on identifying the upstream pathways and core mechanism that

regulates IRF3 activation in ATG9A-deficient cells and exploiting this mechanism to improve anti-tumor immunity.

E-cigarette aerosol exposure increases NF-kB and modulates inflammatory markers in oral epithelial cells

Vengatesh Ganapathy[1], Jimmy Manyanga[1], Dehra McGuire[1], Daniel Brobst[1], Balaji Sadhasivam[1], Mayilvanan Chinnaiyan[1], Constantin Georgescu[2], Jonathan Wren[2], Lurdes Queimado[1]. *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]The Oklahoma Medical Research Foundation, Oklahoma City, OK*

Background**:** E-cigarette use has skyrocketed among youth, in part because e-cigarettes are perceived as a safer substitute for traditional cigarettes. However, the resulting health effects of e-cigarette use are still unclear. E-cigarette aerosols contain harmful and potentially harmful substances such as flavorings, carbonyl compounds, heavy metals, carcinogens and reactive oxygen species (ROS). A recent *in vitro* study from our laboratory showed that e-cigarette aerosols can increase cellular ROS and suppress cellular antioxidant capacity. An imbalance between the ROS production and the availability of antioxidants or free radical scavengers, can lead to chronic inflammation. Here we examine the effect of exposure to e-cigarette aerosols on the expression of the inflammatory regulator NF-kB and its downstream inflammatory targets in oral epithelial cells.
Methods: Human oral epithelial cancer (UM-SCC-1) cells were exposed, every other day for 2 weeks, to e-cigarette aerosol extracts (18 mg/ml of nicotine; tobacco flavor) prepared from two distinct e-cigarette brands. Standard tobacco extracts were used as a positive control. Whole-cell RNA was isolated and processed for RNA-sequencing. The altered gene expression was further validated by western blotting and ELISA using a human cytokine array. Data were analyzed by Student's t-test.
Results: RNA sequencing data showed that a 2-week exposure of oral epithelial cells to e-cigarette aerosol extracts resulted in significant changes in several key cellular signaling pathways, including inflammatory and immune response signals. Exposure to e-cigarette aerosol extracts resulted in a significant increase in the expression of proteins involved in inflammatory pathways, such as TLR3, TGF beta, ERK1/2 and NF-kB. We also observed a significant increase in pro-inflammatory and anti-inflammatory cytokines after exposure to e-cigarette aerosol extracts, including CD54, IL-1a and IL-10.
Conclusion: Our data suggest that chronic exposure to e-cigarette aerosol increases the expression of TLR3, TGF beta, and ERK1/2, which possibly contributed to the observed increase in NF-kB and its down-stream targets (e.g., CD54, IL-1a and IL-10). NF-kB is a pleiotropic transcription factor with key roles in multiple biological processes, such as immune homeostasis and development. Chronic NF-kB activation by e-cigarette aerosol exposure could contribute to chronic inflammation and tumorigenesis.

Reprogramming “cold” NF1 malignancies into “hot” tumors for immunotherapy

Laasya Madana, Lu Q. Le, Nipunika Somatilaka, Renee McKay. *Dermatology, UT Southwestern Medical Center, Dallas, TX*

Introduction: Neurofibromatosis Type 1 (NF1) results from mutations in the *NF1* gene that inactivate the tumor suppressor, neurofibromin. This leads to hyperactive RAS signaling that predisposes NF1 patients to tumor development. Over time, some of these tumors can develop into malignant peripheral nerve sheath tumors (MPNST) which are currently incurable.Immune checkpoint blocking (ICB) programs a patient’s immune system to enhance tumor destruction. However, MPNSTs are cold tumors characterized by low immune cell presence in the tumor microenvironment. Interestingly, MPNSTs show checkpoint protein PD-L1 expression suggesting ICB as potential therapy for MPNST, given the ability to increase immune cell density in the tumor microenvironment. Activation of the intracellular receptor stimulator of interferon genes (STING) enhances antitumor immunity through the induction of pro-inflammatory cytokines and chemokines, including type I interferons. Cyclic GMP-AMP synthase (cGAS) is an enzyme that once bound to cytosolic DNA, synthesizes cyclic GMP-AMP (cGAMP), which activates STING to induce inflammatory cytokines and other immune mediators. Preclinical studies using mouse tumor models have assessed the efficacy of STING agonists that trigger the cGAS-STING-IFN axis, ultimately leading to augmented innate immunity and a T cell-rich tumor environment. Additionally, combining STING agonists with ICB has a synergistic effect in treating tumors. Therefore, we hypothesize that treatment with STING agonists would turn “cold” MPNSTs into “hot” tumors making them susceptible to targeting with ICB. Methods: We treated MPNST cell lines with synthetic STING agonist ADU-S100 for varying durations of 8, 18, 24, and 48 hours. At the end of the treatment, cells were harvested for qRT-PCR and immunoblot analysis.

Results: We measured STING-IFN pathway activation through immunoblotting and observed that phosphorylation of STING effector proteins - a readout of STING activation -- was increased followingby 8 hours after treatment. qRT-PCR analysis showed that STING target cytokine/chemokine gene expression was also upregulated by 8 hours after ADU-S100 treatment.
Conclusions: Theise data demonstrates that ADU-S100 was able to activate the STING pathway in MPNST cell lines leading to proinflammatory cytokine/chemokine production. We will next test STING agonist in vivo use to determine whether ADU-S100 treatment inin mouse MPNST modelss of MPNST to is able to reprogram the tumor microenvironment into an immune inflamed one amenable to immunotherapy.

A mouse model for GvHD: an excellent tool for evaluating the efficacy of anti-GvHD drugs and testing mechanisms of immunoregulation

Meirong Wu[1], Shiru Zhang[1], Fang Zhu[1], Hongyan Sun[1], Jianming Xu[1], Cunxiang Ju[1], Hongyu Wang[1], Santi Suryani Chen[2], Zhiying Li[2], Mark Wade Moore[2], Jing Zhao[1], Xiang Gao[1]. *[1]Gempharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA*

Hematological malignancies, including leukemia, lymphoma and multiple myeloma, account for about 7% of all newly diagnosed cancers. Allogeneic hematopoietic stem cell transplantation (HSCT) is a traditional treatment for hematologic malignancies. Currently, CAR-T cell therapy has made a major breakthrough in the treatment of hematologic malignancies. However, the occurrence of acute Graft-versus-Host Disease (GvHD) represents a major obstacle for HSCT and limits the application of CAR-T cell therapy.
GemPharmatech established and characterized two murine models for anti-GvHD drug evaluation. In the first model, bone marrow from C57BL/6 donor mice was transplanted into a sublethally-irradiated BALB/c recipient mouse. In this model, T cell infiltration, tissue damage, and systemic inflammation were observed, similar to the clinical observations of patients receiving allogeneic HSCT. Efficacy evaluation of anti-GVHD drugs have been carried out based on this model. Our results showed that treatment with the anti-GVHD drug Ibrutinib, the survival rate and the lifespan of the mice was significantly prolonged, and the GvHD score was reduced by about 70% compared with the placebo group.
In the second model, human Peripheral Blood Mononuclear cells (PBMCs) were transplanted into irradiated severe immunodeficient NCG mice. The cohort was irradiated to accelerate GvHD occurrence. The reconstructed human T cells will recognize and attack mouse tissues to cause GvHD. Our results showed that hCD45+ cells infiltrated into heart, liver, and spleen of huPBMC-NCG mice. This model has also been successfully used for anti-GvHD efficacy evaluation. Upon treatment with an anti-GVHD drug, the lifespan of huPBMC-NCG mice was significantly extended and weight loss was alleviated.
Overall, the above-mentioned GvHD models show great potential for preclinical evaluation of anti-GvHD drug development in allogeneic HSCT.

Detection of RAS mutations in colorectal cancer patients using DNA from extracellular vesicles

Sho Kuriyama, Takeshi Yamada, Hiromichi Sonoda, Seiichi Shinji, Akihisa Matsuda, Kazuhide Yonaga, Takuma Iwai, Kohki Takeda, Koji Ueda, Toshimitsu Miyasaka, Shintaro Kanaka, Hiroshi Yoshida. *Nippon Medical School, Tokyo, Japan*

Introduction: Precision medicine is becoming increasingly important in cancer treatment, and liquid biopsy (LB) is a core technique. Circulating tumor DNA (ctDNA) is the main target for LB; however, in some patients, its sensitivity is inadequate. Detection of post-operative ctDNA, called Minimal Residual Disease (MRD), indicates cancer recurrence; however, some patients experience recurrent disease without being MRD-positive. To improve sensitivity of ctDNA detection, we focused on exosomes, small vesicles of endosomal origin that contain DNA (exoDNA) derived from cells, including cancer cells. In this study, we assayed *KRAS* mutations in patients with colorectal cancer using exoDNA, and analyzed the utility of biomarkers in prognosis, using a machine learning algorithm.
Materials and Methods: Patients who underwent curative surgery for colorectal cancer from November 2018 to December 2020 were recruited prospectively. Blood samples were obtained before surgery, and ctDNA was extracted from 1 mL of plasma. Exosomes were isolated from this plasma, followed by exoDNA extraction. *KRAS*

mutations in ctDNA and exoDNA were analyzed using droplet digital PCR. The Random Survival Forest (RSF) algorithm was used for variable importance analysis.
Results: 300 patients (123 with *KRAS* mutation and 177 without) were included. The median patient age was 71 years (range: 35 - 91). Concentrations of exoDNA were significantly higher in Stage IV patients compared to patients at other stages ($p < 0.01$). Numbers of exosomes did not differ by stage. *KRAS* mutations were detected in exoDNA of 56 patients (45.5%) and in ctDNA of 28 patients with *KRAS* mutation in their tumors (22.7%, $p<0.001$). Sensitivity of exoDNA was higher than that of ctDNA in Stage II/III patients with *KRAS* mutations (Stage II; 33.3% vs 14.2%, p=0.02, Stage III 46.7% vs 13.3%, p=0.001). However, sensitivity of cfDNA was almost equal to that of exoDNA in stage IV patients (53.8% vs 50.0%, $p = 0.78$). Surprisingly, in patients without *KRAS* mutations in their tumors, *KRAS* mutations were detected in exoDNA of 24 patients (13.5%) and in ctDNA of one patient (0.5%). Of 103 stage III patients, 31 (30.1%) experienced recurrence. The RSF algorithm showed that the exoDNA concentration is the most important risk factor for recurrence, followed by a lack of adjuvant chemotherapy.
Conclusion: Sensitivity of *KRAS* mutation detection using exoDNA is excellent. Additionally, the concentration of exoDNA appears to be a superior predictor for recurrence of Stage II/III colorectal cancer after curative surgery.

Analytical validation of an NGS-based, personalized and tumor-informed liquid biopsy assay for detecting minimal residual disease (MRD) with high sensitivity and specificity
Wei Gao, Wuqiang Cao, Xiaoling Zeng, Zihan Tian, Xue Zhang, Ning Fu, Pansong Li. *Geneplus-Beijing Institute, Beijing, China*

Introduct**ion:** Circulating tumor DNA (ctDNA) based MRD detection has been proven effective for predicting the relapse of various cancers after curative surgery. We developed a custom-built, tumor-informed MRD detection method named OncoWES-MRD. Somatic variants were identified and prioritized by whole-exome sequencing (WES) of tumor tissues and matched peripheral blood samples. Patient-specific panel targeting up to 50 top-ranked single-nucleotide and Indel variants was designed to analyze plasma for assessing the presence of ctDNA. The ctDNA level was also quantified by in-house software. Here, we report the analytical validation results of this assay.
Methods: The analytical validation was performed on a colorectal cancer cell line SW480. The sheared SW480 DNA was titrated to normal DNA from NA12878 cell line to produce samples with a variant allele frequency (VAF) of 0.1%. The dilution accuracy was confirmed by droplet digital PCR (ddPCR). Then the 0.1% samples were serially diluted to VAF of 0.05%, 0.02%, 0.01%, 0.005%, 0.003%, and 0.001%. As for these dilution gradients below the detection limit blank of the ddPCR assay (0.1%), the changes of exogenously introduced viral DNA copies were used as indicators of the dilution ratio. To explore the relations between the number of variants and the limit of detection (LoD), a customized capture panel covering 200 prioritized variants for SW480 was designed. Each gradient was tested 42 times with an average sequencing depth above 100,000X. The analytical specificity assessment was conducted on 20 NA12878 wild-type samples and 44 blood samples from 22 healthy donors. The library prep starting DNA input was 60 ng for each reaction. ctDNA fraction was evaluated using the maximum likelihood method, and also taking allelic copy number and cancer cell fraction into consideration.
Results: The WES-MRD assay by monitoring 50 variants demonstrated a sample-level sensitivity of 97.6% at VAF of 0.003%, and 76.2% sensitivity at VAF of 0.001%, along with a specificity of 98.4%. The LOD of 0.1% VAF was achieved at the single variant level. The assay performed 95.2% analytical sensitivity at 0.02% VAF, even with 6 somatic mutations, therefore defining the minimal monitoring number. Based on WES sequencing data of 514 solid tumors, 96.1% of samples met the assay requirement of variant numbers. The upper limit monitoring variants number was set to 50, as keep increasing the monitoring variants showed limited sensitivity improvement while specificity was impaired. In the quantitative aspect, a strong linear correlation between the theoretical cell line tumor fractions with the estimated ctDNA fractions ($R^2 = 0.98$).
Conclusions: The WES-based personalized MRD assay demonstrated high sensitivity and high specificity to detect tumor-derived variants down to VAF of 0.003% and accurately quantified.

Single cell characterization of circulating plasma cells and BCMA levels in patients with multiple myeloma
Sonia Maryam Setayesh[1], Stephanie Shishido[1], Libere Ndacayisaba[1], Amin Naghdloo[1], Jeremy Mason[1], Dean Tessone[1], Carli Kaleta[1], Robert Z. Orlowski[2], Elisabet E. Manasanch[2], James Hicks[1], Peter Kuhn[1]. *[1]Convergent*

Science Institute in Cancer, USC - University of Southern California, Los Angeles, CA,[2]Department of Lymphoma/Myeloma, Division of Cancer Medicine, MD Anderson Cancer Center, Houston, TX

Multiple myeloma (MM), a disease caused by the clonal proliferation of plasma cells (PCs), is the second leading hematologic malignancy in the world, with a global incidence rate increase of 126% and mortality rate increasing by 94% in the past decade. Recently, B cell maturation antigen (BCMA) has emerged as a promising biomarker and therapeutic target for MM due to its selective high expression on malignant PCs, improving the treatment landscape. However, the current diagnostic workup relies on bone marrow aspirates (BMA) which are highly invasive and do not allow for the detection of BCMA levels on circulating PCs, severely limiting the options for repeatable assessments and treatment-monitoring. In our study, we report the utility of a blood-based liquid biopsy, using enrichment-free high definition single cell assay (HDSCA) for the detection, quantification, and morphological characterization of circulating PCs and other BCMA+ cells. We applied a previously validated 4-color immunofluorescence assay using DAPI, CD138, BCMA, and CD45 to examine matched peripheral blood and BMAs from 68 patients across the MM disease spectrum (11 monoclonal gammopathy of undetermined significance [MGUS], 21 smoldering MM [SMM], 18 newly diagnosed MM, and 18 relapsed refractory MM [RRMM]) and peripheral blood from 23 normal donors as controls. Our analysis revealed diverse subtypes of circulating CD138(+/-), BCMA(+/-), and CD45(+/-) cells across the patients, representing both normal and abnormal PCs. We detected significantly higher circulating CD138+ BCMA(+/-) cells in MM precursor conditions (MGUS, SMM), compared to the normal donors. Additionally, we were able to detect BCMA+ oncosomes (identified by the lack of a nuclear structure) in the circulation of patients from both precursor and overt disease conditions. Our findings establish the utility of HDSCA blood-based liquid biopsy for early disease detection and anti-BCMA therapy response monitoring in MM and other B-cell malignancies expressing BCMA.

Circulating tumor DNA (ctDNA) identifies genomic alterations associated with resistance to Nivolumab in combination with other agents in metastatic castration-resistant prostate cancer from the CheckMate 9KD trial

Yu Wang, Jun Li, Jonathan Baden, Saurabh Gupta, Justin M. David. *Bristol Myers Squibb Company (New York), Lawrenceville, NJ*

Introduction**:** Metastatic castration-resistant prostate cancer (mCRPC) is characterized by an immunosuppressive tumor microenvironment resulting in resistance to single agent immunotherapy, and several combination strategies are being clinically evaluated to address this resistance. CheckMate 9KD (NCT03338790) was a nonrandomized, open-label, multicohort, phase 2 trial of nivolumab combined with rucaparib, docetaxel, or enzalutamide for mCRPC, which showed encouraging clinical activity for the nivolumab plus docetaxel combination. To identify genetic factors potentially associated with response or resistance in this trial, we conducted a retrospective analysis of the tumor genomic alteration landscape utilizing circulating tumor DNA (ctDNA) from plasma samples.
Methods: We performed integrated analyses of sequence and structural alterations identified through comprehensive genomic profiling of cell-free DNA (cfDNA) obtained from plasma at baseline using the GuardantOMNI™ assay (500 genes). The analysis was performed on 253 unique samples across all cohorts for which both clinical and OMNI datasets were available. Variant prevalence in ctDNA was compared to that of matched tumor tissue using the FoundationONE® assay (395 genes). Hazard ratios with corresponding two-sided 95% CI were estimated via unstratified multivariable Cox modeling adjusted by subject age and homologous recombination repair deficiency (HRD) status. Odds ratios with corresponding two-sided 95% CI were estimated via unstratified logistic regression modeling adjusted by subject age and HRD status.
Results: Most patients (239/253; 94.5%) were ctDNA(+), with a substantially higher prevalence of most gene variants detected in cfDNA compared to patient-matched tumor tissue. Mutations in the *AR*, *TERT*, *DNMT3A*, *HNF1A*, and *TP53* genes had the highest frequency. Amplifications in a number of genes detected in ctDNA including the androgen receptor (*AR*), PI3K/Akt pathway regulators (*PIK3CA*, *PIK3CB*, *PREX2*), and epigenetic regulators (*DNMT3A*, *EZH2*, *KDM6A*), were positively associated with poorer clinical outcomes (rPFS and/or OS) in the nivolumab + docetaxel arm.
Conclusions: This investigation highlights the utility of liquid biopsy for evaluating tumor genomic alterations in late-stage mCRPC trials and provides translational insights into potential resistance mechanisms to inform patient selection and combination strategies for future clinical development.
Acknowledgements: We acknowledge the patients and families, clinical study teams, and investigators who made the CheckMate 9KD study possible, and acknowledge Guardant Health and Foundation Medicine for the

collaborative development and validation of the GuardantOMNI™ and FoundationOne®CDx assays, respectively.

Single-cell genomic analysis of patient-derived circulating tumor cells in pancreatic cancer

Harrison Ball[1], Brittany Rupp[1], Sarah Owen[1], Kaylee Smith[1], Valerie Gunchick[2], Evan T. Keller[3], Vaibhav Sahai[2], Sunitha Nagrath[1]. *[1]Chemical Engineering, University of Michigan, Ann Arbor, MI,[2]Internal Medicine, University of Michigan, Ann Arbor, MI,[3]Urology, University of Michigan, Ann Arbor, MI*

Metastatic pancreatic cancer suffers from an extremely low five-year survival rate of only 3%. While patients with localized disease show marginally better survival rates, 52% of pancreatic cancers are not diagnosed until metastases have already developed. There is therefore a critically unmet need in the early diagnoses of pancreatic cancer patients. Liquid biopsies have emerged as a promising tool for cancer diagnosis through the analysis of various blood-based biomarkers. Among these, circulating tumor cells (CTCs) stand out as a promising target of interest. Over the past decade, CTCs have been identified as a precursor to metastasis. CTCs have also been shown to harbor mutations matching those of the primary tumor, making them a potential surrogate for biopsied tissue. However, CTCs are an extremely heterogenous population of cells, making bulk analysis challenging. In this study, we demonstrate a workflow for the isolation and genomic characterization of single CTCs from pancreatic cancer patients. CTCs are first enriched using a size-based microfluidic system, the Labyrinth, developed in the Nagrath lab. Single CTCs are subsequently isolated using the DEPArray Nxt system, followed by whole genome amplification (WGA) and low-pass sequencing. The pipeline was optimized using three commercially available pancreatic cancer cells lines (Panc-1, Capan-2, and BxPC-3) and two pancreatic cancer CTC cell lines previously developed in-house (CTC-CL-1 and CTC-CL-2). Finally, the workflow was validated using a blood sample from a stage IV pancreatic ductal adenocarcinoma patient. Following WGA, the average nucleic material concentration of the cell lines was 26.24 ± 16.28 ng/μL and 14.43 ng/μL for cells isolated from the patient sample. The average fragment size was 746 ± 232.79 bp for cell line cells and 507 bp for patient sample cells. This was within the expected range of 100-2000 bp. Both CTC cell lines show gains on parts of chromosome 8q (Myc), 10q (FGFR2) and 17q. Myc is a known oncogene and FGFR2 has been associated with cell growth, migration, and invasion. There are also noticeable differences between the two CTC-CL-1 cells, with one cell showing a 3p12.3-3p26.3 gain (CTNNB1), and the other showing a loss of 6q12-6q15 and gain of 6q16.1-6q27 (Myb, ESR1). A patient sample CTC and patient-matched WBC were isolated and sequenced. The CTC has a noticeable gain of chromosome 1q and loss of chromosome 5q. A gain in chromosome 1q has been seen previously in pancreatic cancer and chromosome 5q is the location of multiple oncogenes including APC, CSF1R and FGFR4. The loss of APC is known to affect Wnt/β-catenin signaling, causing an increase in CD34 expression which is linked to increase in cell invasion and migration. These results demonstrate an efficient workflow for the single cell genomic analysis of pancreatic CTCs. Further studies can be conducted to characterize the heterogenous landscape of CTCs in pancreatic cancer.

Liquid biopsy-based comprehensive genomic profiling reveal mutational landscape in real-world patients with unresectable NSCLC

Haoran Tang, Feng Xie, Yue Zhang, Shidong Jia. *Huidu (Shanghai) Medical Sciences, Ltd., Fengxian District, Shanghai, China*

Introduct**ion:** NSCLC accounts for more than 80% of all lung cancer, and has been shown for clinical benefits from targeted therapies, according to tests of multiple genes, such as EGFR, KRAS, ALK, ERBB2. Previous studies revealed molecular characteristics and responses of targeted therapies in NSCLC. However, most studies used tissue biopsies. There is increasing interest to characterize the molecular profile of NSCLC through liquid biopsy. Hence, here we report a comprehensive genomic profiling study in unresectable NSCLC patients using liquid biopsy.

Methods: The prospective study is part of the Predicine's Phoenix Program, a global molecular biomarkers screening program in multiple solid tumors. Currently, the study enrolled 352 unresectable advanced NSCLC patients from 24 centers in China, who were naïve to the 1st line treatment or recurrent after 1st line targeted therapies. 10ml of blood was collected from each patient and delivered to a central lab for ctDNA analysis. The study applied PredicineCARE, an NGS-based liquid biopsy assay, to profile somatic mutations, copy number variations, and gene fusions among these patients.

Results: The study identified 1614 somatic mutations and 202 copy number variants among blood samples from 352 patients. The most common altered genes were TP53(176/352, 50%), EGFR(144/352, 41%), PIK3CA(35/352, 10%), CDNK2A(35/352, 10%), KRAS(28/352, 8%), and RB1(28/352, 8%). Gene copy number gain incidents were identified on MYC(n=22), PIK3CA(n=16), EGFR(n=15), and MET(n=7), etc. Notably, the study also reported gene copy number loss incidents through liquid biopsy, such as CDKN2A(n=16), PTEN(n=11), and RB1(n=10). The study identified 12 gene fusion incidents, including 7 EML4-ALK fusions, 2 RET fusions(KIF5B-RET and NCOA4-RET), 2 NTRK fusions(ETV6-NTRK3 and NOS1AP-NTRK1), and 1 rare CD74-NRG1 fusion.
Conclusions: This study revealed the comprehensive mutational landscape of advanced NSCLC through liquid biopsy, providing novel biomarkers for clinical diagnosis and targeted therapy mechanism studies.

Pre-radiotherapy ctDNA risk-stratifies non-small cell lung cancer patients with oligometastatic disease

Nicholas P. Semenkovich[1], Yun E. Wang[2], Aadel A. Chaudhuri[3]. *[1]Medicine, Washington University In St. Louis, St. Louis, MO,[2]Tempus Labs Inc., Chicago, IL,[3]Radiation Oncology, Washington University In St. Louis, St. Louis, MO*

Background: Oligometastatic non-small cell lung cancer (NSCLC) patients may uniquely benefit from personalized therapies via liquid biopsy. Widespread metastatic disease is incurable, yet some patients with oligometastatic disease experience prolonged progression-free survival when treated with aggressive local stereotactic body radiotherapy (RT). Distinguishing patients who would benefit from aggressive RT from those who would benefit from systemic therapies remains a challenge. We hypothesized that pre-RT ctDNA can be used to risk-stratify those with oligometastatic NSCLC and enable earlier personalized approaches when considering systemic therapy versus aggressive local RT.
Methods: A retrospective multi-institutional cohort of 1,487 patients (median age: 65 years, 53% female [n=784], 47% male [n=703]) who were diagnosed with oligometastatic NSCLC was selected. Each patient underwent liquid biopsy ctDNA analysis using the Tempus xF assay (v2) at least once, with a subset of patients undergoing serial sampling at 2-8 timepoints for a total of 1,880 ctDNA assays. 309 of the patients (20%) underwent RT after liquid biopsy was obtained and oligometastatic NSCLC was diagnosed. Outcomes for overall survival (OS) and progression-free survival (PFS) were defined with respect to the initiation time of RT (i.e., time from RT to death, time from RT to progressive disease).
Results: Across all ctDNA assays, 3,520 pathogenic or likely pathogenic (P/LP) variants were identified (1.8 variants/sample, mean). Among patients with a liquid biopsy obtained prior to RT, 48% (n=151) experienced progressive disease and 11% (n=34) died during the study period. Focusing on patients with ctDNA obtained pre-RT, P/LP variants were detected in 74% (n=230) while 26% (n=79) had zero variants detected. Of those with detectable variants, 76% (n=175) had 1-3 variants, while 24% (n=55) had ≥4 P/LP variants detected in ctDNA. Both overall survival and progression-free survival were significantly worse in patients with detectable ctDNA from pre-RT liquid biopsy compared to those without (median OS 16.8 months vs. 25 months; p=0.027, HR=1.65; median PFS 5.4 months vs. 8.8 months; p=0.021, HR=1.57). Remarkably, survival correlated inversely with the number of detected variants from pre-RT liquid biopsies; when patients were stratified by variant quantity, both OS and PFS were significant (OS p=0.045, PFS p=0.003; stratified by 0, 1-3, and ≥4 variants). This finding was also significant in a multivariate Cox proportional hazards analysis (OS HR=1.15, CI 1.04-1.24; PFS HR=1.16, CI 1.06-1.25), but was not significant for parameters such as age at diagnosis or squamous histology.
Conclusions: These data suggest that a ctDNA-informed approach may be a powerful pre-RT biomarker to help risk-stratify oligometastatic NSCLC patients and potentially enable personalized decision-making for RT versus systemic therapy.

Purpose: Cell-free DNA (cfDNA) analysis in plasma is an emerging technique with numerous applications in oncology. We employed cfDNA to determine chromosomal instability (CIN), nucleosome footprints (NF) and methylation profiles in metastatic colorectal cancer (mCRC) patients and to predict outcome to bevacizumab (BVZ) combination therapy.
Experimental Design: Low coverage whole-genome sequencing (LC-WGS) was performed on matched tumor and plasma samples from 74 mCRC patients participating in the CTRIAL-IE 12-16 AC-ANGIOPREDICT Phase II clinical trial (NCT01822444), prior to receiving BVZ, and analyzed for CIN (3 subclusters with low, intermediate and high CIN, respectively) and nucleosomes. For 61/74 mCRC patients, plasma samples before and after BVZ treatment were available and used for targeted methylation sequencing. A validation cohort of mCRC plasma samples (n= 24) from the University Medical Center Mannheim (UMM) was similarly profiled.
Results: Based on cfDNA CIN profiles, we subtyped mCRC patients with 92.3% accuracy of sample distinction into low and high CIN clusters (cluster 1 against cluster 2 and 3), demonstrating concordance between matched plasma and tumor samples. Improved survival outcome was observed in CIN high patients. Plasma-based CIN clustering and improved survival for CIN high patients was also confirmed in the UMM cohort. NF and methylation profiles differed between CIN clusters and healthy individuals, and could reliably separate cluster 1 from cluster 2 and 3 samples (AUC=0.72 and 0.85 respectively). A large methylation score decrease after BVZ treatment was associated with improved overall survival ($p = 0.013$).
Conclusions: cfDNA can be analyzed to predict outcome to BVZ in mCRC patients. Detection of CNAs, NFs and methylation profiles facilitated stratification of samples into CIN clusters and informed patient response to treatment.

Tissue based next generation sequence is more accurate than ctDNA to detected pathogenic variants in *MTAP* wild type tumors

Andre Luiz De Souza. *Rhode Island Hosp./Brown Univ. Med. School, Providence, RI*

Next generation sequencing (NGS) of circulating tumor DNA (ctDNA) prevents invasive biopsies and captures tumor heterogeneity. In a prior report by Zhang et al (Nat Commun 2021), certain actionable mutations were more prevalent in ctDNA than tissue-based databases (e.g., *EGFR* 48% versus 25.2%). Our group investigated if discrepancies in patterns of pathogenic variants between liquid biopsy and tissue specimens in a subtype of metastatic urothelial carcinoma (*MTAP* deleted) can inform the best approach of utilizing tissue or blood. MTAP (methyl-adenosine phosphorylase) is an enzyme involved in salvage purine biosynthesis and its deletion confers sensitivity to pemetrexed and taxanes, but resistance to immune checkpoint inhibitors. The *MTAP* gene is deleted in 25% of urothelial carcinomas. We report herein the pattern of pathogenic variants from ctDNA in 17 patients with metastatic urothelial carcinoma, 10 with *MTAP*-deletion and 17 with *MTAP* wild-type. Among 10 patients with *MTAP*-deleted urothelial carcinoma with collected ctDNA, 3 had no detected pathogenic variant. The most common pathogenic variants in 7 patients were *TP53* (4/7, 57%), *TERT* (4/7, 57%), *ERBB2* (2/7, 28%); *PIK3CA* (2/7, 28%), and *NFE2L2* (2/7, 28%). The mutations found in paired ctDNA and tissue based NGS were *TP53* in 26.6 % (4/15), *TERT* in 21.0 % (4/19), *ERBB2* in 66.6 % (2/3), *PIK3CA* in 50 % (2/4), and *NFE2L2* in 100% (1/1) of patients. Three of the 10 patients with collected ctDNA had *ELF3* frameshift loss-of- function alterations on tissue not found on ctDNA. Among 54 patients with *MTAP* wild-type urothelial carcinoma, 26 had collected ctDNA. Among these 26 patients, 9 had no detected pathogenic variants. Among the 17 patients with pathogenic variants, the most common mutations were *TP53* (76%, 13/17), *TERT* (47%, 8/17), *ERBB2* (24%, 4/17), *RB1*

(24%, 4/17), and *BRCA1* or *BRCA2* (24%, 4/17). Three of these 17 patients had no or insufficient tissue for NGS. The mutations found in paired ctDNA and tissue based NGS were *TP53* in 100% (14/14), *TERT* in 64% (9/14), *ERBB2* in 43% (6/14), *RB1* in 29% (5/14), and *BRCA1* or *BRCA2* in 36% (5/14) of patients. *MTAP* wild-type patients had a higher frequency of *TERT* alterations (p=0.012), but not *ERBB2*, (p=0.453) than patients with *MTAP*-deleted type tumors. Ongoing evaluation of timing and location of pathogenic variants will inform where (primary tumor, metastatic site) and when (after chemotherapy, immune checkpoint inhibitors, antibody drug conjugates) to biopsy patients on progression after cancer therapies.

Ultra-deep targeted sequencing of cell-free DNA and patient-matched white blood cells for treatment response evaluation in patients with metastatic colorectal cancer

Iris van 't Erve[1], Jamie E. Medina[2], Alessandro Leal[2], Eniko Papp[3], Jillian Phallen[2], Vilmos Adleff[2], Elaine Jiayuee Chiao[2], Adith S. Arun[2], Karen Bolhuis[4], John K. Simmons[3], Aanavi Karandikar[3], Kenneth C. Valkenburg[3], Mark Sausen[3], Samuel V. Angiuoli[3], Robert B. Scharpf[2], Cornelis J. A. Punt[5], Gerrit J. A. Meijer[1], Victor E. Velculescu[2], Remond J. A. Fijneman[1]. *[1]Department of Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands,[2]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Personal Genome Diagnostics, Baltimore, MD,[4]Department of Medical Oncology, Amsterdam University Medical Centers, Amsterdam, Netherlands,[5]Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands*

Background: Treatment response monitoring of patients with metastatic colorectal cancer is currently performed by computed tomography (CT) imaging, which assesses tumor volume. Circulating tumor DNA (ctDNA) testing has the potential to replace or complement CT imaging by assessing the presence and abundance of tumor-specific mutations, allowing for personalized treatment and early adaptation of treatment regimens through risk stratification and the emergence of therapy resistance mutations. However, germline and clonal hematopoiesis-associated alterations can confound the identification of tumor-specific alterations in cell-free DNA (cfDNA), often requiring additional sequencing of tumor tissue.
Aim: The present study assessed whether ctDNA-based treatment response monitoring could be performed in a tumor tissue-independent manner by combining ultra-deep targeted sequencing analyses of cfDNA with patient-matched white blood cell (WBC) derived DNA.
Methods: In total, 183 cfDNA and 49 WBC samples, along with 28 tissue samples, from 52 metastatic colorectal cancer patients participating in the prospective phase III CAIRO5 clinical trial were analyzed using an ultra-deep targeted sequencing liquid biopsy assay.
Results: The combined cfDNA and WBC analysis prevented the reporting of false positives due to germline or hematopoietic variants in 40% of patients. Patient-matched tumor tissue sequencing did not provide additional information. Longitudinal analyses of ctDNA were more predictive of overall survival than standard-of-care radiological response evaluation. ctDNA mutations related to primary or acquired resistance to the EGFR inhibitor panitumumab were identified in 42% of patients.
Conclusions: Accurate ctDNA mutation detection by combined cfDNA and WBC genomic DNA analyses in a tumor tissue-independent manner mitigates sample logistics challenges in the clinical setting, and the application of this approach for evaluation of therapeutic response and resistance opens new avenues for early adaptation of treatment regimens.

Methylated ctDNA dynamics correspond with clinical tumor load in metastatic lung cancer patients on therapy

Patrick Ye[1], Brian Woodward[2], Robb Viens[1], Sydne Langpap[1], Katherine Shelburne[1], Wen Zhou[1], Joyce Zhu[1], Jan Wignall[1], Gary Palmer[1], David Tsao[1], Oguzhan Atay[1], Hatim Husain[2]. *[1]BillionToOne Inc., Menlo Park, CA,[2]UC San Diego Moores Cancer Center, La Jolla, CA*

Treatment monitoring assays are needed to accurately and rapidly assess the efficacy of cancer treatments. While imaging remains the gold standard for monitoring the efficacy of cancer treatment, the use of more sensitive tools, such as liquid biopsy, could be beneficial for the patient's ultimate treatment outcome. Several liquid biopsy-based assays that measure circulating tumor DNA (ctDNA) have been developed to meet this need. However, approaches that rely on quantifying the variant allele fraction (VAF) of somatic variants may be inaccurate or inconsistent due

to a scarcity of detected somatic variants in the ctDNA or may be logistically infeasible if they require a tumor biopsy *a priori*. Methylated ctDNA has shown promise as a biomarker for treatment monitoring without requiring a tumor biopsy, but current efforts are limited in their ability to precisely quantify the amount of methylation present in the ctDNA. We hypothesize that more precise quantification of methylated ctDNA could enable more accurate correspondence with clinical tumor load and cancer treatment outcomes.
Here, we present a retrospective study characterizing how amounts of methylated ctDNA dynamically change through cancer therapy. We tested 75 patient-treatment events, with each event composed of patient samples from one pre-treatment and two post-treatment time points, all from patients with Stage III-IV metastatic lung cancer receiving targeted therapies or immunotherapy. We employed a novel methylation-based, tumor-naive liquid biopsy assay for treatment monitoring by counting the number of methylated molecules in cell-free DNA. We observed methylation amounts ranging from <50 to >50,000 total methylated tumor molecules per 1000 assayed genomic equivalents at individual time points, indicating that the assay can detect a broad range of tumor load in blood. In addition, we measured changes between time points as large as >96% decrease and >2800% increase in methylation. We found that methylation correlated with maximum variant allele fractions as measured by a treatment selection assay ($r^2 = 0.74$). Moreover, in this tumor-naive assay, we identified a median of 58 informative methylated loci, significantly more than a median of ~1-5 informative SNVs identified in VAF-based tumor-naive assays, and ~4-16 informative SNVs identified in VAF-based tumor-informed assays. This ~6-10x increase in the number of informative loci enables much more precise quantification and underlies the assay's robustness and precision across patients, time points, and therapies. Finally, these changes in normalized total tumor molecules correlated with radiographic responses on imaging, duration of response, and time on therapy. Overall, our findings support the utility of methylated ctDNA as a biomarker for monitoring tumor load in cancer patients.

The effect of morphine-based perioperative analgesia on circulating tumor cells dissemination in colorectal cancer patients

Pavel Stejskal[1], Josef Srovnal[2], Emil Berta[1], Alona Rehulkova[1], Lubomír Večeřa[3], Tomas Gabrhelik[3], Filip Haiduk[4], Jan Maca[4], Jan Bruthans[5], Pavel Michalek[5], Pavla Kourilova[1], Marian Hajduch[1]. *[1]Institute of Molecular and Translational Medicine, Palacky Univ. Faculty of Medicine, Olomouc, Czech Republic,[2]Palacky Univ. Faculty of Medicine, Olomouc, Czech Republic,[3]Tomas Bata Hospital, Zlin, Czech Republic,[4]University Hospital Ostrava, Ostrava, Czech Republic,[5]General University Hospital Prague, Prague, Czech Republic*

Purpose: Circulating tumor cells (CTCs) are primary or metastatic tumor cells shed into the bloodstream and are considered precursors of distant metastatic spread and can act as an independent prognostic and predictive biomarker. Colorectal cancer (CRC) is the leading cause of cancer-related deaths worldwide and metastasis is the major cause of death. Previous studies showed poorer survival in CRC patients treated perioperatively with morphine in comparison to piritramide.
Patients and Methods: In total, 150 CRC stage I-III patients undergoing either radical or laparoscopic surgery were enrolled in this prospective multicentric randomized study (NCT03700411). Patients were randomized into three arms using different perioperative analgesia - morphine, piritramide, and epidural analgesia. Three peripheral blood samples were collected preoperatively, one day and one month after surgery respectively. To preserve the cellular content of specimens, Cell-Free DNA BCT® (Streck, Inc.) blood collection tubes were used. The CTCs were identified using CytoTrack CT11™ (2/C, Denmark), a semi-automated immunofluorescence microscopy detecting the pan-cytokeratin and EpCAM signals. The method recovery rate was analyzed using SW-480 cancer cell line by flow cytometry.
Results: The CTCs recovery rate of the method was 72% and the method was certified by ISO 15189. The analyses of CTC presence revealed the highest positivity rate in the samples collected from patients treated with morphine on the first day after surgery (51.4 %). Also, a significant increase in positivity (from 23.5 % for the perioperatively collected samples) compared to samples from patients treated with epidural analgesia (31.1 % to 33.3 %) and piritramide (44.2% to 41.0%) was observed. The CTC presence was lower in control samples collected after one month irrespective of the analgesia type. The highest positivity among the control samples was in those associated with morphine analgesia (32.1 % versus 25.7% for epidural and 25.0% for piritramide analgesia).
Conclusion: A significant increase in CTC levels was found in postoperative blood samples of CRC patients treated with morphine compared to piritramide and epidural analgesia. Enrollment in the study is ongoing.

Acknowledgments: This study was supported by the Ministry of Health of the Czech Republic (NV18-03-00470), Palacky University Olomouc (LF 2022_012), European Union - Next Generation EU (LX22NPO5102) and European Regional Development Fund (ENOCH CZ.02.1.01/0.0/0.0/16_019/0000868).

Liquid biopsy testing in metastatic or advanced breast cancer patients during the COVID-19 pandemic

Benjamin L. S. Furman, Ebru Baran, Sonal Brahmbhatt, Betty Chan, Ka Mun Nip, Adrian Kense, Brenda Murphy, Vincent Funari, David G. Huntsman, Ruth Miller, Melissa K. McConechy. *Imagia Canexia Health, Vancouver, BC, Canada*

Objective: During the COVID-19 pandemic, cancer patients had restricted access to standard of care tissue biopsy. Liquid biopsy assays using next generation sequencing technology provides a less invasive method for determining circulating tumour mutations (ctDNA) associated with targeted treatments or prognosis. As part of deploying technology to help cancer patients obtain molecular testing, a clinical program was initiated to offer liquid biopsy testing for Canadian patients with advanced or metastatic breast cancer.
Methods: Blood was drawn in two 10 mL Streck^{TM} DNA BCTs and sent to the CAP/CLIA/DAP accredited Imagia Canexia Health laboratory for testing using the clinically validated Follow It^{TM} liquid biopsy assay. Plasma was isolated using a double spin protocol and plasma cell-free DNA (cfDNA) extracted using an optimized Promega Maxwell RSC method. Extracted cfDNA was amplified using the multiplex amplicon-based hotspot 30 or 38 gene panel and sequenced. An in-house developed bioinformatics pipeline and reporting platform were used to identify pathogenic single nucleotide variants (SNVs), indels (insertions and deletions), and gene amplification. Included in the panel are genes associated with metastatic breast cancer: *AKT1, BRAF, ERBB2, ESR1, KRAS, PIK3CA, TP53.*
Results: To identify biomarkers, 1214 metastatic or advanced breast cancer patient cfDNA samples were tested. There were 15 cases sent for repeat testing. We reported 48% of samples harboring pathogenic ctDNA mutations in *TP53* (22%), *PIK3CA* (19%), *ESR1* (18%), *AKT1* (2%), *ERBB2* (1.5%). Co-occurring variants were identified in samples with *ESR1*/*PIK3CA* as well as *TP53*/*PIK3CA* (both p-values <0.001). Interestingly, 29% of samples with mutated *ESR1* harbored ≥ 2 *ESR1* ctDNA mutations. In 56% of cases, previous molecular testing indicated the cancer subtype as hormone receptor (ER, PR) positive with/without HER2 negative status. In this specific subgroup, 49% harbored ctDNA mutations with 63% of those being *PIK3CA* and/or *ESR1* mutations.
Conclusions: A population of Canadian women with metastatic breast cancer were tested using a liquid biopsy gene panel during the COVID-19 pandemic for identification of biomarkers for targeted therapeutic options. Over 50% of the samples were identified as hormone positive, with greater than 60% harboring *PIK3CA* and *ESR1* ctDNA mutations. Studies have shown that metastatic *PIK3CA* mutated ER-positive/HER2-negative tumors are predictive to respond to alpelisib therapy and have FDA and Health Canada approval. Additionally, *ESR1* mutations are associated with acquired resistance to antiestrogen therapies, and interestingly we identified 29% of *ESR1* mutated samples with multiple mutations possibly indicating resistance subclones. In future studies, longitudinal monitoring for presence of multiple targetable and resistance mutations could be utilized to predict or improve clinical management.

#5591

Circulating tumor DNA for recurrence prediction and efficacy analysis in the ICONIC trial of peri-operative FLOT and avelumab (PD-L1) in localized esophago-gastric adenocarcinoma

Marco Gerlinger[1], Anderley Gordon[2], Louise J. Barber[3], Georgios Laliotis[4], Avani Athauda[2], Benjamin Challoner[5], Andrew Woolston[3], Sonia Mansukhani[5], Matt Dunstan[2], Nikoletta Petrou[2], Komel Khabra[2], Retchel Lazaro-Alcausi[2], Richard Crux[2], Victoria Borja[2], Ruwaida Begum[2], Isma Rana[2], Charuta Palsuledesai[4], Meenakshi Malhotra[4], Minetta Liu[4], Adham Jurdi[4], Shruti Sharma[4], Sheela Rao[2], Sacheen Kumar[2], David Cunningham[2], Ian Chau[2], Naureen Starling[2], M. Asif Chaudry[2]. *[1]Barts Cancer Institute & St Bartholomew's Hospital, London, United Kingdom,[2]Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom,[3]Barts Cancer Institute, London, United Kingdom,[4]Natera, Austin, TX,[5]The Institute of Cancer Research, London, United Kingdom*

Background: The utility of molecular residual disease (MRD) detection by circulating tumor (ct)DNA in early-stage (pT2+ or N+, M0) esophagogastric adenocarcinoma treated with peri-operative systemic therapy has not been assessed in prospective trials.

Methods: This exploratory analysis of the phase 2 ICONIC trial (NCT03399071), assessed whether ctDNA can predict recurrence and determine the efficacy of 4xFLOT+avelumab (FLOT-A) before and after surgery. Exome sequencing of pre-treatment biopsies was successful in 24/26 patients (pts) (92.3%) who had received FLOT-A and had undergone surgery at the time of analysis. All pts had R0 resections. Tumor-informed ctDNA assays (Signatera^{TM}) were designed for these 24 pts and 220 serial plasma samples were analyzed. Pathologic response was assessed using Mandard tumor regression grading (TRG1 complete, 2 excellent, 3 good, 4 poor and 5 no response). The median follow-up was 17.0m from surgery. Progression free survival (PFS) was calculated from surgery to radiological recurrence or death.
Results: ctDNA was detected in 23/24 pts (95.8%) prior to treatment. PFS was significantly shorter for pts with a mean number of tumor DNA molecules per ml plasma in the middle & highest tertile (p=0.049, HR=8.33, 95% CI: 1.01-1083, Firth Correction for Cox regression). 6 pts remained ctDNA-positive post neoadjuvant chemotherapy (NAC). None of these pts had a TRG1/2, 3 (50.0%) had TRG3 and 3 (50%) TRG4/5 in the resection specimen. Of 18 ctDNA-negative pts 5 (27.8%) had TRG1/2, 10 (55.6%) TRG3 and 3 (16.7%) TRG4/5. Post-surgery and prior to adjuvant therapy, 6/24 pts were ctDNA-positive. ctDNA positivity at this time point was associated with significantly shorter median PFS (12.9m) compared to ctDNA-negative status (PFS not reached, p<0.0001, HR=27, 95%CI: 3.0-241). Nodal status and Mandard TRG are routinely used as clinical predictors. Only the former was significantly associated with poor median PFS (pN+: 13.5m, pN-: not reached, p=0.027, HR=11, 95%CI: 1.3-98). Of 6 pts who remained ctDNA positive post-operatively, none achieved ctDNA clearance despite adjuvant FLOT-A. The median lead-time from ctDNA positivity after surgery to recurrence was 11.4 months.
Conclusions: Post-NAC/pre-surgical ctDNA positivity correlated with worse pathological response. Persistent ctDNA after NAC & surgery was a stronger predictor of recurrence than nodal status or TRG in the resection specimen. Post-operative adjuvant therapy failed to clear ctDNA in any of the pts who were ctDNA positive after surgery, indicating that administering more of the same treatment is ineffective. This provides an opportunity to test new adjuvant therapies in pts who remain ctDNA positive after surgery. Whether post-operative therapy can be omitted in pts who are ctDNA negative after surgery should be assessed in future trials.

Expansion and characterization on ALK positive NSCLC circulating tumor cells isolated using a size based inertial microfluidic Labyrinth device

Yuru Chen, Shamileh Fouladdel, Harrison Ball, Xu Cheng, Liwei Bao, Habib Serhan, Albert Liu, Bryce Vandenburg, Laura Goo, Nathan Merrill, Aaron Udager, Angel Qin, Sofia D. Merajver, Sunitha Nagrath.
University of Michigan, Ann Arbor, MI

Introduct**ion**
Lung cancer (LC) is the leading cause of cancer deaths. 85% of LC are non-small cell lung cancer (NSCLC). Fusions involving anaplastic lymphoma kinase (ALK) are oncogenic drivers in ~ 7% of NSCLC. Previous studies have shown that drug resistance develops within ~2 years after ALK tyrosine kinase inhibitor targeted therapy. Due to resistance mechanisms and the biological heterogeneity that evolves over the treatment of ALK+ NSCLC, it is important to monitor and study those dynamic changes through the clinical treatment course to understand cancer progression.
Circulating tumor cells (CTCs) are rare cells, shed from cancer lesions into the bloodstream. They can be isolated from a patient's peripheral blood sample (~20ml) to enable study of tumor characteristics at multiple time points. They are promising biomarkers that not only offer phenotypic and genotypic information, but also present a potential to expand into patient derived ex vivo tumor models. In this study, we use a high throughput label-free microfluidic device, Labyrinth, developed in the Nagrath lab for cell size based CTC enrichment, followed by expansion of CTCs in organoid models, further molecular characterization, and growth in patient-derived xenograft (PDX) models.
Methods
Blood samples were collected from patients (n=22), three with known ALK status. CTC isolation was performed using Labyrinth at 2.0 mL/min. A part of the isolated CTCs were immunofluorescently stained for pan cytokeratin (pan CK), CD45, DAPI, epithelial cell adhesion molecule (EpCAM), and vimentin markers for enumeration. Others were processed for expansion in ultralow attachment plates with three types of organoid culture media. The rest of the CTCs were used for molecular characterizations.
Growth curves were produced on expanded samples on Day 0, 7, 14, and 21 in different culture conditions. A live/dead assay and in situ hybridization (FISH) were also performed. On Day 7, selected samples were injected

into NSG™ mice. Bulk RNA sequencing was conducted on the original tumor, Day 0 and 7 CTCs, and PDX samples.

Results

The median CTC concentration in this cohort (n=22) was 316.2 CTCs/ ml of blood. Isolated CTCs from ALK+ NSCLC patients showed ALK fusions by FISH. We observed that the number of ALK CTCs was reduced over time consistent with decreased tumor size in CT scans. There were significant differences ($p<0.05$) for vimentin positive CTCs compared to the other three types of CTCs, which indicated a higher prevalence of a mesenchymal state of NSCLC CTCs. One of the two samples successfully developed into PDX after two months. In summary, we demonstrated a successful workflow to enrich and expand CTCs from ALK+ NSCLC patients. The expanded CTCs can be further characterized and can generate tumors in PDX models.

Clonal mutation burden and evolutionary dynamics analysis in metastatic gastro-esophageal adenocarcinoma (GEA) by error corrected whole-exome circulating tumor DNA sequencing

Neil McCafferty[1], Caroline Fong[2], Louise J. Barber[1], Andrew Woolston[1], Dimitrios Kleftogiannis[3], Taqia Rana[2], Susan Cromarty[2], Shannon Kidd[2], Ruwaida Begum[2], Ian Chau[2], Naureen Starling[2], David Cunningham[2], Marco Gerlinger[4]. *[1]Barts Cancer Institute, London, United Kingdom,[2]Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom,[3]University of Bergen, Bergen, Norway,[4]Barts Cancer Institute & St Bartholomew's Hospital, London, United Kingdom*

Introduction: The evolution of metastatic cancers over time can be assessed in circulating tumor DNA (ctDNA) but sequencing and bioinformatics tools for ultra-deep ctDNA whole-exome sequencing (WES) analysis are lacking.

Methods: We developed ctDNA WES that only requires 15ng DNA to achieve sequencing depths of 1000-2000x. Error correction with molecular barcodes and duplex DNA detection allowed calling of mutations ≥0.5% variant frequency (VF). This pilot study applied ctDNA WES to plasma from 20 EGA patients (pts) and standard WES to matched biopsies in order to assess ctDNA WES performance and whether clonal mutation burden (cMB), a critical immunotherapy biomarker and important for neoantigen vaccine designs, differed between ctDNA and biopsies. We furthermore established a mutation and copy number data analysis pipeline using Bayesian clustering to define subclones and track their evolution during therapy in 3pts.

Results: The median age of pts was 71y, 95% had distant metastases and 5% locally advanced EGAs. At a median sequencing depth of ????x after de-duplication, VFs of mutations in pre-treatment ctDNA was low (<2% VF) in 8 pts, and intermediate (2-10%) to high (>10%) in 12. Whether cMB differed in biopsies vs ctDNA was assessed in 7 pts with high VFs in ctDNA and good cancer purity in matching biopsy WES. The median cMB was 82 in biopsies and 111 in ctDNA. The increase was driven by 3 cases with 30%, 35% and 59% higher cMB in ctDNA vs biopsies. In two pts, most mutations that only appeared clonal in ctDNA were subclonal rather than absent in the primary tumor, indicating the subclonal presence of the metastasis progenitor clone. Subclonal intermixing in primary tumors hence limits the accurate identification of mutations that are clonal in metastatic disease. Evolutionary dynamics analyses in 3 pts who had good responses to chemotherapy before progression showed a major clonal sweep in one, supporting monoclonal resistance, and evolution of small subclones in two, indicating polyclonal resistance. A MEK1 K57T mutation evolved at resistance in a *HER2* amplified EGA treated with trastuzumab+chemotherapy, demonstrating the utility to identify mechanisms of acquired resistance.

Conclusions: ctDNA WES can assess the genetics of entire metastatic cancer cell populations over time and deconvolute their evolutionary trajectories. 43% pts had higher cMB in ctDNA compared to biopsies. Liquid biopsy analyses by WES may be superior to tissue-based WES for mutation burden analysis and neoantigen vaccine designs. ctDNA WES identified distinct evolutionary modes of resistance. A larger cohort is being analyzed to define how these differ clinically and whether they can be predicted from pre-treatment ctDNA WES. Efforts to increase the ctDNA WES sensitivity are ongoing as 8 pts had low ctDNA VFs which increased false negative rates.

#5594

Association of circulating cell-free DNA and prostate cancer risk groups in patients undergoing proton therapy

Andrew Bass[1], Johnny Velasquez[1], Moein Rajaei[2], Curtis Bryant[3], Nancy Mendenhall[3], Luisel J. Ricks-Santi[2]. *[1]University of Florida, Gainesville, FL,[2]Pharmacotherapy and Translational Research, University of Florida,*

Gainesville, FL,[3]University of Florida Health Jacksonville Radiation Oncology, University of Florida Health Proton Therapy Institute, Gainesville, FL

Even after radiation treatment, prostate cancer (PCa) patients receiving radiotherapy (RT) are still at risk for disease progression and recurrence. Predicting outcomes associated with cancer treatment is critical to PCa survivorship given that the 5-year survival rates for local and regional stage PCa is nearly 100%. Radiogenomics is a promising field of research focused on identifying genomic markers that can provide clinically useful prognostic predictions regarding radiation response and can potentially serve as the basis for personalized RT where cancer management is tailored to fit each individual patient. Circulating cell-free (ccfDNA) DNA has been found to 1) be associated with radiation sensitivity or toxicity, 2) relapse or recurrence, and 3) risk for the development of metastases before, during or following photon RT. Proton therapy, alternative to photon therapy, is a promising treatment that can reduce excess radiation dose and, in turn, the risk for adverse events. However, few studies have been done to determine if ccfDNA can predict response in proton radiation, which purports superior dose distribution, avoiding healthy tissues, minimizing the exit dose, and potentially reducing overall toxicity. The overall aim of this study is to determine if the quantity of ccfDNA is associated with PCa risk groups. We hypothesized that PCa patients within the highest risk group have quantitatively increased levels of ccfDNA compared to those in low and intermediate risk groups. This study leveraged the University of Florida Health Proton Therapy Institute Outcomes Tracking Protocol biobank of PCa patients with plasma and serum collected before, during and after proton RT. Isolation of ccfDNA at baseline, during treatment, and following treatment was undertaken and ccfDNA quantities were compared among patients in the low, intermediate and high risk groups using ANOVA. Our results indicate that the quantity difference between baseline and day 14 of treatment ($p=0.055$), 2 weeks post-treatment ($p=0.54$), and 4 weeks post-treatment ($p=0.002$) was associated with risk group. There was trend towards increasing ccfDNA quantity, as risk group increased; however, there was no correlation between risk group and treatment times using the Pearson correlation. Our results were consistent in that high ccfDNA quantity was associated with PCa risk. This is the first study determining the application of ccfDNA quantity on prostate cancer outcomes in patients undergoing proton RT. Identifying the determinants of radiation-related adverse outcomes will help inform impending predictive genomic technologies and improve cancer-related outcomes and survivorship.

Serial monitoring of circulating tumor cells and circulating tumor DNA in metastatic lobular breast cancer identifies intra-tumor heterogeneity and precision and immuno-oncology biomarkers of therapeutic importance

Andi K. Cani, Emily M. Dolce, Kevin Hu, Chia-Jen Liu, Elizabeth P. Darga, Dan Robinson, Yi-Mi Wu, Dafydd G. Thomas, Costanza Paoletti, Scott A. Tomlins, James M. Rae, Aaron M. Udager, Arul M. Chinnaiyan, Erin F. Cobain, Daniel F. Hayes. *University of Michigan, Ann Arbor, MI*

Precision and immuno-oncology clinical decisions are based on predictive biomarkers. Circulating biomarkers offer a minimally invasive approach to monitor intra-patient tumor heterogeneity and detect in real-time the clinically-relevant evolving clonal architecture. Although currently underutilized, single-cell DNA next generation sequencing of circulating tumor cells (CTC) is a particularly suitable method to complement tissue and circulating tumor DNA (ctDNA). Here we analyzed 113 individual CTC, 21 ctDNA, 15 white blood cells (WBC) samples and 15 tissue biopsies, from 15 CTC-positive lobular breast cancer patients. CTC were enriched with the CellSearch® system and isolated as single cells with the DEPArray™ system. CTC, WBC, and ctDNA underwent scNGS with the Oncomine Comprehensive Assay covering ~500 genes and 1.1Mb of genomic space to detect mutations, copy number alterations, tumor mutation burden (TMB) and microsatellite instability (MSI). 99.1% of single cells and 95.2% of ctDNA samples were informative. Our CTC-based precision medicine reporting platform, MI-CTCSeq, detected CTC in 9 of 15 patients (60%) with FDA-approved actionable alterations including in the oncogenes *PIK3CA* and *FGFR2* and HER2. 3 of these 9 (33%) harbored actionable alterations not shared between all 3 analyte types (tissue, CTC and ctDNA) including 3 actionable mutations found in CTC and ctDNA only, 1 in tissue and ctDNA only, and 1 in ctDNA only. Two of those ctDNA mutations were identified near the limit of detection and with a priori knowledge from tissue or CTC. Interestingly, 1 patient with plentiful CTC had no detectable ctDNA. Another patient's tissue biopsy was inadequate for sequencing while both liquid biopsy analytes were abundant. 13 patients (87%) displayed intra-patient, inter-CTC genomic heterogeneity of driver mutations. 1 of 4 (25%) patients with CTC available in >1 timepoint displayed fluctuations in their CTC subclonal makeup between timepoints. Data from this patient's 2 tissue biopsies, 4 ctDNA samples, and 27 individual CTC over 6

timepoints, combined to reveal in unprecedented detail inter-metastatic lesion and inter-CTC heterogeneity and evolution in response to endocrine, chemo and immunotherapy selective pressures. In a novel approach we show detection of single-cell CTC TMB and MSI. CTC TMB was highly concordant (R 0.81) with the corresponding tissue biopsies. Further, in a novel observation, we detected intra patient, inter-CTC heterogeneity of TMB and MSI, which has potential implications for immunotherapy response and development of resistance. Taken together, these data support the non-invasive biomarker interrogation and monitoring by liquid biopsy that incorporates CTC to complement tissue in informing treatment approaches.

Cell free DNA levels and fragmentation patterns in different liquid biopsy analytes (blood, urine and vaginal fluid) in cervical cancer patients

Sarah Tadhg Ferrier[1], Erica Mandato[1], Alexandra Bartolomucci[1], Thupten Tsering[1], Shuk On Annie Leung[2], Julia Valdemarin Burnier[1]. *[1]McGill University Health Centre Research Institute, Montreal, QC, Canada,[2]McGill University Health Centre, Montreal, QC, Canada*

Background**:** Cervical cancer (CC) is the 4th most commonly diagnosed cancer among women, with approximately 528,000 new cases annually. Current screening approaches for this disease have certain limitations; Pap tests require dedicated cytopathology infrastructure, while human papillomavirus (HPV) DNA testing may lead to invasive procedures in patients with transient infection. Liquid biopsy has emerged as a minimally invasive approach to detect and monitor disease progression and treatment response. We and others have previously demonstrated the clinical utility of circulating tumor (ct)DNA to monitor HPV+ cancers. Moreover, cell free (cf)DNA fragmentation patterns have been found to be a biomarker of disease burden. This cfDNA is thought to originate largely as a result of cell death, where small fragments of ~167 bp are associated with apoptosis and larger fragments (>1000 bp) are associated with necrosis. Despite advances in liquid biopsy techniques, little is known about the composition of cfDNA from different analytes in CC patients.
Methods: The aim of this study was to compare the presence and composition of cfDNA from different liquid biopsy analytes in patients with CC and high grade cervical intraepithelial neoplasia or dysplasia (CIN/CD). Blood, urine, and vaginal swabs were collected from 20 patients with CC and 9 patients with CIN/CD at the McGill University Health Centre. All samples were centrifuged twice to isolate supernatant. Samples were tested for HPV ctDNA by ddPCR. Analysis of fragment length was performed using the Agilent Bioanalyzer 2100. Dominant fragment was determined as the DNA fragment with the highest concentration, while overall fragment was calculated as the average fragment across all bioanalyzer peaks.
Results: HPV16/18 ctDNA was detectable 14/20 CC patients and 2/6 CIN patients, and 0/3 CD patients in plasma, urine, and vaginal swab. Concordance for all sample types tested was seen in 90% of cases. On average, fragment analysis demonstrated 174, 195, and 183 bp dominant small fragments in plasma, urine and vaginal swab, respectively. Plasma samples showed only smaller fragments (range: 168-187 bp). Other analytes displayed a predominance of larger cfDNA, with an overall fragment size of 3996 and 5194 bp in urine and vaginal swab, respectively.
Conclusions: HPV-DNA was detectable in all analytes sampled in patients with CC and CIN, with a trend of higher detection in CC samples. The fragmentation patterns of cfDNA varied between patients and within patients across analytes, with larger fragments - likely of necrotic origin - seen only in urine and vaginal swab cfDNA. Smaller fragments - likely related to apoptosis - were seen across all sample types studied. Overall, analysis of fragmentation may provide valuable insight into cfDNA origins in different sample types and provide a novel biomarker for diagnosis and surveillance.

Enhanced detection and classification of cell-free DNA alterations through matched normal analyses with PGDx elio™ plasma complete

Tonya N. Watkins, Paul McGregor, David Riley, Tolga Ayazseven, Kristy Waskiewicz, Kelly M. R. Gerding, Ellen L. Verner, Amy Greer, Aanavi Karandikar, Rami Zahr, Kenneth C. Valkenburg, Jamie Platt, Samuel V. Angiuoli, Mark Sausen. *RESEARCH AND DEVELOPMENT, Personal Genome Diagnostics, Baltimore, MD*

Liquid biopsies represent a transformation in the management of cancer as they have the potential to detect, characterize, and monitor cancers earlier than can be achieved with conventional diagnostic modalities. However, cell-free DNA (cfDNA)-based alterations can be derived from the tumor, germline, or may be associated with clonal hematopoiesis (CH), which can confound non-invasive tumor profiling, molecular response assessment, and

clonal evolution analyses through inaccurate variant classification. To facilitate global access to a decentralized liquid biopsy solution to address this, we developed and validated the 521 gene PGDx elio plasma complete test for paired analysis of cfDNA and matched leukocyte DNA. PGDx elio plasma complete enables detection of single nucleotide variants, insertions and deletions, copy number amplifications, translocations, microsatellite instability, blood tumor mutation burden, and loss of heterozygosity. We first optimized the assay workflow to incorporate genomic DNA derived from leukocytes to facilitate direct detection and characterization of germline alterations as well as those that may be associated with CH, resulting in de-duplicated, error-corrected sequencing coverage of approximately 1,750-fold. A fully automated bioinformatics algorithm was then developed and validated to perform integrated analyses of cfDNA-derived alterations to assign the appropriate biological source of these variants. To assess the impact of these paired sample analyses, we analyzed the blood samples obtained from 24 patients representing seven different solid tumor types (breast, colorectal, gastric, gastro-esophageal junction, lung, and melanoma). Across this cohort, of the alterations detected in cfDNA (n=322), 87.3% were correctly classified as somatic, germline or CH without the patient-matched normal blood sample. Specifically, of the variants that were determined to be associated with CH (n=26), only 35% were appropriately assigned without the paired comparison. Additional sources of discordance for somatic and germline alterations were primarily attributed to patients with high levels of ctDNA where differentiation of these variant sources can be challenging through solely computational-based techniques. Taken together, these data demonstrate that through the integrated analysis of cell-free DNA and matched leukocyte DNA, classification of the source of cfDNA-derived alterations can be achieved, which may improve the accuracy of non-invasive tumor profiling, molecular response assessment, and clonal evolution analyses.

Microfluidic isolation and capture of circulating tumor cells and clusters from mouse blood

Celine Macaraniag, Jian Zhou, Ian Papautsky, Jing Li, William Putzbach, Nissim Hay. *University of Illinois at Chicago, Chicago, IL*

Background**.** Circulating tumor cells (CTCs) and their clusters have been regarded as potential targets for therapies and subjects for identifying certain mechanisms of cancer metastasis. Mouse models have been especially useful tools to investigate the process of metastasis, since they are easier to control and are less variable compared to clinical patient samples. Therefore, it is of interest to extract and study CTCs and CTC clusters from such mouse models. However, most isolation systems are designed and tested for human blood and cell lines. Sized-based methods of CTC isolation have been optimized for human cell lines, but mouse CTCs are generally smaller in size (i.e., ~14 μm EO771 breast cancer cells). Therefore, mouse cell separation necessitates a varied protocol for CTC isolation. We used mouse blood and EO771, a mouse breast cancer cell line, to demonstrate the isolation of mouse CTCs from mouse blood using a sized-based microfluidic device. We also validated the presence of endogenous CTCs and CTC-neutrophil clusters in a tumor bearing mouse model.
Methods. Our microfluidic device employs inertial migration in a straight channel segment (150 μm × 50 μm × 24 mm) to isolate CTCs from blood samples. We spiked 100 and 1000 ZsGreen-expressing EO771 cells in 5× diluted blood containing tdTomato-expressing neutrophils, easily distinguishing CTCs from the red-colored neutrophils. To enumerate the recovered cells, we used Cytospin to concentrate the cells into a glass slide. Lastly, we used hydrodynamic traps to capture CTC clusters from tumor-bearing mouse blood. The blood was extracted from the posterior vena cava of the mice at the endpoint experiment.
Results. We achieved an overall recovery rate of 22-29%, which combines the recovery of the isolation device and the Cytospin. Here, we enumerate cells only after their extraction from the collection tube outside of the isolation device. Other methods with higher capture efficiency enumerate the recovered CTCs before they are harvested from the isolation device which is not always representative of the number of cells that are analyzed. We were also able to discover endogenous CTC-neutrophil clusters from tumor-bearing mice which we distinguished apart with anti-EpCAM staining of CTCs (green) and anti-Ly6G (red) staining of neutrophils.
Conclusion. We demonstrated and optimized a procedure for isolating mouse-derived CTCs from naïve mice blood and CTC-neutrophil clusters from tumor-bearing mice with our microfluidic isolation devices, as opposed to the isolation of human CTCs as in other sized-based isolation systems. In future studies, we aim to continue to use our microfluidic devices to capture and study CTC and CTC clusters.

An introduction of a highly sensitive circulating tumor DNA monitoring system for minimal residual disease detection using a library of 1000 digital PCR probes

Satoshi S. Nishizuka, Hayato Hiraki, Masakazu Abe, Akiko Yashima-Abo, Takeshi Iwaya. *Iwate Medical Univ., Yahaba, Japan*

Background: Many patients undergo a next generation sequencing (NGS)-based cancer genome profiling (CGP) test, but it often does not aid in choosing an optimal therapeutic regimen. Therefore, the genomic information should be used for minimal residual disease (MRD) detection, which directly leads to improved post-treatment cancer patient management. Circulating tumor DNA (ctDNA) is a small fraction of DNA present in blood that carries somatic mutations in cancer patients. Our previous studies demonstrated the clinical validity of ctDNA as a tumor marker for MRD detection. However, the variant allele frequency (VAF; reflecting the fraction of somatic mutations) of ctDNA is less than 1%, at which stable detection is difficult for NGS. Instead of NGS, we have established a highly sensitive ctDNA monitoring system for MRD detection using an originally developed library of >1000 digital PCR (dPCR) probes.
Patients and Methods: Using a Clinical Institutional Review Board approval from the Iwate Medical University Hospital, we initiated a dPCR assay system, called off-the-shelf (OTS)-Assay, in April 2022 under a partnership with Quantdetect, Inc (Tokyo, Japan). The OTS-Assay has three main components: OTS-Scan, OTS-Select, and OTS-Monitor. The OTS-Scan can provide an original CGP if a patient comes with no CGP results. The OTS-Select chooses matched somatic mutations from our dPCR probe library. The OTS-Monitor quantifies VAFs of ctDNA periodically in the patient plasma with a sensitivity of 0.05% VAF. There is no strict patient eligibility criteria other than the requirement of previous therapy for treatment of an advanced cancer.
Results: Between April and November 2022, 26 patients visited Iwate Medical University Hospital for the OTS-Assay. Twenty-five patients were referred from other Departments of Iwate Medical University Hospital. The primary cancer types include esophagus (n=21), colorectal (n=2), pancreas (n=2), and breast (n=1). Twenty patients had CGP results at their first visit. OTS-Select were used for 13 patients and picked an average of 11.4 mutations per patient. Among those, each of eight patients were immediately able to start ctDNA monitoring with one of the 1000 dPCR probes. As of November 2022, there are four patients who received OTS-Monitor more than one time. Any unexpected VAF increase of ctDNA has not been noted, although a substantial decrease of ctDNA VAF was found in one patient who received one cycle of chemotherapy.
Conclusion: The OTS-Assay is a practical introduction of our previous clinical research products based on a core technology, which uses an originally developed library of >1000 dPCR probes. The potential of early and accurate MRD detection will improve post-treatment cancer patient management.

Utility of circulating tumor DNA and transcriptomic profiling in predicting outcome in muscle invasive bladder cancer patients

Sia Viborg Lindskrog[1], George Laliotis[2], Karin Birkenkamp-Demtröder[1], Iver Nordentoft[1], Philippe Lamy[1], Elshaddai Z. White[2], Natalia Pajak[2], Tine G. Andreasen[1], Punashi Dutta[2], Meenakshi Malhotra[2], Shruti Sharma[2], Mark Calhoun[2], Adam ElNaggar[2], Minetta C. Liu[2], Mads Agerbæk[3], Jørgen B. Jensen[3], Lars Dyrskjøt[1].
[1]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark,[2]Natera, Austin, TX,[3]Aarhus University Hospital, Aarhus, Denmark

Background: Standard treatment of localized muscle invasive bladder cancer (MIBC) is neoadjuvant chemotherapy (NAC) followed by radical cystectomy (RC); however, only 40-50% respond to NAC and approx. 50% experience relapse. Evaluation of treatment efficacy and early detection of relapse are therefore major clinical challenges.
Methods: We present a clinical update of a previously described cohort of 68 patients who received NAC prior to RC (NAC cohort; Christensen et al. JCO 2019; median follow-up (FU) of 58 months) together with evaluation of a retrospectively collected cohort of 120 patients who did not receive NAC (no-NAC cohort; median FU of 71 months). Circulating tumor DNA (ctDNA) was analyzed before NAC (NAC cohort, n=63), prior to RC (NAC cohort, n=67; no-NAC cohort, n=115) and after RC (NAC cohort, n=66; no-NAC cohort, n=37) using Signatera™. RNA-seq was performed on 176 tumors.
Results: Updated clinical FU for the NAC cohort showed that ctDNA-positive patients had significantly worse recurrence-free survival (RFS) compared to ctDNA-negative patients (before NAC: HR=16, 95%CI=3.6-70.5, p=0.0002; during surveillance after RC: HR=27.6, 95%CI=7.9-96.9, p<0.0001). After NAC prior to RC, 84% (52/62) of patients were ctDNA-negative, and of these 81% (42/52) achieved pathological complete response (pCR), while none of the ctDNA-positive patients achieved pCR (PPV 100%; NPV 81%). For the no-NAC cohort, presence of ctDNA was also prognostic at both time points (before RC: HR=2.5, 95%CI=1.4-4.4, p=0.001; single

time point after RC: HR=10.1, 95%CI=3.2-31.6, $p<0.0001$). In both cohorts, transcriptomic pathway analysis showed an enrichment of oncogenic pathways, namely EMT and hypoxia ($q<0.0001$), in tumors from ctDNA-positive patients (n=62/142). This may reflect a more aggressive cancer phenotype of ctDNA shedding tumors. Among those who were ctDNA-positive after NAC (n=7) we found enrichment of EMT ($q<0.0001$) and TGF-β signaling ($q=0.005$), whereas there was enrichment of anti-tumor immune pathways, including IFNα and IFNγ response ($q=0.03$ and $q=0.04$), in patients with ctDNA clearance after NAC (n=11). Similarly, we found upregulation of IFNα and IFNγ response pathways ($q<0.0001$) in ctDNA-negative patients without relapse in the no-NAC cohort (n=34/57). Finally, we classified all tumors according to the MIBC consensus classes and found more Ba/Sq tumors among the ctDNA-positive patients ($p<0.0001$). We are currently investigating the potential clinical benefit of receiving NAC in ctDNA-positive and -negative patients by comparing the NAC and no-NAC treated patients.
Conclusion: Presence of ctDNA was associated with worse prognosis for both NAC and no-NAC treated patients. Transcriptomic analysis of primary tumors showed that anti-tumor immune responses may be associated with a particularly good outcome whereas EMT may be promoting more aggressive disease.

Oncomine™ dx express CE-IVD liquid biopsy assay for non-small cell lung cancer: Performance review and analytical validation

Nicholas Siepert, Jeoffrey Schageman, Jian Gu, Thilanka Jayaweera, Madhu Jasti, Luming He, Stephen Wunch, Emilia Ostrowska, Tasha Delacour, Diarra Hassell, Thomas Bowden, Daniela Garcia, Stephanie Tong, Swasti Raut, Nader Ezzedine, Elliott Martinez, Kelli Bramlett. *Thermo Fisher Scientific, Austin, TX*

Introduct**ion -** Clinical diagnostics assays for oncology are becoming more readily available due to the advancement and democratization of Next-Generation Sequencing (NGS). Additionally, liquid biopsy can be used in NGS to detect genetic variants in circulating tumor DNA and RNA. Liquid biopsy is a less invasive option compared to traditional biopsy methods for early detection and continuous monitoring of cancer treatment outcomes. Here, we discuss screening of over 3,500 non-small cell lung cancer (NSCLC) samples, and the analytical validation of the Oncomine™ Dx Express Test (ODxET) and Genexus™ Dx Integrated Sequencer for detection of clinically significant variants in liquid biopsy samples.
Methods - Our team screened over 3,500 NSCLC liquid biopsy samples in search of high priority clinical variants. Variants selected for analytical validation studies included ERBB2 exon 20 insertion, EGFR exon 20 insertion, EGFR exon 19 deletion, EGFR T790M, KRAS G12C, BRAF V600E, and RNA fusion isoforms including ALK, NTRK1/2/3, RET, and ROS1 oncogenic drivers. Over 550 screened samples were found to be positive for these variants of interest. This screening was performed on the Genexus™ Dx Integrated Sequencer according to the user guide.
Results - The Genexus™ Dx Integrated Sequencer automates library preparation, sequencing, analysis, and reporting QC metrics and variant calls. Sequencing run setup is quick and straightforward, taking less than 15 minutes to start a run and just over 24 hours to go from nucleic acid to report. Limit of detection (LoD) for DNA SNVs, insertions, and deletions at 5 ng DNA input level ranged from 0.65% to 1.82% allelic frequency (AF), depending on the variant. The higher DNA input of 30 ng resulted in a lower LoD range, from 0.31% to 0.42% AF. RNA fusion and splice variant LoD at 5 ng sample input ranged from 9.9 to 19.6 molecular counts. The higher 30 ng input resulted in a lower LoD range for RNA variants as well, ranging from 6.4 to 8.0 molecular counts. In the analytical accuracy study, the false positive rate was found to be 0.2% for SNVs, 0% for insertions/deletions, and 0% for fusion targets. In the analytical reproducibility study, the average with-in run repeatability call rate (No Calls excluded) was 99.64% for DNA variants and 98.75% for RNA variants.
Conclusion - Here, we demonstrated that the ODxET workflow on Genexus™ Dx Integrated Sequencer is a fast and efficient tool for testing clinical NSCLC liquid biopsy samples with high sensitivity and specificity.
For in vitro diagnostic use. Not available in all regions including the United States.

Markers of hypoxic cells: Testing a pre-clinical detection assay

Beatriz Zayas, Karoline Rios, Luis Ortiz, Osvaldo Cox. *Science, Technology and Environment, University Ana G Mendez, San Juan, PR*

The proposed project aims to test the applicability of a novel set of patented organic compounds as markers of hypoxic circulating tumor cells (H-CTC) with potential pre-clinical relevance. Circulating tumor cells (CTC) are

individual cells or clusters that can move from tumors to circulation invading other tissues. Often cells in the tumor need to adapt to low oxygen levels, generating a population of cells known as hypoxic cells that can survive low oxygen levels. These hypoxic cells can produce more cell junction proteins, augmenting connections between cells causing them to break away in clusters rather than individually. Clustered CTCs are much more efficient at metastasis formation. Release of CTC can also be stimulated by cancer treatments such as radiation and chemotherapy. To date, our research has generated in-vitro studies with a set of 3-nitrobenzazolo[3,2-a]quinolinium chloride salts (NBQS) demonstrating its capacity as markers of hypoxic human cancer cells in vitro. Comparison with the control Pimonidazole demonstrated the advantages of novel NBQ-TOM compounds as hypoxic marker. We here, aim to test the applicability of NBQS to identify hypoxic cells among circulating tumor cells (H-CTC). To date limited commercially CTC detection methods are available. Our application can be described as pre-clinical detection technology of hypoxic cancer cells serving also in cancer management. To determine the capacity of novel compound, NBQ-345 TOM as hypoxic fluorescent marker, colon tumor cells (COLO 205) are culture under hypoxic and aerobic environment and treated with NBQ-345TOM (25uM) for 24 hours. After treatment fluorescence is measured with an OPTIMA BMG Fluorimeter. Fluorescence emission results demonstrated significant formation of the NBQ-234 TOM fluorescent metabolite on hypoxic tumor cells in contrast to cells treated under aerobic environment. Also, fluorescence microscopy analysis of colon cancer cells treated for 24 hours with NBQ-345 TOM at hypoxic and aerobic conditions confirmed the stronger fluorescence generation at hypoxic conditions in contrast to cells at aerobic conditions.

Functional studies on viable circulating tumor cells (v-CTCs) and frequent expression of PD-L1 on v-CTCs in pancreatic cancer

Masahiro Tanemura[1], Masaki Kashiwazaki[1], Kenichi Matsumoto[1], Kenta Furukawa[2], Manabu Mikamori[2], Tadafumi Asaoka[2], Daisaku Yamada[3], Shogo Kobayashi[3], Hidetoshi Eguchi[3]. *[1]Department of Surgery, Rinku General Medical Center, Izumisano, Japan,[2]Department of Surgery, Osaka Police Hospital, Osaka, Japan,[3]Department of Surgery, Osaka University Graduate School of Medicine, Suita, Japan*

Introduction: The analysis of CTCs as liquid biopsies provides the possibility to avoid invasive tissue biopsies, with obvious implications in cancer diagnostics and treatments. We tested new methods for v-CTCs detection in patients (pts) with pancreatic cancer (PC), and investigated the clinical potential of v-CTCs in prognosis. We analyzed the PD-L1(L1) expression in primary PC tumors, metastatic lymph nodes (LN) and v-CTCs.
Pts and Methods: 7.5 ml of venous blood was collected from 39 PC pts, either upfront surgery (U group) or pre-treatment, consisted of Gem:800mg/m^2; and S-1:80mg/m^2 given concurrently with IMRT to 60Gy ((NACRT:N group). To detect v-CTCs, we employed a telomerase-specific replication-selective adenovirus expressing GFP. For U group, samples were obtained before/after resection. For N group, samples were obtained before/after NACRT and after resection. To distinguish between leucocyte and cells with either epithelial or mesenchymal origin, cells were stained by anti-CD45, anti-Cytokeratin and anti-Vimentin Abs. GFP-positive and CD45-negative cells were counted as v-CTCs. To assess L1 expression in PC tissues (PC tumors and LN) and on v-CTCs, L1 IHC kit (22C3, for tissues) and anti-human L1 mAb(MIH1, for CTCs) were employed.
Results: U group: 24 pts aged 53~85 years (male/female=12/12) were enrolled. 24 pts underwent curative resection. No v-CTCs were detected in 6 pts at both before and after resection, and 5 of 6 pts survived without recurrence. V-CTCs were identified in 18 of 24 pts, and 13 of 18 pts developed liver metastasis. Marked decrease of CTC counts were seen after resection in 10 of 18 pts, but 9 pts developed recurrences. N group: 15 PC pts aged 44~77 years (male/female=4/11) were enrolled. 15 pts underwent curative resection. No v-CTCs at 3 sampling points were detected in 5 pts, and 5 pts survived without recurrences. V-CTCs was identified in 10 of 15 pts, and 4 out of 10 pts developed disease recurrence. Marked increase in CTC counts was observed after NACRT in 5 of 6 CTC-positive pts before NACRT, and 3 of 5 pts developed liver metastasis and died. NACRT may induce tumor cell dissemination into the blood circulation for CTC-positive pts. PD-L1 expression: L1 expression were assessed for 21 pts (U group:18, N group: 3). For PC tumors, L1 molecules were expressed in 12 pts and expression level of these pts were all low (57%, ≥50% [high]=0 pts, 1-49% [low]=12 pts {10%=6, 20%=4, 40%=2}, <1% [negative]=9 pts). For metastatic LNs, metastatic LNs were observed in 14 pts and L1-positive expression in these LNs were detected in only 4 pts (28%, all low expression). On the contrary, the majority of detected v-CTCs clearly expressed L1 molecule (92 CTCs out of 103 detected CTCs were L1-positive=89 %).
Conclusions: Viable CTC detection appears as a good prognostic marker. Immunotherapy with anti-PD-1/PD-L1 Abs may target v-CTCs, resulted in improvement of poor prognosis.

#5604

Circulating tumor DNA for predicting peritoneal only disease recurrence in colon cancer

Kevin C. Chang[1], Daniel Berg[2], Chandrika Chandrasekharan[2], Kelsey Steckly[2], Saima Sharif[2], Carlos H. F. Chan[2].
[1]Carver College of Medicine, University of Iowa, Iowa City, IA,[2]University of Iowa Hospitals and Clinics, Iowa City, IA

Background: Peritoneal Carcinomatosis in Colon Cancer (PCCC) is a major cause of morbidity. Early detection of PCCC is important for early intervention like systemic chemotherapy and cytoreductive surgery (CRS) +/- hyperthermic intraperitoneal chemotherapy (HIPEC). Circulating tumor DNA (ctDNA) testing is a promising method to assess recurrence not detectable yet on imaging, identifying 87.5% of recurrences in Stage I-III CRC with a mean lead-time of 8.7 months. It is unclear if ctDNA testing is sensitive in detection of recurrent PCCC ahead of clinical/radiological presentation.
We report data from 6 CRC patients with PCCC who underwent complete CRS and were followed with serial ctDNA testing.
Methods: In this single institution study, patients with PCCC were included from our prospectively enrolled GI cancer patient cohort (GIMER: IRB #201202743). Peritoneal carcinomatosis at CRS was determined using the Peritoneal Cancer Index. ctDNA concentration in mean tumor molecules/mL of plasma was assessed using a commercially available tumor-informed, personalized ctDNA assay (Signatera™, Natera, Inc.) that uses patient-specific somatic single-nucleotide variants. Plasma samples for ctDNA analysis were collected before surgery, 1, 2, 4, 6 months post-surgery, then every 3 months until a positive ctDNA test triggered CT imaging. Patients also had routine CT imaging every 6 months after surgery.
Results: 5 of 6 patients met endpoint with median time of 35 days from positive ctDNA to recurrence on imaging. In 4 patients, positive ctDNA prompted CT imaging which was negative, but follow-up PET scan was positive. Patient 6 was ctDNA negative and recurrence-free at last follow-up.
Conclusions: This analysis demonstrated the potential of longitudinal ctDNA monitoring for early detection of PCCC recurrence by prompting early imaging. PET was more sensitive in detecting recurrence than CT, and should be considered when determining PCCC recurrence. Enrollment and further analysis of ctDNA continues.

Ambient storage and stabilization of proteins and cell-free nucleic acids in whole blood samples

Jing Li, Lisa Bartron, Jordan LaRue, Sama Mehta, Nicholas M. George. *Streck Laboratories, Inc.®, Omaha, NE*

Introduction: Highly anticipated advancements in biotechnology and instrumentation now allows for simultaneous detection of multiple biomarkers. This is accelerating the cancer research field towards the development of multianalyte-based *in vitro* diagnostic tests for early detection and/or monitoring of cancer. These multianalyte liquid biopsy tests are often based on detection of cancer-related proteins and/or tumor-specific genomic and transcriptomic changes (circulating cell-free nucleic acids) in plasma. A specialized and proprietary stabilization reagent has been developed for use in a blood collection tube with the capability to simultaneously stabilize protein biomarkers of interest and cell-free nucleic acids.
Methods: Blood samples from self-proclaimed healthy donors were drawn into evacuated blood collection tubes containing a new stabilization reagent and stored at room temperature. Plasma was isolated using a general double-spin protocol (1800 ×g for 15 min and 2800 ×g for 15 min) and frozen at -80 °C until use. Plasma levels of proteins of interest including cancer markers and immuno-oncology checkpoint markers were measured by Ella Simple Plex Assays (Bio-Techne) and Luminex xMAP® Technology Assays (Bio-Techne, samples tested by LuminexPLORE Lab). Total cell-free nucleic acids were isolated using the QIAamp Circulating Nucleic Acid Kit and the resultant cfDNA or cfRNA was analyzed with fluorometric-based assay (quantitative) and Bioanalyzer / Tapestation (qualitative).
Results: Compared with blood samples collected in EDTA and ACD-A tubes, the new stabilization reagent maintained the draw time levels of plasma proteins of interest such as TGF-β1, MMP-9, IL-8/CXCL8, CCL5/RANTES, Granzyme B, CEA and PD-L1 for up to 5 days of room temperature storage in whole blood. The reagent also effectively maintained draw time levels of plasma cell-free nucleic acids to near draw time levels. In addition, the new reagent also minimized *in vitro* hemolysis during room temperature storage.
Conclusion: This new and breakthrough stabilization reagent simultaneously maintains the draw time levels of proteins of interest and cell-free nucleic acids for an extended period of time in whole blood. It provides cancer researchers and clinical assay developers confidence in blood sample integrity and flexibility in sample storage, transport, and processing at ambient temperature for multianalyte analysis or multiomics profiling.

Dynamics of sequence and structural cell-free DNA landscapes in small-cell lung cancer during systemic therapy

Lavanya Sivapalan[1], Wade T. Iams[2], Zineb Belcaid[1], Susan C. Scott[1], Noushin Niknafs[1], Archana Balan[1], James R. White[1], Prasad Kopparapu[2], Christopher Cann[2], Blair V. Landon[1], Gavin Pereira[1], Victor E. Velculescu[1], Christine L. Hann[1], Christine M. Lovly[2], Valsamo Anagnostou[1]. *[1]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Division of Hematology-Oncology, Department of Medicine, Vanderbilt University Medical Center and Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: Patients with small-cell lung cancer (SCLC) have an exceptionally poor prognosis and may not always undergo biopsies for molecular testing, necessitating real-time non-invasive biomarkers of early therapeutic response to ultimately enable timely intervention and improve patient outcomes.
Methods: We performed targeted error-correction sequencing on serial plasma cell-free DNA (n=139) and matched white blood cell (WBC; n=32) DNA from 33 patients with metastatic SCLC who received treatment with chemotherapy (n=16) or immunotherapy-containing (n=17) regimens. Tumor-derived sequence mutations and plasma aneuploidy were tracked longitudinally using a tumor-agnostic WBC DNA-informed approach and combined to evaluate changes in total cell-free tumor load (cfTL). Dynamic changes in cfTL were monitored for each patient to determine circulating tumor DNA (ctDNA) molecular response during therapy.
Results: Longitudinal assessment of cfTL dynamics allowed for the evaluation of molecular response in all patients studied. Overall, 9 patients were classified as molecular responders based on sustained complete

elimination of cfTL. For 14 patients, we observed initial molecular responses, followed by cfTL recrudescence. In a subset of 10 patients we observed a distinct pattern of molecular progression characterized by cfTL persistence across all timepoints analyzed. Patients with sustained molecular responses attained longer overall (OS; log-rank p=0.0006) and progression-free (PFS; log-rank p<0.0001) survival, with molecular responses detected on average 4 weeks earlier than imaging. Importantly, ctDNA molecular response remained the most significant predictor of OS (molecular response vs molecular progression HR=0.09, 95% CI=0.02-0.42, p=0.002; molecular response f/b recrudescence vs molecular progression HR=0.14, 95% CI=0.04-0.48, p=0.002) and PFS (molecular response vs molecular progression HR=0.02, 95% CI=0.00-0.16, p<0.001; molecular response f/b recrudescence vs molecular progression HR=0.05, 95% CI=0.01-0.26, p<0.001) after adjustment for clinical covariates in a multivariate cox proportional hazards regression model. Analysis of landmark OS and PFS endpoints revealed that molecular responses more accurately predicted OS at 12 (AUC 78.1% vs 73.3%) and 64 months (AUC 87.3% vs 67.6%) and PFS at 3 (AUC 91.7% vs 82.0%) and 12 months (AUC 83.5% vs 78.8%) compared to conventional imaging. Conclusions: Longitudinal tracking of sequence and structural ctDNA features provide an accurate and rapid approach to track changes in tumor burden and prognosticate outcomes during systemic therapy in patients with SCLC. These findings suggest that therapeutic response monitoring based on combined molecular response criteria may be used to provide guidance on clinical decision making for patients with SCLC.

Introduction: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) is a standard modality of the 1st-line treatments for patients with EGFR-mutated non-small-cell lung cancer (NSCLC). The FDA approved osimertinib, a third-generation EGFR-TKI, is highly selective for EGFR-activating mutations (exon 19 deletion [del19] or L858R point mutation in exon 21 [L858R]) as well as EGFR-T790M mutation. Nevertheless, resistance inevitably emerges and leads to disease progression. Acquired EGFR-C797S mutation is the most common on-target resistance mechanism to osimertinib in first- and second-line settings, and there are currently no approved targeted therapies. We aimed to evaluate the efficacy of BI-732, a fourth-generation EGFR-TKI developed to overcome the C797S mutation. Materials and Methods: We constructed several types of Ba/F3 cells expressing EGFR mutations containing the C797S mutation as follows: EGFRdel19/C797S, EGFRL858R/C797S, EGFRdel19/T790M/C797S, and EGFRL858R/T790M/C797S. We also constructed PC9 cells harboring EGFRdel19/C797S (named PC9-DC cells) using the CRISPR/Cas9 system. Furthermore, we generated two patient-derived cells, YU-1097 with EGFRdel19/T790M/C797S and YU-1182 with EGFRL858R/C797S. The in vitro efficacy of BI-732 was tested in several cell lines harboring the EGFR-C797S mutation mentioned above. We further evaluated in vivo antitumor activity of BI-732 in subcutaneous YU-1097 xenograft model and intracranial YU-1097-tumor model.Results: BI-732 effectively inhibited the viability of Ba/F3 cells expressing EGFRdel19/C797S (IC50, 6.8 nM), EGFRL858R/C797S (IC50, 213.4 nM), EGFRdel19/T790M/C797S (IC50, 3.8nM), and EGFRL858R/T790M/C797S (IC50, 15.2 nM), concomitant with marked reduction in EGFR and downstream signal phosphorylation. Moreover, BI-732 exhibited comparable nanomolar in vitro activity to

osimertinib on EGFR activating mutation while sparing wild-type EGFR activity. We further confirmed the superior antiproliferative efficacy of BI-732 in PC9-DC (IC50, 24.9 nM), YU-1182 (IC50, 73 nM) and YU-1097 cells (IC50, 2.9 nM). Oral administration of BI-732 at a concentration of 25 mg/kg as a single agent resulted in significant tumor regression with 183.2% tumor growth inhibition (TGI) in the subcutaneous YU-1097 xenograft model. In a combination treatment strategy with osimertinib, BI-732 showed enhanced antitumor activity at much lower concentrations than monotherapy. BI-732 also demonstrated the ability to penetrate brain-blood barrier (BBB) in the intracranial YU-1097-tumor models.Conclusions: BI-732 is a potent, selective, and orally available fourth-generation EGFR-TKI for EGFR mutations including C797S and has efficient BBB penetration. Our findings suggest that BI-732 can be effective against EGFR mutant NSCLC, especially EGFRDel19/T790M/C797S and EGFRDel19/C797S, that have progressed with previous EGFR inhibitors.

DIACC3010, optimized inhibitor of S6 kinase, combined with endocrine therapy, has potent antitumor activity in treatment-resistant ER-positive HER2-negative metastatic breast cancer

Christel Navarro[1], Apostolia Maria Tsimberidou[2], Cecile Bougeret[1], Elsa Borghi[1], Dominique Bridon[1], Helene Sicard[1]. *[1]DIACCURATE, Paris, France,[2]Investigational Cancer Therapeutics, The University of Texas, MD Anderson Cancer Center, Houston, TX*

Background: Ribosomal protein S6 kinase (S6K) is a key regulator of estrogen receptor (ER) function, and its high expression is associated with poor clinical outcomes in breast cancer (BC). Recent data have demonstrated that S6K is involved in resistance to CDK4/6 inhibitors in metastatic BC (MBC). DIACC3010 (formerly M2698) is an oral brain-penetrant potent inhibitor of S6K. By design, DIACC3010 also selectively inhibits AKT1 and AKT3, while sparing AKT2. DIACC3010 was previously evaluated in a phase 1 trial (NCT01971515). We performed exploratory correlative analyses of the phase 1 trial in ER+ HER2-negative MBC patients in addition to nonclinical experiments to evaluate its role in the CDK4/6 and endocrine therapy (ET) resistant setting.
Methods: DIACC3010 was evaluated as monotherapy, or combined with either trastuzumab or tamoxifen, in a multicenter phase 1 trial that accrued 101 patients with advanced/refractory solid tumors (Tsimberidou et al, J Hematol Oncol 2021 14(1):127). The current analysis focused on patients with ER+ HER2-negative MBC and aimed to explore the efficacy of DIACC3010 according to *ESR1* mutational status. DIACC3010 was also evaluated in tamoxifen resistant patient-derived xenograft (PDX) mouse models, both alone and combined with tamoxifen.
Results: Twenty patients were evaluable at baseline for their tumor mutational status and included in the analysis. Median age was 60 years and median number of prior lines of therapy was 5.5. Twelve of 20 (60%) patients had received prior treatment with CDK4/6 inhibitors. Nine of 20 patients (45%) had *ESR1* mutations, of whom 4 had received CDK4/6 inhibitor. Median progression free survival was 5.6 months in patients with *ESR1* mutations, and 2.6 months in patients with *ESR1* wild-type tumors. Among the 13 ER+ BC PDX models evaluated, 10 provided interpretable results and 4 were found resistant to tamoxifen. The combination of DIACC3010 and tamoxifen significantly reduced tumor growth in 6/10 (60%) of all PDX models, and in 4/4 (100%) of the tamoxifen-resistant PDX models.
Conclusions: Exploratory analyses from the phase 1 trial, along with nonclinical efficacy in PDX models, demonstrate that DIACC3010 may have antitumor activity in MBC patients with ET resistance. Experiments are underway to assess nonclinical efficacy of DIACC3010 combination with elacestrant or CDK4/6 inhibitors in various models of ER+ MBC, including ET resistant.

Up284, A small molecule inhibitor of ADRM1 demonstrates significant anti-tumor efficacy in preclinical models of aggressive breast cancer

Balasubramanyam Karanam[1], Ravi Anchoori[2], Yung-Nien Chang[2], Rachel Martini[3], Florencia Madorsky Rowdo[4], Melissa B. Davis[4]. *[1]Tuskegee University, Tuskegee, AL,[2]Up Therapeutics LLC, Frederick, MD,[3]Surgery, Weill Cornell Medicine, New York, NY,[4]Englander Institute for Precision Medicine, Weill Cornell Medicine, New York, NY*

Quadruple-negative breast cancer (QNBCs) is a highly aggressive and metastatic disease and remains clinically challenging breast cancer subtype with worst prognosis. Due to its exceeding heterogeneity, absence of the AR, ER, PR, Her2 receptors and lack of established therapeutic targets, QNBC is hard to treat cancer and recurs rapidly

with standard chemo regimen. QNBC demonstrated vulnerability to proteasome inhibition due to their higher metabolic needs. But FDA approved 20S proteasome inhibitors failed to treat solid tumors including QNBC. Hence, developing an effective strategy to overcome the limitations associated with current 20S proteasome inhibitors is mandated to provide alternate treatment options for QNBC patients. Preclinical, Up Therapeutics lead candidate small molecule inhibitor Up284 has shown significant tumor growth inhibition as a single agent in animal models. To explore potential synergy of Up284 with other therapeutic agents, we conducted the in vivo combination experiments. In this work, we present ADRM1 amplification in QNBC tumors, identification of a small molecule selective inhibitor of ADRM1, Up284 (Up Therapeutics), Up284 demonstrated efficacy against panel of BC cell lines and patient derived organoids. In vivo combination results for Up284 with widely used BC standard-of care chemotherapy regimen demonstrated strong in vivo synergy in tumor mouse syngeneic models. Taken together, these data demonstrated combination synergy of a small molecule ADRM1 inhibitor with other agents. These results pave the road for potential clinical evaluation of combination treatment of QNBC in patients.

Targeting of eIF4A1 curtails lung metastases in triple-negative breast cancer

Sangita Sridharan[1], Shobhit Srivastava[1], David Terrero[2], Saloni Malla[2], Amit K. Tiwari[3], Dayanidhi Raman[1]. *[1]Cell and Cancer Biology, University of Toledo Health Science Campus, Toledo, OH,[2]Pharmacology & Experimental Therapeutics, University of Toledo, Toledo, OH,[3]Pharmacology and Experimental Therapeutics, University of Toledo, Toledo, OH*

Triple-negative breast cancer (TNBC) is an aggressive type of breast cancer. Patients diagnosed with TNBC benefit less or none from any current targeted therapies and also the standard-of-care neoadjuvant chemotherapies (NACT) which is cytotoxic. TNBC shows an increased risk of tumor relapse, therapy failure, and high proclivity to develop distant metastases. Intrinsic resistance to NACT is mainly due to a small population of breast cancer cells that acquire stem cell-like features (BCSCs). BCSCs are capable of self-renewal, proliferation, plasticity, immune regulation and chemoresistance. These properties mediate tumorigenesis, metastasis, and resistance to NACT and sometimes even to targeted therapy. Overall, FDA-approved drugs that are effective for advanced TNBC are currently unavailable.

The eukaryotic translation initiation factor (eIF4A1) is an mRNA helicase that catalyzes the ATP-dependent unwinding of many oncogenic mRNAs which harbor secondary structures in the 5' leader region. There is preferential reliance on eIF4A1 by tumor cells as many oncogenic mRNAs require the helicase activity of eIF4A1 for their efficient translation. Several eIF4A1-dependent mRNAs (downstream effectors) include: survivin (survival), c-MYC, STAT1 (immunoevasion through transcription and subsequent translation of PD-L1), Rho kinase1 (invasion), and Cyclins D1 and D3. Bioinformatic analyses revealed that higher gene expression of eIF4A1 significantly impacts patient survival. Clinically, an enhanced protein expression of eIF4A1 was evident in histopathologic analyses of drug-resistant human TNBC biospecimens. Importantly, our *in vitro* data indicated that the viability of BCSCs was significantly reduced when eIF4A1 is targeted by nanomolar levels of Rocaglamide A (RocA). Furthermore, in paclitaxel-resistant TNBC cells, there is an upregulation in the total levels of eIF4A1 and its downstream effectors. Pluripotency transcription factors (e.g., SOX2, OCT4 and NANOG) and drug transporters (ABCB1, ABCG2 and ABCC1) were also increased in an eIF4A1-dependent manner. Genetic ablation and pharmacological targeting of eIF4A1 with RocA reversed the drug-resistant profile. Our *in vitro* data implied a key role for eIF4A1 in chemoresistance/therapy failure. Targeting of eIF4A1 may be an effective anti-cancer strategy to overcome drug resistance. To this end, we orthotopically implanted CRISPR-control (CC) and eIF4A1-KO (KO) human TNBC cells and evaluated the primary tumor progression and metastases in NOD/SCID-*beige* mice. Longitudinal tumor progression was followed by IVIS imaging. The tumor volume and the wet weight was significantly higher in CC than KO tumors (n=7 mice). Similarly, the lung metastatic burden is significantly low in KO than CC mice (n=7 mice; $p<0.002$)). Taken together, we propose that eIF4A1 is an actionable molecular target for drug-resistant TNBC using chemotherapy/immunotherapy.

#4480

Treatment of PTEN/PI3K co-mutated endometrial adenocarcinoma with multitarget small molecule inhibitors

Ritchie Delara[1], Cody McHale[2], Dhananjaya Pal[2], Krishnaiah Maddeboina[2], R. Wendel Naumann[1], Erin Crane[1], Jubilee Brown[1], Donald Durden[2]. *[1]Division of Gynecologic Oncology, Levine Cancer Institute, Charlotte, NC,[2]Molecular Targeted Therapeutics Laboratory, Levine Cancer Institute, Charlotte, NC*

Introduction: The objective of this study is to assess the feasibility and safety of treating endometrial adenocarcinoma (EC) with multitarget inhibitors which orthogonally target known oncogenic kinases and epigenetic regulators. The Molecular Targeted Therapeutics Laboratory has developed nanomolar potent multitarget small molecule chemotypes that inhibit the PI3K/Akt/mTOR pathway, cancer-associated kinases, and epigenetic regulatory proteins such as BRD4 *in vitro* and *in vivo*.
Methods: Two EC cell lines (AN3-CA, RL95-2) were treated with varying concentrations of triple PI3K/BRD4/CDK4/6/9 inhibitor LCI132 and dual PI3K/CDK4/6/9 inhibitors LCI133 and LCI136 for 48 hours; and cell viability assays were performed with IC_{50} determination. EC cells were treated with multitarget inhibitors and other indicated inhibitors of PI3K, BET, CDK4/6, and CDK9 for 24 hours; and lysates were prepared accordingly for Western blot (WB) and qRT-PCR analyses. Flow cytometry was conducted for cell cycle and apoptosis assays.
Results: In cell-free assays, LCI132 is a nanomolar inhibitor of PI3K/BRD4/CDK4/6/9, LCI133 is a picomolar inhibitor of CDK9, and LCI136 is a nanomolar inhibitor of PI3K and CDK9. LCI133 demonstrated nanomolar potency towards AN3-CA (IC_{50} 248 nM) and RL95-2 (IC_{50} 105 nM). LCI136 demonstrated nanomolar potency towards AN3-CA (IC_{50} 631 nM) and RL95-2 (IC_{50} 728 nM). WB demonstrated 24-hour treatment of *FBXW7mut* AN3-CA with LCI132 inhibited AKT phosphorylation but an increase in c-MYC protein expression. A corresponding increase in c-Myc gene expression at 24 hours was confirmed on qRT-PCR. In *FBXW7wt* RL95-2, LCI132 decreased c-Myc protein expression. LCI132 demonstrated dose-dependent G1 arrest, and dose-dependent pre-apoptotic and apoptotic activity.
Conclusions: Dual-target inhibitors LCI133 and LCI136 are nanomolar potent in AN3-CA and RL95-2 EC cell lines, suggesting a role of CDK9 inhibition of PTEN/PI3K co-mutated EC. Preliminary studies demonstrate an upregulation of MYC gene and protein expression in *FBXW7mut* EC but not *FBXW7wt*, and the role of FBXW7 as a predictive biomarker in treatment of PTEN/PIK3R1 co-mutated EC warrants further investigation.

#4481
Vrtx153, novel small molecule inhibitor of krasg12d
Prashant Kashinath Bhavar[1], Uday Kumar Surampudi[1], Partha Pratim Sarma[2], Anuj Ramesh Kshirsagar[2]. *[1]VRise Therapeutics Inc., Cambridge, MA,[2]VeGen Therapeutics, Hyderabad, India*

Pancreatic cancer is an intractable malignancy and is the seventh leading cause of global cancer deaths in industrialized countries and the third most common in the USA. Despite advancement in the knowledge of potential risk factors that cause pancreatic cancer and newly available tools for early diagnosis, its incidence is estimated to increase and will include 0.35 mln new cases within 2040. *KRAS* is the predominant isoform mutated in cancer and are found in 92-95% of Pancreatic Cancer patients, dominated by somatic mutations of $KRAS^{G12D}$. $KRAS^{G12D}$, is one of the most frequently mutated oncogenes across adenocarcinoma of *Pancreas (51%), Colon and Rectal (13.4%) and Lung (3%)*. With KRAS mutations found in nearly all PDAC, this cancer type is arguably the most *RAS*-addicted cancer. $KRAS^{G12D}$ is a clinically relevant target but owing to structural complexity of the protein, poses challenges for its effective inhibition. Previously, we reported a series of compound including a proprietary tool compound *VTRX144*, with low nM potency in 2D (<25 nM). Optimized lead from VRise de-novo platform has yielded an unparallel potent, highly selective, inhibitor, namely *VRTX153*. *VRTX153* demonstrated high-affinity for $KRAS^{G12D}$ in a GDP-loaded $KRAS^{G12D}$ assay, with an IC50 value of less than 2 nM and more than1500 -fold selectivity over $KRAS^{WT}$, KRAS mutants and other RAS proteins including HRAS & NRAS. VRTX153 inhibited ERK1/2 phosphorylation (pERK) and cell viability in $KRAS^{G12D}$-mutant cell lines in both 2D and 3D, as evaluated by CellTiter-Glo®. In-vivo translation of activity in a mouse xenograft model representing PDAC is being investigated.

Discovery of GH2616, a potent and selective KIF18A inhibitor with robust *in vivo* efficacy in p53 mutant cancer

Jie Jack Li, Guiping Zhang, Jiapeng Li. *Suzhou Genhouse Pharmaceutical Co., Ltd., Suzhou, China*

Chromosomal instability (CIN) is one of the hallmarks of cancer. Cancer cells often undergo whole-genome doubling (WGD) and P53 represents a major barrier to the proliferation of WGD+ cells. Therefore, cancer cells with either CIN or WGD often harbor the p53 mutation. Recently, KIF18A has emerged as a potential therapeutic target in CIN or WGD cancer cells. We have identified a potent and selective KIF18A inhibitor, GH2616. *In vitro*, GH2616 inhibited the kinesin motor activity with an IC_{50} less than 50 nM, and with an EC_{50} less than 50 nM in the mitotic index assay using HT29 cells (WGD). *In vivo*, GH2616 inhibited the growth of WGD CDX models with a dose dependent manner. GH2616 has good oral bioavailability in different species and metabolic stability for QD dosing. This compound also showed low potential of DDI thus suitable for drug combinations. In a cell panel with more than 200 cell lines, GH2616 selectively inhibit the growth of cells with p53 mutant and some other specific biomarkers in multiple tumor types. In conclusion, we discovered GH2616 as a novel KIF18A inhibitor with potent *in vivo* efficacy. It is currently under evaluation in IND-enabling studies and IND filing is expected in Q4, 2023.

Distinct spatial distribution patterns of ALK-inhibitor naïve versus ALK-inhibitor treated ALK-positive NSCLC brain metastases

Tia Cheunkarndee[1], Paola Ganem[2], Kristen A. Marrone[2], Joseph C. Murray[2], Josephine L. Feliciano[2], Christine L. Hann[2], Susan C. Scott[2], David Ettinger[2], Valsamo Anagnostou[2], Patrick M. Forde[2], Julie R. Brahmer[2], Benjamin P. Levy[2], Vincent Lam[2], David O. Kamson[3]. *[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Thoracic Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Neuro-Oncology, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Non-small cell lung cancer (NSCLC) with anaplastic lymphoma kinase rearrangement (ALK+) has a high affinity to form brain metastases (BrM). The cumulative incidence of BrMs in ALK+ lung cancer is over 50%, despite highly effective ALK tyrosine kinase inhibitors (TKIs) with CNS activity. Pharmacokinetic (PK) data from other CNS-active lung cancer TKIs (e.g., osimertinib) have revealed major brain white vs. gray matter drug concentration differences, raising the possibility of a PK-driven effect on BrM formation and response. This study aims to compare the size and distribution of ALK+ NSCLC BrMs at diagnosis in a TKI-naïve and TKI-exposed cohort.

Methods: We retrospectively reviewed brain MRIs from the date of BrM diagnosis for patients with ALK+ NSCLC at Johns Hopkins. Demographic and clinical information were collected by chart review. Each tumor was marked in a standard space brain model in the corresponding anatomic location represented by a sphere of corresponding diameter using 3D Slicer 4.11. FreeSurfer white-gray matter atlases were used to assess BrM distribution. The data for patients who were on TKI vs TKI-naïve at the time of BrM diagnosis were then analyzed separately. T-tests were used to compare the metastatic burden (sum of BrM diameters), mean BrM diameter per patient, number of BM per patient, per individual mean of *white matter exclusive* (defined as no overlap with gray matter) and *deep white matter* (≥5mm away from gray matter) BrMs between patient groups.
Results: 429 BrMs were identified in 39 patients, with 25 patients being TKI-naïve at the time of BrM diagnosis while 14 patients were on TKI therapy. TKI-exposed patients had significantly smaller BrM diameters than those in the TKI-naïve group (6.1±3.8 vs 10.2±5.5mm, p=0.02). While metastatic burden was very similar between the groups, the mean number of BrM per patient was numerically higher in the TKI-exposed group (10.6±11.9 vs 6.2±9.5; p=0.22). Notably, patients in the TKI-exposed group also had higher numbers of white matter exclusive (3.5±4.4 vs 1.4±2.0, p=0.05) and deep white matter metastases (3.2±4.3 vs 1.3±2.0, p=0.06) than those who were TKI-naïve.
Conclusion: Our data highlight the differences in BrM characteristics among ALK+ NSCLC exposed to ALK TKI. TKI therapy was associated with similar BrM burden but smaller individual lesions that were more likely to be exclusive to the white matter where drug concentrations might be significantly lower. These findings suggest that suboptimal drug CNS distribution in the white matter may underly brain progression of ALK+ NSCLC despite TKI therapy. Spatial analyses evaluating ALK TKIs of varying CNS penetrance and later disease time points in more granular anatomic regions are ongoing.

HER3 expression after systemic therapy and clinical characteristics in patients with hepatocellular carcinoma

Mao Okada[1], Chigusa Morizane[1], Tomoyuki Satake[1], Mariko Nishioka[1], Nobuyoshi Hiraoka[2], Satoshi Nara[3], Tomoya Kakegawa[4], Maki Kobayashi[4], Kumiko Koyama[5], Minoru Esaki[3], Takuji Okusaka[1].
[1]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital - Japan, Tokyo, Japan,[2]Division of Pathology and Clinical Laboratories, National Cancer Center Hospital - Japan, Tokyo, Japan,[3]Department of Hepatobiliary and Pancreatic Surgery, National Cancer Center Hospital - Japan, Tokyo, Japan,[4]Translational Research Department, Daiichi Sankyo RD Novare Co., Ltd., Tokyo, Japan,[5]Translational Science Department I, Daiichi Sankyo Co., Ltd., Tokyo, Japan

Background: In hepatocellular carcinoma (HCC), several standard regimens with angiogenesis inhibitors and immune checkpoint inhibitors have been established; however, novel therapeutic strategies to target key molecules associated with HCC are further required to improve treatment options. ErbB3 (HER3), a member of the HER receptor tyrosine kinase family, has recently emerged as a promising therapeutic target in various cancers. In this study, HER3 expression status after current targeted therapies in HCC was evaluated in order to explore an opportunity for developing anti-HER3 therapy for HCC.
Methods: We collected clinical data and tumor tissue from HCC patients (pts) who received systemic therapy between January 2010 and June 2020 and the tissue samples at post systemic therapy were also obtained. Immunohistochemical staining for HER3 was conducted using HER3/ErbB3 (D22C5) XP Rabbit mAb (Cell Signaling Technology) as a primary antibody. IHC scoring (0, 1+, 2+, 3+) of membranous staining intensity was performed according to HER2 IHC gastric scoring guideline.
Results: Seventeen pts were eligible. Eight pts (47%) were HER3 2+/3+, (2+: 7, 3+: 1,), while nine pts (53%) were 0/1+ (0: 4, 1+: 5). For HER3 2+/3+ and HER3 0/1+ groups, median age (range) was 63(43-71)/69(47-78), median alpha-fetoprotein levels were 6071(4-23620)/19.1(1.2-1138) [ng/ml], and median des-gamma-carboxy prothrombin levels were 1351(135-92650)/302(10-10916) [mAU/ml], respectively. The proportions of patients with HER3 2+/3+ were 67% in HCV+ pts, 25% in HBV+ pts, and 43% in other etiologies. Median overall survival of HER3 2+/3+ and 0/1+ pts after start of first line systemic therapy was 32.3 (95% CI: 8.7-51.4) and 12.9 (95% CI: 6.1-20.7) months, respectively (HR: 0.28, 95% CI: 0.09-0.92,

p=0.036).Paired pre- and post-treatment samples were available for eight pts. The median number of regimens administered between the pre- and post-treatment samples was 2(1-5). Treatment regimens were sorafenib: 7; lenvatinib: 2; ramucirumab: 1; others: 10, including duplicates. At post-treatment, HER3 was upregulated in 4 pts (1 pt: 0 to 1+, 3 pts: 1+ to 2+) and downregulated in 3 pts (all pts: 1+ to 0). Pts with HER3 upregulation had developed resistance after at least one prior tyrosine kinase inhibitor (TKI) with stable disease or partial response as best response.
Conclusion: In this study, 47% of pts were HER3 2+/3+ at post-treatment. In paired analysis, half of pts upregulated HER3 expression after systemic therapy including TKIs, suggesting HER3 might be one of the factors associated with resistance to systemic therapy.

#4485

JPI-547, a novel dual inhibitor of PARP 1/2 and tankyrase 1/2 overcomes olaparib resistance in BRCA 1/2 mutant ovary and breast cancer preclinical model

Min Sil Kang[1], Nar Katuwal[1], Mithun Ghosh[1], Young kyu Jeong[1], Sa deok Hong[1], Sung Min Park[1], John Kim[2], Hyunju Cha[2], Banyoon Cheon[2], Seul-Gi Kim[1], Yong Wha Moon[1]. *[1]CHA University, Seongnam-si, Korea, Republic of,[2]Onconic Therapeutics Inc., Seoul, Korea, Republic of*

PARP inhibitors have prolonged the survival of various cancer patients with homologous recombination (HR) deficiencies. However, most patients eternally acquire resistance. Many attempts have been made, but there are no clear strategies to overcome resistance. We evaluated the efficacy and mechanism of JPI-547, a novel dual inhibitor of PARP1/2 and tankyrase1/2, in olaparib resistant breast and ovary preclinical cancer models. We established olaparib resistance models using mammalian cancer cell lines and patient-derived tumor xenografts (PDTXs). Two olaparib-resistant cells cell lines (BT474-OR/SNU251-OR) were established by exposing parent BRCA1/2 mutation carrying BT474 and SNU251 (breast and ovary cancer) to gradually increasing the concentration of olaparib for 8 months. An olaparib-resistant PDTX model [WJO-003(O2)], the parent BRCA1 mutation carrying ovary cancer PDTX was engrafted and treated with olaparib in 75mg/kg twice daily for 1 month and then 100mg/kg twice daily for 3 months. Using established olaparib resistance models, the anti-tumor efficacy of JPI-547 was compared with olaparib, niraparib, and talazoparib. IC_{50} of BT474-OR and SNU251-OR cell lines showed 5.5 and 6.7 fold increase compared to those of parent cell lines, respectively. While JPI-547 treatment in BT474-OR and SNU251-OR showed similar IC_{50} to the matching parent cells. In the PARPi-sensitive PDTX model, CPDX-013, JPI-547 inhibited tumor growth the greatest among other PARP inhibitors. Remarkably, 4 of 7 mice showed complete regression of the tumors. In the olaparib-resistant PDTX model, WJO-003(O2), JPI-547 inhibited tumor growth the most effectively compared to other PARP inhibitors (at day 60, the mean tumor volume: 2539, 1319, 871, 601, and 29 mm^3 in control, niraparib, olaparib, talazoparib, and JPI-547, respectively; $p<0.01$). Since JPI-547 treated groups suppressed the tumor growth the most effectively both in olaparib-sensitive and resistant PDTX, to test whether JPI-547 is effective in prior PARPi-exposed tumor, we switched a PARPi to JPI-547 when most of PARPi treated tumors slowly retrieved the tumor growth. This subsequent treatment of JPI-547 completely suppressed the growth of tumor compared to a single other PARPi treated groups in both olaparib-sensitive and resistant models. The data suggest that JPI-547 efficiently inhibits growth of the tumor previously exposed to other PAPRi. JPI-547 treated tumors showed a decrease of RAD51 in comparison to other PARPi treated groups, which is likely mediated by inhibition of tankyrase 1/2 by JPI-547 and suppression of TNK1/2-MERIT40 complex. Then this suppression resulted in blockade of HR repair.JPI-547 showed promising efficacy in an olaparib-resistant preclinical model. JPI-547 merits further clinical development in the PARP inhibitor-resistant ovary and breast cancer.

Proof of principle for pharmacogenomic-guided precision oncology for pediatric malignancy

Gi Ju Lee[1], Seung-Won Choi[2], Seung Ah Choi[3], Hee-Jin Cho[4], Robyn Gartrell[5], Ji Won Lee[6], Joo Whan Kim[3], Nam-Gu Her[1], Raul Rabadan[2], Ki Woong Sung[6], Do-Hyun Nam[6], Seung-Ki Kim[3]. *[1]Aimed Bio Inc., Seoul, Korea, Republic of,[2]Columbia University, New York, NY,[3]Seoul National University Hospital, Seoul,*

Korea, Republic of,[4]Kyungpook National University, Daegu, Korea, Republic of,[5]Columbia University Irving Medical Center, New York, NY,[6]Samsung Medical Center, Seoul, Korea, Republic of

Childhood cancers are rare and clinically diverse. They are typically associated with few driver mutational events than adult cancers, constituting potential targets for patient-specific precision therapy approaches. Here, we evaluated the feasibility of using a patient-derived tumor cell (PDC) based drug screening system and integrated multi-omics data to achieve precision oncology for pediatric patients. We established a PDC library derived from a few passage-cultured tumor cells from surgically resected tumor specimens and conducted chemical screening, which composed of various target agents of major oncogenic pathways (e.g. receptor tyrosine kinase inhibitor, proteasome inhibitor and histone deacetylase etc.). Next Generation Sequencing was performed to characterize the genomic and transcriptomic traits of tumors. Overall, success of establishing PDCs of pediatric cancers was high (80.4%) and comparable to adult cancers. The amount of obtained tissue was an important factor for the success of PDC establishment; the estimated optimal weight for PDC establishment was small (1.14g) and it is noteworthy that a small amount of tumor sample is sufficient to identify the potential hit(s) of parental tumors. The platform provided therapeutic options to pediatric tumors regardless of actionable targets. Our PDC approach identified several potential gene-drug associations, including anti-PI3K/Akt agents for neuroblastomas and anti-SHH agents for sarcomas with EWSR1 fusion. Given that a considerable proportion of pediatric tumors still lack actionable targets with matched treatment options, PDC-based drug screening profiles can be an optimal therapeutic strategy for these cases. Collectively, our analysis confirmed the feasibility of PDC-based in vitro drug screening systems to guide the therapeutic strategy for pediatric patients. This approach will accelerate the preclinical research for pediatric tumors to understand their pathophysiology and investigate the potential therapeutic strategies to fulfill the future precision oncology.

#4487

Effective anti-tumor effect in a rare metastatic Wilms tumor xenograft by inhibition of RAS/PI3K hyperactivation

Mohammad Reza Saadatzadeh[1], Khadijeh Bijangi Vishehsaraei[1], Erika A. Dobrota[1], Barbara J. Bailey[1], Lauren E. Hein[2], Kathryn L. Coy[3], Melissa A. Trowbridge[1], Anthony L. Sinn[3], Troy A. Markel[3], Michael J. Ferguson[3], Pankita H. Pandya[1], Karen E. Pollok[1]. *[1]Pediatrics, Indiana University School of Medicine, Indianapolis, IN,[2]University of Michigan, Ann Arbor, MI,[3]Indiana University School of Medicine, Indianapolis, IN*

Wilms Tumor (WT) is an embryonal renal tumor that accounts for more than 90% of kidney tumors in children. Significant advances in multidisciplinary therapeutic approaches have increased survival rates up to 90%. However, approximately 15% of patients with favorable histology and 50% of patients with anaplastic WT experience recurrence of disease. Thus, there is still a critical need to develop therapies that are effective and safe for these patients with progressive disease. To address this, we have developed a pipeline of patient derived xenograft (PDX) models from single academic institution patients with metastatic and aggressive cancers. Among these we have developed 3 xenograft models derived from patients with WT. To gain a detailed understanding of the complex array of mutations and identify therapeutic targets, molecular signatures were obtained at the DNA and protein levels via whole genome sequencing and reverse phase protein array analyses respectively. While PDX derived from encapsulated WT specimens exhibited basal levels of PI3K and MAPK pathway activation, which are well-known for promoting tumor survival, growth, and metastasis, no mutations that drive hyperactivation of these pathways were identified in these PDX. In contrast, a rare WT xenograft (PDX120) was established from a female patient with recurrent disease and metastatic cancer in the liver. -OMICS data indicated hyperactivation of PI3K (PIK3CA p.H1047R) and MAPK (KRAS p.G12_G10ins) which was validated by qPCR and immunoblotting in original tumor sample and serially passaged PDX120 xenografts. -OMICS data also confirmed the fidelity of the molecular signature between the original tumor sample and the serially passaged PDX120. The metastatic WT model was screened with two FDA approved drugs as single agents: Trametinib (MAPK pathway inhibitor; BID M-F 1mg/kg PO Day 1-35) or Alpelisib (PI3K pathway inhibitor; QD M-F 50mg/kg PO: Mice were dosed Day 1-29, followed by a gap period, and then dosing re-initiated, Day 86-103). Trametinib therapy did not

effectively attenuate PDX120 tumor growth. In contrast, the PI3K inhibitor Alpelisib was well tolerated and significantly decreased PDX120 growth and prolonged survival compared to the vehicle control (Two-way ANOVA, Holm-Sidak, $p<0.05$). At the end of the study, histological analyses indicated a complete lack of Ki67+ and tumorigenic cells in the Alpelisb-treated tumors compared to vehicle controls, indicating a dominant growth dependency on PI3K pathway activation. While efficacy data generated in PDX derived from patients is not used to guide clinical decisions at this time, it can validate therapeutic approaches and provide rationale for future clinical trials. In conclusion, these studies provide critical feasibility data that has high translational value and great potential to improve survival and quality of life for children suffering with progressive WT.

#4488

TY-4028: a novel, targeted therapy for non small-cell lung cancer with EGFR exon 20 or HER2 exon 20 insertion mutations

Jun Li[1], Chengshan Niu[2], Zhongwei Guo[2], Huan Wang[3], Bailu Zheng[3], Yuge Dou[2], Apeng Liang[1], Kaige Ji[2], Shengli Dong[1], Meihua Li[1], Yanchao Zhao[2], Yazhen Zhang[2], Aishen Gong[3], Hao Liu[2], Xinmiao Hu[2], Hui Su[3], Mingyu Jiang[3], Shaoqing Chen[3], Xiugui Chen[3], Yusheng Wu[1]. *[1]TYK Medicines, Inc., Huzhou, China,[2]TYK Medicines, Inc., Zhengzhou, China,[3]TYK Medicines, Inc., Shanghai, China*

Epidermal growth factor receptor (EGFR) activating mutations represent major drivers to the development of non-small cell lung cancer (NSCLC). Among the oncogenic EGFR mutations, a significant cohort, counting for approximately 4-10% of the EGFR mutation spectrum, bear EGFR exon 20ins mutations. Meanwhile, approximately 2% of NSCLC patients bear hotspot mutations in HER2. Strikingly, over 90% of the HER2 mutations occurred in NSCLC are identified as exon 20ins mutations. Despite the successful launch of 1st, 2nd, and 3rd generation of EGFR inhibitory agents in the clinic that inactivate oncogenic EGFR signaling through targeting specific EGFR mutations, de novo or acquired, none of these standard-of-care therapies is specific to EGFR exon 20ins or HER2 exon 20ins. In addition, trastuzumab and EGFR-TKIs have limited effectiveness for NSCLC patients with HER2 exon 20ins mutation. TAK-788 (mobocertinib) and JNJ6372 (amivantamab-vmjw) are the FDA approvals for NSCLC driven by EGFR exon 20ins mutations. Only T-Dxd is used as a second-line treatment for NSCLC patients with HER2 mutation. Considering the large population of lung cancer and the fact that many patients are missed in diagnosis due to the heterogeneous characteristics of EGFR and Her2 exon 20ins, there are probably more than ten thousand lung cancer patients suffering the EGFR or Her2 exon 20ins mutations. There are urgent unmet medical needs to develop target therapeutics for EGFR and Her2 exon 20ins mutations. We discovered and developed TY-4028, which is a novel, potent, and orally available inhibitor targeting EGFR and Her2 exon 20ins mutations and is currently in the IND enabling stage. In EGFR-related tumor cells and genetically engineered Ba/F3 cell lines, TY-4028 showed similar or better antitumor effects than TAK-788, and better antitumor effects than DZD9008. The B/P ratio (brain tissue $AUC_{0\text{-}last}$/plasma $AUC_{0\text{-}last}$) of SD rats was 1.63 and 1.04 respectively after oral administration of TY-4028 in male and female SD rats, which suggested that TY-4028 had good potential to cross Blood Brain Barrier (BBB). Preclinical studies showed a good PK profile and manageable toxicity with TY-4028. TY-4028 has remarkable efficacy in mouse models of EGFR exon 20ins and HER2 exon 20ins. The data showed that all doses of TY-4028 had significant effects, and the tumors nearly demonstrated complete regression in the PDX LU0387 model and PC9 CDX model. At the same dose, the efficacy of TY-4028 was similar to that of TAK-788, while the tolerance of TY-4028 was better than that of TAK-788. At the same dose, the efficacy of TY-4028 was better than that of DZD9008. Taken together, the data demonstrated TY-4028 has great potential to meet the unmet medical needs for NSCLC patients with EGFR exon 20ins mutation or HER2 exon 20ins mutation. #Jun Li and Chengshan Niu contributed equally to this work. *They are the correspondent authors.

N-Cadherin acts as a predictive biomarker for anti-FGFR therapy in *KRAS* wild-type NSCLC

Santiago G. Borrego[1], Cristina Cirauqui[1], David Gómez-Sánchez[1], Haiyun Wang[2], Alicia Luengo[1], Chiara Ambrogio[3], Luis Paz-Ares[4], Irene Ferrer[1]. *[1]Research Institute (i+12) Hospital 12 de Octubre / Spanish*

National Cancer Research Center (CNIO) / Biomedical Research Cancer Network Center (CIBERONC), Madrid, Spain,[2]Tongji University, Shanghai, China,[3]Department of Molecular Biotechnology and Health Sciences, Molecular Biotechnology Center (MBC), Torino, Italy,[4]Medical Oncology Department, Research Institute (i+12) Hospital 12 de Octubre / Spanish National Cancer Research Center (CNIO) / Biomedical Research Cancer Network Center (CIBERONC) / Complutense University, Madrid, Spain

Background: Lung cancer is the leading cause of cancer-related deaths worldwide. FGFR1 has been associated with tumorigenesis in a variety of tumor types, including lung cancer. As a therapeutic approach, their inhibition has been attempted and was initially focused on FGFR1-amplified tumors, though with limited success. Preliminary data of our group suggests that N-Cadherin play a key role for the oncogenicity of FGFR1 and predict FGFR-targeted therapy efficacy in Non-small cell lung cancer (NSCLC). However, it is possible that other biomarkers, together with N-Cadherin, can determine the response to anti-FGFR therapy. Therefore, it is essential the identification of new biomarkers that could help to predict more accurately those patients that could benefit from anti-FGFR therapy.
Materials and Methods: We have treated 15 NSCLC PDX models with high FGFR1 expression levels and variable N-Cadherin expression levels, with the FGFR inhibitor (FGFRi) AZD4547. Based on their sensitivity to treatment, the PDX models were classified into two groups: Responders and Non-responders. All PDX models were characterized at the proteomic, genomic, and transcriptomic levels by western blot, whole exome sequencing, and RNA-Seq, respectively, and we used this information for defining the responder versus the non-responder group. Subsequently, the GDSC repository was used to validated our data in a cohort of lung adenocarcinoma (LUAD) cell lines.
Results: Responder and non-responder groups revealed a distinct pattern of genomic alterations and gene expression profile. As expected, GSEA identified an enrichment in Responders group of pathways related to FGFR1 signaling and ECM proteins, among them N-Cadherin stands out. Moreover, we observed an enrichment of *KRAS* mutations and genes related to the *KRAS* signature and to the intrinsic resistance to FGFRi in the non-responder group. To validate our findings and using the GDSC repository, we observed an enriched resistance to inhibitors of FGFR1 signaling in a cohort of *KRAS* mutant LUAD cell lines. Furthermore, we confirm a tendency for increased sensitivity in high N-Cadherin expressing cell lines, but only in *KRAS* wildtype context.
Conclusions: In conclusion, previous research had underlined N-Cadherin as a potential biomarker of response to FGFRi, while not successful in all contexts. Transcriptome study of PDXs classified as responder or non-responder to FGFRi revealed a differential gene expression pattern, with an upregulation of N-Cadherin pathway observed in the Responder group, while an enrichment of KRAS signaling and *KRAS* mutations in non-Responders. Furthermore, we validated our finding using a cell line repository that confirm that N-Cadherin could predict FGFR-targeted therapy efficacy but only in the *KRAS* wildtype context .

TY-0584: A potent, orally available small molecule YAP/TEAD inhibitor, exhibits anti-tumor effects *in vitro* and *in vivo*

Apeng Liang[1], Shengli Dong[1], Guangbin Liu[1], Zhengfei Guo[1], Meihua Li[1], Shuaibo Han[1], Yundi Cao[1], Yian Tu[1], Chao Zhou[1], Yu Yu[1], Linglin Xiao[1], Wei Huang[1], Xinlong Yang[1], Lian Fang[1], Haoyun Li[1], Chengshan Niu[2], Mingyu Jiang[3], Feng Xing[3], Shaoqing Chen[3], Jun Li[4], Yusheng Wu[4]. *[1]TYK Medicines, Inc. (Changxing), Huzhou, Zhenjiang, China,[2]TYK Medicines, Inc. (Zhengzhou), Zhengzhou, Henan Province, China,[3]TYK Medicines, Inc. (Shanghai), Xuhui District, Shanghai, China,[4]TYK Medicines, Inc., Huzhou, Zhenjiang, China*

Hippo/YAP pathway plays an essential role in cell proliferation, tissue regeneration, and tumorigenesis. The emerging evidence shows that hyperactivation of the Hippo/YAP pathway induces metastasis, chemoresistance, and the attribute of cancer stem cells. Dysregulated Hippo/YAP pathway can be a dominant driver of mesothelioma, meningioma, and schwannoma. It has been reported that Hippo/YAP oncogenic activation in mesothelioma is driven by NF2 loss function. In addition, it contributes to 10% of all cancers, including lung, gastric, colon, cervical, ovarian, breast, melanoma, hepatocellular, and squamous cell

carcinoma. Despite the urgent need to develop a therapeutic strategy to curb the dysregulated pathway, YAP/TAZ is difficult to be directly targeted with small molecule inhibitors because of the lack of a catalytic niche. TEADs require auto-palmitoylation to become functional. Therefore, small molecules that target palmitoylation of TEAD have been explored and VT3989 (NCT04665206) and IK-930 (NCT05228015) have success to enter the clinical trials. To target cancers with dysregulated Hippo/Yap pathway, we have discovered and are developing TY-0584, which is a potent and orally available YAP/TEAD inhibitor in the IND enabling stage. The results of PK and toxicity studies of TY-0584 showed a favorable safety profile. TY-0584 had excellent efficacy in the malignant mesothelioma H226 CDX mouse model, which is driven by NF2 deletion mutation. TY-0584 treatment also demonstrated good efficacy in the head and neck cancer PDX tumor mouse model. In previous studies, Hippo/Yap signaling promotes drug resistance to EGFR-targeted therapies in non-small cell lung cancer (NSCLC). To relax the YAP resistance mechanism in EGFR treatment, we asked if combined YAP inhibition grants an extension of responses to EGFR therapy. To this end, we treated EGFR-driven NSCLC cell models with TY-0584 and TY-9591. TY-9591 is a third-generation EGFR inhibitor developed by TYK Medicines and is currently under a pivotal Phase III clinical investigation in China (NCT05382728). The results show that the combination treatment not only offers synergistic effects, but also enhances apoptosis, compared to single drug treatment. Our *in vivo* data further underscores this exciting finding. Our studies showed that TY-9591 had excellent efficacy in the PC9 CDX mouse model, but tumors gradually recurred as many targeted cancer therapies did. In line with the results of the *in-vitro* experiments, another YAP/TEAD inhibitor TY-0536 in combination with TY-9591 significantly delay the tumor regrowth in the PC9 CDX mouse model. In summary, we identified a potent and orally available YAP/TEAD inhibitor TY-0584 which is a promising candidate for further clinical validation. [Shengli Dong and Apeng Liang contributed equally to this work. Jun Li, Shengli Dong, and Apeng Liang are the corresponding authors.]

#4492

A novel and potent FLT3 and IRAK4 dual inhibitor for the treatment of acute myeloid leukemia

Rui Yang[1], Lei Wu[1], Bing Zhang[1], Michael Xiang[2], Suyue Wang[1], Camille Xiang[2], zhijian Lu[2], Jason Xiang[2]. *[1]Polymed Biopharmaceuticals, Inc., Hangzhou, China,[2]Polymed Biopharmaceuticals, Inc., Cambridge, MA*

Several potent FMS-like tyrosine kinase 3 (FLT3) inhibitors have been developed and approved for the treatment of FLT3-mutant acute myeloid leukemia (AML) recently. These inhibitors block the signaling pathways involved in proliferation of leukemic cells, and have shown favorable initial results in early-stage AML patients. However, a significant percentage of patients relapsed with poor prognoses. The relapse is generally caused by a compensatory innate immune stress response, such as Toll-like receptor activation, which induces adaptive resistance to the FLT3 inhibition. Interleukin-1 receptor associated kinase 4 (IRAK4) functions as a mediator of Toll-like receptor and interleukin-1 receptor signaling pathways. Patients harboring a U2AF1 or SF3B1 spliceosome mutation were found to express a longer and more active isoform of IRAK4 kinase, which could result in lasting activation of NF-κB and MAPK in oncogenic and innate immune signaling. Emavusertib (CA-4948), an IRAK4/FLT3 inhibitor, is currently in phase I clinical trials. To address the critically unmet medical needs of myeloid leukemia patients, we have developed a novel and potent FLT3 and IRAK4 dual inhibitor HPB-092 with excellent selectivity to provide durable efficacy in myeloid malignancies by eliminating adaptive resistance .
HPB-092 significantly inhibited MV4-11 tumor cell proliferation at low nanomole concentration. HPB-092 demonstrated good oral bioavailability in several animal species. In a disseminated MV4-11 xenograft mouse model, HPB-092 displayed strong anti-tumor activity at 5mg/kg. HPB-092 was well-tolerated with no obvious adverse events at a dose of 40 mg/kg in two-weeks safety study in SD rats. In addition, no rhabdomyolysis side-effect was observed upon histological analysis. These results underscore the potential therapeutic benefit and safety profile of HPB-092 for the treatment of AML, especially in patients with mutations in U2AF1 or SFF3B1 spliceosome.

#4493

Sudocetaxel Zendusortide (TH1902), a peptide-drug conjugate for the treatment of sortilin-positive (SORT1+) TNBC and Her2-positive breast cancers

Cyndia Charfi[1], Michel Demeule[1], Jean-Christophe Currie[1], Alain Zgheib[2], Bogdan Alexandru Danalache[2], Richard Béliveau[2], Christian Marsolais[1], Borhane Annabi[1]. *[1]Theratechnologies, Montreal, QC, Canada,[2]Université du Québec à Montréal, Montreal, QC, Canada*

Over the last decade, the targeting of specific cell surface receptors such as human epidermal growth factor receptor 2 (Her2) in breast cancer cells has allowed the emergence of innovative strategies for the delivery of anticancer agents. High expression levels of the sortilin receptor (SORT1) have been reported in various tumors of breast cancer patients, including triple-negative breast cancer (TNBC), HR+ and Her2+ breast cancers. Given SORT1 function in ligand internalization, we addressed the sorting and trafficking of the newly designed TH19P01 peptide recognizing SORT1, and of TH1902, an anticancer TH19P01-docetaxel conjugate (PDC), and whether such PDC could target SORT1+ breast cancers. *In vitro*, high expression of SORT1 was found in several TNBC and Her2+ breast cancer cell lines as well as in in more than 88% of cases (H-score >100) from commercial breast cancer tissue microarrays. SORT1-mediated cell surface binding and internalization of TH19P01 was first investigated in TNBC-derived MDA-MB-231 cells. The binding and uptake of Alexa^{488}-labeled TH19P01, at 4 and 37°C respectively, were found significantly reduced upon siRNA-mediated SORT1 silencing. This demonstrates that functional SORT1 processes are required for both cell surface recognition and internalization of TH19P01. Moreover, the internalization of TH19P01 and TH1902 in MDA-MB-231 cells were monitored by fluorescence microscopy using a polyclonal antibody generated against TH19P01. Both TH19P01 and TH1902 showed a rapid uptake and co-localized in the perinuclear region with the late endosomal marker Rab-7 and with the lysosomal marker Lamp-1 within 30 minutes indicating that both compounds are internalized through a receptor-mediated endocytosis pathway. In addition, TH19P01 internalization after 1 hour appeared significantly associated within intracellular compartments of MDA-MB-231 cells whereas Herceptin remained mostly localized at the cell surface of Her2+ BT-474 cells. *In vivo*, weekly administration of intravenous bolus of TH1902 (35 mg/kg) at an equivalent docetaxel MTD dose (15 mg/kg) led to complete tumor regression, while docetaxel only inhibited tumor growth by half in a murine MDA-MB-231 xenograft tumor model. Furthermore, in mice bearing Her2+ HCC-1954 breast tumor xenografts, TH1902 induced complete tumor regression in contrast to docetaxel and Herceptin. Taken together, these preclinical data demonstrate the high anticancer properties of TH1902 against SORT1+ TNBC and Herceptin resistant Her2+ breast cancers. These results demonstrate that TH1902 can be a promising avenue for personalized therapy in the treatment of all SORT1+ breast cancers.

#4494

Multi-specific cMet x EGFR x VEGF antibody for difficult to treat cancers

Mark Chiu. *Tavotek Lab Inc., Springhouse, PA*

Cancers such as TNBC, pancreatic, and gastric are difficult to treat due to diverse etiologies. Several subtypes of these cancers are driven by abnormal EGFR signaling, increased cMET activation, and VEGF linked angiogenesis which are responsible for tumor growth and metastasis. TAVO412, a humanized multi-specific antibody with two distinct anti-EGFR nanobody domains, an anti-cMet Fab arm, and an anti-VEGF ScFv domain, was designed to treat patients with these unmet medical needs. In addition, the Fc domain allows for the heterodimerization, antibody-like pharmacokinetic profile, and additional mutations that enhance the Fc effector functional activity. In preclinical xenograft models, TAVO412 demonstrated strong tumor growth inhibition effects on TNBC, PDAC, GC or NSCLC cell line-derived tumors. The mechanisms of action included selective and potent binding to EGFR, cMet, and VEGF at lower pH values found in the solid tumor environment; effective blocking of EGFR and cMet pathways that drove cancer cell growth and proliferation; shutdown of VEGF mediated angiogenesis; and potent and efficacious Fc effector function that enhanced ADCC, ADCP, and CDC. TAVO412 had better TGI than analogous molecules. TAVO412 also demonstrated strong tumor growth inhibition against NSCLC patient derived xenograft (PDX) models with mutant EGFR and cMet genotypes. Each of the binding arms had cross reactivity with the cynomolgus monkey orthologues allowing the cyno model to be a relevant toxicology model. In the pivotal GLP

toxicology study in cynomolgus monkeys, TAVO412 was well tolerated, had no major organ toxicities, observations were mostly consistent with EGFR-related effects and recoverable. In conclusion, TAVO412 was successfully discovered and developed for hard-to-treat solid tumors. This drug is expected to be safe and efficacious in cancer patients. The IND application was approved by the US FDA in October 2022. A first-in-human, 2-Part Phase 1 study to examine the preliminary efficacy, safety, tolerability, pharmacokinetic / pharmacodynamic parameters; maximum tolerated dose / recommended phase 2 dose of TAVO412 will be starting in the first quarter of 2023.

#4495

A mechanistic study of the TFE3-splicing machinery gene fusions reveals a new druggable target for translocation renal cell carcinoma

Nur Damayanti[1], Sabrina Orsi[2], Ricardo Cordova[3], Christopher Rupert[2], Li Shen[2], William Marston Linehan[4], Kirk Staschke[3], Peter Hollenhorst[5], David Heppner[6], Roberto Pili[2]. *[1]Neurosurgery, Indiana University, Indianapolis, IN,[2]University at Buffalo, Buffalo, NY,[3]Indiana University, Indianapolis, IN,[4]National Cancer Institute, Bethesda, MD,[5]Indiana University, Bloomington, IN,[6]Chemistry, University at Buffalo, Buffalo, NY*

TFE3 is a member of basic helix-loop-helix leucine zipper MiT transcription factor family and its chimeric proteins are associated with translocation renal cell carcinoma (tRCC). Despite the variety of genes fusions, most of *TFE3* fusions partner genes are linked to spliceosome machinery. Dissecting the function of *TFE3* fused to spliceosome machinery factors (TFE3-SF) could direct the development of effective therapies for this lethal disease, which is refractory to standard treatments for kidney cancer. Here, by using a combination of *in silico* structure prediction, molecular cloning, next generation transcriptomics, FRET technology, mutagenesis, proteomics, and high-throughput high-content screening (HTHCS) we interrogated a series of oncogenic mechanisms of TFE3-SF-containing fusions, including spontaneous nuclear translocation, nuclear paraspeckle occupancy, enhanced *in vitro* proliferation and *in vivo* growth, transcriptome remodeling, alternative splicing reprogramming, and novel dimer partner recruitment. Molecular inhibition of TFE3-SF dimerization reverses its oncogenic activity and represents a potential new target for therapeutic intervention. By using HTHCS combined with FRET technology we screened FDA approved drugs library (LOPAC) and small molecule library (Microsource) and identified hits compounds which inhibit TFE3-SF dimerization. Hits compounds were validated in 2D and 3D models utilizing patient derived xenolines expressing TFE3-SF. Ouabain and terfenadine demonstrated decreased cell proliferation, reduced spheroid growth and *in vivo tumor* growth. Overall, our results unmask synthetic vulnerabilities of TFE3-SF dimerization for novel therapeutic strategies in patients with this aggressive type of kidney cancer.

JPI-547, a dual inhibitor of PARP/Tankyrase, shows promising antitumor activity against pancreatic cancers with homologous recombination repair deficiency or Wnt-addiction

Kyoung-Seok Oh[1], Ah-Rong Nam[1], Ju-Hee Bang[1], Yoojin Jeong[1], Sea Young Choo[1], Hyo Jung Kim[1], Su In Lee[1], Jae-Min Kim[1], Jeesun Yoon[2], Tae-Yong Kim[2], Banyoon Cheon[3], Hyunju Cha[3], John Kim[3], Do-Youn Oh[2]. *[1]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Onconic Therapeutics, Seoul, Korea, Republic of*

Background**:** PARP inhibitors have shown antitumor activities against solid tumors with HRD (homologous recombination deficiency). The definition of HRD and other potential biomarkers besides HRD should be further evaluated for PARP inhibitors. JPI-547 is a novel PARP inhibitor, simultaneously targeting tankyrase1/2, other members of the PARP family, that are involved in the Wnt/β-catenin pathway.
Method: Antiproliferative effect of JPI-547 and a variety of PARP inhibitors (olaparib, veliparib, talazoparib, niraparib, and rucaparib) were determined by MTT assay or clonogenic assay in 9 human pancreatic ductal adenocarcinoma (PDAC) cell lines (Capan-1, HPAF-II, Capan-2, AsPC-1, SNU-410, SNU-213, SNU-324, MIA-PaCa2, and PANC-1). Transcriptome data and gene dependency score of the cell lines

were obtained from the CCLE database and DepMap respectively. DNA damage was monitored by immunofluorescent imaging of γ-H2AX and DR-GFP assay determined the homologous recombination repair (HRR) efficiency. A xenograft tumor model was established to substantiate the in vivo antitumor effect of JPI-547.
Results: JPI-547 more potently blocks Poly(ADP-ribosyl)ation than olaparib, and induces a strong antiproliferative effect on Capan-1, a cell line with BRCA2 del. JPI-547 leads to cell cycle arrest and induces enhanced apoptotic cell death than olaparib. JPI-547 inhibits tumor growth of Capan-1 in vivo, suggesting the potent antitumor activity of JPI-547 against PDAC with HRD. Cell lines harboring RNF43 *LOF* mutations (HPAF-II, AsPC-1, and Capan-2), intrinsically addicted to Wnt/ β-catenin pathway, are more sensitive to JPI-547 than cells with RNF43 wild types. Interestingly, RNF43 mutations could not distinguish the sensitivity of other PARP inhibitors except JPI-547. CTNNB1 gene dependency score and β-catenin levels positively correlate with cellular sensitivity to JPI-547. JPI-547-induced DNA damage was alleviated in HR-proficient PDAC cells. DR-GFP assays confirm that JPI-547 does not directly alter the HRR efficiency of Wnt-addicted PDAC cells. Collectively, these data indicate that the vulnerabilities of Wnt-addicted PDAC cells to JPI-547 were irrelevant to HRD mimicking. Rather, JPI-547 stabilizes AXIN-2 in Wnt-addicted PDAC cells and downregulates the active form of β-catenin level in the nucleus, thereby disrupting the transcription of its target genes. Knockdown of β-catenin neutralized the antiproliferative effect of JPI-547, suggesting that inhibition of the β-catenin pathway is an important mode of action by JPI-547 in Wnt-addicted PDAC cells.
Conclusion: JPI-547 shows promising, preclinical antitumor effects against PDAC cells with HRD or Wnt-addiction, providing a rationale for further biomarker-driven clinical development of JPI-547 for the treatment of patients with PDAC.

#4497
Efficacy of Jak1/2 inhibition in murine myeloproliferative neoplasms is mediated by targeting nonmalignant cells
Sivahari Prasad Gorantla[1], Michael Rassner Rassner[2], Tony Andreas Müller[2], Teresa Poggio[2], Kirstyn Anne Crossley[2], Anna-Lena Denecke[2], Kornelia R Fritsch[2], Geoffroy Andrieux[3], Helen Kleinfelder[2], Shifa Khaja Saleem[2], Sudheer Madan Mohan Gambheer[2], Irene Gonzalez Menendez[4], Detlef Bentrop[5], Rainer Trittler[6], Svetlana Rylova[7], Dietmar Pfeifer[2], Leticia Quintanilla Martinez[4], Christine Dierks[2], Robert Zeiser[2], Anna Lena Illert[2], Nikolas von Bubnoff[1], Justus Duyster[2]. *[1]Department of Hematology and Oncology, UKSH, Luebeck, Germany,[2]Hematology, Oncology and Stem cell transplantation, Faculty of Medicine, Clinic for Internal Medicine, Freiburg, Germany,[3]Medical Center, Faculty of Medicine, University of Freiburg, Institute of Medical Bioinformatics and Systems Medicine, Freiburg, Germany,[4]Department of Pathology and Neuropathology, University Hospital Tübingen & Comprehensive Cancer Center Tübingen, Tübingen, Germany,[5]Albert-Ludwigs-Universität Freiburg,, Institute of Physiology, Freiburg, Germany,[6]Albert-Ludwigs-Universität Freiburg, Institute of Pharmaceutical Sciences, Freiburg, Germany,[7]Department of Nuclear Medicine, University Medical Center Freiburg, Freiburg, Germany*

Ruxolitinib (Jakavi) is a potent JAK1/JAK2 specific inhibitor, approved for the treatment of myeloproliferative neoplasia (MPN) such as primary myelofibrosis (PMF) and polycythemia Vera (PV). The primary clinical benefit of ruxolitinib in MPN patients is reduction in spleen size and alleviation of constitutional symptoms and significant improvement in the quality of life. However, the effect of ruxolitinib on bone marrow fibrosis and $JAK2^{V617F}$ allelic burden is modest. In addition, $JAK2^{V617F}$ negative MPNs also demonstrated clinical benefits, thus, is not clear whether the ruxolitinib primarily blocks the proliferation of the malignant clone or exerts its effects by targeting non-malignant cells. To gain the mechanism of ruxolitinib action in MPNs, we developed two $JAK2^{V617F}$-driven MPN mouse models harboring ruxolitinib resistant mutations $JAK2^{V617F+L902Q}$ and $JAK2^{V617F+L983F}$ in the malignant clone. Similar to $JAK2^{V617F}$ recipients, $JAK2^{V617F+L902Q}$ and $JAK2^{V617F+L983F}$ transplanted mice showed an increase in WBC, HCT, RBC, HB and reticulocyte values. Histopathological analysis revealed that the myeloproliferative phenotype resembles PV with a proliferation of all three lineages albeit with only a moderate increase in megakaryopoeisis. Grade II bone marrow fibrosis was observed in $JAK2^{V617F+L902Q}$

and JAK2$^{V617F+L983F}$ after 2-3 months similar to JAK2^{V617F} mice. Surprisingly, these mice respond to ruxolitinib treatment similar to ruxolitinib sensitive JAK2^{V617F} mice, indicated by reduction of spleen size, leukocyte count and proinflammatory cytokines in the serum. Mechanistically, we could identify a direct role of ruxolitinib in the impairment of inflammatory processes in the bone marrow microenvironment, particularly on the cytokine production of mesenchymal stem cells and endothelial cells. These results suggest that the ruxolitinib mediated effects in MPN patients are mainly due to abrogation of inflammatory signaling processes in non-malignant cells. Therefore, combination treatment of JAK1/2 inhibitors with novel inhibitors, which specifically act on malignant cells might improve the clinical benefit for MPN patients to JAK family inhibitors.

#4499

The peptide-drug conjugate sudocetaxel zendusortide (TH1902) potentiates anti-tumoral activity of the anti-PD-L1 checkpoint inhibitor and induces immune cell infiltration in a B16-F10 syngeneic melanoma model

Michel Demeule[1], Jean-Christophe Currie[1], Cyndia Charfi[1], Alain Zgheib[2], Isabelle Cousineau[2], Richard Béliveau[2], Christian Marsolais[1], Borhane Annabi[2]. *[1]Theratechnologies, Montreal, QC, Canada,[2]Université du Québec à Montréal, Montreal, QC, Canada*

Tumor-infiltrating immune cells are involved in the control of cancer and are closely related to clinical outcomes. Sudocetaxel Zendusortide (TH1902), a peptide-drug conjugate (PDC) of the sortilin (SORT1)-binding peptide TH19P01 ester-linked to two docetaxel moieties, has been shown to exert superior anti-cancer activities in multiple cancer models including melanoma syngeneic and xenograft murine models. Melanomas express elevated levels of SORT1 and are considered as one of the most immunogenic tumors where immune checkpoint inhibitors are among the standard of care treatment used. Here, we first questioned whether TH1902 anti-cancer effects involved infiltration of immune cells in a murine SORT1-positive syngeneic, non-immunogenic and highly aggressive B16-F10 melanoma model in C57BL/6 mice. Weekly administration of docetaxel reduced by half the growth of B16-F10 tumor allografts, while administration of TH1902 as a single agent and at equivalent docetaxel doses, was well tolerated and resulted in tumor regression after only 2 treatments. Surprisingly, in this immunologically cold tumor, immunohistochemistry analysis of tumors for immune cell infiltration showed a net increase in total leukocytes (CD45+) infiltration within TH1902-treated tumors compared with docetaxel-treated tumors, especially with for tumor-infiltrating lymphocytes (TILs) and tumor-associated macrophages (TAMs). Furthermore, the increased staining intensities for Perforin and Granzyme B were indicative of the elevated cytotoxic T and natural killer (NK) cells activity in TH1902-treated tumors. This corroborated with increased caspase-3 apoptotic activity. TH1902 and docetaxel doses were next halved and combined with the checkpoint inhibitor anti-PD-L1. In a first study, the TH1902/anti-PD-L1 combination resulted in increased tumor growth inhibition when compared with both agents alone. Interestingly, TH1902 as a single agent showed better tumor growth inhibition than docetaxel or docetaxel/anti-PD-L1 combination. In a second study, the TH1902/anti-PD-L1 combination significantly increased animal survival over either anti-PD-L1 or TH1902 as single agents (21 days increased median survival compared to 2.5 and 12.5 days respectively). We conclude that the superiority of TH1902 anticancer activity over docetaxel involves, in part, the modulation of infiltrating immune cells within the tumor microenvironment. This is the first demonstration that immune cell infiltration patterns play a pivotal role in the TH1902-associated anti-tumoral response. Combination of TH1902 with checkpoint inhibitors (anti-PD-L1) further reveals that this may lead to improved clinical outcomes in future immunotherapy translational approaches.

Enedione derivates as a potential cancer treatment through the inhibition of COPZ1

Allana C. F. Martins[1], Barbara Mitsuyasu Barbosa[2], Ingridhy O. Maia Freitas da Silveira[1], Roberto S. Gomes[1]. *[1]Pharmaceutical Sciences, North Dakota State University, Fargo, ND,[2]Chemical and Biological Sciences, Sao Paulo State University (UNESP), Botucatu, Brazil*

Cancer is a leading cause of death worldwide; it was responsible for approximately 10 million deaths in 2020. Besides surgery for tumor removal, the most common treatments available are chemotherapy and radiation, which are not selective, resulting in side effects such as pain, hair loss, nausea, and vomiting. They are also ineffective against stem-like and dormant tumor cells, which could lead to a relapse and/or metastasis. Consequently, the development of drugs with tumor-specific targets is needed. COPI is a coatomer responsible for the retrograde transport from Golgi complex (GC) to the endoplasmic reticulum (ER). In this context, we developed four compounds targeting disruption of GC through inhibition of COPI and previous results showed that compounds 1-4 significantly decrease cell viability of pancreatic cancer cell lines MIA PaCa-2 and AsPC-1, compared to hTERT-HPNE normal pancreatic cell line. In the present work, RT q-PCR confirmed that the two isoforms of the COPI ζ subunit COPZ1 and COPZ2 are expressed at similar levels in normal cells while COPZ2 is downregulated in tumor cell lines. Our *in vitro* results demonstrated that compounds **1-4** decreased cell viability of breast cancer (HCC1143) and melanoma (A-395) cell lines. The tested compounds are able to target COPZ1-dependent tumor cells, therefore they are great candidates for further studies aiming to develop a selective treatment for cancer.

Novel EHE PDX model used for drug sensitivity

Sandhya Krishnan, Robert Porter, Danh Truong, Salah-Eddine Lamhamedi-Cherradi, Krzysztof Grela, Rafal Zielinski, Sharon Landers, Vinod Ravi, Joseph A. Ludwig. *UT MD Anderson Cancer Center, Houston, TX*

EHE is a low-to-intermediate grade angiocentric non-vasogenic tumor that exhibits a wide survival range dependent upon tumor size, stage, and location. Most tumors originate in the lung (37%), soft tissue (20%), or liver (16%), and those with multifocal peritoneal or pleural spread have a 5-year survival rate of ~22%. Solitary lesions are often resected for curative intent. However, treatment options for those with metastatic disease at diagnosis remain less well-defined. Generally, the chemo-resistant slow-growing soft-tissue EHEs can often be observed off therapy for years or decades. In contrast, pleural or peritoneal tumors required rapid intervention with systemic cytotoxic chemotherapies. Given the lack of effective treatments, there remains a significant unmet need.

Unique among all cancer types, more than 90% of EHEs harbor in-frame chromosomal translocations with WWTR1 (TAZ) or YAP1 in the N-terminal domain. Given that YAP and TAZ are two paralogs, which share numerous epigenetic functions as YAP/TEAD or TAZ/TEAD transcriptional coactivators downstream of the Hippo tumor-suppressor pathway, the oncogenic effect of the resulting EHE-associated TAZ-CAMTA1 (TC) or YAP1-TFE (YT) fusion proteins must, with all certainty, continue to depend on the truncated YAP/TAZ proteins. Since no EHE cell lines exist, one cannot predict if the TC FP behaves similarly in human sarcomas that expose different tissue-specific TEAD binding sites.

Trametinib (a MEK inhibitor) was chosen for initial evaluation. We determined the preclinical efficacy of trametinib in the only available EHE patient-derived tumor explant (PDX) in existence, which genetic testing confirmed harbored a TAZ-CAMTA1 translocation. We propagated EHE PDX tumors in mice, then treated with vehicle or trametinib for more than 80 days. Tumor volumes were measured 2-3 times a week, and tumors were collected for further histology and proteomic analysis. Trametinib demonstrated potent antineoplastic activity, consistent with the limited activity observed in recent clinical studies.

A separate 10-day study was conducted to measure early pharmacodynamic studies of a potent, oral, selective small molecule palmitoylation inhibitor of TEAD provided by Ikena Oncology. Edge-Seq RNA sequencing and western blots were performed to validate the TEAD-dependent gene and protein expression. EdgeSeq analysis demonstrated significant down-regulation of multiple TEAD dependent genes, indicating on-target inhibition of TEAD in this model. Western blot protein analysis of YAP, TAZ, TEAD1, TC FP, CTGF, and CYR61, collected for pharmacodynamic analysis, demonstrated reduced CYR61, indicative of possible TEAD inhibitor activity; CTGF protein levels were unchanged. The use of one EHE PDX was a limitation, as this model may not fully recapitulate human tumor biology. Future research, using additional EHE PDX models, will be required in gauge the effect of different inhibitors.

Aptamer conjugated prostate specific membrane antigen (PSMA) targeting nanobees for prostate cancer prevention and therapy

Islam Rady[1], Sayed Bakry[2], Fatma Abou El-Azm[3], Hasan Mukhtar[4]. *[1]Molecular Biology, Al-Azhar University, Cairo, Egypt,[2]Center for Genetic Engineering, Faculty of Science, Al-Azhar University, Cairo, Egypt,[3]Pharmacology, Mansoura University, Mansoura, Egypt,[4]Department of Dermatology, School of Medicine and Public Health, University of Wisconsin-Madison, Madison, WI*

Melittin (MEL), a major peptide component of bee venom (BV), has shown chemopreventive as well as chemotherapeutic effects against many cancers in preclinical model systems. However, its applicability to humans has met with limited success due to several issues including its toxicity, nonspecificity, degradation, inefficient systemic delivery and limited bioavailability. Earlier, the concept of "nanochemoprevention" i.e. the use of nanotechnology to improve the outcome of cancer chemoprevention is introduced. Then, "non-targeted nanobees" i.e. nanoformulated mellitin is developed to exhibit excellent anti-prostate cancer efficacy *in vitro* and in animal models coining the concept as 'Nanobee- Chemoprevention'. Here, we are extending this work and developed nanobees targeted with small molecular entities (A10 2′-fluoropyrimidine RNA aptamers (Apt)), able to bind to prostate specific membrane antigen (PSMA), a transmembrane protein that is overexpressed in prostate cancer (PCa) and evaluated their efficacy in preclinical studies. The Apt-Nanobees led to an enhanced anti-proliferative activity in PCa cell lines compared to the free melittin. The behavior of Apt-Nanobees in modulating apoptosis and cell-cycle, was also determined. Then, *in vivo* experiments, in mouse xenograft model of prostatic tumor using nanobees with a model of targeted nanosystems, were conducted. The obtained data supported our hypothesis of targeted nanobees enhanced the bioavailability and limited unwanted toxicity of melittin, thus leading to a significant potential for probable clinical outcome.

Polyamine blockade therapy: A strategy to block immunosuppression in pancreatic cancer

Joseph A. Goode[1], Sai Preethi Nakkina[1], Manav Gandhi[1], Otto Phanstiel[2], Deborah A. Altomare[1]. *[1]Burnett School of Biomedical Sciences, University of Central Florida, Orlando, FL,[2]Department of Medical Education, University of Central Florida, Orlando, FL*

Pancreatic ductal adenocarcinoma (PDAC) is characterized by dense desmoplasia which contributes to poor prognosis by hindering tumor entry of immune cells and therapeutics. This leads to PDAC being difficult to treat with gemcitabine, a current standard-of-care, with only a 22% 12-month survival rate. Therapeutic modalities are needed to tackle the PDAC tumor microenvironment (TME). An alternative target is polyamine metabolism which is required for tumor growth, survival, metastasis, and also for modulating generation, survival, and activity of immune cells. Myeloid-derived suppressor cells (MDSCs) are immune cells that have a key role in PDAC metastasis, invasion, progression, and in impeding anti-tumor immune response to therapeutics in PDAC. MDSCs include monocyte-like (M-MDSC) and neutrophil-like (PMN-MDSC) cells. Previous studies have shown that polyamine blockade therapy (PBT), consisting of difluoromethylornithine (DFMO) to block polyamine biosynthesis and a polyamine transport inhibitor (Trimer44NMe), elicits anti-tumor immune response, improved survival, and a decrease in MDSCs in other tumor types. This is of interest given our previous findings that PBT improved survival of PDAC-bearing mice. Here, we tested PBT in altering PDAC-stimulated MDSC survival and whether it shifts their immunosuppressive phenotype. Studies were conducted using CD11b+ bone marrow cells that were differentiated into MDSCs via GM-CSF and tumor-conditioned media from PDAC cells derived from a genetic mouse model for pancreatic cancer (KPC-mice). Bulk RNA-sequencing was conducted on MDSCs treated with PBT, gemcitabine or combination. MDSCs exhibited widespread downregulation of expression in the gemcitabine and combination treatment, but PBT alone exhibited more targeted downregulation. Specifically, Gene Ontology (GO) analysis revealed a decrease in genes associated with immune cell migration and chemotaxis, and KEGG analysis showed downregulation of inflammatory pathways. These findings indicate that PBT may modify MDSCs from their tumor-associated immunosuppressive and pro-inflammatory behavior. MDSC subtype-specific markers were investigated by flow cytometry. Results show subsets of immune cells, such as PMN-MDSCs, are reduced upon PBT treatment alone or in combination with gemcitabine, thereby highlighting the dependence of this subtype on polyamine metabolism. In

conclusion, PBT alters the expression of MDSC immunomodulatory genes, decreases MDSC survival and supports the use of PBT for treatment of PDAC in combination with other immunomodulatory therapeutics.

#4504

Targeting cMYC in metastatic castration resistant and neuroendocrine prostate cancer

Chidiebere U. Awah, Olorunseun O. Ogunwobi. *The City University of New York, New York, NY*

Prostate cancer is the most common cancer in men and the second leading cause of cancer death among men in the United States according to the National Cancer Institute. Current treatment modalities involve prostatectomy, androgen receptor blockade and supportive /palliative care. Despite these treatment options, metastatic castration resistant prostate cancer and neuroendocrine prostate cancer still have very dismal clinical outcomes. Therefore, there is a need to understand the biology of the aggressive prostate cancer subtypes to identify novel targetable molecules. The castration resistant prostate cancer, neuroendocrine prostate cancer and the metastatic prostate cancers that recur have c-MYC amplification. These cancers are not responsive to androgen blockade or deprivation therapy. Attempts to target c-MYC have been difficult due to the intrinsic disordered nature of c-MYC. Various approaches have been attempted to control c-MYC; namely RNAi which has high off target effects, anti-sense oligonucleotides (ASO) which have low cellular penetrance and needs phosphorothioate modification, G-quadruplex inhibitors which are unspecific as they block POLII, the BRD4 and CDK inhibitors which are indirect inhibitors of c-MYC. Only OmoMyc a bHLH domain mutant with enhanced leucine zipper dimerization is in phase 1 trials with limited bioavailability. To explore the possibility of targeting c-MYC in these difficult-to-treat prostate cancers, we transfected C4-2B, a cellular model of metastatic castration resistant prostate cancer, with engineered destabilized 3‘UTR AU rich element of c-MYC. We found that we degraded c-MYC transcript and protein and killed the cancer cells. Taken together, we offer preliminary evidence that we can directly target c-MYC and inhibit these difficult-to-treat cancers. *In vivo* studies to validate these findings are ongoing.

New Approaches in Radiodiagnostics and Theranostics

[^{18}F]FluorThanatrace ([^{18}F]FTT) PET Imaging of PARP-inhibitor drug-target engagement as a biomarker of response in ovarian cancer

Sarah B. Gitto[1], Austin R. Pantel[1], Mehran Makvandi[2], Hyoung Kim[3], Sergey Medvedev[3], Joanna K. Weeks[2], Drew A. Torigian[2], Chia-Ju Hsieh[2], Benjamin Ferman[3], Nawar A. Latif[3], Janos L. Tanyi[3], Lainie P. Martin[3], Shannon M. Lanzo[2], Fang Liu[4], Quy Cao[4], Gordon B. Mills[5], Robert K. Doot[2], David A. Mankoff[2], Robert H. Mach[2], Lilie L. Lin[6], Fiona Simpkins[7]. *[1]Department of Pathology and Laboratory Medicine, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[2]Department of Radiology, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[3]Department of Obstetrics and Gynecology, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[4]Department of Biostatistics, Epidemiology, and Informatics, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA,[5]Department of Cell, Developmental and Cancer Biology, Oregon Health & Science University School of Medicine, Portland, OR,[6]Department of Radiation Oncology, MD Anderson Cancer Center, The University of Texas, Houston, TX,[7]Department of Obstetrics & Gynecology, Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA*

Purpose: Poly(ADP-ribose) polymerase enzyme inhibitors (PARPi) have become the standard-of-care treatment for homologous recombination deficient (HRD) high-grade serous ovarian cancer (HGSOC). However, not all HRD tumors respond to PARPi and biomarkers to predict response are needed. [^{18}F]FluorThanatrace (FTT) is a PARPi-analog PET radiotracer that non-invasively measures PARP-1 expression. Herein, we evaluate the ability of FTT uptake to serve as a biomarker to predict response to PARPi in patient-derived xenograft (PDX) models and patients with HGSOC.
Patients and Methods: In PDX models, FTT-PET was performed before and after PARPi (olaparib), ataxia-telangiectasia inhibitor (ATRi), or both. Changes in FTT were correlated with tumor size changes. Patients

with HRD and HGSOC that were enrolled in CAPRI (PARPi+ATRi), LIGHT (PARPi only), or off-trial (PARPi only) were selected for this single-center, prospective, cohort, IRB-approved study. FTT-PET/CT imagining was obtained from the skull base to the proximal thighs on an Ingenuity TF scanner (Philips Healthcare) 60-90 minutes after intravenous infusion of 8-12 mCi FTT. Subjects were imaged with FTT-PET at baseline and after ~1 week of PARPi monotherapy treatment. Target lesions (primary tumor and/or metastases) were identified at the time of the baseline imaging on correlative anatomic imaging using RECIST 1.1 and maximum standardized uptake value (SUV_{max}) data, normalized by body weight, was collected. Changes in FTT-PET uptake were compared to changes in tumor size, CA-125, and progression free survival (PFS).
Results: A decrease in FTT tumor uptake after 1 week of PARPi treatment correlated with response to PARPi+ATRi treatment in PARPi-resistant PDX models (r=0.81-0.83, P=0.1-0.22). In HGSOC patients (n=13), percent differences in FTT-PET after ~7 days of PARPi compared to baseline correlated with the first RECIST response (r=0.60, P=0.034), best RECIST response (r=0.75, P=0.01), best CA-125 response (r=0.73, P=0.033), and PFS (r=0.67, P=0.027). All patients with >50% reduction in FTT uptake had >6-month PFS and >50% reduction in CA-125 (P=0.004 and P=0.016, respectively). Utilizing only baseline FTT uptake correlated to best RECIST response (r=-0.65, P=0.035) but did not predict response when corelated with other measures. Importantly, a decrease in FTT uptake does not appear to be associated with a reduction in tumor burden or apoptosis in response to drug cytotoxic activity at this early timepoint, indicating specificity for drug-target engagement.
Conclusions: The decline in FTT uptake shortly after PARPi initiation compared to baseline provides an in vivo measure of drug-target engagement and shows promise as an early biomarker to guide PARPi therapy. FTT-PET has both pre-clinical and clinical applications warranting further study, including guiding PARPi combination therapy.

LAG-3 PET imaging in patients with cancer before immune checkpoint inhibitor therapy

Pim P. van de Donk[1], Lotte M. Smit[1], Joyce van Sluis[2], Wim Timens[3], Adrienne H. Brouwers[2], Marjolijn N. Lub-de Hooge[2], Sjoerd G. Elias[4], Jourik A. Gietema[1], Claudia A. J. van Winkel[1], JuAn Wang[5], Jason Giurleo[5], Thomas Uldrick[5], Hung Kam Cheung[5], Hilde Jalving[1], Sjoukje F. Oosting[1], Daan G. Knapen[1], Derk-Jan A. de Groot[1], Elisabeth G. E. de Vries[1]. *[1]Medical Oncology, University Medical Center Groningen, Groningen, Netherlands,[2]Department of Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, Groningen, Netherlands,[3]Department of Pathology and Medical Biology, University Medical Center Groningen, Groningen, Netherlands,[4]Department of Epidemiology, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands,[5]Regeneron Pharmaceuticals, Tarrytown, NY*

Background Immune checkpoint inhibitors (ICIs) can induce durable responses in multiple different tumor types. Lymphocyte activation gene-3 (LAG-3) is one of the immune checkpoints for which therapeutic antibodies are being developed. PET imaging with radiolabeled ICIs can visualize whether the drug reaches the tumor, and might serve as a target expression readout. Therefore, we aimed to evaluate the safety of the radiolabeled LAG-3 antibody ^{89}Zr-DFO-REGN3767, to determine the optimal tracer dose and imaging time point, and to get insight into ^{89}Zr-DFO-REGN3767 whole body distribution.
Methods Patients with advanced solid tumors received 37 MBq ^{89}Zr-DFO-REGN3767 together with unlabeled antibody to achieve a 2, 5, 10, 20, or 40 mg total protein dose (NCT04706715). Patients underwent PET/CT scans on days 0, 2, 4, and 7 after injection, followed by a tumor biopsy. After that, they received treatment with cemiplimab alone or combined with platinum-containing chemotherapy. PET scans were analyzed by placing volumes of interest (VOIs) in tumor lesions and normal tissues. Tracer uptake was measured in the VOIs and expressed as the maximum standardized uptake value (SUV_{max}) for tumor lesions and as the mean standardized uptake value (SUV_{mean}) for normal tissues.
Results The 16 included patients experienced no ^{89}Zr-DFO-REGN3767-related side effects. Tumor-to-blood ratios for all dose levels increased from days 0 to 7. Therefore, imaging 7 days after tracer injection was deemed optimal to achieve the highest contrast. The 40 mg tracer dose resulted in the most favorable blood kinetics. At this dose, tracer uptake in tumor lesions (n = 17) varied between patients (geometric mean

SUV_{max} 6.2; SD 1.7). In normal tissues, uptake was seen in the spleen ($\bar{x}$ 11.2; SD 1.6), and bone marrow ($\bar{x}$ 2.2; SD 0.7), which increased from days 0 to 7. Tracer uptake was visually present in regions with inflammation.
Conclusion ^{89}Zr-DFO-REGN3767 PET imaging is feasible and studied patients did not experience tracer related side effects. Optimal imaging results were achieved with the 40 mg protein dose and imaging on day 7. ^{89}Zr-DFO-REGN3767 shows specific accumulation in LAG-3 rich tissues and tumor lesions.

Shape features of extra-nodal lesions on positron emission tomography identifies responders to CAR-T-cell therapy
Yoganand Balagurunathan[1], Zhouping Wei[1], Jin Qi[1], Erin Dean[1], Zachary Thompson[1], Jung Choi[1], Frederick Locke[2]. *[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]Bone Marrow Transplant, H. Lee Moffitt Cancer Center, Tampa, FL*

Background: Lymphoma is a common primary malignancy consisting of a heterogeneous collection of lymphoid neoplasms. Diffuse large B-cell lymphoma (DLBCL) is the most common, aggressive disease form that accounts for 30% of all lymphoma cases. The disease spreads systemically to involve organs other than lymph nodes 40% of the time, with 5-year survival of about 38% for intermediate grade disease. Recent development in chimeric antigen receptor (CAR) T-cell therapy has shown tremendous promise in providing a cure to patients with relapsed/refractory (R/R) DLBCL. We propose to develop an image-based biomarker to identify patients that would respond to engineer edcell-based treatments.
Methods: We identified a cohort of 58 patients with R/R DLBCL, whose largest lesions on the baseline positron emission tomography /computed tomography (PET/CT) imaging were identified along with their anatomical sites related to non-lymphatics. The lesion's co-registered PET imaging was used to converge on a regional boundary to obtain the most active part of the lesion, applying Standardized Uptake Value definition with 41% regional threshold. The lesion regions were characterized using imaging metrics (radiomics) broadly categorized into: Size (n=38), Shape (n=9), Texture (n=259),followed by principal component (PC) analysis to reduce the dimensionality in each of the feature categories. These Radiomics metrics along with whole body metabolic tumor volume (MTV) were used both collectively and independently to assess risk to disease progression measured by overall survival using Cox-regression model. We also compared the Radiomic metrics to MTV to identify linear dependency measured by Coefficient of Determination (R^2).
Results: PET scans shape features (extra nodal) that describes compactness to sphericity, represented as a principal component across the samples had a 21% increased risk to disease progression compared to 15% using MTV, with a CI of [1.0487, 1.417] and [1.04, 1.30] respectively. Patients have a median follow up of 1 year after CAR-T treatment. Shape-PC (Non-Lymph) lesions were not related to MTV with a correlation coefficient of 41.8% (R^2 of 0.0725). Most non lymphatic lesions (top three sites) in our cohort were from lung, bone and liver. Patients with no non- lymphatic lesions were not part of this cohort.
Conclusion: We identified Non-Size based features that are prognostic to patient response to treatment. These metrics provide complementary information to MTV and may serve as a surrogate to treatment response. Our features would require a secondary validation in a larger cohort prior to clinical use.

Tumor glucose metabolism profiles detected via [18F]-FDG PET/CT correlate with the immune landascape in soft-tissue sarcomas
Amandine Crombe[1], Frédéric Bertolo[2], Jean-Philippe Guegan[3], Alban Bessede[3], Raul Perret[4], Mariella Spalato-Ceruso[5], Maud Toulmonde[5], Audrey Laroche[6], Francois Le Loarer[4], Vanessa Chaire[4], Michèle Kind[1], Carlo Lucchesi[2], Antoine Italiano[5]. *[1]Radiology, Institute Bergonié, Bordeaux, France,[2]Bioinformatics, Institute Bergonié, Bordeaux, France,[3]Explicyte, Bordeaux, France,[4]Biopathology, Institute Bergonié, Bordeaux, France,[5]Medical oncology, Institute Bergonié, Bordeaux, France,[6]Sarcoma unit, Institute Bergonié, Bordeaux, France*

Background: Improving the assessment of the immune landscape of soft-tissue sarcoma (STS) through imaging biomarkers could help better selecting and monitoring patients that could benefit from immunotherapy. Our aim was identify whether metabolic patterns of soft-tissue sarcoma (STS) on pre-treatment 18F-Fluorodeoxyglucose (18F-FDG) positron emission tomography (PET/CT) were associated with different immune profiles on molecular and cellular levels.
Methods: This single-center prospective study included consecutive adult patients with newly-diagnosed, non-metastatic, high-grade STS treated in a curative intent with available pre-treatement 18F-FDG-PET/CT. Maximal standardized uptake value (SUVmax), SUVpeak, SUVmean, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were extracted. A cross-validated principal component analysis (PCA) was developed on the PET/CT metrics. The first two principal components (PC1 and PC2) and an unsupervised metabolic classifications were computed.
Differential gene expression (DGE), oncogenesis pathways analyses, complexity index in sarcoma (CINSARC) molecular signature and immunohistochemistry panels (CD8, CD14, CD20, CD45, CD68, c-MAF) were performed. Correlations between nuclear imaging, immunohistochemistry and transcriptomics data were achieved.
Results: 85 patients were included (median age: 62 years, 37 women) between 2016 and 2021. The robust PCA defined 3 metabolic groups (high [n=21], intermediate [n=15] and low [n=49]). PC1 reflected the tumor metabolism and PC2 the size and amount of necrosis. Transcriptomics and immunohistochemistry data were available in 32 and 31 patients, respectively. PC1 was significantly positively correlated with CINSARC (P=0.0029) and the cellular densities in CD8+, CD14+, CD45+, CD68+ and c-MAF (range of P-values: 0.0175-0.0499). The metabolic-high group was characterized by the upregulation of 13 immune pathways, including ICOS, CD27, IFNG, CXCL9-10/CXCL3 genes.
Conclusion: Metabolic profiles on 18F-FDG-PET/CT of high-grade STS highlights distinct immune profiles, which could pave the way for potential biomarkers of STS immunophenotyping.

Genomic aberrations in circulating tumor DNA (ctDNA) and clinical outcomes from [^{177}Lu]Lu-PSMA-617 in metastatic castration-resistant prostate cancer (mCRPC)

Heidi Fettke[1], Louise Kostos[1], James Buteau[1], Jason A. Steen[2], Elizabeth Medhurst[1], Mo B. Haskali[1], Declan Murphy[1], Maria Docanto[1], Patricia Bukczynska[1], Nicole Ng[1], Shahneen Sandhu[1], Siavash Foroughi[3], Luc Furic[1], Tu Nguyen-Dumont[2], Michael S. Hofman[1], Arun A. Azad[1]. *[1]Peter MacCallum Cancer Centre, Melbourne, Australia,[2]Monash University, Melbourne, Australia,[3]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia*

[^{177}Lu]Lu-PSMA-617 (LuPSMA) radionuclide therapy improves overall survival in mCRPC, and was recently approved by the FDA. Nevertheless, owing to the heterogeneous nature of mCRPC, responses to LuPSMA therapy can be variable, and resistance is inevitable. As a result, biomarkers linked to clinical outcome with LuPSMA are urgently required. Using plasma ctDNA, we present the first comprehensive genomic analysis of a prospective cohort of mCRPC patients treated with LuPSMA. Targeted sequencing of 78 genes was performed on baseline plasma and matched buffy coat samples from patients who received LuPSMA on a prospective registry (NCT04769817). Reportable alterations included pathogenic single-nucleotide and copy number variants. Association between alterations and clinical outcomes were assessed using log rank, cox proportional, and chi-squared analyses. Clinical data collected included PSA decline by ≥50% or ≥90% (PSA50-response rate, PSA50-RR; and PSA90-RR), and PSA progression free survival (PSA-PFS). In total, 100 patients (median age 74 years, range 52-90) received a median of 4 cycles of LuPSMA. 83 patients had detectable ctDNA (median fraction 17%, range 0-94%) with PSA50-RR 50%, PSA90-RR 22%, and a median PSA-PFS of 7.2 months. Patients with an *AR* or *PTEN* aberration had significantly shorter PSA-PFS (HR 0.50 and 0.59, respectively; Table), as did patients with any *PI3K* pathway aberration (HR 0.56). Additionally, patients with a high ctDNA burden had significantly worse PSA-PFS (HR 0.42, Table). There were no significant differences in PSA-RR based on deleterious genomic changes. Our data reveal that aberrations in the *AR* and PI3K pathways, along with pre-treatment ctDNA fraction, whilst not linked to PSA-RR, are prognostic for durability of response to LuPSMA. If validated in

larger cohorts, these data will help to optimise the use of LuPSMA by improving patient selection and enhancing prognostication.

Analysis of clinical endpoints based on deleterious genomic changes in ctDNA

	n	PSA-PFS (months, wild type (wt) vs variant)	PSA-PFS HR (95% CI, wt vs variant)	PSA50-RR (wt vs variant)	PSA90-RR (wt vs variant)
Exonic *AR* variants	47	**8.1 vs 6.0 p=0.005**	**0.50 (0.30-0.83) p=0.006**	58% vs 40% p=0.09	23% vs 21% p=0.8

Novel trop-2-targeted NIR-II fluorescence imaging technique for accurate determination of breast conserving surgery margin *in vivo* and human fresh tissue

Weiling Chen[1], YongQu Zhang[1], LiXin Zhang[1], XiangJie Luo[1], YuanYuan Zhu[1], GuiMei Wang[2], YunZhu Zeng[3], JiaZheng Wang[1], RongHui Li[4], WenHe Huang[5], GuoJun Zhang[5]. *[1]Xiamen University, Xiamen, China,[2]Department of Pathology, Xiang'an Hospital of Xiamen University, Xiamen, China,[3]Department of Pathology, Cancer Hospital of Shantou University Medical College, Shantou, China,[4]Department of Medical Oncology, Xiang'an Hospital of Xiamen University, Xiamen, China,[5]Department of Breast-Thyroid-Surgery and Cancer Center, Xiang'an Hospital of Xiamen University, Xiamen, China*

Purpose Accurate evaluation of tumor boundaries in breast-conserving surgery is very important to reduce the second operation of patients.Near-infrared fluorescence imaging using molecular agents has shown promise for in situ imaging during resection.However, there are very effective probes that can be applied to clinical trials up to now. Here we developed a new technology that can quickly identify the tumor area both in vivo and the resected breast tissue during the operation and distinguish the tumor boundary.
Methods 1. Characterization and biosafety of the probe SG-ICG were performed.2. The targeting of the probe was verified by in vitro fluorescence co-localization and flow cytometry experiment and in vivo fluorescence imaging using tumor-bearing mouse model.3. Fluorescence image-guided surgery in spontaneous breast cancer transgenic mice and transplanted tumor model were to evaluated the specificity and sensitivity of guided tumor resection with the probe.4. The tumors and peritumoral muscle tissues of tumor-bearing mice were surgically removed and incubated with SG-ICG, and then imaged by a NIR-II fuorescence imaging system. 5. Six surgically removed breast tissues were incubated with the probe immediately after intraoperative resection and imaged to identify the tumor area. The accuracy of fuorescence imaging was confirmed by pathological diagnosis.

Results 1. SG-ICG was successfully synthesized with good dispersibility, stability with high intensity of NIR-II fluorescent imaging. 2. SG-ICG could specifically target high expression level of Trop-2 in breast cancer cell lines compared with IgG-ICG.3. SG-ICG was able to detected the MDA-MB-231-luc breast cell tumor-bearing mouse models with tumor-to-background ratios of ~4, correspondingly, nearly 2-fold NIR-II FL signal decrease was detected while blocked by unlabeled SG. 4. SG-ICG was able to detected the minimal residual lesions and the minimum detectable tumor diameter is about 1mm. The NIR-II fluorescence guidance facilitated more complete tumor resection, it has improved the relapse free survival rate, and effectively discriminates between benign and malignant breast tissues in spontaneous breast cancer transgenic mice (AUC= 0.9931; 95% CI: 0.9708, 1.0;P<0.0001)..5. This new technology yielded more than 83.33% specifcity and 100% sensitivity in identifying the tumor area in the resected breast tissue. **Conclusions** By using fuorescently labeled anti-human trop-2 antibody-drug conjugate to incubate freshly isolated tissues during surgery, the probes can quickly accumulate in breast cancer tissues, which can be used to quickly identify tumor areas in the resected breast tissues and distinguish tumor boundaries. This technology is expected to be used for rapid intraoperative pathological detection and margin determination.

Optical metabolic imaging of treatment-naive human NSCLC to determine long-term outcome

Paola Monterroso Diaz*. University of Arkansas, Fayetteville, AR*

Lung cancer remains the leading cause of cancer deaths in the US and worldwide. The five-year survival rate of patients with non-small cell lung carcinoma (NSCLC) remains significantly low given that over half present with locally advanced or metastatic disease at time of diagnosis, and experience tumor recurrence following therapeutic intervention.Current evaluation techniques to assess treatment response are lacking, given they are implemented several weeks after treatment completion and are solely based on anatomical changes in tumor size, forgoing other criteria such as functional or metabolic changes. There is a critical need to identify markers early on following diagnosis that are indicative of patient long-term outcome. Two photon microscopy (TPM) techniques are well-suited to provide non-invasive high-resolution information on cell metabolism within three-dimensional tissue. Specifically, two-photon excited fluorescence imaging of autofluorescent cofactors, nicotinamide adenine dinucleotide (NADH) and flavin adenine dinucleotide (FAD), can be used to metabolically characterize cancerous tissue. The goal of this study is to utilize the optical redox ratio (ORR) of FAD/[NADH+FAD] autofluorescence and NADH fluorescence lifetime decay to identify measurable differences in optical metabolic endpoints of human NSCLC that are indicative of their long-term outcome. Twenty-nine NSCLC specimens were obtained from the Lung Cancer Biospecimen Resource Network. They were resected from the lung prior to the patient receiving therapy. Clinical detail reports were used to evaluate the follow-up data of each patient and classify them into groups that reflected their eventual outcomes: responder (N=21), non-responder (N=18), non-metastatic (N=25), and metastatic (N=14). TPM was used to determine the ORR for each sample. NADH lifetime images were collected and fit to a biexponential model to separate the short (A1) and long (A2) components of free and bound NADH. We observed a significantly higher optical redox ratio for tumors within the metastatic group compared to non-metastatic. This is consistent with previous findings from our lab that revealed increases in the ORR with increasing metastatic potential in cells, as well as other studies reporting a decrease in NADH concentration in metastatic cancers. Additionally, a significantly shorter mean NADH lifetime in the metastatic tumor group was revealed when compared to non-metastatic. This stands in agreement with other studies highlighting decreases in the average lifetime of NADH in metastatic cells compared to non-metastatic. These results demonstrate the feasibility of using optical imaging of autofluorescence and lifetimes of metabolic cofactors to characterize treatment-naïve primary NSCLC tumors and determine differences in their optical metabolic endpoints that are indicative of their long-term outcome.

A novel DNA double-strand breaks biosensor based on fluorescence resonance energy transfer

Jung-Soo Suh, Tae-Jin Kim*. Pusan National University, Busan, Korea, Republic of*

Revealing the spatiotemporal behavior of DNA double-strand breaks (DSBs) is crucial for understanding the processes of DNA damage and repair. Traditionally, γH2AX and DNA damage response (DDR) factors have been used to detect DSBs using classical biochemical assays, such as antibody-based immunostaining. However, a reliable method to visualize and assess DSB activity real-time in living cells is yet to be established. Herein, we developed a novel DNA double-strand breaks biosensor (DSBS) based on fluorescence resonance energy transfer (FRET) by employing the H2AX and BRCT1 domains. By applying FRET imaging with DSBS, we show that DSBS specifically reacts to drug- or ionizing radiation (IR)-induced γH2AX activity, allowing for the quantification of DSB events at high spatiotemporal resolutions. Taken together, we provide a new experimental tool to evaluate the spatiotemporal dynamics of DNA double-strand breaks in response to cancer therapies. Ultimately, our biosensor can be useful for elucidating the molecular mechanisms underlying DNA damage and repair processes and applying for cancer therapies.

Curti[6], Ray Page[7], Aurelie Swalduz[8], Jean-Paul Beregi[9], Jan Chrusciel[10], Eric Snyder[11], Pritam Mukherjee[12], Heather M. Selby[12], Soohee Lee[13], Roshanthi Weerasinghe[14], Shwetha Pindikuri[13], Jakob B. Weiss[15], Andrew L. Wentland[16], Anish Kirpalani[17], An Liu[5], Olivier Gevaert[18], George Simon[19], Hugo JWL Aerts[15]. *[1]Medical Ethics and Health Policy and Medicine, University of Pennsylvania, Philadephia, PA,[2]Onc.AI, San Carlos, CA,[3]Medicine, Hematology/Oncology (SMD), University of Rochester Medical Center, Rochester, NY,[4]Division of Medical Oncology, The Ohio State University, Columbus, OH,[5]Radiation Oncology, City of Hope, Duarte, CA,[6]Clinical Research, Providence Cancer Institute, Portland, OR,[7]The Center for Cancer & Blood Disorders, Fort Worth, TX,[8]Centre Léon Bérard, Lyon, France,[9]CHU Nimes, Nimes, France,[10]Centre Hospitalier de Troyes, Troyes, France,[11]University of Rochester Medical Center, Rochester, NY,[12]Stanford University, Palo Alto, CA,[13]Providence Health & Services, Renton, WA,[14]Providence St. Joseph Health, Portland, OR,[15]Mass General Brigham, Boston, MA,[16]School of Medicine and Public Health, University of Wisconsin, Madison, WI,[17]University of Toronto, Toronto, ON, Canada,[18]Medicine - Biomedical Informatics Research, Stanford University, Palo Alto, CA,[19]Medical Oncology, Moffitt Cancer Center, Tampa, FL*

There is an urgent clinical need to identify patients likely to benefit from immune checkpoint inhibitor ICI treatment. Approaches available in the clinic today, such as PD-L1 immunohistochemistry (IHC) and tumor mutation burden (TMB), are insufficient for this task, in part as differences in microenvironments expressed by individual tumors may lead to heterogeneous response patterns. Recent efforts exploring the utility of quantitative imaging (radiomic) biomarkers to predict response to ICIs have shown promise to provide a more accurate and scalable method. In contrast to previously published models, our work focuses on generalizable models for predicting individual lesion-level as well as patient-level response at 3-month follow-up per RECIST criteria, using a large multi-institutional “real-world” dataset. The models combine radiomics features with demographic, molecular, and laboratory values routinely available in patients’ electronic medical records. We analyzed radiomic characteristics of 6,295 primary and metastatic lesions from 1,206 metastatic NSCLC patients treated with anti-PD-1/anti-PD-L1 ICIs from 8 institutions across the US and Europe. Patients with unavailable PD-L1 IHC, imaging follow-up, or with oncogenic driver mutations were excluded from analysis, resulting in a total dataset of 766 subjects randomly assigned to training (N=514) and validation sets (N=252). Using gradient-boosted decision tree algorithms, we developed a multi-modal predictive model to identify patients responding to ICI therapy at 3-months and evaluated its performance against an imaging-only CT radiomics model and the clinical standard of care, biopsy-based PD-L1 IHC. The multi-modal model contains CT radiomic features capturing lesion heterogeneity and spicularity, patient demographics, PD-L1 TPS, and tumor burden volume in the lung, lymph nodes, and the liver. Under the two-tailed DeLong test, the multi-modal model demonstrated statistically significant benefit over the current standard of care (PD-L1 IHC) in predicting multi-lesion 3-month response: 0.81 (P=.005) area under the receiver operating characteristic curve (ROC-AUC) in first-

line ICI monotherapy patients, 0.72 (P=.044) in all-lines ICI monotherapy, and 0.71 (P=.025) in all-lines ICI-chemotherapy combination. The imaging-only model demonstrated predictive performance comparable to PD-L1 IHC: 0.71 (P=.226), 0.61 (P=.905), 0.62 (P=.674) on the same cohorts respectively. A multi-modal CT radiomics-based approach demonstrated predictive accuracy benefit over the current clinical standard and may provide an opportunity for more personalized patient management, such as risk-based escalation/de-escalation of concurrent chemotherapy in NSCLC patients. We will evaluate this methodology in prospective studies.

Radiomics-based machine learning models to predict progression and biomarker status in non-small cell lung cancer (NSCLC) patients treated with immunotherapy

Jisang Yu[1], Yury Velichko[2], Hyeonseon Kim[1], Moataz Soliman[2], Nicolo Gennnaro[2], Leeseul Kim[3], Youjin Oh[1], Trie Arni Djunadi[1], Jeeyeon Lee[4], Liam Il-Young Chung[1], Sungmi Yoon[5], Zunairah Shah[6], Soowon Lee[7], Cecilia Nam[8], Timothy Hong[8], Rishi Agrawal[2], Pascale Aouad[2], Young Kwang Chae[1]. *[1]Department of Oncology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Department of Radiology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[3]Ascension Saint Francis Hospital Evanston, Evanston, IL,[4]School of Medicine, Kyungpook National University, Daegu, Korea, Republic of,[5]New York City Health and Hospitals Corporation North Central Bronx/Jacobi Medical Center, The Bronx, NY,[6]Weiss Memorial Hospital, Chicago, IL,[7]Baylor University, Waco, TX,[8]Northwestern University, Evanston, IL*

Background: Radiomics is an emerging tool that involves the extraction of high-throughput features from medical images. These quantitative values can be used to develop predictive models for clinical characteristics and treatment outcomes. We evaluated radiomic features-based models as imaging biomarkers in NSCLC patients.

Methods: 71 patients with NSCLC treated with immunotherapy who had pretreatment CT chest with contrast were retrospectively evaluated. The main tumor and 1cm-thick peritumoral space surrounding the tumor were manually segmented using LIFEx software (IMIV/CEA, Orsay, France) by four physicians. Of 255 radiomic features collected, those with >0.4 of Fleiss' kappa coefficient were selected. The Random Forest (RF) algorithm with mixed effects was used to develop multi-reader models and assess feature importance. The dataset was divided into a training set (75%) and a test set (25%). Bootstrapping with 1,000 iterations was conducted to estimate the model performance. Durable disease control was defined as having no progression of diseases per RECIST 1.1 up to 24 weeks from starting immunotherapy.

Results: Among 71 patients, 35 (49.3%) are female and 36 (50.7%) are male. The median age was 66. 48 (67.6%) adenocarcinoma, 13 (18.3%) squamous cell carcinoma, and 10 (14.1%) other histologic types were included. 22 radiomic features were included based on importance in the prediction models from both the tumor and peritumoral space. Each model is trained to predict patients' durable disease control, TTF1 expression, PD-L1 expression, histology (adenocarcinoma or not), and Neutrophils Lymphocyte Ratio (NLR; greater than 5 or not) status. The statistical results from the models to predict clinical outcomes are shown in Table.

Conclusion: The radiomic features-based models lack accuracy in predicting clinical characteristics and outcomes. Further validation with larger cohorts is warranted.

Statistics of radiomics-based models in predicting clinical characteristics and treatment outcomes

Radiogenomic analysis in the patients with primary brain tumor using dual time point ^{18}F-FET PET/CT

Dong Yun Lee, Sang Woo Song, Seungjoo Lee, Minyoung Oh, Jungsu S. Oh, Jaeseung Kim. *Asan Medical Center (AMC), Seoul, Korea, Republic of*

Purpose: To evaluate the association between genomic data and imaging features of dual time point ^{18}F-FET PET/CT in patients with primary brain tumor for radiogenomic mapping.
Methods: From June 2021 to July 2022, we prospectively enrolled the patients under suspicious of *de novo* primary brain tumor in Asan Medical Center. Prior to the surgery, contrast-enhanced MRI and ^{18}F-FET PET/CT scans were routinely performed. Twenty minutes after the post-injecting (p.i.) approximately 5 mCi of ^{18}F-FET, patients underwent early PET/CT acquisition (20-40 min p.i.). Delay PET/CT (80-100 min p.i) was subsequently obtained after 40-minute break. SUVmax, maximum tumor-to-brain ratios and PET-positive volumes using different isocontours of SUVmax (I30, I60, I90%) in tumor were calculated in each sum images. Histopathologic results were made based on 2016 WHO classification and, isocitrate dehydrogenase (IDH) mutation, O^6-methylguanine-DNA methyltransferase (MGMT) methylation, telomerase reverse transcriptase (TERT) mutation and co-deletion of 1p19q status were investigated as well. Spearman's correlation coefficient (r), logistic regression and AUC-ROC analysis were employed using aforementioned radiomics information.
Results: A total of 42 patients (median age 55.5 yrs, range 21-84; M:F=31:11) were recruited and, 29 patients had glioblastoma with grade IV. Except TERT mutation (n=25), IDH mutation (n=11), MGMT methylation (n=19) and co-deletion of 1p19q (n=8) had statistically significant correlation each other (IDH vs. MGMT, r=0.55; IDH vs. 1p19q, r=0.53; MGMT vs. 1p19q, r=0.42). Early scan of I60% was closely related with IDH mutation (positive, 3.92 ± 3.04 vs. negative, 7.96 ± 5.36; p=0.005) meanwhile delay scan of I30% had significant association with co-deletion of 1p19q (present, 34.16 ± 18.67 vs. absent, 71.99 ± 38.79; p=0.01). The accuracy of logistic regression and the corresponding AUC-ROC values for IDH/MGMT/TERT/co-deletion of 1p19q status were 0.86/0.73/0.78/0.85, and 0.88/0.76/0.78/0.91, respectively.
Conclusion: Although this is a preliminary and interim analysis during our prospective study being slated to enroll the patients until December 2023, we suggest that the information acquired from both genetics and ^{18}F-FET could be integrated into better characterization of primary brain tumor.

High grade glioma (HGG) represents a group of devastating diseases with dismal prognosis. Surgical resection of the contrast enhancing (CE) region of HGG remains the mainstay of treatment, but recurrence inevitably arises from the unresected non-contrast enhancing (NE) region, surgically inaccessible due to cancer cell invasion into healthy brain tissue. Due to its critical role in recurrence, understanding of the NE region is central to the improvement of clinical outcomes. We reveal the biological characteristics of this region through image localized multi-regional sampling. We linked microenvironmental characteristics measured by multi-parametric MRI to genomic mutations and transcriptional phenotypes using mixed effect modeling which allowed us to control for individualized patient effects. We first confirmed that T2 is a significant indicator of IDH mutation status in the NE region, being the first description of such a relationship in a HGG cohort. We found the combination of EGFR amplification and CDKN2A homozygous loss was associated with a significantly lower mean diffusivity (MD) compared to double wild type tumors in the NE region, indicating the presence of greater cellular packing and proliferation in EGFR amplification/CDKN2A loss regions. Finally, using single cell pathway based tumor classifications, we showed that nK2, a DSC-MRI metric representing cell size heterogeneity, correlated positively with neuronal signature and negatively with glycolytic/plurimetabolic signature within the NE tumor, indicating that glycolytic/plurimetobolic tumors possessed a high amount of cell size heterogeneity compared to neuronal samples. This hypothesis was supported using digital reference object (DRO) modeling which confirmed that cell size and heterogeneity drove the differential nK2 signal between neuronal and glycolytic/plurimetabolic samples. We identified immune cell infiltrate as one possible mechanism of increased cell size heterogeneity using transcriptomic signature analysis which found more immune cell signatures within glycolytic/plurimetobolic tumors compared to neuronal. Collectively this study demonstrates the central role of multi-parametric MRI as a non-invasive measure of tumor biology and a tool for understanding the clinically critical NE region which can then inform new therapies targeting this region of HGG recurrence.

Integrative cross-platform characterisation of mammographic screen-detected breast cancer

Alison M. Cheung[1], Dan Wang[1], Kela Liu[1], Yutaka Amemiya[1], Elzbieta Slodkowska[2], James G. Mainprize[1], Jane Bayani[3], Arun Seth[1], John Bartlett[4], Martin J. Yaffe[1]. *[1]Sunnybrook Research Institute, Toronto, ON, Canada,[2]Anatomic Pathology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada,[3]Ontario Institute for Cancer Research, Toronto, ON, Canada,[4]Cancer Research UK Edinburgh Centre, Edinburgh, United Kingdom*

Mammography screening is widely used for earlier detection of breast cancer and has been shown to contribute to reduction of mortality and morbidity. Most screen-detected breast cancers are early stage, hormonal receptor-positive, HER2-negative (HR+ HER2-) breast cancers. The majority of HR+ HER2- cancers are assigned to molecular intrinsic subtypes of Luminal A and Luminal B, which generally harbour low recurrence risk, with Luminal B cases being more invasive but still less aggressive than HER2-enriched

or Basal-like subtypes. However, some of these Luminal cancers later recur (5+ years after diagnosis) often as advanced and/or metastatic disease. We studied a cohort of screen-detected breast cancers (42 cases) at Sunnybrook Health Sciences Centre (Toronto, ON Canada) with integrated cross-platform radiomics, molecular and proteomic analysis in an attempt to better characterise these cancers and their proclivity for late recurrence. Utilising a Nanostring 200-gene assay, the molecular subtypes (PAM50 and MammaTyper-like) and a range of recapitulated clinical prognostic scores (50-Gene, 70-Gene and 21-Gene Risk) were determined for these cancers. While a majority of cases (29 out of 42) were subtyped as Luminal A cancers by PAM50, a fraction (12 out of 29) of these were either subtyped as Luminal B/HER2+ based on MammaTyper-like results, or measured as intermediate to high risk of recurrence based on the 70-Gene or 21-Gene Risk classification. Although discordant results from multi-parametric assays are not uncommon, we postulate that here, discordance could suggest presence of heterogeneous cellular or molecular elements with invasive phenotype that could lead to aggressive transformations in the long run. Differential expression analysis between Luminal A cases with consistent subtyping and low risk prognostication and those with discordant subtyping or prognostication results revealed a panel of genes with significant changes in expression. Further analysis of RNA expression of these genes via Receiver Operating Characteristic (ROC) curve demonstrated that some genes showed high Area Under the Curve (AUC) scores in the classification between the two groups of Luminal A breast cancers, further supporting the existence of distinct molecular phenotypes. Targeted sequencing with Oncomine Comprehensive Assay V3 did not reveal particular mutational patterns between the two Luminal A groups. Nevertheless, radiomic analysis of mammographic images of the cancer, as well as single cell phenotyping of the tumor microenvironment with protein multiplexing will be incorporated to further characterise elements that are phenotypically different, and potentially identify mechanistic drivers contributing to late recurrence in Luminal A cancers.

Precision Oncology in Pediatric Cancer: From Genomics to Databases to Real World Evidence

#4509

A pan-Canadian precision oncology program for children, adolescents and young adults with hard-to-cure cancer: The PRecision Oncology For Young peopLE (PROFYLE) Program

Stephanie A. Grover[1], Lesleigh Abbott[2], Jason N. Berman[2], Guillaume Bourque[3], Jennifer A. Chan[4], Avram E. Denburg[1], Rebecca J. Deyell[5], Conrad V. Fernandez[6], Cynthia Hawkins[1], Jan-Willem Henning[7], Meredith S. Irwin[1], Nada Jabado[8], Steven J. M. Jones[9], Philipp F. Lange[5], Paul Moorehead[10], Michael F. Moran[1], Daniel A. Morgenstern[1], Sapna Oberoi[11], Antonia Palmer[12], Shahrad R. Rassekh[5], Donna L. Senger[13], Adam Shlien[1], Daniel Sinnett[14], Caron Strahlendorf[5], Patrick J. Sullivan[15], Michael D. Taylor[1], Suzanne Vercauteren[5], Anita Villani[1], Stephanie Villeneuve[6], James A. Whitlock[1], David Malkin[1], on behalf of the PROFYLE Consortium. *[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada,[3]McGill University, Montreal, QC, Canada,[4]University of Calgary, Calgary, AB, Canada,[5]BC Children's Hospital, Vancouver, BC, Canada,[6]IWK Health Centre, Halifax, NS, Canada,[7]Tom Baker Cancer Centre, Calgary, AB, Canada,[8]McGill University Health Centre, Montreal, QC, Canada,[9]BC Cancer, Vancouver, BC, Canada,[10]Janeway Health and Rehabilitation Centre, St. John's, NL, Canada,[11]CancerCare Manitoba, Winnipeg, MB, Canada,[12]Advocacy for Canadian Childhood Oncology Research Network (Ac2orn), Toronto, ON, Canada,[13]Lady Davis Institute of Medical Research and McGill University, Montreal, QC, Canada,[14]Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada,[15]Childhood Cancer Canada, Toronto, ON, Canada*

Background**:** Over 4,300 children, adolescents, and young adults (CAYA) are diagnosed with cancer each year in Canada, 1/3 of whom have refractory/metastatic disease or will relapse. The PRecision Oncology For Young peopLE (PROFYLE) national, collaborative program, was created to provide equitable access to molecular profiling to identify novel targeted treatment options in a clinically relevant timeframe for all CAYA with hard-to-cure cancers in Canada.

Design: Building upon 3 pre-existing regional precision oncology programs, PROFYLE now includes >20 institutions and has united an interdisciplinary team of experts, leaders, research teams, end-users and advocates from across Canada. The program has 14 domain specific nodes that are unified by a shared

governance structure, and has harmonized biobanking, genomics, bioinformatics and reporting procedures. PROFYLE includes genomic and transcriptomic sequencing of paired germline and cancer fresh/frozen samples, proteomic analysis, and cancer modelling. Inclusion criteria: ≤29y; treatment at a Canadian center; diagnosis of a hard-to-cure cancer. Profiling results are reviewed by multidisciplinary Molecular Tumor Boards. A report including a results/recommendations summary of actionable findings (therapeutic, diagnostic, prognostic, cancer predisposition), potential targeted therapy options including available clinical trials, clarification of diagnosis, and genetic counseling recommendations is provided to the treating oncologist.
Results: >1,000 CAYA are included from all of the provinces. Cancer diagnoses: 34% sarcoma, 16% leukemia/lymphoma, 16% CNS tumor, 11% neuroblastoma, 23% other. 17% of participants had a cancer-predisposing pathogenic/likely pathogenic germline variant, 45% had ≥1 potentially actionable somatic alteration, 22.6% had a therapeutically targetable somatic alteration. The most frequent classes of therapeutic alterations were RAS/MAPK (15%), cell cycle (14%), epigenetic (13%), RTK (12%), PI3K/AKT/mTOR (11%), DNA repair (9%), immune checkpoint (8%). Of clinicians who reported the utility of results, 55% indicated the findings were useful for clinical management.
Future Directions: Collaborations with other national and international initiatives and data from this interdisciplinary, multi-institutional research program will inform the development of a framework to innovatively link research, clinical and system considerations with Canadian values relevant to multi-omic profiling and drug access for CAYA. In addition, we believe that with a comprehensive molecular view of cancer, PROFYLE will transform our understanding of underlying disease mechanisms, facilitate and improve diagnostic and prognostic indicators, and identify new therapeutic strategies and targets for CAYA patients with cancer.

Impact of the comprehensive genomic profiling on the individual therapeutic planning in high-risk/refractory tumors: real-world precision medicine in pediatric oncology
Petra Pokorna[1], Hana Palova[1], Sona Adamcova[1], Vojtech Bystry[2], Michal Kyr[3], Dagmar Al Tukmachi[1], Sona Mejstrikova[1], Peter Mudry[3], Jaroslav Sterba[3], Ondrej Slaby[4]. *[1]CEITEC, Masaryk University, Brno, Czech Republic,[2]Masaryk University, Brno, Czech Republic,[3]Department of Pediatric Oncology, University Hospital Brno, Brno, Czech Republic,[4]CEITEC, Faculty of Medicine, Masaryk University, Brno, Czech Republic*

Background: Despite major improvements in the survival of pediatric cancer patients that were achieved through the intensification of chemotherapy and the perfection of supportive care in the past decades, treatment outcomes for high-risk, relapsed, and refractory solid cancers remain unsatisfactory. Accelerating the progress of pediatric oncology requires both therapeutic advances and attention to reducing the long-term cytotoxic treatment-related side effects. This could be achieved by targeting specific molecular changes that drive pediatric malignancies.
Material and Methods: From September 2016 to August 2020, a total of 192 patients with pediatric high-risk solid tumors successfully underwent comprehensive genomic profiling. Since more than thirty patients had two or more biopsies from recurrent relapses, the total number of samples examined was 295. In the cohort, there were 78 cases of central nervous system tumors, 68 sarcomas, 14 neuroblastomas, 10 lymphomas, and 22 tumors of other histology. Whole-exome sequencing was performed in all patients, fusion gene analysis in 96% of patients, whole-transcriptome profiling in 84% of patients, and CNV analysis in 63% of patients.
Results: The diagnostic yield of therapeutically actionable findings was 40%, with single-nucleotide variants and small insertions/deletions being the most common actionable alteration types. In 23% of patients, a clinically relevant gene fusion was identified. The majority of the identified fusions were of diagnostic significance, and 18% of those were therapeutically targetable gene fusions involving BRAF, RAF1, ALK, FGFR1, or NTRK2. Four patients were eligible for immunotherapy based on high tumor mutational burden (>10 mut/Mb). Lymphomas and CNS tumors showed the highest rate of patients with therapeutically actionable findings (60% and 56%, respectively), followed by neuroblastomas (36%), sarcomas (25%), and other solid tumors (23%). All results and individual treatment plans were discussed at multidisciplinary molecular tumor boards.

Conclusion: Precision medicine in pediatric oncology has rapidly developed over the last decade and resulted in new therapeutic options based on molecular biomarkers and increased our understanding of the complexity of pediatric malignancies. Supported by the Ministry of Health of the Czech Republic, grant nr. NU20-03-00240 and the project National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NPO5102) - Funded by the European Union - Next Generation EU.

My Pediatric and Adult Rare Tumor Network (MyPART): integrating longitudinal, clinical, molecular, and patient-reported outcomes for rare tumors

Shadin Ahmed[1], Margarita Raygada[1], Robin Lockridge[2], Mary Frances Wedekind Malone[1], Jaydira Del Rivero[3], John W. Glod[1], Barbara J. Thomas[1], Donna Bernstein[1], Markku M. Miettinen[4], Liqiang Xi[4], Jung Kim[4], Manoj Tygagi[4], Mark Raffeld[4], Kenneth Aldape[4], Ashkan A. Malayeri[5], Abby B. Sandler[1], Brigitte C. Widemann[1], Karlyne M. Reilly[1]. *[1]Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD,[2]Clinical Research Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Developmental Therapeutics Branch, National Cancer Institute, Bethesda, MD,[4]Laboratory of Pathology, National Cancer Institute, Bethesda, MD,[5]Radiology and Imaging Sciences, Clinical Center, National Institutes of Health, Bethesda, MD*

Background**:** Rare tumors are defined as <15 cases/100,000 people/year and present an unmet need due to lack of effective medical treatments, paucity of biospecimens and research models, and difficulty accruing to clinical trials. **MyPART** (**My** **P**ediatric and **A**dult **R**are **T**umor Network) was established to: 1) engage patients/advocates as partners in rare tumor research, 2) provide expertise and personalized health care to children and young adults with rare tumors, and 3) build databases and tools to advance research on new treatments for rare tumors. We have developed a natural history and biospecimen acquisition study (NCT03739827), enrolling patients with rare solid tumors, their family members, and participants with germline mutations at increased rare tumor risk.
Method: Participants in our natural history study enroll remotely or come to the National Institutes of Health Clinical Center. Participants complete medical and family history forms, patient reported outcomes (PROs), and provide tumor samples and blood and/or saliva for DNA/RNA analysis. For patients coming to the Clinical Center, blood samples are collected for immune phenotyping and cytokine analysis. Clinical staff extract medical records for downstream analyses. Tumors are analyzed using a 500+ gene panel and genomic analysis. Participants are followed yearly to collect data on recurrence, progression, PROs, development of additional tumors, and response to treatments such as standard of care and any treatment trials they may join.
Results: We report a clinical and molecular summary of the first 200 participants (66% female, 35% male), with neuroendocrine neoplasms (NEN), adrenocortical cancer (ACC), SDH-deficient gastrointestinal stromal tumor (sdGIST), chordoma, medullary thyroid cancer (MTC), and other less commonly enrolled tumors totaling 35 different tumor types. Participants come from 46 US states and 9 countries. Early results show tumor-specific differences in mutations, treatment/management, PROs, and self-reported non-tumor health issues. The most common pathogenic germline mutations are *SDHA/SDHB/SDHC* in sdGIST and *RET* in MTC and other tumors. The most common pathogenic tumor mutations are *TP53* and *CTNNB1* in ACC, *SDHA/B* and *TP53* in sdGIST, *MEN1* in NEN, *RET* and *HRAS* in MTC, and *SMARCB1* in chordoma. Clinically significant levels of anxiety and pain are more frequent in ACC, NEN, and sdGIST.
Conclusions: By developing methods to provide value to rare tumor patients, using a large catchment area and opportunity for remote participation, and collecting data in a tumor-agnostic way, we can learn about multiple rare tumors and share findings more quickly than if each rare tumor was studied alone. We describe the MyPART cohort and challenges to overcome for successful longitudinal rare tumor natural history studies.

#4513

St. Jude Survivorship Portal: A data portal for storing, analyzing, and sharing large and complex cancer survivorship datasets

Gavriel Matt[1], Edgar Sioson[1], Jaimin Patel[1], Jian Wang[1], Robin Paul[1], Colleen Reilly[1], Congyu Lu[1], Kyla Shelton[1], Qi Liu[2], Weiyu Qiu[2], Cindy Im[2], Zhaoming Wang[1], Carmen L. Wilson[1], Nickhill Bhakta[1], Kirsten Ness[1], Gregory T. Armstrong[1], Melissa M. Hudson[1], Leslie L. Robison[1], Jinghui Zhang[1], Yutaka Yasui[1], Xin Zhou[1]. *[1]St. Jude Children's Research Hospital, Memphis, TN,[2]University of Alberta, Edmonton, AB, Canada*

Survivors of childhood cancer are at risk for developing various adverse health conditions as adults that are attributable to the cancer and treatments they were exposed to as children. Cancer survivorship research relies on large-scale, longitudinal studies that generate a wide range of demographic, clinical, and genetic data on cancer survivors at multiple time points. To maximize the utility of these comprehensive datasets, we must be able to store and share these datasets in a web-based environment that can be accessed by the broader survivorship research community. Furthermore, this environment should be integrated with analytical tools for performing statistical analyses on the stored data without needing to download the data and import it into third-party analytical software. To address this need, we have created the St. Jude Survivorship Portal (https://survivorship.stjude.cloud > Clinical Data Browser), a web-based data portal for exploring, sharing, and analyzing data from survivors of pediatric cancer. The portal hosts data from two large cohorts of pediatric cancer survivors: the St. Jude Lifetime Cohort Study and the Childhood Cancer Survivor Study. The data stored on the portal consists of demographic data, clinical data, including cancer diagnosis, cancer treatment, clinical outcomes, and patient-reported data, and genetic data, including whole-genome-sequencing-derived genotypes and published polygenic risk scores computed for >500 traits. This data is organized hierarchically in a data dictionary that can be easily explored by the user. Charts and plots of variables can be quickly created, customized, and stratified with other variables, all within the portal environment. Statistical analyses, including cumulative incidence analysis and regression analysis, may also be performed within the portal. In cumulative incidence analysis, users can analyze the incidence of a variety of CTCAE-graded adverse events (e.g., cardiovascular dysfunction, neurological disorders, subsequent neoplasms) in survivors and can also compare them across different survivor populations defined by other variables. In regression analysis, users have the option to perform either a linear, logistic, or cox regression analysis and may use any of the demographic, clinical, or genetic variables on the portal as outcome or explanatory variables in the analysis. In this way, users can assess any risk factor associations within a survivor cohort and generate predictive models for outcomes of interest. Lastly, we also provide the user with the option to download the data on the portal for use in any future analyses. The St. Jude Survivorship Portal provides a comprehensive, powerful, and easy-to-use interface for sharing and analyzing childhood cancer survivorship data that will serve as a valuable research tool for the broader survivorship research community.

Variations of blood DNA methylation associated with cancer treatment exposures among childhood cancer survivors of African ancestry

Qian Dong, Sarmistha Das, Cheng Chen, John Easton, Heather L. Mulder, Emily Walker, Geoffrey Neale, Deo Kumar Srivastava, I-Chan Huang, Jinghui Zhang, Melissa M. Hudson, Leslie L. Robison, Kirsten K. Ness, Nan Song, Zhaoming Wang. *St. Jude Children's Research Hospital, Memphis, TN*

We previously showed that cancer treatment associated DNA methylation (DNAm) signatures were present decades following the cancer diagnosis in childhood cancer survivors (CCS) of European ancestry (EA) and that treatment associated DNAm sites mediated the causal pathway from specific treatment exposures to increased risk of chronic health conditions (CHCs). This new analysis further evaluated and compared the treatment and DNAm associations in CCS of African ancestry (AA) from the St. Jude Lifetime Cohort Study. Cancer treatments were abstracted from medical records. DNAm was measured using MethylationEPIC BeadChip with blood-derived DNA. Among 370 AA CCS (53.2% female, median age at blood draw=31.2 [range=18.4-65.1] years), treatments included alkylating agents (54.6%), anthracyclines (48.6%), epipodophyllotoxins (29.2%), corticosteroids (33.0%), and vincristine (61.6%), and radiation therapy (RT) to brain (26.5%), chest (27.6%), abdomen (22.7%), and pelvis (21.6%). Epigenome-wide association study (EWAS) for each treatment, using multivariable linear regression adjusting for sex, age at blood draw, leukocyte cell subtype proportions, genotype principal components and DNAm principal components, showed little inflation with genomic control (GC) factor between 1.1 (brain-RT) and 1.2 (chest-RT). A total

of 93 5′-cytosine-phosphate-guanine-3′ (CpG) was associated with one or more cancer treatments (GC-adjusted $P<9\times10^{-8}$), including epipodophyllotoxins (n=46), alkylating agents (n=38), corticosteroids (n=3), anthracyclines (n=3), abdominal-RT (n=3), chest-RT (n=2), and pelvic-RT (n=1). A total of 60 differentially methylated regions (DMRs) was identified using DMRcate R package, including alkylating agents (n=28), epipodophyllotoxins (n=22), corticosteroids (n=3), abdominal-RT (n=4), chest-RT (n=2), and anthracyclines (n=1). A total of 39 CpGs from EWAS were nested within 21 DMRs. 92.1% (650/706) chemo-associated CpGs in EA were replicated in AA CCS, and 98.9% (86/87) chemo-associated CpGs in AA were replicated in EA CCS. In contrast, 66.7% (4/6) RT-associated CpGs in AA were replicated in EA CCS, and 71.7% (638/890) RT-associated CpGs in EA were replicated in AA CCS. Moreover, the four CpGs that partially mediated the effect of abdominal-RT on hypercholesterolemia in EA were not associated with abdominal-RT in AA CCS, further suggesting substantial difference in RT-associated CpGs as compared to chemo-associated CpGs between AA and EA CCS. Future studies by including a larger sample size of AA CCS are warranted to assess the difference in treatment-associated DNAm alterations and subsequent disparity in risk of treatment-related CHCs between AA and EA CCS. The DNAm sites can be used as predictors for risk management (treatment decision-making) and potential mechanistic targets for intervention for those at the greatest risk of CHCs.

PIONEER: harnessing multi-omics data to enhance immunotherapeutic target discovery and development

Amber K. Weiner[1], Hemma Murali[2], Rawan Shraim[1], Karina L. Conkrite[1], Alexander B. Radaoui[1], Daniel Martinez[1], Brian Mooney[3], Sandra E. Spencer Miko[3], Gian Negri[3], Alberto Delaidelli[3], Caitlyn de Jong[3], Yuankun Zhu[1], Allison P. Heath[1], Jennifer Pogoriler[1], Yael P. Mosse[1], Deanne M. Taylor[1], Poul H. Sorensen[3], Gregg B. Morin[3], Benjamin A. Garcia[4], John M. Maris[1], Sharon J. Diskin[1]. *[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA,[3]BC Cancer, Vancouver, BC, Canada,[4]Washington University, St. Louis, MO*

Introduction: Immunotherapeutic strategies have produced remarkable results in some malignancies. However, optimal cell surface targets in many childhood cancers remain elusive and tools for novel target discovery are limited. We developed a proteogenomic approach to identify high confidence cell surface proteins for immunotherapy development and applied it to neuroblastoma, an often fatal childhood cancer. Through the Pediatric Immunotherapy Discovery and Development Network (PI-DDN), we have extended this approach to 14 high-risk childhood cancers. This effort includes MS-based surfaceome data generation for 175 patient-derived xenograft (PDX) models, 30 primary patient tumors, and 10 human derived cell line models.

Methods/Results: To optimize the utility of our approach and data, we are developing a web-based application called PIONEER (Pediatric Integrative Omics Network Enhancing Early Research). The goal of PIONEER is to disseminate data to the broader scientific community and to provide the necessary analysis, query and visualization tools to make these data accessible to everyone, regardless of computational expertise. A pilot version of PIONEER was developed using R Shiny Dashboard and is derived from our neuroblastoma efforts. The application is comprised of two main categories: (1) target discovery data and prioritization (2) target validation and preclinical development. Modules include proteomics, transcriptomics, epigenomics, multi-omics, validation and pre-clinical drug development. Cancer ‘omics data currently housed in PIONEER include tumor and cancer cell line mass-spectrometry based proteomics, RNA-sequencing, and chromatin immunoprecipitation (ChIP) sequencing. Extensive normal tissue expression data from GTEx and mass spectrometry will be integrated. Surface proteins are prioritized through an integrative multi-omic analysis of tumor and normal tissue data. Users can perform queries and cancer subtype and cross-histotype studies, apply custom cutoffs, and generate plots for visualization. We are currently adding functionality to support automatic data analysis and integration for surface proteins (SPACE: Surface Protein Analysis for Collaborative Efforts). Through the target validation and preclinical development modules, users can view an antibody repository, immunofluorescence, immunohistochemistry, drugs in development

for each protein, and efficacy in patient derived xenograft models. PIONEER will be deployed using R Connect; data for additional histotypes will be incorporated as available.
Conclusion: PIONEER will provide a comprehensive characterization of the surfaceome of high-risk pediatric cancers and a web-based application for data integration, visualization and sharing. This interface facilitates the discovery of optimal immunotherapeutic drug targets in high-risk childhood cancers.

#4516

Rare high-penetrance and common low-penetrance variants associated with risk of pediatric acute lymphoblastic leukemia

Zhaoming Wang[1], Cheng Chen[2], Na Qin[3], Nan Song[4], Hui Wang[5], Gregory T. Armstrong[1], Kirsten K. Ness[1], Melissa M. Hudson[1], Jinghui Zhang[1], Leslie L. Robison[1], Cindy Im[6]. *[1]St. Jude Children's Research Hospital, Memphis, TN,[2]Shanghai Jiao Tong University, Shanghai, China,[3]Nanjing Medical University, Nanjing, China,[4]Chungbuk National University, Cheongju, Korea, Republic of,[5]Shanghai Jiao Tong University, Shanghai, Chile,[6]University of Minnesota, Minneapolis, MN*

Leveraging existing genetic data for survivors of pediatric acute lymphoblastic leukemia (ALL) from the St. Jude Lifetime Cohort Study (SJLIFE) and Childhood Cancer Survivor Study (CCSS; the CCSS original cohort data was downloaded from dbGaP, phs001327.v2), genetic variants across the full allelic spectrum were analyzed for their associations with ALL risk. A total of 2,695 ALL cases with whole-genome or whole-exome sequencing were available for rare variant analyses. Pathogenic/likely pathogenic (P/LP) variants in 60 genes associated with autosomal dominant cancer predisposition syndromes were characterized and classified with "PeCanPIE" - the Pediatric Cancer Variant Pathogenicity Information Exchange, a web- and cloud-based platform. We subsequently carried out an enrichment analysis of P/LP variants by comparing ALL survivors with a general population from the GnomAD database and found seven significant genes after adjustment for multiple testing (P< 8.3x10-4, i.e., 0.05/60) including: BRCA1 (odds ratio [OR]=4.06; 95% CI, 2.00-7.59; P=1.21×10-4), BRCA2 (OR=3.48; 95% CI, 1.82-6.15; P=1.50×10-4), CDKN2A (OR=22.30; 95% CI, 5.13-96.68; P=3.07×10-5), PALB2 (OR=5.12; 95% CI, 2.39-10.00, P=3.77×10-5), PAX5 (OR=44.58; 95% CI, 6.49-490.68; P=4.77×10-5), PTPN1 (OR=66.85; 95% CI, 11.96-670.57, P=1.63×10-7), and TP53 (OR=17.86; 95% CI, 6.12-50.36; P=3.43×10-7). Two of these genes have also been previously linked with pediatric ALL (CDKN2A and TP53). Repeating these analyses with 309 newly diagnosed patients from the Pediatric Cancer Genome Project, we observed similar results for five of these genes (BRCA1, BRCA2, CDKN2A, PALB2, and TP53). To further investigate common germline variants associated with ALL risk, we performed a genome-wide association analysis using 2,777 ALL cases and 6,255 controls (5,881 other pediatric cancer cases and 374 non-cancer controls) with whole-genome sequencing or imputed SNP-array data. In addition to replicating known associations at ARID5B, IKZF1, CDKN2A, BMI1, PIP4K2A, CCDC26 and CEPBE, we identified a novel variant (rs112425636, chr17:82324152:G:A; OR=1.65; 95% CI, 1.42-1.93; P=2.48×10-10) mapped to the intronic region of SECTM1 gene. Based on RNA sequencing data for 164 pediatric hematological cancer samples, we found that the expression of SECTM1 gene was significantly higher among patients with GG genotype than patients with AA or AG genotypes for rs112425636 (FPKM=1.34 vs. 0.71, P<0.01). Among the subset of 32 B-ALL samples, the magnitude of difference was larger (FPKM=1.90 vs. 0.70, P=0.017). In summary, we found statistical evidence for several cancer predisposition genes harboring rare high-penetrance variants and a novel common low-penetrance variant associated with risk of pediatric ALL. Our novel findings add new knowledge to the full allelic spectrum of genetic architecture of pediatric ALL susceptibility.

Novel prognostic and predictive biomarker for neuroblastoma

Dinesh Babu Somasundaram, Zhongxin Yu, Ashley Baker, Natarajan Aravindan. *University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Recently we showed that Retinal degeneration protein 3 (RD3) is constitutively expressed in healthy adult and fetal tissues beyond retina and, its gradient expression from high to low in ganglioneuroma, ganglioneuroblastoma and neuroblastoma (NB). Crucially, our sequential in *vitro* and *in vivo* studies

identified that RD3 regulates NB progression and metastasis, and its loss prompts the evolution of therapy defying progressive disease (PD). Here we investigated the prognostic significance of RD3 in NB, its predictive benefit and, its association to clinical outcomes. RNA-Seq data mining (4 independent study cohorts, total n = 1013) indicated that high RD3 can predict good NB prognosis. RD3 expression (immunohistochemistry) gauged in our NB patient cohort (n = 100) showed a positive correlation with longer overall survival (OS, P = 1.0E-04) and relapse-free survival (RFS, P = 2.1E-02). Similarly, high RD3 correlated with longer OS (P = 1.2E-03) and RFS (P = 2.1-02) in children presented with high-risk NB (HR-NB), irrespective of MYCN amplification status (MYCN amplified, P = 1.4E-02; non-amplified, P = 5.5E-03) and patient age (<2Y age, P = 2.8E-02; >2Y age, P = 1.0E-04) groups. Significantly, we observed a gradient loss of RD3 with NB progression, from stage 1 through stage 4 disease. Consistently, RD3 loss was substantial in metastatic disease when compared to the primary neuroblastomas, and this loss associated with poor OS in patients presented with metastatic disease (P = 4.0E-02). More importantly, RD3 is significantly lost in therapy resistant progressive NB and corroborated significantly (P = 9.5E-03) with the poor progression free survival. Multivariate analysis identified RD3 as an independent (P = 4.4E-02) prognostic factor for NB. These results demonstrate that RD3-loss can forecast poor prognosis in NB, and further imply that assessing RD3 loss could serve as the good predictor for therapy response and / or PD evolution. Together, these data identify a novel prognostic and predictive factor for neuroblastoma. Highlighting the prenatal, natal, and early childhood risk factors of cancer: seeking better opportunities for cancer prevention

Abeer Abd Elmoneim[1], Ayat Roushdy[2], Ehab Metwally[2]. *[1]Sohag University, Cairo, Egypt,[2]Taibah University, Madinah, Saudi Arabia*

Background: Fostering new public health approaches to cancer prevention is required to reduce the number of new cases. Early life exposures, to carcinogens may affect different phases of the multi-tage clonal expansion model of carcinogenesis. Critical development periods, in-utero and puberty, exposures may induce permanent changes in tissue differentiation, metabolism, and gene expression that influence cancer risk. Epigenetic modifications are also critical for regulating cellular processes and responses during development that are maintained overtime. Therefore, promising strategies should develop for cancer prevention mainly on environmental approaches. We aim in this study to assess the prevalence of risk factors of childhood cancer in Almadinah City, a local community in Saudi Arabia, and to address cancer prevention opportunities during prenatal, natal and early children life.
Patients and Methods: The study is a cross section observational study. The population includes convenient samples of pregnant mothers, neonates and preschool children. Data regarding natal, prenatal and early childhood risk factors of cancer collected using a predesigned questionnaire.
Results: Early life exposure to cancer risks increases prevalence of cancer. Risk factors like high birth weight, maternal obesity and smoking are the most frequent risks followed by chromosomal anomalies and genetic syndromes. Prenatal use of folic acid, breastfeeding and allergy, respectively, are the most frequent protective factors against cancer development.
conclusions: Strict approaches should be designed for preventing early life exposures and their cumulative effect that can lead to cancer development.

Spatial Profiling, Tumor Classification, and Response Assessment

Hong[11], Donald Jackson[12], Christos Sotiriou[10], Laurence Buisseret[10]. *[1]Institut Jules Bordet, Brussels, Belgium,[2]Department of Oncology, Center of Experimental Therapeutics, CHUV, Laussane, Switzerland,[3]Department of Oncology, Center of Experimental Therapeutics, CHUV, Lausanne, Switzerland,[4]Vital-IT Group, SIB Swiss Institute of Bioinformatics, Lausanne, Switzerland,[5]Oscar Lambret Cancer Center, Lille, France,[6]Instituto Português de Oncologia, Porto, Portugal,[7]Service of Medical Oncology, Clinique et Maternité Ste Elizabeth, Namur, Belgium,[8]Institut de Cancérologie Lucien Neuwirth, Saint-Étienne, France,[9]Centro Hospitalar Vila Nova Gaia e Espinho, Vila Nova De Gaia, Portugal,[10]Breast Cancer Translational Research Laboratory, Institut Jules Bordet, Brussels, Belgium,[11]Merck KGaA, Darmstadt, Germany,[12]Acting Head Sanofi, Cambridge, MA*

Background: IMMUcan (SPECTA NCT02834884) is a European public-private effort to generate molecular and cellular profiling data of the human tumor microenvironment (TME) from up to 3,000 patients, to better understand how the immune system and tumors interact. Triple-negative breast cancer (TNBC) is a heterogenous disease with distinct molecular subtypes characterized by different gene expression, genomic profiles, and clinical outcomes. Here, we explored the association between molecular subtypes and response to neoadjuvant chemotherapy as well as levels of immune cell infiltration in the prospective IMMUcan TNBC cohort.
Methods: At the cut-off date on June 29th, 2022, we identified a first cohort of 132 patients to perform preliminary analyses, of which 109 had pre-treatment RNAseq data available. Among those, pathological Complete Response (pCR) information was available for a total of 86 patients. Preliminary data included the density of CD3+, CD20+ and CD8+ immune cells from the stroma and tumor compartments from multiplex-immunofluorescence (mIF) for 69 patients. TNBC subtypes were computed as described by Bareche et al. Association of continuous variables with pCR was evaluated with logistic regression (univariate analysis).
Results: The pCR rates differed across TNBC subtypes (Fisher's test, P = 0.02). In detail, pCR was achieved in 88% (8/9) of basal like (BL), 63% (17/27) of immunomodulatory (IM) and 45% (16/35) of mesenchymal (M) tumors, while lower pCR rates were observed for the mesenchymal stem-like (MSL) and luminal androgen receptor (LAR) subtypes with 37% (3/8) and 14% (1/7), respectively, suggesting differences in the sensitivity to neoadjuvant chemotherapy in line with previous reports. When considered as continuous signature scores, pCR was positively associated to BL levels (OR = 2.7, 95% CI, 1.5-4.8; False Discovery Rate [FDR] = 0.0031), and negatively associated to MSL and LAR signature levels (OR = 0.53, 95% CI, 0.32-0.87; FDR = 0.019; OR = 0.30, 95% CI, 0.12-0.74; FDR= 0.019). In addition, CD3+ cell densities in the tumor and stroma were significantly higher in IM tumors (P = 0.002 and P < 0.001), while lower levels were found in M tumors (P = 0.005, P = 0.002). Similarly, stromal CD20+ levels were higher in IM tumors (P = 0.008) and lower in M tumors (P = 0.006), suggesting a more immunosuppressive TME in the M subtype. CD8+ cells levels were not significantly different between subtypes.
Conclusions: These preliminary results show relevant differences in the pCR rates among TNBC subtypes, to be confirmed on a larger series of patients and further suggesting a substantial TNBC heterogeneity regarding treatment response. Of note, preliminary mIF results suggest a differential role of the immune response across molecular subtypes. Additional analyses integrating mIF and genomic data are currently ongoing.

Small cell lung cancer (SCLC) is a lethal malignancy with few therapeutic options. Tissue resection or biopsy are unusual, so the scarce sample available has limited our knowledge on the biology of SCLC tumors. Recent advances propose novel molecular subtypes (SCLC-A, SCLC-N, SCLC-P, SCLC-I, NAPI classification) to classify SCLC patients and specific treatment susceptibilities of defined subgroups. In this line, we collected 119 tumor samples from a cohort of early-stage SCLC patients with complete clinical annotation, in order to find specific molecular and immune profiles that define new patient characteristics with potential impact on prognosis or therapy selection. For this, we subjected the tumor tissue to RNA-seq targeted panel of onco-immune-related genes and to immune characterization by IHC. In addition, we analyzed molecular aberrations by whole exome sequencing. All data, including clinical annotations, were integrated by multiparametric computational analysis. Based on the computational analysis of the onco-immune transcriptomic data, we found two major groups of patients with either pro-immunogenic or pro-tumorigenic profiles. The transcriptomic pro-immunogenic group shows better survival and higher infiltration of immune cells (CD4+ T cells, CD8+ T cells, B cells and Macrophages). In contrast, the pro-tumorigenic group presents worse survival and less immune cell infiltration. Using bioinformatics, we described a gene signature that can identify both subgroups. This gene signature includes immune cell markers (MS4A1, CD3D), antigen receptor complex (CD79A), adhesion and migration of T cells (CD2) and immunomodulatory genes (IDO1, TIGIT) expressed in the pro-immunogenic group, and, proliferation (MKI67), transcription regulator (TOP2A) and epithelial and mesenchymal transition-related genes (TWIST1) in the pro-tumorigenic group. Exome sequencing analysis resulted in the expected genomic heterogeneity of SCLC tumors beyond TP53 and RB1 mutations in most patients. However, we found a significant enrichment of XIRP2 gene alterations in the pro-tumorigenic group. Consistent with an early-stage of SCLC, most of the samples were described as SCLC-A subtype by the predominant expression of ASCL1. Interestingly, our findings suggest a relevant biological heterogeneity within SCLC-A tumors that impacts immune infiltrate and disease outcome. Here we show a gene signature that can subclassify early-stage SCLC patients according to their clinical, molecular and immune features, and provides prognostic value independently of the NAPI classification. Since immunogenicity of the tumor impacts response to immunotherapy, we speculate that this gene signature might predict therapy response and therefore contribute to tailored treatment of SCLC.

YAP1 in relapsed pulmonary high-grade neuroendocrine carcinomas (NEC) is associated with *CDKN2A* loss, intact *RB1*, EMT and therapeutic vulnerability to MEK1 and CDK4/6 inhibition

C. Allison Stewart[1], Lixia Diao[2], Yuanxin Xi[2], Runsheng Wang[3], Kavya Ramkumar[3], B. Leticia Rodriguez[3], Benjamin B. Morris[3], Li Shen[2], Bingnan Zhang[3], Yan Yang[3], Azusa Tanimoto[3], Veronica Y. Novegil[3], Luisa

M. Solis Soto[4], Pedro F. Simoes da Rocha[5], Natalie Vokes[3], Don L. Gibbons[3], Michael Frumovitz[6], Junya Fujimoto[4], Jing Wang[2], Bonnie Glisson[3], Lauren A. Byers[3], Carl M. Gay[3]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Thoracic/Head & Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[5]Department of Medical Oncology, Hospital del Mar, Barcelona, Spain,[6]Department of Gynecologic Oncology and Reproductive Medicine, UT MD Anderson Cancer Center, Houston, TX*

Neuroendocrine carcinomas (NECs) are clinically aggressive carcinomas commonly arising from the respiratory and gastrointestinal tracts, typically categorized as large-cell neuroendocrine carcinomas (LCNECs) or small cell carcinomas (most commonly small cell lung cancer (SCLC)). Clinically, pulmonary LCNECs (pLCNECs) mirror the course common to SCLC - initial response followed by rapid and insurmountable resistance to one-size-fits-all approaches. Recently, SCLC has been subdivided into four subtypes with unique vulnerabilities, three of which are defined by the transcription factors ASCL1, NEUROD1, and POU2F3, while a fourth group exhibits an inflamed signature. We hypothesize that pLCNEC may be similarly classified into molecularly distinct subsets with unique therapeutic vulnerabilities - a fundamental step toward personalized medicine. We applied our SCLC 1300 gene signature to pLCNEC patient tumors and, as in SCLC, found three distinct subtypes determined by differential expression of *ASCL1*, *NEUROD1*, and *POU2F3*, but with a unique fourth subtype marked by expression of the transcription factor *YAP1*. Unlike in treatment-naïve SCLC, where YAP1 is absent, *YAP1* expression clearly defines pLCNEC as two, roughly equal subsets with the *YAP1*-low tumors encompassing tumors expressing the other three transcription factors. Conversely, *YAP1*-high pLCNEC is more mesenchymal and inflamed, and less neuroendocrine (NE), reminiscent of inflamed SCLC. Additionally, YAP1-high status is associated with smoking exposure ($P<0.001$, FC=81), high frequency of *CDKN2A* homozygous deletion and *SMARCA4* mutations, as well as intact *RB1*. These features are distinct from SCLC, wherein transcriptional subtypes lack distinct genomic characteristics. Consistent with *CDKN2A* deletion, *YAP1*-high pLCNEC cell lines have increased sensitivity to MEK1 and CDK4/6 inhibition. We also demonstrate that RB1 loss downregulates YAP1 expression, which may account for the absence of YAP1 in treatment-naïve SCLC due to ubiquitous loss of *RB1*. In contrast to treatment-naïve SCLC, where our group and others have been unable to detect YAP1, single-cell RNAseq analysis of biopsies from patients with relapsed SCLC identified emerging *YAP1*-positive cancer cell populations, which are similarly associated with increased EMT, immune cell infiltration (CD8+ T-cells), and loss of NE gene expression. This suggests that the ability for cancer cells to acquire YAP1 expression and, perhaps, pLCNEC-like features, may be a resistance mechanism in relapsed SCLC, contributing to the abundant intratumoral heterogeneity and highlighting potential vulnerabilities to overcome resistance. In summary, YAP1 may be a predictive biomarker of intact *RB1* and response to cellular and checkpoint immunotherapy and MEK1/CDK4/6 inhibition in pLCNEC and relapsed SCLC.

Molecular landscape of clonal hematopoiesis in patients with lung cancer: First results of the CHIC study

Marco Tagliamento, Christophe Marzac, Mihaela Aldea, Damien Vasseur, Arnaud Bayle, Anas Gazzah, Maud Ngocamus, Claudio Nicotra, Julieta Rodriguez, Antonin Levy, Capucine Baldini, Santiago Ponce, Felix Blanc-Durand, Etienne Rouleau, Antoine Italiano, Ludovic Lacroix, Luc Friboulet, David Planchard, Fabrice Barlesi, Yohann Loriot, Jean-Baptiste Micol, Benjamin Besse. *Gustave Roussy, Villejuif, France*

Introduct**ion:** CHIC (Clonal Hematopoiesis In Lung Cancer) is a retro-prospective study that aims to describe the characteristics of clonal hematopoiesis (CH) in patients with non-small cell lung cancer (NSCLC). We present preliminary results from the retrospective cohort.

Experimental procedures: A retrospective analysis conducted in patients with metastatic or recurrent NSCLC included in the MATCH-R study (NCT02517892) at Gustave Roussy (Villejuif, France). CH was evaluated by a 74-gene targeted NGS panel (HaloPlex - Agilent) performed on DNA extracted by isolated-by-blood leukocytes. The variant allele frequency (VAF) threshold of detection was set at 1%.

Results: 108 consecutive patients with advanced NSCLC included from October 2015 to July 2019 were evaluated, irrespective of the tumor molecular profile. 46% of the patients were female, 67% were former or current smokers. 82% of the patients had adenocarcinoma and 44%, 23%, 33% had bone, liver and/or brain metastases, respectively. Patients had received a median of 2 lines of systemic therapy and 81% were on active anticancer treatment at the time of CH assessment. At least one CH mutation was found in 38 out of 108 patients (35% prevalence), with an increasing with age trend. Patients carrying CH were older as compared to those without CH and had in 29% vs. 11% of cases tumor histology other than adenocarcinoma (p=0.009). No difference in overall survival was observed according to CH detection (log rank p=0.318). We found 64 mutations in 19 different genes: 63% of the patients carried a single mutation, while co-occurrence of two, three, four or five mutations, within the same gene or in more than one, was found in seven (18%), four (11%), one (3%) and two patients (5%), respectively. Epigenetic modifiers (*DNMT3A*, *TET2*, *ASXL1*) were the most frequently mutated genes: 38 mutations with a median VAF of 6.5% detected in 32 patients. DNA repair genes (*PPM1D*, *TP53*, *CHEK2*, *ATM*) were the second most frequently mutated: 11 mutations at a median VAF of 4% were detected in 9 patients. 7 mutations in genes encoding for the cohesin complex (*SMC3*, *SMC1A*, *RAD21*, *STAG2*) were found in 6 patients, with a median VAF of 5%. A non-simultaneous cfDNA sequencing by FoundationOne Liquid CDx assay (324-gene panel) was performed in 9 patients for tumor profiling. In 2 out of 3 tested cases the presence of CH was confirmed in plasma liquid biopsy. 4 patients with no detectable CH by the targeted blood sequencing subsequently were found having CH mutations in plasma NGS, on average 45 months apart. To note, as many as 5 out of the 19 detected mutated genes (*PPM1D, SMC3, SMC1A, PRPF8, ZRSR2*) are not part of the FDA-approved NGS panel used for cfDNA profiling in solid tumors.
Conclusion: We found a consistent prevalence of CH in patients with NSCLC by using a sequencing approach targeted for hematologic disorders. Prognostic implications of CH are under investigation and will be evaluated in the full cohort.

CD8 T cell-melanoma cell interactions in response and resistance to ipilimumab plus nivolumab: Biopsy analysis of SWOG S1616

Katie M. Campbell[1], Lawrence Kuklinski[1], Zaid Bustami[1], Jessica Maxey[2], Egmidio Medina[1], Sandra Santulli-Marotto[2], Cynthia R. Gonzalez[1], Nataly Naser Aldeen[1], Kari Kendra[3], Sapna Patel[4], Siwen Hu-Lieskovan[5], James Moon[6], Shay Bellasea[6], Christine N. Spencer[2], Marshall A. Thompson[2], Michael Wu[6], Ari Vanderwalde[7], Philip O. Scumpia[1], Antoni Ribas[1]. *[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]Parker Institute for Cancer Immunotherapy, San Francisco, CA,[3]Ohio State University, Columbus, OH,[4]MD Anderson Cancer Center, Houston, TX,[5]Huntsman Cancer Institute, Salt Lake City, UT,[6]SWOG Statistic and Data Management Center, Seattle, WA,[7]West Cancer Center, Memphis, TN*

Background: In the randomized S1616 trial (NCT03033576), patients with metastatic melanoma refractory to anti-PD-1-based therapy had improved progression free survival (PFS, HR = 0.63, p = 0.037) and objective response to ipilimumab plus nivolumab (ipi/nivo, RR 28%) compared to ipilimumab alone (ipi, RR = 9%). We hypothesized that reversal of resistance to PD-1 blockade with CTLA-4 blockade would result in increased CD8 T-cell infiltration in patient biopsies.
Methods: Multiplex ion beam imaging (MIBI) for 32 protein markers, spanning tumor, immune, and stromal cell types, was used to evaluate the tumor microenvironment in melanoma tumor biopsies collected at baseline (N=21 samples) and one month on-treatment (N=22; N=16 paired timepoints). Tumor-immune cell dynamics were determined by comparing baseline and on-treatment biopsies within clinical groups (ipi/nivo response, N=10; ipi/nivo no-response, N=9; ipi no-response, N=8).
Results: Multiplex analysis in ipi/nivo responsive patients demonstrated increased proportions of CD8 (median 1.6X increase), CD4 (2.1X), regulatory T cells (1.6X), and monocytes (1.4X), with a paralleled 8.1X decrease in melanoma cells over the course of treatment. This was confirmed by histopathologic evidence of tumor regression, necrosis, and immune infiltrate in on-treatment, responding tumor biopsies, as determined by dermatopathologists. Melanoma cells had direct, cell-membrane interactions with CD8 T cells in ipi/nivo responsive patients, both at baseline (median 26%) and on-treatment (median 86%). The shared

interface between melanoma and CD8 T-cells had polarized expression of CD3, CD8, and CD45RO. There was no change in T-cell infiltration nor tumor cell content over the course of treatment in ipi/nivo non-responders nor ipi non-responders; similar proportions of melanoma cells were interacting with CD8 T-cells at baseline (median 24%) and on-treatment (27%).
Conclusion: Reversal of resistance to PD-1 blockade is associated with increased frequency of CD8 T-melanoma cell interactions and pathological response, reflective of different stages of antitumor immune responses. Response to ipi/nivo in the anti-PD-1 refractory setting was further associated with increased tumor-polarized and activated CD8 T cells interacting with melanoma cells, demonstrated by the colocalized expression of immune synapse proteins at tumor-CD8-T-cell membrane interfaces.

Evaluation of plasma circulating tumor DNA (ctDNA)-based whole genome sequencing (pWGS) and whole exome sequencing (pWES) and concordance with tumor tissue whole exome sequencing (tWES): a pilot study in patients with recurrent or metastatic head and neck squamous cell carcinoma or metastatic urothelial carcinoma

Razvan Cristescu, Andrew Albright, Steven Townson, Cai Chen, Blanca Homet Moreno, Nati Lerman, Z. Alexander Cao, Carol Peña. *Merck & Co., Inc., Rahway, NJ*

Background: The genetic heterogeneity and clonal evolution of tumors is hypothesized to influence disease response and acquisition of resistance during treatment. However, comprehensive analysis of the changing tumor molecular landscape to support evaluation of such a hypothesis is often difficult to quantify due to the lack of accessibility to longitudinal biopsy samples in a large number of patients (pts). Longitudinal analyses using pWGS or pWES may allow the delineation of the genetic evolution of tumors and its impact on treatment outcomes. We conducted a pilot study to evaluate the feasibility of obtaining pWGS and pWES data from ctDNA in pretreatment samples from pts enrolled in 2 phase 3 trials that evaluated second-line pembrolizumab versus chemotherapy/standard-of-care therapy: KEYNOTE-040 (recurrent or metastatic head and neck squamous cell carcinoma; NCT02252042) and KEYNOTE-045 (metastatic urothelial carcinoma, NCT02256436). Concordance between pWES and tWES was also evaluated.
Methods: Cell-free DNA was isolated from 1-3 mL of plasma; pWGS (via low-pass WGS) and pWES were performed on samples from pts with available tWES data generated as part of planned tissue biomarker analyses for the respective studies. Tumor burden in ctDNA was estimated from pWES data using single nucleotide variant (SNV)-based maximum somatic allele frequency (MSAF) and from pWGS data using a copy number variation-based measure of mutational burden in the tumor fraction. Concordance between the pWES and tWES mutational spectrum was determined using the Jaccard index. Concordance of key driver somatic events (*FGFR3, TP53*, and HPV status) was evaluated.
Results: Plasma samples from 47 pts (KEYNOTE-040, n = 24; KEYNOTE-045, n = 23) were analyzed. Tumor burden estimates from pWGS (median coverage, 5.84; range, 4.28-8.18) and pWES (median coverage, 1806; range, 1038-2413) data were highly correlated (Spearman $\rho = 0.94$). A range of 0 to 956 nonsynonymous SNVs (median, 50) per pt was identified in ctDNA. When the ctDNA tumor burden was high (MSAF ≥5%, observed in two-thirds of pts), a relatively high concordance was observed for individual alterations in *TP53*, *FGFR3*, and HPV status (overall agreement: 0.87, 0.97, and 0.96, respectively); between tissue- and plasma-based tumor mutational burden ($R = 0.49$); and in overall mutational landscape overlap (Jaccard index: median, 0.30; range, 0.002-0.53).
Conclusions: These data show that pWES exhibits reasonably high concordance with tWES when the tumor burden in ctDNA is relatively high and may be informative regarding tumor genomic characteristics. Extensive longitudinal studies are still needed to understand tumor genetic evolution using plasma ctDNA.

#4529

The tumor molecular landscape of nasopharyngeal carcinoma (NPC) in endemic and non endemic areas

Deborah Lenoci[1], Carlo Resteghini[1], Mara Serena Serafini[1], Federico Pistore[1], Silvana Canevari[1], Brigette B.Y. Ma[2], Stefano Cavalieri[1], Annalisa Trama[1], Lisa Licitra[1], Loris De Cecco[1]. *[1]Fondazione IRCCS Istituto*

Nazionale dei Tumori, Milan, Italy,[2]Department of Clinical Oncology, The Chinese University of Hong Kong, Hong Kong SAR, Hong Kong

Nasopharyngeal carcinoma (NPC) is an epithelial malignancy with a higher incidence in Asian endemic areas (EA) than in non endemic areas (NEA). Epstein-Barr virus infection is associated with most NPCs in both areas. We dissected the gene expression (GE) and microenvironment of NPC, leading to the identification of molecular subtypes that might explain the differences between EA and NEA NPCs. We retrieved data from NPC-EA transcriptomic repositories: 6 GE datasets, including tumor and normal samples (GSE12452, GSE34573, GSE132112, GSE53819, GSE68799, GSE102349); one validation dataset with both EA and NEA(https://doi.org/10.5281/zenodo.5347891); 4 GE signatures associated with prognosis and treatment prediction (PMID: 24297049, 35262435, 32596151, 33096113); and NPC EBV related genes/pathways and gene sets (PMID: 35846746, 35394843, 35105963; Liu NPC, Wood EBV EBNA1 Down, Sengupta NPC LMP1 UP, REACTOME DNA Repair; Hallmarks). The 6 datasets were integrated using a bioinformatic meta-analysis approach, and the classifier method was applied to the validation dataset in order to identify the subtype with worst prognosis. Furthermore, RNA sequencing was performed on 50 Italian NEA NPC samples (INT188/19; GSE208281). Biological and functional profiling of EA and NEA were performed using xCell, Gene set enrichment analyses, and treatment prediction methods (PMID: 16103067, pRRophetic R, PMID: 28052254). Four clusters (Cl) were identified through a meta-analysis of EA-NPC. Prognostic analyses revealed that Cl3 had the worst prognosis (P=0.0476), confirmed by three of the four prognostic signatures and in the validation dataset (P=0.0368). Based on the biological and functional characterization of these clusters, we arrived at the following GE subtypes: Cl1, Immune-active; Cl2, Defense-response; Cl3, Proliferation; Cl4, Perineural-interaction/EBV-exhaustion. According to the treatment prediction methods, the sensitivity of each cluster was radiotherapy and immunotherapy for immune-active, radiochemotherapy and immunotherapy for defense-response, chemotherapy for proliferation, and cisplatin treatment for perineural-interaction/EBV-exhaustion. In our NEA cohort, only three clusters were expressed (excluding perineural-interaction/EBV-exhaustion). Immune/biological characterization and treatment prediction analyses of NEA partially replicated the EA results. Our study provides a relevant biological overview of EBV-related NPC in both EA and NEA. The immune microenvironment plays a critical role in NPC owing to the viral etiology of this malignancy. The presence of a perineural-interaction/EBV-exhaustion cluster in EA suggests an inactive EBV infection according to the viral related “hit and run theory”; however, further analyses are needed. The immune/biological characterization of EA and NEA may help predict the response to different therapeutic strategies.

Single-cell analysis of oral squamous cell carcinoma (OSCC) from smoker vs. non-smoker patients highlights two groups of tumors with distinct immune microenvironments

Yannick Le Meitour[1], Béatrice Vanbervliet[1], Sonia Canjura-Rodriguez[1], Cyril Degletagne[1], Laurie Tonon[1], Lucas Michon[1], Jebrane Bouaoud[1], Philippe Zrounba[2], Aude Excoffier[2], Karène Mahtouk[1], Pierre Saintigny[1]. *[1]Univ Lyon, Claude Bernard Lyon 1 University, INSERM 1052, CNRS 5286, Centre Léon Bérard, Cancer Research Center of Lyon, Lyon, France,[2]Department of Surgical Oncology, Centre Léon Bérard, Lyon, France*

Background and Rationale: OSCC is the most frequent head and neck cancer. While it is mainly affecting patients with a smoking and/or alcohol history (SD), 10% to 15% of OSCC are diagnosed in patients with not known risk factors (NSND). We and others have shown that OSCC from NSND patients are characterized by an enrichment in interferon gamma (IFNγ) response and PD-1 signaling pathways together with a higher intratumor T-cell infiltrate. Herein, we seek to gain more insights into the immune and non-immune tumor microenvironment (TME) of OSCC in SD vs. NSND patients.
Material and Methods: We made use of single-cell RNA seq (10x Genomics) from non-sorted and CD45 negative enriched cell suspensions of OSCC biopsies from 11 treatment naïve patients, human papillomavirus negative, including 6 SD and 5 NSND patients.
Results: All samples were characterized by a strong immune cell infiltrate. Consistent with our previous results, the analysis of 51,629 immune cells confirmed that NSND patients’ samples displayed a significantly

higher proportion of T cells (p = 0.005) compared to SD patients. NK cells were also increased, with 2% in SD patients versus 6% in NSND patients (p = 0.008). T cells strongly expressed IFNγ and remarkably, both myeloid cells and tumor cells from NSND patients had an increased enrichment in IFNγ response pathway in NSND as compared to SD patients. The TME of SD patients was characterized by the presence of 15% of plasma cells vs. 3% in NSND patients (p = 0.003). Thus, tumors from NSND versus SD patients represent two distinct groups of tumors characterized by a different immune TME. Moreover, tumors from SD patients displayed 2% vs. 4% Cancer Associated Fibroblasts (CAFs) (p = 0.01). In addition, among CAFs subpopulations, myofibroblast CAFs, defined as the subpopulation producing extracellular matrix proteins were found only in tumors from SD patients, suggesting that distinct CAFs subpopulations may shape the immune TME by affecting the recruitment and function of adaptive immune cells in SD versus NSND patients. Finally, we analyzed tumor cells using non-negative matrix factorization to find Meta Programs (MP), which are set of genes coordinately upregulated. We identified 5 MP associated with different biological functions: epithelial differentiation, stress, cell cycle (G2/M), partial epithelial-to-mesenchymal transition, and epithelial senescence. While the epithelial differentiation MP was found in all patients, the remaining ones were more frequently found in SD patients.
Conclusion: Our results show that the TME of OSCC from NSND vs. SD differs in terms of T, NK, and plasma cells composition, CAFs, and tumor cells MP. Integration with spatial transcriptomics is ongoing. Those biological differences may represent an opportunity to refine the therapeutic approaches in the two populations of patients.

Clinical translation of biomarkers for ZL-1211, an anti-CLDN18.2 antibody, in patients with advanced solid tumors from a phase I dose-escalation study

Zhen Luo[1], Xiao Wang[1], Xuehuo Zeng[1], Jiaqing Yi[1], Tegan Burns[1], Herman Liu[1], Xinyu Zhang[2], Wenyu Liu[2], Karl Hsu[1], Hua Gong[1]. *[1]Zai Lab (US) LLC, Menlo Park, CA,[2]Zai Lab (Shanghai) Co., Ltd., Shanghai, China*

ZL-1211, a humanized monoclonal IgG1 antibody targeting CLDN18.2, induces cancer cell death through antibody-dependent cellular cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC). We developed ex vivo ADCC and CDC assays to study the mechanism of actions of ZL-1211. Our preclinical data has demonstrated greater antitumor activities than the clinical leading benchmark via enhanced ADCC by mutation in Fcγ domain and potent CDC activities. We used those ex vivo assays to further profile the clinical specimens from patients collected at baseline (pre-infusion) and the following cycles (post-infusion) in our phase 1 study (NCT05065710). Preliminary results in clinical samples indicated that baseline ADCC and CDC capabilities were correlated with anti-tumor activity of ZL-1211 in patients with CLDN18.2-positive locally advanced or metastatic solid tumors, suggesting probable predictive biomarkers. Results also showed that changes in circulating ZL-1211 mediated ADCC and CDC activities were dose-dependent and in accordance with the pharmacokinetic (PK) profile. In addition, we performed differential gene expression analysis and real-time PCR to compare gene expression in ZL-1211 responder and non-responder PDX models and CCLE cell lines. Our findings reveal that several immune-related genes may serve to predict the responses to ZL-1211 treatment. Other potential predictive biomarkers such as Fcγ receptor CD16A polymorphism and baseline stromal CD8 expression were also evaluated in clinical samples. Taken together, analytical approaches developed and validated from preclinical studies were successfully translated to characterize clinical samples in the current Phase 1 trial. The exploratory analysis indicated the clinical relevance of multiple biomarkers and their potential as predictive biomarkers of ZL-1211.

Spatial profiling delineates tumor-T-cell dynamics in anti-PD-1-refractory melanoma treated with ipilimumab or ipilimumab plus nivolumab

Nataly Naser Al Deen[1], Katie M. Campbell[1], Egmidio Medina[1], Cynthia R. Gonzalez[1], Philip O. Scumpia[2], Antoni Ribas[1]. *[1]Medicine - Hematology Oncology, UCLA David Geffen School of Medicine, Los Angeles, CA,[2]Medicine, UCLA David Geffen School of Medicine, Los Angeles, CA*

Background**:** Immune checkpoint blockade (ICB) therapies promote anti-tumor activity by facilitating CD8 T-cell activation at the tumor site (e.g., anti-PD-1), or in the lymph node, promoting T-cells trafficking to the tumor site (e.g., anti-CTLA-4). Focusing on patients with metastatic melanoma refractory to anti-PD-1 therapy who received ipilimumab ± nivolumab (ipi±nivo), we hypothesize that combination therapy could overcome anti-PD-1 primary resistance in some patients, by facilitating T-cell trafficking and infiltration into the tumor.
Methods: Visium spatial transcriptomics using 18,000 RNA plex (n=10), multiplexed ion beam imaging (MIBI) using 32 protein plex (n=4), and CosMx single cell imaging using 1000 RNA plex (n=2) were performed on paired baseline (n=5) and on-therapy biopsy samples (n=5). Paired samples were derived from patients with complete response to ipi+nivo (n=3), partial response to ipi+nivo (n=1), and no response to ipi monotherapy (n=1).
Results: Visium spatial transcriptomics revealed a decrease in melanoma gene expression clusters and an increase in expression of immune clusters. Further characterization of the immune clusters revealed signatures of CD4+ and CD8+ T cells displaying stronger activation markers, in particular cytotoxic markers and interferon gamma clusters, along with M1 macrophage transcripts. However, further analysis of the paired biopsies in the ipi monotherapy non-responder revealed a concomitant increase in the immune-suppressive M2 macrophages, tolerogenic DCs, regulatory T cells, and exhausted T cells, which was not observed in the ipi+nivo responders. Confirmatory studies performed in two patients (ipi+nivo responder vs ipi non-responder) using MIBI confirmed a decrease in the tumor burden, and large increases in CD8 (199X in ipi+nivo vs 1.52X in ipi), CD4 (22.3X in ipi+nivo vs 8.56X in ipi), and T cells (26.1X in ipi+nivo vs 2.13X in ipi). Focusing on the non-responder (ipi) paired biopsies, CosMx revealed heterogeneous tumor clusters, with little to no immune infiltration in the baseline biopsy, and a decrease in tumor burden with increased markers of immune response and immune suppression in the on-therapy biopsy.
Conclusion: Integrated single cell spatial analyses, on the RNA and protein levels, revealed increased immune cell recruitment to the tumor site in responders to anti-CTLA-4 + anti-PD-1 therapy compared to a non-responder to anti-CTLA-4 monotherapy, and may provide clues to cancer-immune cell interactions in response to ICB. The presence of immune suppressive clusters at the tumor site in the on-therapy biopsy in the anti-CTLA-4 monotherapy would support our hypothesis that while anti-CTLA-4 facilitates T-cell trafficking and infiltration into the tumor site, anti-CTLA-4 alone without anti-PD-1 may not be sufficient to overcome anti-PD-1 primary resistance in some patients.

#4533
Serum protein changes in patients with desmoid tumors responsive to the TBL1 inhibitor, tegavivint
Stephen Horrigan, Kimberly R. Holloway, David Stenehjem, Casey Cunningham. *Iterion Therapeutics, Houston, TX*

Background: A Phase 1/2 clinical trial (NCT03459469) of the small molecule tegavivint in patients with desmoid tumors (DTs), demonstrated drug safety and tolerability with evidence of clinical activity. Transducin Beta-Like Protein 1 (TBL1) is a necessary co-activator for beta-catenin's oncogenic activity. Wnt-activation promotes formation of a TBL1: beta-catenin complex that protects β-catenin from degradation in the nucleus and promotes Wnt-target gene activation. Tegavivint binds TBL1 preventing the interaction with beta-catenin, which results in nuclear beta-catenin degradation and inhibition of downstream transcription. For patients whose desmoid tumors responded to tegavivint we assayed changes in serum-based proteins, selected based on their cancer-related function and dysregulation by aberrant Wnt/ beta-catenin signaling, to potentially identify suitable biomarkers that may be useful in future studies.
Methods: Whole blood and tumor tissue was collected from desmoid patients before and after administration of tegavivint at dose levels ranging from 1 to 5 mg/kg administered via a 4-hour intravenous (IV) infusion on days 1, 8, and 15 of a 28-day cycle. Collection timepoints were pre-dose and up 1 week (wk.) following the start of the infusion. Secreted protein levels were profiled in the serum using Luminex multiplex technology. Changes in protein levels were compared to the tegavivint pharmacokinetic (PK) profiles. Tissue samples were analyzed for gene expression changes.
Results: Preliminary analyses demonstrated that the majority of tegavivint treated patients with an objective response to tegavivint showed a consistent and expected pattern in serum levels of known Wnt/ beta-catenin

regulated proteins. Decreases in levels of DKK1, FGF-2, MMP-1, PDGF-AA and VEGF-A and an increase in CCL5 levels were observed. In treated patient serum, protein level changes were detected as early as 2 hours (h) following the start of infusion and continued to progress in the predicted direction at 24 h. At the 5 mg/kg dose, all selected biomarkers remained decreased (or in the case of CCL5, increased) during the dosing interval, with a tegavivint half-life of 48.6 h and C_{min} (trough value) 1 wk. post treatment above in vitro IC_{50} values. Gene expression changes were found in tumor tissue in comparing pre- to post-tegavivint treatment.
Conclusion: A panel of beta-catenin regulated proteins and transcripts were identified as candidate pharmacodynamic biomarkers in patients whose desmoid tumor responded to tegavivint. Alterations in these serum proteins continued throughout the dosing interval and, for several proteins, a potential dose response correlation was observed. Further characterization of the relationship between tegavivint plasma levels, serum biomarkers, transcriptional changes and clinical responses in additional patients and time points will be presented.

National Multidisciplinary Tumor Board improves diagnostic stratification and therapeutic management in Cancers of Unknown Primary: the French Experience

Nicolas Jacquin[1], Maud Kamal[2], Ivan Bieche[2], Célia Dupain[2], Isabelle Guillou[2], Linda Larbi-Chérif[2], Etienne Rouleau[3], Julien Masliah Planchon[2], Isabelle Soubeyran[4], Christelle de la Fouchardière[5], Camille Tlemsani[6], Hélène Blons[7], Fabienne Escande[8], Michel Vidaud[6], Jennifer Wong[2], Pierre Saintigny[5], Sandrine Boyault[5], Adrien Buisson[5], Yves Allory[9], Anne Vincent-Salomon[2], Vincent Cockenpot[5], Janick Selves[10], Christophe Le Tourneau[2], Sarah Watson[2]. *[1]Institut Godinot, Reims, France,[2]Institut Curie, Paris, France,[3]Gustave Roussy, Villejuif, France,[4]Institut Bergonié, Bordeaux, France,[5]Centre Léon Bérard, Lyon, France,[6]Institut Cochin, Paris, France,[7]Hôpital Européen Georges Pompidou, Paris, France,[8]CHU de Lille, Lille, France,[9]Institut Curie, Saint Cloud, France,[10]CHU de Toulouse, Toulouse, France*

Introduction: With the increasing complexity of current diagnostic investigations, the integration of clinical, pathological and molecular characteristics is crucial for the management of patients (pts) with cancers of unknown primary (CUP). A national multidisciplinary tumor board (NatCUPMTB) was created 2 years ago in France to discuss the diagnostic and therapeutic management of CUP pts. The objective of this study was to evaluate its diagnostic, prognostic and therapeutic impact after 2 years of activity. Methods: This was a multicenter retrospective study with prospective follow-up. All pts discussed at least once in the NatCUPMTB between June 2020 and August 2022 were included. Pts and tumors characteristics, pathological and molecular analyses including WGS, WES and RNAseq performed on SEQOIA and AURAGEN national large-scale sequencing platforms, multidisciplinary tumor board (MTB) conclusions, and follow-up after MTB were collected. Results: 76 pts for whom a long-term follow-up was available were included. The median age at diagnosis was 57 yo, 54% were female, and the median number of metastatic sites at diagnosis was 2. The median time between diagnosis and first MTB presentation was 3.8 months (0.2-55). MTB investigations enabled to identify a likely primary origin in 44/76 (58%) pts, and the MTB recommended a personalized therapeutic strategy in 50/76 patients (66%). MTB recommendations were based on the combination of clinical, pathological and molecular investigations in 55% of pts. After a median follow-up of 6.2 months, the median overall survival (OS) was 17.7 months from diagnosis and 11.0 months from the 1st MTB presentation. Pts for which the MTB had a diagnostic impact, and having received a treatment following MTB recommendation (based on putative origin or targetable alteration) had increased OS compared to pts with no diagnostic orientation (median OS 18.4 months vs 5.6 months, p=0.003) or having received other treatments (median OS 18.4 vs 4.4 months, p=0.0001). Conclusion: NatCUPMTB provides significant diagnostic and therapeutic benefit in pts with CUP. Early presentation of pts at NatCUPMTB as soon as CUP diagnosis is suspected should be recommended.

Clinical outcomes and molecular features of different histopathologic patterns in patients with stage IB non-squamous non-small-cell lung cancer

Dongsheng Yue, Bin Zhang, Chen Chen, Qiang Zhang, Xinyi Wu, Jiping Xie, Changli Wang, Zhenfa Zhang.
Department of lung cancer, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Background: About 15% to 20% of patients with stage IB non-small-cell lung cancer (NSCLC) may develop recurrence within 5 years. However, the use of adjuvant therapy for resected stage IB patients remains controversial. This study investigated the differences in prognosis and molecular features between different histopathologic patterns of stage IB non-squamous NSCLC (nsNSCLC) and tried to identify patients who most in need of adjuvant therapy.
Methods: A total of 215 patients with completely resected pathologic stage IB (tumor size 3-4 cm) nsNSCLC from Tianjin Medical University Cancer Institute & Hospital between 2014 and 2018 were included in the study. For 130 patients, genomic profiling of tumor tissues was sequenced by a panel of 9 driver genes (OncoScreen® Focus CDx Tissue Kit, Burning Rock Biotech) and the molecular risk stratification was assessed by 14-gene quantitative PCR (qPCR) assay (DetermaRx™, Burning Rock Biotech).
Results: Among the 215 patients, 67.9% were solid/micropapillary-predominant pattern (S/MP), 40.5% had received platinum-based doublet adjuvant chemotherapy, and 5.1% had received adjuvant targeted therapy with or without chemotherapy. Patients with S/MP pattern had significantly worse DFS than those with lepidic/acinar/papillary-predominant (L/A/P) pattern (hazard ratio [HR]: 2.16, 95% confidence interval (CI): 1.28 to 3.67; P = 0.013). However, neither pattern could benefit from adjuvant therapy. *EGFR* mutation was successfully detected in 75 out of 126 patients (59.5%), and the positive rate in S/MP pattern was significantly lower than that in L/A/P pattern (50.6% vs 79.5%, P = 0.002). However, *EGFR* mutation status was not a prognostic factor for DFS in neither overall population nor different histopathologic patterns. *EGFR*-mutant patients showed the trend to benefit from adjuvant targeted-based therapy in the limited samples. Molecular risk stratification was successfully assessed in 99 patients, of which 37.4%, 26.3%, and 36.4% were predicted as molecularly high-risk, intermediate-risk, and low-risk patients, respectively. There were significant differences in the proportion of high- and low-risk patients between S/MP and L/A/P patterns (for high-risk: 46.2% vs 20.6%; for low-risk: 26.2% vs 55.9%; P = 0.009). The high-risk patients had significantly shorter DFS than the low-risk patients (HR, 2.93, 95% CI: 1.31-6.54; P = 0.012), especially those in S/MP pattern (HR, 3.45, 95% CI: 1.46-8.15; P = 0.017).
Conclusion: Our study confirms that S/MP pattern is a significantly worse prognostic factor for DFS in nsNSCLC and that there are significant differences in molecular features between these two different histopathologic patterns. qPCR-based assay could reliably identify patients with a worse prognosis in S/MP pattern, suggesting that such patients are most likely to benefit from personalized adjuvant therapy.

Investigating the correlation between molecular diagnostics, targeted therapies and treatment outcomes in Rosai Dorfman disease: a single-institution experience

Samuel B. Reynolds[1], Sabrina R. Wilcox[2], Moshe Talpaz[1], Asra Z. Ahmed[1]. *[1]Hematology and Medical Oncology, University of Michigan, Ann Arbor, MI,[2]Department of Pediatrics, University of Michigan, Ann Arbor, MI*

Introduction: Rosai Dorfman Disease (RDD) is a non-Langerhans cell histiocytic disease whose pathologic features include sinus histiocytosis with variable emperipolesis. Traditional management consists of local therapies (resection, radiation) for limited lesions and myelosuppressive therapies for systemic disease. Recent studies, however, have identified MAP Kinase pathway mutations in RDD, prompting further research into the utility of targeted agents.
Methods: A retrospective analysis was conducted at a single institution over a 20-year period (2002-2022) of 40 patients with RDD. Inclusion criteria included age ≥18 and histopathologic evidence of RDD without obscuring secondary malignancies. Clinical data points included biological gender, age at diagnosis, molecular diagnostics, imaging and therapies administered. Binary data was utilized for statistical analysis and comparison of outcomes by treatment type, time to diagnosis and use of targeted agents.
Results: In this analysis, 72% of patients were female and 28% male with an average age at diagnosis of 45.8 years, over 50% of whom were diagnosed between 1 and 12 months of presentation. Primary disease was most commonly extranodal (>90%), found in cutaneous, osseous and CNS structures (50%, 36% and 16.6%,

respectively). Regarding management, surgery was most common in >36% of patients, followed by steroid and myelosuppressive therapies (25% each), immunotherapy (13.88%) and targeted molecular therapies (11.1%). Disease responses were considered stable if grossly unchanged during serial exam or imaging surveillance, partial if diminished but still present and complete if disease was grossly and radiographically resolved; a partial response or better was observed in >75% of patients. With respect to treatment rendered, stable disease was equally likely between recipients of molecular and conventional (non-molecular) therapy at 25%. Partial responses were higher in molecular therapy recipients (75% as compared to 42%), although complete responses have not yet been observed in this cohort. Patients diagnosed at <1 month from symptom onset had higher rates of disease stability and complete responses compared to those diagnosed at >24 months.
Conclusions: To our knowledge, this study is the largest of its kind in adult Rosai Dorfman Disease. Early recognition and utilization of targeted molecular therapies, based on our preliminary data, are associated with higher rates of achieving disease stability and at least a partial response. The current absence of complete responses in patients receiving targeted molecular therapy is likely attributable to the still-emerging use of these agents and interim response assessments not yet being completed. Higher complete response rates in targeted agents relative to conventional therapies are anticipated in ongoing analyses.

#4537

Erdheim Chester disease: A retrospective study characterizing the molecular and pathologic footprints with clinical presentation and comparative outcomes in the present era of targeted molecular targeted therapy

Sabrina R. Wilcox[1], Samuel B. Reynolds[2], Jennifer Girard[2], Asra Ahmed[2]. *[1]Internal Medicine and Pediatrics, University of Michigan, Ann Arbor, MI,[2]Oncology and Hematology, University of Michigan, Ann Arbor, MI*

Erdheim Chester Disease (ECD) is a rare, non-Langerhans cell histiocytic disease, characterized as a neoplastic disorder in 2016. MAP Kinase and PI3-AKT pathway somatic mutations and/or fusion genes have been shown to play a significant role in disease pathogenesis. Despite this, molecular sequencing at diagnosis has yet to become a standard of practice.
Retrospective analysis of 19 patients diagnosed with ECD at a single institution over a twenty-years (2002-2022) was conducted. Inclusion criteria were patients 18 years or older, histopathologic diagnosis of ECD, and clinical correlation of disease. The following was collected for each patient: biological sex, age at diagnosis, molecular testing (if utilized), immunohistochemistry, imaging results, therapies administered and best treatment outcomes. Information was translated into binary data for statistical analysis.
In this analysis, 47% of patients were females; average age at diagnosis was 51.2 years. 36% of patients were diagnosed within 12 months of symptoms onset. Molecular diagnostics were utilized in 100% of patients, (immunohistochemistry 94%, sequencing 26%). Primary disease was most commonly extranodal (94%), followed by osseous (63%), dermal (52%) and the central nervous system (36%). Treatment consisted of targeted molecular therapy most often (57%), followed by myelosuppressive therapy and steroids (42%), and immunotherapy or radiation (10% each). Disease responses were considered stable if grossly unchanged clinical exam or imaging surveillance, partial (PR) if diminished but still present and complete (CR) if disease was grossly or radiographically resolved. A PR or better was observed in 83% of patients. Stable disease was seen more often in patients treated with conventional therapy (33%) as compared to targeted molecular therapy (11%). PR was higher in targeted therapy recipients (55%). CR was more common with conventional therapy than molecular (66% vs 33%). Patients diagnosed within 1 month of symptom onset had higher rates of disease stability, compared to diagnosis at > 24 months (50% compared to 25%).
To our knowledge, this is one of the largest studies of its kind conducted in adult ECD. Targeted molecular therapy utilization by this analysis is associated with higher rates of partial disease response as compared to conventional therapy. The opposite was observed in complete responders. Use of targeted molecular therapies is very recent and higher CR rates are expected in ongoing analyses and longer patient follow-up. Moreover, molecular diagnostics were not routinely employed at diagnosis which delayed the initiation of treatment. Thus, we strongly advocate for early genetic profiling at the time of ECD diagnosis and utilization of targeted therapies when actionable mutations are observed.

The heterogeneous immune and molecular landscape of endometrial cancer metastases

Matthew J. Hadfield[1], Sharon Wu[2], Alex Farrell[3], Matthew Oberley[3], Nathaniel Jones[4], Thomas Herzog[5], Premal Thaker[6], Don Dizon[1]. *[1]Medical Oncology, Brown University/Legorreta Cancer Center, Providence, RI,[2]Caris Lifesciences, Phoneix, AZ,[3]Caris Life Sciences, Phoneix, AZ,[4]Gynecological Oncology, University of Southern Alabama, Mobile, AL,[5]Gynecological Oncology, University of Cincinnati, Cincinnati, OH,[6]Gynecological Oncology, Washington University School of Medicine, St. Louis, MO*

Introduction: Endometrial Cancer (EC) is a diverse malignancy with multiple histological subtypes. There is a paucity of data exploring the genomic landscape of endometrial cancer primary lesions (ECP) and endometrial metastatic lesions (ECM.) Correlations with genetic makeup and sites of metastatic disease have not been previously studied.

Methods: Relationships of ECM and alterations detected by NGS (592, NextSeq; WES, NovaSeq) were investigated in 15,489 EC samples (Caris Life Sciences, Phx, AZ). PD-L1 expression was tested by IHC (SP142, >2|5%). Microsatellite instability (MSI) was tested by FA, IHC and NGS. Tumor mutational burden (TMB) was measured by summing somatic mutations per tumor (H: >10 mt/MB). Immune infiltrates estimated by deconvolution of WTS data (NovaSeq) using MCP Counter. Real world overall survival (rwOS) was extracted from insurance claims and calculated using Kaplan-Meier estimates for cohorts defined by biopsy site, using start of treatment to last contact. Statistical significance determined by chi-square and Mann-Whitney U and adjusted for multiple comparisons ($q<0.05$).

Results: ECM had higher HER2 amplification (by CISH) compared to ECP (20.4% vs. 16.9%) but lower PR positivity (45.2% vs. 50.2%) ($q<0.05$). TMB-H was highest in ECM to GI (34.2%) compared to Uterine (22.4%) ($q<0.05$). d-MMR/MSI-H prevalence was highest in ECM to GI (30.3%) and lowest in ECM to lung (11.5%) and liver (10.9%) compared to Uterine (19.5%) ($q<0.05$). Hierarchical clustering of ECM sites by alteration (mutations, amplifications and fusions) frequency revealed ECM to Bone and GU having a distinct pattern compared to Uterine with increased alterations in RTK RAS (Bone vs Uterine: FGF3-amp, 3.45% vs 0.39%, FGF19-amp, 3.36% vs 0.39%), Cell Cycle (Bone vs GU vs Uterine: TP53-mt, 37.6% vs 42.3% vs 53.7%), WNT (GU vs Uterus: RNF43-mt, 15.4% vs 7.06%; CTNNB1-mt, 22.3% vs 12.9%) and Chromatin Remodeling (GU vs Uterine: ASXL1-mt, 23.1% vs 7.64%; KMT2D-mt, 18.9% vs 11.1%, ARID1A, 43.8% vs 33.8%) pathway genes.ECM to Bone had the lowest infiltration of B cells and T cells ($q<0.05$). IFN score was 1.21-fold higher in ECM to Bone compared to ECP of Uterus ($q<0.05$). ECM to GU (n=29, HR: 1.59, 570 days, p=0.04) had worse post-Carboplatin survival than ECP (n=3023, 1096 days) while ECM to Lung had better (n=279, HR: 0.73, 1602 days, p=<0.01). ECM to Liver (PD-1/PD-L1i: n=27, HR: 2.4, 165 days, p=<0.01; Bevacizumab: n=44, HR: 1.5, 286 days, p=0.03) had worse post-tx survival compared to ECP (PD-1/PD-L1i: n=607, 760 days; Bevacizumab: n=693, 463 days). ECM to GI (n=44, HR: 0.56, 1080 days, p=0.003) and Lung (n=86, HR: 0.70, 768 days, p=0.01) had improved post-Gemcitabine treatment compared to ECP (n=533, 452 days).

Conclusions: ECM to Bone and GU organs have unique molecular alterations when compared to ECP of the uterus and have lower infiltration of immune cells. We also highlight differences in OS when comparing different ECM.

Graham[2]. *[1]Medical Clinic and Polyclinic II, Klinikum rechts der Isar, Technical University of Munich, Munich, Germany,[2]Centre for Evolution and Cancer, The Institute of Cancer Research, London, United Kingdom,[3]Centre for Genomics and Computational Biology, Barts Cancer Insitute, London, United*

Kingdom,[4]Clinic for Internal Medicine II, University Medical Center Freiburg, Freiburg, Germany,[5]Centre for Genomics and Computational Biology, Barts Cancer Institute, London, United Kingdom,[6]Department of Pathology, University College London, London, United Kingdom,[7]Department of Mathematics and Geosciences, University of Triest, Triest, Italy,[8]Institute of Pathology, Technical University of Munich, Munich, Germany,[9]Visceral and Transplantation Surgery, University Hospital, Ludwig-Maximilians-Universität (LMU) Munich, Munich, Germany,[10]Division of Infection and Immunity, University College London, London, United Kingdom,[11]Department of Surgery, Klinikum rechts der Isar, Technical University of Munich, Munich, Germany,[12]Signalling Research Centres BIOSS and CIBSS,, University of Freiburg, Freiburg, Germany,[13]Bridge Institute of Experimental Tumor Therapy and Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, Germany

Introduct**ion:** Locally advanced esophageal adenocarcinoma (EAC) remains difficult to treat, and resistance is common. The ecological and evolutionary dynamics responsible for treatment failure are incompletely understood.
Aim & Methods: We performed a multi-omic study with a multi-timepoint strategy to examine neoadjuvant treatment response at clonal resolution and in the surrounding tumor microenvironment. EAC samples from chemotherapy responding (REs) and chemotherapy non-responding (NRs) patients with locally advanced EAC were collected at three time points (prior, during, and after neoadjuvant therapy) within the multicenter *MEMORI* trial. Whole exome sequencing (mean depth 300x) was performed on 47 samples from 17 REs and on 24 samples from 10 NRs. Matched RNA sequencing was performed on 53 samples from 17 REs and on 26 samples from 10 NRs. To characterize immune response we performed imaging mass cytometry (IMC) with a 18-marker panel on 26 samples from 9 REs and 16 samples from 6 NRs and T-cell receptor sequencing in 18 RE-samples and 9 NR-samples.
Results: We observed profound changes in mutation signatures over time, characterized by C>A transitions after exposure to neoadjuvant chemotherapy (FOLFOX), which is consistent with earlier observed oxaliplatin induced mutational signatures. Phylogenetic analysis showed no major changes in the clonal make-up during treatment, suggesting phenotypic plasticity rather than clonal evolution caused treatment resistance. EAC samples displayed widespread copy number alterations (CNAs), as previously described. CNAs arising during treatment were significantly more likely to be small, focal alterations rather than large alterations. At the transcriptome level neoadjuvant treatment led to significant changes with significant upregulation of immune and stromal pathways and oncogenic pathways such as *KRAS, Hedgehog* and *WNT*. The presence of immune escape mechanisms (defined as LOH or mutations in HLA, B2M mutations or PDL-1 overexpression) and a lack of clonal T-cell expansions were linked to poor clinical treatment response. Moreover, IMC analyses showed a less activated T-cell phenotype in NRs than in REs throughout treatment.
Conclusion: Using a multi-timepoint approach, we integrated genetic analyses with transcriptomic analyses and analyses of the tumor immune microenvironment for a holistic understanding of treatment resistance. This study identifies profound transcriptional changes during treatment with limited evidence that clonal replacement is the cause, suggesting phenotypic plasticity as a mechanism for therapy resistance. The presence of immune escape, a less activated T-cell phenotype and a lack of clonal T-cell expansions in patients with poor clinical treatment response has high pharmacological relevance and could be exploited via combined immune-chemotherapy treatments.

Multiregional transcriptomics of colorectal cancers define prognostic features less vulnerable to tumor heterogeneity

Jonas Langerud[1], Ina A. Eilertsen[1], Hossein Moosavi[1], Ingeborg F. Backe[1], Merete Hektoen[1], Marine Jeanmougin[1], Ole Sjo[2], Arild Nesbakken[3], Ragnhild A. Lothe[1], Anita Sveen[1]. *[1]Department of Molecular Oncology, Oslo University Hospital, Institute for Cancer Research, Oslo, Norway,[2]Department of Gastrointestinal Surgery, Oslo University Hospital, Oslo, Norway,[3]Institute for Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway*

Purpose: Tumor heterogeneity compromises the clinical applicability of transcriptomic subtypes of colorectal cancers (CRCs). We performed multiregional tumor sampling to map the intra-tumor heterogeneity of primary CRCs and to evaluate the prognostic relevance of features less vulnerable to heterogeneity.
Methods: Gene expression profiling was performed of 708 primary tumor samples from 515 patients treated by surgery for stage I-IV CRC at Oslo University Hospital (Human Transcriptome 2.0 Arrays). This included 2-4 multiregional samples from each of 97 patients (n=290 samples; mean 2.9 per tumor), and single bulk tumor samples from 418 patients. Intra-tumor heterogeneity was evaluated according to consensus molecular subtype (CMS) classification, including computational assessment in the single samples by CMS enrichment scores. Gene-wise heterogeneity scores were calculated as intra-class correlation coefficients in the multiregional sample set, and genes with low heterogeneity were used as input for subtype discovery by non-negative matrix factorization.
Results: Heterogeneous CMS classification of multiregional samples was found in 40% of tumors. Heterogeneous tumors were enriched with CMS3 (odds ratio 5.0) and CMS4 (odds ratio 12.5), and the most common combinations were CMS2/4 and CMS1/3. Microsatellite instability and *BRAF*^{V600E} mutations were enriched among tumors with a major CMS1 component only. *KRAS*/*NRAS* mutations were most frequent in CMS3 tumors without CMS1. Intra-tumor heterogeneity was primarily driven by mesenchymal-like and stromal signals, but was independently associated with a poor 5-year relapse-free survival among patients with stage I-III CRC (multivariable hazard ratio 1.5 [1.0-2.2]). Heterogeneity explained a larger proportion of variation in survival (14%) than cancer-associated fibroblasts (6%). Genes with low intra-tumor heterogeneity were enriched in cancer cell intrinsic signaling pathways, including cell cycle progression and MYC targets. *De novo* subtyping based on these genes recapitulated the intrinsic iCMS groups identified from single-cell sequencing (Joanito et al., Nat Genet 2022;54:963-75) with high accuracy (Cohen's κ=0.80). Further sub-stratification identified four subtypes with similar biological activity to the original CMS, but lower classification heterogeneity among multiregional samples (25%). The subtypes were called congruent CMS (cCMS) and provided stronger prognostic stratification than CMS in multivariable analysis with clinicopathological and molecular features (cCMS4: hazard ratio 5.9 [2.4-14.7]; cCMS2: 3.4 [1.5-7.6]; cCMS3: 2.0 [0.9-4.3] with cCMS1 as reference).
Conclusion: Multiregional sampling of primary CRCs enabled identification of cancer-intrinsic transcriptomic features robust to intra-tumor heterogeneity and with prognostic relevance.

Development of a one-step molecular classifier for endometrial carcinoma using an amplicon-based gene panel and next generation sequencing technology

Melissa K. McConechy[1], Amy Jamieson[2], Amy Lum[3], Samuel Leung[3], Adrian Kense[1], Sonal Brahmbhatt[1], Ka Mun Nip[1], Ebru Baran[1], Dilmi Perera[1], Kurt Yakimovich[1], Ruth Miller[1], C. Blake Gilks[4], David Huntsman[1], Jessica N. McAlpine[5]. *[1]Imagia Canexia Health, Vancouver, BC, Canada,[2]Department of Gynecology and Obstetrics, University of British Columbia, Vancouver, BC, Canada,[3]Department of Molecular Oncology, University of British Columbia, Vancouver, BC, Canada,[4]Department of Pathology, University of British Columbia, Vancouver, BC, Canada,[5]Department of Gynecology and Obstetrics,, University of British Columbia, Vancouver, BC, Canada*

Objectives: Molecular classification of endometrial carcinoma (EC) is now recommended by the WHO, ESGO/ESTRO/ESP and NCCN guidelines. The pragmatic molecular classification tool, ProMisE, identifies four molecular subtypes based on next generation sequencing (NGS) for the detection of somatic pathogenic *POLE* mutations, and immunohistochemistry for mismatch repair and p53 proteins. ProMisE provides valuable prognostic and predictive information to direct care, however, multiple molecular results are often received from different time periods and/or from different centers which can cause delays. Therefore, we developed a classifier that relies on a single DNA-based NGS test with the goal of recapitulating the prognostic value of ProMisE by producing concordant results.
Methods: Formalin fixed paraffin embedded (FFPE) EC tumor DNA was sequenced using the clinically validated Imagia Canexia Health Find It™ amplicon-based next generation sequencing gene panel assay. The 38 gene panel assessed single nucleotide variants (SNVs), indels (insertions and deletions), gene amplification and microsatellite instability (MSI) using 21 MSI loci. To compare to the original ProMisE classifier, we identified somatic mutations in *POLE*, *TP53* and MSI-High or MS-Stable for molecular classification. Molecular subtypes assigned by both classifiers were assessed for concordance metrics and Kaplan-Meier survival curves.
Results: The one-step NGS molecular classifier assessed 165 unique patient FFPE EC samples that had previously been assessed by ProMisE. There were 152/165 cases that were concordant between molecular subtype assignment from the original ProMisE and the one-step NGS assay with a

kappa statistic of 0.88 and accuracy of 0.92. There were 13 samples that were discordant (original classifications: 3 *POLE*, 3 MMRd, 2 p53abn, 5 NSMP/p53wt), which will be reviewed in detail. Results were concordant in 14 of 15 cases (93%) when both diagnostic biopsy and hysterectomy specimens were tested. Molecular subtypes maintained their associations with clinical outcomes (progression free survival, disease specific survival, overall survival).
Conclusion: The one-step NGS molecular classifier demonstrates high concordance with the original ProMisE classifier including between biopsy and hysterectomy samples. This shows that reliable molecular testing could be obtained from time of first diagnosis. Prognostic value of this new one-step classification tool is maintained. Appropriate interpretation of results is critical, including limiting *POLE* mutation assignment to a confirmed list of pathogenic mutations and correct order of segregation for ECs with more than one molecular feature. Further validation is needed in a larger cohort to implement into standard of care testing.

Identification of tumor-specific breast cancer expression subtypes and subtype-specific drug response prediction

Julie Karam[1], Paul Rejto[2], Jadwiga R. Bienkowska[2], Xinmeng J. Mu[2], Whijae Roh[2]. *[1]Brown University, Providence, RI,[2]Pfizer, San Diego, CA*

Breast cancer is a complex disease with a high degree of inter-tumor heterogeneity. Subtyping the disease and identifying the genomic features driving these subtypes are critical for precision oncology for breast cancer. With increasing availability of single cell RNA-seq data and deconvolution methods, there is unmet need for identifying novel tumor-intrinsic subtypes based on deconvoluted tumor-specific expression profiles as well as novel bulk tumor subtypes based on bulk RNA-seq data. Drug response prediction based on tumor-intrinsic subtypes can be also potentially more robust than drug response prediction based on bulk subtypes because currently available CRISPR and drug screening data are mostly based on only cancer cell lines. Therefore, we applied consensus hierarchical clustering, Bayesian Non-negative Matrix Factorization (BayesNMF), and deconvolution methods to 1,058 TCGA breast cancer samples and identified seven bulk expression subtypes (S1-S7) and five tumor-specific expression subtypes

(S1-S5). In order to characterize our subtypes, we first performed subtype association with previously characterized subtypes, including PAM50, HR status, and METABRIC IntClust subtypes. Notably, Luminal A and METABRIC IntClust 4ER+ breast cancer was further partitioned into our S1 and S5 bulk subtypes. We characterized the subtypes with pathway activity, TME deconvolution, and subtype-associated driver mutations. Our BayesNMF bulk and tumor-specific subtypes showed stronger association with prognosis than PAM50 subtypes, suggesting potential clinical utility of our subtypes. We projected BayesNMF to DepMap cell lines and CPTAC breast cancer samples to identify subtype-specific vulnerabilities and proteogenomic characterization of our subtypes, respectively. We also developed the method to predict CDK4 selective and CDK6 selective drug response in human breast tumor tissues by training the NMF models with CDK4 and CDK6 dependency scores and gene expression features in the DepMap cell lines. Our tumor-specific S5 subtype had significantly lower CDK4 response scores and significantly higher CDK6 response scores than others suggesting that this subtype, which is primarily triple-negative breast cancer, might be potentially a good subtype for CDK6 selective inhibitors. Additionally, our tumor-specific S4 subtype had significantly higher CDK4 response scores and significantly lower CDK6 response scores than others suggesting that this subtype might be a promising patient population for CDK4 selective inhibitors. We further applied machine learning methods to identify biomarkers that associate with subtypes and CDK4/CDK6 dependency scores using gene expression, mutations, and CNAs. Overall, our subtyping approach identifies clinically-relevant novel breast cancer subtypes with subtype-specific cancer vulnerabilities and therapeutic targets.

Lipka[1], Hanno

Glimm[4], Daniel Hübschmann[1], Wolfgang Hartmann[9], Stefan Fröhling[1], Claudia Scholl[1]. *[1]German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT) Heidelberg, Heidelberg, Germany,[2]German Cancer Research Center (DKFZ), Heidelberg, Germany,[3]Heidelberg University Biochemistry Centre, Heidelberg University, Heidelberg, Germany,[4]National Center for Tumor Diseases (NCT/UCC) Dresden, Faculty of Medicine and University Hospital Carl Gustav Carus, Technical University Dresden, Dresden, Germany,[5]University Cancer Center Mainz, Johannes Gutenberg University Mainz, Mainz, Germany,[6]Pediatric Oncology and Coagulation, Karolinska University Hospital, Stockholm, Sweden,[7]Pediatric Oncology and Hematology, Skåne University Hospital, Lund University, Lund, Sweden,[8]Hopp Children's Cancer Center Heidelberg (KiTZ), Heidelberg, Germany,[9]Gerhard Domagk Institute of Pathology, University Hospital Münster, Münster, Germany*

Rhabdomyosarcoma (RMS) is a soft-tissue sarcoma subtype composed of malignant immature precursor cells with myogenic differentiation defined by aberrant expression of the transcription factors MYOD1 and MYOG. Four subtypes are distinguished, characterized by considerable clinical, histologic, and genetic heterogeneity. RMS with fusions of the transcription factor TFCP2 to either FUS or EWSR1 has only recently been observed, but its classification and pathogenesis are unclear. We studied the clinical course, histopathology, and molecular landscape of 12 cases of this new RMS type and determined the functional properties of tumor-specific genetic alterations. Unusually for gene fusion-driven sarcomas, most tumors had highly rearranged genomes, including chromothripsis, and signs of defective homologous recombination DNA repair. All tumors were characterized by extremely high expression of a truncated TERT variant and the receptor tyrosine kinase ALK. The latter was additionally affected by intragenic deletions (33%), which resulted, together with aberrant splicing events, in the expression of shortened ALK variants (58%). Three ALK variants were oncogenic in immortalized cells *in vitro* and after xenotransplantation in mice and responded variably to different ALK inhibitors. Additional recurrent alterations included CDKN2A/MTAP co-deletions (67%) and mutations in PAPPA2 (25%) encoding an IGFBP5-

specific proteinase. DNA methylation analysis of FUS/EWSR1-TFCP2 RMS, along with 19 other soft-tissue sarcoma types, revealed a close relationship with undifferentiated sarcoma but not with other RMS subtypes, suggesting that FUS/EWSR1-TFCP2 RMS is a distinct sarcoma entity possibly arising from a different cell of origin than other RMS types. Transduction of TFCP2 fusions into immortalized human cells conferred anchorage-independent growth and blocked late myogenic differentiation. Genes significantly induced in these cells were also highly expressed in patient tumors, including ALK, TERT, and two known regulators of skeletal muscle cells, IGFBP5 and PTH1R. ACT-seq demonstrated direct binding of FUS-TFCP2 to the ALK and TERT gene loci outside their regular promoters, which correlated with the expression of alternative transcript variants. Finally, FUS-TFCP2 appeared to induce a defect in DNA double-strand repair in immortalized cells, rendering them sensitive to treatment with cisplatin. Together, our study gives insights into the pathogenesis of a new RMS subtype defined by FUS-TFCP2 or EWSR1-TFCP2 fusions and suggests entry points for therapeutic intervention with DNA-damaging agents, ALK inhibitors, and, in the case of additional CDKN2A/MTAP co-deletion, drugs targeting PRMT5.

Integrative immune-genomic comparison of canonical Ewing sarcoma with Ewing-like mimics identifies potential targets for personalized therapies

Zhusheng Zhang[1], Qiyuan Bao[1], Junxiang Wen[1], Zhuochao Liu[1], Qi Liu[1], Yuhui Shen[1], Lin Shao[2], Bing Li[2], Song-An Chen[2], Weibin Zhang[1].
[1]Shanghai Jiaotong University Ruijin Hospital, Shanghai, China,[2]Burning Rock Biotech, Guangzhou, China

Introduction: Ewing sarcoma (ES) is one of the most common types of small round cell sarcoma (SRCS) from the skeletal origin, characterized by small round blue cell morphology and *FET-ETS* fusions. However, recent NGS-based technology has dramatically increased the characterization of other SRCS entities that share morphological, pathological, and clinical similarity with canonical ES. Currently, these sarcomas are often treated with similar regimens derived from ES. Whether any subsets of these

sarcomas might benefit from personalized anti-cancer strategies remains largely unknown.
Methods: To explore potential therapeutic vulnerabilities, 51 FFPE samples from 49 patients (median age 31 years, 65.3% male) diagnosed as ES or its mimics by conventional pathology review were sent to DNA (OncoScreen®Plus) and RNA sequencing (OncoRNA, Burning Rock Biotech) for genomic and immune signature profiling. Tumor samples were classified into 5 groups based on their similarity with classic ES: (a) Canonical ES (n=12), defined as ES with *EWSR1-FLI1* fusion and a primary bone origin; (b) Non-canonical ES, which were found with either non-*EWSR1-FLI1 FET-ETS* fusion, or ES in extra-skeletal sites (n=11); (c) Non-*FET-ETS* fusion SRCS (n=10), defined as SRCS with gene fusions other than *FET-ETS* family; (d) Fusion-negative SRCS (n=4); and (e) non-SRCS, where the diagnosis was primarily suspected as ES but finally re-diagnosed as another histology (n=12).
Results: The NGS-based diagnosis rectified the pathological diagnosis in 9/51 samples, including ES misdiagnosed as other (n=3), other misdiagnosed as ES (n=4), Non-*FET-ETS* fusion SRCS misdiagnosed as ES (n=1) and ALK fusion sarcoma misdiagnosed as SRCS (n=1). In the remaining 42 samples, 23 diagnoses were confirmed by both NGS and FISH, while 11 SRCS were negative in both NGS and FISH assay, yielding a concordance of 81.0% (34/42). In the 8 samples with discordant diagnosis, a definitive diagnosis was achieved by FISH but not NGS in 1 of 8 (12.5%), and vice versa in 7 of 8 (87.5%). Interestingly, genomic profiling revealed that Non-*FET-ETS* fusion SRCS had high frequencies of *TP53* mutations (40%) and copy number loss (including 30% in *CD274* and *JAK2*; 20% in *PTCH1*, *CDKN2A/B*, and *MTAP*) and featured higher levels of homologous recombination deficiency (HRD) (p=0.024) and chromosome instability (p=0.022) than other groups. Remarkably, non-canonical ES demonstrated upregulated *PDCD1* expression (p=0.034). The distribution of immune hot and cold subtypes was comparable among all groups (p=0.334).
Conclusion: Our study shows that NGS could efficiently facilitate the definitive diagnosis of ES and its mimics. We also revealed a diverse immune-genomic landscape of these SRCS, indicative of potential therapeutic opportunities targeting HRD and immune check-point in specific subtypes of these sarcoma entities.

Comprehensive analysis using transcriptional factor based molecular subtypes and correlation to clinical outcomes in small-cell lung cancer

Sehhoon Park, Tae Hee Hong, Soohyun Hwang, Hyun-Ae Jung, Jong-Mu Sun, Jin Seok Ahn, Myung-Ju Ahn, Jong Ho Cho, Yong Soo Choi, Jhingook Kim, Young Mog Shim, Hong Kwan Kim, Yoon-La Choi, Se-hoon Lee, Keunchil Park. *Samsung Medical Center, Seoul, Korea, Republic of*

Background: Several studies have reported the predictive and prognostic value of novel transcriptional factor-based molecular subtypes in small-cell lung cancer (SCLC). We conducted an in-depth analysis using multi-omics data to elucidate the underlying characteristics that lead to differences in clinical outcomes between subtypes.

Patients and Methods: Immunohistochemistry (IHC, n=252), target exome sequencing (n=422), and whole transcriptome sequencing (WTS, n=189) data generated from 427 patients with SCLC patients were comprehensively analyzed. The differences in the mutation profile, gene expression profile were analyzed according to the IHC-based molecular subtype. Clinical implication was evaluated based on treatment outcomes of individual patients.

Results: IHC based molecular subtyping revealed a high incidence of ASCL1 subtype (SCLC-A, 56.3%) followed by ASCL1/NEUROD1 co-expressed (SCLC-trans, 17.9%), NEUROD1 (SCLC-N, 12.3%), POU2F3 (SCLC-P, 9.1%), triple-negative (SCLC-TN, 4.4%) subtypes showing high concordance with WTS-based subtyping. We delineated the SCLC-trans subtype resembling SCLC-A rather than SCLC-N in terms of both gene expression profiles and clinical outcomes. SCLC-TN type was defined as non-significant expression of A, N, P. Favorable overall survival (OS) was observed in SCLC-A compared to SCLC-N (adjusted HR 2.4, 95% CI 1.5-3.9, $p < 0.001$) and SCLC-P (adjusted HR 1.7, 95% CI 0.9-2.9, $p = 0.087$). SCLC-TN showed a similar OS with SCLC-A (adjusted HR 1.2, 95% CI 0.6 -2.7, $p = 0598$). The clinical outcome based on inflamed phenotype, clustered by effector cell gene expression profile which are only found in 5% of SCLC-N but 60% of SCLC-P, was more likely to benefit from first-line immunotherapy treatment than non-inflamed phenotype ($p = 0.013$).

Inflammed phenotype demonstrated longer progression-free survival to the first line immunotherapy compared to the non-inflammed phenotype. (10.5 vs 4.3, $p = 0.013$)
Conclusions: This study provides fundamental data, including the incidence and basic demographics of molecular subtypes of SCLC using both IHC and WTS from a comparably large cohort including potential differences in the distribution of subtypes based on ethnicity. Additionally, our results reveal differences in the underlying biological pathway activities and immunogenicity based on molecular subtype, possibly related to the difference in clinical outcomes, including immunotherapy response.

Spatial Proteomics and Transcriptomics 1

#5626
Multiomic spatial profiling of the tumor immune microenvironment at single cell resolution

Niyati Jhaveri[1], HaYeun Ji[1], Anushka Dikshit[2], Jessica Yuan[1], Emerald Doolittle[2], Steve Zhou[2], Maithreyan Srinivasan[2], Bassem B. Cheikh[1], Fabian Schneider[3], James Mansfield[3], Julia Kennedy-Darling[1], Oliver Braubach[1]. *[1]Akoya Biosciences, Menlo Park, CA,[2]Advanced Cell Diagnostics, a Bio-Techne Brand, Newark, CA,[3]Visiopharm A/S, Horsholm, Denmark*

Background**:** It has been well established that the tumor microenvironment (TME), which comprises cancer cells, stromal cells, and surrounding extracellular matrix, plays a critical role in cancer development, progression, and control. The immunological components within tumors, known as the tumor immune microenvironment (TiME), have also been implicated in tumor development, recurrence, and metastasis. Effective strategies for cancer immunotherapies will require a deep understanding of the factors that shape both the TME and TiME. Here, we describe a spatial multiomics approach that utilizes RNAscope™ ISH technology paired with high-plex whole-slide spatial phenotyping with the PhenoCycler™-Fusion platform. This two-step approach is compatible with human FFPE tissues and enables researchers to characterize the spatial biology of the TiME more accurately by detecting RNA and protein markers on serial sections. The resulting multiomic data more accurately reveal the interplay between

TME and TiME by giving insight into cell lineages, surrounding structures, as well as secreted chemokines and cytokines that exist within the TME ecosystem.
Methods: We performed ultrahigh-plex spatial phenotyping on the PhenoCycler-Fusion on FFPE tumor tissue sections, using an antibody panel that is designed for immune cell phenotyping, evaluation of immune contexture and proliferation across the TME. Using serial sections from the same tissue blocks, we then ran the RNAscope HiPlex v2 assay automated on the PhenoCycler-Fusion system. This assay consisted of a 12-plex immuno-oncology panel of RNA target probes, which were selected to detect macrophages, chemokines, and cytokines within tumors. We used Phenoplex software to analyze the protein and RNA datasets and to compute cell phenotypes and spatial associations.
Results and Conclusions: In this proof-of-concept study, we demonstrate the utility of multiomic spatial profiling on the PhenoCycler-Fusion platform. Analysis of the resulting multiplex imaging data not only revealed the structural organization of cells within the TME, but also activation states of immune cells. Together, this information provides a more complete functional map of immune cells within the TME and TiME and thereby enriches our understanding of tumor biology that may be deterministic of immunotherapy responsiveness. This work paves the way for future research that will rely on deep spatial phenotyping with protein biomarkers coupled with accurate quantification of the expression of regulatory cytokines, chemokines, growth factors, or non-coding RNAs that only RNA probes can detect.

Knight Cancer Institute, Portland, OR,[3]Informatics, University of Oslo, Oslo, Norway,[4]Pathology, Oslo University Hospital, Oslo, Norway

Introduction: A limited number of drugs are available for use in breast cancer patients, and several are not in practical use due to the lack of adequate biomarkers. We have recently demonstrated the feasibility of using machine learning on molecular data from bulk tumor analysis to create a nine-protein signature named VEGF-inhibition Response Predictor (ViRP) for selecting BC patients for treatment with chemotherapy and bevacizumab. The ViRP score is currently being validated in the NAPEER+ clinical trial (EudraCT 2021-005850-27). Increasing evidence suggests that spatial organization of cells within the tumor microenvironment influences survival and response to therapy in numerous cancer types. In methods based on bulk tumor analysis all tumor cells are profiled simultaneously with both colocalized and distant stroma and immune cells. We are thus pursuing information on spatial organization of cellular phenotypes expressing selected cancer related proteins including our nine ViRP proteins.
Methods: From the NeoAva (NCT00773695) clinical trial evaluating the effect of bevacizumab in combination with neoadjuvant chemotherapy (n=132 pts), FFPE tissue sections from patients before, during, and after treatment were made. Cyclic immunofluorescence (cyCIF) was used to profile the spatial expression of 32 cancer-signaling and 32 immune-related proteins, comprising our nine ViRP proteins, on FFPE tissue sections from selected patients (n = 20). The Galaxy-ME platform was used for image processing and downstream analysis of spatial protein profiling.
Results: Use of cyCIF for spatial analysis enabled for evaluation of malignant cells in the context of surrounding microenvironmental cells, including immune cells. We found that cell type-specific protein abundance and subcellular localization formed a highly heterogenous pattern in the tissue. This was particularly evident for the nine ViRP proteins, and differences in expression between tumor cell populations will be further elucidated. Among the patients selected for cyCIF analysis, 4 were chosen based on misclassification by the ViRP signature. Ongoing studies focus on revealing spatial expression patterns to optimize the ViRP biomarker and explore why misclassification occurs. Furthermore, the observed molecular biology of the evolving tissues under treatment in responding and non-

responding patients may reveal new biomarkers indicative of treatment response or resistance.
Conclusion: We observe that the expression of proteins in tumor tissues is highly heterogeneous, and thus include numerous features not captured by bulk tumor analysis. Future development of new predictive tools and biomarkers that integrate molecular data which is multiparametric and spatial will set the stage for a new class of biomarkers in cancer diagnostics.

Spatial genomics and proteomics enable multimodal analyses of oral SCC clonal heterogeneity and interactions with tumor microenvironment

Raju Kumar[1], Rana Ibrahim[1], Bassem Ben Cheikh[2], Emma Bailey[1], Hannah Cottom[3], Oliver Braubach[2], Trevor Graham[4], Jun Wang[5], Ines Sequeira[1]. *[1]Barts Centre for Squamous Cancer, Queen Mary University of London, London, United Kingdom,[2]Akoya Biosciences, Menlo Park, CA,[3]Barts Health NHS Trust, London, United Kingdom,[4]Centre for Evolution and Cancer, The Institute of Cancer Research, London, United Kingdom,[5]Barts Cancer Institute, Queen Mary University of London, London, United Kingdom*

Cancer progression is an evolutionary process governed by the clonal evolution of the genetic mutations acquired during tumor growth, together with the co-evolution of the tumour ecosystem. The nature of cancer subclonal mutations and their effects on the tumour microenvironment are the major drivers of intratumor heterogeneity and contribute to cancer progression, metastasis, therapy resistance and disease recurrence. Therefore, a spatially resolved genetic and cellular profiling of tumors is crucial to investigate tumor architecture and cellular diversity. Oral squamous cell carcinoma (OSCC), a subset of head and neck cancer, accounts for 355,000 new cases annually worldwide and has a 5-year survival rate of only 50%. We recently conducted a multi-level analysis of OSCC genetic and microenvironment heterogeneity (Sequeira et al, 2020, NatComms). Computational analysis of tumour clonal dynamics from DNA sequencing data revealed that high genetic heterogeneity to be a feature of early-stage lesions that are likely to progress to more aggressive tumors (Williams et al 2018, NatGen; Sequeira et al, 2020, NatComms). These

tools can be used to predict tumour behavior and for early diagnosis of aggressive lesions. The goal of this study is to elucidate the functional and spatial intratumor heterogeneity, tumor clonal dynamics and evolutionary landscape of human OSCC, and to study the interaction of tumour cells with the microenvironment, in particular the role of specific mutations in promoting epithelial-to-mesenchymal transition and tumor progression, using an interdisciplinary approach that combines spatial integrative genome analysis and deep single-cell phenotyping of tumor microenvironment. We performed whole-exome sequencing from multifocal OSCC tumor regions and matched metastasis, and used computational methods to investigate the tumor subclonal organization, construct phylogenetic trees for each tumor and assess the genetic diversity of the different tumour regions and metastasis. We then combined Single cell Spatial Phenotyping on the *PhenoCycler* platform (Akoya Biosciences) (Black et al, 2021, NatProtocols) with the subclonal genomic analysis to investigate how different mutational landscapes affect tumor microenvironment and metastasis, at unprecedented detail. Together, this multi-modal integrated spatial genomics and proteomics analysis of the tumor ecosystem highlights the importance of spatial cellular organization and provides a comprehensive human OSCC spatial atlas of tumour heterogeneity, providing a foundation for exploring cancer evolution, heterogeneity and progression.

Robust spatial biomarker discovery through multi-platform multiplex image analysis of breast cancer clinical cohorts

Jennifer R. Eng[1], Elmar Bucher[2], Zhi Hu[3], Melinda Sanders[4], Bapsi Chakravarthy[4], Jennifer Pietenpol[4], Rosalie C. Sears[1], Summer Gibbs[5], Joe W. Gray[5], Koei Chin[6]. *[1]Molecular and Medical Genetics, Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]Intelligent Systems Engineering, Indiana University, Bloomington, IN,[3]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[4]Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN,[5]Biomedical Engineering, Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[6]Center for Early Detection Advanced*

Research, Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Spatial profiling of tissues promises to elucidate tumor-microenvironment interactions and enable development of spatial biomarkers to predict response to immunotherapy and other therapeutics. However, spatial biomarker discovery is often limited to small patient cohorts and single technologies, limiting statistical power and increasing the likelihood of technical artifacts. We utilized cyclic immunofluorescence, (CyCIF), to profile patient tissues from 102 breast cancer patients, 63 with clinical follow up. We then developed methods for comparative analysis of data from three disparate imaging technologies including our CyCIF images, as well as publicly available imaging mass cytometry and multiplex ion-beam imaging breast cancer data sets. We demonstrate similar single-cell phenotyping results across breast cancer patient cohorts imaged with the three methods, and furthermore, show agreement in the prognostic value of cellular and spatial biomarkers across platforms. We identified T cell infiltration as independently associated with longer survival in high-proliferation breast cancer, which was enriched for activated and spatially clustered T cells. A comparison of six spatial analysis methods revealed robust spatial biomarkers, including tumor-macrophage and tumor-fibroblast proximity associated with poor prognosis in estrogen receptor positive and triple negative tumors, respectively. Our methods enable assembly of larger clinical cohorts from diverse platforms to aid in predictive and prognostic spatial biomarker identification and validation.

Expanding tools for multiplex mRNA imaging in spatialomics through the ViewRNA tissue assay kits

Nancie Mooney. *Thermo Fisher Scientific, Eugene, OR*

Spatialomics is a rapidly growing field as it allows researchers to gain a deeper understanding of transcriptomes and corresponding protein expression profiles in cells within complex tissue microenvironments. One critical technology for spatialomics is in-situ hybridization (ISH) technology, which enables direct visualization and quantitation of nucleic acid in cells with single molecule resolution. The Invitrogen ViewRNA ISH

assays incorporate branched DNA (bDNA) technology provides tools for interrogating multiple RNA transcripts at the same time, paving the way for improved spatialomics research. This technology is a powerful tool for spatialomics, giving insight into important mechanisms within cells and tissue. With researchers increasingly using spatialomic data in fields like neuroscience, immuno-oncology & single-cell analysis, these scientists will need the rapid and efficient detection of mRNA co-expression profiles that ViewRNA portfolio provides. In our newest offering, ViewRNA fluorescence tissue kits we extended our branched DNA technology, proprietary probe set design and signal amplification technology with Alexa Fluor probes offering a unique, robust, and sensitive in situ hybridization assay for RNA localization in fixed tissues. With fluorescence detection using Alexa Fluor 488, Alexa Fluor 546, Alexa Fluor 594, Alexa Fluor 647, and Alexa Fluor 750, these kits allow multiplexed detection and imaging paving the way for improved spatialomics. This technology lays the foundation for expanded fluorescent profiles to provide scientists additional tools to probe multiple transcripts per sample, allow broader spatialomics research. For Research Use Only. Not for use in diagnostic procedures.

Evaluating a novel molecular biomarker of angioinvasive lung adenocarcinoma with spatial transcriptomics

Dylan Steiner[1], Lila Sultan[1], Travis Sullivan[2], Emily Green[1], Hanqiao Liu[1], Xiaohui Xiao[1], Gang Liu[1], Avrum Spira[1], Sarah Mazzilli[1], Kimberly Rieger-Christ[2], Eric Burks[1], Jennifer Beane[1], Marc Lenburg[1]. *[1]Boston Univ. School of Medicine, Boston, MA,[2]Lahey Hospital and Medical Center, Burlington, MA*

Microscopic vascular invasion (VI) is predictive of recurrence in stage I lung adenocarcinoma (LUAD) but is difficult to assess in resection specimens and cannot be accurately predicted prior to surgery. Thus, new biomarkers are needed to identify this aggressive subset of stage I LUAD tumors. To assess molecular and tumor microenvironment (TME) features associated with angioinvasive LUAD we profiled 171 resected stage I tumors with and without VI by RNA-seq, including 16 tumors by high-resolution spatial transcriptomics (10x Genomics Visium). Visium capture areas were selected by an experienced thoracic pathologist to include

invasive foci, tumor regions distal to foci, and tumors without invasive foci. We identified a robust molecular signature of VI from the RNA-seq data containing subclusters of genes involved in hallmark programs of tumor suppression, EMT, angiogenesis, growth and metabolism. This VI-associated signature increases across the spectrum of indolent to aggressive stage I LUAD histopathology and is predictive of recurrence-free survival. Analysis of 43,421 Visium spots across 16 tumors revealed high inter-tumor patient heterogeneity, with most spots clustering by tumor identity, suggesting tumor-intrinsic properties. Scoring the Visium data for VI signature expression revealed spatial variability around VI foci, with distinct spatial distributions of different signature subclusters among tumor and stromal compartments within and adjacent to regions of tumor intravasation. We found increased expression of the bulk VI signature in invasive tumors, regardless of whether the capture area contained the invasive focus. We independently verified this finding by performing laser-capture microdissection and RNA-seq from invaded vessel regions and uninvaded parenchyma of 8 additional tumors with VI and tumor regions of non-VI tumors. Given increased signature expression in regions of invasive tumors at a distance from VI foci, we leveraged our bulk RNA-seq dataset to develop a transcriptomic predictor of VI. We applied a nested cross-validation approach within a training cohort to select a machine learning model. We then evaluated the performance of our model in an independent test set. Finally, we generated over 200 pseudo-bulked *in silico* biopsies similar in size to standard transthoracic needle biopsies using the spatial data. The scores from these *in silico* biopsies were similar to predictions from matched bulk RNA-seq data, suggesting robustness to intra-tumor heterogeneity. Our combined bulk and spatial transcriptomics analysis suggests that VI-associated gene expression extends far from the site of intravasation and can be used to predict the presence of VI. This may enable the prediction of angioinvasive LUAD from small biopsy specimens, allowing for more tailored treatment prior to surgery.

Analysis of the immune microenvironment and tumor-infiltrating immune cells across different solid tumors by combined spatial transcriptomics and proteomics

Julia Femel, Emily Neil, Dongju Park, Fabio El Yassouri, Anijutta Appelshoffer, Erica Lloyd, Michael DiBuono, Henry Sauer, Hanna Lafayette, Hsinyi Smith, Jinling Wang, Dominic Mangiardi, Alex Makrigiorgos, Paurush Praveen, Silvia Rüberg, Werner Müller, Tanya Wantenaar, Robert Pinard, Andreas Bosio. *Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany*

With the advent of immunotherapies such as immune checkpoint inhibitors and CAR T cells, the interest in the tumor microenvironment and tumor-infiltrating lymphocytes (TILs) cells has increased in recent years as these play a critical role in predicting response to therapy and clinical outcomes. We have reported on the identification of potential targets for CAR T cell therapies by analyzing a multitude of tumor samples with hundreds of antibodies by flow cytometry and a new spatial proteomics platform, the MACSima Imaging Platform (Schäfer et al. Nat. Commun., 2021; Kinkhabwala et.al. Sci. Rep., 2022). Here we report on the analysis of tumor microenvironment and tumor infiltrating immune cells using a novel combined spatial transcriptomics and proteomics approach. For protein expression analysis we generated a panel of 60 fluorochrome conjugated antibodies (REAscreen Immuno-oncology, human, FFPE, version 01) selected to identify immune cells, cancer associated fibroblasts, matrix, blood vessels, lymphatics and malignant epithelial cell populations. RNA analysis was based on a novel in situ hybridization and amplification method followed by a cyclic spatial decoding of transcripts (RNAsky). To standardize and further ease the process of protein and RNA detection we generated the antigen and RNA detection probes in a ready-to-use format, i.e., dried and sealed in 96 well plates ready to be inserted into the MACSima. FFPE specimens of different tumor entities reviewed by a pathologist were first hybridized to probes, which were amplified, and spatially decoded by fluorochrome conjugated oligonucleotides. Subsequently the same specimen was exposed to fluorescently labeled antibodies by cycles of antibody reaction, image acquisition and erasure of signal. Finally, specimens were stained with H&E to report on tissue integrity and correlate spatial orientation. The 2D image stacks were analyzed for transcript and antigen quantification and pattern recognition using both, pixel and segmented single-cell data (MACS iQ View Analysis Software). Across the specimens we identified more than 20 cell types

including 12 immune cell subsets. The comparison of the tumor microenvironment, tumor-infiltrating immune cells (TILs) and their spatial organization in relation to the tumor cells allowed to identify differences and similarities across the tumor types. In summary we report here on a novel standardized and automated combined spatial RNA and protein expression analysis of the tumor microenvironment and tumor infiltrating immune cells across tumor types. The characterization dataset demonstrates the ability of our platform to perform standardized in-depth phenotyping of sample cohorts. This will enable discovery and further development of predictive and prognostic biomarkers critical to patient stratification for immunotherapy.

Joint secondary transcriptomic analysis of triple negative breast cancer offers a window into new therapeutic possibilities and biomarkers

Naomi Rapier-Sharman, Jenna Birchall Poulsen, Mauri E. Dobbs, Brett E. Pickett. *Microbiology and Molecular Biology, Brigham Young University, Provo, UT*

Breast cancer is a harmful growth of mutated breast tissue that is diagnosed in 2.3 million women yearly, and kills 685,000 patients (15%) each year around the world. Left unchecked, breast cancer can grow proliferatively and metastasize to new tissue sites, monopolizing the body's energy supply and ultimately causing organ failure and death. Due to increased use of treatments targeting the breast tumor-specific markers Estrogen Receptor (ER), Progesterone Receptor (PR), and Human Epidermal growth factor Receptor 2 (HER2), patient survival of breast cancer has increased in recent years. However, patients with triple-negative breast cancer (TNBC), tumors lacking all three commonly-targeted biomarkers, suffer greater illness, experience more frequent relapse, and enjoy a shorter lifespan compared to other breast cancer patients due to the paucity of tumor-selective treatments for TNBC. Further research on TNBC is needed to understand targetable mechanisms and develop treatments capable of targeting the key mechanisms. To investigate the transcriptomic profiles of TNBC tumors, we performed a joint secondary analysis of publicly available RNA-sequencing data for TNBC, consisting of 214 relevant samples across 11 distinct studies in the NCBI Gene Expression Omnibus (GEO). We found

~12,500 significant differentially expressed genes (FDR p-value <= 0.05) and 67 significantly modulated pathways (FDR p-value <= 0.05). Additionally, our novel findings include candidates for drug repurposing, high-integrity predictive biomarkers, and potential new TNBC molecular mechanisms. We found several TNBC drug targets that have not yet been fully leveraged along with drugs that could likely be successfully repurposed for use in TNBC based on previous target history and our transcriptomic results. This joint secondary analysis opens the door to future therapeutic options that could increase patient survival once validated in the wet lab.

#5636

Multiplex digital spatial profiling (DSP) of proteins in the tumor microenvironment in response to GSK-3 inhibition by 9-ING-41 (elraglusib) correlates with novel immunostimulatory effects observed *in vivo*

Kelsey E. Huntington[1], Christoph Schorl[2], Shaolei Lu[1], Daniel Newhouse[1], Benedito A. Carneiro[3], Wafik S. El-Deiry[1]. *[1]Pathology and Laboratory Medicine, Brown University, Providence, RI,[2]Molecular Biology, Cell Biology and Biochemistry, Brown University, Providence, RI,[3]Medicine, Brown University, Providence, RI*

Glycogen synthase kinase 3 (GSK-3) is a serine/threonine kinase with key roles in myriad biological processes such as tumor progression, and inhibition of GSK-3 using the small molecule elraglusib has shown promising preclinical antitumor activity in multiple tumor types. Our preclinical experiments showed that elraglusib treatment increased tumor cell PD-L1 expression, downregulated angiogenic and immunosuppressive signaling pathways, and increased anti-tumor immune responses *in vitro* and *in vivo*. Subsequent studies showed that several circulating factors were predictive of response to PD-1/PD-L1 blockade and GSK-3 inhibition in a murine model of colorectal cancer. To determine the translational relevance of our prior results we evaluated tumor biopsies and plasma samples from patients with refractory solid tumors of multiple tissue origins enrolled in a Phase 1 clinical trial investigating elraglusib (NCT03678883). Plasma samples were collected from patients at baseline and 24 hours post-IV administration of elraglusib and were analyzed using Luminex technology.

Paired FFPE tumor biopsies from patients with colorectal or pancreatic cancer before and after treatment were selected to analyze the tumor microenvironment using NanoString GeoMx DSP technology. The region of interest (ROI) selection strategy focused on mixed tumor and immune cell segments and ROIs were segmented using panCK+ and CD45+ morphology stains. Cytokine analysis revealed that elevated baseline plasma levels of IL-1 beta and reduced levels of VEGF correlated with improved progression-free survival (PFS) and overall survival (OS). PFS was also found to be positively correlated with elevated plasma levels of immunostimulatory analytes such as Granzyme B, IFN-gamma, and IL-2 at 24 hours post-treatment with elraglusib. CD45+ tumor-infiltrating immune cells had lower expression of VISTA, PD-1, and IDO-1 inhibitory checkpoint proteins and higher expression of OX40L and B7-H3 stimulatory checkpoint proteins in post-treatment biopsies as compared to pre-treatment biopsies. Moreover, time-on-study length negatively correlated with CD39 expression in PanCK+ segments and positively correlated with CD163 expression in CD45+ segments. This ongoing study, to our knowledge, represents the first digital spatial analysis of tumor biopsies from patients treated with elraglusib. These novel circulating biomarkers of response to GSK-3 inhibition could provide significant clinical utility and the spatial proteomics data may give us insights into the immunomodulatory mechanisms of GSK-3 inhibition.

Path to the holy grail of spatial biology: Spatial single-cell whole transcriptomes using 6000-plex spatial molecular imaging on FFPE tissue

Shanshan He, Michael Patrick, Jason W. Reeves, Patrick Danaher, Julian Preciado, Joseph Phan, Erin Piazza, Zachary Reitz, Lidan Wu, Rustem Khafizov, Haiyan Zhai, Michael Rhodes, David Ruff, Joseph Beechem.
NanoString Technologies, Inc., Seattle, WA

Cancer research across drug development, molecular biomarkers, and patient response depends on understanding biology that is dependent on complex interactions between malignant, immune, and stromal cells. To survive clearance mechanisms, a tumor can rely on a myriad of escape strategies, and the microenvironment is architected around the current path

of escape. To enable a more comprehensive picture of tumor biology, we have developed the CosMx™ Spatial Molecular Imager (SMI) technology to capture a snapshot of thousands of RNA species resolved subcellularly from a single, standard histopathology slide. Building upon the previously released panels, this study tests a new 6,000-plex panel, the highest RNA plex measured *in situ* within human tissue, allowing the imputation of a spatial whole transcriptome in the tissue. We performed an ultra-high-plex RNA assay to detect 6,000 targets simultaneously *in situ* on an FFPE human liver cancer tissue (~1 cm^2 area) using the CosMx SMI. This RNA panel covers broad biological areas with special emphasis on oncology, immunology, and signal transduction, such that all cancer researchers can benefit from the direct detection of targets of interest (*sans* imputation) in intact tissue. Analysis algorithms were developed to allow robust assessments of cell types, cell states, cell-cell interactions, and pathway activation. Imputation based on reference profiles from HCA, TCGA, and other public repositories allows estimation of non-measured transcripts at a ratio of approximately 1:3, compared to the approximate 1:20-1:70 imputations performed previously for spatial data.Thousands of transcripts were simultaneously detected with high sensitivity and specificity on the FFPE liver cancer tissue section at single-cell subcellular resolution. We were able to accurately map known reference profiles from scRNA-seq into this sample while identifying cancer-specific malignant, immune, and stromal cells in this tissue sample using this ultra-high plex RNA panel. In addition, we constructed sample-specific spatial neighborhoods, defined by cell types, cell states, and nearly unlimited sets of biological pathways through the imputed whole transcriptome. Finally, we measured >1,000 ligand-receptor interactions between key cell types of adjacent cells in the tissue, identifying mechanisms for tumor-mediated escape as well as reactive re-architecting of the native stroma which defines the trajectory of cancer's evolution. Single-cell spatial measurements of gene expression at 6,000 plex from a single FFPE slide has the potential to transform our understanding of tumor biology and facilitate the next advances in cancer research by extracting the highest data density possible from rare specimens collected during patient treatment.

Total-sync ultra-content microscopic opto-biotinylation enables high-sensitivity hypothesis-free subcellular protein discovery

Jung-Chi Liao[1], Chih-Wei Chang[1], Yi-De Chen[1], Chantal Hoi Yin Cheung[1], Chia-Wen Chung[1], Hsiao-Jen Chang[1], Yong-Da Sie[1], You-Pi Liu[1], Yu-Chih Lin[1], Hsiang-Ju Kai[1], Weng Man Chong[1], Hsin-Yi Wu[2]. *[1]Syncell Inc., Taipei, Taiwan,[2]Department of Chemistry, National Taiwan University, Taipei, Taiwan*

High-sensitivity hypothesis-free subcellular proteomics is challenging due to the limited sensitivity of mass spectrometry and the lack of amplification tools for proteins. Without such technology, it is not possible to discover proteins at specific locations of interest in cells or tissue samples. Here, we introduce a total-sync ultra-content microscopic system termed Microscoop^{TM} that integrates microscopy, optics, FPGA-based mechatronics, photochemistry, and deep learning or computer vision to enable high-content in situ photolabeling. Microscoop^{TM} photolabels proteins at user defined regions of interests (ROIs) under a microscope utilizing directed photochemistry in one field of view (FOV) at a time for tens of thousands of FOVs with similar morphological features. With this platform, we are able to photolabel proteins with biotin probes in cellular organelles, granules or cell-cell contact surfaces with a high precision at nanoscale resolution, and obtain sufficient amount of biotinylated proteins for mass spectrometry. We made a robust demonstration in the proteome mapping of human cellular nucleus from single-shot experiment to >1000 nuclear protein identification with > 90% specificity. Further data analysis revealed identification of a hundred of low protein copy number proteins and a high coverage of nuclear complexes. In proteome mapping of the nucleolus, we ranked proteins by order of abundance and revealed that 97 out of the top 100 proteins were annotated as nucleolar proteins. Unexpectedly, in mapping the stress granule (SG) proteome, a relatively low SG specificity (74%) were found in the top 50 abundant proteins, therefore we further characterize the proteins that have no prior SG annotation by immunostaining. Nine out of the thirteen unexplored proteins including PDLIM7, EIF3CL, YWHAE, RPSA, UGDH, DDX17, ANLN, PSMA6, and MCM2 were found to have SG patterns and co-localized with SG marker (G3BP1), raising our top 50 SG specificity to up to 92%. Together, our total-sync ultra-content microscopic platform enables

hypothesis-free, de novo subcellular proteome mapping at user defined ROIs with high sensitivity and specificity, thereby broadly benefits the cell biology field in finding novel proteins or biomarkers.

High throughput spatially resolved laser-activated cell sorting links the genomic molecules with its spatial information

Sumin Lee, Amos C. Lee, Sunghoon Kwon. *Seoul National University, Seoul, Korea, Republic of*

Spatial omics profiling technologies have been recognized recently for its ability to decipher the genetic molecules that are structurally relevant in pathology. Especially, in tumor biology, tumor is not the group of malignant tumor cells, but rather group of various cells such as tumor cells, immune cells, fibroblasts, etc. gathers together, constructing the tumor microenvironments. Technologies to analyze such microstructures have evolved from bulk sequencing, single cell sequencing to spatial omics profiling technologies. Spatial omics profiling technologies have highly influenced in decoding cancerous mechanisms by questioning the tumor heterogeneity, tumor microenvironment and spatial biomarkers. Most of the spatial omics technologies focus on mapping the spatial omics landscape in a large scale. They rather introduces the spatially-barcoded capture probes or fluorescence labeled target probes to spatially locate the genetic molecules. The information depth and the scalability of the techniques varies according to the purpose of the spatial assay techniques. Such technologies are capable of discovering the spatial heterogeneity and the spatial landscape of the consisting cell types due to relatively low depth of the omics information. To effectively address the target molecules for therapeutics or diagnostics, higher depth of the omics information are required. To meet the needs, region of interest (ROI)-based spatial technologies isolated the target regions and applies chemistries for higher coverage omics data. Conventional cell sorters utilizes microfluidic channels to sort cells of interest which requires cell dissociation in a solution phase. For instance, Fluorescence activated cell sorter (FACS) or Magnetic-activated cell sorting (MACS) uses fluorescence or magnetic particles, respectively, to designate the cells of interest in dissociated cell solutions. Spatially isolating techniques such as laser capture

microdissection (LCM) is able to sort out the ROIs while preserving the spatial context, but it approximately takes an hour for isolating the targets. Also, it uses rather UV laser to dissect out cells or IR-activated melting of polymers to stick out cells which might cause damage to cells. Here, I developed the automated spatially resolved laser activated cell sorter that isolates the cells in target per second while preserving the spatial context of the cells. Specific region of indium tin oxide (ITO) coated slide glass evaporates when illuminated by IR laser pulse, plunging the cells into the desired reservoir. The applicability of the suggested cell sorter are demonstrated in omics profiling chemistries such as DNA sequencing, RNA sequencing, mass spectrometry, etc.

Identifying pathophysiological features of mouse tumors using imaging mass cytometry

Qanber Raza, Liang Lim, Thomas D. Pfister, Nick Zabinyakov, Christina Loh. *Research and Development, Standard BioTools, Markham, ON, Canada*

Mouse tumor models are widely utilized for cancer studies and preclinical drug development. An obstacle in predicting therapeutic drug efficacy is the ability to quantitatively evaluate the multi-parametric post-treatment response in the tumor microenvironment (TME). Identification of immuno-oncological processes that dictate tumor growth, metastasis, and immune response is essential for selecting promising drug candidates for further clinical evaluation. Imaging Mass Cytometry™ (IMC™) is a vital and proven high-plex imaging technology that enables deep characterization of the complexity and diversity of tumor tissue without disrupting spatial context. The Hyperion™ Imaging System utilizes IMC technology to simultaneously assess 40-plus individual structural and functional markers in tissues, providing unprecedented insight into the organization and function of the TME. We have previously demonstrated the application of IMC in combination with Maxpar® and Maxpar OnDemand™ antibodies to highlight cellular composition of normal mouse tissues. Here, we showcase the Maxpar OnDemand Mouse Immuno-Oncology IMC Panel Kit for application on a variety of mouse tumor tissues. We compiled the antibody panel to quantitatively assess IO-related processes and applied it

to a tissue microarray (TMA) containing a large variety of mouse tumors. Antibodies in panel kits were selected from the Maxpar and Maxpar OnDemand catalogs. We digitized high-plex data from mouse tissues using the Hyperion Imaging System and generated images demonstrating the detailed layout of the TME. We further conducted single-cell analysis to identify specific populations of tumor and immune cells in the TME. The Mouse Immuno-Oncology IMC Panel Kit successfully identified pathophysiological processes such as immune cell infiltration and activation, signaling pathway activation, biomarkers of epithelial-to-mesenchymal transition (EMT), metabolic activity, growth, and the tissue architecture of the TME. Single-cell analysis of several highly relevant tumor types separated distinct cellular clusters representing tumor, immune, stromal, and vascular cells. Activation of cellular processes associated with signaling, growth, and metastasis were identified in tumor cells. In addition, cytotoxic and inflammatory activation in lymphoid and myeloid immune cell subtypes were detected. Application of IMC based multiparametric analysis successfully identified the spatial landscape of the TME at single-cell resolution. Quantitative analysis of tumor composition revealed critical insights regarding prognostic parameters such as metastatic and growth potential of tumors, and identification and activation of immune cell infiltrates. Overall, we demonstrate the power of IMC and provide evidence of its successful application in mouse tumor models. **For Research Use Only. Not for use in diagnostic procedures.**

Single cell spatial molecular imaging of 76-plex proteins in clinical cancer samples in response to personalized treatment

Zachary R. Lewis[1], Brian Birditt[1], Emily Brown[1], Kan Chantranuvatana[1], Brian Filanoski[1], Chris Corless[2], Tiên Phan-Everson[1], Gary Geiss[1], Tyler Hether[1], Evie Hobbs[3], Brett Johnson[4], Taylor Kelley[4], Charles Lopez[3], Rhonda Meredith[1], Anastasiya Olson[4], Giang Ong[1], Mithra Korukonda[1], Erin Piazza[1], Jason Reeves[1], Alyssa Rosenbloom[1], Kiara Siex[4], Hye Son Yi[1], Edward Zhao[1], Joseph M. Beechem[1], Gordon Mills[4]. *[1]NanoString Technologies, Inc., Seattle, WA,[2]Knight Diagnostic Laboratories, Oregon Health and Sciences University, Portland, OR,[3]Division of Hematology & Medical Oncology, Knight Cancer Institute, Oregon Health and Sciences*

University, Portland, OR,[4]Knight Cancer Institute, Oregon Health and Sciences University, Portland, OR

The power of spatial biology lies in the integration of multiple scales of information from subcellular to tissue scale. Until recently, spatial analysis of protein biomarkers in tissues was limited to a few markers at a time using traditional IHC colorimetric or fluorescent readout. Here, we demonstrate the ability of NanoString's CosMx™ Spatial Molecular Imager (SMI) platform to quantify more than 70 proteins encompassing key targets in immuno-oncology and tumor biology, localize the proteins and analyze protein expression at a single cell level. Key to the technology is the use of fully automated fluidics and imaging systems, short turnaround time, and high sensitivity. The CosMx protein assay has been optimized for FFPE samples, which represent the largest collection of biospecimens available for clinical investigation. To that end, we explored the utility of CosMx spatial proteomics on a series of clinical samples from cancer patients, including the Serial Measurements of Molecular and Architectural Response to Therapy (SMMART) trial, across multiple cancer types. CosMx SMI's high-level protein multiplexing capabilities enabled spatial analysis of metastatic tumors in response to personalized treatment for a single patient over time. Combining spatial data obtained from both CosMx RNA and protein assays on the same sample reveals distinct regions of Tumor Associated Macrophages and their interactions with tumor cells in some samples. Detection of phosphoproteins also allows for analysis of the impact of kinase inhibitor treatment on the spatial environment in longitudinal biopsies. The highly-multiplexed spatial analysis of proteins in longitudinal metastatic breast cancer biopsies under therapeutic pressure provides a unique opportunity to understand evolution of tumors and develop and implement therapeutic approaches that can directly target mutations arising in the tumor cells while effectively engaging the immune system.

Validation of a novel multiplex immuno-fluorescence panel for the spatial analysis of the tumor microenvironment

François Rivest, Victor de Gautard, Vytautas Navikas, Saska Brajkovic, Bastian Nicolai. *Lunaphore Technologies SA, Tolochenaz, Switzerland*

IHC counterparts. Subsequently, the panel was transferred on a multi-organ TMA including several tumoral and non-tumoral specimens, showing robust performance across multiple tissue types. The protocol was optimized to achieve high staining quality for all 13 markers in terms of signal specificity Investigation of the tumor microenvironment (TME) by multiplex immunofluorescence (mIF) has accelerated the understanding of the spatial immune context in tumors. mIF has proven to be a powerful technique for the identification of new potential biomarkers and therapeutical targets. Despite increased application of mIF assays to characterize the TME, state-of-the art protocols remain technically challenging. Manual execution and use of dedicated reagents render them lengthy and costly. Moreover, their reproducibility is often questioned together with their transferability between different tissue types.
Here, we show the development and validation of an Immuno-Oncology (IO) Core Panel of 13 clinically relevant biomarkers to enable spatial analysis of the immune TME on the COMET™ platform across various tissue types. Formalin-fixed paraffin-embedded human tissue sections from tonsil and a 24-cores multi-organ tissue microarray (TMA) were stained using the IO Core Panel from Lunaphore on the COMET™ platform by fully automated sequential immunofluorescence (seqIF™), which consists of cycles of staining, imaging, and elution. The panel allows for simultaneous detection of CD3, CD4, CD8, CD45, FoxP3, PD1, PD-L1, CD11c, CD20, CD56, CD68, aSMA and Ki-67 by indirect immunofluorescence using unlabeled primary antibodies and Alexa Fluor™ Plus secondary antibodies. The 13-plex IO Core panel was initially developed and validated on tonsil as positive control tissue. To compare immunofluorescent (IF) and immunohistochemistry (IHC) staining patterns, the sections retrieved from COMET™ after seqIF™, were stained by a histology facility with standard IHC established for routine pathological diagnosis. All markers demonstrate accurate detection with specific IF staining, comparably to gold-standard, sensitivity, ratio to background and dynamic range. The repeatability and reproducibility of the automated IO Core Panel on the COMET™ platform was verified by day-to-day tests on one platform and tests among multiple platforms, respectively.

Our study demonstrated the robustness of the validated IO Core Panel across multiple tissue types with highly specific and reproducible results. The marker detection with standard indirect immunofluorescence on the COMET™ instrument allows for future, rapid expansion and customization of the panel including additional primary antibodies towards the need of the individual underlying scientific question.

High-spatial-resolution multi-omics analysis of cancer tissues

Emily Neil, Dongju Park, Erica Lloyd, Michael Dibuono, Seiyu Hosono, Reto Muller, Hanna Lafayette, Hsinyi Smith, Robert Pinard. *Miltenyi Biotec, Waltham, MA*

Recent technological breakthroughs in single cell sequencing have revealed that malignant cells and nonmalignant cells are both highly dynamic and in the case of tumor cells, that the intratumoral heterogeneity is quite remarkable. However, several questions remain, especially in a spatial context, and a rapidly growing need has been observed for imaging-based approaches with single-cell resolution to visualize and characterize the tumor microenvironment. In the current study, we used Miltenyi Biotec newly developed spatial gene expression technology and automated imaging platform, to acquire spatial microscopy data for multiple biological analytes and multiple cancer tissues. The approach is based on fluorescence microscopy and the MICS technology principle of cyclic staining (MACSima™ Imaging Cyclic Staining) along with validated fluorochrome-conjugated antibodies and specifically amplified oligonucleotide probes combined with a proprietary signal removal system. FFPE tissue blocks were analyzed and each gene, which display a unique emission spectrum during a single cycle, was decoded. Due to the non-destructive nature of the workflow, H&E staining, immunofluorescence and RNA data can be collected together into a single image and on a single section. Using our antibody and targeted RNA immune-oncology panel coupled with our smart segmentation and flexible gating software suite, we have generated a topographical map of the expression profile level for several cancer tissues i.e.: tonsil, pancreas, kidney and ovary. This technology allows for the analysis of hundreds of protein markers and RNA transcripts on a single tissue, the characterization of the spatial architecture and the expression

topography of tumor tissue sections. A better understanding of tissue microenvironment and implementation of spatial biology approaches will help advance the identification of more suitable biomarkers and for cancer therapy.

Spatially resolved transcriptomics points to distinct malignant cell populations within primary and castration resistant prostate cancer

Antti Kiviaho, Heini M. L. Kallio, Sini K. Eerola, Elisa M. Vuorinen, Tomi Häkkinen, Sinja Taavitsainen, Ebrahim Afyounian, Teemu Tolonen, Juha Kesseli, Alfonso Urbanucci, Kirsi J. Rautajoki, Teuvo L. J. Tammela, Tapio Visakorpi, Matti Nykter. *Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland*

Background: Prostate cancer (PCa) is the second most common cancer in men. Despite its high prevalence, many patients carry an indolent form of the disease and are thus suspect to overtreatment. Conversely, some cases treated with androgen deprivation therapy can develop into castration resistant prostate cancer (CRPC), for which there is no curative treatment. Understanding why some tumors are more aggressive than others could lead to more accurate patient risk stratification. Here we characterize cancer and normal cell subpopulations within prostate tissue in their spatial context using a multimodal integrative approach.
Methods: We performed spatially resolved transcriptomics (ST) on a set of primary tumor PCa, CRPC and benign prostatic hyperplasia (BPH) patient samples. In addition to ST, we produced RNA-seq, DNA-seq and assay for transposase accessible chromatin using sequencing (ATAC-seq) data, allowing for multiomic integration within and across sample categories. We performed extensive analysis of ST data, employing unsupervised clustering, spot expression signal deconvolution, differential gene expression analysis and copy number variation (CNV) inference.
Main Results: The systematic analysis of spot expression profiles revealed a high degree of variation in nearby tissue regions, as we found up to three unique luminal cell populations inside a one millimeter radius in PCa. Similarly in locally recurrent CRPC, we identified cumulative CNVs in proximal luminal cell populations, with the inferred CNV profiles validated through DNA-seq. A set of marker genes was calculated for each unique

cell population, with multiple PCa associated genes found to be differentially expressed. Although we observed significant variation in the luminal cell populations, the stromal gene expression was markedly similar across all samples.
Conclusions: We discovered shared, similar and unique cell populations both within and across different PCa and CRPC sections. We observed various luminal cell populations with distinct gene expression profiles in samples from both progression stages. The close spatial proximity of these cell clusters suggests that ST can be used to discover and examine finely detailed populations in their original spatial environment.

Spatial transcriptomic profiling of the human and mouse retina prepared with CryoJane Tape Transfer System using GeoMx and CosMx spatial analysis

Charles Glaser[1], Su Ma[1], Wei Yang[1], Yan Liang[1], Joeseph Beechem[1], Vera L. Bonilha[2], Sujata Rao[2], William Horrigan[2], Bela Anand-Apte[2].
[1]NanoString Technologies, Inc., Seattle, WA,[2]Cole Eye Institute and Cleveland Clinic Lerner College of Medicine-CWRU, Cleveland, OH

The goal of this study is to identify key transcriptomic markers within layers of the retina by individually profiling layers using cellular and subcellular spatial transcriptomics, additionally, comparing the results between each level. Both human and mouse retina samples, prepared fresh frozen and fixed frozen, are analyzed using the GeoMx® Digital Spatial Profiler (DSP) and CosMx® Spatial Molecular Imager (SMI) using the whole mouse transcriptome atlas and 1000-plex mouse neuro panel, respectively. Samples are fixed using Cryo-Jane Taper Transfer system. Samples are mounted on to adhesive coated slides as well as adhesive tape to mount samples to glass slides. This method is used to secure fragile frozen tissue, such as the retina. Human and mouse samples were stained using immunofluorescent microscopy targeting neurofilament H (NF-H), glial fibrillary acidic protein (GFAP) and NeuN on DSP and 18s rRNA, amyloid-beta and GFAP on SMI. Staining allows for identification of structural layers in the retina. Simultaneously, regions of interest (ROI) for spatial profiling are selected based on immunofluorescent stains. On DSP, each sample had 3x ROIs in the photoreceptor layer, inner nuclear layer and

ganglion cell layer, then, oligonucleotides were collected and sequenced. Finally, raw counts were Q3 normalized for analysis. For SMI data analysis, 6 field of views (FOVs) were put on each section to cover most regions with multiple layers. ~8000 genes were detected on human retina samples using DSP. Around 500 unique genes were detected between the photoreceptor and inner nuclear layer using DSP. Preliminary SMI results show we were able to identify cell types (amacrine, horizontal cell, biopolar cell, ganglion cell, etc) and cell specific markers for outer nuclear layer, inner nuclear layer and ganglion cell layer**.** Data between DSP and SMI showed high concordance with one another, identifying many genes in each layer.

Single cell, multiomic spatial phenotyping of immunotherapy responses in head and neck cancer

HaYeun Ji[1], Niyati Jhaveri[1], Ning Ma[1], Bassem B. Cheikh[1], Aditya Pratapa[1], James Monkman[2], Ken O'Byrne[3], Brett Hughes[4], Arutha Kulasinghe[2], Oliver Braubach[1]. *[1]Akoya Biosciences, Menlo Park, CA,[2]The University of Queensland, Brisbane, Australia,[3]The Princess Alexandra Hospital, Brisbane, Australia,[4]The Royal Brisbane and Women's Hospital, Brisbane, Australia*

Background**:** Immune checkpoint inhibitors (ICI) have proven to be game-changing treatments for mucosal head and neck squamous cell cancer (HNSCC). Emerging successes with anti-PD-1/PD-L1 therapy have led to durable responses and prolonged survival in both human papillomavirus-positive (HPV+) and negative (HPV-) patients. There is now a need for predictive biomarkers to guide patient selection for highly targeted ICI therapies as currently available diagnostic biomarkers have a limited value. The tumor microenvironment (TME) composition, contexture, and cellular architecture are now recognized as key to understanding immune responsive and resistant phenotypes. Here, we are using a spatial biology approach to explore the TME in metastatic/recurrent HNSCC tumors treated with Pembrolizumab / Nivolumab.

Methods: In this study, we used single cell, multiomic spatial phenotyping utilizing the PhenoCycler-Fusion spatial biology platform to characterize the TME of HNSCC tumors from a cohort of n=40 patients. The discovery

cohort consisted of patients who had complete vs. partial vs. stable vs. progressive responses to ICI therapy. We first analyzed tissues using an ultrahigh-plex antibody panel of >60 antibodies that label immune cell lineages, checkpoints, activation markers as well as tissue structure and the stroma. We then conducted whole-slide, single cell resolution RNA detection with complementary markers on serial sections from the same tissue blocks; the combination of these data allowed us to obtain multiomic spatial signatures that offered uniquely comprehensive insight into the TME of our tissue cohorts.
Results: Our study identified highly resolved tissue immune contexture analysis and metabolic tissue signatures associated with resistance and sensitivity to immunotherapy. Most notably, multiomic profiling of HNSCC tumours provided deeper insights into ICI therapy resistance than the single omics based approaches alone.
Conclusions: Our study demonstrates the power of unbiased, multiomic spatial phenotyping with whole-slide imaging to identify biomarkers associated with response to ICI therapy in HNSCC.

Single cell spatial phenotyping of bladder tumors with a novel mechanism of NKG2A and HLA-E mediated resistance to BCG immunotherapy
Dmytro Klymyshyn[1], Niyati Jhaveri[1], Nadine Nelson[1], Michael Prater[2], Zhenqin Wu[3], Steven Hamel[3], Matthew D. Galsky[4], Nina Bhardwaj[4], John P. Sfakianos[4], Subham Basu[2], Oliver Braubach[1], Amir Horowitz[4]. *[1]Akoya Biosciences, Marlborough, MA,[2]Abcam, Cambridge, United Kingdom,[3]Enable Medicine, Menlo Park, CA,[4]Icahn School of Medicine at Mount Sinai, New York, NY*

Background: ~75% of diagnosed bladder tumors are non-muscle-invasive, requiring instillation of *M. bovis* Bacillus Calmette-Guérin (BCG) with recurrence rates observed in ~50% of patients. Treatments for BCG-resistant bladder tumors have lagged because few studies have tried to understand the relationship between timing of tumor recurrence and the state of immune system at the time of recurrence. Natural Killer (NK) cells are very early responders to tumor cells. HLA-E, like PD-L1, is sensitive to IFN-γ and strongly inhibits $NKG2A^+$ NK and CD8 T cells and is commonly

upregulated on tumors. We observed that BCG exposure results in chronic activation of NK and CD8 T cells and their acquisition of NKG2A and PD-1 phenotypes. Upon tumor recurrence in all patients sampled, a subset of the tumor cells aggregated in nests, were activated in response to NK/CD8 T cell-derived IFN-γ, and upregulate HLA-E and PD-L1. Spatial sequencing revealed *HLA-E*^{Bright} tumor nests with high levels of *CXCL9/10/11* and in significantly closer proximity to NK/CD8 T cells (and Tregs) compared with *HLA-E*^{Dim} tumor nests that lacked *CXCL9/10/11*. Here, we apply single cell spatial phenotyping to study major subsets of NK cells in the TME of bladder tumors obtained from patient matched tumor sections before and after BCG therapy.

Purpose of the study: The goal of this study is to understand the underlying cell-to-cell interactions that promote BCG resistance in non-muscle-invasive bladder cancer (NMIBC).

Methods: The PhenoCycler technology centers around an oligo-based barcoding strategy, in which oligonucleotide-labeled antibodies are imaged in iterative cycles of hybridized/dehybridized complementary oligonucleotide fluorescent reporters. The platform enables (1) whole-slide imaging, (2) single-cell and subcellular resolution, (3) compatibility with a wide range of FFPE tissues, (4) customized content and plexing capability and (5) sophisticated analysis of cell phenotypes and cellular neighborhoods.

Results and conclusions: We developed a comprehensive antibody panel for in-depth analysis of the TME of bladder tumors. Our panel centers around a core of 67 markers for cell lineage, immune checkpoints, immune activation markers, tissue structure and vasculature. This core was supplemented with a module of additional antibodies that define complex NK cell phenotypes, including markers of maturation and differentiation, metabolism, activation and inhibition, trafficking, cytolytic killing, as well as cytokines/chemokines that shape the TME. The power of single cell spatial biology is the ability to visualize all major subsets of NK cells and their associated microenvironment simultaneously in single tissue sections. In doing so, we are defining novel functional interactions as new correlates of BCG resistance and identifying pathways that can be exploited for next-gen immunotherapies.

The Next Wave of Precision Oncology: New Drugs, Databases, and Analytics to Refine Care

Bridging the gap between clinical-omics and machine learning to improve cancer treatment

Chang In Moon[1], Byron Jia[2], Bing Zhang[1]. *[1]Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX,[2]Chemistry, Carleton College, Houston, TX*

Background: Few omics data-based prediction models have made a clinical impact due to lack of access to real-world, clinically relevant datasets for method development and evaluation. The expanding integration of omics profiling into cancer clinical trials opens a new opportunity to address this problem. Clinical trials ensure high quality of the treatment response information and clinical relevance of the identified molecular features and constructed prediction models. Here we present a python package ClinicalOmicsDB that provides a framework for systematic benchmarking of machine learning algorithms using a compendium of carefully collected and curated clinical omics datasets. The package further leverages interpretable AI to gain biological insights from high-performing models. Approach: We downloaded omics datasets from 28 clinical trials across 7 cancer types, totaling 6127 patients and 60 treatment arms. For each treatment arm, we performed random stratified splitting of the data into 80% for training and the remaining 20% for testing, and this was repeated 30 times to create 30 simulated train-test pairs. Based on all 60 treatment arms, we created 1800 train-test pairs for prediction model development and evaluation. To illustrate the utility of this package, we benchmarked six supervised machine learning algorithms for their ability to distinguish responders from non-responders. For each training dataset, 5-fold cross-validation was used to select the top 20 non-redundant features and to optimize hyperparameters. The optimized pipeline was used to train a full model based on the complete training dataset, which was then applied to the paired testing dataset for performance evaluation using AUROC. Shapley plots were created for models with satisfactory AUROC scores to facilitate biological interpretation.

Results: Among the 6 algorithms tested, random forests had the best overall performance. It achieved an AUROC>0.75 for 11 treatment arms. Shapley plot identified LPIN1 as a top predictive marker for the combination treatment of fluorouracil, doxorubicin, and cyclophosphamide (AC) in unselected breast cancers. The cancer testis antigen MAGEA1 was among the top predictive markers for combination treatment with pembrolizumab, taxane, and AC in HER2- breast cancers. Shapley plot of a protein-based model identified SRC_Y527 and ERBB3 as the top biomarkers for predicting whether HER2+ breast cancer would respond to the combination of trastuzumab emtansine, pertuzumab, and AC.
Conclusion: We created a computational framework that uses real-world omics data to benchmark machine learning algorithms and to identify predictive markers based on best-performing models. More datasets will be continuously added, and new algorithms can be easily benchmarked against existing ones. ClinicalOmicsDB unifies the efforts from the clinical and machine learning communities to improve cancer treatment.

#5718

Additivity predicts the clinical efficacy of most approved combination therapies for advanced cancer

Haeun Hwangbo[1], Sarah Patterson[1], Andy Dai[2], Deborah Plana[3], Adam C. Palmer[1]. *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]North Carolina School of Science and Mathematics, Chapel Hill, NC,[3]Harvard Medical School, Boston, MA*

Most advanced cancers are treated with drug combinations. Rational designs aim to identify synergistic drug interactions to produce superior treatments. However, metrics of drug interaction (i.e., synergy, additivity, antagonism) apply to pre-clinical experiments, and there has been no established method to quantify synergy versus additivity in clinical settings. Here, we propose and apply a model of drug additivity for progression-free survival (PFS) to assess if the clinical efficacies of approved drug combinations are more than, or equal to, the sum of their parts. This model accounts for the benefit from patient-to-patient variability in the best single drug response, plus the added benefit of the weaker drug per patient. Among all FDA approvals of combination therapies for advanced cancer between 1995 and 2020, we identified 37 combinations across 13 cancer

types (24,723 patients) where the efficacies of monotherapies and combination therapies could be analyzed at matched doses. 95% of combination therapies exhibited progression-free survival times that were additive, or less than additive. Across all trials and follow-up times, the coefficient of determination of the additivity model was R^2=0.90, with no fitting or training, only the operation of addition. While there were deviations from additivity, with several combinations being less than additive, 100% of the approved combinations studied would have been predicted to succeed by the additivity model. This study has two key findings. First, a synergistic effect (more than additive) is neither a necessary nor even common property of clinically effective drug combinations. Second, the predictable efficacy of many of the best drug combinations established over the past 25 years suggests that additivity can be used as a design principle for novel drug combinations and clinical trials, which could be helpful as the number of possible therapies grows and as cancers are increasingly divided into subtypes with distinct drug sensitivities.

#5719

Clinical response to the PDGFRα inhibitor avapritinib in high-grade glioma patients

Institute, Boston, MA,[3]University of Michigan, Ann Arbor, MI,[4]Biomedical Imaging, Medical University of Vienna, Vienna, Austria,[5]Medicine, Massachusetts General Hospital, Boston, MA,[6]Cancer Biology, Dana-Farber Cancer Institute, Boston, MA,[7]Analytical Chemistry, Johannes Kepler University, Linz, Austria,[8]Central European Institute of Technology, Brno, Czech Republic,[9]Neurosurgery, Medical University of Vienna, Vienna, Austria,[10]Medicine, Dana-Farber Cancer Institute, Boston, MA,[11]Pediatric Hematology and Oncology, University Medical Center Göttingen, Göttingen, Germany,[12]Pediatric Hematology and Oncology, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany,[13]Pediatric Neuro-Oncology, Newcastle University, Newcastle, United Kingdom,[14]Oncology, University Children's Hospital Zurich, Zurich, Switzerland,[15]Pediatrics, Neurology, and Neurological Surgery, University of California San Francisco, San Francisco, CA,[16]Hopp Children's Cancer Center Heidelberg, Heidelberg, Germany,[17]Pediatric Oncology, Masaryk University, Brno, Czech Republic,[18]Pathology, Medical University of Vienna, Vienna, Austria,[19]Neuropathology and Neurochemistry, Medical University of Vienna, Vienna, Austria,[20]Pathology, University of Michigan, Ann Arbor, MI,[21]Pediatrics, University of Michigan, Ann Arbor, MI,[22]Children's Minnesota, Minneapolis, MN,[23]Neurology and Neurological Surgery, Jefferson University, Philadelphia, PA,[24]Pediatrics, University of Texas Southwestern Medical Center, Dallas, TX

PDGFRA has been shown to be commonly altered in high-grade gliomas (HGGs), including histone 3 lysine 27-mutated diffuse midline gliomas (H3K27M DMG), a disease with almost no long-term survivors. Here, we performed comprehensive genomic and transcriptomic analysis of 260 high-grade glioma cases, which revealed PDGFRA genomic alterations (mutations and/or amplifications) in 13% of patients. H3K27M DMGs had significantly higher PDGFRA expression compared to H3 wild-type tumors, and PDGFRA gene amplification resulted in even higher expression levels in H3K27M DMGs as well as H3 wild-type HGGs. We tested a panel of patient- derived pHGG/H3K27M DMG models against a range of PDGFRA inhibitors, including avapritinib, a potent small molecule inhibitor with relatively selective activity against both wild-type and mutant

PDGFRA. Avapritinib showed supra-micromolar blood-brain barrier penetration in our pre-clinical models and demonstrated significant survival impact in an aggressive patient-derived H3K27M DMG mouse xenograft model. Finally, building on this preclinical activity, we report here the first clinical experience using avapritinib in eight pediatric and young adult patients with high-grade glioma (H3K27M DMG and/or PDGFRA altered). Avapritinib has thus far been well tolerated with no significant acute toxicities. Most importantly, our preliminary data reveal radiographic response evaluated by RAPNO criteria in 50% of patients, a striking outcome rarely seen in this patient population. In summary, we report that avapritinib is a selective, CNS-penetrant small molecule inhibitor of PDGFRA that shows potent activity in preclinical models and produces promising clinical responses with good tolerability in patients with high-grade glioma. This suggests a promising role for avapritinib therapy in this population with previously dismal outcomes.

Combination therapies in matched 3D in vitro and in vivo preclinical models of rare and recalcitrant cancers from the National Cancer Institute's Patient-Derived Models Repository

Thomas S. Dexheimer[1], Thomas Silvers[1], Rene Delosh[1], Russell Reinhart[1], Chad Ogle[1], Zahra Davoudi[1], Eric Jones[1], Debbie Trail[1], John Carter[1], Justine Mills[1], Kyle Georgius[1], Howard Stotler[1], Michelle Norris[1], Shannon Uzelac[1], Suzanne Borgel[1], Tiffanie Minor[1], Luke Stockwin[1], Michael Mullendore[1], Kevin Plater[1], Keegan Kalmbach[1], Jessica Steed[1], Matthew Murphy[1], Gareth Bliss[1], Carrie Bonomi[1], Kelly Dougherty[1], Marion Gibson[1], Kevin Cooper[1], Dianne Newton[1], Cindy R. Timme[1], Yvonne A. Evrard[1], Melinda G. Hollingshead[2], Nathan P. Coussens[1], Ralph E. Parchment[1], James H. Doroshow[2], Beverly A. Teicher[2]. *[1]Applied and Developmental Research Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Frederick, MD*

There is a major need in oncology drug development to establish predictive preclinical assays with high translational relevance to patient responses. The National Cancer Institute's Patient-Derived Models Repository

(https://pdmr.cancer.gov) offers a collection of highly characterized models from a variety of cancer types including rare and recalcitrant malignancies and tumors from patients of diverse ancestry. This collection includes matched sets of patient-derived cell lines, organoids, and xenografts (PDXs), which allows comparisons of drug responses from *in vitro* and *in vivo* assays performed with the same patient-derived tumor model. A high-throughput screen was conducted using matched sets of patient-derived organoids and cell lines. Patient-derived cell lines were grown as 3D multicellular spheroids mixed with endothelial cells and mesenchymal stem cells. The patient-derived organoids were 100% tumor cells and were plated in 5% basement membrane extract supplemented with growth factors and cytokines. All drugs were tested at concentrations up to their reported clinical C_{max} values and cell viability for individual drug treatments and drug combinations were assayed using CellTiter-Glo 3D after seven days drug exposure. Prior to the endpoint viability measurements, growth curves for spheroid median volume and organoid median surface area were calculated from a series of non-invasive brightfield images collected every 12 hours. For some drug combinations, differential responses were observed between the matched organoids and multicellular spheroids, potentially reflecting the contribution of the stromal component in the spheroids. Overall, the drug-dependent growth responses observed from the two 3D *in vitro* models (i.e., multicellular spheroids and organoids) were frequently comparable to those observed *in vivo* from PDXs. For example, the *in vitro* activities of several drug combinations including: BAY1895344 + temozolomide, erlotinib + cediranib, entinostat + talazoparib, and selumetinib + abemaciclib, demonstrated good agreement with the responses observed *in vivo*. However, among the drug combinations tested ixazomib + panobinostat showed the greatest cytotoxicity *in vitro* but had no activity in the matched PDX models. The availability of matched patent-derived cell lines, organoids and PDXs provides an opportunity to learn about the features of assay methodologies and data analyses that influence the successful translation of preclinical results between *in vitro* and *in vivo* systems. The results of this study are encouraging, but also highlight discrepancies that will be important to investigate, understand and address in order to improve translational capacity of future assays. This project was funded in part with federal funds from the NCI, NIH, under contract no. HHSN261201500003I.

#5721

Automated annotation for large-scale clinicogenomic models of lung cancer treatment response and overall survival

Justin Jee[1], Chris Fong[1], Karl Pichotta[1], Thinh Tran[1], Anisha Luthra[1], Mirella Altoe[1], Steven Maron[1], Ronglai Shen[1], Si-Yang Liu[1], Michele Waters[1], Joseph Kholodenko[1], Brooke Mastrogiacomo[1], Susie Kim[1], A Rose Brannon[1], Michael F. Berger[1], Axel Martin[2], Jason Chang[1], Anton Safonov[1], Jorge S. Reis-Filho[1], Deborah Schrag[1], Sohrab P. Shah[1], Pedram Razavi[1], Bob T. Li[1], Gregory J. Riely[1], Nikolaus Schultz[1]. *[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]New York University, New York, NY*

The digitization of health records and prompt availability of tumor DNA sequencing results offer a chance to study the determinants of cancer outcomes with unprecedented richness; however, abstraction of key attributes from free text presents a major limitation to large-scale analyses. Using natural language processing (NLP), we derived sites of metastasis, prior treatment at outside institutions, programmed death ligand 1 (PD-L1) levels, and smoking status from records of patients with tumor sequencing to create a richly annotated clinicogenomic cohort. We sought to define whether combining features would improve models of overall survival (OS) and treatment response as validated in a multi-institution, manually curated cohort. We leveraged the manually curated AACR GENIE Biopharma Collaborative (BPC) dataset to train NLP algorithms to abstract the aforementioned features from overlapping records available at Memorial Sloan Kettering (MSK). All models achieved precision and recall > 0.85. We deployed these algorithms to records of all MSK patients with non-small cell lung cancer (NSCLC) and tumor profiling with our FDA-authorized institutional targeted sequencing platform (N=7,015). These labels were combined with genomic, demographic, histopathologic, internal treatment and staging data to train random survival forests (RSF) to predict OS and time-to-next-treatment (TTNT) for molecularly targeted and immunotherapies. RSFs trained on the MSK NSCLC cohort were validated with the curated, non-MSK BPC NSCLC cohort (N=977). The addition of NLP-derived variables to genomic features enhanced RSF predictive power

for OS (c-index, 10x bootstrap 95%CI: 0.58, 0.57-0.59 vs 0.75, 0.74-0.76 combined) and targeted and immunotherapy TTNT. The size of the MSK NSCLC cohort enabled discovery of associations between metastatic sites, PD-L1 status, genomics, and TTNTs not apparent in the smaller BPC cohort. We measured the added predictive value of variables not available in BPC with MSK-only cross-validation analyses. White blood cell differential counts and additional tissue genomic features including tumor mutational burden and fraction genome altered added minimally, while circulating tumor DNA sequencing added prognostic power for OS over other factors including disease burden. Using NLP we present a large NSCLC cohort with rich clinicoradiographic annotation, leading to superior models of patient outcomes. Our data uncovers associations not observed in smaller, manually curated cohorts and provides a foundation for further research in therapy choice and prognostication.

The mutational signatures of 100,477 targeted sequenced tumors

Donghyuk Lee[1], Min Hua[2], Difei Wang[2], Lei Song[2], Tongwu Zhang[2], Kai Yu[2], Xiaohong R. Yang[2], Jianxin Shi[2], Stephen J. Chanock[2], Maria Teresa Landi[2], Bin Zhu[2]. *[1]Pusan National University, Busan, Korea, Republic of,[2]National Cancer Institute, Bethesda, MD*

Mutational signatures, the footprints of somatic mutations, are associated with the causes of cancer and have been well-studied for tumors with whole exome or genome sequencing. However, due to the low number of detected mutations, mutational signatures were insufficiently explored for many tumors sequenced by targeted panels in clinics. It impedes the clinical application of mutational signatures. Here, we present a new method, SALMON (Signature Analyzer for Low Mutation cOuNts), to identify mutational signatures in targeted sequenced tumors based on tumor mutational burden. SALMON adjusts for panel size differences and uses a large number of targeted sequenced tumors rather than a large number of mutations per tumor (as with whole exome or genome sequencing) to overcome the challenges of mutational signature analysis for targeted sequencing. Extensive simulations and pseudo-targeted sequenced data show that SALMON can accurately detect spiky or common signatures. We applied SALMON to investigate the pan-cancer patterns of mutational

signatures for 100,477 targeted sequenced tumors in AACR Project GENIE, including 14,428 lung and 11,389 breast tumors. We detected well-established signatures in tumor types that have not previously been associated with these signatures, such as the smoking signature in ovarian tumors. Interestingly, analysis of thousands of tumors per cancer type from diverse populations revealed gender discrepancies, self-described race differences, subtype heterogeneity, and metastatic enrichment of mutational signatures. For instance, most sex-biased signatures are more frequently present in males for non-gender-specific cancers. Thiopurine treatment-induced signature in glioma is enriched in Black patients. And endometrioid ovarian or uterine cancers have a higher prevalence of polymerase epsilon (POLE) deficiency-related signatures than non-endometrioid ovarian or uterine cancers, respectively. Our study demonstrates the feasibility and utility of mutational signature analysis for targeted sequenced tumors, enabling precision applications of mutational signatures in the clinical setting.

An *in vivo* pharmacogenomics platform replicates and extends biomarkers of therapy response identified via causal inference analysis of clinical data

David Amar[1], Erick Scott[1], Ian P. Winters[1], Gregory D. Wall[1], Dmitri A. Petrov[2], Monte M. Winslow[2], Joseph Juan[1], Ian K. Lai[1], Lafia Sebastian[1], Edwin A. Apilado[1], Gabriel Grenot[1], Vy B. Tran[1], Charles Rudin[3], Michael J. Rosen[1]. *[1]D2G Oncology, Mountain View, CA,[2]Stanford University, Stanford, CA,[3]Memorial Sloan Kettering Cancer Center, New York, NY*

Recent development of therapies targeting oncogenes have dramatically improved cancer care for subsets of patients and generated a wave of interest in cancer precision medicine. However, effective targeted therapies are scarce as we have a limited understanding of how drug responses are modulated by tumor genotype. Here, we utilize both human data and in vivo models to identify genetic drivers of therapy response in KRAS-driven non-small cell lung cancer patients treated with chemotherapy. We first present an integrative causal inference analysis of three clinical data resources: (1) the recently released Genomics Evidence Neoplasia Information Exchange, Biopharma Collaboration dataset (GENIE-BPC;

n=197), (2) a selected set of patients from the Tempus Clinico-genomic Database (n=330), and (3) an additional cohort from Memorial Sloan Kettering Cancer Center (n=218). Each dataset was first analyzed separately using a causal inference pipeline. Doubly robust estimators for each variant were inferred within a counting process survival analysis model accounting for time-varying treatments and immortal time bias. Meta-analysis of the results from all three cohorts identified three commonly mutated and highly replicable genes with a significant effect on overall survival: KEAP1, SMARCA4, and CDKN2A.
As further validation, we used our murine in vivo pharmacogenomics (PGx) platform that can quantify the effects of therapies across thousands of tumors of diverse genotypes. These tumors are initiated de novo in the native microenvironmental context in mice with an intact adaptive immune system. We tested a chemotherapy combination of carboplatin and pemetrexed in mice with KrasG12D-driven lung tumors and inactivation of each of 60 putative tumor suppressors. Treatment led to >75% reduction in tumor sizes relative to tumor suppressor inactivated (matched) vehicle-treated controls. These models identified causal effects for two out of the three candidates above: KEAP1 (resistance) and CDKN2A (sensitive). Moreover, our PGx platform identified additional candidate genes beyond those found using the clinical data, which had insufficient sample size for these rarely mutated genes. Together, we demonstrate how leveraging our PGx platform together with human data within a causal inference framework may improve the stratification of patients by their clinical outcomes, profoundly advancing the promise of precision medicine.

Therapeutic Antibodies, Including Engineered Antibodies

#5652
IL-19 blockade reprograms glioblastoma immunosuppressive microenvironment and overcomes chemo-resistance as revealed by single-cell transcriptome analyses

Gilbert A. Lee, Cheng-Yu Chen. *Taipei Medical University, Taipei, Taiwan*

Glioblastoma multiforme (GBM) is the most aggressive brain tumor with chemo-resistant, immunosuppressive, and invasive property. Despite the application of standard therapies which include a combination of surgery,

radiotherapy, and temozolomide (TMZ) chemotherapy, tumor inevitably recurred (in patients) at peritumoral region. Targeting multiple arms of the GBM-mediated immunosuppressive ability and their invasiveness can improve therapeutic efficacy. Genomic screening identified that IL-19 is a predicted immune suppressive cytokine in peritumoral region and was associated with poor survival in patients with GBM. IL-19 blockade inhibited both TMZ-sensitive and resistant tumor progression. Molecular studies revealed that silencing IL-19 markedly abrogated IL-19-WISP1-AKT signaling to inhibit TMZ-resistant GBM cell invasion, as well as weaken its suppressive ability on $CD8^{+}$T cell activation. Single cell transcriptome analysis revealed that IL-19 blockade promoted T cell activation, upregulated effector function of T cell subsets, and reprogrammed tumor-associated macrophage subsets toward a weakened pro-tumoral phenotypes. Thus, Targeting IL-19 can be a novel therapeutic strategy to reverse immunosuppressive microenvironment and restrict invasiveness of chemo-resistant GBM.

LCB97, an antibody drug conjugate (ADC) targeting a novel tumor antigen for the treatment of multiple solid tumors

Yeojin Jeong[1], Gunther Spohn[2], Flavio Mehli[2], Chul-Woong Chung[1], Changsik Park[1]. *[1]LegoChem Biosciences, Inc, Daejeon, Korea, Republic of,[2]Elthera AG, Schlieren, Switzerland*

LCB97 is an antibody-drug conjugate (ADC) directed against a novel tumor antigen, composed of monomethyl auristatin E (MMAE) as payload (DAR 4) and the humanized IgG1 antibody AFF4 generated by Elthera. AFF4 targets a novel antigen preferentially expressed in various solid tumors including pancreatic cancer, ovarian cancer, colon cancer, breast cancer and melanoma. LCB97 generated by using LCB's *ConjuAll*^{TM} technology with AFF4 showed potent cytotoxicity in various cancer cell lines including breast cancer (BC), ovarian cancer (OC), pancreatic cancer (PaC), small cell lung cancer (SCLC), colorectal cancer (CRC) and melanoma. LCB97 also showed excellent anticancer efficacy in several cell line-derived xenograft (CDX) models, including BC, CRC, OC and melanoma. Preliminary toxicity assessment in cynomolgus monkeys (an AFF4 cross reactive species) demonstrated that LCB97 was well tolerated within the

estimated therapeutic index of ~20 for repeat dosing. In conclusion, LCB97, generated by combining theAFF4 monoclonal antibody of Elthera and the highly innovative *ConjuAll*^{TM} platform technology of LegoChem Biosciences is a promising next-generation ADC for the treatment of various solid cancers, including BC, CRC, melanoma, OC and PaC.

#5654

A therapeutic humanized anti-carcinoma monoclonal antibody (mAb) NEO-201 can also target human granulocytic myeloid-derived suppressor cells (gMDSCs) and regulatory T (Tregs) cells

Massimo Fantini[1], Christina M. Annunziata[2], Philip M. Arlen[3], kwong Y. Tsang[1]. *[1]Precision Biologics, Inc, Bethesda, MD,[2]Women's Malignancy Branch, National Cancer Institute, Bethesda, MD,[3]Precision Biologics, Inc., Bethesda, MD*

Background**:** NEO-201 is a humanized IgG1 mAb reactive against multiple human cancers but not against most normal epithelial tissues. NEO-201 binds to core 1 or extended core 1 O-glycans expressed by its target cells, including neutrophils, various carcinomas, and some human hematological malignancies. NEO-201 can mediate antitumor activity through antibody-dependent cellular cytotoxicity (ADCC), complement dependent cytotoxicity (CDC), and blockade of the CEACAM5/CEACAM1 ICI pathway. A previous study using flow cytometry demonstrated that NEO-201^{+}/CD4^{+} T cells were also CD25^{+}/CD127^{-}/Foxp3^{+}/CD15s^{+} using PBMCs from healthy donors (HD). NEO-201 can kill these Treg cells through CDC *in vitro*. NEO-201 does not bind to the majority of CD4^{+} T cells and to other immune subsets. Human gMDSCs are increased in cancer patients and are a population of immature MDSCs deriving from immature neutrophils and alternative activation of mature neutrophils. gMDSC are characterized by HLA-DR^{-}, CD11b^{+}, CD33^{+}, CD15^{+}phenotype.We have shown that NEO-201 recognizes and kill human neutrophils through ADCC. This current investigation was designed to evaluate whether NEO-201 can target and mediate ADCC activity against human gMDSCs. **Methods:** gMDSCs were generated from human neutrophils from 5 HD isolated using EasySep^{TM} direct human neutrophil isolation kit. Isolated neutrophils were cultured in complete RPMI1640 medium supplemented

with human GM-CSF and human IL-6 for 7 days. Phenotypic analysis by flow cytometry was performed on the generated gMDSCs using NEO-201 and mAbs against human CD33, HLA-DR, CD15, CD14, CD66b. Flow cytometry based ADCC assay was performed using gMDSCs stained with both CD33 and HLA-DR as target. PBMCs from a separate HD were used as effectors at different E:T ratios. The ADCC activity of NEO-201 was evaluated comparing the percentage of $CD33^{+}$/$HLA\text{-}DR^{-}$ viable cells in gMDSCs incubated with medium alone to the percentage of $CD33^{+}$/$HLA\text{-}DR^{-}$ viable cells incubated with PBMCs alone and with PBMCs plus NEO-201.
Results: Flow cytometry analysis revealed that gMDSCs can be generated from human neutrophils after 7 days of culture with GM-CSF and IL-6 and that they express the following phenotype: $HLA\text{-}DR^{-}/CD33^{+}/CD15^{+}/CD14^{-}/CD66b^{+}$. NEO-201 bound to the majority of these gMDSCs. NEO-201 was functional in mediating ADCC to kill these gMDSCs.
Conclusion: This study demonstrated that NEO-201 can be used to identify and kill suppressive gMDSCs in addition to Treg cells. Depletion of suppressive Tregs and gMDSCs in the TME could be an effective strategy to prevent hyperprogressive disease when anti-PD-1 is used in cancer immunotherapy. These data support the rationale for the ongoing phase II clinical trial using NEO-201 in combination with pembrolizumab in checkpoint refractory patients with metastatic solid tumors.

preclinical development of a novel anti-tslpr bispecific antibody 1b7/cd3 targeting crlf2-rearranged ph-like b-all
Ze Tian, chunhua shi, Amin AI-Shami, GuoJun Yong, Jason K Allen, Jill Wardell Olson, Melinda G Smith, Qing Chang, Qing Shi, Junping You, Michelle A Gonzalez, Timothy E Lofton, Jasbir Kaur, Qi Zhang, DongXing Zha, Nitin Jain, Marina Y Konopleva, Timothy Heffernan, Jeffrey J Molldrem. *UT MD Anderson Cancer Center, Houston, TX*

Acute lymphocytic leukemia (ALL) is the most common form of leukemia in childhood and adolescence. Outcomes of relapsed/refractory adult B-ALL remain dismal with long-term survival of less than 10%. Although targeted therapies such as blinatumomab, inotuzumab ozogamicin, and CD19 CAR T cell therapy are a significant treatment advance for patients

with B-ALL, there is still an unmet medical need for novel therapies for B-ALL. CRLF2-rearranged B-ALL, a subtype of Philadelphia chromosome-like B-ALL, is a high-risk disease subset with poor long-term outcomes. In an effort to identify new therapeutic targets for B-ALL, we validated by flow cytometry that patients with CRLF2-rearranged Ph-like ALL overexpress thymic stromal lymphopoietin receptor (TSLPR) at levels comparable with CD19. We subsequently generated antibodies against TSLPR from immunized H2L2 Harbor mice through single B cell cloning technology. The lead antibody was further engineered to a CD3-redirecting bispecific antibody (BsAb) using Xencor's CD3e bispecific antibody technology to create 1B7/CD3 BsAb with an Fc-silent region. 1B7/CD3 BsAb exhibits high affinity binding to both human and cynomolgus monkey CD3e and TSLPR by BLI. Additionally, UHPLC-SEC analysis of 1B7/CD3 shows that this BsAb is stable without any aggregation or degradation present after five weeks incubation at 37 ^{o}C. In cell-based analyses,1B7/CD3 BsAb demonstrate potent antigen-specific T cell activation and tumor lysis activity against TSLPR^{+}-REH and MHH-CALL4 cell lines as well as a primary B-ALL patient sample, but none against human peripheral blood mononuclear cells (PBMC) collected from healthy donors. Animal tumor models suggest that 1B7/CD3 triggers a dose-dependent tumor regression or growth inhibition in PBMC humanized TSLPR-REH CDX and BOS-1 PDX models across donors. Correspondingly, T cell activation and expansion were examined by CD69 and CD3^{+} T cells with the best effect observed at the 1mg/kg dose. 1B7/CD3 exhibits durable PK with $T_{1/2}$ in NSG mice of up to ten days. Finally, 1B7/CD3 BsAb demonstrated a tolerable safety margin in a two-dose exploratory toxicity study in cynomolgus monkeys with MTD equal to or less than 1mg/kg. Consistent with clinical observation, we observed a transient increase of six major cytokines (IFNγ, IL-6, IL-8, IL-10, MCP-1 and TNFα) 4hr post the initial dosing, but no notable induction of cytokine levels after the second dosing (except for IL-8). Thus, our preclinical data provide the framework for the clinical evaluation of 1B7/CD3 BsAb in patients with CRLF2-rearranged B-ALL.

HK010, a novel anti-PDL1×CD137 bispecific antibody, exhibits potent anti-tumor immunity and low toxicity

Liangwei Li[1], Wenting Liu[2], Guodong Shen[3], Dayan Zhang[2], Weiming Zhou[2], Fengrong Wang[2], Xiaoli Zeng[2], Yang Huang[1], Liansheng Cheng[2].
[1]Georgia State University, Atlanta, GA,[2]Hefei Hankemab Biotechnology Co., LTD, He Fei, China,[3]The First Affiliated Hospital of University of Science and Technology of China, He Fei, China

Background: Checkpoint inhibitors targeting the PD-1/PD-L1 have changed the treatment and prognosis for patients with advanced solid tumors. There remains a unmet need for additional therapies due to treatment resistance. Tumor-necrosis superfamily members, such as CD137 and CD40, have been shown to synergize with the checkpoint inhibitors in preclinical studies. However, agonists antibodies have exhibited limited clinical activity for severe liver toxicity. Here we have developed a Fc-silenced bispecific antibody targeting PD-L1 and CD137, HK010, which could overcome these limitations by tumor-directed T-cell activation and checkpoint blockade.
Methods: The antigen binding specificity and affinity of HK010 were determined by enzyme-linked immunosorbent assay (ELISA), surface plasmon resonance (SPR) and flow cytometry. The functional activity of HK010 was determined using in vitro cell-based assays and reporter gene assay. Transgenic mice expressing human PD-L1 and 4-1BB were transplanted with human PD-L1-expressing murine MC38 cells to assess in vivo antitumor activity. Cytokine release assay was conducted by incubating HK010 with peripheral blood mononuclear cells (PBMCs) from healthy donors (n=6). The pharmacokinetic (PK) behavior and safety profiles of HK010 were characterized in cynomolgus monkeys.
Results: HK010 is a IgG4 PD-L1x4-1BB bsAb, which was designed to maintain a high affinity for human PD-L1 and a low affinity for human 4-1BB (KD PD-L1: 2.27 nM; KD 4-1BB: 493 nM) to achieve strong blocking of PD-1/PD-L1 and appropriate agonism of 4-1BB. HK010 retained full blockade activity on PD-1/PD-L1 signaling and enhances T-cell proliferation and IFN-γ production in vitro primary cell assays and Mixed lymphoid reaction (MLR). In addition, it led to a dose-dependent increase in the CD137-driven NFκB reporter gene activation through the bridging of PD-L1 on target cells and CD137 on effector cells. In humanized PD-L1/4-1BB transgenic mice bearing with MC38/hPDL1 tumor, HK010 showed robust single agent anti-tumor activity and induced durable antigen-specific

immunological memory that prevents the growth of the same tumor cells in the mice re-challenged. There were no signs of toxicity in human cytokine release assay for HK010. Toxicology data in cynomolgus monkeys showed that HK010 was well-tolerated up to 150 mg/kg (MTD≥150mg/kg) dose without systemic toxicity. Furthermore, HK010 was confirmed to be highly safe in the 5-week repeated-dose toxicity study with no observed treatment-related mortality, abnormality in hematological indexes, important organs. Conclusion: These data demonstrate that HK010, an anti-PD-L1×CD137 bispecific antibody, may exert a strong localized anti-tumor therapeutic efficacy with a low risk of liver toxicity through tumor-directed T-cell activation and checkpoint blockade in tumors.

#5658

MG-Ig (molecularly grafted immunoglobulin): An alternative platform for production of bispecific antibodies

Donglin Liu[1], Li Zeng[1], Berenice E. Liu[2], Chien-Hsing Chang[3]. *[1]FrontAim Biomedicines Inc., Princeton, NJ,[2]Princeton High School, Princeton, NJ,[3]Consultant for FrontAim Biomedicines Inc., Princeton, NJ*

The generation of bispecific molecules, in which two target-specific moieties are engineered into a single entity, offers an attractive approach to optimize biological activity which may improve clinical outcomes. Among various formats of bispecific molecules, the heterodimeric Fc currently is a favorable scaffold for the design of bispecific antibodies because of its structural similarity to the natural antibody. However, development of molecules based on this concept is challenged by the presence of potential homodimer contamination, reduced yield, and stability loss relative to the natural Fc. Here, we report the development of the MG-Ig platform by grafting a single chain fragment variable (scFv) onto the hinge region of a full-size immunoglobulin with a different specificity to produce a trivalent IgG-like bispecific antibody that retains natural homodimer Fc. Whereas the MG-Ig platform is evolved from the Dock-and-Lock (DNL) technology which exploits the interaction between the anchoring domain (AD) of A kinase anchor proteins and the dimerization and docking domain (DDD) of regulatory subunit of cAMP-dependent protein kinase, the main distinctions include 1) the AD-fused scFv monomer is judiciously designed to graft onto the DDD dimer inserted into the hinge region of IgG, forming a bispecific

antibody with three (1+2) binding arms and 2) all modular subunits are expressed in a single host cell and self-assemble to generate the bioactive conjugate *in situ*. To validate the method, bispecific T-cell engagers, designated 3scFv×hL0125C (CD3×Trop2) and 3scFv×hACD20C (CD3×CD20), which redirect T cells to Trop2 and CD20, respectively, have been produced with high yield and purity. Flow cytometry analysis demonstrated the bispecific binding of 3scFv×hL0125C to both CD3 on Jurkat and Trop2 on ME-180 with unaltered affinities. These T-cell redirecting bispecific antibodies mediated dose-dependent killing of target cancer cells when co-incubated with human PBMCs. Based on the 60-h viability assays using MTS, the IC_{50} of 3scFv×hL0125C was about 6 pM for MDA-MB-468, 13 pM for MDA-MB-231, 20 pM for BT-474, and 18 pM for HCT116. In 3D culture of HCT116 cells, the formation of multicellular tumor spheroids was impeded by 3scFv×hL0125C at 19.5 pM or higher, which is consistent with the cytotoxicity assays for tumor cells grown in monolayer. In addition, 3scFv×hL0125C was stable in human plasma for 7 days at 37°C, retaining
bispecific integrity and binding activity. These data are promising and merit further development of MG-Ig bispecific antibodies for preclinical and clinical studies.

Targeting solid cancers with a cancer-specific monoclonal antibody to surface expressed aberrant O-glycosylated proteins

Mikkel K.M. Aasted[1], Aaron C. Groen[2], John T. Keane[3], Sally Dabelsteen[4], Edwin Tan[2], Julia schnabel[2], Fang Liu[3], Hyeon-Gyu S. Lewis[3], Constantine Theodoropulos[2], Avery D. Posey[3], Hans H. Wandall[5]. *[1]ICMM, University of Copenhagen, Faculty of Health, Copenhagen, Denmark,[2]GO Therapeutics, Natick, MA,[3]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[4]University of Copenhagen, Copenhagen, Denmark,[5]Department of Cellular and Molecular Medicine, University of Copenhagen, Faculty of Health, Copenhagen, Denmark*

The lack of antibodies with sufficient cancer selectivity is currently limiting the treatment of solid tumors by immunotherapies. Most current immunotherapeutic targets are tumor-associated antigens also found in

healthy tissues. Such targets often do not display sufficient cancer selectivity to be used for potent antibody based immunotherapeutic treatments, such as chimeric antigen receptor (CAR) T cells. Many solid tumors, however, display aberrant glycosylation that results in the expression of tumor-associated carbohydrate antigens that are not present on healthy tissues. Targeting aberrantly glycosylated glycopeptide epitopes within existing or novel glycoprotein targets may provide the cancer selectivity needed for immunotherapy of solid tumours, but only a few such glycopeptide epitopes have been targeted. Here, we used *O*-glycoproteomics data from multiple cell lines to identify a glycopeptide epitope in CD44v6, a cancer-associated CD44 isoform, and through a glycopeptide immunization strategy developed a cancer-specific monoclonal antibody, 4C8. 4C8 selectively binds to Tn-glycosylated CD44v6 in a site-specific manner with low nanomolar affinity. 4C8 was shown to be highly cancer selective by immunohistochemistry of sections from multiple healthy and cancerous tissues. 4C8 CAR T cells demonstrated target-specific cytotoxicity *in vitro* and significant tumor regression, and increased survival *in vivo*. Importantly, 4C8 CAR T cells selectively killed target cells in a mixed organotypic skin cancer model without affecting healthy CD44v6+ keratinocytes, indicating tolerability and safety. Targeting aberrantly glycosylated glycopeptide epitopes may provide the cancer selectivity needed for solid tumour immunotherapy.

IGM-7354, an immunocytokine with IL-15 fused to an anti-PD-L1 IgM, induces NK and CD8+ T cell mediated cytotoxicity of PD-L1-positive tumor cells

Thierry D. Giffon[1], Melanie Desbois[2], Poonam Yakkundi[1], Susan Calhoun[1], Keerthana Sekar[1], Carolyn Denson[1], Tasnim Kothambawala[1], Alexander Pearson[1], Sivani Pandey[2], Deepal Pandya[3], Rodnie Rosete[1], Daniel Machado[1], Pat Raichlen[1], Dean Ng[3], Abhinav R. Jain[4], Roel Funke[5], Eric Humke[5], Paul R. Hinton[3], Beatrice Wang[1], Bruce A. Keyt[6], Maya F. Kotturi[2], Angus M. Sinclair[1]. *[1]Immuno Oncology, IGM Biosciences, Inc., Mountain View, CA,[2]Preclinical Sciences, IGM Biosciences, Inc., Mountain View, CA,[3]Antibody Discovery, IGM Biosciences, Inc., Mountain View, CA,[4]Process Development, IGM Biosciences, Inc., Mountain View,*

CA,[5]Clinical Sciences, IGM Biosciences, Inc., Mountain View, CA,[6]Research and Development, IGM Biosciences, Inc., Mountain View, CA

Immunostimulatory cytokines are a promising immunotherapy for the treatment of advanced malignancies, but generally have been associated with severe toxicities when administered systemically. The recent development of antibody-cytokine fusion proteins, or immunocytokines, aims to localize cytokine activity to the tumor microenvironment and thus improve their therapeutic index. We have developed IGM-7354, a high affinity, high avidity anti-PD-L1 pentameric IgM antibody with an IL-15Rα chain and IL-15 fused to the joining (J) chain. The IGM-7354 immunocytokine was designed to deliver IL-15-mediated stimulation of NK and CD8+ T cells to PD-L1-expressing tumors and antigen-presenting cells, to enhance anti-tumor immune responses. The multivalent binding of IGM-7354 to PD-L1 provided a stronger binding avidity for human PD-L1 than the monovalent binding of IL-15 to IL-15Rb as confirmed in kinetic binding assays. In vitro IGM-7354 induced the proliferation of a cytotoxic T cell line responsive to IL-15 stimulation and enhanced the proliferation of NK and CD8+ T cells from healthy donor human PBMCs. In cytotoxicity assays with human PBMC and PD-L1+ cancer cell lines, IGM-7354 enhanced cancer cell killing through NK and CD8+ T cell expansion and cytotoxic activity, evidenced by Ki67 and Granzyme B upregulation in these cell populations. Next, in vivo pharmacodynamic studies were performed in two humanized mouse models: non-tumor-bearing BRGSF-HIS mice engrafted with human CD34+ cells, and PD-L1+ MDA-MB-231 tumor-bearing MHC-/- NSG mice engrafted with human PBMCs. In the BRGSF model, IGM-7354 increased NK cell activation and Granzyme B expression as well as NK and CD8+ T cell proliferation. In the tumor-bearing mouse model, IGM-7354 dose-dependently increased NK and CD8+ T cell proliferation in blood and infiltration of lymphocytes into the tumor. This pharmacodynamic activity correlated with IGM-7354 anti-tumor activity in the MDA-MB-231 model. Lastly, IGM-7354 increased the proliferation of NK and CD8+ T cells in cynomolgus monkeys and particularly induced the expansion of effector memory CD8+ T cells in the periphery. In summary, IGM-7354 induces NK and CD8+ T cell proliferation in both in vitro and in vivo preclinical models, resulting in the killing of PD-L1+ tumor cells. The strong avidity of IGM-7354 for PD-L1

may enhance IL-15 delivery to tumors and antigen-presenting cells and thus provide a more favorable safety profile. A Phase 1 clinical trial is planned.

#5661

Pre-clinical development of a dopamine receptor 2, PD-1, and CD47 trispecific antibody for the treatment of solid tumors

Shugang Yao[1], Hiba Zahreddine[1], Dominic Hou[1], Elijus Undzys[2], Liying Gong[1], Richard Wargachuk[1], Xiaowei Wang[2], Alex Zhou[2], Lucy Lai[1], Luis A. Da Cruz[1], David Young[1]. *[1]KisoJi Biotechnology, Montreal, QC, Canada,[2]KisoJi Biotechnology, Toronto, ON, Canada*

Multispecific antibodies can have multiple independent mechanisms of action to achieve better clinical outcomes in cancers with high unmet medical needs. Here we describe the preclinical development of a trispecific antibody (KJ-101) targeting dopamine receptor 2 (DRD2), PD-1, and CD47.

DRD2 is a G protein-coupled receptor upregulated in many cancer types where it correlates with decreased patient survival. In pre-clinical studies, DRD2 is associated with cancer cell stemness and tumor growth. Clinical responses were achieved with small molecules targeting DRD2 and dopaminergic drugs for neuroendocrine tumors. In SCLC, representing 15% of lung cancers, 60-70% of patients showed high expression of DRD2. Checkpoint inhibition has shown some efficacy in lung cancer where PD-L1 inhibitors were approved as first-line therapy in SCLC . SCLC patients rapidly fail chemotherapy, develop resistance to treatment and metastases. These observations suggest a link between DRD2 expression and resistance to treatment, making this receptor an attractive target for multispecific antibody therapy.

The VHH components of KJ-101 (anti-DRD2, anti-PD-1 and anti-CD47) produce multiple effects to achieve a strong anti-tumor activity. The anti-DRD2 VHH induces intracellular signaling and suppresses tumor growth via ADCC. Treatment with anti-DRD2 antibody significantly suppressed tumor growth in the DRD2-positive NCI-H510A SCLC model in SCID mice. The anti-PD-1 VHH restores T cell function, and the anti-CD47 VHH recruits T cells without their generalized activation and blocks the interaction between CD47 and SIRPα. The KJ-101 anti-tumor efficacy was tested in several *in vivo* immuno-oncology xenograft models of human SCLC or TNBC, reconstituted with human PBMC or with CD34+ hemopoietic stem cells. KJ-101 treatment led to tumor regression in the TNBC model, blocked metastases formation in CD34+ humanized NCG mice bearing established NCI-H69 tumors, and blocked metastases formation and increased survival in tail vein metastatic models of SCLC. KJ-101 is produced at a high yield (6 g/L) in a manufacturing cell line. Conventional purification yields 99% purity and notably displays high stability under accelerated stability testing.

In conclusion, the trispecific KJ-101 antibody has strong *in vivo* anti-tumor activity mediated via multiple mechanisms of action, is easily expressed

and purified, and is very stable. Together, this data supports the clinical development of KJ-101 in advanced metastatic neuroendocrine cancer indications, including SCLC.

Early unwanted immunogenicity assessment of immuno oncology drugs

Sofie Pattyn, Martijn Vlaming, Alanah Pieters, Jana Schockaert.
ImmunXperts, a Q2 Solutions Company, Gosselies, Belgium

Bispecifics targeting multiple antigens or epitopes have been showing great promise for treatment of cancer. However, managing unwanted immunogenicity has become a challenge in the development cycle of these promising therapeutics as there is a trend towards higher unwanted immune responses compared with classical monoclonal antibodies. In vitro assays using human primary immune cells can be used to assess the risk of induction of a cytokine release storm or induction of unwanted immunogenicity. For the latter, T cell activation and proliferation assays can be used to assess and predict an unwanted immune response and avoid induction of anti-drug antibodies later on. In order to achieve reliable and consistent results, high quality primary immune cells should be used in combination with sensitive fit-for-purpose in vitro assays.

#5663

Discovery and characterization of anti-LILRB2 antibody SPX-104

Anthony Haight[1], Qian Chen[1], Ernesto Rodriguez[1], Martin Siekierzycki[1], Victoria Hall[1], Brandon Williams[1], Jun Shi[1], Dinh-Duc Nguyen[1], Robert Cai[1], Jichun Ma[1], Michael White[1], Jingdong Qin[1], Jadon Shen[1], Chuanke Zhao[2], Zhuona Rong[2], Lin Meng[2], Chengchao Shou[2]. *[1]Sparx Biopharmaceutical Corp, Mount Prospect, IL,[2]Peking University, Bejing, China*

T-cell based immunotherapies have produced durable remission in certain cancer patients, but owing at least partially to immunosuppression in the tumor microenvironment, response rates with current therapies remains challenging. Reversing the immunosuppression is a recognized pathway for enhancing the activity of existing IO therapies. LILRB2 (ILT4) is a key receptor for macrophage maturation and polarization and an emerging

therapeutic target in immuno-oncology. This research aims to produce anti-LILRB2 antibodies to redirect the polarization of myeloid cells, specifically macrophages, in the tumor microenvironment. The LILRB2 antibodies were generated through the mouse hybridoma method. After humanization and maturation, potent and selective IgG4 anti-LILRB2 antibodies were obtained. Binding affinities were evaluated through ELISA and 293T-LILRB2 cell flow cytometry binding assays which demonstrated sub-nanomolar binding affinity as well as effective blocking of the interaction of LILRB2 with its ligands HLA-G and HLA-A2 for multiple antibodies. SPX-104 was shown to redirect macrophage polarization in primary cultured human PBMC and human monocyte derived macrophage (HMDM) models. SPX-104 treatment induced hTNFa expression and suppressed hIL10 expression in the LPS stimulated PBMC model. In the HMDM model, SPX-104 effectively induced pro-inflammatory cytokine hTNFα expression in M-CSF. Furthermore, an autologous mixed lymphocyte reaction (auto-MLR) assay to evaluate T cell response showed dose-dependent increases in hIFNγ and hGM-CSF expression following SPX-104 treatment. In a CD34-humanized hLILRB2 transgenic mouse efficacy model, SPX-104 in combination with an immune checkpoint inhibitor, effectively inhibited tumor growth. These results confirm enhanced T cell activity following macrophage redirected polarization. The *in vitro* and *in vivo* evaluation, of SPX-104 relative to other anti-LILRB2 antibodies will be presented.

#5664

A novel immunotherapy for relapsed/refractory acute lymphoblastic leukemia (ALL)

Uksha Saini[1], Julie Hixon[2], Gisele Rodrigues[3], Christopher Foley[4], Leniher Castan Chibas[1], Ross Hamilton[1], Wenqing Li[3], Eric S. Schafer[5], Susan Rheingold[6], Michael Heffernan[1], Philip Breitfeld[1], Scott Durum[7], Atul Varadhachary[1]. *[1]Fannin Innovation Studio, Houston, TX,[2]NIH, Bethesda, MD,[3]NIH, Frederick, MD,[4]Bristol Myers Squibb, San Diego, CA,[5]5.Texas Children's Hospital & Baylor College of Medicine, Houston, TX,[6]Children's Hospital of Philadelphia, Philadelphia, PA,[7]National Institutes of Health, Frederick, MD*

Successful treatment of ALL has been a major feat of modern medicine. Overall, 5-year survival in pediatric ALL patients approaches 90%, but 10-15% of patients will relapse. In relapse, ALL is still challenging to cure with 5-year overall survival rates being at or just below 50% and traditional therapies in this space have been highly toxic. Novel immunotherapies such as blinatumomab, inotuzumab and CAR T-cells have improved outcomes and reduced toxicities but are not curated to some of the most vulnerable patients in relapse including T-cell ALL (for which there are no FDA approved immunotherapies) and Philadelphia-like B-ALL. Thus, unmet needs remain in relapsed/refractory (r/r) ALL. The IL-7 and TSLP axes play an important role in B-ALL and T-ALL including in chemotherapy resistance. CD127 (IL7RA) is an attractive target due to limited expression in normal tissues, as confirmed with a GLP.

We are developing 4A10, a novel monoclonal antibody against CD127 which labels ALL cells for degradation via antibody-dependent cell-mediated cytotoxicity (ADCC) and inhibiting IL-7 signaling in T-ALL. 4A10 has demonstrated robust in-vitro and in-vivo anti-cancer activity in pre-clinical PDX models. The antibody substantially reduces circulating tumor burden and organ infiltration, and prolongs overall survival in both naïve and chemotherapy resistant PDX models. Thus, 4A10 holds promise as a novel agent in patients with r/r ALL.

4A10 manufacturing has been successfully scaled up, with a stable master cell bank and good yields at the 200L scale. Our clinical formulation showed no refrigerated or frozen degradation over 3 months and minimal degradation or aggregation at 25°C. In their pre-IND guidance, FDA confirmed that our approach to physicochemical and biological characterization of 4A10 and our proposed analytical methods and tests appear acceptable for early clinical development.

4A10 was well-tolerated in rodent and non-human primate (NHP) toxicological studies with a No Observable Adverse Event Level (NOAEL) in NHPs well in excess of the expected therapeutic dose. Repeat dose NHP pharmacokinetic and pharmacodynamic studies support weekly dosing and do not indicate dose accumulation. Although pivotal GLP toxicology studies have yet to be completed, initial NHP studies do not provide any indications of concern.

We plan to initiate a Phase I/IIA study in 2023 to assess 4A10 in patients with r/r ALL. The Phase I portion of the study will determine the

recommended Phase II dose, and the Phase IIA expansion cohorts have been designed to provide clinical proof of concept. The clinical study will be conducted in partnership with the Therapeutic Advances in Childhood Leukemia and Lymphoma (TACL) consortium and key adult centers. If our Phase I/IIA is successful, we expect to follow with a single pivotal Phase II trial for marketing approval.

#5665

HX301 (ON1232580) a novel kinase inhibitor with potent activity against CSF1R and FLT3, shows strong anti-AML activity in defined preclinical models

Xiaoyu An[1], Henry Li[2], Linda Xue[3], Jinping Liu[4], Lingxin Xiong[1], Hang Ke[2], Cen Chen[2], Bing Gao[4], Jia Zheng[1], Zhengzheng Bao[4], Sheng Guo[3], Lei Zhang[2], Faming Zhang[2]. *[1]Crown Bioscience, Inc., Taicang, China,[2]Hanx Biopharmaceuticals, Ltd, Wuhan, China,[3]Crown Bioscience, Inc., Suzhou, China,[4]Crown Bioscience, Inc., Beijing, China*

Acute myeloid leukemia (AML) is an aggressive leukemia of myeloid lineage with different subtypes of varying treatments/outcomes and a global annual mortality ~150,000. The first-line treatment of AML is usually induction chemotherapy, followed by further chemo-/radiation therapies or stem cell transplant. Targeted therapy tailored for specific driver mutations could be alternative treatment options, *e.g*., new inhibitors targeting IDH mutations and FLT3-ITR CSF1R is a receptor tyrosine kinase (RTK) responsible for the growth, survival and polarization of certain myeloid lineages of cells including macrophages. It is also frequently expressed in certain AML patient populations , thus implicated in the pathogenesis, or a new possible drug target of AML.

To test this hypothesis, a novel kinase inhibitor, HX301 with strong anti-CSF1R activity (IC_{50} of ~0.7nM) as well as anti-FLT3 (IC_{50} of ~7nM), were assessed for anti-AML activity. First, an *in vitro* proliferation assay was performed using primary macrophages and a panel of AML cell lines, confirming that HX-301 has high potency in primary macrophage culture (IC_{50} of ~70nM) and also among cultures of a subsets of AML lines (*e.g*. IC50 < 1μM), such as MV4-11 (medium CSF1R expressing and FLT3-ITD), EOL1, MOL13, *etc*. Next, HX301 was pharmacologically modeled

using four preclinical models to test anti-leukemia activity *in vivo*, including subcutaneous xenograft of MV4-11 cells (CDX) and systemically engrafted PDX models AM8096 (high CSF1R expression but wild type FLT3), AM7577 (FLT3-ITD but little CSF1R expression) and AM5512 (wild-type FLT3 and little CSF1R expression).
Our data demonstrated that HX301 partially inhibited MV4-11 tumor growth as measured by tumor volume, consistent with the *in vitro* observation, possibly due to the inhibition of CSF1R or FLT3-ITD, or both. On the other hand, HX301 completely suppressed leukemogenesis of AM8096, likely due to the inhibition of CSF1R. This observation suggested that CSF1R is likely the driving mechanism for the leukemogenesis of this model; or in another word, for being a PDX, CSF1R likely drives pathogenesis in the original patient. HX301 also suppressed AM7577 growth, likely due to the suppression of FLT3-ITD activity since we previously reported FLT3-ITD being the driver mutation in this model which responded to AC220, a FLT3 TKi. Lastly, HX301 has little activity against AM5512.
All the data suggests that HX301 can potentially be explored for the treatment of AML, at least a subset of the patients with CSF1R and FLT3-ITD as leukemogenic drivers. Further preclinical/translational studies are being conducted in order to reveal predictive biomarkers, in addition to FLT3 mutation and CSF1R expression/mutations. We believe that HX301 could be a potential candidate for treating subset of AML, warranting further clinical investigation.

NAV-003, a full-length IgG1 bispecific antibody targeting a unique mesothelin epitope and CD3 to improve cytotoxicity against humoral immunosuppressed tumors

Luigi Grasso[1], Qun Jiang[2], Raffit Hassan[2], Nicholas C. Nicolaides[1], J. Bradford Kline[1]. *[1]Navrogen, Cheyney, PA,[2]National Cancer Institute, Bethesda, MD*

Mesothelin (MSLN) is a cell surface protein over-expressed in a number of cancer types. Several antibody- and cellular-based MSLN targeting agents have been tested in clinical trials where their therapeutic efficacy has been moderate at best. Previous studies using antibody and CAR-T based agents

have shown the importance of particular MSLN epitopes for optimal therapeutic response, while other studies have found certain MSLN-positive tumors can produce proteins that can bind to subsets of IgG1-type antibodies and suppress their immune-effector activities. In an attempt to develop a more optimized anti-MSLN targeting agent, we engineered a humanized divalent anti-MSLN/anti-CD3ε bispecific antibody called NAV-003 that targets a MSLN epitope proximal to the tumor cell surface and an anti-CD3ε single-chain antibody capable of effectively binding, activating and directing T-cells to the surface of MSLN-bound tumor cells. NAV-003 has shown significantly improved tumor cell killing against lines producing immunosuppressive proteins *in vitro and in vivo*. Moreover, NAV-003 demonstrated good tolerability and efficacy against patient-derived mesothelioma xenograft models co-engrafted with human peripheral blood mononuclear cells. Together these data support the potential for NAV-003 clinical development and human proof-of-concept studies in patients with MSLN-expressing cancers.

CYT-303 FLEX-NK^{TM} engager dose response efficacy mechanisms in HCC tumor model and safety in cynomolgus monkey toxicology studies support clinical evaluation in hepato-cellular carcinoma

Vishal Khairnar, Christine Waters, Solgalim Diaz, David De Franco, Jean Kadouche, Daniel Teper, Wei Li, Antonio Arulanandam. *Cytovia Therapeutics, Natick, MA*

BACKGROUND**:** CYT-303 is a multifunctional bispecific NK engager (NKE) targeting NK cell activating receptor NKp46 and tumor antigen Glypican-3 (GPC3) expressed in HCC (hepatocellular carcinoma). Cytovia's proprietary FLEX-NK^{TM} platform utilizes a novel FLEX-linker and human IgG1 back bone to allow for simultaneous binding to targeted cancer cells and NK cells. We evaluated CYT-303 dose response pharmacology efficacy mechanisms in HCC tumor models and conducted safety assessment studies in cynomolgus monkeys to support first in human clinical studies in HCC patients.

METHODS: CYT-303 dose response pharmacology mechanistic studies were conducted in NSG-hIL-15 mice bearing Hep3B tumors and flow cytometry was used to assess bold and tumor NK cells. A 4-week CYT-303

repeat dose GLP toxicology study in cynomolgus monkeys at 6, 20 and 60 mg/kg dose was conducted following weekly intravenous infusions followed by a 6-week recovery period. CYT-303 toxicokinetic and anti-drug antibody (ADA) assessments were conducted using validated immunoassays.
RESULTS: CYT-303 dose response in HCC tumor models showed increased tumor growth inhibition at the lower 2-3 mg/kg doses compared to higher 5-10 mg/kg doses consistent with the dose response previously reported in NK cell redirected cytotoxicity assays against HCC tumors. The increased anti- tumor efficacy observed at the lower doses were associated increased infiltration of PBNK's to the tumor and corresponding reductions in PBNK's in blood suggesting CYT-303 facilitates PBNK entry and retention in HCC tumors expressing GPC3 tumor antigen. CYT-303 safety assessment in the 4-week toxicology study in cynomolgous monkeys showed no treatment related toxicities or cytokine release and the NOAEL was determined to 60 mg/kg/week the highest dose administered in the study. No treatment related clinical signs, clinical pathology (hematology and clinical chemistry) and anatomic pathology (macroscopic, microscopic and organ weights) changes were observed. CYT-303 toxicokinetic analysis showed dose dependent increases in Cmax and AUC's and no evidence for CYT-303 accumulation. CYT-303 anti-drug antibodies in monkeys were minimal and only observed in one low dose animal (1 out of 22) which also showed reduced CYT-303 exposures. Based on these pharmacology and toxicology results a pharmacologically active dose (PAD) based approach together with pharmacokinetic modeling would be utilized to estimate first in human dosing in HCC patients.
CONCLUSIONS: CYT-303 efficacious doses identified in the HCC model together with safety in cynomolgus monkeys and planned human pharmacokinetic modeling studies support clinical evaluation of CYT-303 in first in human HCC clinical trials.

Using clinical utility index (CUI) to determine the optimal biological dose of a nonfucosylated anti-TIGIT antibody: A proposed alternative to maximum tolerated dose (MTD)
Gabriela Patilea-Vrana, John Harrold, Joseph A. Ware, Shaparak Lonning, Hun Lee, Lisa Brooks, Haley Neff-LaFord, William D. Hanley, Andres

Forero-Torres. *Seagen, Bothell, WA*

SEA-TGT is a human nonfucosylated monoclonal antibody (mAb) targeting the T cell immunoreceptor with immunoglobulin (Ig) and ITIM domains (TIGIT) protein. TIGIT is an immunoregulatory receptor expressed on activated and memory T cells, Tregs, and NK cells. TIGIT binding to CD155 and CD112 on tumor cells drives an inhibitory signal resulting in decreased T cell functionality. TIGIT targeting has been reported to release these inhibitory signals, drive Treg depletion, augment CD8+ T cell generation, and promote anti-tumor responses. SGNTGT-001 (NCT04254107) is a phase 1 clinical trial that evaluated the safety and tolerability of SEA-TGT as monotherapy in solid tumors and lymphomas at doses ranging from 0.01 to 6 mg/kg. Because an MTD was not identified in dose escalation, pharmacokinetic (PK) and pharmacodynamic (PD) endpoints were measured to assess biological activity and inform dose selection. The biological activity of SEA-TGT as monotherapy was compared across different dose levels using a clinical utility index (CUI), which mathematically integrated multiple clinically-meaningful PK and PD endpoints into a single readout. PD endpoints included NK and CD8+ T cell proliferation, maintenance of overall peripheral CD8+ T cell numbers, depletion of peripheral regulatory T cells, and peripheral target engagement. The PK endpoint was pharmacokinetic linearity. Surrogates of predicted tumor efficacy metrics included tumor target engagement and formation of the TIGIT:SEA-TGT:Fc receptor gamma (FcγRIIIa) trimer complexes in the tumor. An increase in the CUI score, representing an increase in biological activity, was observed during dose escalation, with an apparent plateau between the 0.3 and 6.0 mg/kg levels. Based on safety signals at 6 mg/kg and PK variability at lower doses, 1 and 3 mg/kg were of most interest for further evaluation. Both 1 and 3 mg/kg represented biologically active dose levels as they showed PK and PD activity that were within desirable ranges and had similarly high overall CUI scores relative to all doses evaluated. Dose selection for SEA-TGT was based on biological activity as assessed via PK/PD endpoints and integrated into a CUI model. Based on the totality of clinical data and the CUI results from monotherapy dose escalation from SGNTGT-001, the SEA-TGT dose of 1 mg/kg was determined to be the lowest biologically active dose with acceptable safety and tolerability.

MB201, a CD8+ T cell-selective anti-PD-L1 x IL-2 variant fusion protein, exhibits a potent anti-tumor efficacy without peripheral toxicity

Bom Park, Hyojoo Bang, Youngjun Jung, Sunjung Cho, Mi Seong Kim, Seok Chan Kang, Sungyoub Jung, Youngjin Park. *Mustbio, Suwon, Korea, Republic of*

Interleukin-2 (IL-2), a cytokine with pleiotropic immune effects, is the first approved cancer immunotherapy. However, the clinical application of IL-2 is limited by systemic activation of unexpected immune cells, leading to severe toxicities including vascular leakage syndrome (VLS). These adverse effects were mainly caused by the activation of Treg and endothelial cells bearing IL-2 receptor (IL-2R) αβγ. Recently, studies have mainly focused on the optimization of IL-2Rs binding affinity to selectively invigorate $CD8^+$ T cells in tumors, but the toxicity risk has yet to be solved. To overcome these limitations, we developed MB201, a novel anti-PD-L1 x IL-2v fusion protein, which selectively activates $CD8^+$ T cells by attenuating binding affinity to IL-2Rβγ with no binding to IL-2Rα. MB201 showed a strong binding affinity to PD-L1 (K_D value is 0.5 nM) and a weak binding affinity to IL-2Rβγ and IL-2Rαβγ (K_D value is 23.8 nM and 30.6 nM, respectively), indicating the preferential targeting $PD\text{-}L1^+$ tumor cells. MB201 exhibited a preferential activation of $CD8^+$ T cells than Treg cells, which showed remarkably reduced activation compared to rhIL-2 (more than 100-fold based on EC50). Consistently with the result of T cell activation, MB201 only increased the expansion of CD8+ T cells rather than Treg cells in CD3-stimulated PBMC. Indeed, MB201 induced negligible expansion of immune cells and lower pro-inflammatory cytokine release compared to the rhIL-2 in CD3-unstimulated PBMC, indicating the reduced peripheral toxicity risk. When administered to MC38 syngeneic mice, MB201 showed superior anti-tumor efficacy without both body weight reduction and lung weight gain compared to the avelumab monotherapy or combination therapy with rhIL-2. These preclinical observations support that MB201 has characteristics of a superb safety

profile and excellent anti-tumor efficacy, and it may offer an advantageous therapeutic strategy for the treatment of cancer.

Comparative mouse pharmacokinetics of matched- and unmatched-isotype anti-PD-L1 antibodies

Breanna Demestichas, Sam Kleeman, Matthew Chvasta, Tobias Janowitz.
Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Immune checkpoint inhibitors (ICI) are highly effective for a minority of patients with cancer. Pre-clinical research into mechanisms of ICI resistance is reliant upon anti-PD-1 or anti-PD-L1 antibody treatment in mouse models of cancer. Common approaches utilize commercially-available rat isotype anti-PD-L1 antibodies given by intraperitoneal (IP) injection at relatively high doses (5mg/kg every 2-3 days), often for extended periods. However, there has been limited investigation into the pharmacokinetics of these antibodies with single and repeat dosing, which could inform rational dose scheduling. Non-species-matched antibodies are known to induce accelerated anti-drug immune responses, compared to species-matched antibodies. As a result, we hypothesized that matched-isotype anti-PD-L1 (based on the grafting of atezolizumab variable regions onto a mouse IgG2a scaffold) and unmatched-isotype rat IgG2b anti-PD-L1 would be associated with distinct pharmacokinetics on single and repeated dosing. We first confirmed that both matched and unmatched antibodies have nanomolar-range affinity for mouse PD-L1 by surface plasmon resonance (0.85nM and 0.37nM, respectively). Using a single IP injection in 8-week-old male C57BL/6J mice followed by repeated tail-vein plasma sampling and an indirect anti-PD-L1 ELISA, we detected a trend towards prolonged median half-life for the matched (n=17 mice) versus unmatched (n=19) antibody (91.5 versus 39.0 hours). We detected a particularly wide range of half-life measurements for matched antibody experiments (19.8 to 337.7 hours), suggesting that antibody clearance can be highly heterogeneous. Using repeated IP injection (2 doses, 14 days apart), we identified markedly accelerated antibody clearance for both antibodies resulting in comparable antibody half-lives after dose 2 (11.9 versus 12.5 hours, n=13 and n=8 mice, respectively), suggestive of a time-dependent anti-drug adaptive immune response. These findings have significant implications for *in vivo* antibody

treatment experiments, demonstrating that repeat dosing is associated with rapid antibody clearance, irrespective of the antibody species. These data should be taken into consideration when planning longer-term antagonism of PD-1/PD-L1 signaling with antibodies in mice and strengthen the basis for short term window studies that examine the intratumoral immune biology. Furthermore, the high variability in antibody half-life suggests that antibody pharmacokinetics could confound ICI treatment response studies *in vivo*.

Characterization of AB598, a therapeutic anti-human CD39 antibody for the treatment of cancer

Amy E. Anderson, Angelo Kaplan, Urvi Vani, Enzo Stagnaro, Kaustubh Parashar, Julie Clor, Nigel P. C. Walker, Steve W. Young, Matthew J. Walters, Ester Fernandez-Salas, Christine E. Bowman, Lisa Seitz. *Arcus Biosciences Inc., Hayward, CA*

Background: CD39 catalyzes the conversion of extracellular adenosine triphosphate (ATP) into adenosine monophosphate (AMP), resulting in decreased levels of immunostimulatory ATP and increased levels of immunosuppressive adenosine in the tumor microenvironment (TME). By blocking CD39 in the TME, particularly in combination with immunogenic cell death (ICD)-inducing chemotherapies, local levels of ATP can increase, leading to myeloid cell activation and improved tumor control. AB598 potently binds and inhibits enzymatic activity of human and cynomolgus CD39 but not murine CD39. Human CD39 knock-in (hCD39KI) mice have been employed to determine anti-tumor efficacy of AB598 in animals with competent immune systems.
Methods: Binding affinity and enzymatic inhibition of AB598 were determined in primary human immune cells. ATP-mediated activation of monocyte-derived dendritic cells (moDCs) and macrophages were assayed *in vitro* with and without AB598. Whole blood and tissue-based receptor occupancy (RO) assays were developed using AB598-competitive and non-competitive anti-CD39 reagents. *In vitro* binding of AB598 was determined in samples from human and cynomolgus donors. CD39 protein expression, target engagement, and enzymatic inhibition were assessed in whole blood and tissue samples collected from AB598-dosed animals. CD39 expression

patterns in peripheral immune subsets were confirmed in samples from healthy human donors. CD39 enzymatic activity was evaluated in blood-derived cells and serum from healthy human donors and cancer patients. Results: AB598 binds to CD39-expressing monocytes, B cells, and other immune cell populations in human and cynomolgus whole blood with sub-nanomolar affinity. Following AB598 dosing in preclinical species, decreases in CD39 surface expression on peripheral immune cells were observed, consistent with other anti-CD39 therapeutic antibodies. Target engagement and enzymatic inhibition were evident in tissues collected from AB598-dosed animals. Treatment with AB598/chemotherapy combinations resulted in significant syngeneic tumor control in hCD39KI mouse models. Conclusion: When used in combination with an ICD-inducing chemotherapy agent, AB598 can promote anti-tumor immunity by activation of myeloid cells due to increased local ATP levels. Preclinical characterization of the pharmacodynamic effects of AB598 support our therapeutic rationale and demonstrate target engagement and inhibition both peripherally and intratumorally.

Anti-CCR8-based bispecific antibodies engineered to preferentially eliminate tumor-infiltrating regulatory T cells: leaving effectors unharmed

Tianhang Zhai[1], Shuang Dai[1], Weifeng Huang[1], Yuanhong Chen[1], Shaogang Peng[1], Shihui Zhou[1], Liandi Chen[2], Jijui Zhang[1], Chao Wang[2], Chao Wang[2], Zhiyuan Li[1], Andy Tsun[2]. *[1]Biotheus (Suzhou) Co., Ltd., Suzhou, China,[2]Biotheus Inc., Zhuhai, China*

Background: Regulatory T cells (Tregs) play a critical role in maintaining homeostasis and self-tolerance and can hamper anti-tumor immunity through multiple mechanisms. Therefore, the targeted depletion of tumor-infiltrating Tregs is sought to promote effective anti-tumor immunity while preserving peripheral homeostasis. CCR8 has been identified as a potential specific target for tumor-infiltrating Tregs. However, CCR8 is also expressed on memory T cell subpopulations and the consequences of their depletion are still unclear. In an attempt to rationally design highly-specific Treg-depleting agents, TIGIT and CTLA-4 were selected as binding targets for engineering CCR8-based IgG-like bispecifics for highly effective

depletion of CCR8/TIGIT or TIGIT/CTLA-4 double-positive Tregs that are enriched in tumors. Here, we detail our results for an anti-CCR8 x TIGIT bispecific as a best-in-class Treg-targeting agent.
Methods: Anti-CCR8/TIGIT bispecific antibody candidates were generated in a 1+1 format and screened using several anti-CCR8 and anti-TIGIT binding arms with a wide range of affinities. CCR8 and TIGIT single-positive cells and CCR8/TIGIT double-positive cells were generated to screen for bispecifics with preferential binding and killing activity towards double-positive cells over single-positive cells *in vitro*. An anti-CCR8/TIGIT surrogate antibody was generated and used to evaluate anti-tumor efficacy as a proof-of-concept study in human-CCR8 knock-in mice, inoculated with CT-26 tumor cells.
Results: An anti-CCR8/TIGIT bispecific antibody, named PM1024, was selected from several candidate pairs that satisfied our screening criteria. PM1024 showed strong binding to CCR8/TIGIT double-positive cells but minimal binding to CCR8 and TIGIT single-positive cells. As such, PM1024 induced strong ADCC activity towards double positive cells but much weaker activity towards CCR8 or TIGIT single positive cells. An anti-CCR8/TIGIT surrogate antibody demonstrated significant anti-tumor efficacy *in vivo*, with similar or better tumor growth inhibition compared to the corresponding monospecific agents.
Conclusion: We successfully generated an anti-CCR8/TIGIT bispecific antibody (PM1024) that preferentially eliminates CCR8/TIGIT double-positive cells over single-positive cells. PM1024 bears the attributes to selectively eliminate tumor-infiltrating Treg cells over CCR8 or TIGIT single-positive lymphocytes, such as effector T cells and NK cells. PM1024 may thus function as a safer, more specific, and highly effective tumor-infiltrating Treg-depleting agent.

#5675

Discovery and development of an asymmetric IgG-like bispecific antibody targeting EGFR and c-MET, engineered through H-H and H-L chain charge-based heterodimerization

Ping Wang[1], Weifeng Huang[2], Zhenting Zhao[1], Xiaoniu Miao[1], Shaogang Peng[2], Chao Wang[1], Yao Yan[1], Tiantian Dong[1], Andy Tsun[1], Yingda Xu[1], Xiaolin Liu[1], Luo Yi[1]. *[1]Biotheus Inc., Zhuhai, China,[2]Biotheus (Suzhou) Co., Ltd., Suzhou, China*

Background: Lung cancer remains the leading cause of cancer mortality and is the most commonly diagnosed cancer with an estimated 2.2 million cases per year. EGFR, a tyrosine kinase receptor, plays a central role in cellular proliferation, survival, differentiation, and migration. Gain-of-function somatic mutations of EGFR significantly drives disease progression. Small molecule tyrosine kinase inhibitors (TKIs), designed to inhibit EGFR signaling specific to these mutations (e.g., L858R and E19del etc.), have achieved excellent clinical outcomes. However, patients carrying TKI-insensitive mutations (e.g., E20ins) and/or those with disease progression after TKI treatment, by the upregulation of complementary signaling pathways (HGF/c-MET, etc.), remain an unmet medical need. Here, we report the discovery of a fully-human afucosylated anti-EGFR x cMET IgG-like bispecific antibody (PM1080).
Methods: PM1080 was generated by introducing unique mutations to the CH1-CL domains of each binding arm to promote correct HC-LC pairing. KIH mutations were also introduced to each CH3 domain to support HC-HC heterodimerization and generate an IgG-like bispecific with one arm binding to EGFR and the other to cMET. PM1080 was expressed via a four-chain expression system in CHO cells carrying a *fut8*$^{-/-}$ knockout to generate afucosylated molecules with enhanced ADCC activity.
Results: Through monovalent affinity measurements, PM1080 interacted with EGFR at single digit nanomolar affinity and at sub-nanomolar affinity to c-MET. PM1080 preferentially bound to EGFR/c-MET double-positive cells rather than EGFR single-positive cells. PM1080 blocked both EGF/EGFR and HGF/c-MET signals via physical blockade of the interaction between EGF/HGF to their corresponding receptors and induced EGFR/c-MET internalization and degradation from the cell surface. Through intricate engineering, PM1080 was expressed via a four-chain system and produced as an afucosylated antibody with significantly improved ADCC function. PM1080 induced potent anti-tumor efficacy against EGFR/c-MET-positive tumor cells as a single agent. Importantly, PM1080 induced anti-tumor activity regardless of EGFR mutations at the intracellular signaling domain, and thus may serve as a promising combinational agent to TKI therapies. As expected, synergistic anti-tumor activity was observed when PM1080 was combined with either 1st or 3rd generation TKIs in both *in vitro* and *in vivo* models.

Conclusion: PM1080, a bispecific antibody targeting EGFR & c-MET was discovered for cancer treatment. PM1080 displayed potent anti-tumor efficacy either as a single agent or in combination with EGFR TKIs. Preclinical PK and toxicity studies have been conducted to support future first-in-human studies.

#5676

SGN-BB228, a CD228-directed costimulatory antibody anticalin® bispecific provides potent and conditional 4-1BB costimulation to T cells *in vivo* and in an *in vitro* model of T cell exhaustion

Barrett Updegraff, Johannes Urban, James Mutschler, Gregory L. Szeto, Brian P. O'Connor, Shyra J. Gardai, Ryan A. Heiser. *Seagen, Bothell, WA*

Agonist antibodies targeting 4-1BB (CD137) effectively costimulate cytotoxic T cells and are active in preclinical models of cancer. However, the clinical development of these agents has been hampered by limited efficacy and/or poor tolerability at active doses. To overcome the efficacy and safety limitations of this approach, SGN-BB228, a first-in-class, investigational CD228 x 4-1BB costimulatory Antibody Anticalin® bispecific (Mabcalin^{TM}) was created. SGN-BB228 is designed to target CD228 (melanotransferrin), a GPI-anchored oncofetal membrane protein with limited normal tissue expression, but high prevalence and expression in melanoma, mesothelioma, lung cancer, and other tumor types. SGN-BB228 is designed to provide a potent costimulatory bridge between tumor-specific T cells and tumor cells, improving and limiting T cell-mediated cytotoxicity to tumors, potentially expanding the therapeutic window for 4-1BB agonism. Here we describe the anti-tumor activity and pharmacodynamic effects of SGN-BB228 in vivo using humanized mouse tumor models, and the in vitro costimulatory effect of SGN-BB228 in a tumor cell line-based model of functional T cell exhaustion. In vivo, SGN-BB228 improved the quality and magnitude of the cytotoxic T cell response within CD228-expressing tumors, augmenting anti-tumor immunity. In vitro, 4-1BB costimulation provided by SGN-BB228 elicited proliferation, and cytokine production from functionally exhausted human T cells when in culture with CD228-expressing tumor cell lines engineered to engage the T cell receptor. Functionally exhausted T cells in this system are a mixed population that share phenotypic markers and single cell transcriptional

signatures associated with either progenitor exhausted T cells (T_{PEX}) or terminally exhausted T cells (T_{EX}). Interestingly, in this system, anti-PD-1 (nivolumab) failed to reinvigorate functionally exhausted T cells despite high PD-L1 expression by tumor cells. The unique ability of 4-1BB costimulation provided by SGN-BB228 to improve T cell activity in this model suggests the potential to drive immunomodulation in circumstances where PD-1 blockade fails. Together these data highlight SGN-BB228, a first-in-class, investigational CD228 x 4-1BB costimulatory Antibody Anticalin® bispecific with potent and CD228-conditional 4-1BB costimulatory activity with therapeutic potential in multiple solid tumor types. These data support the first-in-human phase 1 clinical trial of SGN-BB228 in advanced melanoma and other solid tumors (NCT05571839), which is currently recruiting.

#5677

MB101, a novel PD-L1 x CD3 targeted bispecific antibody, exhibits potent tumor-killing efficacy with minimal off-tumor toxicity

Suna Kim, Hyojoo Bang, Yongjun Jung, Sunjung Cho, Youngsam Kim, Sang-hyun Park, Seok Chan Kang, Youngjin Park, Sungyoub Jung.
Mustbio, Suwon-si, Korea, Republic of

Bispecific antibody (bsAb) which targets tumor-associated antigens and simultaneously induces CD3-mediated T cell activation, is one of the promising therapeutic approaches for cancer treatment. However, despite numerous CD3-based bsAb have been developed, the clinical application faces pronounced hurdles, such as increased on-target off-tumor toxicity and cytokine release syndrome (CRS) by using high-affinity anti-CD3 moieties. Accordingly, there are still needs for the development of CD3-based bsAb with more favorable properties, which are tumor-specific targeting and potent tumor killing activity without excessive cytokine release. Thus, we developed MB101, a novel PD-L1 x CD3 bsAb with low affinity to CD3, which is uncoupled potent tumor cytotoxicity from severe cytokine release. MB101 showed a strong binding affinity to PD-L1 (K_D = 0.4 nM) but a weak binding affinity to CD3 (K_D = 1.0 μM), indicating preferentially targeting to PD-$L1^+$ tumor cells. MB101 showed an effective tumor cell killing activity with higher Emax compared to avelumab mono-

or combination treatment with CD3 mAb in PD-L1$^+$ MDA-MB-231 cells. T cell-mediated cytotoxicity stimulated by MB101 in co-culture with target cells was accompanied by lower secretion of pro-inflammatory cytokines than CD3 mAb and bsAb comparator with high-affinity anti-CD3 arm. Additionally, in the absence of target cells, MB101 treatment to PBMC induced a very low level of pro-inflammatory cytokines, suggesting the possibility of reduced CRS risk. Furthermore, we proved that T cell-mediated cytotoxicity by MB101 was increased in a PD-L1 expression-dependent manner of tumor cells, but not normal cells, indicating minimal on-target off-tumor toxicity. Consistently with *in vitro* results, MB101 effectively regressed tumor volume (TGI=83%) without induction of excessive cytokine release in human CD3 knock-in mouse model. In addition, MB101 showed superior tumor growth inhibition (TGI=70%) than that of avelumab (TGI=44%) in humanized mouse xenograft model. In summary, MB101 selectively triggers robust PD-L1-dependent tumor cytotoxicity while inducing very low cytokine release, suggesting that MB101 might be a promising therapeutic option as CD3-based bsAb for cancer treatment.

#5679

Tetra-specific antibody GNC-035: guidance and navigation control (GNC) molecule development for treatment of ROR1+ malignancies

Jahan Salar Khalili[1], Sa Xiao[2], Yi Zhu[1]. *[1]SystImmune Inc., Redmond, WA,[2]Sichuan Baili Pharmaceutical Co., Ltd., Chengdu, China*

Cancer-intrinsic immune escape mechanisms and immune cell suppression can progressively diminish the curative potential of currently available T cell-based therapies. Barriers to successful T cell checkpoint therapies may be addressed by redirection of T cells toward tumor antigens using T cell engagers that function independently of MHC presented T cell epitopes. Here we demonstrate that an octavalent, tetraspecific Guidance and Navigation Control (GNC) antibody, GNC-035, binds to ROR1, CD3, PD-L1, and 4-1BB and mediates redirected T cell cytolysis of human solid tumor and leukemia and lymphoma cell lines in a ROR1 specific manner. Experiments using GNC-035 to redirect T cell cytotoxicity toward ROR1+ cancer cell targets show the T cells in PBMC are highly functionalized by pre-exposure to GNC-035. This pre-exposure of PBMC to GNC-035 results

in greater tumor cell killing efficacy compared to concurrent exposure of tumor cells in the presence of T cell effectors. This result suggests that the systemic delivery of GNC-035 can condition the T cell compartment to increase the therapeutic impact of T cells migrating to solid tumors, with or without preexisting infiltrating T cells. This beneficial conditioning of T cells by pre-exposure to GNC-035 is not observed with pre-exposure to CD3xROR1 bi-specific T cell engager controls.
To evaluate the potential for GNC-035 to mediate cytokine release syndrome, the molecule is evaluated in soluble formats in the presence of PBMC and the ROR1+ A549 cancer cells, or HUVEC cells. Under these conditions, the cytolysis of A549 target cells is detectable after exposure to GNC-035 at 100 fM concentrations as well as the release of IFN-γ and certain other inflammatory cytokines at 24 or 48 hours post-treatment. However, consistent with Blinatumomab treatment, PBMC exposed to soluble GNC-035 for 24 or 48 hours on a monolayer of HUVEC cells, produced significantly greater amounts of IFN-γ and IL-6 at concentrations greater than 10 pM. These results indicate GNC-035 has a therapeutic window of activity that is ROR1 dependent, spanning cytolytic activity, and IFN-γ release without a production of IL-6 and which is wider than that indicated by Blinatumomab in PBMC.
Collectively, the GNC-035 represents a class of multi-specific and multi-modal immune cell engagers with potential to mediate ROR1+ cancer regression, overcome TCR-based immune escape and reverse T cell immune suppression in tumor microenvironment. The clinical phase I-b study of GNC-035 is under way in breast cancer and hematologic cancers and the available data exhibit strong signals of efficacy with acceptable tolerability.

#5680

Tetra-specific antibody GNC-039: guidance and navigation control (GNC) molecule development for treatment of EGFRvIII+ malignancies

Jahan Salar Khalili[1], Sa Xiao[2], Yi Zhu[1]. *[1]SystImmune Inc., Redmond, WA,[2]Sichuan Baili Pharmaceutical Co., Ltd., Chengdu, China*

One of the primary challenges in the targeting of the tumor specific antigen EGFRvIII is the expression of the antigen among tumor cells in cranial

glioblastoma tumors. The development of GNC-039 is based on the capability of this protein to redirect T cell cytolysis toward the tumor specific antigen EGFRvIII and guide T cells in the tumor microenvironment. Here we demonstrate that the tetraspecific Guidance and Navigation Control (GNC) antibody, GNC-039, binds to EGFRvIII, CD3, PD-L1, and 4-1BB and mediates T cell cytolysis of the human glioblastoma cancer cell line U87 expressing EGFRvIII in the in vitro tumor spheroid model.

When delivered intravenously, the biodistribution of GNC-039 is an important factor in the development of this intracranial tumor targeting biologic. To better understand the biodistribution of GNC-039, Orthotopic Patient Derived Xenograft (PDX) models of Glioma were utilized and vivo-tag680XL-labelled GNC-039 was evaluable by total flux in the Brain area. Multiple IV infusions of GNC-039 were carried out over the study period (29 Days). Groups received either GNC-039 (n=5), GNC-039 with engrafted PBMC (n=5), Temozolomide(n=5), or Vehicle (n=5). The PDX model was sensitive to Temozolomide, 0/5 mice residual tumor, medial overall survival (mOS) of 15 days. In the Vehicle treatment group, 5/5 mice had residual tumor, mOS was 26 days. Mice receiving GNC-039 without PBMC, could partially respond to the treatment, in this group 3/5 animal had residual brain tumors by end of study, but with only a mOS of 15 days. In these animals, the GNC-039 accumulated in the brain region to its maximal level by the third dose on Day 7 and stayed consistently at that level for the duration of the study period. However, in the mouse group with engraft PBMC, the level of GNC-039 in the brain region could exceed that of the drug when infused alone. Mice receiving GNC-039 with engrafted PBMC completely responded to treatment, 5/5 mice in the group had no residual brain tumor, and a mOS of 20 days. In the presence of the engrafted PBMC, the increased level of GNC-039 in the brain region was delayed compared with treatment in the absence of PBMC. As a point of comparison, the Day 7 levels from GNC-039 treatment alone were not reached until Day 15 in presence of PBMC. However, beyond this timepoint, the level of GNC-039 in the brain region was significantly increased due to the engrafted PBMC.

Collectively this data indicates the functionality of GNC-039 as a multi-specific T cell engager with the potential to target EGFRvIII+ cancer cell cytolysis in primary brain disease. The clinical phase I-b study of GNC-039

is under way and the available data exhibit strong signals of efficacy with acceptable tolerability.

Tetra-specific antibody GNC-038: guidance and navigation control (GNC) molecule development for treatment of CD19+ malignancies

Jahan Salar Khalili[1], Sa Xiao[2], Yi Zhu[1]. *[1]SystImmune Inc., Redmond, WA,[2]Sichuan Baili Pharmaceutical Co., Ltd., Chengdu, China*

B cell malignancies treated with CD19-directed immunotherapies can relapse, in some cases due to clonal selection for reduced CD19 antigen expression or enhancement of immunosuppressive phenotypes. Here we demonstrate that a Guidance and Navigation Control (GNC) tetra-specific antibody, GNC-038, binds to CD19, CD3, PD-L1, and 4-1BB and mediates cytolysis of human leukemia and lymphoma cells by T cells.
Redirected T cell cytolysis (RTCC) occurs in the presence of GNC-038 (Emfizatamab), resulting in the killing of CD19+ leukemia and lymphoma cell lines. The cytolytic functions induced by GNC-038 are similar to Blinatumomab in vitro, as indicated by T cell degranulation and production of IFN-gamma. Human T cells in PBMC exposed to GNC-038 in vitro proliferate in a dose-dependent fashion. Proliferation is further enhanced upon rechallenge with leukemic target cells. Proliferation of T cells from individuals with higher % PD-1+ and Effector polarized compartments is enhanced by GNC-038 compared to Blinatumomab. To evaluate the contribution of each binding domain of GNC-038 in mediating RTCC function, versions of GNC-038 were prepared, replacing each antigen binding domain with anti-FITC binding domains. Under assay conditions using PBMC for RTCC toward the CD19+ target cell line Nalm-6, the results demonstrate the contribution of each domain to the overall, anti-leukemic cytolytic activity.
To evaluate the potential for GNC-038 to mediate cytokine release syndrome, the molecule is evaluated in soluble, and plate bound formats in the presence of PBMC and CD19+ leukemic targets cells. In comparison to Blinatumomab, the production of cytokines is comparable, with some notable differences. PBMC exposed to soluble GNC-038 for 48 hours produced more IFN-γ, IL-2 and TNF-α, while showing no significant difference in production of IL-6. Based on these results, the primary

indicator of CRS, IL-6, does not suggest increased risk compared to Blinatumomab, while the type of T cell activity induced by GNC-038 in PBMC with leukemia cells is distinct.
Collectively, the GNC-038 represents a class of multi-specific and multi-modal immune cell engagers with potential to mediate CD19+ cancer killing, while also increasing the T cell compartment's therapeutic potential to respond to T cell redirection upon subsequent cycles of therapy. The clinical phase I-b study of GNC-038 is under way and the available data exhibit strong signals of efficacy with acceptable tolerability.

Endocrine-related Cancers and Nuclear Receptors: Molecular Biology, Biomarkers, and Genomics

#5277
Activation of TRPM8 channel suppresses prostate cancer growth and progression
Swapna Asuthkar. *University of Illinois College of Medicine (Peoria), Peoria, IL*

Prostate cancer (PC) is one of the most prevalent male malignancies and a leading cause of cancer-related deaths in men. While androgen-deprivation therapy is successful in the early stages of PC, tumor cells eventually become resistant to its effects. With a median survival of 18 months, the shift to androgen-independent prostate cancer (AIPC) has a poor prognosis. Mechanisms causing this change have yet to be explained, however mounting evidence implicates the loss of transient receptor potential melastatin 8 (TRPM8) as a significant contributor. The prostate epithelium normally expresses the ionotropic receptor TRPM8. Our team has recently shown that testosterone-induced activation of TRPM8 enhances Ca^{2+} absorption and causes apoptosis. This prompted us to propose that increased TRPM8 activity on the plasma membrane is cytotoxic to PC cells and that TRPM8 internalization is a crucial step in the pathogenesis of PC. We examined the amounts of TRPM8 mRNA in benign tumor and metastatic PC patient datasets. TRPM8 mRNA is initially elevated in the early stages of PC but is increasingly lost during the progression to AIPC. In addition,

male and female TRPM8$^{-/-}$ mice exhibited increased serum testosterone levels, heightened AR activity, and activation of cell cycle, invasion, and adhesion-related effectors. In both AR^{+} and AR^{-} xenograft models, our research reveals that TRPM8 possesses potent antitumor properties. Given this, investigating the *in vivo* role of TRPM8 in PC has the potential to significantly enhance patient outcomes by preventing progression to the androgen-independent state.

Fbxo22 regulates estrogen signaling and suppresses tamoxifen-induced endometrial cancer

Atsushi Goda[1], Satoru Meguro[2], Yoshikazu Johmura[3], Wenwen Wu[4], Ichiro Maeda[5], Yodo Sugishita[6], Nao Suzuki[7], Yasuo Miyoshi[8], Junki Koike[1], Makoto Nakanishi[2], Tomohiko Ohta[4]. *[1]Department of Pathology, St. Marianna University School of Medicine, Kawasaki, Japan,[2]Division of Cancer Cell Biology, Institute of Medical Science, University of Tokyo, Tokyo, Japan,[3]Department of Cancer and Senescence Biology, Cancer Research Institute, Kanazawa University, Kanazawa, Japan,[4]Department of Translational Oncology, St. Marianna University Graduate School of Medicine, Kawasaki, Japan,[5]Department of Pathology, Kitasato University School of Medicine, Sagamihara, Japan,[6]Department of Frontier Medicine, St. Marianna University Graduate School of Medicine, Kawasaki, Japan,[7]Department of Obstetrics and Gynecology, St. Marianna University School of Medicine, Kawasaki, Japan,[8]Division of Breast and Endocrine Surgery, Department of Surgery, Hyogo College of Medicine, Nishinomiya, Japan*

Introduction: Selective estrogen receptor modulators (SERMs), such as tamoxifen, function as agonists or antagonists for estrogen receptors (ERs) in a tissue-specific manner. We have discovered that Fbxo22, a F-box subunit of SCF ubiquitin ligase complex is critical for the functional alteration of SERM (Johmura, et al., *J Clin Invest*, 2018). SCF^{Fbxo22} ubiquitinates and degrades lysine demethylase 4B (KDM4B) complexed with SERM-bound ER, that triggers release of coactivator SRC from ER, thus mediating antagonistic function of SERM. Without Fbxo22, stabilized KDM4B mediates the interaction of SRC with AF1 domain of ER in the

presence of SERM, which only abrogates the interaction of SRC with AF2 domain, resulting in agonistic function. Accordingly, tamoxifen failed to prevent the growth of Fbxo22-depleted, ER-positive breast cancers in vitro and in vivo, and a low level of Fbxo22 in tumor tissues predicted a poorer outcome in ER-positive luminal breast cancers. Hence, Fbxo22 is a critical regulator of estrogen signaling in breast cancer. However, whether it is also important for other estrogen-associated cancers is unknown. To clarify the significance of Fbxo22 in other estrogen-associated cancers, we investigated its role in endometrial carcinogenesis.
Methods: Fbxo22 expression in 22, 30, 29 and 30 cases of normal human endometrium, endometrial hyperplasia (EH), atypical endometrial hyperplasia (AEH) and endometrial cancer (EC), respectively, were analyzed by immunohistochemistry. In addition, we established endometrial epithelium-specific conditional Fbxo22 knockout (Fbxo22-cKO) mice by developing *Fbxo22*-floxed mice and mated them with *Lactoferrin-iCre* mice, and analyzed spontaneous and tamoxifen-induced endometrial neoplasia. Endometrium of the mice in each phase of estrus cycle was also analyzed after PMSG/hCG-induced synchronization.
Results: Fbxo22 was expressed only in secretory phase and was absent in proliferative phase of the human endometrial epithelium, and the expression was inversely correlated with proliferative marker Ki-67. The Fbxo22 expression was down regulated as the endometrium progressed to malignancy (H-score: 124±69, 85±51 and 25±35 for EH, AEH and EC, respectively) (P<0.0001). In consistent with the expression in human menstrual cycle, Fbxo22 was also expressed in diestrus, but not in other phases in mice. Interestingly, the estrus cycle was prolonged in Fbxo22-cKO mice with paradoxical morphology of proliferative epithelial cells with secretory stromal cells. Finally, all five cKO mice developed EH or AEH in four months. The phenotype was accelerated by tamoxifen treatment, with all nine mice developed AEH or EC after one- or two-month tamoxifen treatment whereas wild type mice only developed EH.
Conclusion: Fbxo22 is an essential regulator of estrogen signaling in endometrium and prevents endometrial carcinogenesis including that induced by tamoxifen.

#5279

Molecular analysis of *AMBRA1* as a candidate tumor suppressor in sporadic parathyroid adenomas

Stephanie Chinwo[1], Justin Bellizzi[1], Jessica Costa-Guda[2], Andrew Arnold[3].
[1]Center for Molecular Oncology, UConn Health, Farmington, CT,[2]Center for Molecular Oncology and Dept of Reconstructive Services, UConn Health, Farmington, CT,[3]Center for Molecular Oncology and Division of Endocrinology and Metabolism, UConn Health, Farmington, CT

Primary hyperparathyroidism is a common endocrine disorder that is most often caused by a sporadic single-gland parathyroid adenoma. Currently, the only known and experimentally validated oncoprotein for parathyroid adenomas is cyclin D1. Overexpression of cyclin D1 has been reported in 20-40% of cases; about 8 percent of cases harbor a DNA rearrangement involving the cyclin D1 (*CCND1*) locus. Other molecular mechanisms underlying this cyclin D1 overexpression have yet to be identified. Here, we explored a potential parathyroid tumorigenic mechanism that could increase cyclin D1 stability through a defect in the AMBRA1 E3 ligase adaptor, a molecule responsible for its degradation. Evidence that *AMBRA1* may be a tumor suppressor gene includes: accumulation of cyclin D with hyperproliferation in AMBRA1-deficient cells, context-dependent growth of tumors in Ambra1-deficient mice, and the correlation between low levels of AMBRA1 and poor clinical outcomes in The Cancer Genome Atlas. Therefore, we examined *AMBRA1* for evidence of tumor suppressor-type inactivation in a cohort of 98 typical parathyroid adenomas. Tumor genomic DNA was subjected to PCR-amplification of all 18 coding exons of *AMBRA1*, followed by Sanger sequencing. Sequences were analyzed by comparison to the normal reference sequence (ENST00000683756.1), seeking to assess any observed intragenic or splice-site variants as potential or likely loss-of-function mutations. Thus far, with 97 percent of the coding region for this 1298-amino acid protein fully sequenced, we have identified an inactivating mutation in 1 of 98 tumors (1%): c.126G>A, resulting in an early stop codon p.Trp42. This mutation showed loss of heterozygosity and was confirmed to be somatic by sequencing of the patient's matched germline DNA. We also identified likely non-pathogenic variants in 5 tumors: missense variant c.3385G>T (p.Ala1129Ser), 3' UTR variants c.*576A>T and c.*491T>C and synonymous variants c.579C>T and c.2776C>T, each in a single tumor. 4 of 5 were found as germline variants

in the normal population and the one missense scored as benign by *in silico* criteria. To conclude, our observations suggest that *AMBRA1* may function as a classical tumor suppressor gene in sporadic parathyroid adenomas at very low frequency. Further study may include protein expression analysis of AMBRA1 to investigate influences on gene expression. To further elucidate the mechanisms behind cyclin D1 overexpression in parathyroid adenomas, other molecules that participate in its degradation should be explored as potential tumor suppressors.

O-GlcNAcylation of progesterone receptor promotes mammary tumorigenesis

Harmony Ivanna Saunders, Sean M. Holloran, Gloria Trinca, Chad Slawson, Christy Hagan. *University of Kansas Medical Center, Kansas City, KS*

The role of hormone receptors in breast cancer has been well established as a key contributor to breast cancer tumorigenesis. Estrogen receptor and progesterone receptors are present in nearly 70% of breast cancers. The role of estrogen receptor and estrogens in breast cancer has been extensively studied and targeted effectively through endocrine therapy, however the impact of progesterone and the progesterone receptor (PR) independent of estrogen is not well understood. We have previously demonstrated that PR promotes tumor growth and drives an immune suppressive environment, therefore understanding the biology of PR in breast cancer is critical. We have also demonstrated that PR attenuates type 1 interferon signaling via inhibition of STAT1 phosphorylation and increased degradation of STAT2. Post-translational modifications such as phosphorylation and SUMOylation can influence PR target gene promoter selectivity thereby altering its function. Our recent work indicates PR is modified by O-GlcNAc, a single N-acetyl-glucosamine sugar that cycles on and off and serine or threonine amino acids in nuclear, cytoplasmic and mitochondrial proteins. Levels of total O-GlcNAc staining are higher in breast cancer tissue compared to adjacent normal tissue. Active O-GlcNAcylation, as evidenced by immunohistochemistry staining of O-GlcNAc-transferase (OGT), is elevated in patients with PR+ tumors compared to PR-. Using T47D breast cancer cells (an ER/PR-positive tumor line), mass spectrometry analysis

revealed an O-GlcNAc site at S499 on PR. We then used a naturally occurring PR-negative variant of T47D cells to introduce stable expression of a mutant PR with serine to alanine substitution at the O-GlcNAc site (S499A), thereby blocking O-GlcNAc flux, in addition to wt PR as a control. RNA-Seq analysis of these cells following treatment with progesterone revealed several significant differential gene expression patterns, including rescue of PR dependent interferon signaling attenuation. T47D-mutant PR cell lines implanted into immune deficient mice had significantly decreased growth as compared to WT-PR control tumors. In syngeneic mice harboring PR-positive and PR-negative tumors, loss of O-GlcNAc flux and increased O-GlcNac levels increased tumor growth only when tumors were expressing PR, corroborating the influence of O-GlcNAc in immunodeficient mice. Together these findings indicate O-GlcNAcylation of PR is potentially a mechanism of PR driven breast cancer tumorigenesis and immune evasion.

Role of TMEM97/Sigma-2 receptor in prostate cancer

Xiangwei Fang[1], Yuanqin Zhang[1], Jiuhui Wang[1], Paul Cacioppo[1], Michael Crider[2], Daotai Nie[1]. *[1]Southern Illinois University School of Medicine, Springfield, IL,[2]Southern Illinois University Edwardsville, Edwardsville, IL*

Introduction: Prostate cancer is the most common cancer in men. About one in eight men will be diagnosed with prostate cancer in his lifetime, and one in forty-one men will die of it. Sigma 2 receptor (σ2R) has been implicated in carcinogenesis including prostate cancer. Its molecular identity remained elusive until 2017 that transmembrane protein 97 (TMEM97) was identified as the bona fide sigma 2 receptor. Past studies have shown that σ2R is highly expressed in various mammalian tumors and TMEM97 works as an oncogene in different cancers. In this study, we examined the expression of TMEM97/σ2 receptor in prostate cancer, evaluated its interaction with androgen receptor (AR), and determined its functions in tumor cell growth and progression.
Methods: The expression of TMEM97 at mRNA levels and its association with clinical parameters were queried in the TCGA database using cBioportal. Its expression pattern in prostate tumor tissues was examined by IHC using a commercially validated antibody. A correlation analysis of

TMEM97 with AR was conducted utilizing both PCTA and TCGA databases. To determine its roles in tumor proliferation, clonogenicity, and responses to hormone deprivation and chemo-therapy, TMEM97 expression was overexpressed and knocked down, and the subsequent effects were determined by cell proliferation MTS assay, colony formation assay with and without enzalutamide treatment. A xenograft model of nu/nu mice was used to assess the impact of TMEM97 overexpression on tumor formation and growth in vivo. The effects of TMEM97 overexpression and knockdown on AR transcriptional activity were examined.
Results: A significant elevation of TMEM97 mRNA levels, with a Z-Score above 2.0, was found in 5% of the prostate cancer patients and was associated with significantly reduced survival. TMEM97 protein was detected in prostate tumor tissues of all stages and grades. Its expression is highly correlated with the expression of AR in prostate cancer. Prostate cancer cells with TMEM97 overexpression showed growth advantage over the control cells both in normal culture conditions and also under treatment of enzalutamide. TMEM97 knockdown weakened growth, and sensitized castration resistant 22Rv1 toward enzalutamide, which is linked to the decrease of AR-V7. TMEM97 overexpression in LNCaP cells also significantly increased tumor formation and growth when xenografted into nu/nu mice. In LNCaP cells, TMEM97 overexpression elevated AR target genes expression. Parallelly, these genes were all significantly downregulated in TMEM97 knockdown cells. A compound with a high affinity to TMEM97 was found to induce apoptosis of prostate cancer cells with preferential degradation of AR-V7.
Conclusion: The observations suggest that TMEM97/sigma2 receptor plays a role in prostate tumor cell proliferation and the increased expression of TMEM97 can elevate AR activity and stimulate prostate tumor formation and growth.

Mitotane induces GDF-15 expression *in vitro* and *in vivo:* A potential therapy-induced mechanism of immune escape in adrenocortical carcinoma

Isabel Weigand[1], Tanja Anderlik[2], Jochen Schreiner[1], Hanna Remde[2], Otilia Kimpel[2], Laura-Sophie Landwehr[2], Eva Hoster[3], Florian Wedekink[4], Alexandra S. Triebig[1], Tanja Maier[1], Jörg Wischhusen[4], Martin Reincke[1],

Martin Fassnacht[2], Matthias Kroiss[1]. *[1]Department of Internal Medicine IV, University Hospital LMU Munich, Munich, Germany,[2]Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Hospital Wuerzburg, University of Wuerzburg, Wuerzburg, Germany,[3]Institute for Medical Informatics, Biometry and Epidemiology, Ludwig-Maximilians-University, Munich, Germany,[4]Experimental Tumor Immunology, Department of Obstetrics and Gynecology, University Hospital, University of Wuerzburg, Wuerzburg, Germany*

Context: Adrenocortical carcinoma (ACC) is a rare endocrine malignancy with poor prognosis and limited treatment options. The only approved therapy is mitotane, an adrenal toxicant, alone or in combination with cytotoxic chemotherapy. Response rate is only ~20%. Results of later line immune checkpoint inhibition (ICI) in ACC are disappointing, most likely due to an immunologically cold, immunosuppressive microenvironment. Among the factors induced in mitotane-treated ACC cell lines, we previously found growth/differentiation factor 15 (GDF-15), an anti-inflammatory cytokine physiologically expressed during pregnancy.
Aim: As GDF-15 is an emerging mediator of tumor immune escape, we investigated changes in GDF-15 secretion upon mitotane treatment in ACC *in vitro* and *in vivo,* and explored a potential correlation with response to therapy and survival.
Methods: Four different human ACC cell lines (NCI-H295R, CU-ACC1, CU-ACC2 and JIL-2266) were treated with mitotane. GDF-15 secretion and expression were determined by ELISA and immunoblot. GDF-15 levels in sera of 142 ACC patients (94 prior and 48 during mitotane) were analyzed by ELISA and correlated with survival from the time point of blood collection. GDF-15 serum levels were quantified in three responders and seven non-responders to ICI treatment.
Results: *In vitro*, 24h treatment with 25 µM mitotane-induced GDF-15 secretion and expression in all cell lines by up to one order of magnitude. In 32 patient samples, GDF-15 serum concentrations increased from 0.6±1 ng/l prior mitotane to 2.1 ± 2.7 ng/l after mitotane initiation, $p<0.0001$.Importantly, patients with low serum GDF-15 levels before and during mitotane treatment had a significantly longer overall survival compared to patients with higher GDF-15 serum levels. This association retained statistical significance after adjustment for the known prognostic

factors Ki67 and ENSAT tumour stage in the mitotane treated group (95% CI 1.15-.1.73, HR1.41, p=0.001). In an exploratory cohort of three responders and seven non-responders to ICI we found a trend for higher GDF-15 serum concentrations in the non-responders.
Conclusion: Mitotane induces GDF-15 both *in vivo* and *in vitro* and potentially contributes to the poor response rates to ICI in ACC.

#5283

Glucocorticoid receptor (GR) activity alters invasive lobular breast cancer (ILC) oncogenic properties

Ishrat Durdana[1], Candace Frerich[1], Muriel Laine[2], Smita Rindhe[1], Lynda Bennett[1], Robert Bachoo[1], Geoffrey Greene[2], Suzanne Conzen[1]. *[1]UT Southwestern Harold C. Simmons Comprehensive Cancer Center, Dallas, TX,[2]The University of Chicago, Chicago, IL*

Invasive breast cancer (BC) is commonly divided into two subtypes, invasive ductal carcinoma (IDC) and invasive lobular carcinoma (ILC). ILC makes up 10-15% of all BC cases. Expression of nuclear hormone receptors further define clinical histology and directs treatment; receptors include estrogen (ER), progesterone (PR), androgen (AR), and glucocorticoid receptors (GR). Tumor GR expression activation is associated with good prognosis in ER+ but poor prognosis in ER- BC. The majority of ILC tumors are ER+, and we have found that GR expression in primary ILC tumors correlates with improved overall survival. We hypothesized that GR activity in ILC may play a role in ILC's indolent natural history and could alter its metastatic tendency. We used two isogenic ILC cell lines, each with and without GR expression (MM134-GR+/GR- and SUM44PE-GR+/GR-) to study GR-mediated ILC associated phenotypes. Specifically, we describe GR's effect on proliferation *in vitro* and tumor formation in the *in vivo* MIND model. We also measured GR-mediated ILC adherence to major components of the extra cellular matrix (collagen I, collagen II, laminin, fibronectin, vitronectin, and tenascin). To recapitulate early metastasis, we examined ILC cell movement through a 10 uM microchannel device. We found that GR expression and activation in ILC cell lines cause decreased cell proliferation and decreased adherence to laminin. Preliminary experiments suggest that GR activation altered ILC cell's ability to enter and navigate through restrictive 10 uM microchannels. Given our

preliminary findings, we will investigate the effect of selective GR modulators (SGRMs) on ILC phenotypes and gene expression. We hypothesize that the gene expression changes following GR activation will be different in ILC compared to IDC. In addition, we are examining the genes required for survival of ILC cells on collagen using an *in vitro* CRISPR-Cas9 screen. *In vivo* experiments examining the association of GR expression with tumor growth *in vivo* are ongoing.

Recurrent Middle Eastern differentiated thyroid carcinoma has worse outcome than persistent disease

Sandeep K. Parvathareddy, Abdul K. Siraj, Padmanaban Annaiyappanaidu, Nabil Siraj, Saeeda O. Ahmed, Zeeshan Qadri, Saud Azam, Khawla S. Al-Kuraya. *King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia*

Background: Differentiated Thyroid Cancer (DTC) is the most common endocrine malignancy. Despite its excellent prognosis, recurrent and persistent disease remain major challenges after initial treatment. Although most studies have considered persistence and recurrent as a single entity, emerging studies to differentiate recurrent and persistent disease are controversial and study on recurrent and persistent DTC from Middle Eastern ethnicity is lacking.
Methods: We retrospectively analyzed 1822 patients who underwent surgery ± I131 treatment for DTC with a median age of 38.9 years and median follow-up of 90 months.
Results: We found a similar prevalence rate of persistent and recurrent disease (16.4% vs. 16.6%) in Middle Eastern DTC patients. Relative to patients with persistent disease, patients with recurrent disease were significantly older (median age 36.1 vs. 45.8 years; $p < 0.0001$), were more likely to have ATA high risk tumors ($p < 0.0001$) and had a higher rate of distant metastasis ($p < 0.0001$). However, structural disease had an almost similar frequency in both recurrent and persistent disease (72.2% vs 73.3%). On multivariant logistic regression analysis, both T status and N status are independent predictors for both recurrent and persistent disease. However, older age, extrathyroidal extension and the presence of distant metastasis were independent predictors of only recurrent disease. In

addition, patients with recurrent disease had significantly worse overall survival (OS; $p < 0.0001$) and cancer specific survival (CSS; $p < 0.0001$), which remained significant in multivariate Cox proportional hazard model (Hazard ratio = 2.72; 95% confidence interval = 1.20 - 7.01; $p = 0.0153$ for OS and Hazard ratio = 5.09; 95% confidence interval = 2.10 - 15.24; $p = 0.0001$ for CSS).
Conclusion: Although persistent and recurrent disease in Middle Eastern DTC have similar frequencies, recurrent disease had worse outcome compared to persistent disease. This has great potential clinical relevance to differentiate recurrene from persistence for therapeutic and follow-up approach for improving outcomes of DTC patients from Middle Eastern ethnicity.

#5285

Identification of therapeutic targets in poorly differentiated carcinoma through a multimodal molecular analysis

Vanessa Zambelli[1], Marta Fornaro[1], Giulia Orlando[2], Ida Rapa[3], Francesca Napoli[1], Susanna Cappia[1], Lorenzo Daniele[4], Simonetta Piana[5], Mauro Papotti[2], Marco Volante[1]. *[1]University of Turin, San Luigi Hospital, Turin, Italy,[2]University of Turin, Molinette Hospital, Turin, Italy,[3]San Luigi Hospital, Orbassano (TO), Italy,[4]Mauriziano Hospital, Turin, Italy,[5]Arcispedale Santa Maria Nuova Azienda USL- IRCCS, Reggio Emilia, Italy*

Poorly differentiated thyroid carcinoma (PDTC) represents a rare subtype of thyroid cancer with aggressive clinical course and peculiar clinical and pathological characteristics. Recent genetic studies highlighted the main molecular pathways involved in its pathogenesis but data are affected by heterogeneity of case selection and relatively limited sample size. Using a multimodal molecular approach, aim of this project was to implement the PDTC molecular characterization and to identify novel prognostic biomarkers and potential therapeutic targets. A total of 84 cases of PDTC classified according to the Turin proposal were selected from a multi-Institutional series. Fifty-nine samples underwent DNA, RNA and protein analyses. Mismatch repair (MMR) defects were tested using immunohistochemistry for MLH1, MSH2, MSH6 and PMS2. DNA and RNA analyses were performed by means of next generation sequencing

(NGS) using Oncomine Comprehensive assay V3. Due to the high failure rate in RNA analysis, gene fusion analysis was enriched by 25 additional samples. MMR protein loss was observed in 7/59 samples (11.9%). In NGS DNA analyses, 51/59 cases were adequate. The most prevalent mutations were in *NRAS* (13/51, 25%) and *TP53* (13/51, 25%), all mutually exclusive each other. *TERT* promoter (*TERTp*) mutations were detected in 11/51 of cases (21.6%). Other genes with a relevant prevalence were *PTEN* (15.7%), *NF1* (13.7%), *ATM* (13.7%), *NOTCH3* (11.8%) and *BAP1* (11.8%). Mean number of alterations was higher in *TP53*-mutated cases (5.8 mutations/case) than in *RAS*-mutated cases (2.8 mutations/case). *TP53*-mutated samples lacked *TERTp* co-mutations but were associated with mutations in *PTEN* and in genes related to MMR system and/or loss of MMR proteins. *PIK3CA* was the most prevalent co-mutated gene (three samples) in *RAS*-mutated cases. A third group (25 cases) lacked *RAS* or *TP53* mutations, had a low mean number of alterations (2.7 mutations/case) and was enriched for *TERTp* mutations (up to 32%). Copy number variations were not detected. Among the 43 cases adequate for NGS RNA analysis, gene fusions in *PAX8-PPARG* (one case) and *TBL1XR1-PIK3CA* (two cases) were detected. This latter fusion has never been reported in thyroid cancer, and was validated by fluorescence in situ hybridization (FISH). In conclusion, PDTC are genomically clustered into *RAS*-mutated tumors (with low mutational burden and co-mutations affecting genes involved in the same pathway), *TP53*-mutated cancers (with high mutational burden, absence of *TERTp* mutations and strong association with MMR defects) and a third “double negative” group enriched for *TERTp* mutations. Overall, targetable gene fusions have a prevalence of 7%. Moreover, 38% of overall cases harbor mutations in genes coding for tyrosine kinases potentially targetable and/or have defects in the MMR that claim a potential role for immunotherapy.

#5286

Matrix metalloproteinase 14 in associated with poor survival in adrenocortical carcinoma

Liudmila V. Popova[1], Elaine Mardis[2], Katherine Miller[3], Priya H. Dedhia[1].
[1]Department of Surgery, The Ohio State University Wexner Medical Ctr., Columbus, OH,[2]The Steve and Cindy Rasmussen Institute for Genomic Medicine, Natiowide Children's Hospital, Columbus, OH,[3]The Steve and

Cindy Rasmussen Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH

Adrenocortical carcinoma (ACC) is an aggressive malignancy of the adrenal cortex. Five-year survival in Stage IV disease is 6%. Surgical resection is the mainstay of treatment; however, most patients present with unresectable disease or experience tumor recurrence after surgery. No targeted therapies are available for treatment of ACC. Thus, there is a critical need to understand molecular mechanisms driving advanced ACC. Matrix metalloproteinases (MMPs) have been associated with worse prognosis in other human cancers. Although pan-inhibition had limited clinical success, recent studies suggest select inhibition may improve patient outcomes. Here, we use The Cancer Genome Atlas (TCGA) and single nuclei RNA sequencing data (snRNAseq) to evaluate the expression of MMPs in ACC. RNA sequencing data from 77 ACC patients in TCGA was downloaded from UCSC Treehouse Public Data Tumor Compendium v11. Using the Kaplan-Meier estimator, survival was compared between the highest and lowest quartile of RNA expression for each MMP in R v.4.1. For snRNAseq, normal adrenal and adrenal adenoma samples were collected from a patient diagnosed with adrenal hypercortisolism. Seven primary and metastatic ACC samples were collected from patients diagnosed with ACC at time of surgical resection and included one primary tumor-metastasis pair. Single nuclei were isolated from frozen samples. Sequencing libraries were generated and sequenced on the Illumina NovaSeq 6000. Data were preprocessed using the 10x Genomics CellRanger software suite. Downstream analysis was performed using Seurat v.4 for R. ACC specimens in TCGA expressed all 24 MMPs with MMP14 demonstrating the highest expression. MMP14 expression was associated with significantly worse survival with a hazard ratio of 3.6 (95% CI 1.2 - 11.1). In addition, increased MMP14 expression was associated with higher AJCC tumor stage ($p < 0.05$). snRNAseq analysis of our ACC primary and metastatic samples identified 7 adrenal cortex clusters and one cluster each - fibroblasts, macrophages, infiltrating lymphocytes, endothelial, and adrenal medulla cells. Two cell clusters were present in primary and metastatic samples but not benign adrenal samples and were characterized by high KI67 expression or high ribosomal content. MMP14 expression was significantly higher in metastatic versus primary tumors in 2

adrenal cortex clusters with 3.6 and 2 fold increased expression, respectively ($p < 0.05$); and one of these clusters was defined by a 15-fold increase in expression of ZNRF3, which is involved in activation of the Wnt pathway. These data suggest that MMP14 expression is associated with worse survival and may be associated with metastatic progression. Further studies are needed to confirm whether simultaneous targeting of Wnt pathway and MMP14 may result in decreased metastatic progression.

Is testosterone the male sex hormone responsible for increased male mortality in melanoma? *In-vitro* studies based on human melanoma (BLM) cell model

Pandurangan Ramaraj. *Biochemistry, A.T. Still Univ. - Missouri Campus, Kirksville, MO*

Clinical studies showed that menstruating females were better protected in melanoma than post-menopausal women and men of any age. But, these studies did not correlate with the steroid status of females. Our in-vitro study with progesterone (P), a female sex hormone showed significant inhibition of human melanoma cell growth. A literature survey showed that progesterone levels ranged between 1000-1500 ng/dl in menstruating females compared to post-menopausal women (20-100 ng/dl) and men (27-90 ng/dl), suggesting increased progesterone levels could offer protection to the menstruating females. Moreover, Elisarray showed that progesterone action was mediated by specific suppression of proinflammatory cytokine IL-8. So, it was proposed that a low level of progesterone in males leading to non-suppression of IL-8 in melanoma, could be responsible for increased melanoma cell growth and male mortality. This hypothesis prompted us to check the effect of male sex hormones androstenedione (AD) and testosterone (T) on melanoma cell growth and IL-8 secretion. Both AD and T decreased IL-8 secretion along with a decrease in cell growth. However, when progesterone was added along with androgens, there was a significant decrease in cell growth and in IL-8 secretion. This raised the question of why male mortality was high when androgens also decreased cell growth and IL-8 secretion. In order to address this question, it was decided to induce endogenous IL-8 in melanoma cells by pre-incubating with endothelin (50ng/ml) and then add steroids. AD and P individually

decreased IL-8 secretion and in combination significantly decreased IL-8 secretion and cell growth even in endothelin pretreated cells when compared to their respective control cells. But, T was not able to suppress endogenous IL-8 induced by endothelin and in fact, cell growth also was slightly increased compared to straight T-treated cells.
Conclusion: So, in males 2 reasons 1) a deficiency of progesterone and 2) inefficiency of T to suppress endogenous IL-8 could possibly result in increased IL-8 levels. This increased IL-8 level in males could lead to increased cell growth and metastasis in melanoma (IL-8 had already been shown to stimulate melanoma cell growth and metastasis by us and others) leading to death. So, a situation arising out of male reproductive endocrine physiology could probably be responsible for increased male mortality in melanoma.

Single-cell multiomics reveal divergent transcriptional and epigenetic cell states in breast cancer
Aysegul Ors[1], Hisham Mohammed[1], Aaron R. Doe[1], Syber Haverlack[1], Mithila Handu[1], Ryan Mulqueen[2]. *[1]Knight Cancer Institute / CEDAR, Oregon Health & Science University, Portland, OR,[2]MD Anderson Cancer Center, University of Texas, Houston, TX*

Over the recent years, single-cell sequencing studies have been used to better describe the highly heterogeneous nature of breast cancers on transcriptional and genetic levels. It is also known that breast cancers are highly driven by estrogen receptor alpha (ER), a transcription factor that's important for mammary tissue homeostasis. However, little is known about how estrogen signaling heterogeneity affects cancer progression and response to anti-estrogen therapy at a single-cell level. Leveraging single-omic and multi-omic single-cell sequencing technologies, we tracked estrogen response in breast cancer cell and organoid models. We developed TITAN, a topic-modeling based analysis tool to reveal signaling gradients in single-cell RNA-seq data. With this approach we showed that distinct cells prioritize distinct gene groups in response to estrogen. We defined two of these gene networks to be driven by either ER or FOXM1. These same networks exist not only in all the models used in the study but also in breast cancer patient datasets. FOXM1 is activated in estrogen treated cells and

the FOXM1 driven gene signature correlates with more aggressive types of disease. Our combined scRNA and scATAC-seq experiments also highlighted distinct chromatin accessibility states associated with either cell group. Using scNMT-seq in patient samples we were able to describe DNA methylation and chromatin accessibility influence on hormone signaling patterns at the single-cell level. Together, our results provide insights into defining transcriptional and epigenetic cell states in ER positive breast cancer.

Proteomic profile of breast carcinomas with unbalanced levels of progesterone receptor isoforms

Andres M. Elia[1], Jana Sanchez[2], Rui Vitorino[3], Leo Saldain[1], Paula Martinez Vazquez[4], Javier Burruchaga[4], Eunice Spengler[4], Javier Muñoz[2], Paola Rojas[1], Luisa Helguero[3], Claudia Lanari[1]. *[1]IBYME-CONICET (Institute of Biology and Experimental Medicine), Buenos Aires, Argentina,[2]Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain,[3]Institute of Biomedicine (IBIMED), University of Aveiro, Aviero, Portugal,[4]Hospital de Agudos "Magdalena V de Martínez", Gral Pacheco, Argentina*

Preclinical studies indicate that progesterone receptors (PR) play a relevant role in breast carcinogenesis. Even more, a misbalanced expression of PR isoforms A (PRA) and B (PRB) differentially affect breast cancer progression and only tumors with higher levels of PRA than PRB (PRA-H) respond to an antiprogestin treatment. There are controversial results regarding the prognosis of PRA-H luminal tumors compared with those with the opposite ratio (PRB-H tumors) highlighting the necessity to further understand the role of PR isoforms in tumor progression and to develop novel methods to discriminate these tumors without performing western blot studies. Along this line we have previously studied the transcriptome of PRA-H or PRB-H breast cancer samples, thus our aim is to expand these results and compare the proteome profile of PRA-H and PRB-H samples obtained from postmenopausal breast cancer patients. Nuclear (Nuc) and cytosolic (Cyt) protein fractions were obtained from 18 breast cancer samples classified as PRA-H or PRB-H and they were studied by LC-MS/MS (UltiMate 3000 LC system - Q Exactive HF-X mass spectrometer -

Thermo). We observed 289 differentially deregulated proteins in Cyt (164 down and 125 up) and 301 in Nuc extracts (131 down and 170 up; logFC > 1, pval < 0.05). Gene set enrichment analysis of the Nuc fractions showed biological processes related to Cell junction organization (pval = 8,87e-05), Collagen formation (pval = 0,0005), and Cell-Cell communication processes (pval = 0,0035) in PRB-H tumors; while in PRA-H tumors, pathways related to Innate Immune System (pval = 8,8e-05), Class I MHC mediated antigen processing & presentation (pval = 8e-05) and Stabilization of p53 (pval = 0,0051) processes were enriched. Similar trends were observed in Cyt fractions. Individual candidates that were overrepresented in both fractions in PRB-H tumors are BAG3 and GH3, related to cell proliferation, and VWF, related to the activation of the Akt pathway. Overrepresented proteins in both fractions of PRA-H tumors are BST2, IFT27 related to invasion, and MIF associated with poor prognosis. As we were interested in looking for differential expressed proteins that could be tested in plasma samples to discriminate both tumor types, using the Vertebrate Secretome Database we focused on those that might be secreted. Noteworthy is CBP1 which was overrepresented in the PRB-H tumors and this was in agreement with the RNA-Seq data and with results obtained using preclinical models, repurposing this protein as one candidate of concern in the search for biomarkers. Other secretory proteins of interest are SFRP2 and SERPIND1, both highly expressed in PRA-H Cyt fractions. In conclusion, this study underscores the biological differences between PRA-H and PRB-H breast carcinomas and provides candidates that deserve to be tested as surrogate markers in plasma to discriminate patients that may benefit from an antiprogestin treatment.

#5292

Characterization of androgen receptor properties and interactome in mediating transcriptional condensates in prostate cancer

Nicholas C. Pinette, Shabnam Massah, Sofia Kochkina, Fan Zhang, Maitree Biswas, Joseph Lee, Jörg Gsponer, Nada Lallous. *Vancouver Prostate Center, Vancouver, BC, Canada*

In The United States of America 1 in 8 men will develop prostate cancer (PCa) in their lifetime. The assembly of phase-separated condensates containing players of the transcriptional machinery such as transcription

factors, coactivators (e.g. MED1), and RNA polymerase II enhances the transcription of key oncogenes in various cancer including PCa. Many proteins undergoing phase-separation possess intrinsically disordered regions (IDR) that mediate multivalent intra- and inter-molecular interactions, essential for condensate formation. We recently demonstrated that full-length AR, the main oncogenic driver in PCa, is more prone to form nuclear transcriptional condensates upon androgen stimulation in PCa models than in benign epithelial prostate models. In this study, we investigated the effects of mutating or truncating key residues or regions involved in AR transcriptional activity on its ability to form nuclear condensates in LNCaP cells as visualized by confocal microscopy. We also used various bioinformatics tools to predict additional AR residues and sequences with high propensity for phase-separation. We thus made various truncations and mutations and evaluated their ability to form condensates in LNCaP cells. We also tested the effect MED1 phosphorylation and treatment with various inhibitors targeting different domains of the AR on the ability of full-length protein to form droplets in vitro. We hope by better understanding what drive AR condensates formation in PCa, to elucidate this new mechanism of transcriptional regulation and to identify new therapeutic avenues for patients with advanced forms of the disease.

Effect of mTOR activity in peripheral blood mononuclear cells with metformin in high-risk prostate cancer patients receiving external beam radiotherapy and androgen deprivation therapy

Febin Antony[1], Anuraag Shrivastav[2], Arbind Dubey[1], Nawaid Usmani[3], Aldrich Ong[1], Rashmi Koul[1], Harvey Quon[4], Gokulan Sivananthan[1], William Hunter[1], Don Yee[5], Lindsay Rowe[5], Brita Danielson[5], Andrew Plesniarski[6], Ruey-Chyi Su[6], Julian O. Kim[1]. *[1]Radiation Oncology, Cancer Care Manitoba, Winnipeg, MB, Canada,[2]Biology, Cancer Care Manitoba Research Institute, Winnipeg, MB, Canada,[3]Radiation Oncology, University of Alberta, Edmonton, AB, Canada,[4]Radiation Oncology, Tom Baker*

Cancer Center, Calgary, AB, Canada,[5]Radiation Oncology, Cross Cancer Institute, Edmonton, AB, Canada,[6]Medical Microbiology & Infectious Diseases, JC Wilt Infectious Diseases Research Centre, Winnipeg, MB, Canada

Introduction: There is considerable interest in the antineoplastic properties of metformin for prostate cancer treatment, however, the underlying mechanism of action of metformin in this setting is poorly understood. It is suspected that metformin's antineoplastic activity is related to inhibition of mTOR (mammalian target of rapamycin), which ultimately inhibits cell proliferation. In this pilot study, we assessed the mTOR activity of peripheral blood mononuclear cells (PBMCs) from high-risk Prostate cancer (PCa) patients treated with androgen deprivation therapy (ADT) and external beam radiotherapy (EBRT) plus metformin versus placebo. We hypothesized decreased mTOR expression in PBMCs from patients receiving metformin versus placebo.
Methods: Normoglycemic adult males with high-risk PCa receiving ADT & EBRT were randomized to metformin 500 mg 3 times daily or placebo. Peripheral blood samples were collected from participants ≥ 6 months after starting study drug, buffy coats were extracted, and PBMCs were isolated ≤2 hours after specimen collection using ficoll-hypaque density gradient method. The mTOR expression was assessed by phosphorylation of serine 2448 (pmTOR; S2448). Activity of mTOR was measured in both unstimulated or stimulated (using CD3/CD28 antibodies) CD4+ and CD8+ T cells.
Results: Samples from 15 patients were analyzed (11 placebo & 4 metformin). We observed lower expression of pmTOR in PBMCs in patients receiving metformin compared to placebo indicating metformin demonstrated inhibition of mTOR activity in PBMCs. A general trend of mTOR inhibition was observed in the metformin group across the cell population and conditions (unstimulated vs. stimulated T cell populations). However, the most pronounced difference was observed in unstimulated CD4+ cells, which is of interest since they represent the closest physiological state to the study participants.
Conclusion: In this pilot study, we observed mTOR inhibition in the PBMCs of PCa patients treated with metformin. Further assessment of

mTOR activity amongst PCa patients receiving metformin is warranted in order to confirm these findings.

Bi-steric mTORC1 inhibitors are superior to rapamycin and induce apoptotic cell death in tumor models with hyperactivated mTORC1

Heng Du[1], Yu Chi Yang[2], Heng-Jia Liu[1], Min Yuan[3], John Asara[3], Kwok-Kin Wong[4], Mallika Singh[5], David Kwiatkowski[1]. *[1]Brigham and Women's Hospital, Boston, MA,[2]Revolution Medicines Inc., Redwood, CA,[3]Beth Israel Deaconess Medical Center, Boston, MA,[4]New York University Langone Medical Center, New York, NY,[5]Revolution Medicines Inc, Redwood, CA*

The PI3K-mTOR pathway is one of the most commonly dysregulated pathways in human tumors. Rapalogs have been used extensively in human clinical trials but exhibit modest clinical benefit for the most part, possibly due to their lack of effect on 4E-BP1, a key target downstream of mTORC1. ATP-competitive mTOR inhibitors can fully inhibit mTORC1 but are poorly tolerated possibly due to their inhibition of mTORC2. A new class of selective mTORC1 inhibitors has been developed and termed ‘bi-steric’, which comprise a rapamycin-like core moiety covalently linked to an mTOR active-site inhibitor. We report that bi-steric mTORC1-selective inhibitors (RMC-4627 and RMC-6272) have greater activity than rapalogs for tumors with mTORC1 hyperactivation. RMC-4627 and RMC-6272 showed more effective growth inhibition in multiple tumor cell lines with mTORC1 dysfunction compared to rapamycin. Both RMC-4627 and RMC-6272 at ~1 nM showed near complete inhibition of p4E-BP1$^{T37/46}$, which was not seen with rapamycin treatment. Rapamycin and both bi-steric compounds markedly reduced kidney tumor burden and human bladder cancer PDX tumor size after four weeks of treatment. Tumor regrowth assessed after two-month treatment cessation was significantly reduced in the RMC-6272 group as compared to the rapamycin group. Finally, TUNEL staining showed RMC-6272 treatment led to a greater induction of apoptosis in kidney tumor cells and human bladder cancer PDX tumors relative to rapamycin after a single dose of each compound. This is the first time that clear evidence for cell death after mTORC1 inhibition has been seen. Integrative multi-omic analysis reveals differential global rewiring

induced by RMC-6272 in comparison to rapamycin. Genes involved in cell cycle transition were downregulated by RMC-6272 vs. rapamycin. Proteins downregulated by RMC-6272 treatment relative to rapamycin were enriched for translation and ribosome-related proteins, consistent with effects of non-phosphorylated 4E-BP1 on synthesis of those proteins. Multiple purine metabolites were decreased to a greater extent in RMC-6272 treated cells as compared to rapamycin treatment, including deoxyadenosine, AICAR, AMP, IMP, and GMP. Notably, there was no significant change in R5P, suggesting that downregulation of the purine de novo synthesis pathway was the cause of these changes. Strong tumor cell apoptosis was induced by the suppression of de novo purine synthesis through mTORC1-PRPS1 axis. PRPS1, the rate-limit enzyme involving in purine synthesis was regulated by mTORC1 activity. In summary, RMC-4627 and RMC-6272 demonstrate improved *in vitro* and *in vivo* inhibition of mTORC1 in comparison to rapamycin, and induced more cell death in preclinical models, indicating the potential of bi-steric mTORC1-selective inhibitors as a novel therapeutic strategy to treat tumors with mTORC1 dysregulation.

PI3K inhibition sensitize cancer cells to tumor treating fields (TTFields)

Anat Klein-Goldberg, Tali Voloshin, Efrat Zemer-Tov, Rom Paz, Lilach Koren, Kerem Wainer-Katsir, Alexandra Volodin, Bella Koltun, Boris Brant, Yiftah Barsheshet, Tal Kan, Cfir David, Tharwat Haj Khalil, Adi Haber, Moshe Giladi, Uri Weinberg, Yoram Palti. *Novocure Ltd, Haifa, Israel*

Introduction: Tumor Treating Fields (TTFields) are electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression, ultimately leading to cell death. TTFields therapy is approved for treatment of adult patients with glioblastoma (GBM) or unresectable pleural mesothelioma. Clinical trials are underway in other solid tumors, including ovarian cancer and non-small cell lung carcinoma (NSCLC). The objective of this study is to identify possible mechanisms involved in reduced sensitivity of cancer cell to TTFields, and explore strategies to circumvent them.

Methods: Ovarian cancer A2780, GBM U-87 MG, and NSCLC H1299 cells with reduced sensitivity to TTFields were generated by continuous long-term application of TTFields. Luminex multiplex assay was employed to examine changes in signaling pathways in these cells, and specific pathway markers were validated by Western blot. *In vivo* validation was performed by immunohistochemistry of ovarian cancer, hepatocellular carcinoma, and NSCLC tumor sections from animals treated with TTFields. Next, TTFields concomitant with alpelisib, an isoform specific PI3K inhibitor, was evaluated both *in vitro* and in an *in-vivo* model of ovarian cancer.
Results: TTFields inflicted a continuous cytotoxic effect on the different cancer cells albeit sensitivity to treatment was reduced following prolonged duration of application. Luminex analysis revealed activation of the PI3K/AKT signaling pathway in treated cells, and kinetics experiments showed that amplitude of AKT signaling increased over time, with significant increases in phosphorylation levels of AKT and focal adhesion kinase (FAK). AKT phosphorylation was also demonstrated in tumor sections of animals treated with TTFields. Experiments performed with concomitant alpelisib sensitized the cells to TTFields and enhanced cytotoxicity *in vitro* and treatment efficacy *in vivo*.
Conclusions: The current study demonstrates that the PI3K/AKT signaling pathway is involved in reduced cancer cell sensitivity to TTFields, and that PI3K inhibition can further sensitize cancer cells to TTFields.

Copanlisib enhances the effectiveness of anti-PD1 therapies for colorectal cancer

Alexa E. Schmitz, Kennedy J. Maduscha, Sarbjeet Makkar, Cheri A. Pasch, Rebecca A. DeStefanis, Philip B. Emmerich, Dustin A. Deming. *University of Wisconsin - Madison, Madison, WI*

Introduction: Immunotherapies are increasingly being used for patients diagnosed with cancer, however, for metastatic colorectal cancer (CRC), more than 95% of patients have shown little to no clinical benefit to immunotherapy. Previous work from our lab has shown that copanlisib, a PI3K inhibitor, was found to enhance MHC class I expression in *Kras* mutant CT26 murine colon cancer cells. Here we examine the potential for

anti-cancer activity with the combination of copanlisib and anti-PD1 treatments using this model.
Methods: The impact of copanlisib on CT26 cells was performed using the WST assay and the expression of MHC class I was assessed using flow cytometry. CT26 flank allografts were generated in Balb/C mice and subsequently treated for 15 days with copanlisib (10 mg/kg), anti-PD1 (0.2 mg, BioXCell) or the combination. An IgG2a antibody (BioXCell) was used as a control. Tumors were measured twice a week using a caliper. Tumors were excised, and prepared for immunohistochemistry for CD8, CD4, perforin, granzyme B, and F480 was performed. Staining was quantified as the number of positive staining cells per 20X field of view (FOV).
Results: CT26 viability in response to 200 nM copanlisib was relatively unchanged as compared with untreated controls. Via flow cytometry, a 75% increase in mean fluorescent intensity (MFI) for MHC class I was observed comparing control to copanlisib ($p=0.003$). *In vivo,* after 15 days there was no difference in the growth rate of those cancers treated with control versus copanlisib or anti-PD1. A significant reduction in growth rate was observed with the combination of anti-PD1 with copanlisib compared to the other arms (median fold change=3.62; control: 7.49, $p=0.002$, copanlisib: 8.88, $p=0.003$; anti-PD1: 8.93, $p=0.002$). There were no differences in CD8 T cell and perforin expression between the treatment groups. Granzyme B expression was higher in the combination compared (median/FOV= 44) to the control (27, $p= 0.01$). Additionally, a significant reduction in F480 expression was seen in the combination compared to the other treatment groups (median/FOV=43; control: 139, $p<0.001$, copanlisib: 110, $p<0.001$; anti-PD1:149, $p<0.001$).
Conclusions: In conclusion, copanlisib in combination with anti-PD1 demonstrated enhanced anti-tumor activity in Balb/c mice that were injected with CT26 CRC cells. This response was correlated with increased granzyme B expression and a reduction in macrophages with the combination treatment. Further studies will expand on the mechanism of this combination therapy.

#4862
Investigation of the JAK/STAT signaling pathway in chemotherapy and PARP inhibitor resistant ovarian cancer

Esther Rodman[1], Michael Emch[1], Elizabeth Bruinsma[2], Xiaonan Hou[2], Scott Kaufmann[2], Saravut J. Weroha[2], John Hawse[1]. *[1]Biochemistry and Molecular Biology, Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Department of Oncology, Mayo Clinic College of Medicine and Science, Rochester, MN*

Ovarian cancer is the 7th most common cancer in women and the most fatal of all female reproductive cancers, with 5-year overall survival of 10-30%. Despite initial responses to first line platinum- and paclitaxel-based chemotherapies, >70% of ovarian cancers recur with increasingly resistant disease; and nearly all of these women die of their disease. Recently, the use of targeted therapies such as bevacizumab and PARP inhibitors have been shown to improve progression-free survival in a subset of patients. However, these agents have thus far failed to improve overall survival in patients without specific genetic signatures, highlighting the continued need for alternative therapies. Through an unbiased drug screen, we have identified lestaurtinib as a potent inhibitor of many sensitive and resistant ovarian cancer cell lines and patient derived organoid models. Lestaurtinib is a known tyrosine kinase inhibitor originally developed to block FLT3, a protein that is not expressed in any of the ovarian cancer cell lines tested. To elucidate the mechanisms by which lestaurtinib inhibits ovarian cancer cells, we have examined its impact on the phospho-proteome in parallel with RNAseq. Results of these studied have identified inhibition of the JAK/STAT signaling pathway as a top hit. Assessment of STAT1 and STAT3 has revealed that these transcription factors are constitutively activated in chemotherapy- and PARP inhibitor-resistant cell lines as reflected by high levels of Tyr701/705 and Ser727 phosphorylation, suggesting that induction of this pathway may drive resistance. Surprisingly, profound differences in the ability of various JAK/STAT inhibitors to block these specific phosphorylation events is observed, which correlates with their potency. Further, STAT1 and STAT3 ChIPseq experiments following cytokine-mediated activation of this pathway reveal that these transcription factors bind to genomic regions encoding genes involved in oncogenic and drug resistance pathways. Genetic knockdown of STAT1 and STAT3 via siRNA, or knockout via CRISPR/Cas9, results in significant growth inhibition of sensitive and resistant models of ovarian cancer, confirming their importance in maintaining cell viability. Finally,

combining lestuartinib with standard-of-care cisplatin or olaparib (a PARP inhibitor) is shown to be synergistic, indicating that pharmacological inhibition of JAK/STAT signaling has the potential to counteract drug resistance. Ongoing studies are aimed at further understanding the role of JAK/STAT signaling in ovarian cancer, elucidating the mechanistic processes by which STAT1/3 mediate progression of this disease, and identifying the most effective pharmacological strategies to study in possible future clinical trials.

PMCA inhibition induces cytotoxic calcium stress and suppression of Wnt signaling in refractory molecular subtype of gastric cancer

Saeli Ban[1], Jungmin Kim[2], Jonghwan Bae[1], Ki Cheong Park[3], Suji Lee[4], Moon Hwan Kim[1], Jae-Ho Cheong[5]. *[1]VERAVERSE Co., Ltd., Seoul, Korea, Republic of,[2]Department of Surgery, Yonsei University Health System, Yonsei University College of Medicine, Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Department of Surgery, Yonsei University Health System, Yonsei University College of Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Department of Surgery, Yonsei University Health System, Yonsei University College of Medicine, VERAVERSE Co., Ltd.; Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of*

Background: Gastric cancer (GC) is the fourth leading cause of cancer-related deaths worldwide, but its genetic heterogeneity retards the development of novel therapeutics. Recently, tumor molecular classification identified clinically refractory SEM (i.e., Stem-like, EMT and Mesenchymal) subtype GC which exhibited over-expression of the plasma membrane Ca2+ ATPase (PMCA) whose role is circumventing calcium overload causing ER stress and apoptosis. Here, we showed that PMCA4 is associated with Wnt signaling activity by regulating Secreted Frizzled-Related Protein 2 (SFRP2) expression and demonstrated that PMCA4 inhibition might achieve dual mechanism-specific anti-cancer effect by inducing calcium-mediated apoptosis and restraining oncogenic Wnt activity in SEM subtype GC.
Materials and Methods: GC cell lines and patient-derived organoids (PDOs) were categorized either SEM-subtype (SNU484, SNU668, SK4, MKN1; GA077T, GA265T, GA333T, GA352T) or non-SEM subtype (MKN45, NCIN87, SNU16, SNU601; GA200T, GA247T, GA215T) based on transcriptome signatures or subtype-specific biomarker genes. PMCA4 expression was confirmed using western blot and its calcium clearance function was examined using Fluo-4 AM fluorescent Ca2+ dye. Biological and molecular characteristics of GC cell lines and PDOs upon PMCA4 inhibition were investigated using RT-qPCR, western blot, and TOPflash/FOPflash reporter assay. The target engagement of novel PMCA inhibitor PM058 (bis-indole maleimide derivative) was evaluated by cellular thermal shift assay (CETSA), and the efficacy was determined by

CCK8 cell viability assay for cell lines and by Cell Titer-Glo for PDOs.Results: PMCA4 was highly expressed in SEM subtype GC cell lines and PDOs. The siRNA-mediated PMCA4 knockdown (KD) or pharmaceutical inhibition of PMCA4 suppressed the calcium clearance, the cell viability, and decreased cell invasion/migration. TCF/LEF-responsive reporter assay revealed that pharmaceutical inhibition of PMCA4 suppressed Wnt/beta-catenin signaling activity, proven by decrease in beta-catenin and Wnt target gene expression. PMCA inhibition was mechanistically associated with the increased expression of SFRP2, a Wnt antagonist. Importantly, PM058, a PMCA inhibitor, treatment resulted in highly efficacious anti-cancer effect in PDOs at nano molar range, which correlated with PMCA4 protein expression.Discussion and Conclusion: Our results provide the proof of concept that PMCA4 can be a promising therapeutic target for refractory subtype cancer. The proposed mechanism of PMCA4 inhibition is calcium overload - induced apoptosis and interfering with Wnt signaling activity via SFRP2 in GC. Importantly, we demonstrated a novel potent inhibitor PM058 that blocks PMCA function in clinically intractable SEM subtype GC cancer.

ALK inhibitors downregulate the expression of death receptor 4 in ALK-mutant NSCLC cells via facilitating Fra-1 and c-Jun degradation and subsequent AP-1 suppression

Wen Zhao[1], Danlei Yu[1], Yifan Zhai[2], Shi-Yong Sun[1]. *[1]Emory University, Atlanta, GA,[2]Ascentage Pharma (Suzhou) Co., Ltd, Suzhou, China*

The successful treatment of patients with advanced non-small cell lung cancer (NSCLC) harboring chromosomal rearrangements of anaplastic lymphoma kinase (ALK) with ALK tyrosine kinase inhibitors (ALK-TKIs) represents a promising targeted therapy. As a result, various ALK-TKIs have been rapidly developed, some of which were already approved while some are being tested in clinical trials. Death receptor 4 (DR4; also called TNFRSF10A or TRAIL-R1) is a cell surface protein, which is supposed to function as a pro-apoptotic protein that transduces TRAIL death signal to trigger apoptosis. Its expression is positively regulated by MEK/ERK signaling and thus can be downregulated by MEK/ERK inhibition. This study thus focused on determining the effects of AKL inhibition on DR4

expression and the underlying mechanisms. ALK-TKIs such as brigatinib and alectinib effectively and preferentially inhibited AKT/mTOR as well as MEK/ERK signaling and decreased cell survival in ALK-mutant (ALKm) NSCLC cells with induction of apoptosis. This was also true to DR4 downregulation, which occurred even at 2 h post treatment. These ALK-TKIs did not affect DR4 protein stability, rather potently decreased DR4 mRNA expression. In parallel, they promoted degradation and decreased the levels of Fra-1 and c-Jun, two critical components of AP-1, and suppressed AP-1 (Fra-1/c-Jun)-dependent transcription/expression of DR4. Hence, it appears that ALK-TKIs downregulate DR4 expression in ALKm NSCLC cells via facilitating Fra-1 and c-Jun degradation and subsequent AP-1 suppression. Our findings thus warrant further investigation on elucidating the biological significance of DR4 downregulation in ALK-targeted cancer therapy.

Mechanisms of EGFR inhibitor sensitivity and resistance in chordoma

Nindo Punturi, Lee Dolat, Joan Levy, Josh Sommer, Daniel M. Freed.
Chordoma Foundation, Durham, NC

Target discovery studies have identified EGFR inhibition as a promising therapeutic strategy in chordoma, motivating ongoing clinical trials. Yet EGFR is not mutated in chordoma, leaving the mechanisms associated with EGFR inhibitor (EGFRi) sensitivity and resistance unclear. In this study, we profiled a panel of over 10 chordoma cell lines to categorize their sensitivity to afatinib, a second-generation EGFRi with potency against the wild-type receptor. Several cell lines, including U-CHCF365, UM-Chor1, MUG-Chor1, and U-CH1, were highly sensitive to afatinib in cell viability assays, with absolute IC50 values below 50 nanomolar. In contrast, other chordoma cell lines, including UM-Chor5C and U-CHCF359B, exhibited limited response to EGFRi at concentrations exceeding 1 micromolar. Among sensitive cell lines, we found that afatinib promoted cell death in some cases (e.g., U-CH1) whereas in others it induced a profound cell cycle arrest. Moreover, in U-CH1 cells, acute afatinib treatment enriched a population of drug-tolerant persister cells with a fusiform morphology, potentially indicative of an epithelial-mesenchymal transition. Ongoing studies are focused on understanding the mechanisms of afatinib-induced

cell death, drug tolerance, and acquired resistance, with a view to designing rational combination strategies capable of enhancing the magnitude and duration of therapeutic response. In cell lines with matched xenograft models, in vitro responses to afatinib were consistent in vivo. In a panel of 12 chordoma patient-derived xenograft (PDX) models treated with afatinib or cetuximab, differential sensitivity to EGFRi was recapitulated - with EGFRi promoting complete or negligent tumor growth inhibition in sensitive or resistant models, respectively. Finally, we combined drug sensitivity profiling of chordoma cell lines and PDXs with whole-exome and whole-transcriptome sequencing to identify genomic and transcriptomic features associated with sensitivity and resistance to EGFRi in chordoma. Collectively, our data identify a striking degree of differential sensitivity to EGFRi in chordoma, and begin to shed light on factors associated with primary and acquired resistance. These results provide a framework for guiding patient selection and identifying potential combination therapy regimens to improve EGFRi efficacy and address resistance.

Pharmacological mechanisms of osimertinib in advanced non-small lung cancer bearing the deletion exon 19 of *EGFR* In an original chicken chorioallantoic membrane (CAM) Model.

David Barthelemy[1], Arnaud Vigneron[2], Xavier Rousset[3], Jerome Guitton[1], Emmanuel Grolleau[1], Margaux Raffin[1], Julie Balandier[1], Gaelle Lescuyer[1], Florence Geiguer[1], Sebastien Couraud[1], Jean Vaillet[3], Nazim Benzerdjeb[1], Lea Payen-Gay[1]. *[1]Centre Hospitalier Lyon Sud - HCL, Pierre Benite, France,[2]Université Claude Bernard Lyon 1, INSERM 1052, CNRS 5286, Centre Léon Bérard, Centre de Recherche en Cancérologie de Lyon, Lyon, France,[3]Inovotion, Grenoble, France*

Introduction: NSCLC accounts for about 80-85% of all lung cancers. Approximately 10-50% of patients with NSCLC harbor EGFR activating mutations, such as in-frame deletions in exon 19 (Ex19del). Currently, for patients with advanced NSCLC, testing for sensitizing mutations in *EGFR* is mandatory prior to the administration of anti-EGFR inhibitors such as Osimertinib. The CAM xenograft offers a rich environment in nutrients and embryonic growth factors, favorable for aggressive tumor development,

with its highly vascularized membrane and natural immunodeficiency at engraftment (at EDD9).
Methods: HCC827 Ex19del cells have been engrafted *in ovo*, and treated with various doses of osimertinib for seven days (4 treatments). The xenografts were collected and immunohistopathological, transcriptional and genetic analyses were carried out. Based on human transcriptional data, supervised multivariate discrimination between conditions and ontology analysis was performed through GSEA.
Results: The xenograft growth was inversely dependent on the exposure dose of osimertinib, with a reduction in tumor weight of 58% for 10 µM (corresponding to 8.3 µg/Kg, $T_{1/2}$ =4hr). The histological analysis showed epithelial tumor cells composed of solid sheets. The quantity of tumor cells was significantly lower in the treated group, with an area of tumor necrosis. The immunohistochemistry of tumor cells confirmed the human pulmonary epithelial origin, with TTF1 positive in treated and control groups. As expected, the ontology analysis of transcriptomic findings highlighted a downregulation of the EGFR pathway and its downstream effectors. Furthermore, the transcriptomic responses associated with chemotaxis, immune cell recruitment, and angiogenesis were dampened in the presence of osimertinib. This suggests that therapeutic efficacy was not uniquely guided through cell-autonomous mechanisms, but also takes place at the tissue level. We confirmed this in an independent experiment of *in ovo* HCC827 engraftment, showing a statically significant reduction of 15% in the number of vessels surrounding the xenograft in the osimertinib-treated condition. This demonstrates the advantage of using the *in ovo* model to decipher the regulations associated with therapeutics in a complex tissue context.
Conclusions: For the first time, we have observed that osimertinib modulates angiogenesis and chemotaxis, which apparently reduces immune system recruitment and immune checkpoint responses. The ontologic analysis of transcriptomic findings in the CAM model strongly support the clinical observations of the pharmacological tumoral response to targeted therapy. The fact that immune infiltration was reduced in osimertinib-treated tumors may partially explain the lower response to immunotherapy regimens in osimertinib resistance contexts.

Effect of FGFR3 activity on Nectin-4 expression in urothelial carcinoma

Sean Clark-Garvey[1], Mi Zhou[2], Andrew Truong[3], Wolfgang Beckabir[4], Michael Sturdivant[3], William Kim[1]. *[1]Lineberger Comprehensive Cancer Center, Division of Oncology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Lineberger Comprehensive Cancer Center, Department of Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Lineberger Comprehensive Cancer Center, Department of Microbiology and Immunology, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Bladder cancer is a common malignancy in the U.S. and cause of significant morbidity and mortality. Combination platinum-based chemotherapy has long been the mainstay in the treatment of metastatic urothelial carcinoma (mUC); however, over the last decade there have been significant advances in systemic therapy, which includes the FDA approval of the pan-FGFR inhibitor erdafitinib (approved for tumors with FGFR2/3 alterations) and the antibody drug conjugate (ADC) enfortumab vedotin (which targets the cell surface protein Nectin-4). Despite these advances, most patients with mUC will progress and succumb from their disease, highlighting the need for further therapeutic development. In parallel to therapeutic advances, there have been significant advances in the molecular characterization of UC, including identification of luminal and basal subsets. *NECTIN4* and *FGFR3* alterations are known to be enriched in luminal subtypes and we have found, via query of the TCGA data, that *NECTIN4* expression was significantly higher in *FGFR3* altered tumors. Given this association we sought to investigate the effect of FGFR3 activity on Nectin-4 expression. Using erdafitinib, in select luminal UC cell lines (RT112, RT4, SW780) with FGFR3 fusion proteins, we found, much to our surprise, that FGFR inhibition increased Nectin-4 expression. Western blots, probing for Nectin-4, following 24H, 48H, and 72H of treatment with erdafitinib (50 nM) showed a significant increase in protein expression in all three cell lines. Importantly, we consistently saw increased expression of what we believe corresponds to the membrane bound form of Nectin-4 and have now confirm such by flow cytometry and immunofluorescence probing for Nectin-4 in the RT112 cell line. We have also seen statistically

significant increases in *NECTIN4* on RT-PCR following treatment with erdafitinib; however, we believe that Nectin-4 regulation by FGFR inhibition is not merely transcriptional because the induction of Nectin-4 protein appears significantly greater than the fold increase in mRNA. Notably, in two additional UC cell lines (HT1376 - a luminal cell line with high Nectin-4 expression & UMUC3 - a basal cell line with low Nectin-4 expression), with no alterations in FGFR3, we did not see a significant change in Nectin-4 expression following treatment with erdafitinib. Based on our above results, we hypothesize that FGFR3 inhibition, in tumors harboring FGFR3 alterations, may act as a sensitize agent to Nectin-4 ADC targeted therapy; however, our results are preliminary and further investigation, particularly with in vivo models, is warranted.

Targeting of ERG positive prostate cancers with ERGi-USU-6 salt derivative

Binil Eldhose[1], Katherine Beck[2], Cyrus Eghtedari[3], Gartrell C. Bowling[2], Mallesh Pandrala[4], Sanjay V. Malhotra[5], Xiaofeng A. Su[6], Albert Dobi[1].
[1]Department of Surgery, Center for Prostate Disease Research, Murtha Cancer Center Research Program, Uniformed Services University of the Health Sciences, The Henry M Jackson Foundation for the Advancement of Military Medicine, Inc, Bethesda, MD,[2]School of Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD,[3]United states Naval Academy, Annapolis, MD,[4]Department of Cell, Development and Cancer Biology, Oregon Health and Science University, Portland, OR,[5]Department of Cell, Development and Cancer Biology, Oregon Health and Science University, Bethesda, OR,[6]David H. Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Cambridge, MA

Introducti**on:** Prostate cancer (PCa) is the second leading cause of cancer deaths among men in the United States. Approximately 50% of patients with PCa harbor an oncogenic TMPRRS2- ERG gene fusion in their primary tumor and 35% of patients with metastatic castration resistant prostate cancers have the gene fusion. We have identified a potent small molecule inhibitor, ERGi-USU-6 salt derivative 7b, that selectively inhibits

the growth of ERG positive tumor. This small molecule inhibitor is also effective in inhibiting the growth of benign and cancerous mouse prostate organoids expressing TMPRSS2-ERG (ERG positive organoids). To gain insights into the cancer-selective properties of ERGi-USU-6 salt 7b we evaluated pathways associated in ERGi-USU induced inhibition.
Methods: The biological activities of salt derivative 7b, were assessed in hormone- refractory metastatic tumor derived ERG positive prostate cancer cell line, VCaP along with organoids. We monitored the pathways associated in the mechanism of drug action through, cell cycle-regulator proteins by immunoblot assays, cell cycle and ferroptosis related analyses in response to 7b treatment. We also monitored the levels of the RIOK2 kinase,
previously shown to bind the parental ERGi-USU compound. The normal primary endothelium derived HUVEC cells were used as normal control due to the normal endogenous expression of ERG in endothelial cells including HUVEC.
Results: Cell growth and immunoblot analysis indicated the inhibition of ERG positive prostate organoid upon ERGi-USU treatments resulting in the downregulation of ERG and RIOK2 protein levels. The cell cycle analyses, pathway mapping by protein assessment and ferroptotic assays suggests that salt derivative 7b treatment inhibits the ERG positive prostate cancer through ferroptosis along with RIOK2 inhibition.
Conclusions: Our results showed that the ferroptosis inducer ATF3 gene is involved in the cancer-selective activity of ERGi-USU-6 salt derivative 7b. Further, based on our observations we hypothesize that ferroptosis, the iron-dependent form of programmed cell-death, may be the mechanism of cancer selective activity of salt derivative 7b.

Furin and Notch signaling pathway as part of the 2OHOA landscape against glioblastoma

Raquel Rodríguez-Lorca[1], Roberto Beteta-Göbel[1], Ramón Román[1], Manuel Torres[2], Victoria Llado[3], Pablo V. Escribá[2], Paula Fernández-García[1].
[1]R&D, Laminar Pharmaceuticals SA, Palma, Spain,[2]Laboratory of Molecular and Cellular Biomedicine, University of Balearic Islands, Palma, Spain,[3]Laminar Pharma, Inc., Acton, MA

Glioblastoma (GBM) is the most common and aggressive cancer tumor of the central nervous system, with only 12-15 months of patients' median survival. Melitherapy is a novel therapeutic platform based on the regulation of the membrane's structure and organization with the consequent modulation of certain cell signals. In this context, 2-hydroxioleic acid (2OHOA, LAM561, INN: idroxioleic acid) has been developed for the treatment of GBM and is currently running a phase IIB/III clinical trial for newly diagnosed GBM patients. 2OHOA modulates the lipid composition and structure of cancer cells, increasing membranes fluidity and altering the activity of membrane-associated proteins, inhibiting the proliferation, inducing ER stress and differentiation, and finally triggering cell death by autophagy. The Notch signaling pathway has been highly related to tumorigenesis and cell survival driving the pathogenesis of GBM. In this work, we studied whether 2OHOA modulates the Notch pathway and its relevance in its mechanism of action (MoA) as an antitumoral drug. For this purpose, the 2OHOA's effect on different components of the pathway was studied by western-blot, Q-PCR, and confocal microscopy. In addition, Notch receptor processing and NICD formation (final effector) were analyzed by cell fractionation and Notch processing enzymes activity, like furin, was evaluated upon 2OHOA treatment. First, the inhibition of this pathway in GBM cells by 2OHOA was confirmed by (i) lower expression levels of some of its components (Notch1, Notch3, and Jagged) and target genes (Hes1, CD3), (ii) less nuclear presence of NICD and Hes1 after 2OHOA treatment, (iii) accumulation of full-length Notch receptor in the membranes, impairing its processing and the NICD formation. Second, the relevance of Notch pathway in 2OHOA's MoA was determined by the partial hindering of 2OHOA antiproliferative effect by Hes1 overexpression. Moreover, the reduction of Hes1 expression induced by the drug in different GBM cells

correlated positively with their sensitivity to 2OHOA. Finally, 2OHOA downregulated furin-like proteases activity by physical association, an enzyme responsible for the Notch processing first step. All together reveals that the inhibition of Notch pathway by 2OHOA plays a role in its antitumoral effect, and this event is unleashed by the direct furin enzyme inhibition, identifying it as a novel target for this drug in the GBM and other pathologies treatment.

Dysregulation of MYC-family proteins sensitizes cancers to NMT inhibition: identification of NMTi sensitivity and mechanism

James Zhang[1], Gregor A. Lueg[1], Monica Faronato[1], Evon Poon[2], Andrii Gorelik[1], Andrea G. Grocin[1], Eva Caamano-Gutierrez[3], Francesco Falciani[4], Roberto Solari[5], Robin Carr[5], Andrew S. Bell[1], Edward Bartlett[1], Jennie Hutton[1], Miriam Llorian-Sopena[6], Probir Chakravarty[6], Bernadette Brzezicha[7], Martin Janz[8], Matther J. Garnett[9], Louis Chesler[2], Dinis P. Calado[6], Edward W. Tate[1]. *[1]Department of Chemistry, Imperial College London, London, United Kingdom,[2]Institute of Cancer Research, Sutton, United Kingdom,[3]Institute of Integrative Biology, University of Liverpool, Liverpool, United Kingdom,[4]University of Liverpool, Liverpool, United Kingdom,[5]Myricx Pharma, London, United Kingdom,[6]Francis Crick Institute, London, United Kingdom,[7]EPO Experimentelle Pharmakologie & Onkologie Berlin-Buch GmbH, Berlin, Germany,[8]Max Delbruck Center for Molecular Medicine and Charite - Universitatmedizin Berlin, Berlin, Germany,[9]Wellcome Sanger Institute, Cambridge, United Kingdom*

N-myristoyltransferases (NMTs) catalyze the protein N-terminal modification *N*-myristoylation, a lipidation event which affects >150 proteins and is involved in protein localization, stability, and function. NMT has been suggested as a target in cancers, but there has been a lack of rationale to identify patients who may respond to NMT inhibition. Additionally, the mechanism of action of NMT inhibitors (NMTi) is difficult to dissect, as NMT substrates feature in multiple biological pathways, and many studies have focused only on a single substrate. Here, a combination of bioinformatic, biochemical, proteomic, and cellular biology techniques have been combined to show that deregulation of MYC-family

proteins sensitizes cells to NMT inhibition. Cell lines sensitive to NMTi were identified through screening of hundreds of cancer cell lines, and the transcriptome of sensitive and insensitive lines compared to obtain a "Sensitive to NMTi" gene set. This gene set correlated well with MYC-related gene sets and mutation, amplification, or chromosomal rearrangement in MYC(N) were predictive for NMTi sensitivity, suggesting that MYC deregulated cancer cells are sensitive to NMTi. This was verified by cytotoxicity assays in B-cell lymphoma and neuroblastoma lines, where highly MYC(N) expressing lines exhibited increased NMTi sensitivity, including in the SHEP21N and P493-6 lines, in which MYC(N) levels can be regulated. Furthermore, proteomic profiling identified multiple pathways which are affected by NMTi, and these were further validated. In particular, an impact on Complex I formation was seen, and mitochondrial dysfunction in high MYC(N) cells upon NMTi was seen through the loss of basal and maximal respiration, ATP production and spare respiratory capacity. Loss of Complex I formation was shown to be caused by the loss of the NMT substrate NDUFAF4 upon NMTi treatment. Furthermore, application of an orally bioavailable NMTi eliminated tumors in mouse models of both diffuse large B-cell lymphoma and neuroblastoma and were well tolerated with no changed in body weight, suggesting that NMT inhibitors are well tolerated and efficacious in vivo.

DCC-3116, a first-in-class selective ULK1/2 inhibitor of autophagy, in combination with the KIT inhibitor ripretinib induces complete regressions in GIST preclinical models

Madhumita Bogdan, Mary J. Timson, Hikmat Al-Hashimi, Bryan D. Smith, Daniel L. Flynn. *Deciphera Pharmaceuticals, LLC, Lawrence, KS*

Background**:** Cancer cells activate autophagy as an adaptive stress response (ASR) mechanism to therapies targeting the RTK/RAS/MAPK/PI3K pathways, limiting antitumor response. Autophagy is initiated through ULK1/2 kinases and is triggered by inhibitors of the MAPK and PI3K pathways. Most gastrointestinal stromal tumors (GIST) are driven by mutations in KIT kinase. KIT signals through MAPK/PI3K pathways, suppressing ULK1/2 kinases and autophagy[1,2,3]. Inhibition of mutant KIT reverses this suppression, activating autophagy and cancer cell survival.

Approved therapies for GIST include imatinib, sunitinib, regorafenib, ripretinib, and avapritinib. Treatment with these inhibitors is initially successful, but drug resistance can develop either through KIT secondary mutations or ASR pathways including autophagy. DCC-3116 is a selective, potent, first-in-class investigational inhibitor of the ULK1/2 in clinical development in combination with targeted therapies that activate the autophagic ASR pathway. Herein we demonstrate that ULK1/2 and autophagy are activated upon treatment with ripretinib in KIT mutant GIST models. A combination of ripretinib with DCC-3116 inhibits autophagy *in vitro* and leads to complete tumor regressions in preclinical models of GIST.

Methods: Inhibition of ULK1/2 in cell assays was measured using an ELISA for the ULK substrate phospho-ATG13 (pATG13). Autophagic flux was measured by monitoring mCherry/GFP tagged LC3 protein in GIST cells. Xenograft studies were performed at CROs.

Results: Ripretinib treatment led to the activation of ULK1/2 by 2-3-fold in mutant KIT GIST cell lines. DCC-3116 inhibited both ripretinib-induced and basal pATG13 with IC_{50} values of 12-32 nM. Treatment of GIST-T1 cells with ripretinib increased autophagic flux 3-fold. DCC-3116 potently inhibited flux with an IC_{50} value of 38 nM. Ripretinib also induced pATG13 and autophagic flux (1.5-2.5-fold) in multiple imatinib-resistant cell lines, which was inhibited by DCC-3116 with IC_{50} values between 8-189 nM. In a GIST T1 PK/PD model, DCC-3116 inhibited ULK1/2-mediated pATG13. The combination of DCC-3116 with ripretinib resulted in complete tumor regressions in comparison to single agent treatment in GIST preclinical models.

Conclusions: These data demonstrate preclinically that, like other receptor tyrosine kinase inhibitors[1], ripretinib activates ULK1/2-mediated autophagy as an ASR resistance mechanism which is inhibited by DCC-3116, providing the rationale to study the combination of DCC-3116 with ripretinib in GIST patients. DCC-3116 is currently in a Phase 1 clinical trial in patients with advanced solid tumors (NCT04892017).

Pimavanserin suppresses glioblastoma progression by modulating the Akt/FOXO/Bim signaling axis

Manas Yogendra Agrawal, Sharavan Ramachandran, Carson Zabel, Sanjay K. Srivastava. *Department of Immunotherapeutics and Biotechnology, Texas Tech University Health Sciences Center, Abilene, TX*

Glioblastoma multiforme (GBM) is a highly aggressive grade IV malignant brain tumor with an average survival time of around 15 months; and a 5-year survival rate of 5%. Drug resistance, blood brain barrier (BBB) impermeability, and drug toxicity are some caveats in treating this malignancy. Current chemotherapeutic agents fail to address these challenges. In this study, we aim to repurpose an FDA-approved anti-psychotic agent Pimavanserin Tartrate (PVT), for the treatment of GBM and further delineate its mechanism. To unravel the oncolytic effects of PVT, cytotoxicity assay on several human (SF268, SF188, SF295, U251) and murine (CT2A-Luc) GBM cell lines was performed. Our results demonstrate that PVT inhibited the growth of various GBM cells with IC_{50} ranging 5 to 8 μM, contrary to Temozolomide (TMZ), a standard care therapy which has an IC_{50} ranging 600 to 1,300 μM after 48- and 72-hours of treatment. Moreover, PVT treatment enhanced the activity of TMZ when given in combination. Pro-apoptotic proteins such as cleaved caspase-3 and Bax were upregulated by PVT treatment as evaluated confirming apoptosis to be the mode of cell death. The apoptotic cell population increased in a dose-dependent fashion, for example, 10μM PVT exhibited 70% increase in apoptosis as observed in the annexin assay. PVT treatment suppressed the phosphorylation of PI3K and Akt, and increased the expression of FOXO proteins, which are the negative downstream regulators of Akt. FOXO proteins translocate to the nucleus leading to the enhanced transcription of Bim, a pro-apoptotic protein resulting in apoptosis. Oral administration of 10mg/kg PVT significantly suppressed the growth of intracranially implanted GBM tumors without any other organ toxicity. Our observations provide a robust foundation for PVT's anti-cancer efficacy against GBM by modulating Akt/FOXO/Bim pathway.

Hyperforin induces apoptosis and inhibits invasion via inhibiting AKT/NF-KB signaling pathway in colorectal cancer cells

Ying-Tzu Chen[1], I-Tsang Chiang[2], Yuan Chang[3], Fei-Ting Hsu[4]. *[1]Chine Medical University, (Individual), Taichung, Taiwan,[2]Medical Administrative Center, Show Chwan Memorial Hospital, Changhua, Taiwan,[3]Department of Medical Imaging, Taipei Medical University-Shuang Ho Hospital, Ministry of Health and Welfare, New Taipei City, Taiwan,[4]Department of Biological Science and Technology, China Medical University, Taichung, Taiwan*

Recently, the incidence of colorectal cancer (CRC) has been increasing year by year and has become the first incidence cancer in Taiwan. Epidermal growth factor receptor inhibitor (EGFR inhibitor) has been recognized as an important target of CRC. Therefore, targeting EGFR and its related signaling could be a potential strategy to overcome this disease. Hyperforin is a natural prenylated phloroglucinol and has been identified as the major molecule responsible for the antidepressant effects. Previous studies indicated that hyperforin has other potentially pharmacologically meaningful biological properties, including antibacterial ability and inhibition of inflammatory mediators. Numerous studies have also pointed out the anti-tumor potential of hyperforin is associated with the induction of apoptosis signaling. However, whether hyperforin may regulate CRC progression and its underlying mechanism is unclear. In our study, we used the MTT assay to prove the cytotoxicity of CRC cells (HT29 and HCT116 cells) was induced by hyperforin. We then used the flow cytometry to confirmed that hyperforin may induce both extrinsic/intrinsic apoptotic pathways in CRC cells. We further demonstrated hyperforin-induced apoptosis pathways is associated with mitochondrial-dependent apoptosis and death receptor dependent apoptosis. Then, transwell invasion, migration, and wound healing assay results proved the inhibition effect by hyperforin in HT29 and HCT116 cells. Additionally, we suggested that hyperforin can effectively inhibit EGFR downstream genes MEK-ERK and AKT signaling, as well as inhibit the phosphorylation of NF-KB and the nuclear translocation in CRC cells. In sum, our results show that hyperforin can inhibit the apoptosis and metastasis ability of CRC cells by inhibiting both AKT/NF- KB and ERK/ NF-KB signaling pathway.

#4875

The anti-tumor effects of GSK-3β inhibitor (9-1NG-41) in ETMR and ATRT pediatric brain tumors

Divya Gandra, Lauren Difabio, Kaitlyn H. Smith, Kimberly Q. McKinney, Giselle S. Sholler. *Atrium Health, Charlotte, NC*

Purpose Embryonal brain tumors (EBTs): ETMR (embryonal tumor with multilayered rosettes) and ATRT (atypical teratoid rhabdoid tumor) are aggressive malignancies with poor prognosis necessitating alternative strategies. GSK-3β is a serine threonine kinase often overexpressed in solid tumors and a positive regulator of NF-κB which promotes tumor growth and chemotherapy resistance. 9-ING-41 is a maleimide-based small molecule that crosses the blood brain barrier and selectively inhibits GSK-3β. Previously we demonstrated that 9-ING-41 decreases ETMR and ATRT cell viability through apoptosis and increases p53 signaling, however the exact mechanism leading to its activation is unknown. This study aims to determine the optimal dosing for 9-ING-41 and describe the phenotypic response of these cell lines to 9-ING-41 using cell viability assay, western blotting and neurosphere assay. This information will help further elucidate the mechanism of action for this drug.

Methods ATRT cell lines ATRT 2141, ATRT-787199, ATRT 803499, LCH-091-07 and the ETMR cell line BT-183 were grown for 24hrs prior to 9-ING-41 treatment in DMEM and Neurocult medium, respectively. Cell viability was assessed after 72hrs of treatment using Cell Titer Glo 2.0. Western blots were analyzed for XIAP, cleaved caspase-3, p53, MDM2 after 24 and 48 hours at 200nM, 400nM and 600nM. Neurosphere assays were done by seeding two cells per well in a 96-well plate followed by treatment with 9-ING-41. Neurosphere frequency and size was monitored weekly for up to 4 weeks using Incucyte® S3 software. Pearson's correlation graph was generated to determine the relationship between GSK-3β expression and sensitivity to 9-ING-41. Graph Pad Prism was used for statistical analysis and level of significance set to p=0.05.

Results The IC50s of 9-ING-41 in cell lines ATRT 2141, ATRT-787199, ATRT 803499 and LCH-091-07 were 194nM, 558nM, 730nM & 5353nM, respectively. We observed decreased expression of NF-κB mediated anti-apoptotic marker XIAP and an increase in expression of apoptotic marker cleaved caspase-3 and tumor suppressor p53 in response to 9-ING-41.

MDM2, a negative regulator of p53 had a significant increase in expression indicating it is not responsible for p53 increase which may suggest ATM pathway could be responsible for regulating p53 increase. GSK-3β expression in vitro, correlated with sensitivity to 9-ING-41. There was a dose dependent decrease in frequency and size of neurospheres in response to 9-ING-41.
Conclusion 9-ING-41 decreases cell viability and neurosphere formation in ETMR and ATRT cell lines within clinically relevant doses. p53 stabilization is not mediated by MDM2 and may be downstream of the ATM pathway. Further studies are underway to demonstrate its efficacy in mouse models.

A systems pharmacology approach to discover synergistic targeted therapy combinations

Cameron T. Flower[1], Chunmei Liu[2], James R. Heath[2], Wei Wei[2], Forest M. White[1]. *[1]Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA,[2]Institute for Systems Biology, Seattle, WA*

The discovery of oncogenic signal transduction in cancer has enabled the development and clinical use of dozens of kinase-directed targeted therapies, but patient response is often transient and resistance invariably develops. In the setting of BRAF-mutant melanoma, for instance, a majority of patients relapse within one year of initiating targeted therapy. Combination therapies blocking compensatory signaling pathways provide a strategy for boosting treatment efficacy and delaying resistance. To find synergistic kinase inhibitor combinations, we used a multimodal systems pharmacology approach to quantify the early adaptive signaling and gene regulatory dynamics in patient-derived $BRAF^{V600E}$-mutant melanoma cells under oncogene inhibition. Cells were treated with vemurafenib or vehicle and sampled longitudinally at timepoints spanning minutes to days. To measure signaling dynamics, thousands of protein phosphorylation sites covering commonly altered signaling axes in cancer were motif-enriched by immunoprecipitation, barcoded with isobaric tandem mass tags (TMT), and quantified by high-resolution mass spectrometry (MS). The resulting time-resolved phosphoproteomics data showed rapid (<15 minutes) and potent (>8-fold) downregulation of ERK1/2, confirming strong BRAF inhibition.

Statistical integration of signaling measurements with time-series RNA-seq data collected at the same timepoints enabled reconstruction of multi-scale regulatory networks governing the adaptive response to oncogene inhibition. In particular, we observed early induction of SRC-family kinase (SFK) signaling and a broad cytoskeletal signaling module, implicating a compensatory prosurvival signaling program. The induction intensified over the 3-day treatment window and was fully reversed following a 6-day drug holiday, suggesting a reversible nature of drug adaptation. Immunoblotting confirmed sustained loss of ERK1/2 activity and concomitant elevated SFK phosphorylation following drug treatment. Accumulation of reactive oxygen species, a known activator of SFKs, strongly correlated with SFK activity, and both were ablated following treatment with the antioxidant precursor N-acetylcysteine. This adaptive response predicted a significant degree of synergy between vemurafenib and the pan-SFK inhibitor dasatinib, which was validated in a panel of patient-derived melanoma cell lines and in melanoma xenograft mouse models. Targeted MS of phospho-ERK1/2 and canonical SFK substrates, including CTTN, PXN, and PAG1, validated the mechanism of action of this combination. Complementary data from patient-derived non small-cell lung cancer (NSCLC) cells under tyrosine kinase inhibitor treatment demonstrates the generality of our integrative approach, and supports the notion that SFK activation may be a hallmark response to oncogenic RTK-RAS-ERK pathway inhibition.

Mutant or overexpressed SF3B1 facilitates endometrial cancer tumorigenesis

Pooja Popli[1], Xinchao Deng[2], Premal Thaker[2], Ramakrishna Kommagani[1].
[1]Baylor College of Medicine, Houston, TX,[2]Washington University in St. Louis, St. Louis, MO

Aberrant expression or mutations in core splicing factors including U2AF1, SRSF2, ZRSR2, and SF3B1 found to drive tumorigenesis of various malignant tumors e.g., myelodysplastic syndromes, chronic lymphocytic leukemia, uveal melanoma, and breast cancer. Importantly, the amplifications and mutations in SF3B1, the pioneer splicing factor, are reportedly far more common than those in other splicing factors. However,

the functional relevance and underlying mechanisms of dysregulated SF3B1 in endometrial cancer are not investigated. Endometrial cancer is the fourth most common cancer in women in the United States and there will be about 65,950 new endometrial cancer cases in the current year alone with 12,550 estimated cancer deaths in the United States. In this study, we thus investigated the role of SF3B1 in endometrial adenocarcinoma. We found SF3B1 is one of the most frequently amplified or mutated splicing factors in endometrial cancer. Specifically, analysis of The Cancer Genome Atlas (TCGA) uterine pan-cancer dataset revealed that up to 9% of endometrial cancers have SF3B1 mutations or amplification. Additionally, we showed that the SF3B1 protein is overexpressed in human as well as mouse endometrial tumor samples. Further analysis found elevated SF3B1 protein in multiple endometrial cancer cell lines even in the absence of SF3B1 mutations. However, we did not observe any altered expression at the transcript level. Further, we identified a correlation between the over-expressed SF3B1 levels and the tumorigenicity/invasive potential of cancer cell lines. For instance, endometrial cancer cell lines (Ishikawa, AN3CA, KLE) with over-expressed SF3B1 levels were much more tumorigenic and invasive than those with low endogenous SF3B1 levels (normal human endometrial epithelial cells, RL-95-2 cells). Moreover, cell viability assays revealed that Ishikawa, AN3CA, and KLE cells were more susceptible to the loss of SF3B1 or treatment with the SF3B1 inhibitor Pladienolide-B (PLAD-B) than RL-95-2 cells. To further ensure that overexpressed or mutated SF3B1 drives endometrial tumorigenesis, we transiently transfected an empty vector or a vector expressing FLAG-tagged wild-type SF3B1 or vector with mutated SF3B1 construct R957Q into RL-95-2 cells which have minimal endogenous SF3B1. Analysis of proliferation assays revealed that cells overexpressing SF3B1 proliferated significantly more than cells expressing empty vector. Intriguingly, we observed that RL-95-2 cells over-expressing R957Q mutants were even more proliferative than the cells expressing wild-type SF3B1. Together, this data suggest that SF3B1 over-expression and mutation play a crucial oncogenic role in endometrial cancer, and these findings may support the development of SF3B1 inhibitors to treat this disease.

Transcriptional response to rocaglate translation inhibitors in lymphoma shows cellular adaptation through induction of stress and survival pathways

Paola Manara[1], Tyler Andrew Cunningham[2], Jr Jyun David Ho[3], Olivia B. Lightfuss[1], Abdessamad Youssfi Alaoui[1], Jonathan Harry Schatz[2].
[1]Medicine, University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL,[2]Medicine, University of Miami, Miller School of Medicine, Miami, FL,[3]Medicine, University of Miami, Sylvester Comprehensive Cancer Center, FL

Background**:** 40% of diffuse large B-cell lymphoma (DLBCL) patients do not achieve cure in response to the standard immunochemotherapy. Relapsed and refractory tumors respond poorly to targeted signaling inhibitors due to pathway redundancies in this genetically heterogenous disease. Pharmacologic disruption of the cap-initiation complex eIF4F is an emerging clinical treatment strategy to bypass resistance. In preclinical experiments, B-lymphomas show high susceptibility to rocaglates, natural and synthetic cap-dependent translation inhibitors. Among these compounds, eFT226 (zotatifin), is currently in phase I/II clinical evaluation for solid tumors. Rocaglate mechanisms remain incompletely defined for use in B-cell lymphoma. Recent findings in our laboratory revealed translationally mediated adaptation that increased synthesis of many targets. Proteins (i.e.CD98hc) that paradoxically increase in production contribute to persistence of cells that survive treatment. By contrast, transcriptional responses to rocaglates remain minimally studied. Here we sought to fill this gap through unbiased transcriptomics.
Method: RNA sequencing (RNA-seq) was performed on zotatifin treated DLBCL cells (SU-DHL10) vs DMSO controls. Genes with a false discovery rate p-value (FDR) ≤0.05, logarithm of counts per million reads (logCPM) ≥ 0 and P value ≤0.05 were considered differentially expressed. Log2 fold change (FC) ≥ +/-2-fold for a specific gene was considered significantly differentially expressed between the two groups. Pathway analysis was performed using Gene Set Enrichment Analysis (GSEA).
Results: We found 4450 differentially expressed genes, 12 significantly upregulated, and 42 significantly downregulated in response to zotatifin (FC ≥ 2). Further pathways analyses showed 4/25 gene sets significantly upregulated, and 3/22 gene sets significantly downregulated (FDR <0.25).

We found significantly upregulated genes related to mechanisms stress and survival pathways including NF-kB induction by TNF signaling (normalized enriched score (NES)=2.28; p-value <0.0001), genes induced in response to hypoxia translational stress responses (NES=1.85; nominal p-value=0.008).
Conclusions: These results implicate induction of specific survival pathways that induce transcriptionally mediated adaptation to the stress of rocaglate therapy, but it is unclear if these responses can result in altered protein production in the context of eIF4A inhibition. Parallel assessment of the translatome currently under analysis will provide a more complete picture of overall adaptation and provide rational combination targets for rocaglates in lymphoma as clinical development progresses.

#4879
Inhibition of amino acid transporters as a novel mechanism of action of the repurposed anti-cancer agent tranexamic acid
Brian K. Law, Mary E. Law, Amanda F. Ghilardi, Elham Yaaghubi, Brad J. Davis, Zaafir M. Dulloo, Mengxiong Wang, Olga A. Guryanova, Coy D. Heldermon, Stephan C. Jahn, Ronald K. Castellano. *University of Florida, Gainesville, FL*

Tranexamic Acid (TA) is an anti-fibrinolytic agent that inhibits Plasminogen activation and is used to control bleeding. Past studies have suggested that the ability of TA to block Plasminogen activation may be useful for ablating the growth or invasion of cancer. Based on the similarity of TA to the amino acid Lysine we hypothesize that TA might exhibit novel mechanisms of action independent of blocking Plasminogen activation. Analysis of a series of signaling pathways indicated that TA inhibits phosphorylation of S6K1 and STAT3 on sites required for their activation and reduces expression of the MYC oncogene in a concentration-dependent manner. Interestingly, MYC transformed MCF10A human mammary epithelial cells exhibited enhanced sensitivity to TA-mediated reduction of cell viability, suggesting that TA may exhibit selectivity for MYC overexpressing breast cancers. Treatment of breast tumor bearing mice with TA strongly blocked tumor growth and was associated with extensive cancer cell death compared with control tumors. Analysis of extracts from TA or vehicle treated tumors showed that TA blocked S6K1

phosphorylation in vivo in a statistically significant manner. Since S6K1 phosphorylation is regulated by amino acid levels, we hypothesized that due to the structural similarity between TA and Lysine and Arginine, TA may block Lysine or Arginine uptake by blocking cationic amino acid transporters (CATs). Molecular docking simulations utilizing the structure of the bacterial CAT predicted that TA binds to CAT with affinity similar to that of Lysine. Amino acid uptake experiments performed with radiolabeled Arginine and Lysine showed that TA blocked both Arginine and Lysine absorption by cancer cells in a concentration-dependent manner. Together, these results indicate a novel mechanism by which TA inhibits uptake of Arginine and Lysine, triggering loss of S6K1 activity in parallel with tumor growth inhibition. Initial studies suggest the feasibility of designing TA analogs with significantly improved potency for amino acid transporters, and with corresponding increases in selective toxicity to breast cancer cells. Based on these novel mechanisms of TA action, we expect TA to exhibit anti-cancer activity against a broad range of human malignancies.

Anti-membrane IgM monoclonal antibody, WBMP-4, induces apoptosis in B-cell malignancies by modulation of kinase expression and phosphorylation

Rachel S. Welt[1], Jonathan A. Welt[2], Virginia Raymond[3], David Kostyal[4], Sydney Welt[1]. *[1]Welt Bio-Molecular Pharmaceutical, Briarcliff Manor, NY,[2]University of California, Irvine, Irvine, CA,[3]Biogent Consultants, LLC, Armonk, NY,[4]ARDL, Akron, OH*

The concept that the B-cell Receptor Complex (BCRC) initiates the dominant driver pathway in leukemia-lymphoma is clinically validated. However, the BCRC has been overlooked as a therapeutic target due to homology between the BCRC's membrane Ig (mIg) subunit and circulating serum Ig. Previously, we reported the generation of a first-in-class antibody, WBMP-4, to a neo-epitope specific to the mIgM-BCRC, which inhibits cell growth and induces apoptosis (Welt et al. 2016).
Here we evaluate kinase activity in Burkitt lymphoma (CA46) cells treated with WBMP-4 (at 5 and 20 ug/mL, and at 6 and 24 hours) via the Pamgene phosphotyrosine kinase assay. This assay measures kinase activity in cell lysates using a microarray chip containing peptide sequences that serve as

substrate for phophsotyrosine sites on well-characterized signaling proteins. We measure kinase activity at 189 phosphosites using this array, as well as protein expression and phosphorylation of key targets downstream of the BCRC using ELISA, flow cytometry, western blot, and immunohistochemistry, in WBMP-4-treated and untreated IgM-expressing B-cells.

Our Pamgene analysis reveals widespread kinase modulation following WBMP-4 treatment, with >180 of 189 phosphosites showing a significant change in phosphorylation signal intensity (with >153 showing a significant decrease) upon treatment. Western blot analyses of downstream BCRC kinases similarly show changes in phosphorylation at analyzed phosphosites (ZAP70, mTOR, AKT, and MEK) with WBMP-4 treatment. However, we also find changes in protein expression levels of CD79b, ZAP70, BTK, MEK, Myc (all decreased), and LCK (increased) following WBMP-4 treatment.

We show that the kinase activity of proteins in multiple signaling pathways is altered upon WBMP-4 binding to the BCRC's mIgM, with the vast majority exhibiting a downregulation of phosphorylation. We also find that protein expression is impacted in several kinases directly under the control of the BCRC. We hypothesize that WBMP-4's impact on protein expression contributes to BCRC signal disruption and the cytotoxic effect achieved by WBMP-4. For example, WBMP-4 induces a profound reduction in CD79b expression (undetectable by western blot following WBMP-4 treatment), which is consistent with the reduction in CD79a kinase activity found via Pamgene assay. These data support the concept that WBMP-4 binds an epitope on mIgM that is critical to its signal transduction to CD79a/b.Due to WBMP-4's specific targeting of IgM-expressing B-cells, we expect that the toxicities associated with approved therapies upon their interaction with non-lymphatic tissue (e.g. bleeding, infection, cytopenia, arrhythmia, secondary malignancies) will be avoided. With potent anti-tumor activity and expected reduced toxicities, WBMP-4 is a compelling candidate for clinical development.

#4881

Anti-cancer efficacy of a novel phenothiazine derivative is independent of dopamine and serotonin receptor inhibition

Marion Vanneste[1], Anita Venzke[1], Soumitra Guin[2], Damian Krysan[3], Marvin Meyers[2], Michael Henry[1]. *[1]Department of Molecular Physiology and Biophysics, Carver College of Medicine, University of Iowa, Iowa City, IA,[2]Department of Chemistry, St. Louis University, Saint-Louis, MO,[3]Department of Microbiology and Immunology, Carver College of Medicine, University of Iowa, Iowa City, IA*

Introducti**on:** An attractive, yet unrealized, goal in cancer therapy is repurposing psychiatric drugs that can readily penetrate the blood-brain barrier for the treatment of deadly primary brain tumors and brain metastasis. The phenothiazine (PTZ) class of anti-psychotic agents were originally developed to inhibit dopamine- and serotonin-receptors (DR/5-HTRs). PTZs have demonstrated anti-cancer properties in numerous studies through a variety of proposed mechanisms, including on-target (DR/5-HTR) and off-target (e.g. calmodulin (CaM) inhibition) effects. PTZs inhibit DR/5-HTRs in the low- to mid-nanomolar range whereas anti-cancer effects tend to be observed only at a higher (low micromolar) dose range. Thus, clinical efficacy of existing PTZs may be limited by toxicity of on-target effects (sedation) of these drugs as DR/5-HTR antagonists. However, it has been unclear whether anti-cancer effects of PTZs are entirely separate from their activity as DR/5-HTR antagonists. Here we evaluate the *in vitro* anti-cancer efficacy of a novel PTZ analog (CWHM-974, a *N*-benzyl-linked fluphenazine (FLU) derivative), originally developed to treat brain-resident fungal infections, that is a 100-1000-fold less potent DR/5-HTR antagonist than FLU.

Experimental procedures: To evaluate the anti-cancer efficacy of FLU and CWHM-974, we assessed cytotoxicity following 72h exposure against a broad panel of cancer cell lines. To investigate CaM as a target for CWHM-974, we evaluated the correlation between the sensitivity to CMW-974 and sensitivity to the CaM inhibitor W-7 as well as CaM gene expression levels in a panel of cancer cell lines. We also tested the anti-cancer efficacy of a sulfoxide analog of CWHM-974 (SLU-0010894) which lacks CaM binding activity.

Results: We confirmed the anti-cancer efficacy of FLU and demonstrated that CWHM-974 is consistently 2-10-fold more potent than FLU in a broad panel of cancer cell lines. Among the most sensitve cancer cell lines are melanoma, which is a cancer that frequently metastasizes to the brain.

Consistent with the hypothesis that CaM is a relevant target for CWHM-974, we found that: 1) CaM mRNA (CALM1) levels are correlated with sensitivity to CWHM-974 ; 2) the activities of CWHM-974 and W7 are correlated, and 3) most importantly, SLU-0010894 does not exhibit anti-cancer activity.
Conclusions: The anti-cancer efficacy of the PTZ derivative CWHM-974 is seperable from DR/5-HTR antagonism. Our data suggests that further optimization of this compound may preserve the desirable pharmacologic properties for targeting brain cancers while reducing toxicity due to DR/5-HTR antagonism. Moreover, we provide a variety of evidence suggesting that anti-cancer efficacy of CWHM-974 is associated with CaM binding. Ongoing efforts will characterize the activity of CWHM-974 in mouse models of brain metastasis.

Multi-omics analysis of mechanisms underlying sensitivity of Merkel cell carcinoma to pyrvinium pamoate
Jiawen Yang[1], James T. Lim[2], Paul Victor[3], Rick G. Schnellmann[3], James A. DeCaprio[4], Megha Padi[2]. *[1]University of Arizona Cancer Center, Tucson, AZ,[2]Department of Molecular and Cellular Biology, University of Arizona, Tucson, AZ,[3]Department of Pharmacology and Toxicology, The University of Arizona R. Ken Coit College of Pharmacy, Tucson, AZ,[4]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Merkel Cell Carcinoma (MCC) is a highly aggressive neuroendocrine cutaneous malignancy arising from either Ultraviolet-induced mutagenesis or Merkel cell polyomavirus (MCPyV) integration. Pyrvinium Pamoate (PP), an FDA-approved anthelminthic drug, has been reported to exhibit anti-tumor abilities in multiple cancers. By integrating transcriptomic, network, and molecular analyses, we discovered that PP is broadly effective against Merkel cell carcinoma cell lines, and that PP targets multiple proposed MCC tumorigenesis pathways.
Methods: We performed time-series RNA-seq profiling on a MCPyV inducible cell model and on PP-treated MCC cell lines, and inferred gene regulatory networks associated with PP response. We then integrated the network models with publicly available MCC tumor profiles and the LINCS L1000 database to explore the targets of PP in MCC. In addition,

we performed protein, RNA, growth rate, metabolic, and apoptosis assays on multiple MCC cell lines exposed to PP.
Results: Analyzing the effect of PP in the L1000 cancer cell line panel suggested that PP could inhibit key drivers of MCC tumorigenesis. We therefore tested the anti-proliferation and pro-apoptosis effects of PP in MCC cell lines. PP effectively inhibits proliferation of MCC at concentrations as low as 100 nM and in a dose and time-dependent manner. RNA-seq analysis of PP treated MCC cells suggested that PP triggers the p53-mediated intrinsic apoptotic signaling pathway, impairs the mitochondria's oxidative phosphorylation function and induces endoplasmic reticulum (ER) stress. Immunoblotting intrinsic apoptotic pathway protein markers and measuring the IC_{50} of PP and the MDM2 inhibitor Nutlin-3a in $p53^{WT}$ and $p53^{mut}$ or $p53^{-/-}$ MCC cell lines, we found that PP does not induce cell apoptosis only through p53 activation, but also through other mechanisms such as increasing Unfolded Protein Response (UPR) stress and decreasing expression of the anti-apoptotic protein survivin (BIRC5). Extracellular flux analysis revealed decreased oxidative phosphorylation rate in PP treated MCC cells. Western blot analysis suggests that PP directly inhibits mitochondria complexes genes ATP5A, MTCO1 and NDUF58 and induces UPR-ER stress. PP has also been reported to inhibit the canonical Wnt pathway. We found that WNT5B, the ligand for the non-canonical Wnt pathway, was significantly decreased in MCC tumors and in our MCPyV inducible cell model, and that PP can upregulate WNT5B significantly. MCC cells treated with WNT5B recombinant protein showed a retarded MCC phenotype.
Conclusion: Our results suggest that PP exerts anti-tumor activity through both non-specific growth inhibition - via the modulation of mitochondrial function, ER stress, and apoptotic signaling - and more specifically by perturbing the non-canonical Wnt pathway.

Pan cancer transcriptomic response to tumor treating fields (TTFields)

Kerem Wainer-Katsir[1], Gitit Lavy-Shahaf[1], Hila Fishman[1], Hila Ena[1], Roni Frechtel-Gerzi[1], Antonia Martinez-Conde[1], Eyal Dor-On[1], Shiri Davidi[1], Sara Jacobovitch[1], Itai Tzchori[1], Yaara Porat[1], Lianghao Ding[2], Michael Story[2], Renfei Du[3], Ulf Kahlert[3], Laura Mannarino[4], Federica Mirimao[5],

Monica Lupi[6], Maurizio D'Incalci[4], Adi Haber[1], Moshe Giladi[1], Uri Weinberg[1], Yoram Palti[1]. *[1]Novocure Ltd, Haifa, Israel,[2]Department of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX,[3]Molecular and Experimental Surgery, University Clinic for General-, Visceral-, Vascular- and Transplantation Surgery, Medical Faculty and University Hospital Magdeburg, Otto-von Guericke University, Magdeburg, Germany,[4]1) Laboratory of Cancer Pharmacology, 2) Department of Biomedical Sciences, IRCCS Humanitas Research Hospital, Rozzano and Humanitas University, Pieve Emanuele, Milan, Italy,[5]Department of Oncology, Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy,[6]Laboratory of Cancer Pharmacology, IRCCS Humanitas Research Hospital, Rozzano, Milan, Italy*

Introduction: Tumor Treating Fields (TTFields) are electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression, ultimately leading to cell death. TTFields therapy is versatile with multiple mechanisms of action, including: anti-mitotic effects, downregulation of DNA double strand break repair, generation of replication stress, upregulation of autophagy, and induction of immunogenic cell death. In this research we were interested in identifying common responses to TTFields across cancer types. We addressed this by integrating whole transcriptome analyses of cancers from various origins.
Methods: Control and TTFields-treated samples examined included gastric, ovarian, pancreatic, non-small cell lung carcinoma, and glioblastoma cell lines, pleural mesothelioma patient-derived cell lines, and a hepatocellular carcinoma animal model. A list of differentially expressed genes (DEGs) was generated from transcriptomics analysis. Gene Set Enrichment Analysis (GSEA) was conducted with the MSigDB, and additional pathway databases. Significantly overlapping pathways were identified using ActivePathways package, and an enrichment map was created according to the number of datasets supporting each pathway.
Results: The response to TTFields showed a positive correlation of expression across different cell lines and indications, including in an animal model. Downregulation was seen in cell cycle related pathways - E2F targets, Myc targets, G2M checkpoint, and mitotic spindle - indicative of cell cycle arrest, which was mediated by increased expression of tumor suppressors. Several DNA repair pathways were downregulated, including

nucleotide excision repair, base excision repair, and the Fanconi Anemia-BRCA pathway. Downregulation was also evident in nuclear envelope, DNA and RNA synthesis, metabolism of amino acids, translation, organelle organization, and splicing. Upregulation was observed in genes associated with the cytoskeleton, adhesion, extracellular proteins and transporters. In the majority of comparisons, an upregulation in the immune response was also observed.
Conclusions: Transcriptomic analysis of datasets from different tumor types revealed common expression patterns and pathways involved in the responses to TTFields. Some of the identified pathways corroborate previously described mechanisms, whereas some reveal new potential mechanisms that require further investigation.

Targeted investigational oncology agents (IOA) in the NCI60: a phenotypic systems-based resource

Joel Morris[1], Mark W. Kunkel[1], Stephen L. White[1], Donn G. Wishka[2], Omar D. Lopez[2], Lori Bowles[2], Penny Sellers[2], Patricia Ramsey[2], Julie Grams[2], Tiffany Rohrer[2], Karen Martin[2], Thomas Dexheimer[2], Dmitriy Sonkin[1], John D. Williams[2], Jerry M. Collins[1], James H. Doroshow[1], Beverly A. Teicher[1]. *[1]National Cancer Institute, Rockville, MD,[2]National Cancer Institute, Frederick, MD*

The NCI60 human tumor cell line panel is a useful tool in the discovery and development of new anticancer agents. The publicly available cell-line characterization and compound screening data from the NCI60 screen have contributed to identifying cellular mechanisms of potential new anticancer agents. Mean-graph sensitivity/resistance patterns in the NCI60 screen serve as a fingerprint for molecular target identification and mechanism of action (MOA). A new NCI60 resource was developed based on screening of 175 FDA-approved oncology drugs (AOD) plus >825 investigational oncology agents (IOA), representing >250 therapeutic targets and MOAs. Compounds targeting different components in a biochemical pathway tend to show high correlations in their GI_{50} patterns through COMPARE analysis forming clusters with similar NCI60 mean-graph patterns. COMPARE evaluation of compounds that target components in the

PI3K/AKT/mTOR pathway form correlation clusters linked by both target and pathway. Only 3 of 15 AKT inhibitors in the IOA set are not found in the connected cluster with a COMPARE correlation of 0.7 including the multi-kinase inhibitors perifosine and AT-13148. The AKT cluster includes both allosteric (MK-2206) and competitive inhibitors highlighting the NCI60 is a functional cell assay. More than 75% of PI3K inhibitors (32/42 agents), including the selective PI3K alpha and PI3K beta inhibitors, form a highly connected cluster at a 0.7 COMPARE correlation. The heat map view showed that >50% of the non-connected PI3K outliers were inactive in the NCI60 assay. The mTOR inhibitors (12/20) form a connected cluster at 0.7 COMPARE correlation, with half of the non-connected mTOR singletons representative of the rapamycin class of inhibitors. The BRAF/MEK/ERK pathway compounds (37) form a highly connected correlation cluster (13/15 BRAF, 14/15 MEK, 8/9 ERK inhibitors) at a 0.75 COMPARE correlation. The NCI60 heat maps for BRAF inhibitors show a consistent pattern of the melanoma cell lines and 2 of the colon cancer lines (COLO 205, HT29). The ERK inhibitors display sensitivity patterns similar to the BRAF agents with additional activity observed against a leukemia (HL-60), ovarian (OVCAR-5) and renal (A498) cell line and 3 other colon cell lines (HCC-298, HCT-116, SW-620). This data analysis resource will be available to the public (https://ioa.cancer.gov). NCI60 compound suppliers can incorporate their test compound(s) data to use the interactive visualization tools with AOD and IOA agents. This project was funded in part with federal funds from the NCI, NIH, under Contract # 75N91019D00024/75N91020F00003.

#4885

APR-246 cytotoxic effects are TP53 independent in endometrial cancer cell lines

Camilla Yu, Aaron Petty, Roberto Vargas. *Cleveland Clinic, Cleveland, OH*

Background**:** The majority (80%) of endometrial cancer (EC) related mortality is due to high-grade tumor histology, which harbor high rates of TP53 mutations. APR-246 is a small-molecule drug designed to restore WT p53 signaling in TP53-mutant cancers and has yet to be explored in EC. We aimed to test the cytotoxic potential for APR-246 in EC and its downstream impact.

Methods: Using 3 parental EC cell lines with differing TP53 statuses, JHUEM2 (WT), Hec108 (hetero P151H), and Hec1B (R248Q), we generated dose-response curves for APR-246. Cells were treated for 24 hours and viability assessed with CellTiter-Glo after 9 days. To assess for mutation specific effect, we generated dose-response curves using a WT non-targeting control (NTC), CRISPR/Cas9 KO of TP53, and five KO cell lines complemented with 5 common TP53 mutations (R248Q, R248W, R273C, R273H, Y220C). Western blot analysis was performed to assess for p53, p21, PUMA, GADD45, and NOXA using whole-cell lysates, after treatment with 20μM of APR-246 for 24 hours. To further evaluate for a time-dependent effect, 2 representative variants (R248Q and R273C) after 6 and 24 hours of incubation with 50μM APR-246 and 10μM of Nutlin-3.
Results: APR-246 demonstrated a negative, dose-dependent effect on cell viability in all EC cell lines. IC50s for JHUEM2, Hec108, and Hec1B were 2.5μM, 4.3μM, and 4.5μM respectively. For NTC, the IC50 was (1.7μM), while TP53-KO (7.5μM) demonstrated similar IC50 values to the variants (6.5-11.9μM). Two variants (Y220C and R248W), had significantly (<0.001 and <0.01 respectively) higher IC50 values (11.9 and 9.1 μM respectively). In Western blot analysis, no p53 downstream signaling via p21, GADD45, PUMA, and NOXA was observed for any variants.
Conclusions: Our results demonstrate that APR-246's cytotoxic effects in EC seem to be p53-independent. Potential mechanisms for the anti-neoplastic effects of APR-246 include activity targeting antioxidant pathways demonstrated in other solid tumors and provides an area for further investigation in TP53mut EC.

#4886

PARP-1 and γ-GCS inhibitors enhance platinum sensitivity in ovarian cancer

Luxmi Devi[1], Ashok Sharma[2], Lalit Kumar[1]. *[1]Medical Oncology, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[2]Biochemistry, All India Institute of Medical Sciences (AIIMS), New Delhi, India*

Background: Ovarian cancer is the most important cause of gynaecological cancer-related mortality globally. Approximately 80% of patients are diagnosed with advanced stage (FIGO stage III-IV) of ovarian cancer. The standard treatment approach for advanced EOC is primary debulking

surgery followed by adjuvant chemotherapy using taxanes plus platinum. Resistance to platinum based chemo remains a key reason for treatment failure in advanced epithelial ovarian cancer (EOC). Therapeutic efficacy of Poly [ADP-ribose] polymerase 1 (PARP1) and Gamma-glutamyl cysteine Synthetase (γ-GCS)inhibitors in ovarian cancer remains undefined, either as a single agent or in combination with cisplatin.
Material and Methods: We determined the combined effect of PJ34 (PARP1 inhibitor) and BSO (Buthionine-sulfoximine- (γ-GCS inhibitor) with cisplatin in ovarian cancer cell lines (OVSAHO, KURAMOCHI, and IGROV1) by MTT assay. PARP1 and GCS levels were analyzed by western blotting. We employed flow cytometry for cell cycle analysis as well as for apoptosis studies. Analysis was done using Graph Pad Prism-6. Results were considered to be statistically significant when p value was < 0.05.
Results and Conclusion: Combination of cisplatin with PJ34 and BSO augmented cisplatin toxicity in vitro by decreasing cell proliferation and enhancing cell cycle block and cell death when compared with either single agent. A significant cell death ($p= <0.05$) was observed with the combination of cisplatin, BSO and PJ34.
Conclusion: In conclusion, our study provide experimental evidence on the combined effect of PARP-1 and GCS inhibition on CDDP-induced cytotoxicity in epithelial ovarian cancer cells. We propose that PARP-1and BSO inhibitors can be combined with cytotoxic chemotherapeutic agents such as CDDP to enhance the cytotoxicity of chemotherapeutic agents and inhibit key signalling pathways involved in cell proliferation and apoptosis. Future comprehensive studies are needed to demonstrate further validation of above combination.
Keywords: Ovarian Cancer, cisplatin, PARP-1, PJ34, γ -GCS, β-actin, Glutathione.

Propidium Iodide(PI).

Anticancer Approaches: Antibody-Drug Conjugates, Epigenetics, and Tumor Environment

#4890

A novel topoisomerase I inhibitor antibody-drug conjugate targeting CEACAM5 has potent anti-tumor activity in colorectal cancer models

Yves Baudat[1], Haley Neff-LaFord[2], Celine Nicolazzi[1], Dave Meyer[2], Johann Petur Sigurjonsson[2], Ryan Lyski[2], Valeria Fantin[3], Marie-Priscille Brun[1], Marielle Chiron[1], Stephanie Decary[1]. *[1]Sanofi R&D, Vitry-Sur-Seine, France,[2]Seagen, Bothell, WA,[3]Sanofi R&D, Cambridge, MA*

Carcinoembryonic antigen cell adhesion molecule 5, CEACAM5, is a glycosylphosphatidylinositol-anchored glycoprotein highly expressed on the cell surface of several epithelial tumors. CEACAM5 is expressed in virtually all colorectal cancer, ~90% of which to high levels while normal tissue expression is limited. The high prevalence of CEACAM5 expression in colorectal tumor cells prompted us to develop an investigational anti-CEACAM5 antibody-drug conjugate (ADC) for the potential treatment of CRC patients. We developed a novel ADC, by conjugating an anti-CEACAM5 antibody with a drug linker to a topoisomerase I inhibitor payload. The anti-CEACAM5 antibody was chosen based on its high selectivity for CEACAM5 and its potential to direct cytotoxic payloads to tumor. The topoisomerase I payload was optimized for potency, reduced PGP efflux and enhanced bystander activity. The novel anti-CEACAM5 topoisomerase I inhibitor ADC binds to CEACAM5 at nanomolar (nM) concentrations and kills CEACAM5-positive colon tumor cells with varying levels of CEACAM5 at sub-nM concentrations with no or very low cytotoxicity towards CEACAM5-negative cells. Mechanistically, the potent anti-tumor activity of the ADC is both mediated by direct internalization, processing, and release of the cytotoxic payload within the CEACAM5-expressing tumor cells, and by a bystander effect mediated by diffusion of the payload to the neighboring CEACAM5-negative tumor cells. The novel anti-CEACAM5 topoisomerase I inhibitor ADC is well tolerated in rats after repeated administration of 30 and 50 mg/kg/day, Q1W x 4. *In vivo* efficacy of this ADC at 1, 3 and 10 mg/kg (single administration) was evaluated in four CRC patient-derived xenografts (PDXs) models. The conjugate elicits potent and specific and dose dependent antitumor activity with complete regression (CR) at 10 mg/kg in the 4 models. This robust anti-tumor activity was further confirmed in a Single Mouse Trial of 16

CRC PDX models, consisting in the use of one animal per PDX model per treatment arm and for which the evaluation of efficacy was based on the criteria RECIST (Response Evaluation Criteria In Solid Tumors) used in clinic. In these criteria, the overall response rate includes complete response (CR) and partial response (PR) and the a disease control rate includes CR , PR and stable disease (SD). The ADC induces a disease control rate of 95% and an overall response rate of 50% following a single dose of 10 mg/kg. The outstanding anti-tumor activity across CRC PDX models and its favorable safety profile in rats support further evaluation of this investigational novel topoisomerase I ADC in CRC patients.

Ifinatamab deruxtecan (I-DXd), a novel B7-H3-targeting antibody-drug conjugate, demonstrates efficient payload delivery into tumor through target-dependent internalization

Len Katsumata[1], Tsuneo Deguchi[1], Jun Hasegawa[1], Michiko Yamato[1], Yumi Nishiya[1], Akiko Watanabe[1], Tomoyo Honda[1], Megumi Minami[2], Naomi Kasanuki[2], Takanori Maejima[1], Sumie Muramatsu[1], Monika Herrmann[3], Nina Schulte[3], Gernot Polier[3], Xuya Wang[4], Takanori Yoshida[2], Nanae Izumi[4], Xiaozhong Qian[4], Toshinori Agatsuma[1], Kenji Nakamaru[1].
[1]Daiichi Sankyo Co., Ltd., Tokyo, Japan,[2]Daiichi Sankyo RD Novare Co., Ltd., Tokyo, Japan,[3]Daiichi Sankyo Europe GmbH, Munich, Germany,[4]Daiichi Sankyo Inc., Basking Ridge, NJ

Ifinatamab deruxtecan (I-DXd; DS-7300) is a novel ADC which consists of an anti-B7-H3 antibody linked with a DNA topoisomerase I inhibiting anti-tumor agent, DXd. I-DXd has demonstrated potent anti-tumor activity in B7-H3-positive preclinical cancer models and showed early signs of promising clinical efficacy in patients with heavily pretreated, advanced solid tumors. ADCs are postulated to exert cytotoxicity specifically in tumors that express the target antigen via target-specific uptake of the compound. Accordingly, effective action of an ADC depends on multiple dynamic steps including antigen-specific binding, internalization, trafficking to lysosomes, linker cleavage and payload release, as well as payload potency. The goal of this research was to characterize I-DXd molecular dynamics in preclinical tumor cell models by investigating the

relationship among target expression and dynamics, its translocation to lysosomes, lysosomal enzyme-mediated linker cleavage, and payload release after I-DXd treatment. As a result, I-DXd demonstrated target dependent internalization, efficient trafficking to lysosomes, and subsequent payload release in the studied tumor cell lines. Payload release levels generally correlated with target expression in vitro using a panel of cell lines with varying levels of B7-H3 expression. Also, in cell-line derived xenograft models, tumor tissue payload concentration corresponded to I-DXd binding at the cell membrane. These results suggest the importance of cell surface B7-H3 expression and ADC dynamics that lead to payload release in target expressing tumors to exert anti-tumor activity in non-clinical model. In addition to target-dependent uptake in tumor cells, it was observed in viable human lung tumor slices that B7-H3 was also expressed in several non-tumor cells including cancer-associated fibroblasts, endothelial cells, and macrophages in the tumor microenvironment and I-DXd was shown to be internalized in these B7-H3-expressing non-tumor cells. In summary, this pre-clinical study characterizes the relationship between B7-H3 expression in the tumor microenvironment and I-DXd molecular dynamics. Our results support developing I-DXd as a targeted therapy against advanced solid tumors known to overexpress B7-H3.

#4892

MMAE drives immunomodulatory changes in a preclinical xenograft model that are distinct from other clinical-stage ADC payloads

Michelle Ulrich, Kerry Klussman, John J. Gosink, Sean Allred, Kelly Hensley, Piper M. Treuting, Nikhil J. Parekh, Elizabeth E. Gray, Shyra J. Gardai. *Seagen, Bothell, WA*

Monomethyl auristatin E (MMAE), the payload delivered by vedotin ADCs, exerts its cytotoxic effects via microtubule disruption and induction of ER stress, leading to apoptosis and tumor cell death. In addition, MMAE also has the ability to induce immunogenic cell death (ICD) and immune modulation in the tumor microenvironment (TME) (Liu, 2020; Gray, 2020). Other clinical-stage and approved ADCs incorporate payloads that also cause microtubule disruption (DM1, DM4), or that drive DNA damage through topoisomerase I inhibition (exatecan) as the primary mechanism of action (MOA). While ADCs with different linker payloads produce clinical

benefit, their long-term impact on survival and how they pair with PD(L)1 agents may differ based on their ability to elicit immune modulation. In this study we have investigated how these payloads compare to MMAE in their ability to drive immune changes in the TME and describe how these changes could support anti-tumor immunity and improve outcomes in the clinic.Building upon an initial in vitro assessment in which we observed superior induction of ICD markers and underlying ER stress with an MMAE ADC, we utilized a B7H4-expressing MDA-MB-468 xenograft model of triple-negative breast cancer to further characterize the ICD properties of ADC payloads. Tumor-bearing mice were treated with a single dose of B7H4-targeted antibody conjugated to either MMAE, DM1, DM4 or exatecan. Tumors were harvested seven days after treatment and processed for immunohistochemistry (IHC) to assess changes in immune cell infiltration and analyzed by RNA-seq to determine alterations in gene expression. Payload-driven anti-tumor activity was observed with all ADC treatments, each leading to a similar reduction in tumor volume compared to vehicle or unconjugated antibody. IHC staining of tumor sections for F4/80, a mouse macrophage marker, revealed that of the microtubule-disrupting agents, only MMAE significantly increased F4/80+ macrophage infiltration in both the tumor nests and stroma. Increased F4/80+ macrophages in tumor nests and stroma was also observed as a result of B7H4-exatecan ADC treatment. RNA-seq analysis revealed a unique profile for the MMAE conjugate, with an increase in human transcripts encoding cytokine and type I interferon response genes. In summary, the anti-tumor activity of the B7H4-MMAE ADC resulted in recruitment of mouse innate immune cells to the xenograft tumors. Importantly, immune response genes related to ICD were increased following B7H4-MMAE treatment compared to DM1, DM4, and exatecan conjugates. Together, these data suggest that treatment with vedotin ADCs results in robust immunomodulatory changes in vivo that are distinct from other clinical ADC payloads.

Evaluation of bystander antitumor effect of Dato-DXd in TROP2 (+) and TROP2 (-) lung cell lines admixed tumor xenograft mouse models

Satoru Yasuda[1], Takanori Maejima[1], Tadashi Toki[1], Tsuyoshi Karibe[1], Daisuke Okajima[1], Penny Phillips[2]. *[1]Daiichi Sankyo Co., Ltd., Tokyo,*

Japan,[2]Daiichi Sankyo, Inc., Basking Ridge, NJ

Background: Datopotamab deruxtecan (Dato-DXd) is an antibody-drug conjugate (ADC) consisting of a humanized anti-TROP2 IgG1 monoclonal antibody covalently linked to a highly potent topoisomerase I inhibitor payload (DXd) via a stable, tumor-selective, tetrapeptide-based cleavable linker (Nakada T. et al. Bioorg Med Chem Lett., 2016). Dato-DXd demonstrated encouraging efficacy in clinical studies in TROP2 expressing tumors, including NSCLC and TNBC (NCT03401385). Clinical efficacy of Dato-DXd in heterogeneous tumors is hypothesized to be derived not only via effective selective delivery of DXd to TROP2 (+) tumor cells but also DXd diffusion from TROP2 (+) tumor cells to nearby TROP2 (-) tumor cells due to high membrane permeability of the DXd payload, an effect called the bystander antitumor effect. In this preclinical study, the bystander antitumor effect was tested by establishing tumor xenograft mouse models containing admixed TROP2 (+) and TROP2 (-) lung cell lines. The antitumor activity of Dato-DXd was tested in these models to demonstrate the bystander antitumor effect of Dato-DXd.
Materials and Methods: EBC-1 cells and NCI-H526 cells or Calu-6 cells were used as models of TROP2 (+) cells and TROP2 (-) cells, respectively. TROP2 (+) cells and TROP2 (-) cells were mixed in various ratios and inoculated subcutaneously in mice to establish heterogeneous xenograft tumor models with various levels of TROP2 expression. Tumor growth inhibition in each model was evaluated by tumor volume after Dato-DXd or control-ADC administration. Immunohistochemistry (IHC) of DXd and TROP2 were performed in Dato-DXd treated tumors to analyze distribution in TROP2 (+) and (-) tumor cells. Tumor cells that responded to Dato-DXd treatment were identified by IHC assay of γH2AX (an indicator of DNA damage).
Results: TROP2 expression analysis showed that various TROP2 positivity tumor models were established by inoculating various ratios of admixed EBC-1 cells with NCI-H526 cells or Calu-6 cells. Dato-DXd did not inhibit growth of tumors consisting of only TROP2 (-) cells, as expected. In contrast, Dato-DXd showed strong tumor growth inhibition effect on all tumors in which TROP2 (+) cells were inoculated in various levels with TROP2 (-) cells. DXd-IHC analysis showed that Dato-DXd distributed to only TROP2 (+) tumor cells in admixed tumors, however, an increase of

γH2AX was observed not only in TROP2 (+) tumor cells but also TROP2 (-) tumor cells, suggesting TROP2 (-) tumor cells responded to DXd generated and distributed from Dato-DXd bound to TROP2 (+) tumor cells. Conclusion: Dato-DXd is effective not only in TROP2 (+) tumor cells but also TROP2 (-) tumor cells adjacent to TROP2 (+) tumor cells, thereby demonstrating the bystander antitumor effect of Dato-DXd. This property suggests Dato-DXd should be active in the clinical setting even given potential heterogeneity of TROP2 expression.

The anti-ROR1 ADC STRO-003 demonstrates immune-modulating properties that may enhance checkpoint blockade

Alice Yam, Helena Kiefel, Andrew McGeehan, Robert Yuan, Sihong Zhou, Dayson Moreira, Indrani Dutta, Xiaofan Li, Cuong Tran, Gang Yin, Kristin Bedard, Trevor Hallam. *Sutro Biopharma, Inc., South San Francisco, CA*

There is growing evidence that tumor-targeted cytotoxins can also enhance anti-tumor immunity by inducing immunogenic cell death (ICD) in tumor cells and promoting recruitment of immune effector cells. We sought to investigate the immune stimulating potential of STRO-003, an antibody drug conjugate (ADC) composed of an anti-Receptor Orphan Receptor Kinase 1 (ROR1) antibody conjugated to a topoisomerase I targeted exatecan warhead via a cleavable linker. ROR1 is an oncofetal transmembrane receptor with restricted expression in normal tissues. Its overexpression in several cancer indications has been described, including in ovarian, non-small cell lung carcinoma (NSCLC), triple negative breast cancer (TNBC), and hematological malignancies, thus making it an ideal ADC target. We have previously demonstrated potent in vivo activity of STRO-003 in a panel of ROR1-expressing lung cancer patient-derived xenograft (PDX) models. Here we show that the exatecan warhead, SC3386, and STRO-003 ADC induced ICD in vitro as evidenced by presentation of cell-surface calreticulin and release of HMGB1. Consistent with this finding, STRO-003-treated cells elicited monocyte activation in a PBMC co-culture assay. To determine if these immunogenic properties could improve therapeutic efficacy, we evaluated STRO-003 in combination with an immune checkpoint inhibitor in a mouse syngeneic model expressing ROR1. We have demonstrated that STRO-003 in

combination with checkpoint inhibition significantly enhances efficacy in a syngeneic mouse model and supports durable anti-tumor immunity. Follow-up vaccination studies were performed to further explore the significance of STRO-003-induced ICD and protective immunity *in vivo*. These results demonstrate that tumor cells pre-treated with STRO-003 or SC3386 undergo potent immunogenic cell damage which can, in turn, mount protective immunity *in vivo*.

Introduction of a platform for preclinical profiling of drug conjugates: a case study with sacituzumab govitecan

Vincent Vuaroqueaux[1], Nadine Obier[2], Anne-Lise Peille[1], Daniel Feger[2], Katharina Schaich[2], Thomas Metz[1], Sebastian Dempe[2], Heinz-Herbert Fiebig[1], Jan Erik Ehlert[2]. *[1]4HF Biotec GmbH, Freiburg, Germany,[2]Reaction Biology Europe GmbH, Freiburg, Germany*

Drug-conjugates are an emerging class of anticancer agents combining the cytotoxic activity of highly potent chemotherapeutic agents with the target specificity of an antibody, a small molecule or a peptide ligand directed against a cancer-associated protein. With nearly half a century of development, profound advancements have been made in the development of these therapeutics. The most advanced are antibody-drug conjugates (ADCs) with currently >100 in development and 11 approved by the FDA. To facilitate preclinical evaluation of novel drug conjugates, Reaction Biology and 4HF Biotec have developed a dedicated platform allowing specific *in vitro* and *in silico* analyses for this class of therapeutics. The platform is intended to provide information on the potency of the drug conjugate over the corresponding stand-alone cytotoxin, the cancer entities to be treated, the target engagement and the determinant(s) of cancer cell sensitivity. Here, we present our platform to refine antitumor potential of Sacituzumab govitecan (ScG), a recently approved TROP-2 targeted ADC used for the treatment of triple-negative breast cancer. First, we used the ProLiFiler™ (Reaction Biology), a cell proliferation and survival assay with 140 human cancer cell lines, to establish the antitumor profile of ScG, its payload SN-38 and three other cytotoxins (camptothecin, MMAE and mertansine) to validate the results of our assay. The IC50 obtained for the cytotoxins were next validated using the MoAFinder (4HF Biotec), a tool

derived from the NIH COMPARE algorithm that ranks drugs based on the similarity of their growth inhibitory profiles. The analysis confirmed that SN-38 and camptothecin antitumor profiles, as established with the ProLiFiler, correlated best with other topoisomerase-1 inhibitors from our database of more than 1,000 compounds. Mertansine and MMAE correlated best with tubulin inhibitors and were more potent than camptothecin and SN-38. Overall, the response to these cytotoxins was stronger in cell lines from hyperproliferative cancers such as hematological malignancies than in those from solid cancers. Next, by using OMICS data (internal and publicly available), qPCR and flow cytometry connected to drug sensitivity profiles, we will present a differential biomarker screen of ScG vs. SN-38 to identify molecular determinants of sensitivity toward the ADC and its cytotoxin. We will address the expression level of TROP2 and its predictivity for tumor cell sensitivity, screen for predictors of SN-38 response and investigate possible off-target effects in cell lines sensitive to ScG but lacking TROP2 expression. Overall, the study demonstrates the potential of our platform to investigate drug conjugates. The comparative profiling of ScG and its payload allows to identify candidate cancer entities for ScG treatment and to improve patient enrollment into clinical trials using biomarkers.

NF1 (neurofibromatosis 1) controls microtubule dynamics and dictates sensitivity to maytansinoids

Bruno A. Duso, Eleonora Messuti, Emanuele Bonetti, Giulia Tini, Alessia Castiglioni, Giuseppe Ciossani, Silvia Monzani, Chiara Soriani, Simona Rodighiero, Luigi Scietti, Costantino Jemos, Luca Mazzarella. *IEO - European Institute of Oncology, Milan, Italy*

The tumor suppressor NF1 is classically considered a negative RAS regulator, but sparse evidence suggests additional RAS-independent roles. Early studies suggested an interaction with tubulin, which remains poorly characterized to date but may be of particular therapeutic interest as NF1 is somatically mutated across multiple tumor types. We showed that multiple CRISPR-Cas9-engineeerd NF1 KO HER2+ breast cancer cells (BT-474, SK-BR3, HCC1954) become exquisitely sensitive to the Antibody-Drug Conjugate (ADC) Trastuzumab emtansine (T-DM1); we here investigate the underlying mechanism.TDM1 hypersensitivy was specific to the maytansin

microtubule-targeting payload, since it was i) replicated by the naked payload but not the naked antibody; ii) absent with other ADCs (T-DxD); iii) not accompanied by increased TDM1 uptake; iv) associated with increased tubulin-maytansin binding in KO cells, as per Cellular Thermal Shift Assay. The mechanism is likely RAS-independent, as KRAS G12V-overexpression did not alter TDM1 sensitivity. RNAseq revealed that KO cells deregulated genes associated with microtubular dynamics and G2-M transition more strongly upon TDM1-treatement. Multiple KO cells investigated by static and live imaging exhibited marked signs of altered mitosis, with longer G2/M, supernumerary centrosomes, chromosome misalignment and frequent aneuploidy, which could also be inferred in multiple public sequencing datasets (TCGA, MSK IMPACT, AACR GENIE). Based on this, we explored NF1 role on microtubule dynamics. We found several lines of evidence for a direct and mitosis-selective interaction between NF1 and tubulin: i) in Immunofluorescence (IF), NF1 was upregulated in mitosis and colocalized with the mitotic spindle; ii) NF1 co-Immunoprecipitated with tubulin in mitosis-enriched but not asynchronous cells; iii) purified NF1 co-eluted with tubulin in size-selection chromatography; iv) in silico modeling with AlphaFold2 predicted an interaction between NF1 central domains and the alpha-beta tubulin dimer. Crucially, KO cells exhibited severe microtubule hypodynamism in cold-induced depolymerization-repolymerization assays, replicated in multiple cell types and accompanied by imbalanced levels of plus/minus-end microtubule-associated proteins. By IF on cocultured WT/KO live cells, KO cells showed significantly higher GTP-tubulin, known to cause microtubular hyperstability, suggesting the intriguing possibility that NF1 may directly regulate tubulin intrinsic GTP-hydrolyzing activity, similar to its role on RAS. In conclusion, we provide extensive mechanistic evidence for a direct and previously underappreciated role of NF1 in microtubular dynamics, which reshapes our understanding of its tumor-suppressive activity and provides a rationale for pharmacological targeting of NF1-mutated tumors.
