targets using TSA-based fluorescent readouts and is compatible with the new fluorescent Vivid™ dyes . Fixed, fresh frozen samples and formalin fixed paraffin embedded (FFPE) tissues are supported by manual and automated workflows using the Leica Bond Rx system. We have leveraged this technology to investigate spatial expression profile of miRNA and associated RNA targets across different tissue types and applications. We can also combine protein detection using a target antibody to visualize cell-type specific markers. This assay was used to demonstrate expression of miRNAs and target genes implicated in tumor initiation, progression, and angiogenesis. Expression of miR-205 , associated tumor target genes such as *PanCK*, *PTEN* and tumor suppressor *TP53* was visualized in head and neck cancer tumors. Downregulation of tumor-suppressor, *TP53* resulted in upregulation of miR-205 which downregulates *PTEN* expression. *Pan-CK* stained the tumor region in the tissue. Similarly, miR-155 expression was observed in niche areas within breast cancer, head and neck cancer and cervical cancer tumors. Expression of miR-155 demonstrated correlation with high *VEGF* expression suggesting its role in angiogenesis. This novel platform will enable researchers to visualize regulatory RNA simultaneously with target RNAs, cell-type and morphology markers in intact cells/tissues with single cell resolution. This technology can provide meaningful insights into disease pathology driven by miRNAs as well as assess biodistribution and efficacy of oligonucleotide therapeutics.

Identification of hypoxia regulated long noncoding RNA, MARVEL in kidney cancer

Ranju Nair[1], Joseph Samuel[2], Philip Marsden[3]. *[1]Laboratory Medicine and Pathobiology, University of Toronto and St. Michael's Hospital, Toronto, ON, Canada,[2]Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada,[3]Laboratory Medicine and Pathobiology, and Department of Nephrology, University of Toronto and St. Michael's Hospital, Toronto, ON, Canada*

Background: The kidney is a highly vascular organ, receiving about 1/4th of the total cardiac output. Not surprisingly, kidney cancer is a highly vascular malignancy. According to WHO, worldwide, there are over 400,000 new cases and over 170,000 deaths yearly due to kidney cancer. The aggressive

subtype of kidney cancer, clear cell renal carcinoma (ccRCC), represents 80% of all cases. The Von Hippel Lindau (VHL) gene, a tumor suppressor, is functionally inactive in 90% of ccRCC, which activates the oxygen-sensing machinery responsible for inducing angiogenesis. Long noncoding RNAs (lncRNAs) are RNA molecules of 200 nucleotides and longer in size. LncRNAs can be highly tissue-specific, defining tumor growth and metastasis, hence potential biomarkers for clinical staging, disease progression, and unique therapeutic targets. We hypothesize that the functional inactivation of VHL induces robust changes in the lncRNA transcription during ccRCC tumorigenesis and vascularization.
Methodology: To understand the pro-angiogenic RNA signals in ccRCC induced by functional VHL inactivation, human 786-O and RCC4 cell lines were used. Microarray analysis comparing the reconstituted functional and non-functional VHL in these tumor cells then defined mRNA and lncRNAs that are VHL- and HIF-dependent. These lncRNAs were further validated in ccRCC patients. 5' RACE (Rapid Amplification of cDNA ends), RT-qPCR, and cellular compartmentalization were used to characterize the most abundant lncRNA in ccRCC.
Results: Microarray-based transcriptomic ccRCC from VHL-deficient cell lines and patients divulged a novel lncRNA- "MARVEL" (Mortality Associated in RCC, VHL-deficient Expressed Long Noncoding RNA). Analysis in The Atlas of Noncoding RNAs in Cancer (TANRIC) database for ccRCC patients with 447 tumor cases and 67 normal kidney tissues revealed MARVEL predicts overall patient survival by log-rank regression analysis with Cox $p < 0.005$ and correlated with a higher stage of the disease by the decision tree analysis. MARVEL is VHL-, hypoxia-, and HIF- dependent. ReMap, ChIP-seq data on HIF1 and HIF2 confirmed binding within 1 Kb upstream of the start site of MARVEL. 5' RACE characterized three transcriptional start sites and three spliced variants. The most abundant transcript of MARVEL has seven exons with six introns that follow the GT-AG rule of splicing. Further, CRISPRi and CRISPRa led loss- and gain-of-function studies on MARVEL are ongoing both *in vitro* and *in vivo* to characterize its role in tumorigenicity and angiogenesis.
Significance: This study defines tumor property of hypoxia and a functional outcome of survival in patients to define the lncRNAs. We identified a novel lncRNA- MARVEL that can be a potential biomarker to predict advanced tumor stage and overall survival in renal cell carcinoma. The

functional characterization of MARVEL can reveal its therapeutic potential in ccRCC.

MicroRNA-inducible CRISPR/Cas9 for cell type-specific genome regulation in cancer

Seung Ja Oh[1], Cheol-Hee Shin[2], Ji Min Lee[3], Juyong Lee[4], Su Chan Park[3]. *[1]Kyung Hee University, Yongin-si, Korea, Republic of,[2]Korea Institute of Science and Technology, Seoul, Korea, Republic of,[3]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[4]Seoul National University, Seoul, Korea, Republic of*

MicroRNA-dependent mRNA decay plays an important role in gene silencing by facilitating posttranscriptional and translational repression. Inspired by this intrinsic nature of microRNA-mediated mRNA cleavage, here, we describe a microRNA-targeting mRNA as a switch platform called mRNA bridge mimetics to regulate the translocation of proteins. We applied the mRNA bridge mimetics platform to Cas9 protein to confer it the ability to translocate into the nucleus via cleavage of the nuclear export signal called CRISPR Self Check-In. This system performed programmed gene editing in vitro and in vivo. Combinatorial treatment with cisplatin and miR-21-EZH2 axis-targeting CRISPR Self Check-In improved sensitivity to chemotherapeutic drugs in vivo. Using the endogenous microRNA mediated mRNA decay mechanism, our platform is able to remodel a cell's natural biology to allow the entry of precise drugs into the nucleus, devoid of non-specific translocation. The mRNA bridge mimetics strategy is promising for applications in which the reaction must be controlled via intracellular stimuli and modulates Cas9 proteins to ensure safe genome modification in diseased conditions.

Genome-Scale CRISPRa and CRISPRi screening for lncRNA drivers of prostate cancer progression

Simone Weiss[1], Allegra Lord[2], Bernhard Schmierer[2], Anne B. Rovsing[3], Emil A. Thomsen[3], Jacob G. Mikkelsen[3], Benedicte Ulhøi[4], Jakob S. Pedersen[1], Michael Borre[5], Karina D. Sørensen[1]. *[1]Department of Molecular*

Medicine, Aarhus University Hospital, Aarhus, Denmark,[2]CRISPR Functional Genomics, SciLifeLab and Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden,[3]Department of Biomedicine, Aarhus University, Aarhus, Denmark,[4]Department of Pathology, Aarhus University Hospital, Aarhus, Denmark,[5]Department of Urology, Aarhus University Hospital, Aarhus, Denmark

Background: Overtreatment of indolent prostate cancer (PC) and delayed treatment of aggressive PC is common due to suboptimal risk stratification tools, thus warranting identification of novel prognostic biomarkers. Although a few long non-coding RNAs (lncRNAs) with biomarker potential in PC are known, the majority of lncRNAs remain uncharacterized. Here, we aimed to identify novel lncRNA biomarker candidates. We hypothesized that strong candidates would have a functional role in driving PC progression in addition to their expression being linked to PC prognosis, and we therefore combined functional CRISPR screening with lncRNA expression profiling of PC patients.
Methods: Total RNA sequencing (RNAseq) data was generated from 31 adjacent normal (AN) and 125 tumor samples from 141 clinically localized PC patients, along with 17 primary tumor samples from metastatic PC patients. Raw reads were mapped to the hg38 reference genome and kallisto was used for quantification. CRISPR activating (CRISPRa) and CRISPR interference (CRISPRi) screens were performed in the LNCaP PC cell line stably expressing either dCas9-VP64 or dCas9-KRAB, respectively. Cells were transduced in duplicate with custom single guide RNA (sgRNA) libraries targeting 20,306 and 20,474 lncRNA transcripts of interest using 72,281 and 72,360 sgRNAs (CRISPRa and CRISPRi, respectively). Cells were harvested and DNA extracted from an early (day 4 post-transduction) and a late (day 17-21) timepoint and next-generation sequenced. MAGeCK was used for data analysis.
Results: To identify lncRNAs with biomarker potential in PC, we analyzed lncRNA expression in total RNAseq data from 158 PC patients. Using differential expression analysis and cox regression analysis with biochemical recurrence as endpoint, we identified 6,928 lncRNAs with biomarker potential. To investigate if any of these had a functional role in driving PC progression, we performed CRISPRa and CRISPRi screens to assess how lncRNA activation/inhibition affected PC cell proliferation.

Based on the screens, lncRNA candidates with the most prominent phenotypes (normalized read count difference >200 and log-fold change >33% between the early and late timepoint for ≥3 sgRNAs in both replicates) were selected for individual validation. This identified 7 (CRISPRa) and 8 (CRISPRi) negative hits (decreased cell proliferation) along with 5 (CRISPRa) and 2 (CRISPRi) positive hits (increased cell proliferation). Individually activated/inhibited LNCaP cell lines have been established for the 22 candidate lncRNAs and proliferation assays are performed to validate their functional role in PC progression.
Conclusion: We identified numerous lncRNAs with biomarker potential and a possible driver role in PC progression.

Evaluation of anti-cancer efficacy of lipid nanoparticles containing siRNA against HPV16 E6 and E7 combined with cisplatin in xenograft model of cervical cancer

Sung Wan Kang[1], Shin-Wha Lee[2], Ji-young Lee[1], Ok Ju Kang[2], Hyejeong Kim[3], Yisak Kim[4], Yong-Man Kim[2]. *[1]Asan Institute for Life Science, Seoul, Korea, Republic of,[2]Obstetrics and Gynecology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[3]EnhancedBio Inc., Seoul, Korea, Republic of,[4]Enhancedbio Inc., Seoul, Korea, Republic of*

Background**:** High-risk human papillomavirus (HPV) type 16 is the major etiological agent found in more than 60% of patients with cervical cancer and associated with cancer development and progression. Persistent expression HPV E6 and E7 oncoproteins are essential for the initiation and maintenance of cervical cancer. The therapeutic approaches targeting HPV E6 and E7 have been proved to be highly efficient in killing malignant cells. The suppression of HPV 16 E6/E7 expression by the short interfering RNA (siRNA) was more effective in combination therapy with cisplatin (CDDP) for cervical cancer. ENB101-LNP is an ionizable lipid nanoparticles (LNPs) encapsulating siRNA against E6/E7 of HPV 16 for delivery to the tumor cells.
Methods: To investigate the anticancer efficacy and mechanism of ENB101-LNP combined with cisplatin in cervical cancer; the xenograft model was generated by the injection of CaSki cells subcutaneously into

BALB/c nude mice. Mice were randomly divided into six groups: 1) blank control; 2) 1mg/kg ENB101-LNP; 3) 3mg/kg ENB101-LNP; 4) CDDP; 5) 1mg/kg ENB101-LNP-CDDP; 6) 3mg/kg ENB101-LNP-CDDP. ENB101-LNP was treated with intravenous injection three times weekly for 3 weeks and CDDP was treated with IP injection once a week for 3 weeks. Tumor growth curves were plotted to calculate the tumor inhibition rate. Mice were sacrificed one week after the last treatment and the tumor tissues were investigated using histopathology, immunohistochemical staining and western blotting.
Results: Compared with the control and the other treatment groups, the tumor growth was significantly inhibited ($P < 0.05$). The tumor inhibition rate was 29.7% in 1mg/kg ENB101-LNP group, 29.6% in 3mg/kg ENB101-LNP group, 34.0% in CDDP group, 47.0% in 1mg/kg ENB101-LNP-CDDP group. At the dose of 3mg ENB101-LNP/kg combined with CDDP exhibited superior antitumor efficacy, the tumor inhibition rate was 68.8%. The successful ENB101-LNP mediated knockdown (with up to 80%) of HPV16 E6/E7 in tumors of both 1mg/kg and 3mg/kg groups was confirmed by RT-PCR. The ENB101-LNP increased p53 and p21 expression in tumors compared to control and CDDP alone groups and combination treatment with CDDP showed decreased expression of PD-L1 expression compared to CDDP alone group. The treatment of ENB101-LNP and combination with CDDP showed significant increase in apoptotic cells compared to control and single-agent groups respectively.
Conclusions: The ENB101-LNP inhibiting E6 and E7 of HPV 16 in combination with CDDP showed promising anticancer activity in the cervical cancer cells xenograft mouse model.

Reciprocal regulation between DNA methyl transferase 3A and 3B and microRNAs 299-3p and -30e are the causal factors for down regulation of microRNAs targeting androgen receptors in prostate cancer
Kavya Ganapathy[1], Christian Harrs[1], Samuel Harris[1], Ayman Khatib[1], Jong Park[2], Ratna Chakrabarti[1]. *[1]University of Central Florida, Orlando, FL,[2]Moffitt Cancer Center, Tampa, FL*

Promoter hypermethylation is one of the events that downregulate microRNAs (miRNA), resulting in differential expression of genes and

progression of cancer. Previously we showed down-regulation of two miRNAs, miR-299-3p and -30e that target androgen receptor (AR) in advanced prostate cancer (PCa), and their function as tumor suppressors. In this study, we examined the contributing events for the loss of expression of these miRNAs and if the expression varies in PCa tissues and cells from racially disparate group of patients. To test whether promoter hypermethylation is one of the reasons, we examined the effect of treatment of DNA methyl transferase (DNMT) inhibitor 5-Aza-2'-deoxycytidine (Aza-C) on expression of these miRNAs in PCa cells. We noted that the expression of miRs-299-3p, -30e and -34c, another AR-targeting miRNA can be restored in PCa cells upon Aza-C treatment, which suggests that promoter hypermethylation is possibly responsible for down regulation of these miRNAs. We noted that miR- miR-299-3p, -34c and -30e are differentially expressed in PCa tissues and cells from African American (AA) and European American (CA) patients. Through bisulfite sequencing, we showed differential promoter methylation of *mir-34c and -299-3p* genes in PCa cell lines from AA and CA origins, which can be reversed through treatment with Aza-C. Differential expression and activities of DNMT3A and DNMT3B were also noted in PCa cells. Analysis of miRNA target prediction databases suggested that both miRs-299-3p and -30e have one or more binding sites at the 3'UTRs of DNMT3A and DNMT3B, which was confirmed by luciferase reporter assays. Interaction of these DNMTs with miR-299-3p was further established by Argonaut (Ago)-2-based RNAIP using induced C4-2B PCa cells overexpressing miR-299-3p. Interaction of miR-30e with these DNMTs was also confirmed by transfection of biotinylated miRNA mimic and streptavidin-based RNA pulldown assays. Overexpression of miRs-299-3p and -30e in PCa cells downregulated expression of mRNAs and proteins, and the activity of DNMTs. Ectopic expression of miR-299-3p restored expression of miR-34c and -30e in PCa cells. Similarly, overexpression of miR-30e restored expression of miR-34c and -299-3p. These observations confirmed that the increased expression of miRs-30e or -299-3p overcomes the loss of expression of miRNAs including miRs-299-3p and -34c, which is potentially mediated by DNMT induced promoter hypermethylation. This study established a reciprocal regulatory loop of AR targeting miRNAs and DNMTs in PCa cells and provides a mechanistic insight into the aberrant expression of AR in

advanced PCa as a result of down regulation of miRs-299-3p, -34c and -30e and stabilization of expression and activities of DNMTs.

NF-κB classical and alternative signaling differentially regulate miRNA expression in ovarian cancer

Rahul D. Kamdar[1], Brittney S. Harrington[1], Soumya Korrapati[1], Emma Attar[2], Nathan Wong[1], Carrie D. House[3], Christina M. Annunziata[1].
[1]National Cancer Institute, Bethesda, MD,[2]Colgate University, Hamilton, NY,[3]Department of Biology, San Diego State University, San Diego, CA

The NF-κB signaling pathway has been shown to contribute to epithelial ovarian cancer (EOC) through its classical and alternative pathways, characterized by the RelA and RelB transcription factors respectively. Previous studies have highlighted the role of RelA in sustaining the proliferative cancer cell population, while RelB aids in promoting the survival of chemoresistant, stem-like tumor-initiating cells (TICs) that promote disease relapse. In further characterizing the downstream effects of NF-κB signaling on EOC, we hypothesize NF-κB signaling differentially regulates the expression of several microRNAs (miRNAs) to promote TIC survival and proliferation through its classical and alternative pathways. miRNAs comprise a subset of small, noncoding RNAs that regulate gene expression, making them amenable for therapeutic targeting. Inducible shRNA stably expressed in OV90 EOC cells to knockdown RelA or RelB were analyzed by miR-seq to identify the differential expression of miRNAs in cells grown in TIC vs adherent (adh) conditions. Several miRNAs were differentially expressed in these conditions with RelA or RelB knockdown; we identified and validated the expression of two candidate miRNAs: hsa-miR-452-5p and hsa-miR-335-5p. We observed the decreased expression of hsa-miR-452-5p when either RelA or RelB is knocked down, while also observing the increased expression of hsa-miR-335-5p when RelA is knocked down. By inhibiting miR-452-5p in conjunction with disrupting NF-κB activity, we found changes in cell viability, sphere formation, and expression of the stem cell marker ALDH. Understanding the role of miRNA signaling in the context of NF-κB will better define the transcriptional roles of RelA and RelB in EOC. Ongoing

work will further characterize the downstream targets of these miRNAs as potential therapeutic targets.

Targeting cancer cells using folate conjugated to a fully modified version of miR-34a (FolamiR-34a) to produce enhanced and sustained anti-tumor activity

Shreyas Ganesan Iyer[1], Ahmed M. Abdelaal[1], Ikjot Singh Sohal[1], Sudarsan R. Kasireddy[2], Andrea L. Kasinski[1]. *[1]Department of Biological Sciences, Purdue University, West Lafayette, IN,[2]Purdue University, West Lafayette, IN*

Due to the pleiotropic nature of miR-34a, including its ability to downregulate multiple genes that drive resistance to currently used anti-cancer therapies, we hypothesize that the best use of miR-34a in a clinical setting would be in combination with standard-of-care treatments. For *in vivo* use, such a molecule would necessitate the following: i) a stabilized version of miR-34a that can withstand the harsh environment in circulation and intracellular nucleases, and ii) a robust, specific, and safe delivery vehicle. With regard to stability, we successfully generated the first fully modified version of miR-34a. This new chemically modified molecule is over 400-fold more stable than the previously used partially modified version and induces enhanced and sustained target gene repression. To assess *in vivo* activity of fully modified miR-34a requires a suitable delivery vehicle. Indeed, while various approaches have been used to restore miR-34a in tumors, clinically relevant mechanisms for delivery of miR-34a have been a challenge due to poor tumor uptake, unfavorable bioavailability, and unwanted toxicity. Previously, we determined that a partially modified version of miR-34a can be delivered specifically and robustly to cancer cells in a targeted, vehicle-free manner through direct conjugation to folate, a ligand of the high-affinity folate receptors. Thus, we conjugated our fully modified miR-34a (FM-miR-34a) to folate generating FM-FolamiR-34a. Following *in vivo* delivery of FM-FolamiR-34a to mice with breast cancer xenografts we observed enhanced and sustained target gene repression, in comparison to our first-generation partially modified folate-miR-34a conjugate (FolamiR). Critical miR-34a target genes involved in promoting resistance, including MET, AXL, and CD44 were downregulated over 90%

for at least 120 hours following a single 1.5 nmol dose of FM-FolamiR-34a. Our final objective is to evaluate FM-FolamiR-34a in combination with standard-of-care agents *in vivo*.

#3783

Role of microRNA 28-3p in prostate cancer progression

Amritha Sreekumar, Sharanjot Saini. *Augusta University, Augusta, GA*

Prostate cancer (PCa) is a leading cause of cancer incidence and mortality among men. Prostate cancer is driven by androgens acting via androgen receptor (AR). Therefore, this cancer is treated with androgen deprivation therapy (ADT) initially. However, the cancer rapidly evolves to be resistant to ADT and progresses to a more invasive stage referred to as 'Castration Resistant prostate cancer' (CRPC). CRPC is treated with second generation of AR pathway inhibitors such as Enzalutamide and Abiraterone. These treatments are effective initially. However, drug resistance develops in a significant fraction of patients and the cancer undergoes 'neuroendocrine trans-differentiation (NED) to a lethal variant called 'neuroendocrine prostate cancer' (NEPC). As a result of NED, PCa cells express neuronal markers such as synaptophysin, chromogranin A and enolase. The molecular basis of NED is not yet fully defined. With a focus on identifying the role of microRNAs (miRNAs) in NEPC, we performed small RNA sequencing in CRPC tumors with and without NED. This sequencing identified miR-28-3p to be significantly downregulated in CRPC-NE samples as compared to CRPC-adenocarcinomas (CRPC-Adeno). In view of this, we examined the role of this miRNA in NEPC. Analyses of TCGA data of prostate adenocarcinomas suggest that miR 28-3p has an oncogenic role in primary prostate tumors. However, its expression declines in tumors with increasing Gleason score. We profiled the expression of miR-28-3p in patient-derived xenograft models and clinical CRPC-NE and CRPC-Adeno tissues by real time PCR. Our profiling showed a trend towards downregulation with increased NED. Basal expression of miR 28-3p in various prostate cancer cell lines showed an elevated level in androgen dependent cell lines whereas significantly less expression in NEPC cell lines, LASCPC-01 and NCI-H660. In this study, we generated PC3 cell line that stably expresses miR-28 for understanding its functional role in regulating PCa. Preliminary functional assays including cell viability assay,

cell cycle studies and invasion and migration assay suggest a tumor suppressor role of miR-28-3p in advanced prostate cancer. In conclusion, our data shows that miR 28-3p potentially has a biphasic role in PCa, where it is oncogenic in early stages and acts as a tumor suppressor in late stage PCa.

miR-489 induces apoptosis and immunogenic cell death through targeting FOXM1 in triple negative breast cancer cells

Gourab Gupta, Ryan Titus, Yogin Patel, Shakthika Sarvanan, Hexin Chen.
Biological Science, University of South Carolina, Columbia, SC

It has been well established that microRNAs (miRNAs) have an important role in cancer sustenance and progression. Our previous studies have established the role of miR-489 as a tumor suppressor miRNA in breast cancer. However, the multiple targets of this miRNA have diversified its mechanism from preventing tumor cell proliferation to promoting cell death pathways. In this study we have aimed to establish the role of miR-489 in cell cycle inhibition, leading to Endoplasmic Reticulum stress (ER stress) and ultimately immunogenic cell death (ICD). Firstly, we found that overexpression of miR-489 in triple negative breast cancer (TNBC) cell lines including MDA-MB-231, BT 549, drastically reduced cell proliferation using colony formation assay and real-time cell analysis. Furthermore, studies like GO analysis, sequence analysis and cell cycle analysis demonstrated that miR-489 induces cell cycle arrest and apoptosis in TNBC by directly targeting FOXM1 and regulating other kinases like CDK1. It was also shown for the first time that miR-489 overexpression induces ER stress and the release of damage associated molecular patterns (DAMPs), consistent with hallmarks of ICD like Calreticulin exposure on cellular surface and ATP release, triggering phagocytosis. It was also established that miR-489-induced apoptosis lead to the elevation of cleaved caspase 3, which was responsible for the activation of PANX1 and the consequent release of ATP. In conclusion, we tried to mechanistically understand the role of miR-489 in cell cycle arrest leading to cellular stress. Stress induced apoptosis and consequent ICD was also a possible outcome and it turned out miR-489 overexpression without any other ICD inducer

was good enough to trigger the release of DAMPs and elucidate an immunogenic response.

Telomerase RNA component lncRNA regulates hsa-miR-320 family and promotes prostate cancer metastasis

Mandisa Mbeje[1], Jeyalakshmi Kandhavelu[2], Clement Penny[3], Zodwa Dlamini[1], Rahaba Marima[1]. *[1]University of Pretoria, Pretoria, South Africa,[2]Georgetown University Medical Center, Washington, DC, WA,[3]University of the Witwatersrand, Johannesburg, South Africa*

Telomerase RNA component (TERC) is a long non-coding (lncRNA) associated with prostate cancer progression and has novel prognostic biomarker potential. Differential methylation patterns of lncRNAs affect their expression levels, leading to cancer. This study aimed to profile and elucidate differential lncRNA expression patterns in prostate cancer (PCa). A 384-well plate of PCa associated lncRNA gene array panel was used in castration resistant PC-3 PCa cells vs androgen-sensitive PCa LNCaP cells. Annotation and enrichment analysis of lncRNA differential gene expression was performed using a human lncRNA sets database, LncSEA. Furthermore, digital droplet PCR (ddPCR) was used to verify the PCR array results. Up or down-regulation of ±2 and $p < 0.05$ were considered significant. Decreased hsa-miR-320 gene family expression has been reported in various tumors including PCa. However, the precise mechanisms of hsa-miR-320 gene family in PCa remain to be elucidated. Thirty six of 84 lncRNAs were shown to be upregulated, while 14% of the lncRNA genes were downregulated. Notably, TERC lncRNA was upregulated in high metastatic PC-3 cells. Hypermethylation patterns of this lncRNA in high metastatic PC-3 cells was also shown by enrichment analysis. Furthermore, TERC lncRNA was demonstrated to regulate the hsa-miR-320 family, suggesting a correlation between TERC hypermethylation and downregulation of hsa-miR-320 gene family expression in PCa, as revealed by bioinformatics analysis. TERC lncRNA promotes PCa cell proliferation, migration, invasion and metastasis by sponging hsa-miR-320 family. This TERC/hsa-miR-320 interaction holds potential to understanding PCa prognostic mechanisms by lncRNAs and may also be targeted for novel therapeutics.

#3786

In vivo miR-449b mimic-based nanotherapy suppresses growth and progression of triple-negative breast cancer

Goknur Kara, Bulent Ozpolat. *Houston Methodist Research Institute, Houston, TX*

Triple-negative breast cancer (TNBC) comprises 15-20% of breast cancers and is associated with an aggressive course and the highest mortality rate in all breast cancer subtypes owing to high rates of early metastasis recurrence, and a low response to adjuvant chemotherapy. Currently, there is no effective targeted therapy strategy for TNBC due to significant genetic heterogeneity and a lack of defined molecular targets. Recent evidence from our and other laboratories revealed that non-coding RNAs such as tumor suppressor microRNAs (miRNAs) are dysregulated in cancer cells by regulating the expression of target genes (mRNAs) that are involved in critical cellular processes such as cell cycle, proliferation, differentiation, and migration/invasion, drug resistance, and tumor growth. Analyzing the TCGA-patient database, we recently found that reduced miR-449b expression was associated with significantly shorter survival in TNBC patients (n=56 patients with high expression, n=41 patients with low expression, p=0.0011). Our studies revealed that miR449b expression is reduced in TNBC cell lines and its ectopic expression using commercially available transfection reagent inhibited TNBC cell proliferation, migration, and invasion. Since in vivo delivery of miRNA therapeutics has been challenging, we developed magnetic nanoparticles for miR-449b delivery which inhibited in vitro cell proliferation, invasion, and migration. To elucidate molecular mechanisms underlying miR-449b-induced tumor suppressive effects, we investigated potential targets of miR449b using several target prediction algorithms and found that miR-449b has binding sites in the 3'-UTR of the proto-oncogene, eukaryotic elongation factor-2 kinase (eEF2K) gene. We demonstrated eEF2K expression is highly upregulated in TNBC cell lines and eEF2K expression correlates with shorter overall survival in patients with TNBC. More importantly, eEF2K expression was markedly inhibited after ectopic expression of miR-449b in TNBC cells. TNBC cells were also treated with siRNAs specific for eEF2K which led to reduced cell growth and invasion/migration, recapitulating the

effects of miR-449b expression Furthermore, in vivo administration of miR-449b-loaded magnetic nanoparticles (0.6 mg/kg once a week in TNBC orthotopic xenograft models (MDA-MB-231) in mice resulted in significant inhibition of eEF2K and tumor growth. Additionally, magnetic nanoparticles-miR-449b treatment in mice did not cause detectable side effects. These findings suggest that miR-449b functions as a tumor suppressor by targeting eEF2K-mediated oncogenic signaling leading to the tumor growth and progression of TNBC. Taken together, our study suggests that the miR-449 nanotherapy using magnetic nanoparticles may be a promising therapeutic strategy that provides a safe and effective antitumor efficacy against TNBC.

miR 2355-5p regulates tumor growth and angiogenesis in VHL-inactivated clear cell renal cell carcinoma

Patric Page[1], Sandra Turcotte[1], Mykella Martin[1], Patrick Richard[2], Tamiko Nishimura[3], Yasser Riazalhosseini[3]. *[1]Chemistry and Biochemistry, Université de Moncton, Moncton, NB, Canada,[2]Université de Sherbrooke, Sherbrooke, QC, Canada,[3]McGill University, Montreal, QC, Canada*

Background: Clear Cell Renal Cell Carcinoma (ccRCC) constitutes more than 75% of kidney cancer diagnostics. Inactivation of the tumor suppressor gene termed von Hippel-Lindau (VHL) is considered the major truncal event and occurs in more than 85% of patients. The most notable role of VHL is its ability to negatively regulate the Hypoxia-Induced Factors (HIFα), which in turn, stimulate the transcription of multiple oncogenes, including microRNAs (miRNAs). MiRNAs are small non-coding RNAs that negatively regulate gene expression through complementary base pairing. Using ccRCC cell models, we observed an overexpression of the miR 2355-5p following the loss of VHL in a HIF2α dependent manner. Hypothesis: We hypothesize that the miR 2355-5p overexpression is involved in the tumorigenesis of VHL-inactivated ccRCC. Our specific aims are to i) quantify the expression of miR 2355-5p in ccRCC clinical samples, ii) characterize the functional impact of miR 2355-5p in ccRCC development, and iii) identify miR 2355-5p targeted genes in ccRCC tumors.

Methods: Clinical samples (tissues and plasma) from consented patients with ccRCC were recruited through the Université de Sherbrooke. Normal adjacent tissue and plasma from healthy individuals were used as controls. miR 2355-5p expression was quantified through RT-qPCR with Taqman probes. Then, 786-0 and A498 VHL-deficient ccRCC cell lines were used. miR 2355-5p knockout models (KO) were generated using CRISPR/cas9 technology or stably overexpressed using miRNA precursor plasmid (786-0++2355). The impact on cell survival and proliferation was assessed with clonogenic assay and daily cell counts, respectively. Furthermore, cell models were injected into immunodeficient mice. Angiogenesis was evaluated by tube formation assay and angiogenesis proteome profiler kit. Finally, miRNA pulldown was performed to identify miR 2355-5p potential targets.
Results: Our findings showed a significant increase in miR 2355-5p expression in tumor tissue compared to normal adjacent tissue as well as in plasma samples compared to healthy individuals. Inhibition of miR 2355-5p significantly reduced cell survival and cell proliferation *in vitro* and *in vivo*. Altered expression of the miRNA also disturbed the expression of multiple angiogenic factors and reduced the ability of cells to stimulate tube formation. MiRNA pulldown identified over 267 potential targets, where 161 were mRNA coding for functioning proteins. Close to 80% of identified proteins were direct targets of miR 2355-5p according to prediction software. Further analysis showed an inverse correlation between the tumor suppressor gene SPRY4 and miR 2355-5p, uncovering a potential link between the two.
Discussion: Our results demonstrate an important role of miR 2355-5p on angiogenesis and ccRCC tumor growth. Further research on the interaction between miR-2355-5p, BTG2, SLIT2, and CMTM4 could unlock new potential avenues for targeted therapies.

Profiling of microRNAs in androgen independent prostate cancer cells

Shashwat Sharad, Hua Li. *Murtha Cancer Center, Department of Surgery, USUHS, Center for Prostate Disease Research (CDPR), Bethesda, MD*

Introducti**on:** Short noncoding microRNAs (miRNAs) function as tumor suppressors or oncogenes playing important roles in tumorigenesis and

metastasis. In prostate cancer, the studies had indicated the potential roles of miRNA as biomarkers for earlier detection, diagnosis, prognosis evaluation and therapy targets. The castration resistance and metastasis remain the major challenges for the administration of prostate cancer patients, and the underlying biology is still not fully understood. Here, we reported the comparative profiling of miRNAs in hormone dependent and independent prostate cancer cells, aiming to identify novel miRNAs for monitoring aggressive disease progression and therapy targets.

Methods: The hormone sensitive LNCaP cells, and androgen independent C42B and PC3 cells were used to miRNA sequencing. The miRNA sequencing libraries were prepared with NanoDrop ND-1000. The DNA fragments were denatured to generate single-stranded DNA molecules and amplified in situ with TruSeq Rapid SR Cluster kit. Sequencing was performed using the Illumina NextSeq 500. Raw sequencing data passing the Illumina chastity filter were used for further analysis. Trimmed reads were aligned to reference genome with bowtie software. The expression levels of miRNAs were calculated using mirdeep2. Differentially expressed miRNAs analysis were performed with R package edgeR. miRNA target prediction was filtered based on miRNA Target databases. The analysis of Gene Oncology (GO) enrichment and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway were further conducted for miRNA biological function assessments.

Results: Among 777 known miRNAs, high expression (CPM>30) of 356, 325 and 358 miRNAs were detected in LNCaP, C42B and PC3 cells, respectively. No expression (CPM=0) of 93, 114 and 75 miRNAs were detected in LNCaP, C42B and PC3 cells, respectively. Only miR-1247-3p was detected with high expression in LNCaP cells but no expression in C42B cells. Furthermore, there were 19 miRNAs with high expression in PC3 cells, and 20 miRNAs with high expression in PC3 cells but no expression in C42B cells including miR-125b-1-3p, miR-181a-3p, miR-31-3p, miR-1247-3p and miR-873-5p. In contrast, only 5 miRNAs with high expression in LNCaP cells and 7 miRNAs with high expression in C42B cells but not detectable in PC3 cells such as miR-141-5p. Pathway analysis further revealed that the miRNA regulated pathway of TGF-β, Hippo and Wnt were activated and the pathway of FoxO, P53, MAPK and Hedgehog were suppressed in C42B cells compared to LNCaP cells. Similarly, the

pathway of HIF-1 was activated and the pathways of PI3K-Akt, ErbB and GnRH were inhibited in PC3 cells.
Conclusion: The sequencing of miRNA of hormone dependent and independent prostate cancer cells generated the distinct miRNA signatures which granted further validation in human prostate cancer samples and underlying biology study in aggressive disease progression.

Circular RNA expression is enriched in breast cancer extracellular vesicles and is associated with chemotherapy resistance
Harrison Ngue[1], Jitendra Shrestha[2], Hyejin Kim[2], Shobha Vasudevan[2].
[1]Harvard University, Cambridge, MA,[2]Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA

Up to 90% of failures in chemotherapy treatment are associated with metastatic-related drug resistance. Extracellular vesicles (EVs) are believed to play a role in the spread of chemotherapy resistance through the horizontal transfer of oncoproteins and noncoding RNA species, but the underlying mechanisms for this are not fully understood. Here, we study EV biogenesis, release, and uptake in the context of breast cancer chemoresistance. Specifically, we characterized the bioactive cargoes in EVs secreted by chemoresistant triple negative breast cancer cells and chemoresistant estrogen receptor-positive breast cancer cell lines. Preliminary data show that these EVs contain unusually high levels of circular RNAs, small RNA species formed covalently through backsplicing and are typically noncoding. When chemosensitive cells absorb these circRNA-enriched EVs, they experience a significant increase in resistance phenotypes. Moreover, knockdown of the circRNAs via antisense oligonucleotides results in decreased chemoresistance, suggesting a role of circRNAs in the development of chemotherapy resistance. Previous studies have shown that tumor-derived exosomal circRNAs may confer resistance by sponging microRNAs. We are exploring what the circRNAs do mechanistically to promote tumor survival, and clarifying these mechanisms as a whole will serve to potentially provide therapeutic targets against chemotherapy resistance and cancer recurrence.

Non-coding RNAs in Gastrointestinal, Blood, and Bone Marrow Cancers

Regulation of miR-124 expression by promoter methylation in CRC and its relationship with KITENIN expression

So-Yeon Park, Rui Zhou, Chathurika D. B. Gamage, Sultan Pulat, Mücahit Varlı, Hangun Kim. *Sunchon National University, College of Pharmacy and Research Institute of Life and Pharmaceutical Sciences, Sunchon, Korea, Republic of*

The mechanisms that regulate microRNA expression in cancer are not fully understood. However, recently reported data show that the epigenetic mechanism plays an important role in the regulation of microRNA expression. In in this study, we investigated the relationship between miR-124 promoter methylation and target genes in CRC. The expression of miR-124 was increased by Aza treatment and the expression of KITENIN was decreased in CRC cells. First, we examined the methylation status of miR-124 promoter in two normal cell lines and seven CRC cell lines using pyrosequencing assay. As a result, miR-124 promoter was hypermethylated in CRC cells and low in normal cells. Next, we evaluated the DNA methylation status for a miR-124 promoter in paired colorectal normal tissues and colorectal cancer tissues specimens from 10 patients. Overall, methylation of the miR-124 promoter was high in cancer among clinical tissues, and the expression of miR-124 was low in cancer tissues. The expression of the KITENIN was also higher in cancer tissues than in normal tissues. These results prove that DNA hypermethylation contributes to the transcriptional down-regulation of miR-124 in colon cancer, and that the epigenetic silencing of miR-124 in cancer cells modulate the activity of KITENIN. Our findings provide basic data that can be useful for clinical treatment of CRC patients through the mechanism of miR-124 regulation identified as a regulator of KITENIN.

Sensitive detection of microRNA biomarkers of pancreatic cancer using one-pot endonucleolytically exponentiated rolling circle amplification by CRISPR-Cas12a

He Yan, Song Han, Steven Hughes, Yong Zeng. *University of Florida, Gainesville, FL*

While miRNAs offer a promising source for developing diagnostic cancer biomarkers, the progress towards clinical utilities remains largely limited, due in part to the long-standing challenge in sensitive, specific, and robust detection of miRNAs in human biofluids. Emerging next-generation molecular technologies, such as the CRISPR-based methods, promise to transform nucleic acid testing. The prevailing strategy used in existing CRISPR-based methods is to orthogonally hyphenate two separate reactions for pre-amplification, e.g., rolling circle amplification (RCA), and amplicon detection by Cas12a/13a trans-cleavage in tandem. Thus, existing CRISPR-based miRNA assays require multiple manual steps and lack the analytical performance of the gold standard, RT-qPCR. Radically deviating from the existing strategies, we developed a one-step, one-pot isothermal miRNA assay termed "Endonucleolytically eXponenTiated Rolling circle Amplification with the dual-functional CRISPR-Cas12a" (EXTRA-CRISPR) for miRNA detection with RT-qPCR-like analytical performance, including high sensitivity with a single-digit fM detection limit, single-nucleotide specificity, and rapid and flexible turnaround (from 20 min to 3 h for the entire analysis depending on targets and samples). We adapted the EXTRA-CRISPR assay to quantifying miRNA biomarkers in extracellular vesicles (EVs), a major carrier of miRNAs in human biofluids, for liquid biopsy diagnosis of pancreatic ductal adenocarcinoma (PDAC). Using the EXTRA-CRISPR, we demonstrated highly sensitive and specific profiling of a panel of four miRNA markers (miR-21, miR-196a, miR-451a, and miR-1246) in plasma EVs (PDAC patients (n = 20) and healthy donors (n = 15)). Based on the individual EV-miRNA tests (AUC values ranging from 0.677 for miR-196a to 0.793 for miR-451a), an EV signature (EV-Sig) combining miR-21, miR-451a and miR-1246 was devised with a machine learning method to improve the diagnostic performance for PDAC (AUC = 0.853). The diagnostic performance of the EXTRA-CRSPR tests were

rigorously validated by parallel RT-qPCR analysis of the same clinical samples, and the RT-qPCR signature combining the three markers confers a similar AUC of 0.874 for PDAC detection. Overall, the analytical and diagnostic performance of our method were shown to be comparable with that of the commercial RT-qPCR assays, while greatly simplifying the analysis workflow. Therefore, we envision that our technology provides a promising tool to advance miRNA analysis and clinical marker development for liquid biopsy-based cancer diagnosis and prognosis. Moreover, this simple and robust assay permitted direct coupling with a 3D printed smartphone-based portable device and the lateral flow assay for signal readout, demonstrating its potential adaptability to low-cost point-of-care diagnostics.

Deciphering the *in vivo* roles of a novel long non-coding RNA in chronic lymphocytic leukemia and Richter syndrome

Swati Mohapatra[1], Erik Knutsen[2], Mihai Iurascu Gagea[3], Linda Fabris[1], George Adrian Calin[1]. *[1]Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Medical Biology, UiT The Arctic University of Norway, Tromsø, Norway,[3]The University of Texas MD Anderson Cancer Center, Houston, TX*

The ultraconserved regions (UCRs) are the genomic segments manifesting perfect conservation between the orthologous genomes of humans, rats, and mice that get transcribed into mono-exonic long non-coding RNAs (lncRNAs) known as transcribed ultraconserved regions (T-UCRs). Increasing evidence demonstrates the importance of T-UCRs in human cancers, however, their involvement in the pathogenesis of Chronic Lymphocytic Leukemia (CLL) is poorly understood. Our lab has recently identified a lncRNA transcribed from a UCR and named it TRUC-16 (Translational Regulatory UltraConserved gene affecting p16), which is overexpressed in CLL and correlates with treatment-free survival. We have developed a transgenic C57BL6 mouse model to overexpress TRUC-16 in B cells. We monitored the number and development of B cell subsets over time in peripheral blood and lymphoid organs (lymph nodes, spleen, and bone marrow), and performed immunophenotyping to assess clonality and

proportion of the cells considered to be the origin for CLL (i.e. B1 cells and IgM memory B cells that are CD5+). We followed mice survival (n=10 for each gender) and performed necropsy with histopathologic and immunophenotypic analysis. If blood sampling suggests developing a CLL-like state, we will monitor for evolution to Richter Syndrome by flow cytometry analysis and biochemistry markers. We have validated the TRUC-16 overexpression specific to the B-cell compartment in the mice cohorts and have observed lymphoma in several organs. Interestingly, TRUC-16 overexpressing mice showed significantly higher splenic weights compared to controls. The mice were found to develop adulthood lymphoma that we are now analyzing molecularly and phenotypically. We are planning to further characterize the subtype of lymphoma by utilizing specific diagnostic markers through immunohistochemistry and flow cytometry. This is the first-ever transgenic mice modeling overexpression of UCR in the context of cancer. Validation of the functional correlation between the TRUC-16 phenotype and CLL patients' clinical data will provide a valuable resource to pursue a multitude of preclinical studies to find targets that might help better understand the disease pathophysiology.

Exosomes enhance the radiation sensitivity via miR-6823-5p and modulate metastases in pancreatic cancer model

Ai Nakaoka[1], Makiko Nakahana[1], Sachiko Inubushi[2], Yasuyuki Shimizu[1], Kazuma Iwashita[1], Naritoshi Mukumoto[1], Kana Kobayashi[1], Takeaki Ishihara[1], Daisuke Miyawaki[1], Ryohei Sasaki[1]. *[1]Division of Radiation Oncology, Kobe University Graduate School of Medicine, Kobe, Japan,[2]Division of Breast Surgery, Kobe University Graduate School of Medicine, Kobe, Japan*

Introduction: Pancreatic cancer (PC) is believed to be a difficult disease because of its radio-resistance and metastases. Radiotherapy reported to modify tumor microenvironment (TME) and to affect PC progression. Exosomes containing such as microRNAs (miRNAs), messenger RNAs (mRNAs), and proteins of cells, play essential roles in cell-to-cell communications. However, characteristics and mechanisms for radiation responsive exosomes remain unclear. Here, we first report mechanisms of

exosomes-mediated radiation response and regulation in PC metastasis with focusing on intra/intercellular communications via miRNA.
Methods: MIAPaCa-2 cells, human pancreatic carcinoma, was used. To isolate exosomes, cell culture media was ultracentrifuged at 100,000 x g for 90 min at 4℃. Exosomes derived from non-irradiated culture media was named ‘0 Gy-Exo’ and those from irradiated with 5 Gy culture media is called ‘5 Gy-Exo’. Exosome sizes and features were evaluated by transmission electron microscopy (TEM). Intracellular reactive oxygen species (ROS) levels induced by exosomes and by X-ray irradiation were evaluated by the C-H_2DCF dye staining. To detect DNA damage, cells were fixed and stained by γ-H2AX antibody. The expression of superoxide dismutase 1 (SOD1) was evaluated by using immunoblots. Total RNA was extracted from 0 Gy-Exo and 5 Gy-Exo, and then comprehensive miRNA expression analysis was performed to analyze 2,565 human miRNA sequences. The Gene Expression Omnibus database (GSE163133) and the TargetScan were used for specific miRNAs identification. Living MIAPaCa-2 cells in the presence or absence of those exosomes were injected in the spleen of Balb/c nude mice to establish liver metastatic models. Eight weeks after the injection, mice were sacrificed, and then the spleen and the liver were harvested as a whole organ. H-E staining and immunohisitochemical analyses using S100A4 and SMAD4 antibodies were performed to detect liver metastases.
Results: Isolated exosomes were shaped in the form of closed, round vesicles with a diameter of 10~100 nm. Intracellular ROS levels and the numbers of γ-H2AX foci in the cells with 5 Gy-Exo were significantly increased compared to those the control (without adding exosomes, $p<0.01$). Intracellular SOD1 expression in the cells with the 5 Gy-Exo was decreased compared with that in the control. The miR-6823-5p was identified to have a complementary base sequence to SOD1. The average occupied proportions with MIAPaCa-2 cells in the liver was modulated according to those exosomes. The SMAD4 expression was highly observed in the liver and the spleen suggesting that the SMAD4 could be a useful marker of liver metastases.
Conclusion: Exosomes increased radiation sensitivity through increase of intracellular ROS levels via exosomal miRNAs and also could affect liver metastases in pancreatic cancer models.

Fecal miRNA profiles and gut metagenome composition in Lynch syndrome: results from a mouse model study and human subjects

Giulia Francescato[1], Giulio Ferrero[2], Marc Beltrà[2], Sonia Tarallo[1], Giulia Piaggeschi[1], Carla Di Battista[1], Antonio Francavilla[1], Carlijn Bruggeling[3], Fabio Penna[2], Barbara Pardini[1], Paola Costelli[2], Annemarie Boleij[4], Alessio Naccarati[1]. *[1]Italian Institute for Genomic Medicine (IIGM), Candiolo, Italy,[2]Department of Clinical and Biological Sciences, University of Turin, Turin, Italy,[3]Radboud Institute for Molecular Life Sciences (RIMLS), Radboud University Medical Center, Nijmegen, Netherlands,[4]Department of Pathology, Radboud Institute for Molecular Life Sciences (RIMLS), Radboud University Medical Center, Nijmegen, Netherlands*

Bsacground: Lynch Syndrome (LS) is an inherited cancer syndrome associated with an increased lifetime risk of colorectal cancer (CRC) and characterised by germline mutations in DNA mismatch repair (MMR) genes. Abnormalities in the function of MMR genes lead to errors during DNA replication, including microsatellite instability. Despite regular colonoscopies, up to 15% of LS patients still develop CRC. Gut microbiome, bowel inflammation, the environment and host genetic and epigenetic factors are involved in CRC development. In this sense, the concomitant analysis of stool host microRNA (miRNA) profiles and gut microbiome composition may arise to the identification of specific fecal markers in LS explaining the molecular basis for the development of cancer in these patients. PURPOSE: In the present study, the fecal miRNome and microbiome were characterized in a time progression in an *in vivo* model using a mismatch repair deficient mice model that recapitulates human LS. The main aim was to evaluate the changes and crosstalk of miRNAs released in the stool by the host and the microbial population residing in the gut during the carcinogenesis process induced in animals. Findings in mice were compared and correlated to data obtained from a cohort of human subjects affected by LS.

Methods: We used an *in vivo* model for LS based on a conditional knockout mouse with the tissue-specific inactivation of Msh2 ($Msh2^{LoxP}$) in the intestinal mucosa, combining $Msh2^{LoxP}$ allele with the Villin-Cre transgene ($VCMsh2^{LoxP}$). Stool from mice were collected at different time points (6, 9

and 12 months of age). Small RNA-sequencing (sRNA-seq) and shotgun metagenomics analyses were performed in stool from all samples. In concomitance, we collected 78 stool samples of clinically diagnosed LS subjects, at different follow up time. At the sampling, 36 resulted negative for colorectal adenomas/lesions, 12 were negative but with a previous history of lesions, 23 presented a neoplasia and 6 developed a lesion in the follow-up. Twenty-two stool samples from healthy subjects were used as controls.
Results: In mice, preliminary results from sRNA-seq and metagenomics analyses showed several dysregulated miRNAs and differential microbial relative abundances, either between *VCMsh2*^{loxP} and controls or at different time points. In humans, we identified 41 and 17 miRNAs respectively up- and downregulated in LS subjects who presented a lesion compared to those not having any lesion at follow-up. In the same comparison the metagenomic data showed significantly different microbial abundances, including those of *Eubacterium ramulus*.
Conclusions: This is the first study characterizing the concomitant alterations in microbial composition and host miRNome overtime in relation to the onset of cancerous/precancerous lesions due to LS.

lncRNA LIMp27 promotes p53-defective cancer pathogenesis
Ting La[1], Song Chen[2], Xiao Hong Zhao[1], Yuan Yuan Zhang[1], Yu Chen Feng[1], Xu Dong Zhang[1], Lei Jin[1]. *[1]University of Newcastle, Australia, Callaghan, Australia,[2]Zhengzhou University, Zhengzhou, China*

Inactivation of p53 occurs in approximately 50% of human cancers, where p53-mediated p21 activation is devoid and p27 becomes essential for the establishment of the G1/S checkpoint upon DNA damage. Here, we show that the E2F1-responsive lncRNA LIMp27 selectively represses p27 expression and promotes proliferation, tumorigenicity, and treatment resistance in p53-defective colon adenocarcinoma (COAD) cells. LIMp27 competes with p27 mRNA for binding to cytoplasmically localized hnRNA0, which otherwise stabilizes p27 mRNA, leading to cell cycle arrest at the G0/G1 phase. In response to DNA damage, LIMp27 is upregulated in both wild-type and p53-mutant COAD cells, whereas cytoplasmic hnRNPA0 is only increased in p53-mutant COAD cells due to

translocation from the nucleus. Moreover, high LIMp27 expression is associated with poor survival of p53-mutant but not wild-type p53 COAD patients. These results uncover a lncRNA mechanism that promotes p53-defective cancer pathogenesis and suggest that LIMp27 may constitute a target for the treatment of such cancers.

#3799

Regulation of p16-E2F1-CDK4/6 signaling by TRUC-16 ultraconserved long non-coding RNA

Linda Fabris[1], Erik Knutsen[2], Maria Teresa S. Bertilaccio[1], Steliana Calin[1], Recep Bayraktar[1], George T. Eisenhoffer[1], Leonard Girnita[3], George A. Calin[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]The Arctic University of Norway, Tromsø, Norway,[3]Karolinska Institutet, Stockholm, Sweden*

High phylogenetic conservation of genomic loci is a potential marker of essential biological functionality. Ultraconserved elements (UCEs) are DNA sequences entirely conserved through millions of years of evolution, but their functions are not well understood. Several long non-coding RNAs (lncRNAs) are transcribed from UCEs and play active roles in cancer development. Using a combination of *in vitro* and *in vivo* experiments with two animal models and 4 patient cohorts, we discovered several remarkable aspects of ultraconservation. Using a multi-step genetically defined carcinogenesis model, we identified one UCE, uc.206, and its associated overexpressed lncRNA *TRUC-16* as a regulator of cell proliferation in chronic lymphocytic leukemia (CLL). High levels of *TRUC-16* inhibit $p16^{INK4A}$ translation, causing increased proliferation through an E2F1-mediated mechanism in CLL patients, as well as in zebrafish and murine models. uc.206/*TRUC-16* function is extremely conserved throughout evolution. We found cell cycle-related effects of *TRUC-16* in both mice and zebrafish, in which we observed increased proliferation of blood cells after overexpression of the human *TRUC-16*. High levels of CDK4/6 consequent to *TRUC-16* overexpression and p16 decrease can be specifically targeted in both CLL and Richter's Transformation (RT), a rare but deadly consequence of CLL. Inhibition of CDK6 is a therapeutic option never tested in CLL, but in use for another type of B cell malignancy, such as the mantle cell lymphoma. Our results highlight the multifaceted contribution

of a UCE to human tumorigenesis and open new possibilities for the use of long-noncoding RNAs in cancer therapies.

The disruption of miR-125b-SLC1A5 cascade defines the oncogenicity and differential immune profile in oral carcinoma

Ying-Chieh Liu, So-Yu Liu, Yu-Cheng Lin, Chung-Ji Liu, Kuo-Wei Chang, Shu-Chun Lin. *National Yang Ming Chiao Tung University, Taipei, Taiwan*

Head and neck squamous carcinoma (HNSCC) including oral SCC (OSCC) is a worldwide malignancy that requires vigorous efforts for interception. The metabolic reprogramming sustains malignant tumor cells to overcome stressful microenvironments. As the glutamine is the one of the essential components which helps cells to erase reactive oxygen species and energy production, the increased uptake of glutamine is a common metabolic hallmark in cancers. Bioinformatic analysis of TCGA HNSCC datasets and RNAseq results in our cohort indicated that solute carrier family 1 member 5 (SLC1A5) is the most eminently dysregulated transporter member among the seven glutamate or neutral amino acid transporters in SLC1A family. This work identified that the knockdown of SLC1A5 expression decreased *in vitro* oncogenicity, xenografic tumorigenesis and glutamine uptake; increased oxidative stress, cell cycle arrest, and sensitivity to cisplatin and ferroptosis inducer in OSCC cells. By way of contrast, the upregulation of endogenous SLC1A5 expression mediated by CRISPR/dCas9 activation system drove the OSCC oncogenesis. The reporter assay and functional analysis demonstrated that suppressor miRNA miR-125b targeted and attenuated SLC1A5, while NEAT1 lncRNA sponged and ablated miR-125b-SLC1A5 axis. The analysis of TCGA and GEO datasets confirmed the concordant upregulation of NEAT1 and downregulation of miR-125b along with the SLC1A5 upregulation in tumors. Besides, SLC1A5 upregulation defined the worse HNSCC patient survival. In our tumor cohort, OSCC harboring higher SLC1A5 expression had lower CD4+ immune score, and higher scores in M0 and M1 macrophage. GSEA algorithm further deciphered that tumors having higher SLC1A5 expression manifested the repression in glycolysis, apoptosis and p53 signaling. This study concludes that the frequent disruption of NEAT1-miR-125b-SLC1A5

cascade modulates the pluripotent oncogenic activities, the treatment efficacy and the immune landscape in oral carcinoma.

#3801

Identification of circular RNAs associated with the ferroptosis of pancreatic cancer cells

Jessica Jazmin Pena Paladines, Shao Weng Wang, Chi Hin Wong, Yang Chao Chen. *The Chinese University of Hong Kong, Hong Kong, Hong Kong*

The five-year survival rate for pancreatic cancer patients is significantly low which is predominately due to the lack of early-detection biomarkers, and poor response to currently available treatments that include drug resistance development. Recent studies suggest cancer cells can be highly sensitive to a newly defined type of cell death, ferroptosis, which is related to the development of resistance to standard chemotherapy drugs for pancreatic cancer such as gemcitabine and 5-Fluorouracil. However, the role of circular RNAs (circRNAs) in ferroptosis remains largely unexplored. Hence, this project aims to identify circRNAs in ferroptosis to uncover further components and mechanisms, and potentially provide specific effective targets for anticancer therapies. To achieve this, different ferroptosis inducers were tested, where the cystine-depletion method demonstrated higher efficiency based on cell viability and ferroptosis markers such as iron and lipid peroxidation levels. This method was used to induce ferroptosis for 24 hours in pancreatic cancer cells for subsequent circRNA sequencing, and to establish a ferroptosis-resistant cell line. From the sequencing data, 31 differentially expressed (DE) circRNAs were obtained, and eight were selected for further validation. Three circRNAs; circPPP2R2B, circNDUFAB1, and circNLN, showed consistent differential expression in ferroptosis non-resistant (downregulated) and resistant (upregulated) cells after cystine-depletion treatment. The knockdown of these circRNAs decreased the viability, invasion, migration, and colony formation ability of PDAC cells. Simultaneously, lipid peroxidation and intracellular iron levels, which are ferroptosis markers, were increased. Additionally, bioinformatic analysis of these circRNAs demonstrated their possible interaction with proteins and miRNAs with reported ferroptosis-related functions. In summary, these findings suggest that circPPP2R2B,

circNDUFAB1, and circNLN may be critically involved in PDAC progression and the evasion of ferroptosis which supports the further investigation of their oncogenic and ferroptosis-related action mechanism to propose a potential target for anticancer therapies.

miR-199a and miR-199b stimulate the progression of diffuse gastric cancer through direct targeting of Frizzled-6

Jihye Park[1], Sieun Lee[1], Soon Auck Hong[2], Yoon Ho Ko[3], Young-Ho Ahn[1].
[1]Department of Molecular Medicine, Ewha Womans University College of Medicine, Seoul, Korea, Republic of,[2]Department of Pathology, Chung-Ang University College of Medicine, Seoul, Korea, Republic of,[3]Division of Oncology, The Catholic University of Korea, Seoul, Korea, Republic of

There is no pathological difference between early and advanced diffuse gastric cancer (DGC), particularly in the gastric mucosa. In this study, we tried to identify microRNAs (miRNAs) as diagnostic biomarkers that can differentiate between early and advanced DGC. miRNA expression profiling was performed by NanoString nCounter method in human DGC tumors. miR-199a and miR-199b (miR-199a/b) were particularly up-regulated in advanced DGC compared with early DGC. Ectopic expression of miR-199a/b accelerated growth, viability, and motility of SNU601, human GC cells, and expedited tumor development in a mouse xenograft model. miR-199a/b also inhibited cell adhesion. Through 3'-UTR luciferase assay, Frizzled-6 (FZD6) was confirmed as a direct target of miR-199a/b. siRNA-mediated depletion of FZD6 increased cell growth and motility and addback of FZD6 restored cell growth, motility, and adhesion. To explore their clinicopathological roles in patients, miR-199a/b levels were measured by in situ hybridization in human DGC tumor sections. High miR-199a/b was correlated with advanced lymphovascular invasion, advanced T stages, and lymph node metastasis. Collectively, miR-199a/b promote the progression of DGC via targeting FZD6. These results imply that miR-199a/b can be used as diagnostic and prognostic biomarkers of DGC.

#3803

The landscape of circular RNAs in metastatic colorectal cancer

Sidi Zhao, Amy Ly, Jacqueline L. Mudd, Emily B. Rozycki, Ghofran Othoum, Jingqin Luo, Ha X. Dang, Ryan C. Fields, Christopher A. Maher.
Washington University in St. Louis, St. Louis, MO

Colorectal cancer (CRC) is the most common gastrointestinal malignancy and a leading cause of cancer death in the U.S.. Approximately 50% of patients with CRC develop metastatic disease (mCRC) with an average 5-year survival rate of 13%. Circular RNAs (circRNAs), covalently closed RNA molecules produced from pre-mRNAs through backsplicing, have recently emerged as an important class of non-coding RNAs regulating CRC tumorigenesis and progression. In this study we established a comprehensive catalog of circRNAs in mCRC. To evaluate circRNAs in mCRC progression, total RNA-Seq was performed on 30 matched normal, primary, and distant metastatic samples from 14 mCRC patients. Additionally, the transcriptome of five CRC cell lines were sequenced to evaluate circRNAs expressed in cell lines. CircRNAs were identified and quantified using the number of backspliced reads, normalized against the total number of mapped reads. Differential expression (DE) analysis was performed to identify circRNAs deregulated between normal, primary, and metastatic tissues. Our analysis identified approximately 62,000 expressed circRNAs in mCRC including approximately 32,000 expressed in patients and 48,000 expressed in cell lines, originating from approximately 9200 linear genes. Approximately 42,000 circRNAs (67%) were unannotated when compared with the circRNA consortium MiOncoCirc annotation. DE analysis identified 376 circRNAs deregulated in CRC progression from normal to primary, and metastasis. A higher proportion of DE circRNAs (82%) was downregulated in primary or metastasis, consistent with earlier reports of lower circRNA concentration in tumor due to rapid cell cycles. Among DE circRNAs were the downregulation of circRNAs that have been known to suppress tumor proliferation, migration, and invasion in mCRC such as circSMARCA5, circFBXW7, and circSETD3, and the upregulation of circFIRRE, a circRNA known to promote tumor progression in osteosarcoma. A significant portion (37%) of deregulated circRNAs also had their parental linear genes found to be deregulated, suggesting parental gene regulation contributed to circRNA regulation. Interestingly, a large portion of circRNAs (63%) were found to be deregulated while their parental linear gene expression was unchanged, suggesting alternative

mechanisms of circRNA deregulation. Gene set enrichment analysis showed that linear genes co-deregulated with circRNAs were enriched in signatures of tumor progression including proliferation, epithelial mesenchymal transition, and metastasis, suggesting potential involvement of deregulated circRNAs in tumor progression. Through RNA sequencing of both patients and cell lines, we established a comprehensive compendium of circRNAs and identified those deregulated in mCRC. This provides a valuable resource for further experimental characterization of circRNAs function in mCRC progression.

Lille, Inserm, U1192—Proteomique Reponse Inflammatoire Spectrometrie de Masse (PRISM), France, Italy*

The human *Plasmacytoma Variant Translocation 1* (*PVT1*) gene encodes for 176 linear (*PVT1*, lncipedia.org) and 29 circular isoforms (circPVT1, www.circbase.org). The most common isoform of circPVT1 is 410bp and is a product of back-splicing containing the whole exon 2 of *PVT1* in a closed

loop-like structure (*hsa_circ_0001821)*. *PVT1* and circPVT1 have oncogenic roles in several tumor types and can contribute to the suppression of anti-tumor immune responses. Our study aims to investigate whether and how *PVT1* isoforms and circPVT1 promote an aggressive phenotype in acute myeloid leukemia (AML) and are involved in the crosstalk between leukemic and immune cells. Six out of the 14 *PVT1* isoforms expressed by white blood cells and lymphnodes (noncode.org) were detected in a panel of AML cell lines along with circPVT1. Downregulation (KD) of groups of linear isoforms (based on sequence homology) or of circPVT1 by antisense-oligonucleotides (ASOs) in the t(8;21) KASUMI-1 and the *NPM1*-mut OCI-AML3 cells induced an impairment of leukemia cell growth especially when all the 6 linear isoforms were silenced by ASO combination , in both cell lines, under normoxia and hypoxia mimicking the bone-marrow microenvironment. Interestingly circPVT1-KD induced apoptosis in OCI-AML3 cells. Moreover, MYC protein expression decreased by ASO combination or circPVT1_KD in OCI-AML3 under normoxia and in KASUMI-1 under hypoxia. To further investigate the biological consequences of *PVT1*/circPVT1-KD, we performed RNAseq. Analysis on AML cell lines revealed that downregulation of *PVT1* and, especially circPVT1, altered the expression of genes involved in RNA transport and degradation, as expected for a long non-coding genes, but also in DNA damage response (DDR) and immunological pathways, as also confirmed by transcriptomic data of primary AML cases and proteomic analysis of both cell lines. Based on these novel findings, we tested the downregulation of *PVT1*/circPVT1 in combination with inhibition of ATM or ATR, key DDR transducers. Interestingly, circPVT1-KD sensitized OCI-AML3 to ATM (71% *vs* 95% live cells) or ATR (75% *vs* 90% live cells) inhibitors. *PVT1* and circPVT1 expression was also detected at the level of cell-free RNA in primary AML samples, the latter showing higher levels. We then analyzed extracellular vesicles (EVs) from AML peripheral blood and healthy subjects. EVs from patients were larger, increased in number and expressed higher levels of myeloid lineage markers. Finally AML EVs had more circPVT1 cargo. In conclusion, we uncovered novel potential roles of *PVT1* isoforms and circPVT1 in the DDR and in the tumor microenvironment that pave the way for novel therapeutic combinations.

Revealing the role of microRNAs in the emergence of cancer stem cell heterogeneity during colorectal cancer progression

Molly Lausten[1], Victoria Stark[2], Caroline Facey[3], Lynn Opdenaker[3], Bruce M. Boman[1]. *[1]Biological Sciences, University of Delaware, Newark, DE,[2]University of Delaware, Newark, DE,[3]Cawley Center for Translational Cancer Research, Newark, DE*

Our goal is to identify microRNAs (miRNAs) that target mRNAs involved in stem cell (SC) signaling pathways involved in colorectal cancer (CRC) tumorigenesis. SC overpopulation drives CRC progression but exact mechanism is unclear. *Hypothesis*: specific miRNAs target SC genes, which leads to the emergence of multiple cancer SC (CSC) sub-populations and tumor heterogeneity. We used flow cytometry to identify CSC sub-populations based on expression of SC markers including ALDH1, LGR5 and others in the HT-29 CRC cell line. CSC sub-populations were isolated and measured using FACS and expression of miRNAs in each CSC sub-population was quantified using NanoString profiling. The level of miRNA upregulation in each CSC sub-population was ranked based on differential expression of the miRNAs between different CSC sub-populations. We chose to further analyze the LGR5 and ALDH SC sub-populations because they showed: *i*) the largest difference between CSC sub-population sizes, *ii*) the smallest size (<1%) of the co-positive (LGR5+/ALDH+) cell sub-population, *iii*) the highest numbers of differentially expressed miRNAs. Note that WNT signaling mainly occurs via LGR5+ CSC and retinoic acid (RA) signaling mainly occurs via ALDH+ CSCs. We report herein miRNAs that are differentially expressed between ALDH+/LGR5- compared to ALDH-/LGR5- subpopulation and LGR5+/ALDH- versus ALDH-/LGR5-. The mRNAs expressed in CSC subpopulations identified from Nanostring profiling were analyzed using bioinformatics for their predicted binding by upregulated miRNAs. Our findings show that: *1*) multiple CSC subpopulations exist in the HT-29 cell population; *2*) each CSC subpopulation has a unique miRNA signature. Notably, *RXRA* mRNA is significantly upregulated in the ALDH+/LGR5- CSC sub-population but not in the LGR5+/ALDH- CSC subpopulation. We identified 5 miRs upregulated in the LGR5+/ALDH- CSC subpopulation that are predicted to target the 3'UTR of *RXRA* mRNA. One of these miRs, miR-660-3p, is specifically upregulated in the LGR5+/ALDH- CSC subpopulation and

binding of miR-660-3p to *RXRA* mRNA was validated using luciferase assay in HT-29 cells. We previously reported that RXRA is selectively expressed in ALDH + CSC sub-populations. Also, RXRA is known to bind with β-catenin leading to its degradation and suppression of WNT-based transcriptional activity. Taken together, these results indicate that expression of miR-660-3p, by inhibiting *RXRA* expression, increases WNT signaling and decreases RA signaling in LGR5+/ALDH- CSCs. Thus, upregulated miR-660-3p targets a key gene in the RA signaling pathway (*RXRA*) which could contribute to the emergence of SC sub-populations during CRC development.

Investigating the role of miRNA-34a in the resistance of esophageal adenocarcinoma to neoadjuvant chemoradiation therapy

Christina Cahill[1], Stephen G. Maher[1], Rebecca O'Brien[1], Wei-Lin Winnie Wang[2], John V. Reynolds[1], Jacintha O'Sullivan[1], Niamh Lynam-Lennon[1].
[1]Department of Surgery, Trinity St. James's Cancer Institute, Dublin, Ireland,[2]miR Scientific LLC, Rensselaer, NY

Background**:** The current standard of care for locally advanced esophageal adenocarcinoma (EAC) involves neo-adjuvant chemoradiation therapy (neo-CRT) followed by surgery. However, response to neo-CRT is poor and resistance remains a significant barrier to effective treatment. There are currently no clinical biomarkers to predict treatment response in EAC. Evidence supports a role for microRNA-34a (miR-34a) as a tumor suppressor in cancer, however, the role of miR-34a in the tumor response to therapy in EAC is largely unknown.
Methods: Irradiation of EAC cell lines was performed using an Xstrahl RS225 X-ray irradiator at a clinically-relevant dose of 2 Gy. Radiosensitivity of EAC cell lines (OE33 P, OE33 R, OE33, OE19, Flo-1^{Par} and Flo-1^{LM}) was assessed by the gold standard clonogenic assay. miR-34a expression was assessed by qPCR. EAC tumor biopsies were obtained from consenting patients undergoing diagnostic endoscopy. Pathological response of the resected tumor was assigned by a pathologist using the Mandard Tumor Regression scale. miRTarBase and KEGG pathway analysis were used to identify predicted target genes and pathways of miR-34a.

Results: miR-34a was demonstrated to be expressed in a panel of EAC cell lines (OE33 P, OE33 R, OE19, Flo-1^{Par} and Flo-1^{LM} cells). Interestingly, miR-34a expression was significantly decreased in EAC cell line models of both acquired radioresistance (OE33 R) and inherent radioresistance (OE19). miR-34a was also significantly decreased in a model of radioresistant metastatic EAC (Flo-1^{LM}). Supporting *in vitro* data, in pre-treatment tumor biopsies from EAC patients (n=18), miR-34a was significantly decreased in patients having a subsequent poor pathological response to neo-CRT, when compared to patients having a good pathological response to neo-CRT. Target and pathway analysis demonstrated miR-34a-mediated regulation of genes and pathways associated with treatment resistance, including the complement system, cellular metabolism and p53 signaling, among others.
Conclusion: Decreased miR-34a expression is associated with radioresistance across a panel of *in vitro* EAC models and in pre-treatment tumor biopsies from EAC patients having a poor pathological response to neo-CRT. This highlights a potential role for miR-34a as a novel biomarker predicting response to neo-CRT in EAC. Analysis of validated and predicted gene targets of miR-34a identified a number of pathways associated with treatment resistance. We are currently investigating the functional role of miR-34a in modulating tumor response to radiation *in vitro* to determine its potential as a novel therapeutic target to boost treatment response in EAC.

MicroRNA-29a synergizes with PD-1 therapy to regulate anti-tumor immunity

Xuebing Leng, Svetlana Ristin, Christine Rafie, Lance Buchness, Alejandro Villarino, Erietta Stelekati. *University of Miami Miller School of Medicine, Miami, FL*

CD8 T cells initiate potent anti-tumor immune responses. However, tumor cells employ PD-1 ligand, (PD-L1) to obstruct CD8 T cell responses and drive exhausted T cells (T_{EX}) differentiation. T_{EX} are characterized by sub-optimal functionality and inability to efficiently eliminate tumor cells. Checkpoint inhibitor therapy such as anti-PD-1 can partially restore the effector functions of T_{EX}, but the stable epigenetic programs of T_{EX} lead to

the loss of reinvigoration and tumor relapse, providing a challenge for the efficacy of checkpoint blockade therapy. We recently demonstrated that miR-29a acts as a key regulator of T_{EX} differentiation, promotes memory-like differentiation and attenuates exhaustion during chronic infection. Importantly, miR-29a favors the expansion of a progenitor T_{EX} subset expressing the transcription factor TCF-1 that responds to immunotherapy. Therefore, we hypothesized that miR-29a can substantially alter T_{EX} differentiation and synergize with checkpoint blockade to enhance anti-tumor immune responses. A well-established mouse model of chronic infection (LCMV clone-13) was used to induce T_{EX} differentiation, with transcriptional and epigenetic profiles similar to T_{EX} from human tumors. We found that combination of miR-29a overexpression and anti-PD-L1 treatment enhanced CD8 T cell expansion > 20 fold, whereas anti-PD-L1 alone marginally increased the number of CD8 T cells, suggesting that miR-29a synergizes with anti-PD-L1 to enhance CD8 T cell responses. Immune reinvigoration induced by anti-PD-L1 therapy is characterized by a partial reduction of inhibitory receptors and increase in effector responses. Instead, miR-29a overexpression combined with anti-PD-L1 promoted memory-like differentiation and long-term persistence of CD8 T cells, without compromising effector functions. Mechanistically, miR-29a synergized with anti-PD-L1 by inducing expression of a key memory-associated transcription factor, TCF-1, and antagonizing the master epigenetic regulator of exhaustion, TOX. To further understand whether miR-29a promotes only expansion of a progenitor $TCF1^+$ subset or fundamentally alters T_{EX} subset differentiation, equal numbers of miR-29a overexpressing and control $TCF1^+$ CD8 T cells were isolated and adoptively transferred to secondary host mice followed by PD-L1 blockade. $TCF1^+$ CD8 T cells with enforced miR-29a expression responded to PD-L1 blockade more efficiently than control TCF^+ CD8 T cells. These results suggest that miR-29a fundamentally alters T_{EX} differentiation by regulating key exhaustion-related transcriptional and epigenetic circuits. Therefore, we suggest that miR29a has the potential to be used as a novel therapeutic inducing robust and durable immune responses upon PD-1 therapy.

MicroRNA-206 drives antitumor immunity by disrupting the communication between Kupffer cells and Tregs

Guisheng Song, Ningning Liu. *Medicine, University of Minnesota Medical School, Minneapolis, MN*

Kupffer cells (KCs) account for 15% of the total liver cells. However, their roles in hepatocellular carcinoma (HCC) is poorly described. Clec4fCre-tdTomato knock-in mice expressing Cre recombinase and tdTomato-NLS under the KC-specific Clec4f promoter were hydrodynamically injected with oncogenic AKT and Nras (AKT/Ras) to induce HCC. A LoxP-stop-LoxP (LSL) system was used to express miR-206 in KCs of mice. AKT activation was observed in hepatocytes and KCs of HCC patients. Hydrodynamic injection (HDI) of AKT/Ras led to activation of AKT signaling in KCs and hepatocytes. AKT/Ras mice developed lethal HCC within 6-8 weeks post injection. Activation of AKT signaling led to M2 polarization of KCs, increased hepatic Tregs and exhaustion of CTLs. MicroRNA (miR) profiling revealed that AKT/Ras impaired miR-206 biogenesis in KCs by driving translation of Yin Yang 1 (YY1), a transcription repressor of miR-206. HDI of miR-206 into AKT/Ras mice fully prevented HCC, while all control mice died of HCC 6-8 weeks post injection. However, HDI of miR-206 only transfected ~ 20% of hepatocytes, indicating that it is unreasonable to conclude that the full prevention of HCC in AKT/Ras/miR-206 mice is caused by inhibited proliferation of HCC cells. We, therefore, posited that miR-206-mediated recovery of immune surveillance, at least in part, accounted for the full prevention of HCC in AKT/Ras/miR-206 mice. We next used the LSL system to overexpress miR-206 in KCs of Clec4fCretdTomato mice injected with AKT/Ras. KC-specific expression of miR-206 fully prevented HCC in AKT/Ras mice, while 100% control mice died of HCC. Mechanistically, AKT signaling in KCs drove CCL22 (C-C motif chemokine ligand 22) production by phosphorylating β-catenin that activates transcription of *Ccl22*. In contrast, miR-206 disrupted β-catenin signaling by targeting LEF1 (lymphoid enhancer-binding factor 1), an "architectural" transcription factor of β-catenin. CCL22 recruits Tregs. Indeed, KC-specific expression of miR-206 led to elevated CCL22, M2 to M1 transition of KCs, reduced hepatic Tregs, and elevated CTLs. Depletion

of CTLs in AKT/Ras mice fully offset the ability of miR-206 to prevent HCC.
Conclusions: AKT-educated KCs initiate Treg recruitment via a regulatory loop consisting of YY1, β-catenin/LEF1, miR-206, and CCL22; once this loop is activated, AKT activates β-catenin axis, which drives CCL22 production, Treg recruitment and HCC growth; while KC-specific expression of miR-206 reversed this process by blocking β-catenin axis in KCs. miR-206 represents a novel immunotherapy against HCC.

Differential regulation of novel long non coding RNAs and their mechanism of action in p73 dependent manner
Chanchal Bareja, Apoorva Uboveja, Daman Saluja. *University of Delhi, New Delhi, India*

The p53 tumor suppressor family is classically activated after DNA damage and plays a central role in cell fate decisions. Although, the p53 family activates many of the same genes in response to DNA damage, p73 plays distinct biological functions in development and metastasis. It is likely that p73 activates a unique transcriptional network which is critical for its anti-metastatic and anti-invasive action. Long non-coding RNAs (lncRNAs) are a class of mRNA- like transcripts longer than 200 nucleotides. They lack protein-coding ability and are believed to be involved in various kinds of biological processes. Increasing evidence suggests that lncRNA are frequently aberrantly expressed in cancers. Therefore, the roles of dysregulated functional lncRNA in human malignant tumors have attracted considerable scientific interest. The objective of our study is to find out novel long non-coding RNAs that can act as transcriptional targets of p73 and to delineate their role in p73-mediated anti-metastatic response. For this purpose, we performed transcriptome sequencing in HCT116p73wt and HCT116p73KD cells and screened the data for modulation of expression of lncRNAs in differential manner. Quantitative Real Time PCR was further carried out to validate the data obtained after screening RNA seq Data. Promoter analysis was carried out for the identification of p73 binding sites in the selected upregulated or downregulated lncRNAs which was further confirmed by Luciferase reporter, ChIP and site directed mutagenesis assays. About six lncRNAs were observed to be significantly upregulated

while four were down-regulated upon knockdown of p73. The promoters of selected lncRNAs were analysed *in silico* using TF Bind and JASPAR software for p73 binding sites and luciferase reporter assays suggested regulation of lncRNAs by p73. Chromatin immunoprecipitation showed promoter enrichment of the selected lncRNAs. Together, our study provides insights into the differential regulation of long non- coding RNAs in p73 dependent manner which further will provide the mechanism of their action at the genome level.

MicroRNA-483-5p inhibits cell steatosis and fibrosis by targeting PPARa, TIMP2 and HCC cell proliferation by modulating notch signaling

Suryakant Niture[1], Sashi Gadi[1], Qi Qi[1], Maxwell Gyamfi[2], Leslimar Rios-Colon[1], Rency Varghese[3], Habtom Ressom[3], Deepak Kumar[1]. *[1]BBRI, North Carolina Central University, Durham, NC,[2]Department of Pharmaceutical Sciences, College of Pharmacy, The University of Tennessee Health Science Center, Memphis, TN,[3]Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC*

MicroRNAs (miRNAs) are small non-coding RNA molecules that bind with 3' untranslated regions (UTRs) of genes and regulate expression. Downregulation of miR-483-5p (miR-483), is associated with the progression of hepatocellular carcinoma (HCC). However, the molecular and mechanistic role of miR-483 in nonalcoholic fatty liver disease (NAFLD), alcoholic fatty liver diseases (AFLD), and HCC remain elusive. In the current study, we investigated the biological significance of miR-483-5p in NAFLD, AFLD, and HCC *in vitro* and *in vivo*. Our data show that the expression of miR-483 was downregulated in tumor samples from HCC patients. Overexpression of miR-483 in HCC cells dysregulated Notch signaling, inhibited cell proliferation/migration, induced apoptosis, and increased sensitivity towards sorafenib/regorafenib; anti-HCC drugs. Interestingly, miR-483 overexpression downregulated cell steatosis and fibrogenic signaling in HCC cells. Mechanistically, miR-483 targets peroxisome proliferator-activated receptor α (PPARα) and tissue inhibitor of metalloproteinases 2 (TIMP2) gene expression by binding to 3'-UTR and suppress cell steatosis and fibrosis. Down-regulation of miR-483 was

observed in mice fed with a high-fat diet (HFD) or alcohol which lead to increased hepatic steatosis/fibrosis. Our data suggest that miR-483 inhibits cell steatosis and fibrogenic signaling, and functions as a tumor suppressor in HCC. Therefore, miR-483 may be used as a novel therapeutic target for NAFLD/AFLD/HCC management in patients with fatty live diseases/ HCC.

Micro-RNA induced inactivation of inflammatory cytokine signaling pathways in Waldenstrom macroglobulinemia compared to IgM-MGUS

Karan Chohan[1], Jonas Paludo[2], Surendra Dasari[2], Jithma P. Abeykoon[2], Prashant Kapoor[2], Esteban Braggio[3], Michelle K. Manske[2], Aneel Paulus[4], Craig B. Reeder[3], Sikander Ailawadhi[4], Asher A. Chanan-Khan[4], Robert A. Kyle[2], Morie A. Gertz[2], Anne J. Novak[2], Stephen M. Ansell[2]. *[1]Medicine, Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Rochester, MN,[3]Mayo Clinic, Scottsdale, AZ,[4]Mayo Clinic, Jacksonville, FL*

Introducti**on:** Cytokines are protein factors that regulate diverse cellular processes. The malignant progression of immunoglobulin M monoclonal gammopathy of undetermined significance (IgM-MGUS) to Waldenstrom macroglobulinemia (WM) is in part cytokine mediated, and we have previously shown IL-6 mediates IgM secretion in WM via the JAK/STAT pathway. Cytokine signaling can be epigenetically modulated by micro-RNAs (miRs). We aimed to identify the role of miRs in the regulation of inflammatory cytokine pathways between these diseases.
Methods: Bone marrow samples of patients with IgM-MGUS (n=7) and WM (n=25) were prospectively collected and sorted for CD19+ and/or CD138+ malignant cells. Total RNA extraction and sequencing were performed, miR and mRNA profiling was conducted, and differential expression was calculated between WM and IgM-MGUS using a log2 fold change (FC)>0.5 and <-0.5, false discovery rate<0.05. Experimental differentially expressed miR-mRNA pairing was performed, and pairs were filtered for correlated expression (i.e., upregulated miR/downregulated mRNA, and vice-versa). Filtered pairs were analyzed using the Ingenuity Pathway Analysis to identify pathways between WM and IgM-MGUS with absolute activation Z-score ≥1.

Results: We identified 34 differentially expressed miRs experimentally targeting 1132 mRNAs. Pathway analysis showed overall miR-based inactivation of inflammatory cytokine signaling pathways in WM compared to IgM-MGUS, especially of the interleukin (IL) family: IL-2, IL-6, IL-8, IL-9, IL-15, and IL-17. Underlying multiple pathways was upregulation of miRs-146a, 150, 194, all targets of Signal Transducer and Activator of Transcription 1 (*STAT1)*, observed to be downregulated. Of relevance, miR-146a has been previously shown to be an inhibitor of inflammatory cytokines, including IL-6. Next, we observed upregulation of miR-142 which targets phosphoinositide-3-kinase regulatory subunit 6 (*PIK3R6*), observed to be downregulated. Both the STAT and PIK3 families are important cytokine signal transducers, and we have previously shown the PI3k-AKT-IkB-p65 pathway induces expression of IL-6 via a GLI2-mediated mechanism. We additionally observed granulocyte-macrophage colony-stimulating factor (GM-CSF) signaling to be inactivated in WM. Here, miR-19b and miR-30e were upregulated, both target CSF 2 receptor subunit beta (*CSF2RB)*, found to be downregulated. CSF2RB is the common receptor subunit of GM-CSF, IL-3, and IL-5.
Conclusion: Our study identifies multiple cytokines pathways involved in inflammation and the tumor microenvironment to be potentially inactivated by differentially expressed miRs in WM compared to IgM-MGUS. Downregulation of these pathways and targeting of the STAT and PIK3 family indicates a possible miR-based negative feedback loop to down-modulate inflammatory cytokine signaling in WM.

Circular RNAs from the PAX5 oncogene are overexpressed in B-cell malignancies and modulate cancer processes

Danick M. Martin[1], Brandon Hannay[2], Alexis Martin[1], Vanessa Veilleux[1], Nicholas Finn[3], Gilles A. Robichaud[1]. *[1]Chemistry and biochemistry, Université de Moncton, Moncton, NB, Canada,[2]Atlantic Cancer Research Institute, Moncton, NB, Canada,[3]Dr. Georges-L.-Dumont University Hospital Centre, Moncton, NB, Canada*

Circular RNAs (circRNAs) represent a new class of gene products involved in many biological processes. Due to their ability to bind and modulate co-interacting proteins and microRNAs (miRs), circRNAs represent new

signaling mediators in cell biology and cancer processes. Recently, we identified circRNAs from the *PAX5* oncogene (circPAX5) in B-cells. Given that *PAX5* gene products are well established as potent oncogenic regulators of B-cell cancer lesions, we hypothesized that circPAX5 may also be potentially involved in pathogenic processes of B-cell malignancies. In this study, we wanted to understand the role of circPAX5 in B-cell cancer processes and elucidate new potential targets for diagnostic and therapeutic avenues. Using a series of B-cell cancer models and clinical samples, we sequenced, mapped, and profiled circPAX5 expression profiles and found that circPAX5 products are indeed overexpressed in various cancer cell types where the predominant expressed isoform consisted of exons 2 to 5 (circPAX5_2-5) of the *PAX5* locus. In addition, we isolated circPAX5 complexes from cancer cells and identified co-interacting small non-coding RNAs, notably microARNs (miRs) by deep sequencing. To further elucidate the functional role of circPAX5 and miR co-interactions, selected miRs from the list were then conditionally overexpressed in B-cells followed by cellular phenotypic assays. Altogether, our results characterize new signaling products and pathways in B-cells. Our data also suggests that circPAX5 products are involved in B-cell cancer processes and could potentially represent new cancer pathways targeted for strategic therapeutic and/or diagnostic strategies in B-cell cancer lesions

#3813

Role of CDKN2B antisense RNA 1 in Epstein-Barr virus associated gastric carcinoma

Keila Torres[1], Wilda Olivares[1], Gonzalo Carrasco[2], Andres Rodriguez[1], Alejandro H. Corvalan[3]. *[1]Pontificia Universidad Catolica de Chile, Santiago, Chile,[2]Hospital Clinico Universidad de Chile, Santiago, Chile,[3]Advanced Center for Chronic Diseases (ACCDiS), Pontificia Universidad Catolica de Chile, Santiago, Chile*

Background: Epstein-Barr Virus (EBV)-associated gastric carcinoma (GC) (EBVaGC) is a subtype of GC which represents approximately 10% of this tumor. CDKN2B antisense RNA 1 (CDKN2B-AS1) is a long non-coding RNA associated with chronic diseases like cardiovascular disease and cancer. This study aimed to evaluate if the loss of CDKN2B-AS1 shifted the balance of the competing endogenous RNA (ceRNA) networks favoring

an apoptosis resistant phenotype through ebv-miR-BART4-5p/BID in EBVaGC.
Material and Methods: Seven gastric cancer cell lines were used to determine the expression of CDKN2B-AS1. Specific cell lines were used for CDKN2B-AS1 inhibition assays, the transfection of ebv-miR-BART4-5p and the binding between CDKN2B-AS1 and ebv-miR-BART4-5p. The detection of BID protein was determined by Western Blot. To validate the *in vitro* results, we detected CDKN2B-AS1, BID, and ebv-miR-BART4-5p expression levels by RT-qPCR in four EBVaGC positive and five negative cases. Apoptosis was detected by in situ hybridization (ISH).
Results and Discussion: CDKN2B-AS1 is expressed at higher levels in NCI-N87 and SNU-1 cell lines and at lower levels in AGS and KATO-III. A significant decrease in BID protein expression was observed after co-transfection with ebv-miR-BART4-5p and CDKN2B-AS1 inhibitor. However, these results were not significant at mRNA level. The luciferase assay validated the predicted binding between ebv-miR-BART4-5p and CDKN2B-AS1. In EBVaGC samples, a significant decrease in BID expression and cleaved caspase-3 in the presence of miR-BART4-5p was observed. Our results show that decreasing CDKN2B-AS1 expression favors viral miR binding on BID mRNAs through ceRNA networks. Also, these results could explain why positive EBVaGCs have lower apoptosis rate than EBVaGC negative cases.

In CLL the U1 snRNA driver mutation alters splicing in multiple genes and pathways

Andrea Senff-Ribeiro[1], Fatemeh Almodaresi[1], Quang Trinh[1], Shimin Shuai[2], David Spaner[3], Xose S. Puente[4], Elias Campo[4], Lincoln D. Stein[1].
[1]Ontario Institute for Cancer Research, Toronto, ON, Canada,[2]Southern University of Science and Technology (SUSTech), Shenzhen, China,[3]Sunnybrook Health Sciences Centre, Toronto, ON, Canada,[4]Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), Madrid, Spain

5-10% of patients with the IGHV wild type form of chronic lymphocytic leukemia (CLL) carry a g.3A>C driver mutation in the U1 small nuclear RNA (snRNA). We investigatedthe patterns of mis-splicing and their pathway consequences in three U1-mutant CLL cellline models using long read sequencing in order to better understand the mechanisms ofoncogenicity in tumors carrying this mutation. CLL cell lines (HG3, JVM3 and MEC1) expressing the U1 mutation and their wild-type counterparts were submitted to Oxford Nanopore sequencing to generate full-length RNA transcripts. This transcriptomic datawas evaluated, together with previously obtained short-read data. The g.3A>C mutation occurs at a specific location of the U1 snRNA, a core component of the eukaryotic spliceosome, and acts by altering the 5' splice site (5'SS) recognition sequence to cause consistent patterns of mis-splicing. Long read analysis identified multiple instances of intron retention and suppression of exon skipping, and in silico translation of these mis-splicing events predicted stop-gain and other loss of function mutations in several expressed genes, as well as widespread changes in gene expression levels. We performed a pathway overrepresentation analysis of the altered gene expression patterns in the mutant cells using the Reactome knowledgebase and identified an enrichment in the processes of translation, non-sense mediated decay (NMD) and immune signaling, including interferon signaling. In particular, there was a marked down-regulation of genes related to ribosomal assembly and the translational machinery. A more comprehensiveanalysis of the U1 mutation phenotype in CLL may accelerate the development of better therapeutic and diagnostic approaches in patients.

Oxidative Stress, Metabolism, and Cell Senescence

Prevention of doxorubicin-induced cardiotoxicity by benfotiamine

Justin R. Taylor, Kyra Harames. *Biomedical Sciences, Noorda College of Osteopathic Medicine, Provo, UT*

Anthracyclines such as daunorubicin and doxorubicin (DOX) are currently used as chemotherapeutic agents in the prevention of various cancers including breast cancer, lung cancer, leukemia, and lymphoma. Although,

anthracyclines are successful in controlling various cancers growth, the major drawback is the unwanted cardiotoxicity. Specifically, high doses of DOX used for the therapy of advanced cancers could cause life threating conditions. Therefore, specific interventions are required to decrease the cardiac toxicity associated with the DOX. Benfotiamine, a lipid soluble vitamin B1 derivative has shown be a potent anti-oxidant and anti-inflammatory agent. However, the efficacy of benfotiamine in the prevention of cardiotoxicity associated with the anthracyclines is not known. In this study, we examined the effect of benfotiamine in the prevention of DOX-induced cytotoxicity in the human umbilical vascular endothelial cells (HUVECs). Treatment of HUVECs with DOX caused significant endothelial cells death and benfotiamine in a concentration-dependent manner prevented the dox-induced endothelial cell death. Further, benfotiamine prevents the DOX-induced apoptosis in endothelial cells by preventing the activation of caspase-3. Benfotiamine also prevents DOX-induced reactive oxygen species generation. Our results also indicate that benfotiamine regulates DOX-induced expression of pro-apoptotic mediators such as BAD, phosphor-P53, and pro-caspase-3, and anti-apoptotic mediators such as BCL-2, BCL-x, IAPs, and HSP and others such as FADD, DR5, and SMAC/diablo. We plan to further explore how benfotiamine prevents DOX-induced cardiotoxicity using human cardiac myocytes and mouse models. Thus, based on our cell culture studies, benfotiamine through its potent anti-oxidative property could prevent endothelial cytotoxicity and suggests that it could be further developed as adjuvant therapy in controlling cardiotoxicity associated with the anthracycline chemotherapy.

β3-adrenoceptor minimize doxorubicin effect in Ewing sarcoma by UCP2 activation

Claudia Masi[1], Amada Pasha[1], Francesco Carrozzo[1], Martina Rosati[1], Alessandro Pini[2], Maura Calvani[1], Claudio Favre[1]. *[1]Meyer Children's Hospital, Firenze, Italy,[2]University of Florence, Firenze, Italy*

The phenomenon of “Oxygen Paradox” arises when reactive oxygen species (ROS) overcome the cellular anti-oxidant defense system through either an escalation in ROS levels or a reduced capability of the cells to

increase an antioxidant response. The deregulated redox signaling that stimulate an uncontrolled ROS increase, could induce both tumor initiation and progression, and cell death after chemotherapy treatment. In recent decades, the therapeutic choice for Ewing Sarcomas (ES) consisting of a multi-drug chemotherapy regimen combined with radiotherapy and surgery, has significantly improved the survival up to 70% in localized diseases. ES patients, often show resistance to multi chemotherapeutic agents since ES cells exhibit a high sensitivity to rapid changes in intracellular redox environment. In this context, an antioxidant-inhibiting strategy was evaluated *in vitro* to test chemotherapeutic efficacy used in the standard treatment of ES such as the anthracycline doxorubicin (DOX) that increases ROS generation and oxidative stress (OS) in mitochondria. DOX is a strong exogenous ROS generator but lacks target specificity thereby it also affects normal cells resulting in several side-effects. Literature shows that DOX ability to reduce tumor progression is due to a DOX-induced ROS overproduction that occurs in mitochondria, known to be the main site of constant ROS production, and this effect is mediated by the mitochondrial NADPH oxidase (NADPHox) activity. To investigate why DOX causes resistance in ES patients, experiments *in vitro* were conducted with A673 ES cell line. A673 cells express a high level of the β3-adrenergic receptor (β3-AR) and are high susceptible to OS. Recently, β3-AR has become highly attractive in cancer biology for its ability to reduce tumor growth, metastasis, and its antioxidant properties as main regulator of the cellular response to OS. β3-AR working as ROS sensor control the redox state of the cells, driving them to life or death through mitochondria bioenergetics function. In our experimental setting DOX induced β3-AR expression which influenced the uncoupling protein 2 (UCP2) expression. β3-AR/UCP2 axis strongly decreased the mitochondrial activity by reducing ATP synthesis and mitochondrial ROS content and this effect was reverted by β3-AR antagonist, SR59230A. In summary, the DOX chemotherapy promotes β3-AR expression that decreases ROS levels through β3-AR/UCP2 axis. Decreased ROS levels allow ES cells to survive chemotherapy.

#4773
DEAD Box 1 (DDX1) protects its RNA targets in cells exposed to oxidative stress

Mansi Garg, Roseline Godbout. *University of Alberta, Edmonton, AB, Canada*

DEAD box 1 (DDX1) belongs to the family of RNA helicases involved in all aspects of RNA metabolism, from transcription to transport, expression, and decay. DDX1 is overexpressed in a subset of retinoblastoma, neuroblastoma, and breast cancers. In breast cancer, the overexpression and cytoplasmic localization of DDX1 is correlated with poor prognosis. Cancer cells often exhibit high metabolic rates which can lead to genomic instability, oxidative stress, and endoplasmic stress. DDX1 is known to play a role in resolving genotoxic stress by participating in DNA double-strand break (DSB) repair. We propose that DDX1 also plays a key role as a stress response regulator in cells undergoing oxidative stress. When cells are exposed to oxidative stress, DDX1 is recruited to cytoplasmic stress granules (SGs). Although the exact function of SGs remains elusive, it is generally believed that tightly controlled SG assembly and disassembly are important for cell survival under stress. We found that while DDX1 is dispensable for SG assembly, depletion of DDX1 leads to impaired SG disassembly and hence, delayed stress recovery. Thus, DDX1 may play a role in stress resolution after the removal of stress conditions. To further understand the role of DDX1 in stress resolution, we performed RNA-immunoprecipitation followed by next-generation sequencing and identified DDX1-bound RNAs under normal and oxidative stress conditions. We found enhanced binding of DDX1 to its RNA targets in the presence of oxidative stress. Furthermore, we observed that DDX1 protects its target RNAs from degradation in the cytoplasm of cells undergoing oxidative stress. This RNA protection after stress exposure was more prominent in DDX1-overexpressing neuroblastoma cells, possibly explaining the faster stress recovery observed in these cells. Taken together, our results suggest that DDX1 plays a role in protecting cells from oxidative stress. This study may shed light on our understanding of cancer cell resistance to anticancer therapies.

Adaptation to chronic oxidative stress promotes metabolic rewiring to maintain redox balance in HER2+ breast tumors

Caitlynn Nicole Mirabelli[1], Rachel La Selva[1], Matthew Annis[1], Ouafa Najyb[2], Steven Hébert[2], Claudia Kleinman[3], Julie St-Pierre[4], Peter Siegel[1], Josie Ursini-Siegel[5]. *[1]Medicine, McGill University, Montreal, QC, Canada,[2]Lady Davis Institute for Medical Research, Montreal, QC, Canada,[3]Human Genetics, Lady Davis Institute for Medical Research, Montreal, QC, Canada,[4]Biochemistry, Microbiology and Immunology, University of Ottawa, Ottawa, ON, Canada,[5]Oncology, Lady Davis Institute for Medical Research, Montreal, QC, Canada*

Breast cancer is the most commonly diagnosed malignancy in women worldwide. Breast tumors possess a high degree of intra- and inter-tumoral heterogeneity, enabling the emergence of aggressive, therapy-resistant tumors. One contributor to breast tumor heterogeneity is reactive oxygen species (ROS), which are unstable oxygen-containing molecules that modify proteins, lipids, and DNA. Our lab has developed unique models of HER2+ breast cancer that evolved in vivo under conditions of low (ROS^{LOW}) and high (ROS^{HIGH}) chronic oxidative stress to acquire more aggressive properties. As such, we became interested in understanding the underlying mechanisms by which breast cancer cells capitalize on sustained oxidative stress to acquire more aggressive properties. We show that, relative to their parental and ROS^{LOW} counterparts, ROS^{HIGH}-evolved tumors are better able to maintain redox balance by coping with ROS-induced damage in vivo and following H_2O_2 treatment in vitro. Moreover, ROS^{HIGH}-evolved breast cancer cells lose their aggressive phenotype in vitro, implying a necessary microenvironmental contribution. RNAseq analysis of parental and aggressive breast cancers further identified glycolytic and hypoxic transcriptional signatures that were preferentially induced in breast cancers that adapted to chronic oxidative stress. Therefore, we hypothesized that breast cancer cells conditioned to cope with chronic oxidative stress may re-wire their glucose metabolism to support ROS buffering, which may be facilitated by a hypoxic tumor microenvironment. Notably, ROS^{HIGH}-evolved tumors are insensitive to inhibition of glycolysis using 2-deoxyglucose (2-DG); however, we show that they are specifically sensitized to inhibition of glutathione synthesis, and this sensitivity is exacerbated when treated in combination with 2-DG. As well, we show through glucose tracing that ROS^{HIGH}-evolved tumors

exhibit increased incorporation of glucose-derived carbons into glutathione. This data confirms that breast tumor adaptation to chronic oxidative stress promotes metabolic re-wiring to support ROS scavenging. To begin interrogating the role hypoxia plays in this phenotype, we assessed cell proliferation and levels of hypoxia-responsive genes following hypoxia exposure in our breast cancer models in vitro. Relative to their parental counterparts, breast cancer cells that adapted to chronic oxidative stress exhibit enhanced proliferation in hypoxia and are better able to upregulate hypoxia-responsive genes, even in response to modest changes in oxygen levels. Overall, our study shows that tumor adaptation under chronic oxidative stress promotes metabolic rewiring which may be facilitated by a hypoxic microenvironment.

Knockout of *Sod2* accelerates *Kras^{G12D}*-driven formation of pancreatic cancerous lesions

Alicia K. Fleming Martinez[1], Brandy H. Edenfield[1], Irene Esposito[2], Peter Storz[1]. *[1]Department of Cancer Biology, Mayo Clinic, Jacksonville, FL,[2]Institute of Pathology, Heinrich-Heine-University and University Hospital Duesseldorf, Düsseldorf, Germany*

Recent studies demonstrate that mitochondrially-generated reactive oxygen species (ROS) downstream of oncogenic KRAS drive acinar-to-ductal metaplasia (ADM), a key first step in the pancreatic ductal adenocarcinoma (PDA) progression model. MnSOD/*SOD2* is a mitochondrial enzyme that converts superoxide into hydrogen peroxide. Previous studies have shown that *SOD2* is biologically relevant to the study of pancreatic cancer. Some patients with a *SOD2* polymorphism resulting in less active MnSOD at the mitochondrial matrix are at increased risk of developing pancreatic cancer. Additionally, MnSOD is lost in high-grade human PanIN, further suggesting a role in tumor development. To elucidate the role of MnSOD in pancreatic cancer initiation and progression, we crossed *Sod2$^{lox/lox}$* mice into the *p48^{Cre};LSL-Kras^{G12D}* (KC) mouse model. We found increased ROS, abundantly more abnormal tissue development and presence of flat lesions indicating accelerated early progression. However, Kaplan Meyer survival analysis of KC and KC;*Sod2$^{-/-}$* mice did not indicate faster

progression to cancer, suggesting that for later steps additional signaling is needed. In summary, we identify MnSOD as a key antioxidant molecule preventing initiation of PDA.

NRF2 is overexpressed in esophageal adenocarcinoma and its targeting sensitizes tumor cells to cisplatin through induction of ferroptosis and apoptosis

Farah Ballout, Heng Lu, Zheng Chen, Tianling Hu, Lei Chen, Wael El-Rifai, Dunfa Peng. *University of Miami, Miami, FL*

Background: Esophageal adenocarcinoma (EAC) is the predominant type of esophageal cancer in the United States, with the 5-year survival rate is below 20%. EAC develops through Barrett's esophagus (BE)-dysplasia-carcinoma cascade. Gastroesophageal reflux disease (GERD), where acidic bile salts refluxate into the esophagus, is the main risk factor for the development of BE and its progression to EAC. The NFE2-related factor 2 (NRF2) is the master cellular antioxidant regulator, involving in many cancer hallmarks.
Methods and Results: Using western blotting and immunohistochemistry technologies, we detected high NRF2 protein levels in EAC cell lines and primary EAC tissues, as compared with normal esophagus and non-neoplastic Barrett's esophagus samples. The knockdown of NRF2 using NRF2 specific siRNAs significantly increased oxidative stress in response to cellular stress stimuli by bile salts or cisplatin. This was associated with an increase in DNA damage and inhibition of EAC cell growth. Brusatol, a NRF2 inhibitor, significantly inhibited NRF2 transcriptional activity and downregulated NRF2 target genes. We discovered that in addition to inducing apoptosis, Brusatol alone or in combination with CDDP induced significant lipid peroxidation and ferroptosis as evidenced by reduced xCT and GPX4 expression, two known ferroptosis markers. Moreover, the combination of Brusatol and CDDP significantly inhibited EAC tumor xenografts growth in vivo. We confirmed the in vitro data showing ferroptosis as an important mechanism in the xenografted tumors treated with Brusatol or Brusatol and CDDP combination using IHC staining.
Conclusion: Our data support the role of NRF2 in protecting against stress-induced apoptosis and ferroptosis in EACs. Targeting NRF2 in combination

with platinum therapy can be an effective strategy for eliminating cancer cells in EAC.

Exploring ferroptosis pathway for the development of therapeutic strategy in liposarcoma

Chueh-Chuan Yen[1], San-Chi Chen[2], Chih-Hsueh Chen[3], Jir-You Wang[4], Chao-Ming Chen[4], Po-Kuei Wu[4], Muh-Hwa Yang[2]. *[1]Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan,[2]Department of Oncology, Taipei Veterans General Hospital, Taipei, Taiwan,[3]Department of Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei, Taiwan,[4]Department of Orthopedics, Taipei Veterans General Hospital, Taipei, Taiwan*

Background: Liposarcoma (LPS) is one of the most common soft tissue sarcoma (STS) subtypes. Both well-differentiated LPS (WDLPS) and dedifferentiated LPS (DDLPS) have 12q13-15 amplification. Mouse double minute 2 homolog (MDM2) is one of the most important oncogenes within this region. Ferroptosis is a unique type of necrotic cell death featured accumulation of lipid-based reactive oxygen species (ROS) derived from the oxidative modification of phospholipid membranes. Cysteine metabolism is the critical part of ferroptosis regulation. Cystine-glutamate antiporter (system xc-; xCT), encoded by two subcomponents, the solute carrier family 7 member 11 (SLC7A11) and SLC3A2, is responsible for cystine supply from extra-cellular environment. Imported cystine is then reduced to cysteine, a key component of tripeptide glutathione (GSH). Glutathione peroxidase 4 (GPX4) requires GSH to repair lipid peroxidation and prevent ferroptosis. Inactivation of GPX4, either through cystine deprivation due to xCT inhibitor erastin, or by GPX4 inhibitor Ras-selective lethal small molecule 3 (RSL3), will lead to accumulation of lipid-based ROS, and eventually ferroptosis cell death. The tumor suppressor p53 (TP53) could suppress the expression of SLC7A11 and induce ferroptosis. TP53 could also indirectly suppress 3-hydroxy-3-methyl-glutaryl (HMG)-coenzyme A (CoA) reductase (HMGCR) activity, a key pathway for generation of biomolecules with anti-ferroptosis property. MDM2, the key oncogene in DDLPS, and homolog MDM4 could facilitate ferroptotic death in TP53-dependent or -independent mechanisms.

Methods: We explored public domain database to identify possible aberrations of ferroptosis-related genes in DDLPS. We then examined the sensitivity of DDLPS cell lines to possible ferroptosis-inducing agents. Furthermore, we used nutlin-3, a MDM2 inhibitor, to modulate the MDM2 expression in DDLPS cell line, and explored the potential synergistic effect of nutlin-3 with ferroptosis-inducing agents. Finally, we used immunoblotting study to reveal the potential mechanism responsible to possible synergistic effect.
Results: Expression level of GPX4 is significantly lower in DDLPS than adipose tissue and WDLPS, and DPP4 was general higher in LPS than adipose tissue. HMGCR, SLC7A11 and SLC3A2 were mostly up-regulated in LPS in comparison with benign counterpart. Both DDLPS cell lines showed sensitivity to erastin and RSL3. In addition, nutlin-3 could exert synergistic ferroptosis-inducing effect and cytotoxicity with erastin and RSL3 in sequential manner. Furthermore, nultin-3 treatment could upregulate SLC3A2 with altered cystine/glutamate exchange in DDLPS cell lines, indicating possible mechanism responsible for nultin-3 resistance and the synergistic effect of nultin-3 with erastin or RSL3.
Conclusion: Our study showed that modulation of ferroptosis is a potential treatment strategy in DDLPS.

Novel bioluminescence approaches for measuring fatty acid β-oxidation and production of reactive oxygen and nitrogen species

Kim Haupt[1], Matt Larsen[2], Hui Wang[2], Natasha Karassina[1], Mike Valley[1], Wenhui Zhou[2], Jolanta Vidugiriene[1]. *[1]Promega, Madison, WI,[2]Promega, San Luis Obispo, CA*

Energy uptake and utilization in eukaryotic cells is a dynamic process regulated by a series of interacting metabolic networks. Interrogation of this complex network relies on rapid, sensitive approaches that do not require extensive sample handling and are easily adaptable to 96- and 384-well plates. Previously, using the Ultra-Glo luciferase reaction we developed a panel of bioluminescent assays that can be used to monitor numerous aspects of cellular metabolism and mitochondrial function including ATP production, glucose and amino acid metabolism, and the TCA cycle. Here, we extend the use of the luciferase reaction and report on the development

of novel bioluminescence probes for studying two important metabolic cellular responses: fatty acid β-oxidation (FAO) and production of reactive oxygen and nitrogen species. For studying FAO, we developed a cell permeable probe with caged-luciferin attached to a fatty acid chain. The probe enters the cells and following FAO cycling, free luciferin is released and detected using Luciferin Detection Reagent. We validated the approach using known FAO activators and inhibitors and used it to monitor the changes in FAO during T-cell activation. For measuring reactive oxygen and nitrogen species, highly selective bioluminescence probes were developed. Upon reaction of the probes with their corresponding ROS target, they form the stable D-luciferin reporter molecule, causing luciferin to accumulate. Upon treatment with luciferase in the detection step, the generated light allows for quantification of the superoxide or nitric oxide formed. Both probes are suitable for in vitro and cell-based detection of ROS in an "add and read" format, providing for a simple workflow amenable to high throughput experimentation.

MnSOD mimetic mitoquinone mesylate (MitoQ) increases DCLK1^{+}pancreatic cancer stem cells

Jeffrey Mario Perera, Alicia K. Fleming Martinez, Peter Storz. *Department of Cancer Biology, Mayo Clinic Florida, Jacksonville, FL*

Mitochondrially-generated reactive oxygen species (mROS) have been shown to induce acinar-to-ductal metaplasia (ADM). ADM, in presence of an oncogenic KRAS mutation, is an initiating step for progression to pancreatic intraepithelial neoplasia (PanIN) and eventually pancreatic ductal adenocarcinoma (PDA). Here, we utilize primary murine cells as well as the *p48^{Cre};LSL-Kras^{G12D}* (KC) mouse model to explore the use of the mitochondria-targeted mimetic of manganese superoxide dismutase MitoQ for targeting PDA initiation and progression. Previously published data by our laboratory has shown that treatment with MitoQ decreases the abundance of pancreatic low-grade lesions in KC mice. However, we here demonstrate that superoxide depletion by MitoQ at the same time increases formation of DCLK1^{+} cancer stem cells in such lesions. We here evaluate if the detoxification of mitochondrial superoxide results in a build-up of hydrogen peroxide, which is a major driver of the DCLK1^{+} cell type. We

determine how altered expression of ROS detoxifying enzymes in different cell types contribute to PDA stem cell formation and PDA development. Eventually we test if the increase in DCLK1^{+} cancer stem cells can contribute to changes in the microenvironment and accelerated progression of abnormal tissue.

Comparison of safety and efficacy outcomes with nonthermal plasma and tirapazamine in porcine skin and mouse melanoma models

Matthew Yehl[1], Dominik Kucharski[2], Michelle Eubank[2], Xavier Ramadan[1], Ahmad Dianat[2], Bianca Pham[1], Timothy C. Hutcherson[1], Sandra Sexton[3], Shoshanna N. Zucker[1]. *[1]D'Youville College School of Pharmacy, Buffalo, NY,[2]University at Buffalo, Buffalo, NY,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY*

A novel preclinical experimental therapy for various cancer types including melanoma is the combination of nonthermal plasma (NTP) and tirapazamine (TPZ) delivered *in situ*. This patented combination therapy delivers reactive oxygen species (ROS) and reactive nitrogen species (RNS) from the atmosphere that are activated and ionized with helium gas to create the state of matter known as plasma. The combination with the prodrug, TPZ, that only activates to become a ROS in hypoxic environments, shows synergistic targeting of cancer cells. In this study, we assayed the effects of the dual therapy on porcine skin, which is the closest model to represent human skin and is commonly used for testing drug therapy. The results demonstrated that porcine skin showed no significant cell killing with the therapy. We also compared the combination therapy in normal skin keratinocytes and 1205Lu cells derived from a melanoma metastasis to the lung. The cells were treated with NTP and TPZ and maintained in a hypoxic chamber. Four days following therapy the keratinocytes continued to grow in culture, whereas the melanoma cells expressing endogenous gap junctions, or overexpressed Cx43 gap junctions showed decreased viability. However, the melanoma cells with a dominant negative Cx43 mutant did not show this loss in viability. This confirms our previous report that gap junctions mediate the passage of derivatives of ROS to increase the extent of cell death. To determine the effects of NTP on

regulating the lethal dose of TPZ, we performed IC_{50} curves for TPZ in the presence or absence of NTP in B16-F10 murine metastatic melanoma cells. We demonstrated a decrease in the IC_{50} from 28 μM without NTP to 17.4 μM with NTP. In further analysis, the effects of treating with NTP in the presence or absence of tissue culture media were compared. The results showed a highly significant increased efficacy of NTP in the absence of media. The combination therapy was more effective than each independent treatment. To further confirm the experimental analysis, we induced tumor formation with the B16-F10 cells in a syngeneic C57BL/6 mouse model. The tumors from mice that were untreated or treated with NTP or TPZ alone, showed a significant increase in tumor volume as compared to the tumors from mice receiving the combination treatment *in situ*. In comparison of the tumor growth rates, the control, NTP-, or TPZ-treated tumors had increased by approximately 350% by day 10, whereas the tumors in the mice that received the dual therapy only increased by an average of 70%. The results from these studies collectively implicate the combination of NTP and TPZ as a potential synergistic treatment for *in situ* melanomas that offer selectivity as compared to normal tissue.

#4781

New generation of fluorescent probes for cell-based measurements of caspase activation and mitochondrial superoxide

Bhaskar S. Mandavilli, Daniel Beacham, Yi Zhen Hu, Jongtae Yang, Aimei Chen. *Thermo Fisher Scientific, Eugene, OR*

Cell health and stress readouts are critical indicators of altered or impaired function in normal and diseased states of cells, and work has been underway to develop improved small molecule sensor dyes compatible with traditional imaging and High Content Analysis (HCA) interrogation of apoptotic and mitochondrial stress pathways.
The CellEvent™ Caspase Green dye effectively reports caspase activation, but suffers complications in assay configuration when attempting to multiplex with the Green Fluorescent Protein (GFP), calcein, or other 488 laser line tools in fluorescence microscopy. Here, we describe the testing and functional characterization of a new candidate molecule for measuring apoptosis in living cells. Our sensor is comprised of a fluorogenic reporter dye that is liberated from a DEVD peptide substrate by caspase activation,

but operates in the Texas Red, 590nm excitation band, with an emission peak near 610 nm, permitting easy multiplex with GFP or calcein stained neurons in both traditional and HCA microscopy configurations. Similarly, mitochondrial superoxide accompanying cell stress is probed in microscopy with the MitoSOX™ Red Mitochondrial Superoxide Indicator dye, which localizes to mitochondria and reports superoxide generation, ignoring other Reactive Oxygen Species (ROS) and Reactive Nitrogen Species (RNS). This dye has an unusually long Stokes' shift, requiring specialized microscopy and HCA filters that excite at 405nm, and capture emission at 610nm for specific superoxide detection. This unconventional spectroscopic profile prevents the dye's use on many imaging platforms and promotes phototoxicity. To this end, our team has produced a dye with the same level of specificity for superoxide that will operate in one of the traditional fluorescence microscopy channels. Our candidate dye, here named MitoSOX™ Green Mitochondrial Superoxide Indicator also localizes to mitochondria of live cells and selectively reports superoxide generation, while ignoring other ROS and RNS species in ex vivo testing. With an Excitation/Emission profile in the GFP/FITC microscopy channel, a series of comparative studies in immortalized and neural cells are shown, highlighting photostability, specificity and signal amplitude from the dye. These reagents are research use only, not for diagnostic purposes

#4782

A biflavonoid TY1 induced mitochondrial oxidative stress in 5-fluorouracil-resistant colorectal cancer cells to suppress tumor progression

Ting-Yan Jian[1], Shian-Ying Sung[2], Yu-Ling Lin[1]. *[1]Agricultural Biotechnology Research Center, Academia Sinica, Taipei, Taiwan,[2]International Ph.D. Program for Translational Science, Taipei Medical University, Taipei, Taiwan*

The high metastasis and drug resistance of colorectal cancer (CRC) cause high mortality and rank third among the top ten cancer deaths. TY1 is a biflavonoid isolated from *Taxus* x *media* cv. Hicksii. We have previously reported that TY1 inhibits metastatic behavior by inhibiting F-actin polymerization. However, the biological activities of TY1 to overcome drug resistance remain unclear. In this study, we investigated the

pharmacological mechanism of TY1 for inhibiting 5-fluorouracil (5-FU)-resistant CRC cells and its therapeutic effect. The 5-FU sensitive (COLO205) and 5-FU resistant (HT-29) CRC cells were used to determine the antitumor activity of TY1. Bioinformatic analysis was conducted to explore the antitumor effects of TY1 in 5-FU resistant HT-29 cells. The effects of TY1 on 5-FU-resistant CRC cells were determined by cell-based analyses, including MTT assay, cellular and mitochondrial ROS-superoxide detection, and confocal images. Finally, the therapeutic effects of TY1 were evaluated in HT-29 xenograft CRC mice. We found TY1 inhibited cell proliferation but did not affect the cell cycle. TEM images showed that TY1 induced vacuole production. Transcriptome data indicated that interferon-related genes specifically mitochondrial interferon alpha-inducible protein (IFIP) were significantly decreased after TY1 treatment. TY1 increased oxidative stress generated by reactive oxygen species (ROS) and superoxide. When IFIP was overexpressed, TY1-induced oxidative stress was reduced. In xenograft CRC mouse, TY1 effectively inhibited tumor growth. The anticancer activity of TY1 is attributed to TY1-induced ROS and superoxide by downregulating mitochondrial IFIP expression. Therefore, these data suggest that TY1 may be a promising new compound in the treatment of 5-FU-resistant CRC.

#4783

ADO is essential for redox homeostasis in liver cancer

Sandy C-E S. Lee[1], Andrea H. A. Pyo[1], Helia Mohammadi[1], Ji Zhang[1], Anna Dvorkin-Gheva[1], Lucie Malbeteau[1], Stephen Chung[1], Shahbaz Khan[1], Thomas Kislinger[1], Julie A. Reisz[2], Courtney Jones[1], Marianne Koritzinsky[1]. *[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]University of Colorado, Aurora, CO*

2-Aminoethanethiol dioxygenase (ADO) is a thiol dioxygenase that plays a direct role in both metabolism and protein stability. Oxidation of the metabolite cysteamine produces hypotaurine, while oxidation of N-terminal cysteines targets protein substrates for N-degron pathway-mediated degradation. Despite these known functions, the (patho)physiological roles of ADO remain obscure. By analyzing TCGA datasets we discovered that high ADO expression is associated with poor outcome for patients with hepatocellular carcinoma (HCC) (HR 1.2, $p<0.001$). HCC is linked to viral

hepatitis, alcohol, metabolic syndrome, non-alcoholic fatty liver disease and chronic inflammation. It is the third leading cause of cancer-related deaths worldwide and is significantly more common in males than females. With poor outcomes, there is a need to better understand HCC biology and vulnerabilities. To assess the functional roles of ADO, we created ADO knockout mice as well as two liver cancer cell line models where ADO was depleted by siRNA, doxycycline-inducible shRNA, or CRISPR/Cas9. While male ADO knockout mice were viable, fertile and healthy, depletion of ADO in liver cancer models significantly reduced cancer cell proliferation and colony formation. ADO was also essential for supporting xenograft growth when implanted subcutaneously in immune-compromised mice. Taken together, this suggested that ADO depletion represents a cancer-specific vulnerability. Comprehensive metabolomic, transcriptomic and proteomic characterization of HCC cells isogenic for ADO demonstrated that loss of ADO resulted in dysregulation of glutathione, ascorbate, polyamine and proline metabolism. Consistent with this, ADO depleted cells had high levels of reactive oxygen species (ROS) measured by CellROX flowcytometry, and an increased ratio of oxidized to reduced glutathione, indicative of oxidative stress. Since mitochondria represent a substantial source of ROS, we assessed mitochondrial mass and function using Mitotracker^{TM} flow cytometry and Seahorse stress tests, respectively. ADO depleted cancer cells had higher mitochondrial mass and higher maximal respiration rates compared to control cells. Finally, exogenously supplied antioxidants could rescue the survival of HCC cells with ADO depletion, demonstrating that the observed loss of viability is due to oxidative stress. This work shows that ADO is essential for redox homeostasis in liver cancer models and suggests that interfering with ADO function may represent a novel targeting strategy for HCC.

#4784

Multiomic landscape of evolution of Warburg effect identifies drivers of breast cancer

Rafael Renatino Canevarolo[1], Praneeth Reddy Sudalagunta[1], Joon-Hyun Song[2], Erez Persi[3], Mehdi Damaghi[2], Ariosto Siqueira Silva[1]. *[1]Cancer Physiology, H. Lee Moffitt Cancer Center, Tampa, FL,[2]Pathology, Stony Brook University, New York, NY,[3]NCBI/NIH, Bethesda, MD*

Early breast carcinogenesis is characterized by an intermittently hypoxic, acidic and nutrient-deprived microenvironment, eventually selecting for the invasive, aerobically glycolytic phenotype known as Warburg Effect (WE), a universal cancer hallmark. We have reproduced the emergence of WE *in vitro*, by subjecting the nontumorigenic breast epithelial cell line MCF10A to multiple intermittent cycles of media starvation followed by recovery in growth media. Clonal expansion of surviving cells demonstrated increased lactate production in aerobic conditions (WE). A comprehensive molecular characterization, through WES and single cell multiomics, was performed to study the relationship between mutations, CNA, cytogenetic abnormalities, transcriptional dysregulation, and epigenetic modifications. Mutational analysis of 6 WE clones identified 249 shared mutations, including *HRAS*(G12V), *BRAF*(P523L) and *ALK*(Q180X). COSMIC mutational signature 18 (ROS-induced) was identified as the main DNA lesion across all WE clones, suggesting oxidative stress as a main source of mutagenesis associated with WE development. Non-synonymous mutations in *FUS*, *HDAC3*, *EZH2*, *MAZ*, *KMTD2*, *MET*, and other oncogenes were found in the clones, consisting in secondary events in the WE transformation. Geneset enrichment analysis identified over-expression of MYC/E2F targets, MTORC1 signaling, glycolysis and cell cycle pathways, as well as under-expression of EMT/cell adhesion pathways, in WE clones. CNA, based on a consensus from WES, scRNAseq (inferCNV) and scATACseq (epiAneufinder), confirmed amplification of MYC, E2F1 and MYBL2, as well as Gain(19q) and Gain(20) in all WE clones, as well as loss of *TP63* in 5 out of 6 WE clones. Integrative single cell transcriptome/chromatin accessibility analysis (ArchR) identified decreased accessibility and expression of EMT-related genes, as a consequence of differential expression of *pioneer* transcription factors (i.e. reduced expression of *TP63*, due to deletion, led to silencing of TP53/63/73 targeted genes), as well as well-established EMT regulators (ZEB1, SNAI1/2, NFKB1), among others. We propose that the WE phenotype emerges after intermittent nutrient-derived oxidative stress induces increased expression of *HRAS*-regulated genes, acutely increasing mutation rate and transcriptionally inducing an EMT-like state. Once *HRAS*(G12V), MYC/E2F1 amplification and *TP53* deletions are fixed in the population, the clones will maintain the ROS production and EMT-like state, even in optimum growth media conditions, completing the transition from an acute

response to a chronic-inheritable phenotype known as WE. These findings reinforce the importance of microenvironmental stress driving early carcinogenesis, bridges the gap between environment and genomic-driven causes of malignant transformation and provides testable hypotheses of causal events in connection with WE.

#4785

S-nitrosylation of p53 in melanoma alters p53-DNA binding and downstream gene expression

Jordan Winfield[1], Mariana Grigoruta[1], Yiliang Li[2], Fancui Meng[2], Yong Qin[1], Elizabeth Grimm[3], Leyuan Chen[2], Kevin Rosenblatt[4], Li Li[5]. *[1]The University of Texas at El Paso, El Paso, TX,[2]Tianjin Key Laboratory of Radiation Medicine and Molecular Nuclear Medicine, Tianjin, China,[3]MD Anderson Cancer Center the University of Texas, Houston, TX,[4]The University of Texas Health Science Center at Houston, Houston, Houston, TX,[5]The University of Texas Health Science Center at Houston, Houston, TX*

Aberrant expression of inducible nitric oxide synthase (iNOS) and chronic nitrosative stress is correlated with growth, metastasis, resistance to therapy, and poor patient survival of metastatic melanoma. One physiological influence of nitric oxide (NO) is exerted directly through the post-translational modification of many proteins, including the unique S-nitrosylation (SNO). To date, the role of SNO in melanoma development has not been fully characterized. Herein, we focus on the mechanism of how nitrosative stress regulates the tumor suppressor p53 in melanoma cells. We first examined the effects of different levels of NO donors, S-nitrosoglutathione (GSNO) and diethylenetriamine (DETA) NONOate, on the growth of melanoma cells by the MTT assay. Low levels of nitrosative stress (NO donors ≤ 20 μM) did not suppress the growth of human melanoma A375 and SB2 cells, but high levels of nitrosative stress (NO donors ≥ 50 μM) inhibited melanoma cell growth. Our biotin switch assays (BSA) showed that the treatment of NO donors significantly increased total S-nitrosylated proteins in A375 and SB2 cells. Markedly, p53 is confirmed to be one of the S-nitrosylated proteins derived from BSA. Our mass spectrometry analysis of SNO proteins in melanoma cells confirms that p53 is S-nitrosylated in A375 cells under nitrosative stress. Further proteomic

characterization identifies Cys242, Cys275, and Cys277 as the SNO sites of p53. We conducted a molecular dynamics (MD) simulation of p53-DNA binding under SNO modification. The structural analysis shows that the SNO of Cys277 reduces the hydrogen bonds between p53 and the targeted DNA, interfering with the recognition and binding of p53 to DNA. Moreover, the chelating ability of Cys242 for Zn2+ is weakened after SNO, indicating the SNO of p53 reduces p53 binding to Zn^{2+} and affects its active form. The electrophoretic mobility shift assay also confirmed that the treatment of 100 μM of DETA NONOate, significantly decreased the nuclear p53 of A375 and SB2 cells binding to the consensus p53-binding DNA. The induction of nitrosative stress by NO donors also significantly increased mouse double minute 2 homolog (MDM2), p21, and p53 expression but decreased p53 upregulated modulator of apoptosis (PUMA) expression.This study confirms that the crucial tumor suppressor, p53, is S-nitrosylated in melanoma cells under nitrosative stress. Notably, for the first time, the SNO sites of p53 and the effects of SNO on p53 functions were characterized. Our results describe an important mechanism of how nitrosative stress modifies crucial cysteines of p53, alters p53 DNA-binding activities, and regulates downstream gene expression through SNO. Our study provides much-needed insights into identifying novel NO-driven SNO proteins in melanoma as new biomarkers and targets for drug development.

Imipridones induce lipid peroxidation and oxidative stress in gastrointestinal malignancies

Arielle De La Cruz[1], Praveen R. Srinivasan[1], Andrew George[1], Varun V. Prabhu[2], Maximilian P. Pinho-Schwermann[1], Wafik S. El-Deiry[1]. *[1]Brown University, Providence, RI,[2]Chimerix Inc., Durham, NC*

Colorectal and pancreatic cancer collectively comprise 20% of all cancer-related deaths in the United States. Despite therapeutic advancements, the current standard of care often results in significant toxicity. Therefore, there is an urgent need to develop more efficacious novel therapies. The imipridones, ONC201/TIC10, ONC206, and ONC212, are novel small-molecules that bind mitochondrial ClpP and induce activation of the integrated stress response (ISR), tumor necrosis factor-related apoptosis-

inducing ligand (TRAIL) signaling, and oxidative stress. Each has previously demonstrated antitumor effects in a variety of preclinical *in vitro* and *in vivo* cancer subtypes, including colorectal cancer, with limited toxicity. Reactive oxidation species (ROS) are natural biproducts of cellular oxidative metabolism and play important roles in the modulation of cell death pathways, differentiation, and immune response. Using varying doses of ONC201, ONC206, and ONC212, we observed increased lipid peroxidation in several colorectal and pancreatic cancer cell lines using the C-11 BODIPY assay which measures lipid-specific peroxides. Lipid peroxidation was reversed by the ferroptosis inhibitor liproxstatin-1, suggesting that in addition to inducing apoptosis, imipridones may be involved in ferroptosis induction. Future directions include mechanistic work, investigation of the effect of imipridone-induced lipid peroxidation on immune cell cytotoxicity, and understanding the relative importance of lipid peroxidation in the clinical efficacy of imipridones.

The cancer targeting synergy of tertbutylhydroquinone and a manganese porphyrin

Joseph P. LaMorte, Sandra Tamarin, Margueritte Lalo, David J. Sokoloski, Jared J. Paul, Aimee L. Eggler. *Villanova University, Villanova, PA*

Cancer cells utilize high basal levels of reactive oxygen species (ROS) to create conditions that facilitate rapid cell proliferation. This creates an Achilles heel, making cancer cells more susceptible than normal cells to cell death caused by a bolus dose of ROS. The common food preservative, tert-butylhydroquinone (tBHQ), generates ROS intracellularly via redox cycling. Herein, we tested the effect of combining tBHQ with a manganese porphyrin, compounds originally designed as super oxide dismutase mimetics which can also generate ROS intracellularly in cancer cells and have radioprotective effects under clinical investigation. We find that the combination treatment of tBHQ and the commercially available Mn(III) tetrakis(1-methyl-4-pyridyl)porphyrin pentachloride (MnTMPyP) is much more toxic to leukemic Jurkat lymphocytes than either compound alone, e.g., lowering the LC50 of tBHQ by two orders of magnitude to 1.0 μM. MnTMPyP acts as a catalyst to oxidize tBHQ, shown by UV-Vis spectroscopy. Flow cytometry analysis revealed that while 5 μM tBHQ

decreases cell viability by less than 10% in 4 hours, the combination of 5 μM tBHQ and 12 μM MnTMPyP decreases viability by 60%, primarily by apoptosis. A clinically tested manganese porphyrin, Mn(III) *meso*-tetrakis(N-n-butoxyethylpyridinium-2-yl)porphyrin (Mn2BuOE), was as effective and more potent than MnTMPyP. We evaluated the cancer-targeting effect of tBHQ and Mn2BuOE in both Jurkats and a matched primary CD4 T cell line. The combination treatment induced significantly more cell death in cancerous Jurkats than in the normal CD4 cells. With the promise Mn2BuOE shows in pre-clinical studies and early clinical trials as adjunctive to radiotherapy, and the wide use of tBHQ in prepared food, the results shown here in CD4 cells suggest their combination may be an effective therapy to target cancer cells.

Oxidative stress promotes colorectal cancer aggressiveness through transmembrane chloride intracellular channel 1 (tmCLIC1) antioxidant activity

Francesca Cianci[1], Ivan Verduci[1], Carlotta Tacconi[1], Gaetano Cannavale[1], Matteo Ranucci[1], Giulia Bertolini[2], Paolo Malatesta[3], Federica Barbieri[3], Alessandro Fantin[1], Luca Roz[2], Tullio Florio[3], Michele Mazzanti[1].
[1]University of Milan, Milan, Italy,[2]IRCCS Istituto dei tumori, Milan, Italy,[3]University of Genova, Genova, Italy

In developed countries, colorectal cancer is the third leading cause of mortality. Despite significant advances in therapeutic approaches, metastases remain the primary concern in the treatment of colorectal cancer. Ion channels have an important role in the development of aggressive behavior, but the majority of them are involved in regular physiological activities. Chloride Intracellular Channel 1 (CLIC1) is a promising contender among the new possible biomarkers. CLIC1 is expressed as a cytosolic monomer by all cell types during physiological homeostasis. The main characteristic of this protein is that it can exist in both cytosolic and transmembrane forms (tmCLIC1), with the latter being involved in a variety of clinical conditions, including cancer. CLIC1 mRNA overexpression in colorectal cancer cells has been linked to a poor prognosis. The primary goal of this study is to understand the role of tmCLIC1 in the carcinogenesis, invasion, and migratory potential of colorectal cancer. We

initially investigated the level of CLIC1 protein expression and the activity of its transmembrane form as an ion channel in numerous colorectal cancer cells at various stages of development. Our results show that tmCLIC1 protein expression and activity are related to cell aggressiveness, and that its role in cellular proliferation, migration, and invasion is critical. The role of tmCLIC1 activity in colorectal cancer was confirmed also in *in vivo* models. Experiments in zebrafish and mouse models have shown that silencing CLIC1 impairs primary tumor development and significantly reduces the generation of distal metastases. Furthermore, when the CLIC1 protein is missing, many distinct metastatic genes are downregulated, particularly those associated to oxidative stress, typical of cancer cells. As a matter of fact, CLIC1's peculiar activity and its interaction with glutathione make this protein critical for the redox equilibrium of colorectal cancer cells. Overall, the findings could be considered as a beginning point for elucidating a mechanism of action that could constitute a new milestone in anticancer research.

Spin oscillating magnetic field sOMF of oncomagnetic device selectively kills glioma cancer cells by inducing oxidative stress and DNA damage

Shashank Hambarde[1], Arvind Pandey[1], David S. Baskin[2], Santosh A. Helekar[2]. *[1]Houston Methodist Research Institute, Houston, TX,[2]Neurosurgery, Houston Methodist Research Institute, Houston, TX*

A new noninvasive therapeutic device developed in our laboratory called the Oncomagnetic device provides a novel approach to glioblastoma (GBM) treatment. It involves repeated stimulation with oscillating magnetic fields (sOMF) produced by spinning permanent magnets. It is technologically and mechanistically distinct from the Optune® device approved by the FDA for the treatment of newly diagnosed and recurrent GBM. Use of this device in end-stage GBM patients reversed the progression of their recurrent tumor causing >30% reduction in its contrast-enhanced volume within 4-6 weeks of treatment. Mice with implanted mouse glioma cells in their brains also showed marked reduction in tumor size, increased survival ($p< 0.05$, $n = 10$) and higher DNA damage (γ-H2AX foci) after sOMF treatment with a whole-body stimulation method developed by us. Normal mice exposed to sOMF for 4 months had no

adverse effects on the brain and other organs. *In-vitro*, sOMF markedly increased reactive oxygen species (ROS) levels in cancer cells leading to the selective death of these cells, while sparing normal neurons and astrocytes. Detection of γ-H2AX and 53BP1 foci showed that sOMF caused significant DNA damage in GBM cells and diffuse intrinsic pontine glioma (DIPG) cells but not in normal astroglial SVGp12 cells. Furthermore, sOMF exposure for just 2 h resulted in >40% loss of surviving GBM and DIPG cell colonies detected by clonogenic cell survival assay, similar to that produced by 2 Gy radiation dose. This loss was rescued by the antioxidant Trolox. These results indicate that sOMF stimulation has high anticancer potency comparable to low dose radiation therapy at the cellular level with an underlying mechanism of action that is substantially different from that proposed for Optune® TTF.

Oxidation in the nucleotide pool as a novel targetable vulnerability in pancreatic ductal adenocarcinoma

Beatriz Mateo-Victoriano[1], Ling Zhang[2], Govindi J. Samaranayake[1], Cassie Due[3], Clara Troccoli[1], Julia Zaias[4], Nagaraj Nagathihalli[5], Michael VanSaun[6], Michael G. Mohsen[7], Eric T. Kool[7], Priyamvada Rai[2]. *[1]Sheila and David Fuente Graduate Program in Cancer Biology, University of Miami Miller School of Medicine, Miami, FL,[2]Radiation Oncology, University of Miami Miller School of Medicine, Miami, FL,[3]School of Nursing and Health Studies, University of Miami Miller School of Medicine, Miami, FL,[4]Department of Pathology and Laboratory Medicin, University of Miami Miller School of Medicine, Miami, FL,[5]Department of Surgical Oncology, University of Miami Miller School of Medicine, Miami, FL,[6]Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL,[7]Department of Chemistry, Stanford University, Stanford, CA*

Oncogenic RAS signaling is mediated by reactive oxygen species (ROS) signaling. However, oncogenic ROS also evoke tumor suppressive damage, necessitating adaptive redox protective mechanisms. We previously reported that MTH1, the main mammalian 8-oxodGTPase, comprises one such critical adaptation. High MTH1 expression significantly correlates

with poor disease-free survival in several KRAS-driven tumors. We have shown in RAS-driven xenograft cancer models that MTH1 is critical for the maintenance of ROS-driven signaling and prevention of DNA damage-induced senescence. However, how MTH1 loss affects KRAS-driven spontaneous tumor formation is unknown. We focused on pancreatic ductal adenocarcinoma (PDAC) due to the high prevalence of driving oncogenic KRASG12D mutations, and the lack of MTH1 studies. Therefore, we depleted MTH1 via shRNA in MIA PacCa-2 and SU.86.86 cell lines and generated novel MTH1-null Pdx1^{Cre}; LSL-Kras$^{G12D/+}$; LSL-Trp53$^{R172H/+}$ (KPC), Ptf1a$^{cre/+}$;LSL-Kras$^{G12D/+}$;Tgfbr2$^{flox/flox}$ (PKT) and corresponding MTH1-wildtype strains. We found MTH1 knockdown significantly reduced growth of KRAS-driven PDAC cells, and that germline MTH1 deficiency reduced tumor burden in the short latency PKT but not the long latency KPC animals. The PKT tumors exhibited higher overall 8-oxodGTPase activity and reduced total 8-oxo-dGTPase activity in the MTH1-deficient background, unlike KPC tumors. This finding suggests that in aggressive KRAS-driven tumors, redundant 8-oxodGTPase activity cannot compensate for MTH1 loss to prevent oncogenic stress-induced tumor suppression. Additionally, both MTH1-depleted PDAC cell lines and the smaller MTH1-null PKT tumors had decreased EGFR expression, suggesting MTH1 loss compromises this ROS-driven pathway. RNA-seq analysis revealed MTH1 deficiency altered MDSC gene expression in the PKT model, suggesting better anti-tumor response through improved immune infiltration in a typically immunologically cold tumor. Our results indicate MTH1 targeting could benefit aggressive PDAC stages. We further show PDAC tumors possess redundancy in MTH1 8-oxodGTPase function, which needs to be better understood in order to therapeutically leverage current MTH1 inhibitors, which do not target this redundancy.

Characterizing cellular senescence response to senolytic compounds using cell culture media analysis

Evelyn Wang[1], Stephen Kurzyniec[1], Ethan Hain[1], Yoshiyuki Okamura[1], Yang Yang[2], Dongwen Lv[2]. *[1]Shimadzu Scientific Instruments Incorporated, Columbia, MD,[2]University of Texas Health Science Center, San Antonio, TX*

Cellular senescence is an emerging hallmark of cancer. Senescent cells can lead to tumor development and chronic inflammation that stimulate age-related diseases. The secretion of senescent cells also generates an inflammatory environment that promotes tumor growth. Senolytics are pharmaceutical agents that selectively eliminate senescent cells through various mechanisms. Identifying the mechanism is crucial for the further development of senolytic drugs. ABT263 (also named navitoclax), a Bcl-2 and Bcl-xl dual inhibitor, is a well-known senolytic agent. Recently the first Bcl-2 and Bcl-xl dual-targeting proteolysis-targeting chimera (PROTAC), 753b, was developed, which has increased potency against senescent cells but minimized platelet toxicity. EF24 is another senolytic agent but the direct target is still unclear. Comprehensive analysis and comparison of the media environments from young cells, senescent cells, and senescent cells dosed with different senolytics can contribute toward solving senolytic mechanisms and make the drug discovery process more efficient and effective. WI38 cell culture media was used to grow young, senescence, and senolytic (753b or EF24)-dosed senescent cells for 72 hours. Cell culture media was collected at 10 different growth time points, subjected to protein crash using acetonitrile, and diluted with water prior to analysis. A 17-minute liquid chromatography triple quadrupole mass spectrometry method was developed for senescent cell and senolytic-added senescent cell culture media analysis. One hundred and forty-five cell culture related compounds including amino acids, nucleic acids, metabolites, sugars, and vitamins were simultaneously analyzed. A relative concentration trend graph was generated as the result for each of the cell growth related analytes. Thirteen compounds exhibited trends that distinguished at least one experimental group from the others in the 72 hours growth period. These compounds were asparagine, 5’-Methylthioadenosin, saccharopine, serotonin, alanyl-glutamine, urocanic acid, o-phosphoethanolamine, hypoxanthine, xanthosine, uracil, pyridoxal, nicotinic acid, and pyruvic acid. The differences observed in the cell environment reflect the differences of the activated pathways and mechanisms between the young, senescent, and senolytics-dosed senescent cells. This rapid and multicomponent cell culture analysis method enables scientists to analyze the environment as senescent cell and senolytic-dosed senescent cells grow. Comparing the chemical profile in the cell environments can be a potential strategy in understanding the mechanisms of the senolytic drugs. This information may

also be valuable in predicting the toxicity and side effects of the new senolytic drugs.

A role for fibroblast derived SASP factors in the activation of non-apoptotic cell death in normal mammary epithelial cells

Lisa M. Hom[1], Seunghoon Sun[2], Jamie Campbell[2], Ireland Murphy[2], Shannon Culbert[2]. *[1]University of Notre Dame, Notre Dame, IN,[2]Biological Sciences, University of Notre Dame, Notre Dame, IN*

In normal tissue homeostasis, bidirectional communication between different cell types can shape numerous, biological outcomes. Fibroblasts are one cell type in constant communication with neighboring epithelial cells, and as a result, can alter various cellular parameters. Additionally, fibroblasts are prone to undergo senescence, exemplified by an irreversible cell cycle arrest, in response to a variety of stimuli. Senescent cells exhibit alterations in gene expression and are characterized by substantial changes in their secretome; termed the senescence associated secretory phenotype (SASP). The role of fibroblast derived SASP factors on normal epithelial cells is an area that remains poorly understood. Our studies have found that treatment of normal mammary epithelial cells with conditioned media from senescent fibroblasts (SASP CM) results in a robust programmed cell death. The capacity of SASP CM to cause cell death is maintained across multiple senescence-inducing stimuli. Interestingly, our data suggest that the cell death caused by SASP CM is dependent on caspase activation, but independent of canonical extrinsic or intrinsic apoptotic pathways. shRNA-mediated reduction of caspase 1 or GSDMD in normal mammary epithelial cells ameliorates the ability of the SASP CM to induce cell death, suggesting that these cells are dying by pyroptosis. Interestingly, breast cancer cells and normal mammary epithelial cells engineered to express oncogenic signals are not susceptible to this SASP CM induced cell death, suggesting that cancer cells have evolved a mechanism to evade SASP CM-mediated pyroptosis.. Taken together, our data reveal a novel relationship between the activation of senescence in stromal cells and the induction of non-apoptotic cell death in normal mammary epithelial cells.

Deciphering tumor recurrence post-therapy: Interactions between the tumor microenvironment and therapy-induced senescent glioblastoma

Valerie DeLuca, Priya Digumarti, Michael E. Berens. *TGen (The Translational Genomics Research Institute), Phoenix, AZ*

Glioblastoma (GBM) remains one of the most lethal forms of cancer due, in part, to the capacity of tumor cells to persist during therapy and then recover. Understanding how these residual tumor cells survive is therefore imperative to developing more effective treatment strategies. We have demonstrated that GBM cells, including those from patient-derived xenografts, undergo a state of therapy-induced senescence (TIS) rather than cell death following temozolomide (TMZ) and radiation (IR). Both TMZ and IR treatment at physiologically relevant doses result in elevated senescence-associated-β-galactosidase, altered morphology, p21 induction, and increased expression of the senescence-associated-heterochromatic-foci marker H3K9Me3. Further, despite TIS-induction in a majority of the residual cells post-treatment, GBM viable cell number increases after a prolonged stasis, indicating that populations are capable of reentering a proliferative state. However, our current understanding of how the tumor microenvironment influences this growth arrest and subsequent proliferative recovery is underdeveloped. We aim to bridge that gap by investigating the paracrine communications between astrocytes and GBM cells undergoing IR-induced senescence in order to identify how these interactions foster disease progression. Current studies are focused on evaluating the effect of astrocytes on the induction and durability of TIS in GBM cells. Proteomic studies will be pursued to characterize the secretome of astrocyte-GBM co-cultures and identify factors that drive GBM senescent response to IR. Finally, based on preliminary data demonstrating that normal astrocytes are also damaged by IR, we will undertake mechanistic studies to understand how cell-intrinsic events within the astrocyte population drive extrinsic-influence on GBM cells. We anticipate that these identified signaling events may serve as potential therapeutic targets.

Conditionally active biologics eliminates senescence cells in cancer and aging

Jian Chen[1], Christina Wheeler[1], Jing Wang[1], Matt Lucas[1], Haizhen Liu[1], Kyrie Johnson[1], Kathryn Woodard[1], Solmarie Joyner[1], Cathy Chang[1], William J. Boyle[2], Jay M. Short[2]. *[1]R&D, BioAtla, Inc., San Diego, CA,[2]BioAtla, Inc., San Diego, CA*

The aberrant accumulation of senescent cells in aged and cancerous tissue triggers inflammatory signaling through a senescence-associated secretory phenotype (SASP), promoting aging and tumor progression. Pharmacologically, clearing senescent cells has been shown to have promising effects against cancer and age-related pathologies in preclinical models as well as early human clinical trials. However, current senescent cell elimination strategies are focused on targets that do not distinguish between hyper-inflamed or SASP senescent cells versus relatively non-inflamed senescent cells. In addition, current senescence targets are predominately intracellular with important functions in normal cell population. Therefore, the use of senolytics in the clinic is still limited due to their cytotoxicity to either normal cells or potentially beneficial senescent cells. A more effective senescence cell targeted approach is needed to reduce side effects and increase the efficiency of senescence cell removal or reduction. Conditionally Active Biologics (CAB) technology is a proprietary platform that is unique in its ability to selectively activate in the context of diseased tissues, but not normal tissues, taking advantage of the acidic pH conditions in the inflammatory tumor/aged tissue microenvironment. Senescent cells, similar to tumor cells, are dependent on glycolysis to support molecule synthesis, for hyperinflammation in the case of senescent cells, and thus generate a glycolytic microenvironment (GME), resembling that of the tumor microenvironment. Since our CAB technology is already being deployed in cancer therapy by targeting cell surface markers such as AXL, ROR2, and CTLA4 in clinical studies, we explored whether CAB technology allows selective removal of senescent cells in SASP-associated microenvironments. To identify senescence-specific surface antigens that are broadly and specifically upregulated in senescent cells, we screened our CAB cell surface antigen library in different senescence *in vitro* models, *in vivo* aging mouse tissues and a chronic kidney disease mouse model. We have identified several novel senescence markers. Furthermore, *in vitro* binding assays demonstrated that CAB antibodies targeting these senescence markers have no or very low binding

to the target antigen on senescence cells in physiological, alkaline conditions, but have strong binding in glycolytic, acidic SASP conditions. Moreover, we performed antibody-dependent cell-mediated cytotoxicity assays and demonstrated that CAB antibodies were more potent against senescent cells compared to proliferating cells and displayed high selectivity for the glycolytic, acidic microenvironment condition. In conclusion, CAB technology provides a new generation of biologics with an increased safety margin and therapeutic index targeting SASP, acidic senescence cells in cancer and age-related diseases.

#4796

Chemotherapy induced senescence drives peripheral neuropathy

Taylor Malachowski, Ganesh Raut, Satarupa Mullick Bagchi, Shelia Stewart. *Washington University in St. Louis, St. Louis, MO*

Chemotherapy is a mainstay of cancer therapy. Unfortunately, while chemotherapy can profoundly impact disease free survival, it's often accompanied with devastating side effects, including peripheral neuropathy. Indeed, 30-40% of patients treated with neurotoxic chemotherapy develop long-term and often debilitating chemotherapy-induced peripheral neuropathy (CIPN). Unfortunately, there are currently no preventative measures for CIPN and while it is transitory in some patients, for others the side effects can persist for months or even years after the cessation of chemotherapy. Recent work suggests that cellular senescence, which is robustly induced by chemotherapy, contributes to CIPN. Senescent cells are typically characterized by increased CDKn2a (i.e., p16) expression, increased SA-β-gal hydrolyzation, and expression of the senescence-associated secretory phenotype (SASP) that can influence multiple cell types in the microenvironment. Through utilization of a mouse model that employs paclitaxel (PTX), we find that PTX robustly induces senescence in the hindpaws and dorsal root ganglia (DRG) of mice that display loss of peripheral axons and decreased response to mechanical stimuli. To address the role of senescence in CIPN, we utilized the INKATTAC mouse that allows for inducible elimination senescent cells. Using this model, we find that the elimination of senescent cells rescues CIPN. Further, the use of senolytics, drugs that kill senescent cells, also rescues CIPN, raising the possibility that we can treat patients with CIPN. To address the mechanism

behind CIPN we have carried out single cell RNA-Seq to identify the population of senescent cells senescing in response to chemotherapy. These analyses will allow us to understand the mechanisms that drive CIPN and may lead to new treatments for patients suffering from CIPN.

β3-AR blockade induces differentiation of malignant leukemia T cells in mature T lymphocytes

Francesco Carrozzo, Gennaro Bruno, Claudia Masi, Alessia Boaretto, Claudio Favre, Maura Calvani. *AOU Meyer, Firenze, Italy*

Acute lymphoblastic leukemia (ALL) is a genetically heterogeneous cancer that arises from diverse genetic alterations during early lymphocyte development. About 10-15% of T-cell acute lymphoblastic leukemia (T-ALL) cases occur in childhood; despite having an event-free survival (EFS) rate of 85%, relapse is the main problem of this type of cancer. Mitochondria metabolic reprogramming plays a crucial role in the development of lymphocytes both in physiological and pathological processes such as differentiation and neoplastic transformation respectively. Mitochondria are the main actors of cellular homeostasis. They use glycolysis products exploiting them in the Krebs cycle and in oxidative phosphorylation to produce energy and plays key roles in reactive oxygen species (ROS) generation, Ca2+ signaling, cell death induction, and cellular differentiation. In particular, the increase of ROS is important to reduce tumor cell viability and at the same time is involved in induction of hematopoiesis. β3-adrenoreceptors (β3-Ars) is a class of receptors associated with pro-tumoral signaling in different tumors. In this study, we first have observed the expression of β3-Ars in leukemia T cells and then we studied how the modulation of this receptors affected tumor-related pathways. The treatment with an antagonist of β3-Ars (SR59230A) induced an increase of ROS leading to lymphoblastic cells differentiation, decrease of proliferation and enhanced induction of apoptosis signaling. Overall, these results suggest that β3-Ars could be a possible target for treatment of T-ALL.

Responses to Hypoxic, Proteotoxic, and Other Novel Forms of Cell Stress

Laurine acid enhances GEM-chemosensitivity targeting hypoxia-induced mitochondrial disfunction and stemness in pancreatic ductal adenocarcinoma

Tadataka Takagi[1], Hiroki Kuniyasu[2], Masayuki Sho[3], Rina Tani[2], Shiori Mori[2], Shingo Kishi[2], Yukiko Nishiguchi[2], Yudai Hojo[2]. *[1]Department of Molecular Pathology, Department of Surgery, Nara Medical University, Kashihara, Japan,[2]Department of Molecular Pathology, Nara Medical University, Kashihara, Japan,[3]Department of Surgery, Nara Medical University, Kashihara, Japan*

Hypoxia is a feature of the pancreatic ductal adenocarcinoma (PDA). Although gemcitabine (GEM) is widely used in chemotherapy for PDA, drug resistance restricts its clinical effectiveness. We have found that hypoxia contributes to chemoresistance, however the mechanism is still unclear. The aim of this study is to clarify the mechanism and to develop a new therapeutic strategy. First, we examined the effect of hypoxia to GEM sensitivity, stemness and energy metabolism in three human pancreatic ductal carcinoma cell lines. The inhibition rate by GEM was lower under CoCl2-induced chemical hypoxia than normoxia. Reactive oxygen species (ROS) after GEM was increased under normoxia but not under hypoxia. Flux analysis showed that both oxidative phosphorylation (OXPHOS) and glycolysis were suppressed under hypoxia, indicating a quiescent state. Next, we investigated the relationship between hypoxia and stemness. Hypoxia increased stem cell markers mRNA (C-Myc, Oct-3/4, CD24, CD44, CD133) expression and tumorsphere formation efficiency (TFE). In addition, hypoxia and GEM administration reduced sphere size but increased the number of spheres and TFE. This indicated that hypoxia and GEM suppressed proliferation, however promoted stemness. Second, to examine the mechanism of GEM resistance, we established two GEM-resistant cell lines from human PDA cells by continuous treatment with GEM and CoCl2-induced chemical hypoxia. One resistant cell line possessed reduced OXPHOS and decreased mitochondrial ROS levels, while the other resistant cell line possessed increased stemness. In both cell lines, ethidium bromide-stained mitochondrial DNA levels decreased, suggesting mitochondrial DNA damage. In addition, tetramethylrhodamine-

stained mitochondrial membrane potential levels decreased, suggesting mitochondrial impairment. This indicated that long hypoxia and treatment with GEM induced mitochondrial impairment and acquisition of stemness, causing chemoresistance. We further investigated the effect of lauric acid (LAA), a medium-chain fatty acid, on GEM resistance. We have previously reported that LAA causes reprogramming of energy metabolism and induces cell death in cancer cells. Treatment with LAA restored GEM sensitivity in both GEM-resistant cell lines. Flux analysis showed that both OXPHOS and glycolysis were promoted, indicating displacement from quiescent state by LAA. These results suggest that decreased energy production, decreased mitochondrial ROS levels, and increased stemness associated with mitochondrial damage caused by GEM lead to GEM resistance, and that hypoxia may promote this process. Furthermore, forced activation of OXPHOS by LAA could be a tool to overcome GEM resistance.

Identification of critical hypoxia induced factors in castrate resistant prostate cancer

Oloruntoba I. Osagie, Jordann Smakk, Deborah E. Citrin, Travis H. Stracker. *NIH-NCI, Maryland, MD*

Background**:** Prostate cancer (PCa) is the second most diagnosed cancer in men and the second cause of cancer-related death amongst men worldwide. PCa is a heterogeneous disease, and the outcome is worse for patients when the disease progresses from localized PCa to a castrate-resistant disease. Androgen receptor (AR) signaling is crucial for PCa development and has been a major therapeutic target for decades. Despite the success made with hormone therapy to block AR signaling, castration resistant disease can arise through mutations and amplifications of the androgen receptor (AR) and AR splice variants (AR-Vs). Amongst them, AR-V7 and AR-V12 can promote AR signaling independent of androgen. Furthermore, prostate tumors are highly hypoxic due to abnormal tumor vasculature. Hypoxia influences the efficacy of local and systemic treatment strategies, such as radiotherapy, hormone therapy, and chemotherapy, resulting in poorer clinical outcomes for PCa patients. Therefore, a complete understanding of

AR and AR variant function, as well as how they are modulated by hypoxia and therapy is warranted for developing new strategies to treat PCa.
Methods: To identify the transcriptional apparatus associated with the AR and its variants under normal and hypoxic conditions, we carried out Bio-ID proximity labeling mass spectrometry (BioID-MS). We generated stable androgen-independent human prostate cancer cell lines, PC-3 and DU145, expressing AR and the AR-V7 and AR-V12 variants fused to a MiniTurboID (MTID) enzyme. To delineate the AR proximal interaction network, we treated cells with androgen or vehicle for 3 hours and affinity-purified biotinylated proteins after the addition of biotin for the final 2 hours. Cells were grown in normoxia (20% O_2) or treated with hypoxia (95% N2,5% CO_2 and 0.5% O_2) for 24 h. Nonspecific interactions were filtered using controls and statistical methods to identify high-confidence interactomes.
Results: BioID proximity labeling in PC3 cells identified several AR-associated proteins, including many knowninteractors, validating the approach. Hypoxic conditions led to a striking alteration in proximal interactions and many metabolic proteins were highly enriched with AR upon exposure of cells to hypoxia for 24h. Among these, phosphoglycerate kinase 1 (PGK1) was a top hit. PGK1 has been reported to interact with AR to mediate the expression of genes that regulates cell proliferation and apoptosis. Additionally, PGK1 has an essential role in metabolic reprogramming induced by c-MYC and HIF-1α, leading to enhanced tumorigenesis.
Conclusion: Bio-ID mass spectrometry was used to map the proximal interactome of AR and its variants, identifying novel interactions partners for further analysis. We found that hypoxia strongly alters interactors with the AR, and we identified PGK1 as a hypoxia induced AR interaction in PCA. Current work to functionally validate this interaction will be presented.

To identify novel drivers of PDA malignancy, we employed a regulatory network analysis, which accurately infers the activity of transcription factors and other regulatory proteins based on the integrated expression of their positive and negative target genes. This highly validated approach enables the identification of the most hyper-activated and hyper-repressed regulatory proteins (i.e. the “master regulators (MRs)”) that drive phenotypic distinctions. We applied this technique to a set of 200 laser capture microdissected human PDA samples as well as 45 low-grade precursors for which we had matched histopathological, clinical, and epidemiological annotation. We identified the MRs associated with four malignancy phenotypes: precursors vs. PDA (initiation), low-grade vs. high grade histopathology (progression), survival post resection, and association with KRAS activity. Integrating across these phenotypes, the top MR of PDA malignancy was found to be BMAL2, a member of the PAS family of bHLH transcription factors. Although the canonical function of BMAL2 is linked to the circadian rhythm protein CLOCK, gene set enrichment analysis highlighted a potential role in hypoxia response. We previously demonstrated that PDA in humans and in the genetically engineered “KPC” mouse model is hypovascularized, hypoperfused, and profoundly hypoxic, with a partial oxygen pressure <1mmHg. Given the close homology of BMAL2 to HIF1B (ARNT) and its potential to heterodimerize with HIF1A, we investigated whether BMAL2 plays a role in the hypoxic response of PDA. Indeed, BMAL2 activity was induced in response to hypoxia and inhibited following treatment with multiple RAF, MEK, and ERK inhibitors, validating its computationally-inferred association with RAS activity. Strikingly, knockout or knockdown of BMAL2 in human PDAC

cells led to defects in viability and invasion in the setting of hypoxia. BMAL2 knockout cells lost the ability to induce glycolysis upon exposure to severe hypoxia and this was associated with a loss of expression of the glycolysis enzyme LDHA. A large-scale CRISPR screen found that LDHA was the single most critical gene necessary for viability of PDA cells in the setting of hypoxia. Moreover, the set of inferred transcriptional targets of BMAL2 were highly enriched in hypoxia-responsive proteins, including GLUT1, the second top hit in our hypoxia survival CRISPR screen. Strikingly, knockout of BMAL2 led to a complete loss of HIF1A stabilization in response to hypoxia, consistent with the stabilizing role of HIF1A heterodimerization partners such as HIF1B. By contrast, HIF2A was further upregulated under hypoxia in the setting BMAL2 loss. We conclude that BMAL2 is a key master regulator of hypoxia responses in PDA that serves as a molecular switch between the disparate metabolic roles of HIF1A- and HIF2A-dependent hypoxia responses. This will be further validated in ongoing metabolomic studies

p38 MAPK-dependent regulation of HIF-1 and expression of the hypoxia-inducible gene *IGFBP-3* in leiomyosarcoma cells

Nuha Haque, Eric Shelden. *School of Molecular Biosciences, Washington State University, Pullman, WA*

Hypoxia is a common feature of tumor microenvironments and stimulates a variety of responses in a cell. Tumor hypoxia is also associated with poor prognosis in soft tissue sarcomas (STS), including leiomyosarcomas. Genes upregulated under hypoxia contribute to the adaptation of tumor cells and promote tumor progression. Using transcriptome-wide gene expression analysis, we identified *IGFBP-3* as one of the most highly upregulated genes in SK-LMS-1 leiomyosarcoma cells in hypoxic conditions. IGFBP-3 has been studied in several tumor types, including STS, and is associated with their altered pathogenesis. Mechanisms responsible for the hypoxia-induced expression of *IGFBP-3* in STS have not been previously well defined. Hypoxia results in the stabilization of the hypoxia-inducible transcription factor, HIF-1, and production of reactive oxygen species (ROS) in other cell types. Here, we examined HIF-1 and ROS-dependent mechanisms to determine their roles in the hypoxia-induced expression of

IGFBP-3 and other genes in SK-LMS-1 cells. Our data indicate that both ROS production and HIF-1 activation are required for the enhanced *IGFBP-3* mRNA expression in hypoxic SK-LMS-1 cells. We also tested the roles of the stress activated protein kinase p38 and the tumor suppressor p53 for their potential to contribute to the regulation of *IGFBP-3* expression in these cells. Inhibition of p53 tumor suppressor activity only partially reduced *IGFBP-3* expression. We also determined that neither hypoxia nor inhibition of p53 affected the expression of the p53 target gene, *CDKN1A* (p21), in these cells. In contrast, inhibition of p38 MAPK completely prevented the hypoxia-induced increase in *IGFBP-3* expression. Additionally, we found that p38 MAPK inhibition reduced HIF-1 protein accumulation and activity but had no effect on its mRNA expression under hypoxic conditions. Together these results suggest that ROS-dependent activation of p38 MAPK stabilizes HIF-1 and promotes the downstream expression of *IGFBP-3*. In contrast, p53 appears to have a limited effect on the expression of *IGFBP-3* in SK-LMS-1 cells. Our results clarify the signaling pathway involved in the response of soft tissue sarcoma cells to hypoxia and may provide new avenues for intervention in cancer progression.

Spry1 as a potential new hypoxia modulator in cutaneous melanoma

Barbara Montico[1], Giorgio Giurato[2], Roberto Guerrieri[1], Annamaria Salvati[2], Francesca Colizzi[1], Lorena Baboci[1], Luca Sigalotti[1], Alessia Covre[3], Michele Maio[3], Agostino Steffan[1], Tuula A. Nyman[4], Alessandro Weisz[2], Maurizio Mongiat[1], Eva Andreuzzi[1], Elisabetta Fratta[1]. *[1]Centro di Riferimento Oncologico IRCCS, Aviano, Italy,[2]'Scuola Medica Salernitana', University of Salerno, Salerno, Italy,[3]Center for Immuno-Oncology, University Hospital of Siena, Siena, Italy,[4]Institute of Clinical Medicine, University of Oslo, Oslo, Norway*

Introducti**on:** At present, the precise role of Spry proteins in tumor progression is still debated. Our previous study showed that Spry1 knockdown ($Spry1^{KO}$) in $BRAF^{V600}$-mutant cutaneous melanoma (CM) promoted cell cycle arrest and apoptosis, repressed cell proliferation *in vitro*, and reduced tumor growth *in vivo*. Furthermore, we observed that

Spry1 loss impaired angiogenesis *in vivo*. Hypoxia has been recognized as one of the crucial features of CM. Hypoxia results in the activation of the transcription factor hypoxia-inducible factor 1α (HIF-1α), which represents a master regulator of angiogenesis. Hence, the present study was designed to explore a possible role of Spry1 in modulating angiogenesis and hypoxia in CM.

Material and method: SPRY1 gene was knocked-out using the CRISPR-strategy in the BRAF wild-type (wt) Mel 313 and in the BRAF-mutant Mel 593 cell lines. Angiogenic potential was assessed through *in vivo* CD31 staining and *in vitro* tube formation assays. By using *in vitro* and *in vivo* models, the effects of $Spry1^{KO}$ on hypoxia-related genes were investigated through RNA-sequencing (RNA-seq), quantitative real-time PCR, western blot, and immunofluorescence analyses. To gain insight into Spry1 interactome, immunoprecipitation coupled to mass-spectrometry (IP-MS) was employed.

Results and discussion: Consistent with our previous data, tumors arising from Mel 313 and Mel 593 $Spry1^{KO}$ clones were significantly smaller than those from their corresponding parental cells. Tumor growth inhibition was accompanied by a substantial reduction of angiogenesis, as assessed by the immunofluorescence staining of CD31 *in vivo* and the tube formation assay *in vitro*. Accordingly, RNA-seq analysis indicated that the vascular endothelial growth factor A was significantly down-regulated following Spry1 silencing. Notably, Ingenuity Pathway Analysis identified "HIF-1α Signaling" as the most significant molecular and cellular function affected *in vivo* by Spry1 silencing regardless of the BRAF mutational status. Analyses of tumor tissues confirmed that $Spry1^{KO}$ significantly reduced HIF1-α protein abundance. Interestingly, HIF-1α mRNA levels were minimally affected, thus suggesting that $Spry1^{KO}$ might impact on HIF-1α expression post-translationally. IP-MS identified about 50 Spry1 protein partners, and most of them were mitochondrial. Importantly, western blot analysis of cytosolic and mitochondrial proteins revealed that Spry1 was largely expressed in CM cell lines irrespective of BRAF mutation.

Conclusions: Altogether, these data lead us to speculate that Spry1 might play a role in mitochondria homeostasis, thus impacting on hypoxia and angiogenesis in CM.

BACH1 proline hydroxylation regulates the hypoxia response and metastasis in triple negative breast cancer

Long Chi Nguyen[1], Christopher Dann[1], Dongbo Yang[1], Emily Shi[1], Thomas Li[1], Joseph Wynne[2], Letícia Stock[1], Madeline Henn[1], Zeyu Qiao[3], Andrea Valdespino[1], Raven Watson[4], Wenchao Liu[1], Lydia Robinson-Mailman[1], Galina Khramtsova[5], Mitsuyo Matsumoto[6], Raymond Moellering[3], Olufunmilayo I. Olopade[5], Kazuhiko Igarashi[6], Marsha R. Rosner[1]. *[1]Ben May Department for Cancer Research, University of Chicago, Chicago, IL,[2]Ben May Department for Cancer Research, Food and Drug Administration, Washington, DC,[3]Department of Chemistry, University of Chicago, Chicago, IL,[4]Department of Pathology, University of Chicago, Chicago, IL,[5]Section of Hematology and Oncology, Department of Medicine, University of Chicago, Chicago, IL,[6]Department of Biochemistry, Tohoku University Graduate School of Medicine, Sendai, Japan*

Hypoxia is an important hallmark of aggressive solid tumors. Here we show that the pro-metastatic BTB and CNC homology 1 (BACH1) transcription factor is prolyl-hydroxylated by the HIF Prolyl Hydroxylase 1 (PHD1) in an oxygen-dependent manner. Using mass spectrometry, we identified two major prolyl hydroxylation sites in BACH1 and demonstrate that prolyl hydroxylation increased protein turnover in normoxia. Notably, a clinically relevant BACH1 mutant ($BACH1^{M}$) resistant to hydroxylation displays enhanced BACH1 DNA binding capacity. Triple-negative breast cancer (TNBC) cells expressing $BACH1^{M}$ showed higher invasion in vitro and increased metastasis in vivo. Loss of BACH1 reduced the cellular transcriptional hypoxic response. Under hypoxia, BACH1 increases chromatin accessibility and gene expression through chromatin remodeling involving direct BACH1 binding and indirect epigenetic regulation. These results indicate that hypoxia stabilizes and enhances the pro-metastatic transcriptional activity of BACH1 through loss of prolyl hydoxylation in TNBC. Our findings identify BACH1 as an oxygen sensitive effector of the hypoxia response and a clinically relevant target for attenuating hypoxia induced, pro-metastatic signaling and therapeutic resistance in cancers.

Hypoxic HIF-1α stabilization dependent on β3-adrenoceptor localization in Ewing sarcoma

Amada Pasha[1], Claudia Masi[1], Francesco Carrozzo[1], Martina Rosati[1], Alessia Boaretto[1], Alessandro Pini[2], Claudio Favre[1], Maura Calvani[1].
[1]Meyer Children's Hospital, Firenze, Italy,[2]University of Florence, Firenze, Italy

Hypoxia is a condition of oxygen deficiency which occurs in most growing solid tumors and stimulates a cascade of cell signals through a family of transcription factors named as hypoxia inducible factors (HIFs) that transactivate several regulatory genes involved in tumor proliferation. β3-adrenoceptors (β3-ARs) are involved in several hypoxic scenarios and in pathological conditions where hypoxia leads to important steps for cancer progression. Studies showed that β-AR blockade of mice suppressed hypoxia induction of renal HIF-1α accumulation, erythropoietin production, and erythropoiesis *in vivo*. In this work we assumed that β3-AR mediates hypoxia sensing and that it was necessary for HIF-1α stabilization thus we investigated a putative correlation between β3-AR/HIF-1α. Data showed a similar outcome of β3-ARs and HIF-1α at short time of hypoxia, and that β3-AR antagonist, SR59230A reduced HIF-1α protein expression under hypoxia. β3-AR silencing under hypoxia revealed an evident reduction of HIF-1α protein expression that confirmed the β3-AR modulation of HIF-1α expression. SR59230A treatment strongly reduced the HIF-1α target genes as *GLUT1, HK-2* and *HIF-1α* expression at long time treatment confirming the β3-AR modulation of HIF-1α transcriptional activity. Conversely, the HIF-1α-transcriptional inhibitor Topotecan did not affect β3-AR expression confirming that is β3-AR that mediates HIF-1α activation. Immunofluorescence analysis showed that β3-AR co-localized with the nucleus under hypoxia more than normoxia. These results were confirmed by nuclear-cytoplasmic fragmentation that showed the presence of both β3-AR and HIF-1α proteins in the nucleus under hypoxia. Co-immunoprecipitation of β3-AR/HIF-1α revealed that under hypoxia, HIF-1α dissociates from β3-AR binding, but this process was abrogated by SR59230A. HIF-1α, released under hypoxia from the link with β3-AR, can play its transcriptional activity in the nucleus, while the binding with β3-AR blocks its transcriptional activity. Moreover, β3-AR regulation on HIF-1α was exerted through PHD2 activity at short time as SR59230A treatment

under hypoxia increased the PHD2 protein expression but not at long time treatment, thus showing a different regulation of HIF-1α at different time points. In conclusion, the β3-AR upstream of the signaling β3-AR/HIF-1α axis exerts its role by PHD2 activity.

A novel microfluidic platform for PDAC organoid culture and drug screening

Marlene Geyer[1], Daniel Schreyer[2], Lisa-Marie Gaul[1], Désiréé Goubert[1], Susanne Pfeffer[1], Christian Pilarsky[3], Karla S. Queiroz[1]. *[1]MIMETAS, Oegstgeest, Netherlands,[2]University of Glasgow, Glasgoow, United Kingdom,[3]Universitätsklinikum Erlangen, Erlangen, Netherlands*

Pancreatic Ductal Adenocarcinoma (PDAC), the most common pancreatic cancer type, will become the second leading cause of cancer-related deaths by 2030 with mortality rates of up to 93%. Current standard-of-care for patients with PDAC includes chemotherapeutic regimens and pancreatic cancer surgery. However, only 20% of the patients are eligible for surgery due to late diagnosis. Although chemotherapeutic regimens are the leading treatment to PDAC patients, these are still very limited and the development of resistance to treatment is often observed. PDAC tumors are characterized by high-density stroma and hypovascularization, therefore these present high interstitial pressure and hypoxia. These features potentially interfere with the efficiency of chemotherapeutic drugs and highlight the urgent need for novel PDAC screening platforms. Here, we describe the establishment of PDAC organoid cultures in the MIMETAS OrganoPlate®. The aim of this project was to determine the treatment response of PDAC organoids in mono-, and co-culture with pancreatic stellate cells (PSCs) under hypoxic and normoxic conditions. To recapitulate in-vivo like conditions, the 2-lane OrganoPlate® from MIMETAS was used to study organoid growth and sensitivity to treatment. Several standard of care (chemo-)therapeutics were tested on PDAC organoids embedded within an extracellular matrix in the Organoplate® 2-lane. These were exposed to chemotherapeutic treatments for 72h. PDAC organoids showed an overall better survival when grown in co-culture with PSCs. Interestingly, organoids grown in co-culture showed a higher survival rate under hypoxic conditions. In contrast, when grown in monoculture cell

viability was higher or similar under normoxic conditions than in hypoxia for the different chemotherapeutics. The OrganoPlate® 2-lane provides an excellent platform for (co-) cultivation and high-throughput phenotypic drug screening of PDAC organoids, thereby potentially enabling the development of novel *in-vivo* like model systems for efficient patient stratification and drug discovery.

HIF1α is involved in radiation-induced DNA damage repair and anti-apoptotic pathways in pancreatic ductal adenocarcinoma

Kevin J. Tu[1], Sanjit K. Roy[2], Amit Sawant[2], Hem D. Shukla[2]. *[1]Cell Biology and Molecular Genetics, University of Maryland, College Park, MD,[2]Radiation Oncology, University of Maryland School of Medicine, Baltimore, MD*

Purpose/Objective(s): Pancreatic ductal adenocarcinoma (PDAC) is characterized by an unusually high degree of hypoxia in the tumor microenvironment, which activates hypoxic signaling pathways orchestrated by hypoxia-inducible factor 1α (HIF1α). It has been shown previously that HIF1α significantly increases PDAC radioresistance and growth, though its mechanism of action is unknown. Here, we test the hypothesis that HIF1α confers these traits in PDAC through involvement in DNA damage repair and KRAS signaling *in vitro*.

Materials/Methods: We performed studies with the KPC cell line ($Kras^{LSL\text{-}G12D/+}$;$TP53^{LSL\text{-}R172H/+}$). We used CRISPR-Cas9, a genome editing tool, to generate a HIF1α knockout (KO) cell line. Hypoxic microenvironments were induced using 100uM of the oxygen scavenger $CoCl_2$. Radioresistance and double-strand DNA damage was evaluated and compared between wild-type (WT) and KO cells after treatment with increasing doses of ionizing radiation using neutral comet assays. Tumor signaling pathways were mapped and analyzed using western blot and co-immunoprecipitation. The $KRAS^{G12D}$ inhibitor, BI-2852, was obtained from Boehringer-Ingelheim. Cancer cells were evaluated for growth and migration using cell proliferation assays and scratch wound assays following treatment with 50 uM BI-2852. Bioinformatic analysis was conducted using TCGA (The

Cancer Genome Atlas) data; high and low expression were defined as samples with mRNA expression z-scores ≥ 1 and ≤ -1, respectively,
Results: HIF1α KO cells demonstrated significantly increased radioresistance compared to WT cells following 8 and 10 Gy of radiation in hypoxic conditions (t-test, $P<0.05$). The olive moment of KO cells treated with the IC_{50} radiation dose (4 Gy) was significantly higher than that of WT cells (t-test, $P<0.0001$), suggesting that the DNA damage repair was upregulated by HIF1α. In addition, WT cells demonstrated higher tumor proliferation (t-test, $P<0.01$) and migration (t-test, $P<0.05$) compared to KO cells under hypoxia, suggesting HIF1α promoted tumor growth. WT cells treated with BI-2852 demonstrated significantly lower levels of TP53; using coimmunoprecipitation, we show that TP53 was likely degraded through Mdm2. HIF1α KO was necessary to induce high levels of apoptosis in cells treated with BI-2852. Our results suggest that HIF1α may act synergistically with KRAS to promote tumor survival through anti-apoptotic pathways that target TP53 for degradation. TCGA data also suggest that tumors with high expression of HIF1α is are associated with significantly poorer prognosis coimpared to tumors with low expression of HIF1α (Logrank test, $P=0.003$).
Conclusion: Overall, this study demonstrates that HIF1α promotes DNA damage repair in PDAC and reveals a HIF1α/KRAS/p53 signaling axis. Future studies will test anti-HIF1α and anti-KRAS combination therapies in PDAC mouse models.

Oxygen tension - dependent differences in cancer cell kinome

Adedeji K. Adebayo[1], Brijesh Kumar[2], Christopher Davis[3], Steven P. Angus[3], Harikrishna Nakshatri[2]. *[1]Department of Biochemistry and Molecular Biology, Indiana University School of Medicine, Indianapolis, IN,[2]Department of Surgery, Indiana University School of Medicine, Indianapolis, IN,[3]Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN*

Current approaches to preclinical cancer research often fail to consider the impact of ambient oxygen (O_2; ~21%) on cancer cells. This is also true for hypoxia studies that typically involves cancer cells previously grown in

ambient O_2 before subsequent transfer to hypoxia. However, the tumor microenvironment is characterized by significantly lower O_2 levels. We have previously demonstrated the impact of ambient O_2 on stem cell populations, signaling pathways and resistance to therapy. We developed an experimental approach that allows us to collect and process tumor tissues from transgenic mammary tumor mouse models and ovarian cancer patients under physioxia (3% O_2), such that they are never exposed to ambient O_2. In this study, our goal was to explore oxygen-dependent signaling pathway alterations and to determine how these pathways are influenced by targeted drugs in the context of physioxia or ambient air (AA). Our studies revealed increased basal phosphorylation levels of EGFR (Y1068) in the tumor cells in AA, relative to physioxia. However, downstream signaling effectors AKT and ERK showed higher phosphorylation levels under physioxia, compared to AA, suggesting that their activation is independent of EGFR signaling. These findings correlate with the decreased sensitivity of the tumor cells under physioxia to target drugs lapatinib and alpelisib. We then sought to examine basal and target drug induced kinome changes in tumor cells under physioxia and AA via Multiplexed Inhibitor Beads (MIBs) kinome assay. This assay revealed significant differences in the kinome of the tumor cells under physioxia compared to AA. Although direct comparison between vehicle and lapatinib treated cells in physioxia and ambient air showed very minimal changes, pairwise comparison between lapatinib treated physioxia cells and vehicle treated AA cells revealed an increase in the activity of PDGFRB in lapatinib treated physioxia cells. Similarly, a receptor tyrosine kinase (RTK) array and western blotting showed increased basal and lapatinib induced phosphorylation of PDGFRB (Y751) under physioxia. Next, we determined the potential role of PDGFRB in downstream signaling pathway activation of AKT and ERK and resistance to lapatinib. We found that sunitinib, a multitarget RTK inhibitor with high affinity for PDGFR effectively decreased PGDFRB activity under physioxia, with a concurrent decrease in the phosphorylation of AKT. Moreover, tumor cells under physioxia were more sensitive to sunitinib treatment, relative to ambient air. Furthermore, a combination of lapatinib and sunitinib rendered tumor cells under physioxia more sensitive to treatment than with lapatinib alone. These findings suggest that ambient and physioxic oxygen tensions differentially impact cancer relevant

signaling pathways. Therefore, it may be necessary to carry out preclinical cancer studies in the context of physiologically relevant oxygen tensions to aid translatability.

Inhibition of Smurf2 E3 ubiquitin ligase by heclin and its analogues enhances HIF-1α expression and transcriptional activity in normoxia or hypoxia

Shuai Zhao, Wafik S. El-Deiry. *Brown University, Providence, RI*

Hypoxia-inducible factors (HIFs) act as transcription factors and play an essential role in cellular and systemic responses to low oxygen environments. HIF-1α expression is induced in acute hypoxia typically through failure of its ubiquitination and degradation mediated by Von Hippel-Lindau (VHL). Previously we discovered a non-canonical mechanism where the SMAD specific E3 ubiquitin protein ligase 2 (Smurf2) promotes the ubiquitination of HIF-1α and reduces HIF-1α level in HCT116 colorectal cancer cells. Smurf2 is a HECT-type ubiquitin ligase known to interact with Smad proteins, leading to their ubiquitination and proteasomal degradation. Overexpression of Smurf2 decreased HIF-1α expression in HCT116 and SW480 colorectal cancer cells under hypoxia as well as in RCC4 VHL-deficient kidney renal clear cell carcinoma cells under normoxia. Treatment with MG132 at least partially rescued the expression of HIF-1α following Smurf2 overexpression, indicating involvement of proteasome-dependent degradation in Smurf2-mediated HIF-1α destabilization. Knockdown of *SMURF2* increased HIF-1α expression under normoxia in HCT116 and RCC4 cells. To investigate the effect of Smurf2 inhibition, we tested a selective reversible inhibitor of HECT E3 ubiquitin ligases, heclin, along with its analogues, PYR-41, C646 and 4E1RCat. Treatment with heclin increased HIF-1α expression in HCT116 under hypoxia as well as in SW480 and RCC4 cells under normoxia in a dose-dependent manner. PYR-41 elevated the level of HIF-1α level in HCT116 cells under hypoxia, in RCC4 cells under normoxia and in SW480 cells under both normoxia and hypoxia. To examine the effect on HIF transcriptional activity, we performed luciferase reporter assay using plasmids containing the hypoxia response element (HRE) from the *PGK1* promoter and the *VEGF* promoter, respectively. PYR-41 induced

transcriptional activity on *PGK1*-HRE in both HCT116 and SW480 cells. 4E1RCat robustly activated transcription on both *VEGF*-HRE and *PGK1*-HRE in HCT116 and SW480 cells. In summary, Smurf2 targets HIF-1α for ubiquitination and degradation independently of oxygen concentration and inhibition of Smurf2 to stimulate HIF activity under normoxia or hypoxia may be beneficial in pathological circumstances featuring anemia and hypoxemia.

ERX-208 as a novel therapeutic for treating ovarian cancer by enhancing endoplasmic reticulum stress

Suryavathi Viswanadhapalli[1], Tae-Kyung Lee[2], Kara Kassees[2], Gaurav Sharma[3], Rahul Gopalam[1], Karla Parra[3], Tanner Reese[3], Michael Hsieh[3], Uday P. Pratap[1], Xue Yang[1], Behnam Ebrahimi[1], Chia Yuan Chen[2], Scott Terry Elmore[2], Christian Cervantes[1], Zhenming Xu[1], Edward Kost[1], Gangadhara Reddy Sareddy[1], Rajeshwar Rao Tekmal[1], Jung-Mo Ann[2], Ganesh V. Raj[3], Ratna K. Vadlamudi[1]. *[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]UT Dallas, Richardson, TX,[3]UT Southwestern Medical Center, Dallas, TX*

Background: Ovarian cancer (OCa) is the deadliest of all gynecologic cancers in the United States. Despite initial response to chemotherapy, most OCa patients become chemo resistant and progress to metastatic disease. Here, we tested the hypothesis that the high basal level of endoplasmic reticulum stress (ERS) in OCa represents a critical vulnerability and drugs that further aggravate this already engaged system in OCa may exhaust its protective features and contribute to apoptosis induction. The objective of this proposal is to identify a hit compound that enhances ERS in OCa and to conduct mechanistic studies.
Methods: We synthesized a small library of >200 chemically distinct oligobenzamide analogs with maintenance of the chemical backbone but altered R groups of ERX-11. We performed the primary screening of this library to evaluate the induction of mRNA levels of two canonical ERS/UPR (unfolded protein response) genes- sXBP1 and CHOP. Biological activity of ERX-208 was validated using multiple OCa cells. Mechanistic studies were conducted using CRISPR/Cas9 KO, Western blotting, reporter

gene assays, IHC and RNA-seq analysis. PK (pharmacokinetics) and toxicity studies were done using C57BL/6 mice. Cell line-derived xenografts (CDXs), patient-derived xenografts (PDXs), patient-derived explants (PDEs), and patient-derived organoids (PDO) were used for preclinical evaluation.
Results: From a screen of a curated ERX-11 derived oligobenzamide library, we identified a hit compound, ERX-208 that potently (IC_{50}~100nM) induces ERS/UPR and apoptosis in multiple OCa cells *in vitro.* CRISPR KO screen identified the lysosomal acid lipase A (LIPA) protein as the critical target of ERX-208. LIPA KO abrogates response to ERX-208, while reconstitution of LIPA restores ERX-208 response. The time course studies showed a robust and consistent induction (>15-fold CHOP, and >10-fold sXBP1) by ERX-208 treatment within 24h. We confirmed induction of classic UPR components peIF2α, CHOP and LC3B using Western blotting in multiple OCa cells. Functionally, ERX-208 causes growth inhibition of OCa cells, as noted by MTT cell viability assays using 15 OCa cells with an IC_{50} of ~50-100nM. The activity of ERX-208 is distinct among oligobenzamides as ERX-11 has limited/no activity against OCa cells. RNA-seq analysis confirmed that ERX-208 induces significant ERS, UPR, and apoptosis. Further, ERX-208 reduced the growth of OCa PDO's *in vitro*, PDEs *ex vivo* and CDXs and PDXs *in vivo.* ERX-208 treatment did not show any signs of toxicity and body weight of mice was not affected. IHC analyses showed increased activation of ERS/UPR markers such as GRP78, p-PERK and decreased proliferation measured by Ki67.
Conclusions: Collectively, our results demonstrated the utility of ERX-208 and will establish a novel therapeutic paradigm in OCa that overcomes tumor heterogeneity by targeting LIPA and enhancing ERS leading to apoptosis.

Compensatory interplay of p97 segregase and HSP70 chaperone protect cancer cells from heat-induced proteotoxicity

Zdenek Skrott[1], Katarina Chroma[1], Petr Muller[2], Ales Panacek[3], Jiri Bartek[4], Martin Mistrik[1]. *[1]Insitute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacký University in Olomouc, Olomouc, Czech Republic,[2]Regional Centre for Applied*

Molecular Oncology, Masaryk Memorial Cancer Institute, Brno, Czech Republic,[3]Department of Physical Chemistry, Regional Centre of Advanced Technologies and Materials, Faculty of Science, Palacký University in Olomouc, Olomouc, Czech Republic,[4]Danish Cancer Society Research Center, Copenhagen, Denmark

Due to malignant transformation, cancer cells are characterized by elevated levels of genotoxic, replication or proteotoxic stresses, which makes them vulnerable to various external conditions, including increased temperature. Thus, hyperthermia represents a very effective therapeutic modality usually combined with standard chemotherapy or radiation. Moreover, the elevated temperature is often used in experimental studies related to protein aggregation, cellular heat shock response and other proteostasis mechanisms relevant to cancer progression and treatment. Recently, we developed a single-cell method to inflict defined, subcellular thermal damage, adopting the plasmon resonance principle. Dose-defined heat causes protein damage in subcellular compartments, rapid heat-shock chaperone recruitment, and ensuing engagement of the ubiquitin-proteasome system, providing unprecedented insights into spatiotemporal response to protein damage relevant to cancer. Using this versatile method, we discovered so-far unsuspected compensatory interplay of p97 translocase, the ubiquitin-proteasome system and heat shock protein chaperones in the processing of heat-damaged proteins. As both, p97 and heat shock proteins, represent potential cancer-relevant drug targets, these results can contribute to the development and better implementation of related therapies in cancer treatment.

#4815

TMEM9 decreases ER stress-induced misfolded proteins via lysosomal protein degradation

Dong-Han Wi[1], Su-Rin Jung[1], Seong-Ju Lee[1], Ye-seul Jeon[1], Youn-Sang Jung[1], Jae-Il Park[2]. *[1]Life Science, Chung-Ang University, Seoul, Korea, Republic of,[2]Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

The endoplasmic reticulum (ER) contributes to various protein modifications such as protein folding. Also, the ER-associated degradation

(ERAD) complex removes defective proteins, which prevents the accumulation of misfolded proteins to avoid abnormality of physiological activity. Several physiological and pathological stimuli, such as hypoxia and nutrient starvation lead to unfolded protein responses (UPRs). Given that hyper-proliferation causes hypoxia and glucose shortening, cancer cells might induce UPRs resulting in misfolded protein accumulation and aggregation. Although the ERAD complex removes defective proteins, the capacity of the proteasomal degradation pathway is not enough to completely clear defective proteins in hyper-proliferative cancer cells. Thus, it is likely that cancer cells require additional misfolded protein degradation systems. Transmembrane protein 9 (TMEM9) has been identified as a vesicular acidification amplifier, which is upregulated in cancer cells for Wnt/β-catenin signaling activation via lysosomal protein degradation. In this study, TMEM9 downregulated ER stress-induced misfolded proteins that decrease cancer cell proliferation and viability. ERAD inhibitor declined cancer cell proliferation, reverted by TMEM9. Intriguingly, TMEM9 decreased ERAD-induced apoptosis instead of promoted autophagic cell death under glucose shorten conditions. Here we suggest that lysosomal protein degradation is an additional protein degradation system for the removal of defective proteins and contributes to stable cancer cell proliferation via the clearing of garbage proteins.

Targeting GCN2 regulation of amino acid homeostasis sensitizes prostate cancer cells to senolytic therapies

Noah R. Sommers[1], Ricardo A. Cordova[1], Angela J. Klunk[1], Roberto Pili[2], Ronald C. Wek[1], Kirk A. Staschke[1]. *[1]Biochemistry and Molecular Biology, Indiana University School of Medicine, Indianapolis, IN,[2]Medicine, University at Buffalo, Buffalo, NY*

The integrated stress response (ISR) features a family of eIF2 kinases that sense cellular stress, triggering translational and transcriptional modes of gene expression that enhance cell adaptation to the underlying stress. Previously we reported (Cordova et al., 2022 *eLife*) that prostate cancer (PCa) cells rely on one of these eIF2 kinases, GCN2, for maintenance of amino acid homeostasis and sustained proliferation. GCN2 functions to enhance expression of amino acid transporters and subsequent import of

essential amino acids (EAAs) that are necessary to sustain PCa growth. Genetic loss or pharmacological inhibition of GCN2 results in decreased expression of amino acid transporters, severe depletion of intracellular EAAs, and decreased proliferation of PCa cells in culture and mouse xenograft models. Although loss of GCN2 in PCa cells reduces proliferation, depletion of this eIF2 kinase is suggested to lead to cell stasis and modest cell death. We hypothesize that the static phenotype by GCN2 inhibition in PCa cells renders these cells vulnerable to senolytic treatment and is a potential therapeutic target in combination therapies. To address this idea, we utilized models of androgen-sensitive and castration-resistant PCa and non-tumorigenic prostate epithelial cells. GCN2 inhibition induced a static phenotype in PCa cell lines, but not non-tumorigenic prostate epithelial cells, and this was accompanied by increased expression of the senescent markers p53, p21, p27, and MCL-1. Furthermore, induction of senescent markers following GCN2 inhibition in PCa cells was reversed by supplementation with EAAs, suggesting that limitation of EAAs is critical to the induction of cell stasis. Of importance, treatment of PCa cells with Navitoclax, a senolytic agent that targets Bcl-2 family of anti-apoptotic proteins, in combination with GCN2 inhibition resulted in enhanced cell death and apoptosis compared to each single treatment alone. Our results suggest that GCN2 inhibition in PCa cells leads to depletion of EAAs and induction of a static phenotype, rendering these cells vulnerable to targeting the Bcl-2 family of proteins to expedite cell death. As such, therapies integrating GCN2 inhibition and senolytic agents are proposed to be effective strategies for treatment of PCa.

Protein aggregation promotes HSF1 activity enhancing cell survival during metastatic breast cancer colonization

Natasha Hockaden, Gabi Leriger, John Wang, Haimanti Ray, Richard Carpenter. *Indiana University School of Medicine, Bloomington, IN*

Breast cancer is the most commonly diagnosed cancer in women and is the second leading cause of cancer-related deaths in women. Approximately 20-30% of patients will develop metastases and metastasis is responsible for greater than 90% of breast cancer deaths. Metastasis is a complex process in which the cells combat many forces to survive and spread to

different areas of the body. Metastatic colonization is the rate-limiting step of metastasis and is an inefficient process in which most cells die and only a small fraction of those that survive can form metastases. We have previously shown that heat shock factor 1 (HSF1) promoted epithelial-to-mesenchymal transition (EMT) and the breast cancer stem-like population, potentially linking HSF1 to metastasis. Utilizing an HSF1 gene expression signature that assesses HSF1 transcriptional activity, we further found that patients with high HSF1 activity have significantly worse metastasis-free survival. The physiological function of HSF1 is the master regulator of the heat shock response wherein it upregulates chaperone proteins under stress conditions. Because of these functions and the fact that the process of metastatic colonization is known to involve the stem cell population and incur external stressors, we hypothesized that HSF1 may function in metastatic colonization. To test this, we subjected human breast cancer MDA- MB-231 cells with or without HSF1 knockdown to intracardiac injections in nude mice. This model injects cells directly into the circulation allowing for assessment of metastatic tumor formation in which the major barrier will be metastatic colonization. Mice receiving cells with knockdown of HSF1 had a significantly reduced metastatic burden, indicating HSF1 is necessary for the completion of metastasis and colonization. Consistent with these findings, bone metastatic tumor specimens from patients show increased HSF1 activation compared to their matched primary breast tumors. The mechanism by which HSF1 enables metastatic colonization is unknown. Metastatic colonization likely requires at least two stages that include tumor initiation (or early colonization) characterized by the seeding of a tumor followed by tumor expansion (or late colonization) characterized by rapid proliferation and an increase in tumor size. We observed increased protein amyloid aggregates that correlate with an increase in HSF1 activity during mammosphere formation, suggesting that colonization induces aggregation leading to HSF1 activation that promotes a cell survival response. Overall, my results indicate that HSF1 activity increased during breast cancer metastasis and HSF1 is necessary for colonization. Going forward, I want to understand what controls HSF1 activation during metastasis, which I hypothesize that protein aggregation is increased leading to HSF1 activation.

GCN2 eIF2 kinase and p53 coordinate amino acid homeostasis and metabolism in prostate cancer

Ricardo A. Cordova[1], Noah R. Sommers[1], Angela J. Klunk[1], Haroon M. Mohiuddin[1], Roberto Pili[2], Ronald C. Wek[1], Kirk A. Staschke[1].
[1]Biochemistry and Molecular Biology, Indiana University School of Medicine, Indianapolis, IN,[2]Department of Medicine, University at Bufallo, Bufallo, NY

Activation of the integrated stress response (ISR) contributes to the progression of many cancers, including prostate cancer (PCa). The ISR features a family of protein kinases that phosphorylate the eukaryotic translation initiation factor 2 (eIF2) during different stress conditions, resulting in repression of global protein synthesis. In parallel, eIF2 phosphorylation also enhances the translation of select gene transcripts, such as ATF4, which directs the transcription of ISR-target genes that are critical for cancer stress adaptation. We recently reported (Cordova et al., 2022 *eLife*) that the eIF2 kinase GCN2 is a driver of the ISR in PCa and is critical for the maintenance of essential amino acid (EAA) homeostasis. GCN2 is activated in PCa due to EAA limitations, resulting in increased expression of key amino acid transporters which provide for nutrient import to facilitate protein synthesis and metabolism that drive PCa proliferation. Genetic loss or pharmacological inhibition of GCN2 results in lowered expression of amino acid transporters, leading to severe depletion of intracellular essential amino acids and reduced proliferation in PCa cell lines and xenograft models. These results support the therapeutic potential of targeting GCN2 in PCa.We recently determined that loss of GCN2 in PCa triggers a G1 nutrient-sensitive cell cycle checkpoint that is dependent on p53 and its target gene CDKN1A, encoding p21 inhibitor of cell cycle. Induced G1 arrest and p53/p21 signaling by GCN2 inhibition is reversed by supplementation with EAAs, suggesting amino acid limitation is critical for activation of p53. Metabolic stresses, such as amino acid starvation, have been suggested to activate p53 in different cancers and p53 regulates metabolic pathways that are critical for cancer cells adaptation to stresses. We also showed that depletion of specific amino acids activates GCN2 and p53 in cultured PCa cells. Using transcriptomic and metabolomic analyses, we determined that loss of GCN2 or p53 in PCa cells impacted multiple metabolic pathways, specifically those involved in amino acid and

nucleotide metabolism, supporting the importance of GCN2 and p53 in metabolic homeostasis. In addition, deletion of p53 in PCa cells exacerbates the activation of GCN2 and the ISR, suggesting that loss of p53 results in amino acid imbalances that further activate GCN2. Importantly, inhibition of GCN2 in combination with loss of p53 resulted in increased cell death and apoptosis in PCa. Our study suggests that GCN2 and p53 can be activated in parallel in PCa and these stress response pathways are crucial for PCa cells to maintain homeostasis and adapt to metabolic stress. We propose that GCN2 and p53 function to coordinate PCa growth and progression by regulating metabolism and cell cycle control. Targeting these stress pathways in combination may provide enhanced efficacy for the treatment of PCa.

Mechanism of disturbance of nuclear size homeostasis in cancer cells

Changgon Kim, Joon Kim. *Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of*

Abnormal increase in nuclear size is one of the criteria for distinguishing cancer cells. The main causes and functional consequences of nuclear size increase in cancer cells are not well known. In this study, we analyzed genome-wide RNAi library screen data to discover genes involved in the maintenance of nuclear size homeostasis. Importantly, many of the screen hits mapped to the functional categories of replication stress and DNA damage repair. We confirmed that depletion of genes required to prevent replication fork collapse causes a significant increase in nuclear size. Excessive replication stress and defects in the DNA repair system are common in many cancers. Therefore, disturbances of nuclear size homeostasis may be due to excessive replication stress and enhanced DNA damage response. To identify effectors that link replication stress and nuclear size change, we investigated candidates such as cell cycle progression, the mTOR pathway, and the cytoskeleton. As previously known, cell cycle arrest at G2 phase increased nuclear size, but replication fork collapse increased nuclear size even more excessively, suggesting the existence of other mechanisms. Inhibition of the mTOR pathway did not block replication stress-induced nuclear enlargement. Interestingly, we found that actin polymerization inside the nucleus plays a role in

determining nuclear size in replication stress condition. Inhibition of nuclear actin polymerization reversed nuclear enlargement due to replication fork collapses. The Increase in nuclear size appeared to reduce the invasive ability of cancer cells. In addition, the enlarged nuclei resisted mechanical stress-mediated nuclear envelope rupture. We also observed a change in the abundance of the tri-methylation of lysine 27 on histone H3. These results suggest that nuclear size homeostasis is perturbed as a result of excessive replication stress, and changes in nuclear size affect the invasive capacity and gene expression of cancer cells. However, it is not clear whether nuclear enlargement act as a strong barrier to metastasis, as nuclear size can readily change through changes in nuclear actin dynamics. Further studies are needed to understand the impact of nuclear size changes on cancer initiation and progression.

The disassembly of amyloid-bodies

Chloe Kirk, Michael Bokros, Alex Grunfeld, Stephen Lee. *University of Miami Miller School of Medicine, Miami, FL*

The ability of cells to adapt to a wide variety of stress conditions plays a critical role in various physiological and pathological settings, including development, cancer and neurological disorders. We recently reported the discovery of stress-induced low complexity noncoding RNA derived from stimuli-specific loci of the ribosomal intergenic spacer (rIGSRNA); an enigmatic region of the human genome historically dismissed as “junk” DNA. We showed that low complexity rIGSRNA activate a physiological amyloidogenic program that converts the nucleolus into Amyloid-bodies: a molecular prison of immobilized proteins in an amyloid-like state. This conserved post-translational regulatory pathway enables cells to rapidly and reversibly store an array of endogenous proteins in Amyloid-bodies and enter a dormant-like phenotype in response to severe environmental insults. While many membrane-less compartments have been described as liquid-like (e.g., stress granules, P-bodies, germ cell granules), our discovery of Amyloid-bodies provided evidence of an amyloidogenic process that can physiologically transition biological matter to a solid-like state. The ability of mammalian cells to efficiently dissemble Amyloid-bodies raises a fundamental question: Are mammalian cell disaggregases involved in

Amyloid-body disassembly? Here, we show that Amyloid-bodies undergo a solid-to-liquid-phase transition to release sequestered proteins and restore nucleolar functions. An RNAi screened identified key Heat Shock Proteins (Hsps) that remodel Amyloid-bodies back to the liquid nucleoli on stress termination. The composition of mammalian disaggregases differs considerably from non-metazoans and those involved in disassembly of pathological amyloids in vitro. Activation of mammalian disaggregases and Amyloid-body disassembly is dependent on ATP concentration. Conceptually, this work identifies metazoan disaggregases challenging the widely accepted paradigm that the amyloid state is irreversible in mammalian cells. The data also provides alternative insights into pathogenic amyloids by examining their disassembly in cellular systems.

Exploring the role of a solid-like condensate in breast and prostate cancer

Alexander Grunfeld, Michael Bokros, Chloe Kirk, Stephen Lee.
Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL

Cancer cells are exposed to harsh environmental conditions, which they adapt to by engaging various stress response pathways. A common cellular response to these stressors is the assembly of membraneless compartments known as biomolecular condensates. Our lab discovered one such pathway where exposure to environmental stressors reversibly converts nucleoli into solid-like condensates known as Amyloid bodies (A-bodies). A-bodies induce a state of cellular dormancy by sequestering in an amyloid-like state key proteins involved in processes such as DNA replication and cell cycle progression. *In vitro* experiments showed that suppressing A-body formation in cancer cell lines accelerates tumorigenesis, suggesting that system-wide amyloidogenesis is a mechanism of tumor suppression. The goal of this project was to investigate how A-bodies correlate with tumorigenesis in the context of human tissues. Using formalin-fixed paraffin embedded (FFPE) sections of breast invasive ductal carcinoma and prostate adenocarcinoma, we first confirmed the presence of A-bodies in tumors by staining with the amyloidophilic dye Amylo-glo. In agreement with *in vitro* data in breast and prostate cancer cell lines,

immunohistochemical staining further showed these condensates contain known A-body constituent proteins. Co-staining tissues with Amylo-glo and the proliferation marker Ki67 revealed a negative correlation between A-bodies and cell proliferation, supporting the hypothesis that A-bodies suppress cell growth. Finally, tissue staining comparing primary tumors with distant metastases suggests that A-body biogenesis is reduced in the progression to metastatic disease. Together, our preliminary data presents a biomolecular condensate which can be visualized in human tissues and inversely correlates with cell proliferation. Future directions include examining additional tumor types for the presence of A-bodies and testing the correlation between A-bodies and other markers of proliferation, cell cycle arrest, and environmental stress.

Signaling pathways associated with stress factors in gastrointestinal cancers

Amayrani Sanchez, Kyle D. Doxtater, Samantha Lopez, Sophia Leslie, Elias George, Vijian Dhevan, Meena Jaggi, Subhash Chauhan, Manish K. Tripathi. *Immunology and Microbiology, University of Texas Rio Grande Valley, McAllen, TX*

Gastrointestinal (GI) cancer affects various significant organs along the gastrointestinal tract, which contains several of the leading cancer-related deaths in the United States. According to the American Cancer Society, colorectal and liver cancers are among the top ten leading deaths due to cancer, ranking third and sixth, respectively. In the Rio Grande Valley region with a majority Hispanic population, colorectal cancer and liver have a higher occurrence than in the entire state of Texas. However, for many, a cancer diagnosis can worsen with stress, which is also a common occurrence within the Rio Grande Valley region due to 30% of its population living in poverty. Stress can cause changes to the immune system's functionality and the inflammatory response that could lead to insufficient surveillance for any potential oncogenicity. When the Hypothalamic-Pituitary-Adrenal (HPA) axis becomes activated by stress, it will release several stress hormones, such as leptin and cortisol, in response that can play a role in the progression and growth of cancer tumors. To further explore this relationship, hepatocellular carcinoma (HCC) cells and

colorectal cancer (CRC) cells were treated with cortisol and leptin at various time points to create models mimicking acute and chronic stress exposure. Afterward, the mRNA mean fold change levels were obtained utilizing the RT-PCR method to determine the levels of each gene in various liver and colorectal cancer cell lines.Additionally, a kinase assay will provide further insight and evidence into the signaling pathway based on the results of the RT-PCR. The current results have shown an upregulation of lncRNA MALAT1, ZNF384, and YB-1 genes at varying degrees depending on the cell line, stress hormone, and duration of treatment. Consequently, these findings have shown an upregulation of oncogenic long non-coding RNA and transcription factors, presenting a signaling oncogenic pathway model by stress factors in HCC and CRC cell lines. Therefore, understanding the role of stress-factors in the oncogenicity and progression of cancer can aid in creating therapeutics for a population where stress can play a role in cancer disparity.

The novel miR-15a/Fra-2/IGF1R axis drives response to starvation-induced cell stress in pancreatic ductal adenocarcinoma

Gian Luca Rampioni Vinciguerra[1], Marina Capece[1], Luca Reggiani Bonetti[2], Paolo Magistri[3], Federica Calore[1], Giovanni Nigita[1], Rosario Distefano[1], Roberto Ballarin[4], Fabrizio Di Benedetto[3], Andrea Vecchione[5], Barbara Belletti[6], Gustavo Baldassarre[6], Francesca Lovat[1], Carlo M. Croce[1]. *[1]The Ohio State University, Columbus, OH,[2]Department of Diagnostic, Clinic and Public Health Medicine, University of Modena and Reggio Emilia, Modena, Italy,[3]Hepato-pancreato-biliary Surgery and Liver Transplantation Unit, University of Modena and Reggio Emilia, Modena, Italy,[4]3Hepato-pancreato-biliary Surgery and Liver Transplantation Unit, University of Modena and Reggio Emilia, Modena, Italy,[5]4Department of Clinical and Molecular Medicine, Faculty of Medicine and Psychology, University of Rome "Sapienza", Rome, Italy,[6]5Division of Molecular Oncology, Centro di Riferimento Oncologico di Aviano (CRO), Aviano, Italy*

Pancreatic ductal adenocarcinoma (PDAC) is a relatively uncommon malignancy; however, its incidence is rising worldwide, and it is expected

to become the second-leading cause of cancer-related death by 2030. From a histological point of view, PDAC is characterized by a prominent desmoplastic reaction that compresses blood vessels, limiting oxygen and nutrient availability in the tumor microenvironment. Despite that, PDAC cells are capable to adapt dynamically to these stress conditions, adopting different strategies that includes the strict regulation of the autophagic flux. Thus, studying these adaptive mechanisms is crucial to understand PDAC progression and to establish new therapeutic modalities to tackle it. Here, we explore the role of the tumor suppressor miR-15a in the regulation of its putative target Fra-2, a transcription factor, commonly activated by cell stress. By employing IPA on PDAC tumors from TCGA dataset, we found that both miR-15a and its target Fra-2 are predicted to regulate the IGF-1 signaling pathway. In an independent cohort of 44 PDAC samples, miR-15a levels inversely correlated with both Fra-2 and IGF1R expression; conversely, Fra-2 significantly correlated with IGF1R. By chromatin immunoprecipitation and luciferase assay, we assessed that miR-15a directly targeted Fra-2 and IGF1R that, in turn, is transcriptionally regulated by Fra-2 activity. Then, we investigated the role of miR-15a/Fra-2 regulation of IGF1R in the response to starvation-induced cell stress. In starved PDAC cell lines, Fra-2 transcriptional activity triggered IGF1R promoter, causing IGF1R overexpression in control cells but not in miR-15a-overexpressing cells. Consistently, the IGF1 release after starvation induced phosphorylation of IGF1R and activation of the downstream mTOR pathway in control cells but not in miR-15a-overexpressing cells. Therefore, TEM and western blot analysis demonstrated that activation of mTOR *via* IGF1 release reduced the autophagic flux of PDAC control cell lines compared to miR-15a overexpressing cells under starvation. To assess our results in vivo, we injected PDAC cells wild type or Fra-2 knockout into the flank of nude mice. At tumor onset, mice were randomly divided in two groups and fed with control or hypoproteic diet for three weeks. Hypoproteic diet did not interfere with the growth of wild-type tumors, by contrast, significantly impaired Fra-2^{KO} tumors growth rate. Tumor analysis revealed that hypoproteic diet potently induced IGF1R overexpression and mTOR pathway activation in wild-type tumors but not in Fra-2^{KO} tumors. Our findings demonstrate that IGF1R expression is regulated by miR-15a directly and indirectly *via* Fra-2 in PDAC. This novel miR-15a/Fra-2/IGF1R axis, triggered by starvation, regulates the autophagic flux and

growth of PDAC cells in stress condition, and could be targeted by specific small inhibitors.

Intracellular ferritin expression levels regulate growth and resistance to ferroptosis in pancreatic cancer cell lines

Masataka Maruno[1], Yo-hei Kanamori[2], Takashi Matsumoto[1], Yuta Shiraishi[1], Toru Takematsu[1], Tatsunori Miyata[1], Kosuke Mima[1], Shigeki Nakagawa[1], Hidetoshi Nitta[1], Hiromitsu Hayashi[1], Toshiro Moroishi[2], Hideo Baba[1]. *[1]Gastroenterological Surgery, Kumamoto Univ Graduate School of Medical Sci, Kumamoto City, Japan,[2]Department of Cell Signaling and Metabolic Medicine, Kumamoto Univ Graduate School of Medical Sci, Kumamoto City, Japan*

Background: Pancreatic cancer is one of the cancers with the highest mortality rate, and it is important to develop effective treatments and elucidate prognostic factors. It has been reported that elevated serum ferritin is associated with the prognosis of pancreatic cancer. However, there are few reports on how ferritin in pancreatic cancer tissue acts in pancreatic cancer. Ferritin heavy chain (FTH) is a major component of ferritin, which stores iron and plays a role in suppressing iron-induced generation of reactive oxygen species. In this study, we aimed to examine the expression level of FTH in pancreatic cancer cells and its prognostic and cell biological roles.
Methods: We performed immunostaining of FTH in pancreatic cancer tissue specimens operated on at our hospital and classified the expression level of FTH by scoring the immunostaining intensity and staining rate. The expression levels and prognosis were then evaluated. The overexpression and knockout strains of FTH were generated using a human pancreatic cancer cell line (MIAPaCa-2), and their proliferative and stress tolerance abilities were compared with those of the control group.
Results: Immunostaining of 149 pancreatic cancer surgical specimens showed that the group with high FTH had a significantly shorter overall survival rate than the group with low FTH (5-year survival rate; 16.8% vs. 36.9%, p = 0.018). In multivariate analysis, high FTH expression was also a prognostic factor: in vitro, cell lines overexpressing FTH had enhanced proliferative potential compared to controls, while knockout lines were

suppressed. In addition, the knockout lines showed decreased resistance to RSL-3, an inducer of ferroptosis. Additional studies are currently underway to examine resistance to other drugs and the production of reactive oxygen species in the cells.
Conclusion: In pancreatic cancer, high ferritin expression is associated with worse prognosis and may enhance cell proliferation and stress tolerance, and might be a new treatment or biomarker.

Role of Mitochondria and Signaling Pathways in Cancer

#4828
Therapeutic targeting of P2X4 receptor and mitochondrial membrane potential in renal cell carcinoma
Christopher Rupert[1], Roberto Pili[1], Filomena DeNigris[2]. *[1]University at Buffalo, Buffalo, NY,[2]Universita di Napoli, Luigi Vanvitelli, Naples, Italy*

Clear cell renal cell carcinoma (ccRCC) is the most common lethal subtype of kidney cancer. Large-scale metabolomics data have associated metabolic alterations with the pathogenesis and progression of renal cell carcinoma and have correlated mitochondrial activity with poor patient survival. Our group has recently reported that the lysosome purinergic receptor P2X4 (P2X4R) regulates neoangiogenesis. As ccRCC is characterized by increased angiogenesis we hypothesized that P2X4R may play a role in this disease. Interestingly, TCGA data suggest that P2X4R over-expression correlates with poor overall ccRCC patient survival. Our preliminary results also suggest that oxophosphorylation is the main source of tumor-derived ATP, which exerts a critical impact on tumor energy metabolism and mitochondrial activity in ccRCC. P2X4 receptor expression appears to contribute to the homeostasis of intracellular calcium and integrity of mitochondrial membrane potential in different ccRCC models. Seahorse experiments showed that P2X4R inhibition by 5BDBD, a potent and selective antagonist, caused a rapid dose-dependent reduction of mitochondrial activity. Moreover, prolonged mitochondrial failure induced by 5BDBD was associated with increased radical oxygen species, changes in mitochondrial permeability (i.e. opening of the transition pore complex, dissipation of membrane potential and calcium overload), and cell death *via* both necrosis and apoptosis. P2X4R inhibition by 5BDBD was associated

with a significant anti-tumor effect both *in vitro* and *in vivo* by utilizing several ccRCC cell lines and patient-derived organoids. Interestingly, higher mitochondrial activity was associated with greater sensitivity to 5BDBD. Overall, our results suggest that the perturbed balance between lysosomal integrity and mitochondrial activity induced by P2X4R inhibition may be a therapeutic strategy for a subset of renal carcinoma patients

Monitoring metabolic plasticity in the tumor microenvironment *in vivo*

Marissa Ashton Howard. *George Mason University, Manassas, VA*

Tumor metabolic reprogramming is a hallmark of cancer progression, survival, and therapeutic resistance. A targetable class of cancer metabolic adaptation exploits mitophagy, a specialized autophagy pathway known to be linked to the cancer phenotype. Mitophagy selectively eliminates dysfunctional mitochondria by targeting them, via autophagosome shuttling, to the lysosome for degradation. Cancer cell mitophagy is triggered by elevated oxidative stress and mitochondria DNA damage caused by hypoxia, radiotherapy, molecular therapy, and immunotherapy. A high mitophagy demand can overwhelm the lysosome capacity resulting in the accumulation of damaged mitochondria that is harmful to the cell, and can suppress biogenesis of healthy mitochondria. We hypothesize that the newly discovered process of secretory mitophagy exports damaged mitochondrial fission-released segments to reduce the overload pressure on the lysosomal system, and thereby sustains cancer cell survival in the face of therapeutic mitochondrial stress. We have discovered a form of secretory mitophagy occurring *in vivo* in a growing solid tumor. Our molecular analysis of the full repertoire of extracellular vesicles (EV) shed into the resident tumor interstitial fluid (IF) *in vivo* yielded a rich set of information about the functional state of mitochondria within the tumor cells, and the host cells. A set of proteins required for sequential steps of fission-induced mitophagy preferentially populated the CD81+/PD-L1+ IF EVs; including PINK1 and ARIH1 E3 ubiquitin ligase (required for Parkin-independent mitophagy), DRP1 and FIS1 (mitochondrial pinching), VDAC-1 (ubiquitination state triggers mitophagy away from apoptosis), and VPS35, SEC22b, and Rab33b (vacuolar sorting). Comparing *in vivo* IF EVs to *in vitro* EVs revealed 40% concordance, with an elevation of mitophagy

proteins in the CD81+ EVs for both murine and human cell lines subjected to metabolic stress. The export of cellular mitochondria proteins to CD81+ EVs was confirmed by density gradient isolation from the bulk EV isolate followed by anti-CD81 immunoprecipitation, MitoTracker export into CD81+ EVs, and ultrastructural characterization. Further, we stimulated mitochondrial oxidative stress and blocked the fusion of the mitophagosome with the lysosome, which markedly stimulated the export of the secretory mitophagy unit. We also found that mitophagy inducer PINK1 cleavage status (full length versus cleaved), is prominently reflected in the set of mitochondrial proteins exported within IF EVs, and may constitute a new quantitative measurement tool to monitor the real-time state of tumor intracellular mitophagy. The outcome is new understanding of the importance of secretory mitophagy that can constitute an important therapeutic target, and a new clinically relevant means of monitoring the in vivo state of mitophagic flux within the tumor microenvironment.

Uncoupling protein 2 (UCP2) loss of function mediates PDAC tumor suppression by mitochondrial fusion

Ariana Carolina Acevedo-Diaz[1], Emily G. Caggiano[2], Meifang Yu[1], Cullen Taniguchi[1]. *[1]Department of Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]The University of Texas MD Anderson Cancer Center UT Health Graduate School of Biomedical Sciences, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pancreatic ductal adenocarcinoma (PDAC) is a lethal cancer with a dependence on highly active mitochondria to grow and metastasize. We previously found that mitochondrial fusion suppressed PDAC growth and metastasis, leading to improved survival in a preclinical model. The tumor suppressive mechanisms of mitochondrial fusion remain unclear, and thus we explored the role of redox homeostasis through uncoupling protein 2 (UCP2).
Methods/Results: Murine pancreatic cancer cells (KPC) with enhanced mitochondrial fusion (sgDrp1) exhibited higher levels of mitochondrial ROS compared to controls targeting GFP (sgGFP), suggesting altered redox homeostasis. We performed RNAseq on these two cell lines and found that

sgDRP1 cells exhibited reduced levels of UCP2. The UCP2 protein is known to have indirect antioxidant effects by reducing mitochondrial reactive oxygen species via uncoupling of ATP production from the electron transport chain. We found that abrogating UCP2 in KPC cells reduced its capacity for OXPHOS. Moreover, rescue of UCP2 in sgDrp1 cells restored their mitochondrial activity.
Conclusions: Mitochondrial fusion may suppress tumor growth and induce mitophagy by altering redox homeostasis. UCP2 may be a mediator of the tumor suppressive phenotype induced by mitochondrial fusion**,** thus linking mitochondrial dynamics and PDAC antioxidant strategies.
Future Work: These results will be explored for their translation *in vivo* and the effects of pharmacological inhibition of UCP2, both *in vitro* and *in vivo*, via the specific inhibitor Genipin, will be explored.

Mitochondrial plasticity enables metabolic reprogramming and metastatic latency
Pravat Kumar Parida[1], Srinivas Malladi[2]. *[1]UT Southwestern Medical Center, Dallas, TX,[2]Pathology, UT Southwestern Medical Center, Dallas, TX*

Introduction: Metastatic relapses are common in epidermal growth factor receptor 2 (HER2) amplified breast cancer patients considered disease-free after primary diagnosis and treatment. Stem-like disseminated tumor cells with specialized metastatic traits adapt and survive as latent metastases in distal organs by overcoming oxidative stress, nutrient limitation, microenvironmental and immune defenses. These latent subclinical metastatic cells are responsible for late recurrences. Understanding the traits and vulnerabilities of these cells is critical for developing strategies to prevent metastatic relapse.
Method: Here, we employed mouse models and patient samples along with RNA sequencing, Steady-state metabolite analysis, Lipid profiling, C^{13}-isotope tracing, C12-BODIPY pulse chase, Lentiviral shRNA Knockdown, Transmission electron microscopy etc. to investigate how disseminated latent metastatic cells meet their cellular energetic demands and initiate overt metastasis in the lipid-rich brain microenvironment.

Result: The ability to utilize available nutrients in distal organs and rewire metabolism is critical for survival of disseminated tumor cells. We report that latent metastatic cells in the brain uptake, store, and utilize fatty acids secreted by tumor-associated reactive astrocytes to meet their cellular energetic needs. Fatty acid oxidation (FAO) and dynamin-related protein 1(DRP1) driven punctate mitochondria enabled utilization of fatty acids and promote survival of latent cells by maintaining cellular bioenergetics and redox homeostasis. Attenuating fatty acid oxidation by genetic and pharmacological inhibition disrupted mitochondrial dynamics and limits metastatic incidence. Likewise, depleting DRP1 altered mitochondrial dynamics that results in reduced FAO, increased reactive oxygen species and attenuated metastatic latency and relapse in HER2+ breast cancer brain metastatic models. Furthermore, comparison with patient-matched primary tumor and brain metastasis identified increased pDRP1 expression in brain metastatic lesions. Moreover, pharmacological inhibition of DRP1 reduced brain metastatic burden in these preclinical models.
Conclusion: Despite significant advances in targeted therapies, HER2+ breast cancer patients often develop brain metastasis and their prevention and management remain an unmet need. Our findings in latent HER2+ breast cancer brain metastatic models demonstrate mitochondrial plasticity and altered fatty acid metabolism are key determinants of metastatic adaptation to the brain and establish DRP1 as a promising therapeutic target for treating brain metastasis.

Copy number amplification of OXPHOS genes drives tumor hypoxia in NSCLC

Martin Benej, Katarina Benejova, McKenzie Kreamer, Jinghai Wu, Syed Ashraf, Caroline Wheeler, Rebecca Hoyd, Daniel Spakowicz, Nicholas C. Denko. *The Ohio State University Wexner Medical Ctr., Columbus, OH*

Non-small cell lung cancer (NSCLC) is a highly aggressive disease with a dismal prognosis associated with high rates of treatment resistance and disease recurrence. High-dose stereotactic body radiation therapy (SBRT) is the standard of care for locally advanced non-resectable NSCLC. However,

as discovered more than six decades ago, tumor hypoxia is a significant barrier to effective radiation therapy. In the last decade, immunotherapy targeting immune checkpoints such as programmed cell death 1 (PD-1) has been introduced as first-line NSCLC treatment, yet long-term disease control occurs in less than 25% of patients. Therefore, understanding the mechanisms of the treatment resistance is essential to address the need for novel synergistic therapies to sensitize refractory NSCLC tumors to anti-cancer treatment. Tumor hypoxia has been associated with treatment resistance for decades, yet its role in the clinical management of NSCLC remains largely unexplored. The basis of tumor hypoxia has traditionally been attributed to the oxygen supply deficit as malformed tumor vasculature fails to meet the high demand of the rapidly proliferating tumor mass. However, our preliminary analysis of NSCLC patient datasets in the Cancer Genome Atlas (TCGA) revealed a significant correlation between high-level expression of nuclear genes encoding mitochondrial subunits essential for oxidative phosphorylation (OXPHOS) and the expression of validated hypoxia-regulated genes (Buffa hypoxia score). The oxygen-consumption expression signature was implemented in software that enables the calculation of numerous tumor microenvironment expression signatures, called tmesig. Furthermore, we have observed a direct positive correlation between the hypoxia expression signatures levels in NSCLC patient samples and the copy number amplification (CNA) of essential OXPHOS genes. Because mitochondrial function consumes up to 90% of available cellular oxygen, its activity may indirectly regulate oxygen availability in the tumor microenvironment by rapidly consuming oxygen upon its delivery to the tumor. Mechanistically, this leads to the hypothesis that OXPHOS gene amplification drives mitochondrial function, which may, in turn, promote tumor hypoxia and treatment resistance in NSCLC.

Inhibiting the mitochondrial RNA degradosome complex SUV3 and PNPase increases dsRNA in the cytoplasm, triggers a viral mimicry response and kills AML cells and progenitors

Geethu Emily Thomas[1], Kazem Nouri[1], Jong Bok Lee[2], Rose Hurren[1], Yongran Yan[1], Neil MacLean[1], Yulia Jitkova[1], Li Ma[1], Xiao Ming Wang[1], Chaitra Sarathy[1], Andrea Arruda[1], Mark D. Minden[1], Li Zhang[2], Vito Spadavecchio[3], Aaron Schimmer[1]. *[1]UHN Princess Margaret Cancer*

Centre, Toronto, ON, Canada,[2]Toronto General Hospital Research Institute, Toronto, ON, Canada,[3]Interlinked Therapeutics LLC, Portland, OR

Eukaryotic cells have two separate genomes; nuclear chromosomal DNA and circular mitochondrial DNA. Mitochondrial DNA lacks introns, and encodes 2 rRNAs, 22 t-RNAs and 13 of the 90 proteins that constitute the mitochondrial respiratory chain. To maintain homeostasis, mitochondrial RNA degradation machinery regulates RNA turnover. ATP-dependent helicase, SUV3 (gene SUPV3L1), and exonuclease PNPase (gene PNPT1) function as a complex to degrade mitochondrial dsRNA. By immunoblotting, PNPase and SUV3 proteins were increased in 7/7 AML patient samples and 13/13 of AML cell lines, compared to the normal hematopoietic cells. Analysis of the TARGET AML dataset revealed AML patients with increased expression of SUPV3L1 ($p = 0.051$, $p= 0.045$) and PNPT1 ($p = 0.0013$, $p = 0.018$) had decreased overall and event free survival. Genetic knockdown or knockout using shRNA or sgRNA against PNPT1 or SUPV3L1 decreased growth and viability of OCI-AML2, TEX, K562, U937, NB4 and OCI-AML 8227 cells. Furthermore, SUPV3L1 & PNPT1 ranked in the top 5.2% and 7.4% of essential genes in 26 leukemia cell lines in CRISPR screens and 2.7% and 4.9% in RNAi screens (depmap.org). Knockdown of PNPT1 & SUPV3L1 also reduced the clonogenic growth of OCI-AML2, TEX and U937 cells and significantly reduced engraftment of TEX cells into the marrow of immune deficient mice, demonstrating the functional importance on leukemia initiating cells in vivo. SUPV3L1 knockdown in primary AML cells reduced engraftment in marrow of immune deficient mice. Bioinformatics analysis to detect processes associated with PNPT1 and SUPV3L1, we identified associations with Response to exogenous dsRNA, Response to virus, and RNA catabolic process ontologies. Consistent with this, we observed knockdown of PNPT1 or SUPV3L1 increased expression of genes (INFgR1, ICAM, IRF7 & JAK/STAT) suggesting an interferon response. As PNPT1 and SUPV3L1 degrade mitochondrial dsRNA, we measured levels of dsRNA after knockdown of these genes. Knockdown of PNPT1 and SUPV3L1 in OCI-AML2 cells increased levels of cytoplasmic/mitochondrial dsRNA 3-4 fold compared to control. Knockdown of PNPT1 and SUPV3L1 also increased dsRNA in 143B cells, but not Rho (0) 143B cells that lack mitochondrial DNA. Upregulation of inflammatory genes leads to viral mimicry and can

increase sensitivity to immune mediated killing. We observed enhanced sensitivity to Double Negative T (DNT) cells mediated killing in PNPT1 and SUPV3L1 knockdown OCI-AML2 cells compared to control cells. In summary, RNA degradosome complex proteins SUPV3L1 and PNPT1 are overexpressed in AML, and are essential for the survival of AML cells and AML stem/progenitors. These enzymes regulate levels of mitochondrial dsRNA, and their inhibition leads to increased cytoplasmic dsRNA triggering a viral mimicry response and enhanced sensitivity to immune-mediated killing.

Mitochondrial ClpXP degrades serine phosphorylated protein aggregates

Yue Feng, Yulia Jitkova, Alexander Keszei, Jonathan St-Germain, Yongran Yan, Brian Raught, Mohammad Mazhab-Jafari, Aaron Schimmer. *UHN Princess Margaret Cancer Centre, Toronto, ON, Canada*

ClpXP is a serine protease localized to the mitochondrial matrix and maintains mitochondrial proteostasis by degrading damaged/aggregated respiratory chain complex proteins. Both inhibition and hyperactivation of ClpP lead to impaired OXPHOS function and kill leukemic cells *in vitro* and *in vivo*. Yet, the marks that tag proteins for degradation by ClpXP remain unknown.

The bacterial homologue of ClpXP degrades damaged proteins with arginine phosphorylation. Therefore, we assessed how phosphorylation affects ClpXP protease activity. Recombinant ClpXP was incubated with its unnatural substrate, FITC-tagged casein, in the presence of increasing concentrations of phospho-serine (pSer), phospho-threonine (pThr), phospho-arginine (pArg), or phospho-tyrosine (pTyr). In a dose-dependent manner, pSer and pThr free amino acids and short peptides inhibited casein degradation by ClpXP. In contrast, free Ser, Thr, phosphate, pArg and pTyr did not inhibit ClpXP protease activity. In addition, we characterized ClpP peptidase activity and ClpX ATPase activity using the Ac-Trp-Leu-Ala-AMC (Ac-WLA-AMC) peptidase activity assay and the Malachite Green ATPase assay. Neither pSer nor pThr inhibited ClpX ATPase activity or ClpP peptidase activity. Thus, pSer and pThr only blocked ClpXP from

degrading full-length protein without altering the enzymatic activity of the complex.
Next, we characterized pSer and pThr binding to ClpXP by thermal shift binding assay. pSer and pThr free amino acids and short peptides bound to ClpX but not ClpP. All the dephosphorylated counterparts did not bind to ClpX. Therefore, pSer and pThr interact with ClpX outside the ATPase site. cyroEM studies of ClpX and pSer peptides indicated a putative pSer docking site in the central pore of ClpX.
Previously, we identified OXPHOS complex II subunit SDHA as a potential ClpXP endogenous substrate. Therefore, we used SDHA as a model to assess whether serine phosphorylation influenced ClpXP protein degradation in intact cells. Using pSer immunoprecipitation, we observed increased serine phosphorylated SDHA in AML cells after ClpP and ClpX knockdown. The increased serine phosphorylated SDHA was specifically found in the insoluble fraction of the mitochondrial proteins. Supporting that serine phosphorylated SDHA represents aggregated protein, treatment of cells with ROS-inducing antimycin or 42°C heat shock also increased levels of serine phosphorylated SDHA in the fraction of insoluble mitochondrial proteins. Finally, adding recombinant ClpXP to mitochondrial lysates specifically degraded SDHA with serine phosphorylation.
In summary, mitochondrial ClpXP degrades aggregated mitochondrial proteins marked by serine phosphorylated. Thus, this work identifies new degradation machinery for mitochondrial protease, advances the function of mitochondrial ClpXP, and highlights a new therapeutic strategy to target this protease.

EP4 increases the mitochondrial respiration and promotes cell migration in oral cancer

Rina Nakakaji[1], Masanari Umemura[1], Kohei Osawa[1], Soichiro Ishikawa[1], Kenji Mitsudo[2], Yoshihiro Ishikawa[1]. *[1]Cardiovascular Research Institute, Yokohama City University Graduate School of Medicine, Yokohama, Japan,[2]Department of Oral and Maxillofacial Surgery, Yokohama City University Graduate School of Medicine, Yokohama, Japan*

Introduction: EP4 is one of the prostaglandin E_2 (PGE_2) receptors. We previously reported that EP4 promoted cell migration via Ca^{2+} signaling, however the underlying mechanism has remained unclear. In Ca^{2+} signaling, Store-operated Ca^{2+}entry (SOCE) is a major mechanism of Ca^{2+} import from the extracellular to the intracellular space. Orai1, one of the selective Ca^{2+} channels, plays an important role in SOCE. We focused on the correlation with EP4 and Orai1. Additionally, we found that EP4 promoted the phosphorylation of calcium/calmodulin-dependent protein kinase kinase 2 (CaMKK2) and AMP-activated protein kinase (AMPK) located downstream of CaMKK2, *i.e.*, cell energy regulators. AMPK activation can control positively or negatively the cellular adenosine triphosphate (ATP) supply. Therefore, we investigated how EP4 regulated the mitochondrial function via Ca^{2+} and promoted the cell migration in oral cancer cells.
Materials and Methods: HSC-3, human tongue squamous cell carcinoma cell line was used. ONO-AE1-437 was used as EP4 agonist. HSC-3 cells were transduced with Orai1 shRNA, and control shRNA using lentivirus. The migration ability was evaluated by scratch assay. Measurement of intracellular Ca^{2+} concentration was measured using Fura-2. Immunoprecipitation was performed to evaluate the interaction between EP4 and Orai1. XF Cell Mito Stress Test and XF Real-Time ATP Rate Assay were performed to evaluate the mitochondrial aspiration and the ATP production using Extracellular Flux Analyzer.
Results: Scratch assay showed EP4 promoted cell migration in oral cancer cells (n=4, $p<0.05$). In contrast, Orai1 knockdown negated EP4-induced cell migration. EP4 rapidly increased the intracellular Ca^{2+} concentration, while Orai1 knockdown negated EP4-indued Ca^{2+} increase (n=4, $p<0.05$). Immunoprecipitation showed that EP4 was colocalized and formed complexes with Orai1 (n=4, $p<0.05$). These results indicated that EP4 promoted the cell migration via Ca^{2+} signaling through Orai1. EP4 increased the maximal respiration 3h after the stimulation (n=6, $p<0.05$). ATP production rate shifted mitoATP dominant. These data indicated that EP4 increased the mitochondrial function and the respiratory capacity, potentially regulating its energy supply. These results demonstrated that EP4 promoted mitochondria respiration and then increased the energy production from mitochondria in oral cancer cells.

Conclusion: We concluded that EP4 regulated the mitochondrial function via Ca^{2+} through Orai1 and promoted the cell migration in oral cancer cells.

Fasting induces greater expression of mitochondrial proteins associated with fatty acid metabolism and non-shivering thermogenesis in brown adipose tissue of knock-in ACSS1K635Q mice

Aishani Sivasai Gargapati[1], Mahboubeh Varmazyad[2], David Gius[2]. *[1]Rice University, Houston, TX,[2]Department of Radiation Oncology, The University of Texas Health San Antonio, San Antonio, TX*

Introduction: Acyl-CoA Synthetase Short Chain Family Member 1 (ACSS1) is an important mitochondrial enzyme for the production of ATP from short chain fatty acids under energetic stress. ACSS1 is highly expressed in brown adipose tissue, heart, and skeletal muscle. ACSS1 is regulated in part by a post-translational modification of ACSS1, whereby the side chain of Lysine-635 is acetylated. The activity of ACSS1 is downregulated by the acetylation of Lysine-635. The downregulation of ACSS1 activity has been shown to impose changes on fatty acid metabolism and body temperature. Our lab observed that homozygous knock-in ACSS1 mice that fasted for 48 hours were hypothermic with a temperature of 30 °C. Here, we utilized mutant mice to simulate acetylated ACSS1, to investigate the role of ACSS1K635Q in mitochondrial fatty acid metabolism and maintenance of body temperature under fasting conditions. Methods: A knock-in ACSS1 mouse model with a mutation of ACSS1K635Q was designed to model the downregulation of ACSS1. Wild Type mice and Homozygous Knock-in ACSS1K635Q mice were either fasted for 48 hours (F48) or fed with a normal diet (ND). Four experimental groups - Wild Type ND and F48 mice and Homozygous Knock-in ACSS1K635Q ND and F48 mice - were examined. Protein was extracted from 10 samples each containing 20 mg of brown adipose tissue. Tissue samples were lysed and immunoblotted with primary and secondary antibodies. Western Blot Western Blot was performed on the proteins Uncoupling Protein 1 (UCP1), UCP2, ACC, and AMPK. Membranes were imaged using the FluorChem M system, and chemiluminescence was quantified using the NIH ImageJ software. ANOVA and t-test were used to conduct statistical analysis ($P < 0.05$).

Results: Homozygous Ki-ACSS1K635Q F48 mice expressed higher levels of UCP1 and UCP2 in BAT than Homozygous Ki-ACSS1K635Q ND mice. We observed a greater difference in UCP1 expression between Homozygous Ki-CSS1K635Q ND and F48 mice compared to the difference in UCP1 expression between Wild Type ND and F48 mice. In Wild Type and Homozygous Ki-ACSS1K635Q mice, UCP1 expression was lower than UCP2 expression. Fasting for 48 hours significantly upregulated p-AMPK in Wild Type mice.
Conclusions: Under fasting conditions, metabolic processes may shift towards a greater proportion of non-shivering thermogenesis due to ACSS1 inactivity. UCP1 likely contributes more to non-shivering thermogenesis than UCP2. Understanding the impact of acetylating ACSS1 provides avenues towards developing personalized treatments that effectively respond to metabolic stressors.

Inhibition of mitochondrial fission activates glycogen storage to support cell survival in colon cancer

Sumati Hasani[1], Lyndsay E. A. Young[1], Moumita Banerjee[2], Dylan Rivas[2], Jinhwan Kim[2], Ramon Sun[3], Matthew Gentry[3], Xiaopeng Xiong[2], Tianyan Gao[2]. *[1]Molecular and Cellular Biochemistry, University of Kentucky, Lexington, KY,[2]Markey Cancer Center, University of Kentucky, Lexington, KY,[3]Biochemistry and Molecular Biology, University of Florida, Gainesville, FL*

Metabolic reprogramming has been increasingly recognized as one of the major mechanisms that fuels tumorigenesis and disease progression. Our previous studies have shown that in response to fatty acid uptake, colon cancer cells activate mitochondrial fission to support fatty acid oxidation and downstream Wnt signaling. Given the potential benefit of inhibiting mitochondrial fission, Dynamin-Related Protein 1 (Drp1), a pro-fission factor, has become an attractive target for developing anticancer agents. Here we investigated the role of Drp1 in promoting metabolic adaptation in colon cancer. We found that knockdown of Drp1 decreased mitochondrial respiration which resulted in increased glucose uptake and lactate production. In addition, downregulation of Drp1 increased AMP-activated protein kinase (AMPK) activity which coincided with glycogen

accumulation. Consistently, results from GC/MS analysis of cellular metabolites revealed that the levels of glucose-6-phosphate, a precursor for glycogenesis, were significantly elevated in Drp1 knockdown cells whereas pyruvate and other TCA cycle metabolites remained unchanged. Mechanistically, AMPK transcriptionally activates the expression of glycogen synthase 1 (GYS1) and hexokinase 2 (HK2) genes and silencing GYS1 abolished the glycogen accumulation phenotype in Drp1 knockdown cells. Using APC-derived 3D organoids, we demonstrated that the glycogen levels were elevated in $Apc^{f/f}$ $Drp1^{f/f}$ tumor organoids upon deletion of Drp1. Similarly, increased GYS1 expression and glycogen levels were detected in xenograft tumors derived from Drp1 knockdown colon cancer cells compared to control. Functionally, increased glycogen storage allowed Drp1 knockdown cells to survive glucose starvation conditions suggesting an enhanced survival capacity compared to control cells. Taken together, our findings indicate that Drp1 inhibition by itself is unlikely to be sufficient to eradicate cancer cells as adaptive metabolic mechanisms are activated to promote cell survival. However, combining Drp1 inhibition may enhance the efficacy of chemotherapeutic agents for colon cancer treatment.

Exploiting mitochondrial metabolism to enhance the response to standard of care treatments in ovarian cancer

Laura Formenti, Alessandra Decio, Valentina Dematteis, Giulia Dellavedova, Maria Rosa Bani, Raffaella Giavazzi, Carmen Ghilardi.
Oncology, Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milano, Italy

Ovarian cancer best practice consists of debulking surgery followed by platinum/taxane based chemotherapy combined with the angiogenesis inhibitor bevacizumab, and the PARP inhibitor olaparib for HRD positive tumors. However, despite significant improvements in its treatment, the 5-year survival rate remains low due to disease recurrence and resistance to therapy. Emerging evidence suggests that the metabolic requirements of cancer cells change after exposure to chemotherapy or targeted therapies, generating a potential Achilles' heel. Here, we focused on exploiting the intrinsic or therapy-induced metabolic vulnerabilities of ovarian cancer to

improve its response to the standard medical care. To this aim, ovarian cancer patient-derived xenografts (OC-PDX), injected orthotopically in nude mice, were used to assess i) the association between the metabolic profile of OC-PDXs and their responsiveness to treatments (i.e. cisplatin, bevacizumab, olaparib), ii) the metabolic changes induced by the treatments and iii) the therapeutic benefit of combining an OXPHOS inhibitor with the above-stated therapies. The effect on tumor progression was evaluated as increase of survival of OC-PDX bearing mice. First, we characterized the metabolic profile of OC-PDXs and divided them into high- and low-OXPHOS according to their dependence on mitochondrial metabolism. Then, we evaluated their response to the standard of care treatments and found that 75% of high-OXPHOS OC-PDXs were sensitive to cisplatin and olaparib, while 100% of low-OXPHOS OC-PDXs were poorly responsive. Response to bevacizumab varied in the two OC-PDX subsets. Further, we demonstrated that cisplatin or bevacizumab treatment induced the emergence of a sub-population of cells from malignant ascites with higher mitochondrial content and tricarboxylic acid cycle (TCA) intermediates and reduced expression of glycolysis-related genes, thus suggesting a shift toward oxidative metabolism in the residual cancer cells after treatment. Targeting these OXPHOS-dependent cells with the respiratory chain complex I inhibitor IACS-010759 improved the survival of mice. These results indicate that the metabolic profile of ovarian cancer cells is associated with the response to cisplatin and olaparib and lay the ground for the rational combination with OXPHOS inhibition to prolong therapies efficacy and eventually delay the development of recurrent disease.

Chemotherapy alters mitochondrial metabolism in melanoma

Alexander W. Loftus[1], Mehrdad Zarei[2], Omid Hajihassani[2], Johnathan J. Hue[3], Hallie J. Graor[2], Ali Vaziri-Gohar[2], Jordan M. Winter[4], Luke D. Rothermel[4]. *[1]University Hospitals Cleveland Medical Center, Cleveland, OH,[2]Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH,[3]Surgery, University Hospitals Cleveland Medical Center, Cleveland, OH,[4]Department of Surgical Oncology, University Hospitals Cleveland Medical Center, Cleveland, OH*

Background: Advanced and metastatic melanoma carries significant mortality despite recent advances. Metabolic plasticity is a hallmark of cancer and an important resistance mechanism in the face of anti-neoplastic therapies. We sought to understand the effect of chemotherapy, Temozolomide (TMZ), on OXPHOS and TCA cycle metabolism in melanoma cell lines. By understanding these metabolic adaptations to chemotherapy, we hope to identify novel combination therapies.
Methods: A375 and SK-MEL-28 cell lines were used for all experiments. Cell viability assays were performed with 1500 cells per well, treated with TMZ and oligomycin or phenformin, and viability was assessed using PicoGreen dsDNA assay. Western blot was used with primary antibodies against TOM20 and B-actin. LCMS metabolites were assessed by QTRAP triple quadrupole mass spectrometry coupled to a Prominence UFLC HPLC system. This assessed approximately 299 metabolites. Seahorse XFp miniextracellular analyzer was used to obtain OCR with and without TMZ exposure, and after sequential injections of oligomycin, FCCP, and rotenone with antimycin A. Mitochondrial assays included TMRE staining (membrane potential) and Mitotracker Green (mitochondrial mass).
Results: Metabolic profiles of melanoma cell lines change with exposure to chemotherapy. After melanoma cells are exposed to IC30 dose of TMZ, LCMS metabolomics revealed statistically significant increase in TCA cycle metabolites such as succinate, succinyl CoA, malate, oxaloacetate, isocitrate, alpha-ketoglutarate, and fumarate. Melanoma increases OXPHOS in the presence of chemotherapy. Mitochondrial mass, measured by Mitotracker, increased in response to TMZ exposure. We also found increased mitochondrial membrane potential and increased TOM20 expression after cells were treated with TMZ. Seahorse XF Cell Mito Stress Assay demonstrated increased oxygen consumption rate after exposure to TMZ. We then combined TMZ and two mitochondrial inhibitors, phenformin (complex I) and oligomycin (complex V). Combination of phenformin and TMZ was synergistic in cell viability assays as determined by Bliss equation. Oligomycin sensitized both cell lines to TMZ.
Discussion: We have shown that melanoma cells rely on mitochondrial function when exposed to TMZ by increasing levels of TCA cycle intermediates, increasing mitochondrial tropism, and increased expression of mitochondrial enzymes. This demonstrates a metabolic resistance mechanism in response to chemotherapy to promote melanoma cell

survival. Finally, we exploit this adaptation by pharmacologic inhibition of mitochondrial electron transport chain (ETC) with phenformin and oligomycin A. This treatment was synergistic with conventional chemotherapy. Our findings point out that the ETC compartment of mitochondria could be a novel and readily available combination treatment strategy for patients with advanced and refractory melanoma.

Dysregulation of mitochondrial function by PLK1-mediated PDHA1 phosphorylation promotes Cr(VI)-associated lung cancer progression

Qiongsi Zhang[1], Zhiguo Li[1], Xiongjian Rao[1], Derek B. Allison[2], Qi Qiao[3], Zhuangzhuang Zhang[1], Yifan Kong[1], Ruixin Wang[1], Teresa W. M. Fan[1], Richard M. Higashi[1], Andrew N. Lane[1], Xiaoqi Liu[1]. *[1]Department of Toxicology and Cancer Biology, University of Kentucky, Lexington, KY,[2]Department of Pathology and Laboratory Medicine, University of Kentucky, Lexington, KY,[3]Department of Chemical and Materials Engineering, University of Kentucky, Lexington, KY*

Hexavalent chromium (Cr(VI)), an class I environmental carcinogen, not only induces lung epithelial cell transformation but also promotes lung cancer progression by alterations of the cell cycle and cellular energy metabolism. Using Cr(VI)-transformed (CrT) bronchial epithelial cells (BEAS-2B) and parental BEAS-2B cells, we demonstrate that the level of polo-like kinase 1 (PLK1) is highly upregulated in CrT cells, which blocks mitochondrial function, and further promotes cell proliferation both in vitro and in vivo. Cells expressing a high level of PLK1 exhibited repressed mitochondrial activity due to defective modulation of pyruvate dehydrogenase E1 subunit alpha 1 (PDHA1), which facilitates the carbon influx to TCA cycle via catalyzing pyruvate/ Acetyl-CoA conversion. Mechanistically, we show that PDHA1 can be directly phosphorylated by PLK1 at T57, which triggers collapse of E1 and PDHA1 degradation via activation of mitophagy. These defects resulted in the inhibition of oxidative phosphorylation and reduction of mitochondrial reactive oxygen species (ROS) generation, eventually inhibiting mitochondrial-mediated apoptotic response. Defining the role of PLK1 in metabolic reprogramming in Cr(VI)-associated cancer progression may give us a new perspective and a target to inhibit Cr(VI)-induced cancer development. In addition, PLK1

inhibitors may be used to increase the chemo-sensitivity of cancer cells by restoring the normal function of mitochondria, thus alleviating the drug resistance caused by dysfunction and hyperpolarization of mitochondria.

SLC25A46 as a novel mitochondrial regulator and biomarker in breast cancer

Heather K. Beasley[1], Ky'Era V. Actkins[2], Tyne Miller-Flemming[2], Nancy J. Cox[2], Rachel Martini[3], Melissa B. Davis[4], Timothy Chu[5], Nicolas Robine[5], Bret C. Mobley[2], Antentor O. Hinton[1]. *[1]Vanderbilt University, Nashville, TN,[2]Vanderbilt University Medical Center, Nashville, TN,[3]Weill Cornell Medical College, NY, NY,[4]Weill Cornell Medical College, Nashville, TN,[5]New York Genome Center, New York, NY*

Triple-negative breast cancer (TNBC) is an aggressive, highly malignant breast cancer (BC) subtype further characterized by poor prognosis and chemoresistance. TNBC disproportionately affects African American and Latina women, where the differences in treatment efficacy cannot only be explained by social determinants of health. A better understanding of treatment outcomes requires a deep analysis of the ancestral-related underpinnings that affects treatment. Accounting for the role of ancestry in BC prognosis and progression, we hypothesize that ancestry has significant influences on BC etiology. Metabolic reprogramming of TNBC cells is shown to influence response to treatments. These distinct metabolic adaptations require the proper function of the mitochondrion, a highly dynamic organelle that coordinates and maintains the energetic demands of the cell. To this end, we sought to investigate novel proteins important in mitochondria function yet are understudied in BC phenotypes. *SLC25A46* plays a significant role in regulating mitochondrial dynamics, cristae maintenance, and respiratory function. Although SLC25A46 poorly characterized, it has been demonstrated to interact with mitochondrial proteins, such as MFN-2 and OPA1, and the MICOS complex, making it an attractive pharmacological target. We were therefore interested if *SLC25A46* has any potential as a target or biomarker in BC. First, we applied PrediXcan, a gene-based statistical algorithm, to calculate genetically predicted gene expression for *SLC25A46* in 70,349 patients of European descent and 14,462 patients of African descent in BioVU, the

Vanderbilt University Medical Center (VUMC) biorepository linked to de-identified electronic health records (EHRs). Models were built using RNA-seq data from the publicly available GTEX version 8 dataset. After fitting a multivariable logistic regression model to test *SLC25A46* predicted expression against 1,704 phenotypes for each tissue, we observed that patients with high predicted expression were more likely to receive diagnosis of 'abnormal findings in mammograms' (P=2.76E-06, OR=2.26) or 'lump or mass in breast' (P=8.9E-06, OR=2.61) in the European descent group, which is well powered; however, we are not powered to replicate this finding in the African descent group. Therefore, we investigated *SLC25A46* expression in an international RNAseq cohort enriched with women of African ancestry, including African Americans (AA), West and East Africans with TNBC (n=26). Interestingly, *SLC25A46* shows significantly higher expression among self-reported AA than Ghanaian or Ethiopian women with TNBC (P=0.003). Thus, we postulated that these differences in *SLC25A46* for patients of African ancestry might serve as a novel biomarker for cancer outcomes. Together, these data suggest that *SLC25A46* has implications in BC as a novel target in cancer development, specifically in patients with admixed ancestry.

#4842

Stress-induced mitochondrial adaptations in the polyaneuploid cancer cell state

Melvin Li, Laurie G. Kostecka, Sarah R. Amend, Kenneth J. Pienta. *Cancer Ecology Center, The Brady Urological Institute, Johns Hopkins University School of Medicine, Baltimore, MD*

Metastatic cancer is responsible for 90% of cancer deaths and is incurable due to resistance to all systemic anticancer therapies. While the classic model of therapy resistance is described by the presence of pre-existing resistant clones from tumor cell heterogeneity, our lab proposes the polyaneuploid cancer cell (PACC) state as a survival mechanism that cancer cells access when exposed to environmental stress such as hypoxia and chemotherapy. Our preliminary data has shown that cells that enter the PACC state exhibit repeated whole genome doubling, an increase in cell size, and proliferative arrest. In addition, we observed that a subpopulation of PACCs can give rise to non-polyploid, proliferative progeny after release from chemotherapy, modeling cancer recurrence. We hypothesize that the PACC state drives therapeutic resistance and elimination of this adaptive state is key in tackling the incurability of cancer. Mitochondria are essential organelles that have multifaceted roles in the cellular stress response and drug resistance. They integrate metabolic pathways for ATP generation and macromolecule biosynthesis, regulate apoptotic cell death, and activate stress response mechanisms in presence of drug treatment. We found that cells in the PACC state increase mitochondrial biogenesis and live cell imaging with MitoTraker dyes indicate that they also have higher activity per mitochondria when compared to parental cells. Cells that accessed the PACC state also had higher levels of TCA cycle metabolites including citrate, isocitrate, alpha-ketoglutarate, succinate, fumarate, and malate, suggesting increased mitochondrial function. Future work includes analysis of mitochondrial morphology via live cell confocal microscopy and of mitochondrial function via metabolic flux analysis on glucose and glutamine metabolism of cells in the PACC state. Our eventual goal is to characterize how cells in the PACC state alter their mitochondrial structure and function to survive therapy. Identifying vulnerabilities of the PACC phenotype will enable new therapeutic approaches to overcome therapy resistance in cancer.

Characterization of T-cell metabolic defects in chronic lymphocytic leukemia preclinical model

Wael Gamal[1], Melanie Mediavilla-Varela[2], Kamira Maharaj[2], Angimar Uriepero[2], Vishaal Kunta[2], Eva Sahakian[2], Javier Pinilla-Ibarz[2].
[1]Department of Molecular Medicine, Morsani College of Medicine, University of South Florida, Tampa, FL,[2]Department of Immunology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

Chronic lymphocytic leukemia (CLL) is the most predominant leukemia affecting elderly population in western countries. T-cell dysfunction is a CLL hallmark contributing to the low success rates of adoptive cell therapy in patients. Generally, exhausted states of tumor infiltrating lymphocytes are associated with defects in metabolic and mitochondrial adaptation, preventing normal cytotoxic functions. A handful of recent reports have demonstrated metabolic defects in CLL patients' T-cells. Nevertheless, the field is still lacking sufficient studies to validate these metabolic changes in the preclinical Eμ-TCL1 murine model which is the most established model for CLL. Our aim is to uncover T-cell mitochondrial and metabolic defects in the Eμ-TCL1 splenic microenvironment. In this study, CLL was induced in mice via the adoptive transfer of leukemic splenocytes from transgenic Eμ-TCL1 mice into wild type (WT) recipients. Multiparameter flow cytometry was used to investigate mitochondrial properties and cellular glucose uptake of splenic CLL $CD8^+$ T-cells. Moreover, we measured the expression levels of PGC-1α, a master regulator of mitochondrial function, and exhaustion-related markers in $CD8^+$ T-cells. T-cell mitochondrial function was measured using mitochondrial stress test following *in vitro* CD3/CD28 stimulation for 72 hours. Nanostring gene expression analysis was done to compare metabolic gene expression profiles of $CD8^+$ T-cells from either WT or Eμ-TCL1 mice. Probing Eμ-TCL1 splenocytes with mitotracker green and tetramethylrhodamine methyl ester revealed accumulation of depolarized mitochondria in $CD8^+$ T-cells compared to WT counterparts. Our results also showed significant changes in mitochondrial and cellular reactive oxygen species levels as indicated by mitosox and H_2DCFDA staining, respectively. Additionally, marked reduction of

glucose uptake by Eμ-TCL1 $CD8^+$ T-cells was noted following incubation with 2-NBDG glucose analog. Observed mitochondrial abnormalities in the Eμ-TCL1 $CD8^+$ T-cells were associated with a significant downregulation of PGC-1α expression. Flow cytometry analysis demonstrated a significant increase in the expression of exhaustion markers in Eμ-TCL1 $CD8^+$ T-cells and reduction in self-renewal marker, TCF-1. Interestingly, the abnormal mitochondrial properties were directly correlated with PD-1 expression in Eμ-TCL1 T-cells. Nanostring significance score analysis of Eμ-TCL1 versus WT $CD8^+$ T-cell RNA revealed upregulation of glycolysis, mitochondrial respiration, T-cell receptor and costimulatory pathways. On the other hand, there was a downregulation in autophagy, AMPK and amino acid transporter pathways. In conclusion, our work characterizes for the first time the metabolic and mitochondrial defects of $CD8^+$ T-cells from Eμ-TCL1 murine model and outlines the correlation of these defects with T-cell exhaustion in CLL.

Development of an oxygen consumption rate assay for a standard plate reader

Ian Marozas, Zhiyang Zeng, Mike Valley, Jolanta Vidugiriene, James Cali, Wenhui Zhou. *Promega, San Luis Obispo, CA*

Cells generate ATP by two metabolic pathways, oxidative phosphorylation (OXPHOS) and glycolysis. Together, the amount of ATP generated by both OXPHOS and glycolysis define a cell's metabolic phenotype and fitness. Researchers are interested in methods to characterize cellular metabolic fitness, which can be a powerful a selection criterion for cell-based therapies such as CAR-T cell therapy. Researchers are also interested in measuring the effects of drug treatment on metabolic fitness, to identify metabolic targets for cancer therapeutics and to determine mitochondrial toxicity of novel therapeutics. Here, we have developed a low-cost strategy for a standard plate reader to monitor the rate change of oxygen concentration, or the oxygen consumption rate (OCR), which is a measure of OXPHOS activity. In our assay, oxygen quenches a phosphorescent porphyrin dye in a concentration dependent manner, allowing one to calculate the oxygen concentration of the culture system with the Stern-Volmer relationship. The porphyrin dye is embedded within nanobeads that

are suspended above the cell monolayer and the phosphorescence of the beads is measured from the bottom of the well with a standard plate reader. We found that the OCR increased with cell seeding density in three separate cell lines: HEP-G2, HCT-116, and K-562 suspension cells. We showed that inhibitors of the electron transport chain (ETC) decreased OCR, whereas an uncoupler of the electron transport chain, FCCP, increased OCR in a dose dependent manner. Lastly, mitochondrial fitness (e.g., spare respiratory capacity) was determined by sequentially dosing the mitochondria with poisons specific to the different ETC complexes.

#4845

Ultra-deep sequencing of mitochondrial genome to explore the dynamic mutational changes associated with oral cavity squamous cell carcinoma progression

Alka Singh[1], Ashwin Lakshman Koppayi[1], Ping Wu[2], Mark Lingen[3], Vasudha Mishra[1], Alexander Pearson[1], Ari Rosenberg[1], Nishant Agrawal[4], Karthik Suresh[5], Evgeny Izumchenko[1]. *[1]Medicine, Section of Hematology and Oncology, University of Chicago, Chicago, IL,[2]Otorhinolaryngology Head and Neck Surgery, Central South University, Changsha, China,[3]Pathology, University of Chicago, University of Chicago, IL,[4]Surgery, Section of Otolaryngology-Head and Neck Surgery, University of Chicago, Chicago, IL,[5]Pulmonary Critical Care Medicine, Johns Hopkins University, Baltimore, MD*

Oral cavity squamous cell carcinoma (OCSCC) is a devastating disease, causing substantial morbidity and mortality. While many OCSCCs arise from an existing dysplastic lesion, not all oral premalignant lesions progress to OCSCC. Current methods for oral premalignancy and OCSCC diagnosis (visual and tactile exam followed by tissue biopsy and histologic evaluation) cannot discriminate between benign inflammatory changes and high-risk premalignant lesions that require interventions, underscoring the need for molecular-based biomarkers. The multi-step cancer progression from normal epithelium to premalignant lesion and invasive SCC is driven by the accumulation of genetic alterations, including changes in mitochondrial DNA (mtDNA). Due to the lack of protective histones and limited repair mechanisms, mtDNA is susceptible to damage by

environmental carcinogens and reactive oxygen species, a byproduct of the oxidative phosphorylation system. As a result, mutation rate in mtDNA is ~10 times higher than in nuclear DNA, and may greatly facilitate the risk of mitochondrial dysfunction. Previous studies underscore that acquisition of somatic mtDNA mutations directly involved in tumorigenesis, and not merely epiphenomena. However, the impact of these studies is limited by an incomplete understanding of mitochondrial genomic alterations in the transition of preneoplastic lesions to invasive disease. In this study we used a unique cohort of 27 patients with matched longitudinally collected samples (histologically normal mucosa, dysplastic lesion, and SCC) coupled with novel ultra-deep mitochondrial sequencing (mtDNA-Seq) method to assess the mtDNA mutational landscape throughout the continuum of OCSCC progression. Using a custom bioinformatics workflow, somatic mutations were detected in a subset of the premalignant lesions, with overall higher mutational load observed in OCSCC specimens. While sequencing revealed a large degree of inter-patient heterogeneity, a panel of non-synonymous aberrations were present in both premalignant and invasive neoplasms. The majority of shared mutations showed an increase in fractional abundance in tumors, compared to the precursor lesions (suggesting a spatial expansion of these clones as they progressed histologically), and were enriched for coding mutations in complex-I subunits (critical region for ATP production), which is associated with an oncogenic phenotype. Additionally, mtDNA content increased in OCSCC tumor in a subset of patients, suggesting a cell compensation for defective oxidative phosphorylation and lower ATP production per mitochondria. Here we report the first comprehensive characterization of mitochondrial mutational landscape in dysplastic and invasive SCC lesions, and reveal key molecular events associated with the transition from non-invasive to invasive state.

Mitochondria packaged from platelet-derived microvesicles modulate the metabolism and mitochondrial dynamics of breast cancer cells

Vanessa L. Gauvin, Vanessa Veilleux, Nicolas Pichaud, Gilles A. Robichaud, Luc H. Boudreau. *Université de Moncton, Moncton, NB, Canada*

The incidence of breast cancer among women far exceeds those of other cancers where metastasis accounts for the majority of deaths associated with the disease. It is well established that platelets play a prominent role in breast cancer malignancy and disease progression. Recently, activated platelets have been characterized to release platelet-derived microparticles (PMPs), which can also package functional mitochondria of platelet origin (termed mitoMPs). We recently demonstrated that mitoMPs can interact with breast cancer cells where they transfer their cargo (i.e., mitochondria) to recipient cancer cells upon their internalization. Given that metabolic reprogramming through mitochondrial dynamics represents a hallmark trait of cancer progression, the intercellular trafficking of foreign mitochondria provided by mitoMPs represent a new mechanistic avenue for cancer cell metabolic plasticity and disease progression.Therefore, the aim of this study was to evaluate the impact of mitoMP-packaged mitochondria on recipient breast cancer cell mitochondrial dynamics upon internalization. Technically, a series of breast cancer cell models (MB231, MCF7 and MCF10A) were co-cultured with mitoMPs and profiled for mitochondrial dynamics and function using complementing experimental approaches, such as flow cytometry, confocal microscopy, and RT-qPCR. We show that mitoMPs and their mitochondria cargo internalize primarily into the malignant MB231 cell model. To investigate the impact of mitoMP uptake by cancer cells on the mitochondrial dynamics, RT-qPCR and Western blot analyses were performed to profile the expression levels of several fusion and fission proteins, including OPA1, MFF, DRP1, MitoFusin 1 and MitoFusin 2. Finally, using fluorescent-based assays, we confirmed that mitoMPs modulated ATP production in MB231 breast cancer cells through upregulation of the OXPHOS pathway. Our research provides a new mechanism by which extracellular vesicles (mitoMPs) play an important role in cancer cell mitochondrial dynamics and function to support metabolic plasticity during the metastatic journey of cancer cells. The knowledge gained from these studies will further provide new avenues for strategic intervention to mitigate the morbidity and mortality associated with breast cancer disease.

Investigating the transcriptional regulation by estrogen-related receptor alpha (ERRα) under different metabolic conditions

Brittney A. Hua, Chien-yu Chen, Yang Li, Lina He, Bangyan Stiles, Ielyzaveta Slarve. *Pharmacology and Pharmaceutical Sciences, University of Southern California, Los Angeles, CA*

Estrogen-related receptors (ERRs) are orphan nuclear receptors identified based on their high sequence similarity to estrogen receptors (ERs), but ERRs do not have a known endogenous ligand. ERRs play a primary role in regulating the transcription of genes involved in mitochondrial and lipid metabolism and are abundantly expressed across tissues. Because of ERR's role in metabolism, it is suggested that they may also play a role in tumor metabolism, where dysfunction in lipid metabolism promotes tumor cell growth. The ERR subfamily is comprised of three isoforms: ERRα, ERRβ, and ERRγ. Studies targeting the ERR isoforms found that the absence of ERRα presents obesity and insulin resistance with an increase in bone mass, deletion of ERRβ causes placental abnormalities and embryonic lethality, and deletion of ERRγ leads to mitochondrial dysfunction. Together, these studies strongly suggest that ERRs, particularly ERR α and γ, function primarily as metabolic regulators, with ERRα being the predominant isoform expressed in the liver. In addition, the mechanisms leading to lipid accumulation vary under different feeding conditions. Previous studies from our lab showed that PTEN and PI3K/AKT signaling regulates ERRa expression and its function. Furthermore, we demonstrated that inhibiting ERRα blocks liver steatosis and steatohepatitis developed in a mouse model where loss of tumor suppressor PTEN drives both steatosis and cancer development. In addition, we found that ERR-PA, a small molecule inhibitor for ERR, attenuated cancer cell growth and proliferation in both mouse hepatocytes and human cancer cell lines. Here, we report transcriptome network regulated by ERRα under different metabolic conditions and further explored its regulation by the PI3K/AKT pathway. A better understanding of the role ERRα plays in physiology will allow further development of ERR-PA as a potential therapy for liver steatohepatitis, which progresses to end stage cirrhosis and ultimately liver cancer.

#4848

Effects of cinnamon extracted under acidic conditions on proliferation of MCF7 cells

Madison Anderson, Amy Stockert. *Ohio Northern Univ., Ada, OH*

Recent evidence suggests that MCF7 cells utilize free fatty acids as a primary energy source by increasing lipase activity in neighboring adipocytes. Research in our lab suggests that lipase activity is increased by cinnamon extract in differentiated 3T3-L1 adipocytes. We hypothesized that since co-cultures between adipocytes and MCF7 cells demonstrated an increase in lipase activity and increased proliferation, cinnamon extract may increase proliferation of MCF7 cells, making cinnamon an important ingredient to avoid in patients with breast cancer. Cells were plated and treated with varying amounts of cinnamon and monitored for proliferation using the MTT assay. Cells consistently, albeit not significantly, showed an increase in proliferation when treated with cinnamon. Additional studies need to be completed in order to confirm these effects and look for significance, although the importance of this finding warrants rapid reporting. Our lab will examine the effects of cinnamon extract at varying concentrations on MCF7 cell proliferation under variable media conditions as well as monitoring the lipase activity in the MCF7 cells.

#4849

PPARγ and FoxO1 expression and activity in aqueous cinnamon extract treated cells

Sean Mild, Cole Swartz, Amy Aulthouse, Amy Stockert. *Ohio Northern Univ., Ada, OH*

Peroxisome-proliferator activated receptor (PPARγ) has been proven to have inhibitory effects on tumor angiogenesis. Research has demonstrated that natural PPARγ ligands are anti-tumorigenic due to growth inhibition and anti-proliferative effects. Cinnamon is one potential PPARγ ligand tested to explore its effects on PPARγ and FoxO1 expression and activity. Literature also suggests that breast cancer proliferation is increased with obesity and co-cultures of adipocytes with MCF-7 cells have suggested an increase in lipase activity. We therefore sought to explore the effects of cinnamon on these transcription factors and lipase activity in 3T3-L1 cells to determine if cinnamon is a plausible co-therapeutic for breast cancer patients. 3T3-L1 cells were cinnamon treated for 48-96 hours post differentiation. Nuclear protein was extracted for ELISA quantification of

PPARγ and FoxO1 binding potential. Cytosolic and nuclear protein extracts were analyzed via Western blot of FoxO1 and PPARγ. Copy DNA was produced from the total RNA and expression levels of PPARγ and FoxO1 were examined by TaqMan real-time PCR assays. A lipase activity assay was performed on freshly extracted protein from cultured cells. Western blot data demonstrates an increase in FoxO1 protein with cinnamon treatment at 96 hours post differentiation. PPARγ data shows no significant changes in protein quantity, however ELISA data suggests increases in binding potential PPARγ as well as FoxO1 transcription factors with cinnamon treatment. Preliminary expression analysis suggests changes in both PPARγ and FoxO1. Lipase activity data suggests a significant increase in cinnamon treated adipocytes. Data from the study suggests that cinnamon activates PPARγ and that it may play a role in decreasing tumorigenic activity. However, with particular concern in breast cancer cells, the activation of PPARγ in adipocytes appears to increase the lipase activity, thus producing more free fatty acids and potentially enhancing energy dependent proliferation.

#4850

High salt diet induced tumor initiating stem cells mediate breast cancer progression

Lisa Tucker[1], Sonya Reid[2], Jeffrey C. Rathmell[2], Venkataswarup Tiriveedhi[1]. *[1]Tennessee State University, Nashville, TN,[2]Vanderbilt University, Nashville, TN*

High-salt (sodium chloride) diets have been associated with several chronic inflammatory diseases. While the role of chronic inflammation in cancer is well established, the specific role of high salt diet in carcinogenesis is unknown. Previous studies with syngeneic murine breast cancer models, both in our laboratory and others, have shown that high salt (HS) diet induced tumor regression through inflammatory activation of anti-tumor adaptive immune responses. We tested this counter-intuitive and suspiciously beneficial role of HS diet by performing sequential passage studies in preclinical murine models. Six week old mice were placed on high salt diet for 2 weeks prior to injection with syngeneic 4T1 and Py230 triple negative breast cancer cells (into BALB/c and C57Bl/6J mice, respectively, referred to as passage-1). Tumors were harvested after four

weeks of injection. The cancer cells depleted of immune cells were collected from these harvested tumors and reinjected into new non-tumor bearing mice. This cycle was repeated three times. In passage-1 cohort, by day 28, HS diet induced reduced tumor progression in both 4T1-BALB/c (267 ± 59 mm^3) and Py230-C57Bl/6J (238 ± 54 mm^3) as compared to regular salt (RS) diet cohort (611 ± 94 mm^3 and 473 ± 69 mm^3, respectively; $p<0.05$ for both). However, in passage-4 cohort, by day 28, HS diet induced significantly higher tumor progression in both 4T1-BALB/c (806 ± 91 mm^3) and Py230-C57Bl/6J (743 ± 81 mm^3) models, as compared to regular salt (RS) diet cohort (577 ± 83 mm^3 and 462 ± 77 mm^3, respectively; $p<0.05$ for both). Cellular analysis by flow cytometry revealed that there was a 12-19 fold increase in tumor initiating stems cells (TISCs) in passage-4 HS diet cohort compared to RS diet cohort. Mechanistic studies have demonstrated that there was increased TGFβ expression on TISCs obtained from passage-4 HS diet cohort which correlated with enhanced exhaustion phenotype ($CTLA4^+$) of tumor infiltrating adaptive immune cells (CD4 and CD8 T cells) in this cohort. Co-treatment with anti-TGFβ and anti-CTLA4 monoclonal antibodies (mAb) in passage-4 HS diet cohort, significantly reduced tumor progression ($p<0.05$), as compared to treatment with either mAb alone. Taken together, these data demonstrated that chronic HS diet leads to expansion of TGFβ expressing TISCs leading to host immune exhaustion and tumorigenesis. Importantly, anti-TGFβ mAb exerted a favorable synergistic effect to enhance the anti-tumor efficacy of immune check-point inhibitors.

Improving the efficacy of dual ERK-MAPK and autophagy inhibition as a therapeutic strategy for pancreatic ductal adenocarcinoma

Jonathan M. DeLiberty, Clint A. Stalnecker, Kristina Drizyte-Miller, Elyse G. Schechter, Noah L. Pieper, Runying Yang, Channing J. Der, Adrienne D. Cox, Kirsten L. Bryant. *University of North Carolina at Chapel Hill, Chapel Hill, NC*

Pancreatic ductal adenocarcinoma (PDAC) is characterized by KRAS- and autophagy-dependent growth. We and others recently demonstrated that inhibition of the RAF-MEK-ERK pathway resulted in upregulated autophagy, and that dual treatment with the autophagy inhibitor

hydroxychloroquine (HCQ)/chloroquine (CQ) and MEK or ERK inhibitors (MEKi, ERKi) synergistically blocked PDAC growth. These findings provided rationale for our initiation of Phase I/II clinical trials evaluating the combination of MEKi (binimetinib; NCT04132505) or ERKi (LY3214996; NCT04386057) with HCQ in PDAC. However, HCQ/CQ are not specific or potent autophagy inhibitors. Thus, we sought to identify a more efficacious autophagy inhibition strategy. To this end, we performed a CRISPR-Cas9 mediated genetic loss-of-function screen with a library encompassing cancer signaling pathways in the presence or absence of CQ. In the absence of CQ, we identified PIKfyve, a lipid kinase critical for the recycling dynamics of lysosomes, as an essential autophagy-related gene in PDAC cells. PIKfyve inhibition, by the clinical candidate inhibitor apilimod, resulted in potent reduction of autophagic flux and growth. Additionally, PIKfyve inhibition resulted in robust intracellular vacuolization. Vacuoles stained positive for the lysosomal marker, LAMP1, and exhibited reduced acidity and impaired cargo degradation. Importantly, when we inhibited MEK, with the clinical stage MEKi mirdametinib, and PIKfyve (with apilimod) together, we observed decreased MEKi-induced autophagic flux and synergistic impairment of PDAC cell proliferation. Growth inhibition was due in part to an induction of apoptosis unique to combination treatment. Synergistic growth suppression was maintained in a panel of patient derived PDAC organoids, suggesting this may be an efficacious therapeutic strategy for PDAC treatment. In the presence of CQ, our CRISPR-Cas9 screen showed that loss of upstream autophagy-related genes sensitized PDAC cells to CQ treatment. Validation indicated that vertical inhibition (dual inhibition of distinct nodes of a linear pathway) of the autophagy pathway further reduced autophagic flux relative to inhibition of any single node and synergistically reduced PDAC cell growth. Furthermore, combining ERK-MAPK inhibition with vertical inhibition of autophagy improves the *in vitro* efficacy of this treatment strategy. Ongoing studies are aimed at delineating the mechanism underlying the synergy observed with anti-autophagy inhibitor combinations and further validation in more advanced preclinical models of PDAC.

Metabolomic rewiring in endocrine therapy resistant estrogen receptor positive breast cancer

Songyeon Ahn[1], Junhyoung Park[1], Sandra L. Grimm[1], Badrajee WB Piyarathna[1], Nagireddy Putluri[1], Gokul Das[2], Cristian Coarfa[1], Benny A. Kaipparettu[1]. *[1]Baylor College of Medicine, Houston, TX,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Breast cancer (BC) is one of the most commonly diagnosed cancers worldwide and the most common in women in the United States. The majority of the BC are estrogen receptor alpha positive (ER+) and are likely to respond to endocrine therapy. Tamoxifen and fulvestrant are the most widely used hormonal treatments for ER+ BC. However, nearly half of patients receiving endocrine therapy suffer from the risk of recurrence due to either intrinsic or acquired resistance. Thus, it is vital to understand the mechanisms of resistance to endocrine therapy in ER+ BC. Metabolic reprogramming is one of the significant hallmarks of cancer and it is now known that many tumors utilize mitochondrial oxidative phosphorylation (OXPHOS) for their energy needs. Our lab previously reported that metastatic triple-negative breast cancer (TNBC), which does not express ER, has a high energy dependency on mitochondrial fatty acid beta-oxidation (FAO). In this project, we developed a gene signature by integrating the transcriptomic, metabolomic, and lipidomic data from FAO rate-limiting gene (CPT1) modulated TNBC cells. Our signature represented the FAO-regulated gene set relevant to metabolic or lipidomic changes. We discovered a significant reliance on this TNBC signature in endocrine-resistant ER+ BC. Clinical data suggests that our gene signature predicts the survival of endocrine-treated ER+ BC patients. Though increased fatty acid consumption is reported in tamoxifen-resistant cells, the role of FAO in endocrine treatment resistance is largely unclear. We then analyzed the metabolic reprogramming in ER+ BC cell lines after tamoxifen or fulvestrant therapy. Molecular, genetic, and metabolic analyses suggested that endocrine therapy-induce AMPK-FAO-OXPHOS signal activation in ER+ BC cells. Furthermore, the knockdown of CPT1, the rate-limiting enzyme of FAO, or treatment with FAO inhibitors significantly enhanced the response to endocrine therapies. We have also reported that FAO induces the autophosphorylation of the c-Src proto-oncogene in TNBC tumors. Thus, we analyzed this phenomenon in the

endocrine-resistant ER+ BC cells. As expected, endocrine therapy-induced FAO activated the Src pathway in ER+ BC also. Moreover, in vitro, and in vivo studies confirmed that endocrine-resistant ER+ BC cells have increased sensitivity to FAO, OXPHOS, and Src inhibitors. Finally, analysis of clinical data suggests that low expression of FAO rate-limiting genes in the ER+ primary tumors have better recurrence-free and distant metastasis-free survival after endocrine therapy. Overall, our findings suggest that the gene signature generated from FAO-modulated TNBC cells predicts response to endocrine therapy in ER+ BC. Moreover, metabolic reprogramming in endocrine-resistant ER+ tumors induce FAO, OXPHOS, and Src pathways, providing potential targets to overcome endocrine-resistance ER+ BC patients.

Evaluating the role of melatonin in thyroid cancer cell (MDA-T41) apoptosis and metabolism modulation

Angela Huang, Daniel Sanches. *Natural Sciences, South Florida State College, Sebring, FL*

Melatonin, a hormone produced by the pineal gland, is typically known for its modulation of a number of physiological functions, alongside its ability to synchronize the sleep-wake rhythms. In recent years, however, its interactions with cancerous cells and role in prevention and treatment have been increasingly studied. It has been demonstrated that melatonin can improve the efficacy of chemotherapeutic drugs and directly inhibit tumorigenesis in experimental models of neoplasia. In addition, while melatonin typically displays anti-apoptotic effects in normal cells, it holds pro-apoptotic effects in cancer cells. Despite this, the mechanisms by which melatonin affects cell death and metabolism remain unclear due to the seeming difference from cell to cell. We aim to better understand the role of melatonin in regulating thyroid cancer cell apoptosis and metabolism. The MDA-T41 thyroid cancer cell line was cultured with varying quantities of melatonin. Steady volumes of staurosporine (an inductor of apoptotic cell death) were applied to cultures, and cell death levels were subsequently measured using the Realtime-Glo Annexin V Apoptosis and Necrosis assay. Our results showed that melatonin provided anti-apoptotic effects to MDA-T41 cells treated with staurosporine. Both apoptosis and necrosis were

reduced by 50% in melatonin-treated cells 24 hours after staurosporine-induced cell death. Our next steps will be to evaluate the mechanisms and further signaling pathways involved in this apoptosis inhibition through Bcl-2 and p53 protein expression.

PKM2 Modulates hepatic macrophage regulation of NASH, ferroptosis and HCC through TGF-β signaling

Kazufumi Ohshiro[1], Krishanu Bhowmick[1], Xiaochun Yang[1], Addison Klebanov[1], Sahara John[1], Dillon Voss[2], Adrian Krainer[2], Lopa Mishra[1].
[1]The Institute for Bioelectronic Medicine, Dept of Medicine, Div. of Gastroenterology and Hepatology, The Feinstein Institutes for Medical Research, & Cold Spring Harbor Laboratory, Northwell Health, Manhasset, NY,[2]Cancer Center, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Background**:** Non-alcoholic steatohepatitis (NASH) and cirrhosis are major risk factors for hepatocellular carcinoma (HCC), which affects men 2-4 times more than women. In tumors Pyruvate kinase M2 (PKM2), induces aerobic glycolysis (Warburg effect) and proinflammatory and non-apoptotic cell death, ferroptosis. Raised levels of hepatic macrophage PKM2 expression are associated with poor prognosis HCC. We previously found that liver specific TGF-β/SMAD4 knockout mice develop iron deposition and hemochromatosis due to a dramatic loss of hepcidin. Moreover, *Smad4*$^{+/-}$*Sptbn1*$^{+/-}$ mice develop gastrointestinal cancers but only in the presence of an altered microbiome. Recently, we found that liver-specific knockout of a TGF-β/SMAD3/4 adaptor protein, βII-spectrin (LSKO) blocks diet-induced NASH and HCC in mice, as well as in siRNA treated human NASH microfluidic cultures (*Sci Transl Med.* 2021;13(624): eabk2267). We hypothesized that βII-spectrin modulates PKM2 expression in NASH fatty liver, promoting proinflammatory cytokine release, inflammation and tumorigenesis. In addition, microbiome changes could alter hepcidin function and modulate ferroptosis. Our goal is to understand the molecular mechanism underlying PKM2 driven NASH and HCC.
Methods: For our NASH mouse model, we fed SPTBN1^{Flox} (control) and liver-specific βII-spectrin knockout (SPTBN1^{LSKO}) mice a Western diet

(WD). Body weight, total cholesterol, and triglyceride concentrations in serum were monitored, and PKM2 expression levels in the liver tissues was analyzed. SPTBN1^{Flox} and SPTBN1^{LSKO} mice were treated with both WD and Diethylnitrosamine (DEN) for HCC, and gut microbiome profiles were performed in these mice. To evaluate PKM2 expression in the NASH-associated HCC mouse model, immunohistochemical labeling was performed on liver tissues of these mice with PKM2-specific antibody. Inflammation, lipidosis and fibrosis were determined with H&E, Oil Red O and Sirius Red staining.
Results: We found upregulation of PKM2 expression in NASH and HCC Kupffer cells (WD SPTBN1^{Flox} mice). In contrast, PKM2 expression was markedly reduced in the liver in WD SPTBN1^{LSKO} that blocked NASH and HCC. Interestingly, microbiome profiles were altered and TGF-β/SMAD3-regulated fibrosis as well as expression of inflammatory genes were significantly reduced in LSKO mice, compared to the NASH mice.
Conclusions: Our findings suggest that the knockdown of the Smad3/4 adaptor βII-spectrin decreases PKM2 expression in Kupffer cells, thereby suppressing pro-inflammatory cytokine production, blocking NASH-associated HCC. Hepatic macrophages such as Kupffer cells and monocyte-derived macrophages could therefore play a critical role in the ferroptosis-mediated protumor immune microenvironment. In addition, our work provides new insight into potential mechanism for two disorders that affect males more than females, hemochromatosis and HCC.

CCNE1 amplification in high-grade serous ovarian cancer: analysis of the GENIE database

Ashaar Al-Akhras, Shaden Tashtoush, Alina Ghazou. *Faculty of Medicine, Jordan University of Science and Technology, Irbid, Jordan*

Background: High-grade serous ovarian cancer (HGSOC) is the most common histological subtype of ovarian cancer as well as the most lethal. A primary oncogenic driver in a subset of HGSOC patients, CCNE1

amplification is associated with poorer outcomes and resistance to standard treatment. This study aims to investigate the copy number gain of CCNE1 and the genetic mutations associated with CCNE1 amplification using a large cohort of clinico-genomic data. Methods: We queried the American Association of Cancer Research-Genomics Evidence Neoplasia Information Exchange (GENIE) registry database v12.1 for patients with HGSOC. We studied CCNE1 amplification and the clinical, demographic, and genetic mutation associations. Results: A total of 3297 HGSOC samples were extracted from the registry. The mean age of patients at sequencing was 62 ± 10 years. Out of 2416 samples profiled for copy number alterations, CCNE1 amplification was found in 13.6%, being the most commonly amplified gene, followed by AGO2 (11.7%) and MYC (9.7%). Co-amplification between CCNE1 and AKT2 was demonstrated. Between the 397 samples with CCNE1 amplification and 2088 without, the genes that were more frequently mutated in the CCNE1 amplified group were AKT2 (20.4% vs 3.2%, $p<0.001$), KRAS (11.3% vs 4.3%, $p<0.001$), BRD4 (8.0% vs 4.4%, $p = 0.006$), and ERBB2 (7.9% vs 4.0%, $p = 0.003$). Other genes were less frequently mutated in the CCNE1 amplified cohort such as NF1 (7.6 % vs 12.9%, $p = 0.009$), BRCA1 (3.7% vs 10.0%, $p<0.001$), BRCA2 (2.7% vs 7.4%, $p = 0.003$), RB1 (2.7% vs 6.4%, $p = 0.013$), and PTEN (1.2% vs 4.0%, $p = 0.02$). Frequencies of MYC, PIK3CA, KMT2D, CDK12, and TSC2 mutations were similar between the two groups. TP53 was mutated in 100% of samples. There were no significant differences between the two groups in primary race or total mutation count, and mean age at sequencing was similar. Conclusion: Somatic sequencing is warranted to identify patients of this subset of HGSOC, and understanding the co-amplifications and co-mutations is essential so that they are targeted for optimal survival outcomes.

Pan-cancer analysis of *XPO1* R749Q mutations across 217,570 patients reveals association with high tumor mutational burden and therapy resistance

Tulasigeri M. Totiger[1], Yasmine Baca[2], Wannasiri Chiraphapphaiboon[3], Sana Chaudhry[1], Skye Montoya[1], Monika Chojnacka[1], Gabriel Gaidosh[1], Jumana Afaghani[1], Maurizio Affer[1], Christopher D. Armstrong[1], Ryan Notti[4], Jenna Zabroski[1], Jacob Jahn[1], Vindhya Nawaratne[1], Ramiro

Verdun[1], Hai Dang Nguyen[3], Chadi Nabhan[5], Thomas J. Herzog[6], Phil Walker[2], Andrew Elliott[2], Emil Lou[7], Wafik S. El-Deiry[8], Edith Mitchell[9], Jose Antonio Rodriguez[10], Justin Taylor[11]. *[1]Medicine/Hematology, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL,[2]Caris Life Sciences, Phoenix, AZ,[3]Department of Pharmacology, Masonic Cancer Center, University of Minnesota, Minneapolis, MN,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]Medicine/Hematology, Caris Life Sciences, Phoenix, AZ,[6]University of Cincinnati, Cincinnati, OH,[7]Hematology, Oncology and Transplantation, University of Minnesota, Minneapolis, MN,[8]Brown University, Providence, RI,[9]Medical Oncology, Thomas Jefferson University, Sidney Kimmel Cancer Center, Philadelphia, PA,[10]Genetics, Physical Anthropology and Animal Physiology, University of the Basque Country(UPV/EHU), Barrio Sarriena s/n, Leioa, Spain,[11]Translational and Clinical Oncology Program, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL*

Background: XPO1 is a nuclear export receptor responsible for exporting >200 proteins out of the nucleus, including many cancer-related proteins. We previously reported recurrent hotspot mutations occurring in XPO1 in cancer and identified *XPO1* R749Q variant only in solid tumors. To determine the prevalence of XPO1 mutations across cancer types, we performed a large-scale genomic analysis of 217,570 patients with cancer to identify and characterize *XPO1* variants from real-world patient tumors.
Methods: Solid tumor samples representing 14 cancer types were submitted to Caris Life Sciences (Phoenix, AZ) for Next-generation sequencing of DNA (592 genes or WES). TMB-High (defined as $\geq$10 mt/MB) and dMMR/MSI-H was tested by IHC/NGS. We engineered CRISPR knock-in HCT116 and LS-174T colon cancer isogenic cell lines bearing XPO1 R749Q mutations and Stochastic Optical Reconstruction Microscopy (STORM) analysis was performed. Structural modeling was performed with published XPO1 structures by mapping XPO1 mutations from the MSKCC-IMPACT dataset.
Results: A total of 96 patients with *XPO1* R749Q mutations were identified (50% occurred in endometrial cancer and 23% occurred in colorectal cancer). TMB-H was observed in 92% of *XPO1* R749Q mt tumors (9% were dMMR/MSI-H), while 86% of *XPO1* R749Q mt tumors were *POLE*-

mutated within the endonuclease domain. Median variant allele frequency for *XPO1* R749Q mt and *POLE* mt were 25% and 29%, respectively. STORM imaging revealed that *XPO1* R749Q mutant cells had significant localization of *XPO1* in the cytoplasm compared to *XPO1* WT cells, especially at the outside edge of the nuclear pores. Structural modeling predicted that *XPO1* R749Q mt affected the regulatory H9-loop of XPO1 favoring increased shuttling and retention in the cytoplasm. Mass spectrometry analysis of nuclear and cytoplasmic fractionated proteomes confirmed that *XPO1* R749Q mt cells had increased export of proteins compared to *XPO1* WT cells. A library screen of >200 FDA-approved drugs revealed a strong therapeutic resistance of *XPO1* R749Q cells, especially to chemotherapies used in the treatment of colon cancer. XPO1 inhibition with selinexor synergized with chemotherapy in *XPO1* R749Q mt cells *in vitro* and overcame resistance to irinotecan *in vivo* in xenograft mice models.
Conclusion: This study sheds novel insights into the role of nuclear export in cancers. Specifically, *XPO1* R749Q mutations are enriched in TMB-H endometrial and colon cancers and increase nuclear export of key proteins that confer resistance to therapies using DNA-damaging agents. Our current work aims to identify novel therapies that can overcome resistance to DNA-damaging therapies seen in *XPO1* mutant cells, such as immune checkpoint inhibitor (ICI) therapy given the co-occurrence with *POLE* mutations and recent reports of high level of response to ICI therapy in TMB-H and *POLE* mt colorectal cancers.

#4254

The ratio of key metabolic transcripts is a predictive biomarker of breast cancer metastasis to the lung

Deepti Mathur[1], Chen Liao[1], Wendy Lin[1], Alessandro La Ferlita[2], Salvatore Alaimo[2], Alfredo Ferro[2], Yi Zhong[3], Christine Iacobuzio-Donahue[1], Joao Xavier[1]. *[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]University of Catania, Catania, Italy,[3]Hackensack Meridian Health Center for Discovery and Innovation, Hackensack, NJ*

Understanding the rewired metabolism of organ-specific metastasis in breast cancer is an under-appreciated problem, with implications for the treatment and prevention of metastatic disease. Here, we used a systems

biology approach and the MDA-MB 231 model to compare metabolic fluxes used by parental breast cancer cells and their brain- and lung-homing derivatives. We combined metabolomic profiling, flux measurements, spatial tissue mimetic systems, and mathematical modeling to dissect the cells' metabolic rewiring, and identified changes specific for lung metastatic selection. We validated our results in other cell lines as well as patient data from project GENIE and the MBCP. Our results produced five biological insights: First, levels of mRNA and metabolic intermediates may *anticorrelate* with flux. Second, different lineages evolved from the same line can have distinct heritable metabolic fluxes. Metastatic lineages in our model display higher glycolytic flux and bioenergetics than parental cells, with lung-homing cells exhibiting by far the greatest glucose uptake and lactate production. Importantly, this occurs despite low levels of glycolytic intermediates in lung-homing cells. Third, this apparent paradox can be reconciled if feedback inhibition of the glycolysis pathway is prevented, a finding we modeled with flux-balance analysis and confirmed by ^{13}C glucose tracing and measuring glycolytic enzymatic activities directly. Fourth, this distinct metabolic behavior in lung-homing cells is maintained by a high ratio of lactate dehydrogenase (LDH) to pyruvate dehydrogenase (PDH) gene expression, which also correlates with lung metastases in patients with breast cancer. Feature classification models trained on clinical characteristics alone were unable to predict tropism; however, the LDH/PDH ratio was a significant predictor for lung but not brain metastases, independent of other transcriptomic signatures, suggesting that this feature is a potential biomarker for lung metastasis. Fifth, this metabolic effect did not increase cellular growth rate, suggesting that lactate secretion may itself be a trait under selection in breast cancer lung metastasis. Follow up experiments and game theory-based models in a spatially structured tissue-mimetic system showed that lung-homing cells grow more favorably than brain-homing cells in nutrient-deprived gradients, demonstrating how divergent metabolisms of the lineages could lead to selection in different environments. Notably, lung metastases in a mouse model of pancreatic cancer had higher lactate production than other metastases, suggesting that this metabolic trait could be important for other cancer types. Together, our *in vitro*, *in silico*, and clinical data analyses highlight that metabolism—currency of all physiological processes—plays

an essential role in the connection from gene to phenotype in metastatic disease.

Concurrent KRAS and TP53 mutations in pancreatic cancer real-world data (RWD) highlight convergent tumor evolutionary patterns

Kaumudi Bhawe, Adrienne Nugent, Deb Christensen, Lauren Levine, Emma Shtivelman. *Cancer Commons, Mountain View, CA*

Pancreatic cancer is one of the most fatal of all cancers. Pancreatic adenocarcinomas have been historically difficult to treat, in part due to lack of early detection, and due to their resistance to conventional chemotherapy. There has recently been an improved understanding of the biologic processes driving pancreatic tumorigenesis, and an increase in clinical trial options available to patients, especially in the context of KRAS mutation positive pancreatic ductal adenocarcinoma (PDAC). KRAS is a known driver of pancreatic cancer initiation, with concurrent loss of TP53 in many cases. Among all mutated genes in pancreatic cancer, KRAS, TP53, CDKN2A, and SMAD4 are most frequently reported, followed by CDKN2B and ARID1A among others. Mutations in TP53 commonly found in pancreatic cancer are either missense or truncating. The specific type of mutation may be important to note since point mutations may produce dysfunctional proteins that acquire gain of functions that are tumor-promoting, although the most well-agreed upon effects of TP53 mutations stem from the absence or decrease of its normal physiologic functions including cell cycle arrest, apoptosis promotion, DNA damage response triggering, maintenance of cell polarity, and maintenance of genomic stability. Here we present an in-depth multi-dimensional analysis of 29 pancreatic adenocarcinoma patients, consisting of 11 patients with KRAS G12D mutations, 5 patients with KRAS G12V mutations, 3 patients with non-canonical KRAS mutations, and 10 patients with no KRAS mutations identified in their tumors. Individual TP53 mutations were highlighted in the context of associated KRAS mutations and tumor genomic landscape at the time of testing. Real-world data was collected with patient consent through community embedded Oncology Clinical Team (ceOCT) facilitated engagement. Tumor evolution prediction rules were constructed based on mutational landscapes of the 29 patients and evidence published in peer-

reviewed journals. Pancreatic cancer patient data from the AACR GENIE Cohort v12.0-public database and the cBioportal for Cancer Genomics public site was subsequently used for testing predicted tumor evolutionary trajectories. Here we describe multiple independent combinations of KRAS and TP53 mutations leading to convergent functional outcomes for tumor cells, in the context of patient-specific gene mutation landscapes. Recurrent patterns of paired mutations with common cellular function dysregulation outcomes highlight core underlying mechanisms of pancreatic tumor evolution.

cBioPortal for Cancer Genomics is an open-source platform for interactive, exploratory analysis of large-scale clinico-genomic data sets. cBioPortal provides a suite of user-friendly visualizations and analyses, including OncoPrints, mutation “lollipop” plots, variant interpretation, group comparison, survival analysis, expression correlation analysis, alteration enrichment analysis, cohort and patient-level visualization.

The public site (https://www.cbioportal.org) is accessed by >35,000 unique visitors each month and hosts data from >350 studies spanning individual labs and large consortia. In addition, at least 74 instances of cBioPortal are installed at academic institutions and companies worldwide. To better support all users, we unified our documentation (https://docs.cbioportal.org) and added a user guide and an ongoing series of 'how-to' videos to address common questions.

In 2022 we added 32 studies (>38,000 samples) to the public site. In addition, we added a nonsynonymous tumor mutation burden (TMB) value for all samples and enhanced the TCGA PanCancer Atlas studies with DNA methylation and treatment data. All data is available in the cBioPortal Datahub: https://github.com/cBioPortal/datahub.

We also host a dedicated instance for AACR Project GENIE, enabling access to the GENIE cohort of >165,000 clinically sequenced samples from 19 institutions (https://genie.cbioportal.org). The GENIE Biopharma Collaborative (BPC) enables the collection of comprehensive clinical annotations, including response, outcome, and treatment history. The first BPC cohorts are now available: ~2,000 non-small cell lung cancer samples and ~1,500 colorectal cancer samples.

Support for multimodal data analysis has been a major focus, including several new integrations with external tools. Single cell data is now available in the CPTAC GBM study and can be visualized throughout cBioPortal, and via integration with cellxgene. On the patient page, H&E and mIF images can be visualized via integration with Minerva, and the genomic overview now integrates IGV.

We continue to enhance existing features. In the study view, users can now add charts comparing categorical vs continuous data, and the plots tab includes a heatmap option. We replaced the existing fusion data type with a generalized structural variant data type that supports detailed information including breakpoints and orientation, to enable new visualizations and analyses. Pathway level analysis has been extended with a new integration with NDEx.

cBioPortal is fully open source (https://github.com/cBioPortal/). Development is a collaborative effort among groups at Memorial Sloan Kettering Cancer Center, Dana-Farber Cancer Institute, Children's Hospital of Philadelphia, Princess Margaret Cancer Centre, Caris Life Sciences,

Bilkent University and The Hyve. We welcome open source contributions from others in the cancer research community.

Using Multilevel Regression and Poststratification (MRP) to inform estimates of biomarker prevalence for target populations of interest using linked clinico-genomic databases

Jeremy W. Snider[1], Brennan Beal[1], Lilia Bouzit[1], Cheryl Cho-Phan[1], Leah Comment[2], Garrett Frampton[2], Tamara Snow[1]. *[1]Flatiron Health, New York, NY,[2]Foundation Medicine, Boston, MA*

Background

Contemporary evidence on the size of biomarker-defined cancer populations is crucial for clinical and economic healthcare decision makers. Estimates can be derived from real-world data (RWD), but may be affected by biases stemming from differences in observed populations vs. general populations of patients under the purview of decision makers. These differences may be driven by patient or clinical characteristics, as well as differences in assays used to assess biomarker status. This study demonstrates the applicability of an emerging method in survey science (Multilevel Regression and Poststratification (MRP)), which leverages common covariates across source data and larger, more representative set of observations to inform estimates of biomarker prevalence for target populations of interest.

Methods

In disease-agnostic cohorts of patients with solid-tumor cancers from two, large clinico-genomic cancer databases (AACR GENIE 12.0, and nationwide (US-based) de-identified Flatiron Health - Foundation Medicine Clinico-Genomic Database(CGDB)), we used covariate-adjusted regression (age, sex, race, stage at diagnosis (for CGDB patients), and cancer type) to predict the probability of a patient having an NTRK fusion and/or a BRAF V600E mutation detected in their sequenced cancer tissue. AACR Project GENIE (n = 118,649) is a cancer registry of real-world data assembled through data sharing between 19 international cancer centers. The de-identified data in the CGDB (n = 91,719) originated from approximately 280 US cancer clinics (~800 sites of care).We then implemented post-stratification adjustments (Gelman, 2006; Downes 2018) using the

Surveillance, Epidemiology, and End Results (SEER) 17 2022 cancer registry to estimate prevalence of the alterations in the large, population-based registry.
Results
Prevalence estimates were generally consistent between sources. Adjusted prevalence (%) estimates for NTRK Fusion (AACR: 0.25% (raw), adjusted to 0.21% (0.01%-0.48%) (MRP-adjusted mean % (95% quantile intervals)); CGDB: 0.29, adjusted to 0.26 (0.02-0.63), and for BRAF V600E (AACR: 2.19, adjusted to 1.72 (0.77-2.66); CGDB: 2.44, adjusted to 2.68 (1.50-3.89)) reflected differential patient characteristics (predominantly tumor type) in these sources compared to SEER. MRP also enabled creation, from posterior distributions, of tumor-level estimates, along with credible interval bounds.
Conclusion
While both clinico-genomic databases offered generally consistent estimates of biomarker prevalence, representativeness methods that are used in the survey literature may be suited for addressing biases in RWD sources to improve biomarker prevalence estimates of target populations of patients with cancer.

Racial and ethnic differences in the mutational landscape of low-grade serous ovarian cancer
Muhammad Danyal Ahsan, Emily M. Webster, Sarah R. Levi, Natalie T. Nguyen, Juan R. Cubillos-Ruiz, Evelyn Cantillo, Eloise Chapman-Davis, Melissa K. Frey, Kevin Holcomb. *Gynecologic Oncology, Weill Cornell Medicine, New York, NY*

Objective To characterize the mutational landscape of low grade serous ovarian cancer (LGSOC) with racial/ethnic stratification.
Methods The AACR Project GENIE database version 12.0 was queried via cBioPortal (http://genie.cbioportal.org) for low-grade serous ovarian cancer (LGSOC) samples. This is a publicly available, de-identified, multi-institutional database of next-generation sequencing genomic profiling results for tumor samples. Mutation frequencies for 9 homologous recombination deficiency (HRD) genes, 4 MAP-Kinase (MAP-K) pathway genes and 6 mismatch-repair (MMR) deficiency genes were reported and

compared between racial/ethnic groups using chi-squared or Fischer's exact tests. The threshold used for statistical significance was a two-sided alpha of 0.05.

Results Among 317 tumor samples of LGSOC, there were high rates of MAP-K pathway gene mutations but low rates of HRD, MMR and TP53 gene mutations (Table 1). Non-Hispanic Black patients had significantly higher rates of KRAS mutations compared to non-Hispanic White patients (6/7, 86% vs 48/178, 27%, $p<0.01$). There was no difference in KRAS mutation frequency among Asian (6/17, 35%), Hispanic (7/24, 29%) and Native American (2/2, 100%) patients when compared to non-Hispanic White patients. BRAF mutations were less common compared to KRAS mutations (32/317, 10%), with no racial/ethnic differences in mutation frequency.

Conclusion High rates of MAP-K pathway mutations in LGSOC support development and trials of drugs targeting this pathway, such as MEK protein inhibitors. Furthermore, prior literature has demonstrated the prognostic advantage of KRAS and BRAF mutations in LGSOC as well as the association of KRAS mutations with progression of serous borderline tumors to LGSOC. These racial/ethnic differences in frequencies of these mutations are thus hypothesis generating for clinical research to evaluate the impact of race/ethnicity on the development and prognosis of this rare ovarian cancer.

Mutation frequencies of HR, MAP-kinase, MMR and TP53 genes in low-grade serous ovarian cancer

Gene	No. of samples with ≥1 mutation	No. of samples profiled for mutation	Mutation frequency
BRCA1	3	287	1.05
BRCA2	7	287	2.44
BRIP1	5	271	1.85
CHEK2	2	278	0.72
BARD1	2	239	0.84
RAD51B	-	-	-
RAD51C	-	-	-
RAD51D	2	246	0.81
PALB2	2	279	0.72

KRAS	93	317	29.34
NRAS	29	317	9.15
BRAF	32	317	10.09
EIF1AX	14	144	9.72
MSH2	3	275	1.09
MSH3	1	113	0.88
MSH6	6	286	2.10
MLH1	1	317	0.32
MLH3	3	96	3.13
PMS2	1	270	0.37
TP53	12	317	3.79

Identification of anti-neoplastic therapy given before initial visit at a referral center using natural language processing applied to medical oncology initial consultation notes

Thinh N. Tran[1], Karl B. Pichotta[2], Si-Yang Liu[3], Christopher Fong[3], Anisha Luthra[3], Brooke Mastrogiacomo[3], Steven Maron[3], Deborah Schrag[3], Sohrab P. Shah[3], Pedram Razavi[3], Bob T. Li[1], Gregory J. Riely[3], Nikolaus Schultz[3], Justin Jee[3]. *[1]Gerstner Sloan Kettering Graduate School, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Sloan Kettering Institute, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Memorial Sloan Kettering Cancer Center, New York, NY*

Anticancer therapy changes tumor physiology and genomics, making it a key variable in cancer studies. Although antineoplastics given at a single institution may be available in research-ready format, treatment at external institutions prior to receiving care at academic medical centers, common among patients at these centers, is often only described in free-text clinical notes, necessitating manual curation for downstream analysis. To overcome this bottleneck, we trained and validated natural language processing (NLP) models using initial consult notes to identify whether patients had received treatment at external institutions and studied the impact of these putative treatments on tumor genomics.

Training data were derived from the AACR Project GENIE Biopharma Collaborative (BPC) for 2,663 patients at Memorial Sloan Kettering (MSK) across four cancer types. For each patient, we selected initial visits with medical and radiation oncologists based on an a priori note prioritization scheme and determined "ground-truth" prior external medications based on manually curated BPC administration records, whitelisting MSK-given medications. We trained logistic regression and clinical longformer models to identify external treatment receipt and evaluated model performance with 5-fold cross-validation. The clinical longformer model performed best across evaluation metrics, with an average area under the receiver operating characteristic curve of 0.972, macro-averaged precision/recall of 0.854/0.902 and macro-averaged F1 score of 0.876. Re-review of discrepant cases suggested that 75% of "false positives" may be due to curation error. We used our model to infer treatment status in a pan-cancer cohort with tumor genomic profiling using our institutional sequencing platform. Out of 48,447 patients, 11,900 were predicted to have received external treatment. Patients with putative external treatment had higher alteration frequencies in resistance-related genes than untreated patients and comparable to known pre-treated patients, including ESR1 in patients with breast cancer, AR in patients with prostate cancer, and EGFR T790M in patients with EGFR-mutated non-small cell lung cancer. Patients with putative external treatments, similar to known pre-treated patients, had shorter survival compared to treatment-naïve patients of the same cancer type.
NLP can abstract external treatment status from clinical notes. When applied at scale, our model could help mitigate confounding variables and identify relationships between clinicogenomic variables and anticancer therapy.

Berger[5], Gregory J. Riely[2], Nikolaus Schultz[1], Sanna Goyert[7], Adam Schoenfeld[2], Francesca Gany[3], Jian Carrot-Zhang[1]. *[1]Computational*

Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Immigrant Health and Cancer Disparities Service, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Gerstner Sloan Kettering Graduate School of Biomedical Sciences, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Human Oncology & Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Memorial Sloan Kettering Cancer Center, New York, NY,[7]CUNY School of Medicine, City University of New York, New York, NY

Compared with previous standards of care, the use of immune checkpoint inhibitors (ICI) has brought significant improvements in survival and quality of life for lung cancer patients. However, only a small proportion of these patients respond durably. People with different ancestries differ probabilistically in genetic factors, environmental exposures, and socio-economic conditions. Whether patients of different ancestry benefit equally from ICIs remains unclear.

We studied the impact of genomic ancestry, tumor genomics, and social determinants of health (SDH) factors and factors that are impacted from SDH including recorded race/ethnicity, inferred low-income status from patient zip codes, exposure to smoking, and BMI on ICI response, defined by cancer progression-free survival (PFS, minimum 6 months FU), for non-small cell lung cancer (NSCLC) patients with MSK-IMPACT targeted panel sequencing. This FDA approved assay includes matched tumor-white blood cell sequencing to distinguish germline from somatic variants and has been applied to 1,802 NSCLC patients who received ICI treatment, including 81 and 117 patients with at least 80% of African (AFR) and East Asian (EAS) ancestry, respectively. Moreover, 173 samples were derived from admixed patients with more than one major ancestry.

We first used a natural language processing (NLP) model to obtain PFS from free-text clinical notes. A multivariable cox proportional hazard model was then used to associate PFS with ancestry, race, smoking status, ICI drug regimen, PD-L1 status, disease stage, tumor mutational burden (TMB), inferred income, and BMI. Neither genetic ancestry nor self-reported race/ethnicity was associated with the PFS. Moreover, ICI drug regimen types, low-income status, and BMI were not associated with PFS in our cohort. TMB-high was associated with longer PFS across all ancestries,

although TMB was lower in patients with EAS ancestry (Median 7.9 vs. 5.3 mut/Mb, $p<0.001$).
These results suggest that the benefits of ICI extend across ancestry, race, and income lines in a single institution, arguing for more equitable patient access to these medications. We also show that TMB is a generalizable biomarker for ICI outcome across ancestries. However, more diverse patient populations are needed to understand whether there is ancestry-specificity in other ICI outcome biomarkers.

#4261

Genomic landscape of 2128 thyroid cancers from the aacr genie database: Implications for targeted therapies

Blessie Elizabeth Nelson[1], Mohammed Gouda[1], Jason Roszik[2], Mimi L. Hu[3], Maria Cabanillas[3], Vivek Subbiah[1]. *[1]Investigational Cancer Therapuetics, UT MD Anderson Cancer Center, Houston, TX,[2]Melanoma Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[3]Endocrine Neoplasia and Hormonal Disorders, UT MD Anderson Cancer Center, Houston, TX*

Background**:** Understanding molecular biology of thyroid cancer has revolutionized diagnosis, tumor classifications and identifying effective precision oncology therapies.
Methods: Using AACR GENIE database v.12, we cataloged genetic and co-occurring alterations in all thyroid cancers.
Results: We identified 2128 cases from 153,834 samples where tumor sub-histologies included Papillary Thyroid Cancer (PTC: 55%; 1162), Poorly Differentiated Thyroid Cancer (PDTC: 12%; 262); Medullary Thyroid Cancer (MTC: 12%; 244), Anaplastic Thyroid Cancer (ATC: 10%; 220); Follicular Thyroid Cancer (FTC: 5%; 111); Hurthle Cell Thyroid Cancer (HCTC: 5%; 95); and others (1; 34). Median age at sequencing was 59 years. Gender distribution was higher in female (54%; n=1104) compared to male (46%; n=933). Ethnicities included 73.2% (n=1,493) White, 8.9% (n=178) Asian, and others.Most frequent genomic mutational alterations overall were *BRAF* (40.8%; 868) [96% (n=845) V600E, 0.6% (n=5) G469A, 0.6% (n=5) V600_K601delinsE, 0.2% (n=2) K601E, 0.2% (n=2) A404Cfs*9, and 2.7% (n=24) others]; *TERT* (35%; 624); *NRAS* (11.6%;

247); *TP53* (11.6%; 247) and *RET* (9.3%; 197) genes. There was variability in genomic alterations between sub-histologies (Table 1).

Histology	Most frequent Alterations	%	n
PTC	BRAF	62.3%	724
	TERT	32.7%	332
PDTC	TERT	49%	117
	NRAS	28.2%	74
MTC	RET	71.3%	174
	HRAS	7.8%	19
ATC	TP53	58.2%	128
	TERT	56.7%	106
FTC	TERT	41%	27
	NRAS	26.1%	29
HCTC	TERT	41%	34
	TP53	17.9%	17

There was statistically significant co-occurrence between *BRAF and TERT, TERT* and *TP53*, *TERT* and *NRAS* alterations ($p<0.001$). Mutually exclusive alterations were *BRAF* and *NRAS, BRAF* and *RET, TERT* and *RET, NRAS* and *RET, TP53* and *RET,* and *BRAF* and *TP53 ($p<0.001$).*Copy number alterations (CNA) were observed in 497 samples and were most frequent in *CDKN2A, NKX2-1, CDKN2B, NF2,* and *CRKL* genes (16.5%, 16%, 15.5%, 13.1%, and 13%). 362 oncogenic fusions were noted predominantly in *CCDC6-RET, RET-NCOA4, ETV6-NTRK3, BRAF*-Intragenic (20%, 7.2%, 3%, 1.6%).

Conclusion: Genomic profiling identified full breadth of BRAF, RET and NRAS alterations and co-occurring oncogenic driver alterations. This approach may refine use of targeted therapy in thyroid cancer.

#4262

Genomic profiling of uveal melanoma patients using the GENIE database

Shaden Tashtoush, Ashaar Al-Akhras, Alina Ghazou, Sebawe Syaj. *Jordan University of Science & Technology, Irbid, Jordan*

Uveal melanoma (UM) is the most common primary adult intraocular tumor. Frequently mutated genes in UM include BAP1, EIF1AX, GNA11, GNAQ CHEK2, and SF3B1. This study aims to investigate the genomic characteristics of UM patients using a large cohort of clinicogenomic data. We assessed the frequency of genetic mutations in UM patients obtained from the AACR Project Genomics Evidence Neoplasia Information Exchange (GENIE) cohort v12.1. We excluded patients with samples from a local recurrence, not otherwise specified tumor samples, and data not collected for sampling localization from our cohort. A total of 296 UM patients were included in this study, 164 (55.4%) of which were male and 131 (44.6%) were female. The sample mean age was 59.5 (SD: 14.1), and most patients were of white ethnicity (83.8%). Of 243 patients with known vital status, 32.1% (n = 78) of them were alive, while 67.9% (n = 165) of them were deceased. Sequencing samples were collected from the primary tumor in 141 patients, and from a metastatic nodule in 146 patients. We found that GNAQ and GNA11 were mutated in 43.9% and 43.6% of patients, respectively. BAP1 was mutated in 35.1%, SF3B1 in 22.3%, and EIF1AX in 13.2% of patients. No patients had GNAQ and GNA11 mutations concurrently. All patients had a median mutation count of 3, with no differences between the two genders. No significant differences were found in the frequency of mutations in regard to gender. GNAQ and GNA11 mutations were identified to be the most frequent mutations among UM patients, with a mutual exclusivity relationship between the two genes. New therapeutic modalities should consider the comprehensive genomic profiling of UM patients to improve their overall survival rate and quality of life.

Anti-Siglec 7 antibody displays potent anti-tumor immunity and demonstrates improved tumor control in combination with anti-PD1 in ovarian cancer

Devivasha Bordoloi[1], Abhijeet J. Kulkarni[1], Opeyemi S. Adeniji[1], M. Betina Pampena[2], Pratik S. Bhojnagarwala[1], Shushu Zhao[1], Elizabeth M. Parzych[1], Rugang Zhang[3], Michael R. Betts[2], Mohamed Abdel-Mohsen[1], David B. Weiner[1]. *[1]Vaccine & Immunotherapy Center, The Wistar Institute, Philadelphia, PA,[2]Department of Microbiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[3]Department of*

Microbiology, Perelman School of Medicine, The Wistar Institute, Philadelphia, PA

High grade serous ovarian cancer (OC) and ovarian carcinosarcoma, referred as “Cold” tumors have restricted treatment choices and being associated with high mortality. Current immune checkpoint inhibitors (CPIs) have had modest impact for OC treatment; with anti PD-1/PD-L1 single therapies reported response rates of 4-15%. Accordingly, additional approaches are important for these patients. Natural killer (NK) cells represent an important subset of effector lymphocytes with strategic approaches for maximizing NK reactivity to target OC are likely important. Of interest, an inhibitory receptor and glyco immune checkpoint- Siglec 7 is expressed on 100% of peripheral blood and umbilical cord NK cells**.** We have generated antibodies against Siglec 7 through an optimized human Siglec 7 DNA/protein immunization approach in humanized next generation transgenic mice. By high throughput flow screening, we identified several Siglec 7 antibodies and down selected relevant clones. A unique clone DB7.2 was highly specific for Siglec 7. We demonstrated the ability of DB7.2 (human IgG1) to activate NK cells and induce OC cell killing using xCELLigence RTCA for in vivo OC challenge studies. DB7.2 (1μg/ml) bound to >90% of NK cells including both CD56dim and CD56bright subsets, evaluated in the PBMCs of multiple donors. It showed strong binding to recombinant Siglec 7 and Siglec 7 transduced HEK293T but not to wild type 293T cells supporting specificity. DB7.2 induced specific killing of multiple OC lines (OVCAR3&10,TOV21G, CaOV3, OVISE, PEO4) carrying different mutations; BRCA1&2, AKT, TP53, PIK3CA, BRAF etc. and resistant against a wide array of cancer drug targets; HSP90, HDAC, MTORC, DNA alkylating agents, EGFR, PARP, PI3K, and WEE1. Tumor killing was indicated to be mediated via enhanced secretion of soluble Fas, perforin, granulysin as well as granzyme A. Of note, OVISE (BRCA1mutated) and PEO4 (BRCA2 mutated, PARPi resistant) were susceptible to DB7.2 killing with EC50- 82.67 and 68.67 nM respectively. A single dose of in vivo expressed DB7.2 significantly reduced the tumor burden in an OVISE challenged humanized mice model enhancing median survival by 57 days. As OCs are highly diverse in nature and likely to require combinatorial approaches for simultaneous targeting of immune pathways; we combined DB7.2 with anti-PD1 for further

investigation. In xCELLigence assay, anti-PD1 demonstrated killing of PEO4 cells with EC50 680 nM. The combination of anti PD-1 with DB7.2 showed further enhancement of OC killing in the presence of human PBMCs. This is the first demonstration of the impact of Siglec 7 targeting mAb alone as well as in combination with anti-PD1 (NK and T cell CPIs) studied for targeting OC or any human tumor. These studies have important implications for tumor therapy and provide a novel non T cell CPI potential approach to augment current immune therapy strategies.

#4264

The genomic landscape of RET fusions in non-small cell lung cancer and the impact of co-occurring genomic alterations on the efficacy of selective RET inhibitors

Tuqa Al Khalaf[1], Simon Heeke[1], Lei Feng[1], Leylah M. Drusbosky[2], Jeff Lewis[1], Waree Rinsurongkawong[1], Vadeerat Rinsurongkawong[1], Jack Lee[1], Jianjun Zhang[1], Don Gibbons[1], Ara Vaporciyan[1], Vincent Lam[3], Vivek Subbiah[1], John Heymach[1], Yasir Elamin[1]. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Guardant Health, Inc., Redwood City, CA,[3]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Purpose: *RET* fusions drive oncogenesis in 1-2% of non-small cell lung cancer (NSCLC) and are sensitive to the selective RET inhibitors selpercatinib and pralsetinib. They have also emerged as mechanisms of acquired resistance to other targeted therapies. The genomic landscape of *RET* fusions and the impact of co-occurring genomic alterations on the efficacy of selective RET inhibitors is yet to be fully described.
Methods: A total of 678 *RET* fusion-positive samples were analyzed from three cohorts: Guardant360® circulating tumor DNA (ctDNA) (n=467), tissue and/or plasma from the American Association for Cancer Research Project Genomics Evidence Neoplasia Information Exchange (AACR Project GENIE) non-squamous NSCLC cohort (n=161), and the MD Anderson Cancer Center (MDACC) cohort of patients treated with selpercatinib or pralsetinib (n=50). Molecular characteristics were compared across all three cohorts and to the entire non-*RET* non-squamous NSCLC AACR Project GENIE cohort (n=17770). Fisher's exact test was used to evaluate the difference in response rate between patient groups, and

Cox proportional hazard models were used to calculate hazard ratios for time-to-event endpoints for patients in the MDACC clinical cohort (n=51, 50 patients with *RET* fusion, 1 patient with *RET* point mutation).
Results: The most common fusion partner in all cohorts was *KIF5B* (ctDNA: 73%; GENIE: 69%; MDACC: 71%), followed by *CCDC6* (19%; 17%; 18%) and *NCOA4* (5%; 1%; 7%). Across all cohorts, co-mutations in *TP53* were most common (60%; 34%; 40%) and *EGFR, CDKN2A/B*, *MET*, and *ATM* consistently co-occurred across all cohorts. *EGFR* co-occurred more frequently with non-*KIF5B* fusion partners (chi-square $p < 0.006$). *MYC* and *CCND1* amplifications were enriched in all three cohorts compared to the non-*RET* cohort. In the MDACC clinical cohort (n=51), the majority were female, never-smokers, with adenocarcinoma histology. The median follow-up time was 28.3 months (95% CI: 15.2 ~ 35 months). Overall response rate (ORR) was 74.4% (95% CI: 58.8 ~ 86.5%), where patients with *TP53* mutation had numerically lower ORR compared to patients without *TP53* mutation (58.5% vs. 87.5%; $p = 0.0632$). Median progression-free survival (PFS) time was 16.5 months (95% CI: 13.5 ~ 27.4 months) and *KIF5B* fusions trended towards worse PFS outcome compared to non-*KIF5B* fusions (HR: 2.24; 95% CI: 0.88 ~ 5.67; $p = 0.0896$). *TP53* alterations were associated with a significantly worse overall survival (OS) (HR: 2.93; 95% CI: 1.08 ~ 7.95; $p = 0.0346$).
Conclusion: In the largest *RET* fusion-positive NSCLC cohort to date, *RET* fusions frequently co-occurred with other genomic alterations, most commonly in *TP53*. *TP53* alterations are associated with a significant reduction in overall survival in patients treated with the selective *RET* inhibitors. Additional analysis is underway.

Humanized 3D tumor models that are mutationally aligned with AACR GENIE patients predict IMM-1-104 activity in RAS-addicted tumors

Praveen Nair[1], Sarah Kolitz[2], Jason Funt[1], Peter J. King[1], Kevin D. Fowler[1], Anna Travesa[1], Ian Rose[1], John Brothers[2], Amy Axel[1], Scott Barrett[3], Benjamin J. Zeskind[3], Brett M. Hall[1]. *[1]Immuneering Corporation, San Diego, CA,[2]Immuneering Corporation, Cambridge, MA,[3]Immuneering Corporation, New York, NY*

Introducti**on:** IMM-1-104, with pan-RAS activity through deep cyclic inhibition MEK, was evaluated in humanized 3D preclinical tumor models displaying diverse MAPK pathway activation events. Based on drug-response, sensitivity and resistance profiles, a biomarker signature for IMM-1-104 was developed in order to project potential therapeutic response of cancer patients found in the AACR Project GENIE (GENIE) database.

Experimental Procedures: Humanized 3D preclinical models better predict *in vivo* tumor responses versus 2D culture and more accurately replicate biology of human tumors. Therefore, the antitumor activity of IMM-1-104 was evaluated in over 130 tumor models spanning 12 distinct histologies in the humanized 3D tumor growth assay (3D-TGA). Cell-based whole exome sequencing readouts were combined with 3D-TGA results to build a pharmacogenomic response algorithm. When applied to the GENIE patient database, resultant tumor-specific response landscapes helped to inform an early pan-RAS clinical trial design for IMM-1-104.

Summary of New Data: A machine learning model was developed to predict IMM-1-104 sensitivity using response-associated genes and signaling networks that were identified using 3D-TGA pharmacogenomics data. This model was used to estimate GENIE patient IMM-1-104 response profiles across key solid tumor indications. In addition, mutation constellations from GENIE were compared with those observed in cell lines to identify preclinical models that best resemble real-world patients. This effort was designed to further enrich the translational fidelity of specific tumor models with the goal of translationally identifying patient populations most likely to benefit from IMM-1-104 treatment.

Conclusions: The depth of response to IMM-1-104 was evaluated across a panel of diverse 3D-TGA tumor models and led to identification of a biomarker signature for therapeutically addressable MAPK pathway addiction. To translate these findings into a relevant clinical application, a response algorithm was developed and applied to the GENIE database, which has cataloged the molecular profiles of over 100,000 cancer patients. Mutational landscapes of patients within GENIE helped identify preclinical models that better represent patient profiles likely to be encountered in the clinic. This approach could, as a general principle, be applied as a tool for improving biomarker discovery and clinical translation of oncology drugs.

Genomic landscape of prostate cancer: Bioinformatic analysis of TCGA PanCancer data by race and identification of key pathways and genes in PTEN mutation

Olumide Arigbede, Sarah G. Buxbaum, Sara Falzarano, Suhn K. Rhie.
Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

Issue: Prostate cancer (Pca) is still among the most frequently diagnosed cancers in adults. The most often mutated gene in PCa is PTEN (Phosphatase and Tensin Homolog), making it a possible biomarker for prospective customized therapy. The root causes of health inequalities in PCa have not received much attention. Numerous online databases, like The Cancer Genome Atlas (TCGA), provide gene expression data and other data, allowing researchers to further investigate new processes or therapy options. However, there hasn't been much study on tailored therapy up to this point since there may have been difficulties with access to genomic information and bioinformatic tools.
Methods: The PCa data in cBioPortal comprises 494 samples. We selected 154 samples comprising 7 Blacks and 147 Whites. We used the TCGA database to obtain the PCa gene expression and DNA methylation data for study. In order to examine the data by race/ethnicity, gene expression, DNA methylation, and genomic changes, we evaluated at the differentially expressed and methylated genes using online tools (cBioPortal). To evaluate gene methylation, expression, and alterations, log ratios of means in Blacks to means in Whites were computed across the data. Additionally, Kaplan-Meier survival analysis, protein interaction analysis, and multivariable data analysis were carried out.
Results: PCa data in the TCGA database showed PTEN mutation in 20% patients. The median age of participants was 63 years (range: 42-78). For every category of data assessed, there were significant differences by race/ethnicity ($q < 0.05$). In the survival analysis, SLC2A1, NUDT12, CUTALP, and other genes were associated with survival.
Conclusion: Genetic alteration, expression, and DNA methylation are each significantly different by the two race groups compared. According to our research, PTEN mutation in PCa may influence several genes and biological processes.

Serum PVT1 exon 9 copy number is a better predictor of positive prostate biopsy in Black and Hispanic men than serum prostate specific antigen

Emmanuel Owusu Asante-Asamani[1], Sobana Handi D. Sewwandi De Silva[1], Gargi Pal[2], Micheal Liss[3], Robin J. Leach[4], Olorunseun O. Ogunwobi[5]. *[1]Mathematics, Clarkson University, Potsdam, NY,[2]Biology, Hunter College, New York, NY,[3]UT Health San Antonio, San Antonio, TX,[4]Department of Cell Systems and Anatomy, University of Texas Health San Antonio, San Antonio, TX,[5]Biology, Hunter College of CUNY, New York, NY*

Background: Men of African ancestry (moAA) experience the highest incidence and mortality rates of prostate Cancer (PCa) in the United States, where 1 in 8 men are expected to be diagnosed with the disease in their lifetime. Yet, most biomarkers used in PCa screening today, which are based on prostate specific antigen (PSA), are developed and validated in predominantly White populations with weak or nonexistent validation in moAA, making moAA more likely to be subjected to unnecessary prostate biopsies. To reduce this disparity in PCa detection and management, there is a critical need for new biomarkers that target the unique genetic make-up of moAA. We recently showed that plasmacytoma variant translocation 1 (PVT1), exons 4A, 4B, and 9 are overexpressed in the prostate tissues and detected in higher copy numbers in serum of moAA with PCa. In this study, we investigated the predictive power of these potential biomarkers in detecting PCa across different racial populations.
Methodology: Forty serum samples from White, Hispanic, and Black men, 50 percent of whom had PCa, were analyzed to obtain copy numbers for PVT1 exons 4A, 4B, and 9. Seven logistic regression models were developed to predict PCa using single biomarkers, all pairwise combinations of biomarkers and all three biomarkers. The median area under the receiver operator characteristic curve (AUC) was used to measure

the predictive accuracy of each model after a repeated, stratified k-fold cross validation. Model accuracy was first evaluated using data from all races and then for just the Black or Hispanic subpopulation. Our best performing models were compared with PSA as a predictor of PCa. We also evaluated the predictive accuracy of composite models that combined our biomarkers with PSA.
Results: In predicting PCa for all races, our model with only PVT1 exon 9 achieved the highest median AUC of 0.71, which was better than the AUC of 0.63 obtained with just PSA. When PSA and PVT1 exon 9 were combined, the median AUC increased to 0.75. Combining all three biomarkers with PSA increased the median AUC to 0.813. For the Black or Hispanic subpopulation, PVT1 exon 9 achieved the highest AUC of 0.92 which was significantly higher than the median AUC of 0.63 achieved with PSA. No significant change in AUC was observed when the PVT1 biomarkers were combined with PSA. Conclusion: Our results show that PVT1 exon 9 is more accurate than PSA in predicting PCa, achieving near perfect accuracy within the Black or Hispanic subpopulation. Whereas combining PSA with PVT1 biomarkers improved the performance of PSA for all races, no significant improvement in PSA's performance was observed in Black or Hispanic subpopulation. Thus, PVT1 exon 9 may hold the key to reducing disparity in PCa detection among moAA while improving the predictive accuracy of PSA for the general population.

Lipidome of mammographic breast density in premenopausal women

Kayla R. Getz, Myung S. Jeon, Chongliang Luo, Jingqin Luo, Adetunji T. Toriola. *Department of Surgery, Division of Public Health Sciences, Washington University School of Medicine in St. Louis, St. Louis, MO*

Introducti**on:** High mammographic breast density (MBD) is a strong risk factor for breast cancer, but the biological mechanisms underlying high MBD are not well understood. We, therefore, comprehensively investigated for the first time the associations of lipid species with volumetric measures of MBD to elucidate potential biological mechanisms of high MBD in premenopausal women.
Methods: We performed lipidomic profiling on 705 premenopausal women recruited during their annual screening mammogram at Washington

University School of Medicine, St. Louis, MO. Lipidomic profiling for 982 lipid species was completed at Metabolon (Durham, NC®). Lipid species with greater than 300 missing values (N=125) were excluded from the analysis. Using nearest neighbor methods, we imputed the lipid species missing less than 300 values. We used Volpara 1.5 (Volpara Health®) to quantify volumetric measures of MBD - volumetric percent density (VPD), dense volume (DV), and non-dense volume (NDV). We investigated the associations of the lipid species with MBD measures using multivariable linear regression models adjusting for age, age at menarche, body shape at age 10, race/ethnicity, body fat %, family history of breast cancer, oral contraceptive use, parity/age at first birth, and alcohol use. MBD measures were $\log_{10}$-transformed, and lipid species were standardized. Linear coefficients were back-transformed to the original scale and considered significant if the Bonferroni corrected $p<0.05$.
Results: In multivariable linear regression models, 34 lipid species were inversely associated with VPD. The lipid species belong to the triacylglycerol (TAG, N=26), diacylglycerol (DAG, N=6), phosphatidylcholine (PC, N=1), and cholesterol ester (N=1) pathways. DAG(16:0/18:2) and TAG54:6-FA20:4 displayed the largest inverse associations with one standard deviation increase in DAG(16:0/18:2), and TAG54:6-FA20:4 corresponding to 9.9% (p=0.002), and 9.6% (p=0.007) decrease in VPD, respectively. Eleven lipid species were significantly associated with NDV, with 10 species (all TAG) having a positive association and 1 inverse association PC(18:1/18:1). The strongest positive association was observed with TAG54:6-FA20:4. One standard deviation increase in TAG54:6-FA20:4 was associated with a 9.8% increase in NDV (p=0.01). Several of the lipid species (N=8, 23.5%) that were associated with VPD were also associated with NDV, but in opposite directions. No lipid species were significantly associated with DV.
Conclusions: Our study identified many lipid species, especially in TAG and DAG pathways, that were associated with VPD and NDV and offer new insights into the biological mechanisms underlying high MBD in premenopausal women. Future studies are needed to validate our results and the translational potential.

Incorporating continuous mammographic density into the BOADICEA breast cancer risk prediction model

Lorenzo Ficorella[1], Mikael Eriksson[2], Kamila Czene[2], Goska Leslie[1], Xin Yang[1], Tim J. Carver[1], Douglas F. Easton[1], Per F. L. Hall[2], Antonis C. Antoniou[1]. *[1]Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom,[2]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden*

BOADICEA, implemented in the CanRisk tool (www.canrisk.org) can be used to calculate future breast cancer risk using data on cancer family history, genetics (rare high- or moderate-risk pathogenic variants; polygenic scores (PGS)), questionnaire-based risk factors and mammographic density (MD) measured using the BI-RADS classification. The BI-RADS categorization requires manual reading which is not feasible at population level. Moreover, BI-RADS captures MD in 4 categories, whereas continuous measures are stronger risk predictors. Here, BOADICEA was extended to incorporate continuous breast density measured by the fully automated Volpara and STRATUS software, working on raw and processed images, respectively. We used data from the KARMA prospective screening cohort (60,276 participants; 1,167 incident breast cancers). The associations between Volpara or STRATUS density measurements and incident breast cancer risk were estimated in a randomly selected training subset consisting of two-thirds of the full dataset. For this, we calculated density residuals after regressing on participant's age at mammography. Hazard ratios (HR) for the normalized residuals were calculated using a Cox proportional hazards model, adjusting for family history, BMI and all risk factors included in BOADICEA. Multiple Imputation by Chained Equations (MICE) was used to impute missing data. The remaining one-third of the KARMA cohort was used to assess the performance of BOADICEA in predicting 5-year risks, after including the estimated Volpara and STRATUS associations.Under the best fitting multivariable model including PGS, the HRs per SD of residual STRATUS density were estimated to be 1.67 (95%CI: 1.44-1.93) and 1.38 (95%CI: 1.26-1.51) for pre- and post-menopausal women, respectively. The HR estimates per SD of residual Volpara density were 1.38 (95%CI: 1.19-1.59) and 1.39 (95%CI: 1.27-1.52) for pre- and post-menopausal women, respectively. After incorporating these associations in BOADICEA, there was a marked improvement in the

model discriminatory ability in the test dataset, compared to using the BI-RADS classification. The largest increase in AUC was observed for STRATUS residual density, with a 3% increase compared to using BI-RADS vs a 1.6% increase in AUC when using Volpara residual density. These increases were consistent across BOADICEA models considering different combinations of risk factors, including PGS.Including continuous breast density in BOADICEA can lead to improved breast cancer risk stratification and could allow for automated measures of MD to be more readily deployed in breast cancer risk prediction. Additional prospective studies are required to further validate the findings. The models will be implemented in the CanRisk tool.

Development of breast cancer risk assessment tool: The Korean decision aid for cancer screening (K-DACS) study

Wonyoung Jung[1], Yong-Moon Mark Park[2], Sang Hyun Park[3], Kyungdo Han[4], Junhee Park[5], Yohwan Yeo[6], Jung Kwon Lee[7], Dale P. Sandler[8], Dong Wook Shin[5]. *[1]Kangdong Sacred Heart Hospital, Seoul, Korea, Republic of,[2]Department of Epidemiology, University of Arkansas for Medical Sciences, Little Rock, AR,[3]Department of Biostatistics, The Catholic University of Korea, Seoul, Korea, Republic of,[4]Department of Statistics and Actuarial Science, Soongsil University, Seoul, Korea, Republic of,[5]Department of Family Medicine and Supportive Care Center, Samsung Medical Center, Seoul, Korea, Republic of,[6]Department of Family Medicine, Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Korea, Republic of,[7]Department of Medicine, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[8]Epidemiology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, NC*

Purpose: Widely used breast cancer risk prediction tools are based on data from Western countries, but risk factors may differ for Asian women. Hence, we aimed to develop a risk assessment tool for breast cancer in Asian women, using a nationwide, population-based cohort in Korea. Methods: Women aged ≥ 40 years who participated in both breast cancer screening and general health examination in 2009 were eligible for this

study. Age, body mass index (BMI), breast density, lifestyle and reproductive factors, and comorbidities were used to develop 5-year breast cancer risk prediction models in premenopausal (n=771,856) and postmenopausal (n=1,108,047) women at baseline. Backward stepwise selection in the Cox proportional hazards model was used to construct the best-fit risk prediction model, which was then converted into a risk score nomogram, representing an individual probability estimate of incident breast cancer. Model performance was evaluated by discrimination and calibration. Results: Among premenopausal women, high BMI, low parity, short breastfeeding period, early age at menarche, high breast density, history of benign breast mass, and family history of breast cancer contributed to breast cancer risk prediction. The appropriate predictors in postmenopausal women additionally included age, type 2 diabetes, dyslipidemia, late age at menopause, hormone replacement therapy use, except for number of parities. The concordant statistic of risk prediction model was 0.58 (95% confidence interval [CI] 0.57-0.59) for premenopausal women, and 0.64 (95% CI 0.63-0.65) for postmenopausal women. Our model correlated well in the calibration plot in both premenopausal and postmenopausal women.Conclusions: Our breast cancer risk prediction model showed good performance for postmenopausal women, providing the background for risk-based screening recommendations in Asian women.

Timing of pregnancy-related factors and breast cancer risk for women across a range of absolute risk

Jasmine A. McDonald[1], Yuyan Liao[1], Esther M. John[2], Allison W. Kurian[2], Jeanine M. Genkinger[1], Saundra S. Buys[3], John L. Hopper[4], kConFab Investigators, Mary Beth Terry[1]. *[1]Department of Epidemiology, Columbia University Irving Medical Center, New York, NY,[2]Department of Epidemiology & Population Health, Stanford University School of Medicine, Palo Alto, CA,[3]Department of Medicine, Huntsman Cancer Institute, Salt Lake City, UT,[4]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia*

Background**:** Studies in women with pathogenic variants in *BRCA1* or *BRCA2* suggest that underlying breast cancer (BC) risk modifies the associations between pregnancy-related factors and BC risk. Less is known about whether the associations are modified across a range of predicted absolute BC risk based on age and the extent of BC family history.
Objective: Examine the association between pregnancy-related factors and BC risk and modification by predicted absolute BC risk in the Prospective Family Study Cohort (ProF-SC) with women enrolled between 1992-2011 and a median 10.0 years of follow-up time.
Methods: ProF-SC includes the six international sites of the Breast Cancer Family Registry [USA, Canada, and Australia] and the Kathleen Cuningham Foundation Consortium for Research into Familial Breast Cancer (kConFab). 17,274 women with 943 prospectively ascertained BC cases were eligible for the prospective analysis with 87% of cases self-identifying as non-Hispanic White. Questionnaires at study entry assessed self-reported pregnancy-related factors (parity, number of full-term pregnancies (FTP), age at first FTP, years since last FTP, breastfeeding, and age at menarche). We used Cox proportional hazards regression models with age as a time scale to estimate Hazard Ratios (HR) and the 95% Confidence Intervals (CI) for each reproductive variable (main effect) and examined modification by predicted absolute risk of BC, measured by a 1-year absolute risk score (continuous) estimated by the BOADICEA (interaction effect). We also examined associations stratified by estrogen receptor (ER) subtype.
Results: Women with a first FTP at age ≥30 vs. <20 years had an increased risk of BC (HR=1.49, 95% CI 1.10, 2.02); no other pregnancy-related factors were associated with BC risk. Compared to nulliparous women, the main effect for higher parity was associated with increased ER-negative BC (PARS*≥4 FTP HR 2.34, 95% CI 1.09, 5.01). In contrast, increasing absolute BC risk for women with higher parity was associated with reduced risk of ER-negative BC (PARS*≥4 FTP $HR_{interaction}$ 0.66, 95% CI 0.48, 0.90; $p_{interaction}$=0.01). Increasing absolute BC risk for nulliparous or first FTP at age ≥25 years had a >20% increased risk of ER-negative BC compared to first FTP at age <20 years ($p_{interaction}$=0.002); the main effects for nulliparity and first FTP at age ≥25 years and ER-negative BC were null (*p-values*=0.2-1.0). Compared to nulliparous women, increasing absolute risk for women who were within 5 years of their last FTP was positively

associated with ER-negative BC ($HR_{interaction}$=1.54, 95% CI 1.03, 2.31); main effects were null (HR=1.00, 95% CI 0.39, 2.54).
Conclusion: The association between pregnancy-related factors and BC risk are modified by predicted absolute BC risk, with stronger associations observed for ER-negative BC. Women at higher absolute BC risk may benefit from more frequent BC monitoring following childbirth.

Genetic testing for hereditary colorectal cancer syndromes in Algerian patients: A multicenter study

Farid Cherbal[1], Asma-Lamia Boumehdi[1], Feriel Khider[1], Karima Landelouci[1], Abdelwahab Zemam[1], Sarah Sabri[1], Adam.Walid Damache[1], Mohammed Oukkal[2], Hassen Mahfouf[3], Ferhat Zebboudj[4], Mustapha Maaoui[5]. *[1]Molecular Genetics Team, LMCB, Faculty of Biological Sciences,University of Science and Technology Houari Boumediene (USTHB), Algiers, Algeria,[2]Clinic of Medical Oncology Amine Zirout, University Hospital of Beni-Messous, School of Medicine, University of Algiers-1, Algiers, Algeria,[3]Mohamed El Kolli Public Hospital, Academic Medical Oncology Services, School of Medicine, University of Algiers-1, Rouiba, Algiers, Algeria,[4]Mohamed El Kolli Public Hospital, Academic General Surgery Services, School of Medicine, University of Algiers-1, Rouiba, Algiers, Algeria,[5]Bachir Mentouri Public Hospital, Academic General Surgery Services, School of Medicine, University of Algiers-1, Kouba, Algiers, Algeria*

Background To date, 5% to 6 % of all colorectal cancers (CRCs) are associated with germline pathogenic variants in cancer predisposition genes that confer inherited predisposition to CRC. The use of genetic testing to identify individuals at risk for hereditary CRC syndromes can help to prevent the development of cancer and in the clinical management of the colorectal patients in the areas of both prevention and treatment. We report here the experience of our research laboratory of genetic testing for hereditary polyposis syndromes and Lynch syndrome (LS), respectively, in 126 patients.
Methods Fifty four (54) severe familial adenomatous polyposis (FAP) patients and 72-suspected Lynch syndrome (LS) patients, respectively, were

selected from 2851 consecutive colorectal patients at five public hospitals during 2012-2019. Family histories of cancer were obtained from interviews, pedigrees and medical records of patients. Index cases and relatives diagnosed with FAP syndrome or Lynch syndrome have been tested for germline variants in *APC*, *MLH1*, *MSH2*, *MSH6* and *PMS2* genes, respectively, using PCR-Sanger Sequencing or by NGS using a cancer panel of 30 hereditary cancer genes (Color Genomics).
Results We detected 13 germline pathogenic variants in *APC* gene in 17 unrelated families, one germline pathogenic variant in *BMPRA1* gene in juvenile polyposis syndrome (JPS) patient; seven (7) germline pathogenic variants and 2 variants of uncertain clinical significance (VUS) in MMR genes. Interestingly, 4 novel germline pathogenic variants in *APC* gene and 3 novel germline pathogenic variants in MMR genes, respectively, have been detected in our study. The most occurring germline pathogenic variants in APC gene were c.3927_3931del and c.4728dup that were identified in four and two index cases in 6 unrelated FAP families, respectively. In Lynch syndrome patients, the rare germline pathogenic variant *MLH1* c.1546C>T has been found in 21 individuals from 9 LS families, 6 of them related, with two large kindreds. In addition, the recurrent germline pathogenic variant *MSH2* c.942+3A>T has been detected in five unrelated index cases with a strong family history of LS syndrome. Moreover, the rare germline VUS *PMS2* c.989-107_989-106insA has been detected in 14 unrelated LS patients and could be reclassified as likely benign. Interestingly, our NGS analysis detected the novel *BMPR1A* pathogenic variant c.1474-1G>C in young JPS patient that has been misdiagnosed as FAP. The *in-silico* analysis for this novel variant showed an alteration of the wild type acceptor site and an activation of a cryptic acceptor site, respectively, most probably affecting splicing.
Conclusions Our current study will contribute to the molecular genetics characterization of hereditary colorectal cancer syndromes in Algerian population that is relevant for clinical management in the areas of genetic testing, early diagnosis, treatment and prevention.

#4178
Lysosomal storage dysfunction as a risk factor in pancreatic cancer
Hyemin Kim[1], Youngil Koh[2], Joo Kyung Park[1]. *[1]Samsung Medical Center, Sungkyunkwan University, Seoul, Korea, Republic of,[2]Seoul National*

University Hospital, Seoul, Korea, Republic of

Background: Lysosome is closely linked to autophagy activity which has an important role in pancreatic adenocarcinoma (PDAC). We investigated whether lysosome storage dysfunction (LSD) contributes to PDAC development.
Materials and Methods: Comparison of germline putative pathogenic variants (PPV) in genes involved in lysosome functions was performed between PDAC patients (N=418) and healthy controls (N=745) using next generation sequencing. Using mouse pancreas organoid, consequences of GALC downregulation in PDAC development was evaluated. Transcriptome data analysis of human PDAC organoid according to PPV status was followed.
Results: PPV in LSD related genes were enriched in PDAC patients compared to healthy controls (Log2OR = 1.65, P = 3.08×10^{-3}). For limited stage PDAC patients, PPV carriers were diagnosed with PDAC in younger age compared to non-carriers (mean age 61.5 vs. 65.1 years, p=0.038). In mouse pancreas organoid, Ki-67 index significantly increased as GALC was downregulated. Altered autophagy activity with increased autophagy flux following GALC dysfunction was observed in both human cancer cell line and mouse organoid. mTOR downregulation was noted in mouse pancreas organoid. RNA sequencing analysis of human PDAC organoid revealed metabolism alteration related to LSD.
Conclusion: Genetically defined lysosome dysfunction is frequently observed in young age onset PDACs. Lysosome dysfunction might contribute to PDAC development via altered metabolism and autophagy activity.
Key words: lysosomal storage disease (LSD), germline, pancreatic ductal adenocarcinoma (PDAC)

Anal cancer risk factors and utilization of cancer preventive strategies in people living with HIV in Puerto Rico

Sandra I. Garcia-Camacho[1], Jeslie M. Ramos-Cartagena[1], Marievelisse Soto-Salgado[2], Vivian Colon-Lopez[2], Karen J. Ortiz-Ortiz[2], Ashish A. Deshmukh[3], Ana P. Ortiz[2]. *[1]Graduate School of Public Health, University of Puerto Rico, San Juan, PR,[2]University of Puerto Rico Comprehensive*

Cancer Center, San Juan, PR,[3]Medical University of South Carolina, Charleston, SC

Introducti**on:** Anal cancer (AC) risk is greatly elevated among persons living with HIV (PLWH), particularly men who have sex with men (MSM). The incidence of anal cancer among PLWH in Puerto Rico is 60.5 per 100,000 in MSM. Smoking and sexual behaviors may enhance anal cancer risk among PLWH. Therefore, we describe the prevalence of risk factors for AC, overall and by sexual risk group (MSM, women, and men who have sex with women [MSW]). We also evaluated receipt of cancer preventive strategies: HPV vaccination and AC screening, among a sample of PLWH in Puerto Rico.

Methods: A cross-sectional study was conducted (Sept 2020 - Dec 2021) among PLWH ≥26 aged in Puerto Rico (n=212). Participants answered a phone interview that collected information on relevant characteristics. AC risk factors evaluated were current smoking, age of sexual initiation (≤15 years), lifetime anal sex, 10 or more lifetime sexual partners, history of AIDS, genital warts, and HPV infection. HPV vaccination and AC screening status were also evaluated. The overall and sexual risk group specific prevalence of AC risk factors and preventive behaviors were described. In addition, the prevalence ratio (PR) of the variables of interest, comparing the sexual risk groups, was estimated with 95% confidence intervals using Poisson regression.

Results: Mean age of participants was 52.8 ± (SD=10.2); 44.1% were MSM, 23.2% were MSW, and 32.7% were women. Most PLWH had public health insurance (84.4%), an education level of high-school or less (45.7%), and 9.5% had a history of intravenous drug use. Regarding the prevalence of AC risk factors, 58.3% had 10 or more lifetime sex partners, 51% had their first sexual relationship at age ≤15 years, 29.3% were current smokers, and 75.8% of women had history of anal sex. In addition, 20.8% reported being diagnosed with AIDS, 16.5% had a history of genital warts, and 12.0% had HPV infection. Only 7.5% reported HPV vaccination and 52.2% reported ever having had an anal pap test. MSM had the highest prevalence of risky sexual behaviors, although no statistical difference was seen in the PRs. For preventive strategies, women (PR: 3.13, 95% CI 1.52-6.46) and MSM (PR: 3.42, 95% CI 1.70-6.90) had higher prevalence of anal pap uptake than MSW.

Conclusion: Persons living with HIV in Puerto Rico had high prevalence of current smoking use and risky sexual behavior. Despite their increased risk of AC, and only over half had been screened for AC. Continued education and awareness about AC risk factors, smoking cessation, and importance of prevention strategies are important among PLWH.

#4180

Knowledge and barriers to colorectal cancer screenings in people experiencing homelessness in Central Florida

Harini Sankar, Cassie L. Odahowski. *Health Sciences, University of Central Florida, Orlando, FL*

Purpose of the study: The purpose of this study is to assess how existing knowledge about colorectal cancer screenings and access to resources affect the ability to obtain colorectal cancer screening in people experiencing homelessness in Central Florida.
Procedures: A team of researchers from the University of Central Florida will survey subjects who do not have stable housing in two Central Florida locations: a local shelter for men, women, and children and a resource center for the unsheltered. The survey will take place in February 2023 with a sample size goal of 400. The survey will assess current understanding of CRC screenings and available/lacking resources necessary for completing CRC screening in this population. Our inclusion criteria include those who are undomiciled, age 45 and over who speak Spanish or English.
Preliminary Results: Anticipated results from previous work by our research team with this population indicate that we will have a large, diverse study sample. The results will include demographic data, frequency of insurance coverage, type of insurance coverage, knowledge of CRC screening recommendations, concerns related to CRC, rate of past completed screening, and perceived barriers to accessing CRC screening.
Conclusions: This study will be the first to examine this research topic in Florida. The results will identify the knowledge of CRC screening recommendations, barriers to CRC screening and identify resources needed for the unhoused population to achieve CRC screening in the future.
Key words: homelessness, colorectal cancer screenings, barriers to screening

#4181

Geospatial heterogeneity in colorectal cancer screening among Hispanic subgroups

Robert Blake Buchalter[1], Johnie Rose[2], Mariana C. Stern[3], Jane C. Figueiredo[4], Stephanie L. Schmit[5]. *[1]Quantitative Health Sciences, Cleveland Clinic Lerner Research Institute, Cleveland, OH,[2]Center for Community Health Integration, Case Western Reserve University, Cleveland, OH,[3]Keck School of Medicine, University of Southern California, Los Angeles, CA,[4]Samuel Oschin Comprehensive Cancer Center, Cedars-Sinai Medical Center, Los Angeles, CA,[5]Genomic Medicine Institute, Cleveland Clinic Lerner Research Institute, Cleveland, OH*

The U.S. Hispanic population has significantly lower colorectal cancer (CRC) screening rates than any other racial/ethnic group, resulting in unchanged incidence and mortality rates over recent decades. Recent studies have identified geographic variation in Hispanic CRC screening rates, but little is known about patterns among Hispanic subgroups. Here, we examine statistical and geographic relationships between broadly defined racial groups, Hispanic subgroups, and nationwide CRC screening rates. USPSTF guideline-adherent CRC screening rates for census tracts were obtained from 2018 CDC Places. Tract race/ethnicity %s, including non-Hispanic White (NHW), non-Hispanic Black (NHB), Asian, and Hispanic subgroups (Mexican, Cuban, Puerto Rican (PR), Dominican, Central/South American (CSAm), and other Hispanic), female %, and area deprivation index (ADI) were obtained from 2015-2019 American Community Survey 5-year estimates. Race/ethnicity %s were transformed using additive log ratios to account for the compositional nature of racial categories. A linear model and geographically weighted regression (GWR) were fit with CRC screening rate as the outcome. The mean CRC screening rate for 72,117 U.S. census tracts (99% of tracts) was 63.7% (SD=7.0). Linear modeling (R^2=0.68) showed significant positive linear associations between CRC screening and female % ($p<0.001$), NHW % ($p<0.001$), NHB % ($p<0.001$), and Asian % ($p=0.002$), and significant negative associations between screening and ADI ($p<0.001$) and all Hispanic subgroups ($p<0.001$). Mexican, Cuban, PR, Dominican, and CSAm subgroups had significant screening rate drops of -1.48%, -0.26%, -0.15%, -0.30%, and

-0.52%, respectively, per 1 unit increase in subgroup %. ADI had strong effects on all screening-race associations, with a flip in directionality for NHB% (negative to positive) and weakening of slopes for all other racial categories after adding ADI in the final adjusted model. GWR results (R^2=0.94) displayed spatial heterogeneity in local coefficients of all predictor variables, with distinct regional patterns in relationships between screening and ADI (strongly negative local coefficients in OH and OK), Mexican % (strongly negative in TX, AZ, NV, and CA), and NHB % (strongly negative in FL, GA, MS and WI; positive in SC and NC). This work suggests Mexican, CSAm, and Dominican subpopulations may be driving the low CRC screening rates among Hispanics overall. Local variability suggested the importance of where subpopulations live in determining guideline-concordant screening. ADI strongly altered screening-race relationships, with directionality changing for NHB %, further displaying the importance of area deprivation in CRC screening. Future work should explore micro-level drivers of spatial heterogeneity in screening rates across both broadly defined racial groups and Hispanic subgroups in the U.S.

#4182

Genetic associations with smoking relapse and proportion of follow-up in relapse throughout adulthood in pre- and post-menopausal women

Stephanie K. Jones[1], Anthony J. Alberg[2], Kristin Wallace[3], Brett Froeliger[4], Matthew J. Carpenter[3], Bethany J. Wolf[3]. *[1]Baylor University, Waco, TX,[2]University of South Carolina, Columbia, SC,[3]Medical University of South Carolina, Charleston, SC,[4]University of Missouri, Columbia, MO*

Cigarette smoking is a major contributor to the cancer burden, so identifying genetic variants associated with smoking cessation is important for cancer prevention. Prior genetic studies of smoking cessation have been limited by short-term follow-up and not accounting for quit attempts and relapse events experienced by most smokers. In this study, candidate SNPs previously found to be associated with smoking cessation were studied in relation to smoking relapse throughout adulthood. Participants were from two, all-female longitudinal cohort studies with repeated smoking behavior measurements collected every 2 years. The study included 12,060 ever-smokers of European ancestry with genotype data who quit smoking at ≥1

timepoint. Median follow-up after first quitting smoking was 32 years. Associations between selected single nucleotide polymorphisms (SNPs) and odds of smoking relapse and, conditional on relapse, SNP associations with the proportion of follow-up in relapse were modeled using zero-inflated beta regression. Genotype by menopausal status interactions were evaluated. Women with AA genotypes for *CHRNA5* SNP rs16969968 G>A or *CHRNA3* SNP rs1051730 G>A (p-value = 0.04 for both) had lower odds of relapse. Among women who relapsed, those with AA genotypes for *CHRNA5* SNPs rs588765 G>A or rs680244 G>A had 2.6% [95% CI 0.1 - 5.0%] and 2.4% [95% CI 0.2 - 4.9%] more follow-up in smoking relapse, respectively, compared to women with AG or GG genotypes. Women with AA or AG genotypes for *DRD2* SNP rs6277 G>A had 3.3% [95% CI 0.8 - 5.7%] more follow-up in relapse than women with GG genotypes. In contrast, women with AA genotypes for *COMT* SNP rs4680 G>A had 2.7% [95% CI 0.2 - 5.2%] lower proportion of follow-up in relapse than women with AG or GG genotypes. These associations with the proportion of follow-up in relapse were stronger among post-menopausal women. The association of SNPs rs588765, rs680244, and rs6277 with a higher proportion of follow-up in relapse was significantly stronger among women who quit smoking post-menopause [rs588765 difference in proportion follow-up in relapse = 9.5% (95% CI 3.8 -15.2%), rs680244 difference in proportion follow-up in relapse = 10.1% (95% CI 4.4% - 15.9%), rs6277 difference in proportion follow-up in relapse = 7.6% (95% CI 1.5 - 13.6%)]. No statistically significant difference in proportion follow-up in relapse by genotype was observed among women who quit smoking prior to menopause. Several SNPs were not associated with odds of smoking relapse but, conditional on relapse, were associated with the proportion of follow-up in relapse. The findings show selected genetic variants contribute to susceptibility to smoking relapse in the long term and that the genetic risk can differ by the stage of smoking cessation. For several SNPs stronger associations were observed among post-menopausal women, indicating the importance of menopausal status.

#4183

Employment status moderates the relationship between patient-provider communication and prostate cancer screening among Black men

Brian J. Carter[1], Tzuan A. Chen[2], Dalnim Cho[1], Lorna H. McNeill[1], Lorraine R. Reitzel[1]. *[1]Health Disparities Research, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Psychological, Health, & Learning Sciences, University of Houston, Houston, TX*

Purpose: Black men have 76% higher prostate cancer incidence rate than White men, and 120% higher mortality rate. They are also less likely to be screened via prostate-specific antigen (PSA) testing. Potential harms of PSA testing include overdiagnosis and overtreatment, but recent research suggests that the harm-benefit trade-off may be uniquely favorable for Black men. Increasing Black men's PSA testing rates may therefore reduce prostate cancer disparities. Studies suggest that employment status and accompanying roles (e.g., family breadwinner or workplace leader) are often central to masculine identity and that employed men may thus anticipate prostate cancer diagnosis and work-disruptive treatment threatening their identity, engendering screening avoidance. Patient-provider communication (PPC), if ideal, may help to reframe PSA testing and overcome barriers unique to employed men. The current work explored this possibility.
Methods: A convenience sample of 246 Black men aged ≥45 (M_{age} = 56.94±7.88) was recruited from Houston, TX. Self-reported data included satisfaction with PPC (Consumer Assessment of Healthcare Providers and Systems; ideal vs not ideal), current employment status (employed for wages or self-employed vs none), and receipt of PSA test in the past 2 years (yes vs no). A logistic regression model examining the association between PPC and PSA testing assessed moderation using an interaction term, controlling for sociodemographic variables (e.g., age, income, insurance status), family/personal cancer history, cancer risk perceptions, spirituality, and social support.
Results: Overall, 67% of respondents were employed, 39% endorsed ideal PPC, and 73% had a PSA test in the past 2 years. Employed men comprised 68% of those screened. Moderation was significant; employed men reporting nonideal PPC were less likely to have had a PSA test than employed men reporting ideal PPC (OR: 0.262, $CI_{95\%}$ = 0.097-0.708). For unemployed men, there was no significant association between PPC and having had a PSA test in the past 2 years.

Conclusion: Ideal PPC may be important to effectively mitigate unique employment-related patient concerns and spur PSA testing for employed Black men. Ideal PPC may be developed by providers building trust with patients, asking them about concerns, verifying their understanding, and engaging them in shared decision-making that respects their values. Employee wellness programs, health insurance companies, cancer centers, cancer survivors, church leaders, and health ministries can work to improve PPC by encouraging patients to have open discussions about prostate cancer with their providers by sharing concerns and asking questions. PSA testing may be cost-prohibitive for unemployed men regardless of PPC; more work is needed to reach this group.

#4184

Congruent views among substance use treatment center leadership on organizational readiness to implement a tobacco-free workplace program is linked to provider uptake of non-cigarette tobacco use treatment

Brian J. Carter[1], Tzuan A. Chen[2], Maggie Britton[1], Isabel Martinez Leal[1], Virmarie Correa-Fernández[2], Anastasia Rogova[1], Bryce Kyburz[3], Teresa Williams[3], Kathleen Casey[3], Lorraine R. Reitzel[1]. *[1]Health Disparities Research, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Psychological, Health, & Learning Sciences, University of Houston, Houston, TX,[3]Integral Care, Austin, TX*

Purpose: Tobacco use, linked to 17 cancers, is the leading cause of preventable death in the US. Despite elevated tobacco use among patients, substance use treatment centers (SUTCs) do not routinely address tobacco use. A tobacco-free workplace program (TFWP) implemented in SUTCs included tobacco-free policy guidance, provision of resources, and education for providers on evidence-based tobacco use treatment, which emphasized use of the 5As: Asking about tobacco use, Advising to quit, Assessing willingness to quit, Assisting with quitting, and Arranging follow-up. Congruent SUTC leadership views on readiness for TFWP implementation may forecast greater organizational support for implementation and thus enhanced provider uptake. Given the increasing use of non-cigarette tobacco products, this study examined associations between congruent views among SUTC leadership on readiness to

implement the TFWP and changes in providers' delivery of the 5As for non-cigarette tobacco-using patients (i.e., uptake) from pre- to post-program implementation.
Methods: Post-enrollment but before TFWP implementation, CEOs and Directors from each of 15 participating SUTCs (n=84) completed the Organizational Readiness for Implementing Change (ORIC), which has an overall readiness score and 5 subscale scores (resource availability, change efficacy, change valence, change commitment, and task knowledge). Center-level ORIC congruence was measured by calculating the difference between CEO-reported ORIC and mean Director-reported ORIC scores. Providers from each SUTC completed pre- and post-implementation surveys (pre n=259, post n=194) on their delivery of the 5As to non-cigarette tobacco-using patients during the prior month. Generalized linear regression analyses explored the effect of ORIC congruence on changes in the use of each of the 5As over time.
Results: Use of each of the 5As increased over time. Providers from SUTCs with more leadership congruence on (a) task knowledge and overall readiness had greater increases in Assisting with quitting and (b) resource availability, change efficacy, task knowledge, and overall readiness had larger increases in Arranging follow-up.
Conclusion: Reducing the research-to-practice translation gap in tobacco control through TFWP implementation in settings where users receive care is a critical cancer prevention strategy. TFWPs may facilitate greater provider uptake of evidence-based treatment and more effectively address patients' non-cigarette tobacco use in SUTCs by purposefully aligning leadership support for change. Strategies to align leadership support may include convening CEOs and Directors to identify multi-level organizational barriers and facilitators and engage in group problem-solving with respect to any barriers.

Inclusive basic and advanced translational laboratory research competencies for research in cancer biology and therapeutics
Wafik S. El-Deiry, Andrew George, Francesca Di Cristofano, Praveen Srinivasan, Lindsey Carlsen, Kelsey E. Huntington, Arielle De La Cruz, Leiqing Zhang, Marina Hahn, Shuai Zhao, Attila Seyhan, Bradley D. DeNardo, Aaron W. P. Maxwell, Dae Hee Kim, Alex Raufi, Hina Khan,

Stephanie L. Graff, Don S. Dizon, Christopher Azzoli, Abbas E. Abbas, Roxanne Wood, Rishi R. Lulla, Howard P. Safran, Benedito A. Carneiro, Arunasalam Navaraj, Xiaobing Tian, Shengliang Zhang, Lanlan Zhou.
Legorreta Cancer Center at Brown University, Providence, RI

Our Laboratory was established in 1994 at Univ. of Pennsylvania. Lab members demonstrated initial competencies by performing cell culture, western blots, immunofluorescence, and flow cytometry showing induction of p53/p21(WAF1) in cells treated with chemotherapy. Years later, our Laboratory of Translational Oncology & Experimental Cancer Therapeutics moved to Penn State Univ., Fox Chase Cancer Center/Temple Univ. and then Brown Univ. By 2020, with desire for inclusiveness (everyone succeeds), scientific rigor/reproducibility mandated by NIH, and as a training and mentoring activity (lab scientists/trainees/students mentoring others at High School level and beyond), we established a process for onboarding and training new cancer researchers. By Fall of 2022, there were 17 current Brown University undergraduate students (10 receiving research credit and 7 not receiving credit), HS students, 7 graduate students (PhD, masters, MD/PhD), and 6 medical students working with collaborating faculty at our laboratory at Brown's Legorreta Cancer Center. After completion of biosafety training, and required trainings such as by IACUC, new lab members complete basic competencies in cell culture, cell viability, and western blot analysis that include technical, presentation quality output, and quantitative/statistical rigor to satisfy current standards for journal publication. For cell culture this includes pathogen free conditions, authentication, attention to details of routine procedures, documentation of morphology, freezing, thawing, passaging, seeding density, and managing cell populations to not run out of cells. Cell viability assessment includes attention to culture conditions, synergy analysis, data robustness, and presentation, and for western blots attention to quality of blots, protein quantification, loading, labeling, antibody specificity and sensitivity controls, presentation at 2022 standards, conventions for splicing, and issues with reproducibility including biological replicates, and generalizability. Additional and advanced competencies include RT-PCR, long-term colony assays, 3-D cultures (spheroids, organoids), transfection (overexpression, knockdown, CRISPR), co-culture and triculture with immune cells and fibroblasts, cytokine profiling, in vivo studies, in vivo

imaging, immunohistochemistry, flow cytometric analysis, single cell techniques, viral infection, circulating tumor cell isolation, blood immune and cytokine analysis, and work with transgenic organoids and inducible cancer predisposing alleles. Modeling the tumor microenvironment, relevance to human cancer and translational directions are emphasized. Shared online lab resources, protocols, practices, videos, and manuscripts are available for lab members. The framework herein may be of interest to others involved in similar training programs.

#4186

Underrepresentation of low- and middle-income country affiliated authors in NCI-supported cancer research

Linsey Eldridge, Elise Garton, Kalina Duncan, Satish Gopal. *National Cancer Institute, Rockville, MD*

Introduction: We conducted a bibliometric analysis to assess authorship of recent publications involving collaborations in low- and middle-income countries (LMICs) supported by the National Cancer Institute (NCI) of the National Institutes of Health (NIH).
Methods: We identified active NCI grants awarded directly to LMIC institutions or to US institutions with a collaborator site or sites exclusively in LMICs between 2015-2019 in NIH Query View Report (QVR). Grants were linked to resulting publications using Dimensions for NIH. Because grants may have been active in 2015 while beginning in earlier years, we analyzed any linked publications from 2011 to 2020. Publications with missing author information were excluded. Author institutional affiliation was used to classify author country income level as defined by the World Bank. Authors with multiple institutional affiliations from a high-income country (HIC) and LMIC were classified as such. Relative citation ratio (RCR) and Altmetric data from Dimensions were used to compare citation impact measures using the Wilcoxon rank sum test.
Results: NCI funded 159 grants to US institutions exclusively with LMIC collaborators and five awards directly to institutions in LMICs from 2015 to 2019, resulting in 2,428 publications between 2011 and 2020, of which 49% had at least one author affiliated with an LMIC institution. Of all publications, 78% and 83% had a first and last author with high-income country (HIC) affiliation, respectively. Publications with HIC-affiliated last

authors had significantly higher median RCR and Altmetric attention scores than publications with LMIC-affiliated last authors (p=0.0134 and p=0.0004, respectively). Publications with HIC-affiliated first authors had significantly higher Altmetric scores than publications with LMIC-affiliated first authors (p=0.001).
Conclusion: LMIC-affiliated authors are represented on only approximately half of publications resulting from NCI grants awarded directly to LMIC institutions or to US institutions with LMIC collaborators, and rarely in the first or last author position. LMIC-affiliated authors also receive less bibliometric attention when represented. Increased scientific capacity and more equitable collaboration should be critical priorities for the cancer research community working in LMICs moving forward.

#4187

Development of a virtual platform to improve global access to oncology education & combat healthcare inequities

Yan Leyfman[1], William B. Wilkerson[2], Shubhadarshini G. Pawar[3], Muskan Joshi[4], Gayathri P. Menon[4], Pallavi Pai[4], Sean Jackewicz[5], Alexandra van de Kieft[6], Chandler Park[7]. *[1]Icahn School of Medicine at Mount Sinai South Nassau, Rockville Centre, NY,[2]Dickinson College, Carlisle, PA,[3]Shree Vighnaharta Superspecialty Hospital, Maharashtra, India,[4]Tbilisi State Medical University, Tbilisi, Georgia,[5]Mercer University School of Medicine, Macon, GA,[6]Cornell University, Ithaca, NY,[7]Norton Cancer Center, Louisville, KY*

Introduction: Social media has emerged as a formidable outlet for medical information through its vast global reach of individuals of all educational levels and socioeconomic statuses but especially those in resource limited regions. However, misinformation has presented a universal challenge and contributed to adverse medical outcomes. *MedNews Week*, a virtual education platform, was developed to combat medical misinformation, especially within hematology-oncology, and contribute to global health education by providing the mainstream public with free access to its weekly programming. Keynote Conference is a weekly show featuring live presentations from hematology-oncology's premier global leaders discussing the latest developments in their field before a global mainstream

audience. The goal of this study was to assess the global reach and impact of MedNews Week's programming.
Methods: From January to June 2022, *MedNews Week* hosted 22 global leaders (h-index = 60) as Keynote Speakers discussing the latest developments in oncology. Viewership, impressions, and outreach data was collected from *MedNews Week*'s and its respective members' social media accounts and with the help of Symplur, data was analyzed to provide insight on global reach and engagement. A mixed-method approach was used to analyze engagement.
Results: *MedNews Week* generated over 11.9K tweets, 5.7K retweets, and 41 million Twitter impressions over this six-month time period reaching over 54 countries. A network analysis of *MedNews Week's* main accounts demonstrated cross-community engagement on Twitter. Hashtags successfully showcased Keynote Conferences, expanded global audience viewership, and enhanced overall engagement. To estimate the level of incoming and outgoing communications between *MedNews Week* and our audience, we focused our analysis on the *MedNews Week* Twitter chat organizers (@yleyfman and @CParkMD) and supporting researcher (@ShimaghavimiMD). We identified these usernames on the network map. Not all other participants were identified. We have also noticed a steady increase in the number of attendees at Keynote Conference.
Conclusion: Given *MedNews Week'*s continued growth in global viewership and international reach, it has emerged as a viable platform to combat medical misinformation, especially in lower socioeconomic regions. Although internet access is one of the main barriers to high quality medical information, as technology involves and internet access becomes more widespread, the positive impact of medical education platforms like *MedNews Week* will continue to grow. The platform's ability to showcase global leaders to a mainstream audience for free offers a practical approach to combat educational inequity. *MedNews Week* has the potential to positively impact global hematology-oncology education.

#4188
Multifaceted approach to engaging basic cancer scientists in community-based research
Namoonga M. Mantina, Juan Contreras, Monica Yellowhair, Cynthia Miranti, Jennifer Hatcher. *University of Arizona Cancer Center, Tucson, AZ*

Background**:** The University of Arizona Cancer Center (UACC) is the only NCI-designated Comprehensive Cancer Center in Arizona, serving a 5-county catchment area that is approximately 40% Hispanic/Latinx. To ensure that UACC is conducting culturally relevant and meaningful research that is aligned with community priorities, we established the Research Outreach for Southern Arizona (ROSA) program. The ROSA program aims to facilitate bidirectional learning opportunities between scientists and the community, focusing on cancer biology and basic science. Multiple approaches were taken to engage cancer biology researchers with the communities in the catchment area with an ultimate aim of developing Basic science Community based participatory research projects.
Method: Through a partnership between the UACC's Office of Community Outreach and Engagement and the Cancer Biology Program, the ROSA program employed multiple strategies to educate and engage basic scientists on best practices to effectively engage community members, which included: collaborative working groups, meet the scientist learning opportunities, student and community ambassadors, and creation of the ROSA Café Series (community conversations with UACC basic scientist). These strategies facilitated avenues for scientists to educate, learn from, and engage with the community.
Results: The working group consisted of UACC basic scientists and community members that helped develop a ROSA survey that will be used to gain community input and learn more about community research priorities, knowledge base and culturally appropriate research. Additionally, ROSA community and student ambassadors were enrolled into a curriculum where they learned fundamentals of cancer biology via conversations with the basic scientists and provided opportunities for scientists to practice using lay language to express scientific ideas. Bidirectional learning opportunities were also presented within the structure of the ROSA Café's with the ultimate goal of having community members learn directly from the researchers about current and potential projects. These strategies have ultimately led to interactions between the basic science and lay community that serve as a basis for future basic science projects that are community inspired and have potential for high community input and impact.
Discussion: Helping basic scientists integrate their science more fully into communities has the potential for advancing science and promoting health

equity in minoritized communities. This partnership is predicated on preparing basic scientists to interact comfortably and effectively with community members, necessitating common language and fuller understanding of community ways of knowing. The strategies employed and explicated here provide a model for cancer centers to develop culturally and community relevant basic science programs.

#4189

Community cancer scientist program: A model for community member advocacy for cancer research

Brooke M. Hensel[1], Fern J. Webb[2], Eduardo Ibarra[3], Carolina Aristizabal[4], Rosa Barahona[5], Diana J. Wilkie[6], Sandra Suther[7], Lourdes Baezconde-Garbanati[3], Mariana C. Stern[3]. *[1]University of Florida, Orlando, FL,[2]University of Florida, Jacksonville, FL,[3]University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA,[4]University of Sothern California Norris Comprehensive Cancer Center, Los Angeles, CA,[5]University of California Norris Comprehensive Cancer Center, Los Angeles, CA,[6]University of Florida, Gainesville, FL,[7]Florida Agricultural and Mechanical University, Tallahassee, FL*

Community Cancer Scientist (CCS) programs are designed to educate community members on the importance and ethical conduct of clinical research that serves to connect researchers and the general population. This type of program allows research advocates to interact with their community, helping minoritized individuals to form trust with cancer researchers and in clinical trials.The purpose of our study was to develop and evaluate a novel bi-coastal and bilingual program to inform, educate and empower community members to become cancer research advocates in Florida (FL) and California (CA). Our program was tailored for African American (AA) and Hispanic/Latinx (H/L) adults. Primary objectives are to increase person power for cancer research advocacy and increase multi-directional communication between cancer advocates with cancer survivors, community members, academic scientists and policy makers. The CCS program is a 13-week program implemented 100% virtual by the FL-CA Cancer Research, Education and Engagement (CaRE^2) Health Equity Center, a bi-coastal partnership between the Florida A&M University,

University of Florida, and University of Southern California where participants learned about cancers that disproportionately impact AA and H/L adults. Participants completed surveys at program start, midway, and end to assess knowledge gained and satisfaction, and a mentored advocacy project for community implementation. Five months after program end, we surveyed participants on impact and to provide support for their research advocacy.To date, a total of 26 adults have graduated from our program. We present data from the 2022 CCS cohort (N = 20) that included participants from FL and CA, which are among the top five states in the U.S with the largest AA and H/L populations. Regarding race and ethnicity, 13 participants were AA, 6 H/L, and 1 White, with 80% female participants. This cohort had 90% program completion (N = 18) and 5 advocacy projects: 2 on breast cancer, 1 on lung cancer, 1 on pancreas cancer, and 1 on prostate cancer. More than 50% of participants showed increased knowledge regarding cancer incidence, mortality and standard screening practices while program satisfaction remained high at end of program. Participants also provided feedback and recommendations such as offering a hybrid model for participants to interact with cancer researchers, and desired visiting CaRE^2 scientific laboratories for hands-on engagement. In conclusion, we present findings from a novel virtual CCS bi-coastal and bilingual training program tailored for AA and H/L adults that can foster multi-directional communication between cancer research advocates with multiple stakeholders. We also discuss how these research advocacy cancer programs can be tailored to focus on specific initiatives important to eliminate cancer health disparities such as or examining cancer health disparities from a lifespan perspective.

#4190

Current educational needs in the management of patients with advanced NSCLC: Results of a US case-based survey

Emily Belcher, Gregory D. Salinas, Asa Renfroe. *CE Outcomes, LLC, Birmingham, AL*

According to the American Cancer Society, over 80% of lung cancers present in the form of non-small cell lung cancer (NSCLC). This study evaluated the current attitudes, practice patterns, and educational gaps of United States oncology clinicians to better understand clinician educational

needs in the treatment of advanced NSCLC. A case-based survey was developed in collaboration with an expert in NSCLC. The survey was then evaluated by practicing clinicians within the target audience with experience managing patients with advanced NSCLC. The survey was programmed on a Web-based platform and fielded in March 2022. Study inclusion criteria consisted of clinicians who see at least 1 patient with NSCLC per month and at least 1% of NSCLC patients having advanced disease.

Responses were gathered from oncologists (n = 135), oncology nurse practitioners/physician associates (NPs/PAs) (n = 43), and oncology nurses (n = 52) for analysis. The most important factors regarding treatment choice for a patient with advanced NSCLC were overall and progression-free survival associated with the treatment regimen, response rate, and treatment safety profile. 90% of clinicians reported referring to clinical practice guidelines when managing patients with NSCLC, most commonly NCCN. When managing patients with advanced NSCLC, clinicians reported being very comfortable monitoring for and managing the adverse effects of therapy as well as discussing the risks involved. Oncologists, but particularly NPs/PAs, were less comfortable determining optimal second and third-line treatment options. When presented with a second-line treatment patient case scenario, clinicians were split in their treatment approach—with 25% of oncologists, 30% of NPs/PAs, and 46% of nurses referring the patient for a clinical trial.

Oncologists' and NPs/PAs' top goal in managing and treating advanced NSCLC was to extend survival, whereas nurses prioritized maintaining quality of life. In terms of barriers to treatment, clinicians overall highlighted obtaining biomarker testing for diagnosis, adverse effects of available treatments, and managing adverse effects as most significant. Nurses considered lack of patient support systems, limitations to accessing care, and insurance status as the most significant barriers.Oncologists were most interested in future education covering appropriate sequencing of treatment and new/emerging therapies. NPs/PAs were most likely to choose education on new/emerging treatments and side effects. Nurses demonstrated the most interest in side effects and oncology genetics. Clinicians are requesting education on topics aligned with practice variation identified in this study. Once past initial management, there is little consensus on the most appropriate treatment to use. Expert opinion and

guidance on progression of therapy is important for future education initiatives.

#4191

Assessing performance of biomarker extraction from electronic health records: Data augmentation methods for a hierarchical self-attention network (HiSAN)

Shalini Priya, Alina Peluso, Mayanka Chandra Shekhar, Ioana Danciu, Jordan Miller, Heidi A. Hanson. *Oak Ridge National Laboratory, Oak Ridge, Tennessee, TN*

Background: Extraction of HER2 status from electronic health records (EHR) may expedite clinical trials matching and be used for survivorship research. Deep learning (DL) algorithms have potential to extract this data; however, inherent class imbalance leads to reduced model performance. We compare state of the art strategies to handle class imbalance in models trained to extract HER2 status. This comparative analysis may be used as a guideline for HER2 extraction.
Methods: 680,117 pathology reports collected from 2017-2021 by the National Cancer Institutes' Surveillance, Epidemiology, and End-Results (SEER) program were used for this study. Pathology reports are manually labelled by cancer registrars as HER2 -, HER2+, or Unknown (class ratio 65%, 11%, 24% respectively). We compare six data augmentation (DA) methods: balanced frequency weighting, ROS while up-sampling HER2+ by 595%, RUS while down-sampling HER2- by 83% , SMOTE, ADASYN, and SMOTE-Tomek. As a comparison we consider the HiSAN model i.e., a DL architecture currently used by SEER for automatic classification of reports.
Result: Applying DA strategies did not improve the performance of the HiSAN model (Table 1). Frequency based class-weighting (Acc=0.78), ROS (Acc=0.81), and RUS (Acc=0.80) perform worse than the baseline model, suggesting simple data augmentation methods do not boost performance for this task. Advanced oversampling with SMOTE (Acc=0.88) and ADASYN (Acc=0.88) perform better than simple approaches, but do not improve the predictive accuracy of the baseline HiSAN. Table 1

Method	Accuracy	Sensitivity	Specificity	Precision

	(Acc)			
HiSAN (Baseline)	0.8898	0.7583	0.8944	0.8507
Frequency class weighting	0.7826	0.8033	0.8932	0.7040
Random Over Sampling (ROS)	0.8057	0.7672	0.8883	0.7130
Random Under Sampling (RUS)	0.8042	0.7883	0.8930	0.6902
Synthetic Minority Oversampling Technique (SMOTE)	0.8796	0.7341	0.8827	0.8340
Adaptive Synthetic Sampling (ADASYN)	0.8764	0.7467	0.8863	0.8142
SMOTE-Tomek	0.8823	0.7620	0.8956	0.8200

Conclusion: Common DA methods do not improve the performance of the HiSAN biomaker method. While the overall accuracy of the baseline HiSAN model is quite high, other methods for improved accuracy should be explored.

***CervicalMethDx*: A precision DNA methylation test to identify advanced disease risk in cervical cancer screening algorithms**

Laura Palmieri[1], Fernando T. Zamuner[1], Dieila Giomo De Lima[1], Keerthana Gosala[1], Eli Winkler[1], Yash Prashar[1], Ana Purcell-Wiltz[2], Amanda García-Negrón[2], Ashley Ramos-Lopez[3], David Sidransky[1], Mariana Brait[1], Rafael Guerrero-Preston[4]. *[1]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]LifeGene-Biomarks, Inc, San Juan, Puerto Rico,[3]LifeGene-Biomarks, Inc, San Juan, PR,[4]LifeGene-Biomarks, Inc, Baltimore, MD*

Cervical cancer is one of the most common cancers in women. Despite progress in prevention through Human Papilloma Virus [HPV] vaccination and success in early detection of cervical cancer through cytologic screening and HPV detection, there remains an unequal burden in low-resource settings in developed and developing countries. Applying novel

methylation-based detection methods, we validated a panel of three human methylated genes (*ZNF516*, *FKBP6* and *INTS1*) on discarded cervical liquid cytology samples from clinical laboratories in the United States during the development of the *CervicalMethDx* test. We hypothesized that the *CervicalMethDx* test can identify HPV positive women most likely to be diagnosed with Cervical Intraepithelial Neoplasia (CIN) grades 2 and 3 by anatomic pathologists, before they are referred to colposcopy-driven biopsies. We assessed DNA methylation by Quantitative Real Time Methylation Specific PCR (QMSP) analysis of sodium bisulfite-modified genomic DNA. Primers and probes were previously designed to specifically amplify the promoters of the 3 genes of interest and the promoter of a reference gene, *β-actin*, to assess DNA input. We performed blinded retrospective studies on well-characterized, discarded, HPV-positive clinical samples in PreservCyt sample transport media (Thin Prep, Hologic), comparing DNA methylation levels in samples from CIN2 and CIN3 cases (346), and 120 controls without evidence of Intraepithelial Lesions or Malignancy (NILM) as an endpoint. Our results showed that the *CervicalMethDx* test can correctly classify 96% of CIN2 (n=197) samples with 93% Sensitivity, 100% Specificity, and an AUC of 0.96 as well as 95% of CIN3 (n=149) samples with 91% Sensitivity, 100% Specificity, and an AUC of 0.96. Moreover, the assay correctly classified 94% of CIN2-CIN3 samples combined (n=346) with 92% Sensitivity, 100% Specificity, an AUC of 0.96, and a 100% positive predictive value (PPV), when compared to samples with NILM (n=120). The *CervicalMethDx* test high PPV supports the addition of this low-cost molecular test to cervical cancer screening algorithms worldwide. Our results suggest that the *CervicalMethDx* test is a new and valuable tool to stratify HPV positive women prior to colposcopy-driven biopsies in developed countries and ablative treatment in developing countries, most of which are unnecessary. These results warrant further evaluation of the *CervicalMethDX* test in prospective, population-based studies, assessing the use of precision DNA methylation algorithms to triage women before colposcopy-driven biopsies or ablative treatments worldwide.

N-NOSE technology based on *C. elegans* olfaction. Multi-cancer early detection with high sensitivity using urine. Pancreatic-cancer-specific early detection with high sensitivity using urine

Eric Di Luccio[1], Takaaki Hirotsu[2]. *[1]Hirotsu Bio Science INC., Fujisawa city, Japan,[2]Hirotsu Bio Science INC., Tokyo, Japan*

N-NOSE (Nematode Nose) is a cancer screening test based on the chemotactic characteristics of the nematode *C. elegans*. *C. elegans* shows avoidance of the urine of healthy individuals while displaying a chemotactic attraction toward the urine of patients with 15 types of cancer (stomach, colon-rectum, lung, breast, pancreas, liver, prostate, uterus, esophagus, gallbladder, bile duct, kidney, urinary bladder, ovary, oropharynx) rendering N-NOSE a primary multi-cancer screening test. N-NOSE has a high sensitivity of 87.5% and 90.2% specificity, on average, from early stage 0-I. N-NOSE is non-invasive because it relies on a urine sample and is affordable (JPY 13,800, ~USD 100).N-NOSE by Hirotsu Bio Science has been available in Japan since late 2020 and is a commercial hit with over 250,000 screenings performed, rapidly increasing. In this presentation, we outline the N-NOSE technology and business in Japan. We review N-NOSE clinical research and critical findings compared to competitors that highlight its excellent performance as a non-invasive primary cancer screening for early detection. N-NOSE is a multi-cancer early detection test. Next, we introduce an evolution of N-NOSE for identifying the cancer type. Pancreatic cancer is the 12th most common cancer worldwide but remains one the deadliest cancer with a 5-year relative survival rate at only 11%, all stages combined. An affordable, non-invasive, and highly sensitive early-stage pancreatic cancer screening test is sorely needed. As an evolution of N-NOSE we genetically engineered *C. elegans* by knocking out in AWC olfactory neurons a specific olfactory receptor (GPCR), triggering a chemotactic response particular to the only pancreatic cancer urine specimen at an early stage. In this study, we outline, for the first time, the critical discovery of *cr-4* GPCR in AWC, which is crucial for a specific chemotaxis response to the urine of patients with pancreatic cancer. Next, we briefly conclude by outlining the link between N-NOSE primary cancer screening followed by N-NOSE cancer type identification, effectively completing the whole cancer screening and identification process in a non-invasive way.

#4194

The FuSion Project of Pan-Cancer Early Screening in Chinese-- An integrative study by Fudan University and Singlera

Chen Suo[1], Renjia Zhao[1], Yanfeng Jiang[1], Yunzhi Zhang[2], Qiye He[2], Zhixi Su[2], Rui Liu[2], Li Jin[1], Xingdong Chen[1]. *[1]Fudan University, Shanghai, China,[2]Singlera Genomics (Shanghai) Ltd, Shanghai, China*

Background: Cancer is the leading cause of premature deaths. Screening in the population can effectively improve the prognosis by diagnosing cancer early. Previous studies have found that cancer biomarkers, for example, ctDNA methylation and protein biomarkers are clearly associated with the occurrence and development of cancer. To evaluate the performance of reported biomarkers for cancer early screening in real world, we launched an integrative study by Fudan University and SInglera for pan-cancer early detectiON (FuSion) project since 2021. Method: The FuSion Project (NCT05159544) is a prospective and multicenter cohort study of pan-cancer screening in Chinese population. We will construct a stepwise model of risk stratification for screening of multiple cancer types, including lung, esophagus, stomach, liver, pancreatic and colorectal cancers. A total of 50,137 individuals recruited in the Taizhou Longitudinal Study (TLS) between 2012 and 2021 are investigated. Eligible participants are aged 20-75 years and without

history of cancer. They have completed a questionnaire and provided blood samples for baseline tests, which measure a total of about 50 indicators in the routine blood work, blood biochemistry, and serum cancer biomarkers, such as carbohydrate antigen 19-9 and carcinoembryonic antigen. Informed consent is obtained from all participants. We build risk stratification models based on risk factors collected in the questionnaire and from baseline test results for each cancer type, respectively. Then, 10,000 high-risk- and 5,000 low-risk individuals of cancers are identified by the cancer-specific risk stratification model. They will be screened by the PanSeerX assay using cancer-related DNA methylation markers, and medically followed-up for at least two years. Sensitivity, specificity, positive- and negative-predictive values of the screening models will be determined based on the true cancer incidences. Finally, we will validate the cancer screening strategies using 10,000 average-risk participants recruited from multiple centers by regular checkups and from other large-scale cohort studies.

#4195

Spatially resolved single cell transcriptomic profiling in formalin-fixed paraffin-embedded (FFPE) tissues

Jiang He, Justin He, Timothy Wiggin, Rob Foreman, Renchao Chen, Nicolas Fernandez, George Emanuel. *Vizgen, Cambridge, MA*

Formalin-fixed paraffin-embedded (FFPE) tissues are the most widely used clinical sample types in histology and molecular diagnosis, but these samples are often challenging for single-cell transcriptomic analysis due to RNA degradation and protein crosslinking. A spatial transcriptomics technique with high detection efficiency and single molecule resolution is required in order to accurately profile the gene expression in FFPE samples in situ. Vizgen's MERSCOPE platform, built on multiplexed error robust in situ hybridization MERFISH technology, directly profiles intact tissue's transcriptome with subcellular spatial resolution. Here, we demonstrate the FFPE MERSCOPE workflow in tissues from 10 mouse and human samples, including archival clinical samples. In each sample, hundreds of thousands of cells were captured with >100 million transcript counts, generating detailed spatial transcriptomic data for the profiled genes in each sample. A comparison of FFPE and matched fresh frozen samples indicated that the FFPE workflow performs similarly in detection efficiency as compared to the fresh frozen protocol. We further demonstrated the MERSCOPE FFPE workflow is compatible with protein imaging by performing simultaneous protein-based cell boundary staining with MERFISH to accurately profile gene expression and map cell types in archival clinical human samples. Finally, we constructed a spatially resolved single cell atlas across eight major tumor types, mapped and cataloged different cell types within the tumor microenvironment and systematically characterized the gene expression among cells. This study demonstrates the potential for spatially resolved transcriptomic profiling of FFPE samples at single cell level to contribute to a wide range of biomedical research areas, including many applications to study human diseases.

Background: Previous studies have investigated the association between reproductive factors and lung cancer risk; however, findings have been inconsistent. This study aims to assess the association between reproductive factors with lung cancer incidence and mortality among Asian women.
Methods: A total of 308,949 female participants with a mean age of 55.13 from 11 prospective cohorts and four Asian countries (Japan, Korea, China, and Singapore) in the Asia Cohort Consortium (ACC) were included. Cox proportional hazards regression models were used to estimate the hazard ratios (HR) and 95% confidence intervals (CIs).
Results: A total of 3,119 primary lung cancer cases and 2,247 lung cancer deaths were identified with a mean follow-up of 16.4 years. Parous women had a lower risk of lung cancer incidence and mortality as compared with nulliparous women, with HRs of 0.82 (95% CI = 0.70 - 0.96) and 0.78 (95% CI = 0.65 - 0.94). Corresponding HRs were lowest among women with 1-2 children, with HRs of 0.78 (95% CI = 0.66 - 0.93) and 0.72 (95% CI = 0.59 - 0.87) for lung cancer incidence and mortality. The protective association of parity and lung cancer incidence was greater among ever-smokers (HR=0.66, 95% CI = 0.49 - 0.87) than in never-smokers (HR=0.90, 95% CI = 0.74 - 1.09) (*P*-interaction = 0.029). Compared with age at first delivery ≤20 years, older age at first delivery (≥26 years) was associated with a lower risk of lung cancer incidence and mortality. Compared with age at menopause <45 years, older age at menopause (≥55 years) was associated with a decreased risk of lung cancer mortality (HR=0.75, 95% CI = 0.58 - 0.96). Women who ever used hormone replacements had a higher likelihood of developing non-small cell lung cancer (HR = 1.30, 95% CI = 1.01 - 1.67), compared to those who never used hormone replacements.
Conclusions: Distinct from Western women, Asian parous women, especially those who have 1-2 children had a lower risk of lung cancer incidence and mortality compared with nulliparous women. Future studies are needed to assess the underlying mechanisms, the relationships within these female reproductive factors, and the potential changes in smoking habits over time.

#4201

Associations of pre-diagnostic serum liver enzymes levels with lung cancer risk: results from the Southern Community Cohort Study

Shuai Xu[1], Hui Cai[2], Jie Wu[2], Hyung-Suk Yoon[2], Regina Courtney[2], Xiao-Ou Shu[1], William J. Blot[2], Wei Zheng[1], Qiuyin Cai[1]. *[1]Vanderbilt University, Nashville, TN,[2]Vanderbilt University Medical Center, Nashville, TN*

Introduction: Lung cancer is the leading cause of cancer death in the United States (U.S.). Lung cancer disproportionately affects African Americans (AAs) more than other racial/ethnic groups. Previous studies have linked liver diseases to lung cancer risk; however, few studies have evaluated the associations of circulating liver enzyme levels with lung cancer risk. In this study, we evaluated the associations of the serum alanine transaminase (ALT) and alkaline phosphatase (ALP) levels with the risk of subsequently developing lung cancer.
Methods: We conducted a nested case-control study within the Southern Community Cohort Study, a well-conducted prospective cohort study in the southern U.S. mainly consisting of low-income AAs and European Americans (EAs). We included 552 incident lung cancer cases and 1,039 controls individually matched on age, sex, recruitment sites, and date of blood draw. Baseline serum levels of ALT and ALP were measured using the Beckman Coulter clinical chemistry analyzer. Conditional logistic regression and generalized estimating models were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) after adjusting for age, education, household income, body mass index (BMI), smoking status, pack-years, alcohol consumption, physical activity levels, history of chronic obstructive pulmonary disease, hypertension, and diabetes.

Results: Higher serum levels of ALT were associated with a lower overall risk of lung cancer. Compared with the lowest tertile, participants in the second and third tertiles had OR (95% CI) of 0.74 (0.48-1.14) and 0.47 (0.28-0.78) ($P_{trend} < 0.01$). The inverse association was observed in both AAs and EAs. However, the inverse associations between serum ALT levels and lung cancer risk were more evident among men [$OR_{T3\ vs\ T1} = 0.36$ (0.18-0.70)], current smokers [$OR_{T3\ vs\ T1}$ =0.65 (0.47-0.90)], participants with lower BMI [$OR_{T3\ vs\ T1}$=0.55 (0.38-0.79)], or lower physical activity [$OR_{T3\ vs\ T1} = 0.55$ (0.37-0.83)]. Stratified analyses by time interval between blood collection and lung cancer diagnosis showed that the inverse associations were observed in both those diagnosed within [$OR_{T3\ vs\ T1}$ =0.48 (0.23-1.00)] and after [$OR_{T3\ vs\ T1} = 0.36$ (0.19-0.69)] a median follow up time of 3 years. The serum ALT level was not associated with overall lung cancer; however, higher serum ALP levels were significantly associated with increased lung cancer risk among AA men [$OR_{T3\ vs\ T1} = 1.98$ (1.18-3.34)].
Conclusion: Our results indicate that in a predominantly low-income AA and EA population, serum ALT levels may be related to a lower risk of lung cancer. Further studies are warranted to confirm our findings and elucidate the potential underlying mechanisms of the associations.

#4202
Kidney function and risk of renal cell carcinoma
Karine Alcala[1], Nicolas Alcala[1], Richard Martin[2], Paul Brennan[1], David Muller[3], Hilary A. Robbins[1], Mattias Johansson[1]. *[1]Genomic Epidemiology Branch, International Agency for Research on Cancer, Lyon, France,[2]Bristol Medical School, University of Bristol, Bristol, United Kingdom,[3]Imperial College London, London, United Kingdom*

Background: The relationship between kidney function and risk of renal cell carcinoma (RCC) is not well understood. In this study, we evaluated the association between estimated glomerular filtration rate (eGFR) and risk of incident RCC, and assessed whether this association depends on time between eGFR measurement and RCC diagnosis. We also sought to evaluate if eGFR may be useful to predict RCC risk.
Methods: We conducted this study in the UK Biobank cohort based on 440,983 participants of whom 984 were diagnosed with RCC during 4,552,747 person-years of follow-up. The temporal relation between kidney function and RCC was evaluated with flexible parametric survival models for eGFR calculated from creatinine, cystatin C and both, adjusted for C-reactive protein (CRP) and common RCC risk factors. We also assessed the benefit of combining CRP and eGFR with a published RCC risk prediction model by estimating calibration and discrimination using a resampling algorithm as internal validation.
Results: We found that a lower eGFR - an indication of poor kidney function - was associated with higher RCC risk when measured up to five years prior to diagnosis. We estimated the RCC hazard ratio per standard deviation decrease in eGFR when measured one year before diagnosis at 1.22 (95% confidence interval [95% CI]: 1.11-1.34), and at 1.14 (95% CI: 1.05-1.19) when measured five years before diagnosis. The corresponding RCC HR for eGFR measured ten years before diagnosis was 1.03 (95% CI: 0.95-1.12). Adding eGFR to the RCC risk model provided a small improvement in risk discrimination 2 years before diagnosis with a C-index of 0.76 (95% CI: 0.71-0.81) compared to the published model (0.73, 95% CI: 0.68-0.79).
Conclusion: This study demonstrated that markers of kidney function are robustly associated with RCC risk when measured within the last five years leading up to diagnosis. However, kidney function markers do not seem to provide important improvements in RCC risk discrimination beyond established risk factors.

#4203

A prospective study of birth weight and prostate cancer risk: extended analysis in the Health Professionals Follow-up Study

Qinran Liu[1], Yiwen Zhang[2], Jane B. Vaselkiv[2], Lorelei A. Mucci[2], Edward L. Giovannucci[2], Elizabeth A. Platz[3], Siobhan Sutcliffe[4]. *[1]Department of Public Health Sciences, Miller School of Medicine, University of Miami, Miami, FL,[2]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, Boston, MA,[3]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[4]Department of Surgery, Washington University School of Medicine Division of Public Health Sciences, St. Louis, MO*

Introduction: Birth weight, a potential marker of the *in utero* hormonal and growth factor milieu, has been associated with an increased risk of prostate cancer (PCa) in some, but not all, previous studies. It was also associated with a non-significantly greater risk of advanced stage PCa (relative risk [RR] = 1.37, 95% confidence interval [CI]: 0.61-3.05 for ≥10 lbs compared to 7.0-8.4 lbs, *p*-trend = 0.087) in our previous analysis in the Health Professionals Follow-up Study (HPFS). However, these suggestive findings were based on a relatively small number of advanced stage cases and short follow-up. We have now updated our previous analysis of birthweight and PCa risk in the HPFS with an additional 14 years of follow-up.

Method: Birth weight was assessed by self-report on the 1994 follow-up questionnaire using pre-specified categories. PCa diagnoses were ascertained on each biennial follow-up questionnaire and confirmed by medical record review. Cox proportional hazards regression was used to evaluate the association between birth weight and PCa risk through 2016.

Result: Of the 17,949 eligible men who reported their birth weight in 1994, 3,167 were subsequently diagnosed with PCa. With the exception of a suggestive positive trend between increasing birth weight and high-grade PCa (RR_{adj} per pound: 1.06; 95% CI: 0.98-1.16; *p*-trend=0.15), no associations were observed between birth weight and risk of total, organ-confined, low-grade, advanced stage, lethal, or fatal PCa.

Conclusion: Overall, no association was observed between birth weight and PCa risk and mortality in this large prospective cohort study of US male health professionals.

Table 1. Associations between self-reported birth weight and prostate cancer in the Health Professionals Follow-up Study, 1994-2016

		Birth weight (lbs)					
		<5.5(<2,495 g)	5.5-6.9*(2,495-3,174 g)*	7.0-8.4*(3,175-3,855 g)*	8.5-9.9*(3,856-4,535 g)*	≥10.0*(≥4,536 g)*	Per 1 lb *(454g)* increase
Total prostate cancer	Cases/person-years	125/17,019	518/80,053	1,931/297,495	396/60,445	197/22,993	
	HR[a] (95% CI)	0.98 (0.81-1.18)	0.86 (0.78-0.95)	1.00	0.85 (0.76-0.95)	0.98 (0.84-1.13)	1.01 (0.96-1.05)
High-grade prostate cancer (Score	Cases/person-years	23/17,117	119/80,434	453/299,015	105/60,741	52/23,148	

4+3 and higher)							
	HR[a] (95% CI)	0.76 (0.50-1.16)	0.83 (0.68-1.03)	1.00	0.93 (0.75-1.16)	1.03 (0.76-1.39)	1.06 (0.98-1.16)
Advanced stage prostate cancer (T3b+) at diagnosis	Cases/person-years	4/17,135	29/80,516	109/299,370	25/60,811	12/23,195	
	HR[a] (95% CI)	0.53 (0.19-1.46)	0.91 (0.60-1.40)	1.00	0.98 (0.62-1.54)	1.02 (0.54-1.92)	1.08 (0.91-1.29)
Lethal prostate cancer	Cases/person-years	11/17,127	70/80,491	225/299,247	51/60,791	27/23,178	
	HR[a] (95% CI)	0.81 (0.43-1.50)	1.15 (0.86-1.52)	1.00	1.07 (0.78-1.47)	1.01 (0.66-1.54)	1.00 (0.89-1.13)
Fatal prostate cancer	Cases/person-years	10/17,551	59/82,316	197/307,363	43/62,246	23/23,996	
	HR[a] (95% CI)	0.88 (0.45-1.67)	1.17 (0.86-1.60)	1.00	1.11 (0.78-1.56)	1.03 (0.65-1.63)	1.00 (0.87-1.14)

RR=relative risk; CI = confidence interval. [a] Adjusted for age, calendar time, race, smoking status, family history of prostate cancer (yes or no), PSA testing in >50% of previous cycles (yes or no), physical activity, diabetes, diet (tomato sauce intake, coffee, and energy intake), alcohol intake, multivitamin use, vitamin E supplement use, and aspirin use.

Incidence of early-onset and average-onset colon cancer among Medicaid beneficiaries with and without HIV: a cohort study

Corinne Joshu[1], Keri Calkins[2], Jacqueline E. Rudolph[1], Xiaoqiang Xu[3], Eryka Wentz[1], Maneet Kaur[1], Filip Pirsl[1], Sally B. Coburn[1], Richard D. Moore[3], Bryan Lau[1]. *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[2]Mathematica, Ann Arbor, MI,[3]Johns Hopkins School of Medicine, Baltimore, MD*

Background: Colorectal cancer has increased among people living with HIV (PLWH). Studies have reported either no difference or lower risk of colorectal cancer incidence among PLWH as compared to the general population. We evaluated the incidence of colon cancer, both average-onset (diagnosed at 50 or older) and early-onset (diagnosed at less than 50), among a diverse population of people with and without HIV who have comparable sociodemographic factors and access to care.

Methods: We obtained Medicaid Analytic eXtract (MAX) data from 2001-2015 for 14 states. We included 42,244,679 unique individuals with at least 7 months of continuous eligibility. HIV and colon cancer diagnoses were identified from inpatient and other non-drug claims. We used Cox proportional hazards regression models to assess the incidence of colon cancer, controlling for age, sex, race/ethnicity, calendar year of enrollment, state of enrollment, and number of comorbidities. Analyses were also adjusted for or stratified by age, sex, and race/ethnicity.
Findings: We identified 191 colon cancer cases among 523,969 person-years among PLWH and 15,098 colon cancer cases among 63,579,078 person-years among beneficiaries without HIV. Colon cancer incidence increased with age among beneficiaries with and without HIV. Overall, HIV was modestly, inversely associated with colon cancer incidence (HR:0.84, 95%CI: 0.73, 0.98). PLWH 18-39 years old had increased hazard of colon cancer as compared to those without HIV (HR:1.67, 95%CI: 1.06, 2.65); this association was attenuated after adjustment for co-morbidities. HRs were null when early-onset colon cancer was assessed among all beneficiaries less than 50 years. PLWH had lower hazard of average-onset colon cancer compared to those without HIV (HR:0.81, 95%CI: 0.68, 0.96); this association was statistically significant among male, but not female, beneficiaries.
Interpretation: Compared to beneficiaries without HIV, PLWH had a lower risk of average-onset colon cancer. PLWH had higher incidence of early-onset colon cancer, but this difference was attenuated after adjustment for comorbid conditions.

Profiling symptom burden of RAS and BRAF mutations in patients with colorectal cancer: Results from the ColoCare Study

Gazelle Rouhani[1], Amanda M. Bloomer[2], Maria F. Gomez[2], Gillian K. Trujillo[2], Devon N. Conant[2], Seth I. Felder[2], Cornelia M. Ulrich[3], Christopher I. Li[4], Jane C. Figueiredo[5], Adetunji T. Toriola[6], Biljana Gigic[7], Martin Schneider[7], David Shibata[8], Erin M. Siegel[2]. *[1]University of Miami Miller School of Medicine, Miami, FL,[2]Moffitt Cancer Center, Tampa, FL,[3]Huntsman Cancer Institute, Salt Lake City, UT,[4]Fred Hutchinson Cancer Center, Seattle, WA,[5]Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[6]Washington University School of Medicine, St. Louis, MO,[7]Heidelberg University Hospital, Heidelberg, Germany,[8]University of Tennessee Health Science Center, Memphis, TN*

Background**:** Colorectal cancer (CRC) is a complex and heterogeneous disease characterized by distinct molecular features such as RAS and BRAF mutations. Assessing these molecular aberrations provides clinical guidance for selecting and predicting response with therapeutic modalities. Few reports have suggested that patient symptom burden at diagnosis differs across molecular subtypes of CRC. However, the association of RAS and BRAF mutations and symptom burden post-diagnosis in CRC patients has yet to be examined in a prospective cohort.
Methods: We assessed CRC patients, stage I-IV, enrolled in the Moffitt ColoCare Study site with clinical molecular testing results and who completed a six-month questionnaire. Tumor mutation (MT) status (RAS/BRAF/Wildtype (WT)) was abstracted from the medical record. The MD Anderson Symptom Inventory (MDASI) was used to assess the severity of 13 cancer-related symptoms on a 1-to-10 scale. Mean scores in mutation subgroups were compared with one-way ANOVA. Linear regression analysis evaluated the association between symptom burden and mutation status. Multivariable regression models were adjusted for age, sex, stage at diagnosis, treatment, and microsatellite instability (MSI).
Results: Among the 158 patients, the mean age at diagnosis was 60.9 ± 11.58 years. The prevalence of RAS and BRAF mutations was 30.4% (N=48) and 6.3% (N=10), respectively.

Statistically significant mean differences between the mutation subgroups were distress (p=0.005), difficulty remembering (p=0.015), lack of appetite (p=0.042), and sadness (p=0.007). Patients with a BRAF-MT reported significantly more distress (p=0.001), difficulty remembering (p=0.029), and sadness (p=0.002) at six months compared to RAS-MT or RAS/BRAF-WT. Patients with a RAS-MT reported an increased lack of appetite (p=0.038) compared to BRAF-MT or RAS/BRAF-WT. Patients with a BRAF-MT reported higher severity of symptoms interfering with the enjoyment of life (p<0.001), work (p=0.005), and mood (p<0.001) compared to RAS-MT or RAS/BRAF-WT. In an adjusted multivariable model, patients with BRAF-MT tumors reported significantly greater distress compared with RAS/BRAF-WT patients [β = 3.18 per unit increase in severity, 95% CI (1.30 - 5.07), p=0.001)]. Overall symptom burden was associated with greater interference with daily activities for BRAF-MT patients when compared to RAS/BRAF-WT patients [β = 2.95, 95% CI (1.42 - 4.48), p<0.001)].
Conclusions: Tumors with BRAF-MT are molecularly classified into the serrated pathway, which has distinct clinical characteristics and risk factor profile. In this study, patients with tumors harboring BRAF-MT reported a higher symptom burden six months post-diagnosis than those with RAS-MT or RAS/BRAF-WT tumors. While the prevalence of BRAF-MT was low in this population, these findings warrant further investigation in a larger cohort.

The impact of two decades of multidisciplinary efforts to reduce the risk of recurrence from colorectal cancer - a Danish population-based registry-study
Jesper Nors[1], Kaare A. Gotschalck[2], Rune Erichsen[3], Lene H. Iversen[4], Claus L. Andersen[1].
[1]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark,[2]Department of Surgery, Horsens Regional Hospital, Horsens, Denmark,[3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark,[4]Department of Surgery, Aarhus University Hospital, Aarhus, Denmark

Purpose: Over the last two decades, several initiatives have aimed at reducing risk of recurrence in patients operated for non-metastatic colorectal cancer (CRC). The focus has been on improving treatment in a multidisciplinary setting and implementing a population-based screening program. However, the combined impact of these initiatives on the risk of recurrence is not well described. Therefore, the primary aim of this study was to determine and compare recurrence rates for three calendar periods 2004-2008, 2009-2013, and 2014-2019 (after implementation of screening) in CRC. Material and Methods: Patients undergoing surgery for UICC TNM stage I-III CRC in the period 2004 to 2019 were included. All patients were identified using the nationwide clinical quality database DCCG, and hereafter linked with data from the Danish Cancer Registry, the Danish National Registry of Patients, and the Danish Pathology Registry. Recurrence status was determined using a validated algorithm defining recurrence based on diagnosis codes of local recurrence or metastases, the receipt of chemotherapy, or a pathological tissue assessment code of recurrence. The algorithm has shown a positive predictive value of 94% and a negative predictive value of 99%. Cumulative risk of recurrence and relapse-free survival (RFS) was reported by grouping the patients in calendar periods.
Results: Of 33,470 stage I-III patients, 7,002 developed recurrence within 5 years after primary surgery (incidence rate = 60.4 per 1,000 person years, 95% CI: 59-61.8) with highest incidence among rectal cancer patients. The 5-year cumulative incidence of recurrence decreased for both colon cancers (2004-2009: 26% (95% CI: 25-27%); 2009-2013: 21% (95% CI: 20-22%); 2014-2019: 15% (95% CI: 14-16%)) and rectal cancers (2004-2009: 30% (95% CI: 29-32%); 2009-2013: 25% (95% CI: 24-27%); 2014-2019: 19% (95% CI: 18-20%)). The same pattern was found

within each of stages I, II and III when stratifying by the three calendar periods. Screening-detected (SD) patients had lower risk of recurrence when compared to non-screening detected patients. The 5-year cumulative incidence of recurrence remained lower for 2014-2019 compared to previous calendar periods when excluding SD patients. Adjusted RFS improved significantly from 2004-2008 (reference) to 2014-2019 for colon cancer patients across all UICC stages; I) HR=0.49 (95%CI: 0.42-0.57), II) HR=0.56 (0.51-0.62) and III) HR=0.67 (0.62-0.73). The same pattern was seen for rectal cancer patients with HR=0.50 (0.42-0.60), HR=0.60 (0.52-0.69) and HR=0.67 (0.60-0.75) for stage I, II and III, respectively.
Conclusion: The national multidisciplinary initiatives to improve the outcome of CRC within the past two decades have borne fruit, as reflected by significant reductions in CRC recurrence risk and prolonged RFS observed for Danish stage I-III CRC patients.

Systematic review and meta-analysis of cancer incidence after blood transfusion in the general population

Youjin Oh[1], Soowon Lee[2], Sebin Bok[1], Chan Mi Jung[1], Ilene Hong[1], Liam Il-Young Chung[1], Jeeyeon Lee[3], Young Kwang Chae[1]. *[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Baylor University, Waco, TX,[3]Kyungpook National University Chilgok Hospital, Daegu, Korea, Republic of*

Background: The impact of blood transfusion on cancer survival and mortality has been widely studied. However, few studies have investigated its relationship with cancer incidence. This is the first systematic review and meta-analysis evaluating the correlation between blood transfusion and cancer incidence.
Methods: Five studies were identified through Pubmed, Embase, and Cochrane library. Four cohort studies and one case-control study (N = 3,048,906) were included. Over seventy percent were female (N =2,167,580), and about thirty-one percent (N = 956,522) were transfused. Meta-analysis was conducted between blood transfusion and cancer incidence. Subgroup analyses were performed by cancer types, follow-up period, and units of transfused blood. We pooled available risk estimates, which were adjusted for confounding factors, including age and sex, were pooled.
Results: Overall cancer risk increased statistically significantly in people who received transfusion compared to the population that did not (1.70, 95% CI, 1.30 to 2.10). The result was consistent regardless of time intervals from transfusion or units of transfused blood. Cancer incidences in all solid tumors, except breast, thyroid, and uterine cancer, were higher in blood transfusion recipients (Table 1). The elevated risk of stomach, bladder, and kidney cancer was sustained for up to fifteen years. Furthermore, lung cancer, liver cancer, and non-Hodgkin lymphoma risk remained high among the blood transfusions group even after fifteen years. The three types of cancer with the highest incidence following transfusion were leukemia, stomach cancer, and liver cancer.
Conclusions: Blood transfusion increases the risk of cancer in transfusion recipients. The impact of blood transfusion on cancer development varies depending on the cancer type and the time from transfusion. Further prospective studies are warranted to validate the findings and investigate the underlying mechanism.

The pooled risk of cancer according to cancer types, units of transfusion, and time from transfusion

	Risk* (95% CI)			
	Total	< 5 yrs	5-15 yrs	≧ 15 yrs
All cancer types	1.70 (1.30 - 2.10)	1.89 (1.13 - 2.65)	1.18 (0.97 - 1.40)	1.10 (1.06 - 1.14)

Leukemia	2.79 (2.00 - 3.57)	4.07 (2.72 - 5.42)	1.15 (1.04 - 1.27)	0.91 (0.66 - 1.16)

Incidence of papillary thyroid cancer: comparison of the military with the general population by race, gender, and tumor stage/size

Julie A. Bytnar[1], Lindsey Enewold[2], Craig D. Shriver[1], Kangmin Zhu[1]. *[1]Murtha Cancer Center Research Program, Uniformed Services University Walter Reed Surgery, Henry M. J, Bethesda, MD,[2]Division of Cancer Control & Population Science, National Cancer Institute, Rockville, MD*

Background: A previous study found that the incidence of papillary thyroid cancer was higher in the US military than in the general population and the difference was larger among Black than White patients for both men and women. This study compared the military to the general population in thyroid cancer incidence by not only race and gender but also tumor stage and size to assess possible factors related to the identified differences.
Methods: The study subjects were men and women aged 18-59 histologically diagnosed with papillary thyroid cancer from 1990-2013 in the military and the general population. The data were from the Department of Defense's Automated Central Tumor Registry (ACTUR) and the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) program. Age adjusted rates and incidence rate ratios (IRR) and 95% confidence intervals (95% CI) comparing ACTUR to SEER were calculated. Comparisons were made by race (Black, White), gender, cancer stage (local, regional, distant), and tumor size (0-2 cm, >2 cm).
Results: Higher age-adjusted incidence rates in ACTUR than SEER were more obvious for Black (IRR=2.07, 95% CI=1.56-2.70) than White (IRR=1.17, 95% CI=1.07-1.26) men and for Black (IRR=2.30, 95% CI=1.91-2.71) than White (IRR=1.50, 95% CI=1.38-1.64) women, respectively. In further analysis by tumor stage, the difference between the two populations was observed only for localized tumors, which was larger for Blacks for both men and women. The analysis by tumor size showed that the difference between the populations existed in both 0-2 cm and >2 cm tumors, but only in Blacks among men and was larger for Blacks than Whites among women.

Conclusion: The observations that a higher incidence in the military than the general population primarily existed in localized tumors suggest that universal care in the military may lead to earlier detection of the cancer. The larger differences for Blacks than Whites suggest that such impact may be larger for Blacks, who are less likely to have timely care in the general population. Nevertheless, the observed differences between the populations for tumors larger than 2cm suggest that other factors may also play a role.

Cancers of unknown primary: survival by histologic type, demographic features, and treatment in the US Military Health System

Julie A. Bytnar[1], Jie Lin[1], Joel T. Moncur[2], Craig D. Shriver[1], Kangmin Zhu[1]. *[1]Murtha Cancer Center Research Program, Uniformed Services University Walter Reed Surgery, Henry M. J, Bethesda, MD,[2]The Joint Pathology Center, Silver Springs, MD*

Background: Cancers of unknown primary (CUP), a group of heterogenous metastatic cancers lacking a known primary site, have poor prognosis. This study compared survival by histologic type, patient characteristics, and treatment in the U.S. Military Health System (MHS), which provides universal care to its members.
Methods: Patients diagnosed with CUP were identified from the U.S. Department of Defense's Automated Central Tumor Registry. Median survival with 95% confidence intervals was calculated for demographic and treatment variables by histologic type. A multivariable accelerated failure time model estimated time ratios and 95% confidence intervals.
Results: The study included 3,358 CUP patients. The most prevalent CUP in this study was well and moderately differentiated adenocarcinomas. Median survival varied by histologic type with squamous cell carcinoma having the longest at 25.1 months and poorly differentiated carcinomas having the shortest at 3.0 months. For each histologic type, survival was generally similar by sex and active-duty status. Younger patients tended to have longer survival than those aged 65 years or older. Women with well and moderately differentiated adenocarcinoma had longer survival than their male counterparts. Generally, there were no racial differences in survival except poorer survival for Blacks than Whites with other histologic types. Patents with chemotherapy and radiation treatment generally had improved survival whereas patients with squamous cell carcinoma who received chemotherapy had shorter survival than those without.
Conclusion: Survival generally did not differ between racial groups, which may be related to equal healthcare access despite racial background. Further studies are warranted to better understand how survival in the MHS compares with that in the general U.S. population.
Disclaimer: The contents of this publication are the sole responsibility of the authors and do not necessarily reflect the views, opinions or policies of USUHS, HJF, the DoD or the Departments of the Army, Navy or Air Force. Mention of trade names, commercial products or organizations does not imply endorsement by the US Government.

Over 10 years since HPV vaccine approval, awareness of the causal link between HPV and HPV-associated cancers remains low in the US

Eric Adjei Boakye[1], Mrudula Nair[1], Joel Fokom Domgue[2], Dina K. Abouelella[3], Heena Y. Khan[4], Nosayaba Osazuwa-Peters[3]. *[1]Henry Ford Health System, Detroit, MI,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Duke University School of Medicine, Durham, NC,[4]Saint Louis University, Saint Louis, MO*

Background**:** Over 90% of Human papillomavirus (HPV)-associated cancers could be prevented with the HPV vaccination; yet vaccine uptake remains suboptimal. Awareness that HPV causes several cancers has been shown to improve HPV vaccination uptake. While several efforts to increase HPV-associated diseases awareness as a way to improve vaccine uptake have been made, it is unclear if these efforts have resulted in increased HPV-associated cancers awareness over the years. We examined the awareness of the link between HPV and HPV-associated cancers between 2014 and 2020 in the US.

Methods: We used the Health Information National Trends Survey (HINTS) data from 2014 (HINTS 4 cycle 4) to 2020 (HINTS 5 cycle 4). HINTS is a nationally representative survey of adults aged ≥18 in the civilian non-institutionalized US population. HPV-associated cancer awareness was assessed with the question "Do you think HPV can cause i) anal ii) cervical iii) oral and iv) penile cancers". Responses were "yes", "no" and "not sure". Weighted prevalence estimates and corresponding 95% CIs were calculated for all four HPV-associated cancer awareness questions at each timepoint.

Results: There were five timepoints included in the study: HINTS 4 cycle 4 (2014, n=2239), HINTS 5 cycle 1 (2017, n=2034), HINTS 5 cycle 2 (2018, n=2050), HINTS 5 cycle 3 (2019, n=2270), and HINTS 5 cycle 4 (2020, n=2340). Awareness of the link between HPV and cervical cancer was high (77.6% in 2014) but decreased by 7.4% between 2014 and 2020 (Table). However, awareness of the link between HPV and anal, oral, and penile cancers was low (around 30% for each cancer type) and remained stable between 2014 and 2020 (Table).

Conclusions: Awareness of the link between HPV and HPV-associated cancers has remained steady for anal, oral and penile cancers or declined slightly for cervical cancer over time. There is a need for implementing novel and target interventions to increase awareness and counteract HPV vaccine disinformation.

Awareness of the link between HPV and HPV-associated cancers

			Weighted percent (95% CI)		
	H4C4 (2014)	**H5C1 (2017)**	**H5C2 (2018)**	**H5C3 (2019)**	**H5C4 (2020)**
HPV cause anal cancer	27.9 (24.7, 31.1)	29.1 (25.7, 32.5)	24.4 (21.3, 27.5)	28.8 (25.5, 32.0)	27.4 (24.3, 30.6)
HPV cause oral cancer	31.2 (28.0, 34.4)	30.7 (27.6, 33.9)	27.0 (23.8, 30.1)	31.1 (27.8, 34.4)	29.5 (26.3, 32.8)
HPV cause penile cancer	30.3 (27.1, 33.6)	31.2 (28.1, 34.2)	29.2 (25.9, 32.5)	32.0 (28.7, 35.4)	28.4 (25.1, 31.6)
HPV cause cervical cancer	77.6 (74.9, 80.3)	81.5 (78.9, 84.2)	75.0 (72.0, 78.1)	73.9 (70.4, 77.3)	70.2 (67.0, 73.5)

Geospatial analyses identify hot spots of late-stage cervical cancer at diagnosis in Texas

Itunu O. Sokale, Aaron P. Thrift, Abiodun O. Oluyomi. *Medicine, Baylor College of Medicine, Houston, TX*

Background: Women with advanced cervical cancer at diagnosis have higher morbidity and mortality. Despite advancements in prevention and early detection, cervical cancer care disparities persist by race/ethnicity and geographical distribution. We aimed to identify spatial clusters of late-stage cervical cancer at diagnosis in Texas, a state with a higher than national cervical cancer rate, especially among racial/ethnic minority populations.**Methods**: Incident cervical cancer data were obtained from the Texas Cancer Registry for women aged 18 years or older diagnosed from 2000 to 2018. First, we conducted purely spatial scan analysis using the SaTScan Bernoulli model to identify geographic clusters (hot spots and cold spots) of late-stage cervical cancer (vs. early-stage) at diagnosis. Maximum cluster size was set at 50% of the at-risk population, and statistical significance at p <0.005 was explored by 999 Monte Carlo simulations. Finally, we used multivariable logistic regression models to investigate the characteristics of cases within each of the identified clusters.**Results**: SaTScan identified six clusters, three with significantly lower than expected number of late-stage cervical cancer cases (cold spots) and three with significantly higher than expected number of late-stage cervical cancers cases at diagnosis (hot spots). Hot spots were found around Public Health Regions 5/6 (Houston, a large metropolitan city with the highest rate of uninsured residents in Texas), Region 10 (El Paso, a border region) and Region 8 (San Antonio, the largest majority Hispanic population region). Compared to White women, Black women were less likely to be in cold spots (Cluster 1: odds ratio (OR) 0.44 (95% CI 0.33-0.57), Cluster 2: OR 0.42 (95% CI 0.28-0.64)), but more likely to be in hot spots (Cluster 3 OR 1.33 (1.15-1.54). Similarly, Hispanic women had greater odds of being in hot spots (Cluster 4: OR 5.26 (95% CI 4.15-6.68), Cluster 5: OR 12.43 (95% CI 8.82-17.52)) than non-Hispanic women. Likewise, compared to women living in census tracts with lower neighborhood-level poverty, those women living in census tracts with higher deprivation were more likely to be in the hot spots (Cluster 3: OR 1.28 (95% CI 1.10-1.49), Cluster 4: OR 55.07 (95% CI 17.63-172.00), Cluster 5: OR 8.24 (95% CI 4.87-13.95)). **Conclusions**: Considerable inequalities exist in late-stage cervical cancer diagnosis in Texas, in terms of place, race/ethnicity, and neighborhood disadvantages. Strategic and multicomponent population-based interventions are needed to address cancer care inequities.**Impact:** The study findings could be incorporated into designing effective multilevel interventions, including place-based and race-targeted strategies to improve cervical cancer outcomes.

#4212

Comparison of thirty-year population-based incidence rates of invasive lobular vs ductal vs mixed breast carcinoma in Ontario, Canada

David Wai Lim[1], Vasily Giannakeas[1], Steven Narod[1], Kelly A. Metcalfe[2]. *[1]Women's College Research Institute, Women's College Hospital, Toronto, ON, Canada,[2]Lawrence S. Bloomberg Faculty of Nursing, University of Toronto, Toronto, ON, Canada*

Purpose: We calculated crude, age-adjusted and age-specific incidence rates for invasive lobular, ductal and mixed ductal-lobular breast carcinoma from 1990 to 2020 in the province of Ontario, Canada. We further examined incidence relationships between clinical stage, age at diagnosis and time.

Methods: We used population-based administrative healthcare datasets from the Institute of Clinical Evaluative Sciences (ICES Ontario), including the Ontario Cancer Registry, to identify all women diagnosed with breast cancer between 1990 and 2020. We calculated crude, age-adjusted

and age-specific incidence rates for invasive lobular (ILC), ductal (IDC) and mixed ductal-lobular (IDC-ILC) breast carcinoma. Incidence rates were adjusted to the 2011 Canadian female standard population. We further examined the incidence relationships between clinical stage and age at diagnosis over time.
Results: From 1990 to 2020, the 5-year crude incidence rates of ILC increased from 53.1 to 73.4 per 100,000 (+38%), while IDC increased from 501 to 746.5 per 100,000 (+49%). The crude incidence of mixed IDC-ILC peaked at 45 per 100,000 between 2005 and 2009 and is currently 29 per 100,000. The age-adjusted 5-year incidence rate of ILC has slightly increased from 64 to 70 per 100,000 (+9%) while that of IDC has increased from 598 to 726 per 100,000 (+21%). The age-adjusted 5-year incidence of mixed IDC-ILC peaked at 47 per 100.000 between 2005 and 2009 and has declined to 29 per 100,000. Age-specific 5-year incidence rates for ILC has decreased over time in women < 40 years of age and increased in women over the age of 65. In contrast, age-specific 5-year incidence rates for IDC have remained stable in women over 75. For mixed IDC-ILC, age-specific 5-year incidence rates have increased over time in all age categories. Among women with ILC, there is a greater proportion of women under the age of 50 diagnosed with stage III disease (30%) compared with women diagnosed over the age of 50 (16%). Women between the ages of 50 and 74 have higher rates of being diagnosed at stage I (43%) compared with 35% and 31% for women diagnosed between the ages of 40-49 and over 75, respectively.
Conclusions: The incidence of invasive lobular breast carcinoma in increasing, particularly in women over the age 65. Consequently, the burden of lobular breast carcinoma is expected to increase, as the proportion of women over the age of 65 is expected to rise exponentially in the foreseeable future, highlighting a need for further study of this not uncommon breast cancer subtype. While representing a smaller proportion of breast cancer diagnoses, the incidence of mixed invasive ductal-lobular subtype is increasing in all age groups.

#4213

Comparison of benign breast disease subtypes and breast cancer risk among Hispanic and non-Hispanic white women in New Mexico

Kush Raj Lohani[1], Andrea M. Nibbe[2], Robert A. Vierkant[3], Laura M. Pacheco-Spann[4], Lisa R. Seymour[5], Celine M. Vachon[6], Mark E. Sherman[7], Amy C. Degnim[8], Deirdre Hill[9]. *[1]Division of Breast and Melanoma Surgical Oncology, Department of Surgery, Mayo Clinic, Rochester, MN,[2]Consultant, Department of Biostatistics, The University of New Mexico Health Sciences, Albuquerque, NM,[3]Consultant, Department of Biostatistics, Mayo Clinic, Rochester, MN,[4]Sr. Program Coordinator & Department Diversity Leader, Quantitative Health Sciences, Mayo Clinic, Jacksonville, FL,[5]Senior Research Protocol Specialist, Department of Surgery Research, Mayo Clinic, Rochester, MN,[6]Professor and Chair, Division of Epidemiology, Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[7]Professor, Division of Epidemiology, Department of Health Sciences Research, Mayo Clinic, Jacksonville, FL,[8]Professor, Division of Breast and Melanoma Surgical Oncology, Department of Surgery, Mayo Clinic, Rochester, MN,[9]Research Assistant Professor, Department of Internal Medicine, Division of Epidemiology, The University of New Mexico Health Sciences, Albuquerque, NM*

Introduction: Benign breast disease (BBD) is an important breast cancer (BC) risk factor, which may be classified as non-proliferative disease (NPD), proliferative disease without atypia (PDWA), or atypical hyperplasia (AH) for risk stratification. Data related to the frequency of specific types of BBD and their relationship to BC risk in the Hispanic American population are limited. To

address this knowledge gap, we compared BBD and associated BC risk among Hispanic white (HW) and non-Hispanic white (NHW) in New Mexico (NM).
Methodology: A retrospective IRB-approved study was performed of women 19 years or older residing in six counties in NM (Bernalillo, Sandoval, Sante Fe, Socorro, Torrance, Cibola/Valencia) between 1996 and mid-2007 to compare the frequency of BBD subtypes and BC risk among HW and NHW. We excluded women who had a history of BC prior to BBD diagnosis or who were diagnosed with BC within 6 months after BBD biopsy. Race and ethnicity were self-reported by women at the time of biopsy. BBD was categorized as NPD, PDWA, or AH based on medical records. Incident BC (in-situ or invasive) was ascertained via linkage to the NM Surveillance Epidemiology End Results (SEER) Registry and BC risk was assessed using standardized incidence ratios (SIRs), comparing the observed number of BC events to that expected based on the NM SEER six-county race- and ethnicity-specific incidence rates, accounting for age and calendar period.
Results: Our analysis included 3,870 HW and 6,996 NHW women with BBD. The HW were younger (47.1 vs. 51 years) compared to NHW. HW women had slightly more NPD (69.4% vs. 66.6%) but less PDWA (26.2% vs. 29.4%) and similar frequency of AH (4.3% vs. 3.9%) as compared to NHW. Over a median post-BBD follow-up period of 13 years (range 6 months-17 years), 644 BCs were observed (4.81% in HW and 6.55% in NHW). The observed BC risk among women with BBD was higher than population-based expected rates (SIR 1.98, 95% CI 1.82-2.13, $p<0.001$) and showed expected increases in risk with increasing degrees of BBD abnormality: SIR=1.90 for NPD, 2.00 for PDWA, and 3.01 for AH. Comparing BC risk by ethnic subgroups, HW women had an overall risk of BC after BBD that was statistically indistinguishable from NHW women (SIR=2.17, 95% CI 1.86-2.48 in HW women, and SIR=1.91, 95% CI 1.73-2.08 in NHW women). Within the major subgroups of the BBD findings, there were no significant differences in risk of BC after BBD for HW versus NHW women.
Conclusions: In this population-based study, benign breast disease subtypes and their associated breast cancer risk were similar among the Hispanic and non-Hispanic white women.

#4214

Exposure to air pollution during pregnancy and risk of premenopausal breast cancer: A Swedish nation-wide cohort study including more than 1 million women

Jessica Lena Edlund[1], Malin Gustafsson[2], Jenny Linden[2], Wendy Yi-Ying Wu[1], Anna Oudin[3], Sophia Harlid[1]. *[1]Radiation Sciences, Oncology, Umeå University, Umeå, Sweden,[2]Swedish Environmental Research Institute, Göteborg, Sweden,[3]Department of Laboratory Medicine, Lund University, Lund, Sweden*

Background: Air pollution has been linked to an increased risk of breast cancer, but most previous studies have not considered if the exposure occurred during windows of susceptibility, such as pregnancy. Pregnancy is a period of rapid changes to both the breast tissue and the surrounding microenvironment. Exposures during this sensitive time-period could therefore result in erosion of the protective effect of pregnancy and make women more susceptible to external breast cancer risk factors. Aim: The aim of this study was to identify associations between air pollution exposure, occurring specifically during pregnancy, and risk of premenopausal breast cancer.
Method: Using nation-wide data from Swedish registers we constructed a cohort consisting of all women in Sweden who gave birth to their first child between January 1st 1991 and December 31st 2015. Women with a cancer diagnosis prior to pregnancy were excluded. Data on air pollution (yearly averages of PM_{10}, $PM_{2.5}$ and NO_2), was collected from the residence of women during, and to some extent between, pregnancies. Associations between air pollution and premenopausal breast

cancer is evaluated using Cox proportional hazards regression to estimate hazard ratios (HR), using age as the time scale and including appropriate confounders such as socioeconomic variables, comorbidities and family history of breast or ovarian cancer.
Results: The full cohort included 1 074 925 unique women and 2 302 256 pregnancies (the mean number of pregnancies for each woman was 1.75). During the study period, 13 292 (1.2 %) were diagnosed with breast cancer before they turned 50 years.
Conclusion: Our working hypothesis is that women exposed to higher levels of air pollution during pregnancy will have a higher risk of breast cancer. This large-scale study will have enough statistical power to detect the effect of air pollution on breast cancer risk, taking into account exposure both during and between pregnancies.

#4215

Air pollution exposure during pregnancy and risk of premenopausal breast cancer among women with a family history of cancer

Anna Hettinger[1], Jessica Edlund[1], Malin Gustafsson[2], Jenny Lindén[2], Wendy Yi-Ying Wu[1], Anna Oudin[3], Sophia Harlid[1]. *[1]Radiation sciences, Oncology, Umeå University, Umea, Sweden,[2]Swedish Environmental Research Institute, Göteborg, Sweden,[3]Department of Public Health and Clinical Medicine, Division for Sustainable Health, Umeå University, Umea, Sweden*

Background: Having a family history of breast or ovarian cancer is an important risk factor for premenopausal breast cancer. One reason for this could be that women with an underlying genetic susceptibility are more sensitive to environmental exposures due to gene-environment interactions. This might be especially important if the exposure occur during windows of susceptibility, such as pregnancy. Aim: The aim of this project is to determine if exposure to air pollution during pregnancy is associated with premenopausal breast cancer in a population with a known family history of breast or ovarian cancer.
Methods: The project is based on nation-wide data from Sweden's national registers and utilizes a cohort study design. The original cohort consists of women who gave birth to their first child between 1992 and 2015 (n=1 074 925), from this cohort we will select women with at least one first degree relative with breast or ovarian cancer (confirmed through register linkage). The primary outcome is primary breast cancer diagnosed before 50 years of age, and the exposure is levels of air pollution (PM_{10}, $PM_{2.5}$ and NO_2) at the participant's home address during each pregnancy. Cox proportional hazards regression will be used to determine hazard ratios using age as the time-scale.
Results: The registry based linkage makes it possible to distinguish between both relational context (mother or sister), number of afflicted first degree relatives and type of cancer (breast or ovarian). All included women also have at least one recorded pregnancy (prior to any cancer diagnosis).
Conclusion: This large scale study will be able to provide important information about the impact of air pollution exposure during pregnancy on breast cancer risk in a population with a documented family history of breast or ovarian cancer.

#4216

Interactions of greenness with air pollution in relation to postmenopausal breast cancer risk in UK Biobank

Carmen Smotherman[1], Brian Sprague[2], Susmita Datta[3], Dejana Braithwaite[1], Huaizhen Qin[1], Lusine Yaghjyan[1]. *[1]Epidemiology, University of Florida, Gainesville, FL,[2]Surgery, University of Vermont, Burlington, VT,[3]Biostatistics, University of Florida, Gainesville, FL*

Purpose: The evidence of the association between natural vegetation, or greenness, and breast cancer (BCa) remains inconsistent, with some studies reporting possible interactions with air pollution. We previously found a positive association of particulate matter with diameters than are 10 micrometers or smaller (PM_{10}) with BCa risk among postmenopausal women in the UK Biobank. In this study, we investigated the associations of greenness with postmenopausal BCa risk, as well as whether association of PM_{10} with BCa differ by the level of greenness.
Methods: This study included 155,235 postmenopausal women (6,146 with BCa) from UK Biobank, a population-based prospective cohort. Cancer diagnoses were ascertained through the linkage to the UK National Health Service Central Registers. Greenness measures (Greenspace percentage [GP], Natural environment percentage [NEP], and the Normalized Difference Vegetation Index [NDVI]) were available at baseline assessment (2006 -2010). GP and NEP coverage were calculated at 300 m and 1000 m, respectively, around participant residence locations, while the mean NDVI was calculated within a 500 m residential buffer of each UK Biobank participant. Annual averages for PM_{10} were available from 2007 and 2010. Information on BCa risk factors was collected at baseline. We used Cox proportional hazards regression to evaluate associations between greenness (continuous as well as quartiles) and BCa risk, while adjusting for BCa risk factors. Next, we examined associations for year-specific and cumulative average PM_{10} exposure measures (per 5 $\mu g/m^3$) within each stratum of greenness measure. Interactions between PM_{10} and greenness measures were assessed by including an interaction term in the main models.
Results: BCa risk increased by 29% per one unit increase in NDVI (Hazard ratio [HR]=1.29, 95% CI 1.03, 1.61). Compared to women in the lowest NDVI quartile, women with higher levels of NDVI had higher risk of BCa (HR=1.10, 95% CI 1.01, 1.21 for 2nd quartile, HR=1.10, 95% CI 1.00, 1.20 for 3rd quartile, and HR=1.13, 95% CI 1.04, 1.24 for 4th quartile, p-trend=0.012). No significant associations were found for any other greenness measure in relation to BCa risk. We found a significant interaction between NDVI and cumulative average PM10 exposure ($p<0.0001$). The association of PM10 cumulative average with BCa risk was stronger at lower levels of NDVI (HR per 5 $\mu g/m^3$=1.12, 95% CI 1.07, 1.17 for 1st quartile) compared to higher levels of NDVI (HR=1.04, 95% CI 1.02, 1.07 for 4th quartile). We found no interactions with other greenness measures.
Conclusions: We found a positive association of NDVI with BCa risk and an interaction between cumulative average PM_{10} and NDVI, with stronger positive association of cumulative average PM_{10} exposure with postmenopausal BCa risk at lower compared to higher levels of greenness.

#4217

Cumulative environmental quality is associated with breast cancer incidence differentially by summary stage and urbanicity

Larisa M. Gearhart-Serna[1], Kate Hoffman[2], Hillary Hsu[3], Gayathri R. Devi[4]. *[1]Department of Surgery, Duke University Medical Center, Durham, NC,[2]Nicholas School of the Environment, Duke University, Durham, NC,[3]Trinity College of Arts and Sciences, Duke University, Durham, NC,[4]Department of Surgery; Cancer Risk, Detection, and Interception Program, Duke Cancer Institute, Department of Surgery, Duke University Medical Center; Cancer Risk, Detection, and Interception Program, Duke Cancer Institute, Durham, NC*

Individual environmental contaminants have been associated with breast cancer (BCa); however, simultaneous evaluations of multiple exposures are limited. The USEPA has constructed an

environmental quality index (EQI) that includes different exposures across air, water, land, sociodemographic, and built environments. As links between BCa and the EQI have so far been confined to total BCa incidence, herein we investigated if these multiple exposures in broad EQI domains were associated with BCa incidence stratified by stage of disease.
Incidence rates of total, in situ, localized, regional, and distant breast cancer were assessed by linking the EQI dataset to county-level age-standardized incidence rates obtained from the North Carolina Central Cancer Registry (2010-2014), which reports all cancer cases diagnosed in NC residents. Generalized linear models (SAS 9.3) were constructed to determine the associations between breast cancer incidence rates by summary stage and the EQI in total and by domain, compared across rural versus urban counties. Models were adjusted for percent African American (AA), percent smokers, and mammography screening rates in each county. Mann-Whitney rank tests and D'Agostino-Pearson normality tests were used to determine statistical significance.
Results showed that the EQI is variable across NC, akin to variability across the U.S. (interquartile range 25th-75th% for total EQI in NC: -0.187 to 0.734 vs in the U.S.: –0.606 to 0.706). In counties with poor total EQI scores, and thus poor overall environmental quality, total BCa incidence increased by 10.82 cases per 100,000 persons (95%CI: 2.04, 19.60, p=0.016). This association was most pronounced for localized BCa (β=5.59, 95%CI: 0.59, 10.58, p=0.029). Higher incidence of early-stage disease (carcinoma in situ β=5.25, 95%CI: 2.34, 8.16, p=0.001 and localized BCa β=6.98, 95%CI: 2.24, 11.73, p=0.004) and total breast cancer (β=11.44, 95%CI: 3.01, 19.87, p=0.008) also occurred in counties with poor land quality, especially urban counties. The county AA percentage was associated with increased incidence of regional (0.12 cases per % increase, 95% CI 0.01, 0.22, p=0.022) and distant BCa (0.06 per % increase, 95% CI 0.02, 0.10, p=0.003). Associations persisted and were strengthened in urban counties for regional BCa, and in rural counties for distant BCa.
In sum, we found that BCa is associated with environmental quality differentially by disease stage, environmental domain, and urbanicity. Although what drives poor EQI varies by region, our analyses are generalizable to other states and counties across the U.S. and suggest that cumulative environmental exposures should be assessed in the context of cancer stage. Funding: Duke Cancer Institute pilot (GRD, KPH) in P30 Cancer Ctr grant; NIEHS T32-ESO21432-05; NCI-3P20CA202925-04S2 Diversity Supplement (LGS).

#4218

Cancer prevalence among Ohio firefighters: data from the Ohio Cancer Incidence Surveillance System (OCISS) 1996-2019

Susan E. Olivo-Marston[1], Shashank Singh[2], Robert B. Hood[3], Olorunfemi Adetona[4]. *[1]Medical Microbiology, Immunology and Cell Biology, Simmons Cancer Institute at Southern Illinois University School of Medicine, Springfield, IL,[2]West Virginia School of Osteopathic Medicine, Lewisburg, WV,[3]Epidemiology, Rollins School of Public Health at Emory University, Atlanta, GA,[4]Environmental Health Sciences, The Ohio State University College of Public Health, Columbus, OH*

Firefighting is classified as a Group 1 carcinogen or “carcinogenic to humans” by the International Agency for Research on Cancer. Compared to the general population, firefighters have a 9% increased risk of cancer incidence and a 14% increased risk of cancer mortality. Although there have been previous studies of cancer incidence among firefighters in Florida and Massachusetts, there have been no studies examining cancer incidence among firefighters in the state of Ohio. Therefore, this is the first study to examine cancer prevalence among Ohio firefighters. The study utilized data from the Ohio Cancer Incidence Surveillance System (OCISS), the Ohio state cancer

registry. This study examined data from 1996-2019, including a total of 1,314,318 people. Occupation was classified as firefighter, police, or general population. The odds of being a firefighter versus a police officer or the general population was calculated for specific cancer types. In addition, this analysis was stratified by gender. Police were used as a comparison group because it is an occupation similar to firefighters with the exception of exposure. There was a total of 3,397 firefighters, 3,341 police, and 1,307,580 people in the general population. Among firefighters, they were mostly male (86.8%), White (92.7%), Non-Hispanic (3.4%), married (67.7%), and never used tobacco (19.8%). The mean age at cancer diagnosis among firefighters was 66 years and most of them were diagnosed between 2010 and 2014. A similar distribution was seen among police except the mean age at cancer diagnosis was 63 years and most of them were current tobacco users (18.5%). The distribution was similar among the general population except the majority of them were female (51.6%). Firefighters had increased odds of esophageal cancer, cancers of the soft tissue including the heart, skin, prostate, testis, bladder, and brain compared to the general population. Cancer of the oral cavity, pharynx, and kidney were also increased among firefighters; however, they did not reach statistical significance. Compared to police, firefighters had increased odds of breast, uterine, prostate, brain, and thyroid cancer. In addition, they had decreased odds of pancreatic and bladder cancer. When stratified by gender, among the 2,948 male firefighters, there were increased odds of cancer of the soft tissue including heart, prostate, brain, cranial nerves, and thyroid cancer compared to the general population. They also had decreased odds of cancer of the larynx, lung & bronchus, and bladder. Number of female firefighters was small generating unstable odds ratios. We observed increased prevalence of several types of cancer among Ohio firefighters, similar to previous studies. Although there were limitations present due to many people lacking data on occupation, the current study supports that Ohio firefighters have an increased risk of many different types of cancer.

#4219

Smoky coal exposure is associated with epigenetic accelerated aging

Batel Blechter[1], Andres Cardenas[2], Seraphina (Junming) Shi[3], Mohammad L. Rahman[1], Jason Y.Y. Wong[1], Wei Hu[1], George S. Downward[4], Lutzen Portengen[4], Richard Cawthon[5], H. Dean Hosgood[6], Jihua Li[7], Debra T. Silverman[1], Yunchao Huang[8], Roel Vermeulen[4], Nathaniel Rothman[1], Qing Lan[1]. *[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[2]Department: Epidemiology and Population Health, Stanford University, Palo Alto, CA,[3]Department of Biostatistics, UC Berkeley School of Public Health, Berkeley, CA,[4]Division of Environmental Epidemiology, Utrecht University, Utrecht, Netherlands,[5]Department of Human Genetics, University of Utah School of Medicine, Salt Lake City, UT,[6]Division of Epidemiology, Albert Einstein College of Medicine, Bronx, NY,[7]Quijing Center for Diseases Control and Prevention, Quijing, China,[8]Department of Cardiothoracic Surgery, Third Affiliated Hospital of Kunming Medical University, Kunming, China*

Household air pollution (HAP) from indoor combustion of solid fuel is a global health burden that has been linked to lung cancer. A striking example occurs in Xuanwei, China where the lung cancer rate for never smoking women is among the highest in the world and largely attributed to high levels of various toxic constituents, including polycyclic aromatic hydrocarbons (PAHs), a combustion product of smoky (bituminous) coal used for cooking and heating. Several air pollution constituents have been associated with epigenetic accelerated aging (EAA) derived from DNA methylation (DNAm)-based biomarkers that are highly correlated with biological processes

underlying aging-related diseases. We aim to assess the association between HAP exposure and EAA in Xuanwei, China.
We analyzed 106 never smoking women in an exposure assessment study in Xuanwei, China with a repeat DNA sample from 23 subjects. Household fuel type used for cooking and heating (smoky vs. smokeless coal) was collected using a questionnaire, and exposure models were used to predict levels of 43 individual HAP constituents for current and childhood exposure. Leukocyte DNAm was measured using Illumina EPIC array. EAA was derived for five clocks using the Horvath calculator and defined as the residuals resulting from regressing each clock on chronological age. We used generalized estimating equations to assess the associations between fuel type, clusters derived from predicted levels of HAP exposure, and ambient 5-methylchrysene (5-MC), a carcinogenic PAH previously associated with lung cancer in Xuanwei and selected *a priori* for analyses, as independent variables and EAA clocks as dependent variables, while accounting for repeated-measurements.
We observed a significant increase in GrimAge EAA among smoky coal users compared to smokeless coal users for current (β=1.84 years (y), 95% confidence interval (CI): 0.59, 3.09, P-value=0.004) and childhood (β=4.14 y, 95% CI: 1.63, 6.64, P-value=0.001) exposures. We also observed a monotonic increase in GrimAge EAA for a cluster of 31 PAHs reflecting current exposure (β=0.77 y, 95% CI: 0.36, 1.19, P-value=$3x10^{-4}$) and for a cluster of 33 PAHs reflecting childhood exposure (β=0.92 y, 95% CI: 0.40, 1.45, P-value=0.001). Ambient 5-MC, one of the constituents within the PAH clusters, was found to have an increasing monotonic relationship with GrimAge EAA for current (β=0.15 y, 95% CI: 0.05, 0.25, P-value=0.003) and childhood (β=0.30 y, 95% CI: 0.13, 0.47, P-value=$4.7x10^{-4}$) exposures.
Our findings suggest that exposure to PAH from indoor smoky coal combustion is associated with EAA, particularly for the GrimAge clock, a strong biomarker of mortality. This finding is consistent with our recent observation linking accelerated GrimAge to increased risk of lung cancer in a prospective study of never smoking women in China. Additionally, our study provides further support for 5-MC as a prominent carcinogenic component of smoky coal emissions.

Occupational pesticide use and relative leukocyte telomere length in the biomarkers of exposure and effect in agriculture study

Patricia A. Erickson[1], Vicky C. Chang[1], Casey L. Dagnall[2], Kedest Teshome[2], Mitchell J. Machiela[3], Kathryn H. Barry[4], Shahinaz M. Gadalla[5], Laura E. Beane Freeman[1], Gabriella Andreotti[1], Jonathan N. Hofmann[1]. *[1]Occupational and Environmental Epidemiology Branch, National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Rockville, MD,[2]Cancer Genomics Research Laboratory, Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Rockville, MD,[3]Integrative Tumor Epidemiology Branch, Clinical Genetics Branch, National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Rockville, MD,[4]Dept. of Epidemiology & Public Health, Greenebaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore, MD,[5]Clinical Genetics Branch, National Cancer Inst. Div. of Cancer Epidemiology & Genetics, Rockville, MD*

Background: Previous epidemiologic studies have reported increased risks of certain cancers in relation to specific pesticide exposures, although the mechanisms underlying many of these associations remain poorly understood. Within the Biomarkers of Exposure and Effect in Agriculture (BEEA) study, a molecular epidemiologic investigation of pesticide applicators in Iowa and North Carolina, we examined whether occupational use of pesticides is associated with

alterations in leukocyte telomere length. Telomeres are essential in maintaining chromosomal stability and altered telomere length has been linked to various malignancies.
Methods: Relative telomere length (RTL) was measured using quantitative PCR in leukocytes from 1,539 male pesticide applicators ≥50 years of age. Using self-reported information on pesticide use, we characterized lifetime use of specific pesticides in terms of ever use and intensity-weighted lifetime days (IWLDs), a metric integrating total lifetime days of use and other factors influencing exposure. Multivariable linear regression models were used to estimate differences in geometric mean RTL (and corresponding 95% confidence intervals) by ever vs. never use of 48 pesticides and in exposure-response analyses for IWLDs of use of 46 pesticides, adjusting for age, state of residence, race/ethnicity, body mass index, and cigarette smoking status and pack-years.
Results: Among ever users of the insecticides lindane and aldicarb, mean RTL was significantly longer compared to never users (p=0.01 and 0.03, respectively); in exposure-response analyses, we also observed a suggestive but non-statistically significant trend between increasing IWLDs of lindane use and longer RTL (p-trend=0.07). Higher IWLDs of use of the insecticide diazinon was also associated with longer RTL (p-trend=0.03) while increasing IWLDs of the insecticide heptachlor and the herbicide 2,4,5-TP were associated with shorter RTL (p-trends=0.04 and 0.03, respectively).
Conclusions: This is, to our knowledge, the largest investigation of occupational pesticide use and RTL to date. Our findings provide novel evidence suggesting that use of certain pesticides could be associated with altered leukocyte telomere length. Notably, diazinon and lindane have previously been associated with increased risks of lung and lymphoid malignancies, respectively, and longer leukocyte telomere length has been implicated in the development of these cancers.

Aflatoxin exposure in a population-based representative sample of adults in Mexico in 2018

Adriana Monge[1], Katherine McGlynn[2], Luis Santiago-Ruiz[1], Jose Maria Remes-Troche[3], Karina Hernandez-Flores[3], Salvador Villapando-Hernandez[1], Martin Romero[1], John Groopman[4], Martin Lajous[1]. *[1]Instituto Nacional de Salud Pública, Ciudad de Mexico, Mexico,[2]National Cancer Institute, Rockville, MD,[3]Universidad Veracruzana, Veracruz, Mexico,[4]Johns Hopkins University, Baltimore, MD*

Importance: Southern Mexico and Guatemala, together represent the region with the highest liver cancer burden in the Americas. There is a higher burden of liver cancer in rural regions in eastern and southern Mexico and remarkably there is an equal number of cases in men and women. Reasons for this increased burden are not clear, but previous studies of food samples have found that contamination of maize with aflatoxin B1 (AFB1), a potent liver carcinogen, is common in the region while HBV and HCV seroprevalence is less than 0.5%. Few examinations of AFB1 levels in persons have been conducted.
Objective: To estimate the prevalence of exposure and circulating levels AFB1 in a representative sample of adults living in five regions across Mexico.
Study Design: We randomly selected a subsample of 955 adults ≥40 years who participated in Mexico's National Health and Nutrition Survey 2018 (ENSANUT). These residents were from five states in eastern and southern Mexico and all provided a venous blood sample. We assessed AFB1 levels as pg AFB1-lys/µL in serum using mass spectrometry. The limits of detection and quantification were both 0.010 pg/µL.
Results: The mean age of participants was 56 years (± SD 11.7) and 54% were female. The overall prevalence of AFB1-lys detection was 92% (95% confidence intervals; 95%CI 88, 94%). The region with the lowest prevalence, 88% (95%CI 78, 94%), was Chiapas and the region with the

highest prevalence was Veracruz 95% (95%CI 84, 98). Median AFB1 was 0.127 pg AFB1-lys/μL (interquartile range; IQR 0.054, 0.446) with a range from 0.066 (IQR, 0.033, 0.147) in Yucatán to 0.476 (IQR, 0.199, 1.355) in Veracruz. AFB1 exposure levels were higher in persons aged ≥60 years, men, and participants living in rural areas. We observed decreasing levels of AFB1 exposure with increasing socioeconomic status.
Conclusions: In a representative sample of adults in eastern and southern Mexico we observed a high prevalence of exposure to AFB1. For certain regions, AFB1 levels are comparable to those in Guatemala. These results suggest that AFB1 may be related to the increased burden of liver cancer in eastern and southern Mexico.

#4222

Glyphosate and AMPA exposure: Associations with dietary intake and other factors

Rachel McFarland Lucia[1], Xiyue Liao[2], Wei-Lin Huang[1], Danielle Forman[3], Alexis Kim[4], Argyrios Ziogas[1], Trina M. Norden-Krichmar[1], Deborah Goodman[1], Andrea Alvarez[1], Irene Masunaka[1], Khyatiben Pathak[5], Marissa McGilvrey[5], Victoria David-Dirgo[5], Apurva Hegde[5], Patrick Pirrotte[5], Hannah Lui Park[1]. *[1]University of California, Irvine, Irvine, CA,[2]California State University, Long Beach, CA,[3]University of California, Los Angeles, Los Angeles, CA,[4]Yale University, New Haven, CT,[5]Translational Genomics Research Institute, Phoenix, AZ*

Background: Animal and epidemiologic studies suggest that exposure to the weed killer, glyphosate, and its primary metabolite aminomethylphosphonic acid (AMPA), is associated with increased risk for cancer, including breast cancer and non-Hodgkin's lymphoma. The International Agency for Research on Cancer (IARC) has categorized glyphosate as a “probable carcinogen,” yet glyphosate is the most highly used pesticide in the world. Biomonitoring studies assessing levels of human glyphosate and AMPA exposure in the United States have been limited. Thus, we examined urinary levels of these chemicals in a cohort of postmenopausal women residing in Southern California and evaluated associations with demographics, dietary intake, and other behavioral factors.
Methods: 338 postmenopausal women provided two first-morning urine samples and at least one paired 24-hour dietary recall. Participants also reported on demographic and other factors. Urinary glyphosate and AMPA were measured using LC-MS/MS.
Results: Glyphosate was detected in nearly 90% of urine samples and AMPA in 67.2%. Urinary glyphosate and AMPA levels were lower in women who reported high levels of organic eating (p=0.04 and p=0.01, respectively). Urinary glyphosate was lower in women who reported higher levels of physical activity (p=0.03). Multivariate analysis showed that grain consumption, particularly refined grains, was significantly associated with higher urinary glyphosate levels (adjusted p=0.004). Alcohol consumption (adjusted p=0.001) and frequency of eating fast-food (adjusted p=0.006) were associated with higher urinary AMPA levels, while fruit (adjusted p=0.03) and corn (adjusted p=0.008) consumption were associated with lower AMPA.
Conclusions: In the largest study to date examining paired dietary recall data and measurements of urinary glyphosate and AMPA, the vast majority of women sampled had detectable levels. Consumption of certain foods, including grains and alcoholic beverages, were associated with higher urinary levels of glyphosate and AMPA.

A metabolomic investigation of serum perfluorooctane sulfonate and perfluorooctanoate

Jongeun Rhee[1], Steven C. Moore[2], Demetrius Albanes[2], Tracy M. Layne[3], Erikka Loftfield[2], Rachael Stolzenberg-Solomon[2], Linda M. Liao[2], Mary C. Playdon[4], Mark P. Purdue[1].

[1]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[2]Metabolic Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[3]Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, NY,[4]Division of Cancer Population Sciences, Huntsman Cancer Institute, Salt Lake City, UT

Background: Per- and polyfluoroalkyl substances (PFAS) are environmentally persistent synthetic chemicals detectable in the blood of most Americans. Elevated exposures to perfluorooctane sulfonate (PFOS) and perfluorooctanoate (PFOA), the two most prevalent PFAS, have been associated with several health outcomes including metabolic outcomes and some cancers. To evaluate possible mechanisms related to the biological effects of these chemicals, we conducted a pooled metabolome-wide association study (MWAS) of circulating PFOS and PFOA among 3,647 participants included in one of eight nested case-control serum metabolomic profiling studies conducted in the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO) population.
Methods: All metabolomic profiling was conducted by Metabolon Inc, using liquid-phase or gas chromatography coupled with mass spectrometry. All metabolites including PFOS and PFOA were centered (mean=0, standard deviation=1) and log-transformed. We conducted multivariable linear regression analyses to estimate study-specific associations between metabolite levels and PFOS and PFOA, adjusted for age at specimen collection, race/ethnicity, body mass index, smoking, case-control status, study center, and year of specimen collection. Sex was additionally adjusted for studies including both men and women. We then conducted combined the study-specific findings through meta-analysis using random effects models.
Results: The meta-analysis results of 1,040 metabolites for PFOS and 1,103 for PFOA identified 83 and 67 metabolites, respectively, associated at Bonferroni-corrected significance thresholds ($P=4.81 \times 10^{-5}$ for PFOS; $P=4.53 \times 10^{-5}$ for PFOA). For both PFOS and PFOA, the strongest positive associations were observed for the xenobiotics 3,5-dichloro-2,6-dihydroxybenzoic acid [PFOS, summary beta coefficient =0.74, 95% confidence interval=0.67,0.80; PFOA, 0.48 (0.35,0.61)] and 3-bromo-5-chloro-2,6-dihydroxybenzoic acid [0.57 (0.43,0.72) and 0.39 (0.23,0.55)]. We also observed strong positive associations with PFOS and PFOA for metabolites related to the sphingomyelin (SM) pathway, such as hydroxypalmitoyl sphingomyelin (d18:1/16:0(OH)) [PFOS, 0.44 (0.24,0.64)] and SM (d18:1/18:0) [PFOS, 0.35 (0.24,0.46); PFOA, 0.25 (0.16,0.34)], and SM (d18:2/24:2) [PFOS, 0.32 (0.17,0.47)]. The PFOS metabolite associations remained after model adjustment for PFOA; however, the PFOA associations were greatly attenuated after controlling for PFOS.
Conclusions: In this MWAS of PFAS, to our knowledge the largest to date, we observed robust positive associations with serum PFOS for several xenobiotic compounds and for metabolites related to the sphingomyelin pathway. Further investigation of these metabolites may offer insight into PFOS-related biologic effects contributing to disease development.

University of Chicago Comprehensive Cancer Center catchment area informatics platform

Ahmed Fadiel Metwaly[1], Adam Thomas Koster[2], Mohammad Abbasi[2], Adekunle Odunsi[1].
[1]Comprehensive Cancer Center, University of Chicago, Chicago, IL,[2]Research and Development, Interactome Bio, Kalamazoo, MI

Every cancer center has a surrounding geolocation known as a catchment area (CA). Data about this CA can help cancer centers better understand the population and type of patients the center is

targeting. In addition, collecting, analyzing, and visualizing this data can help the cancer center better understand population needs and gain more insights to provide predictive care instead of reactive care. However, the multidimensionality and complexity of the CA data requires the build of a specialized platform that can handle this heterogenous data. Motivated by this need and to answer specific questions about the CA, the UCCCC developed a new informatics platform that provides access to analytical tools, data handling, and an exchange environment. The goal of this platform is also to support a collaborative community to study CA dynamics related to health disparity and cancer. Here we present a new Geoinformatics platform that offers capabilities for using and modifying spatial data. It facilitates interrogating, modifying, executing, and mapping data. Data includes imagery, features, and base maps linked to spreadsheets and tables. The data is kept in the RDBMS (Relational Database Management System). Other query software tools are needed to deal with the database system including a server to launch the GIS application with specific RAM, GPU, and good SSD to back up the database. The database could be saved on google firebase to handle real-time queries. Thus, the maps can be easily shared and embedded in apps and accessible by virtually everyone, everywhere. The datasets used were downloaded from conventional websites (listed in the appendix) and internal datasets. The goal is to answer basic questions including the count of patients in that area, socioeconomic status, distribution in terms of demography (race, age, gender), physical environment, and other factors. Furthermore, it will be able to find correlations across many variables given the response variable, such as type of disease (lung, ovarian, breast cancer). Solving Critical Problems in Cancer Control using Spatial Science as well as being able to select a geographic location/region/area and plot the data across different dimensions, possibly on a map or another type of view. Geographic information needs a way to integrate data from several sources with varying degrees of accuracy. The platform provides real-time changes in the CA, so it needs to be updated frequently to stay current. The tool will connect the dataset to maps, integrating location data (where things are) with all kinds of descriptive information (how things are). Thus, a unique method of retrieval and manipulation is required for a significant portion of the data stored in GIS for practical usage.

Expanding the spectrum of germline-driven cancers by leveraging population-scale targeted tumor and normal sequencing

Miika Mehine, Rebecca Caeser, Yelena Kemel, Daniel Muldoon, Sebastià Franch-Expósito, A. Rose Brannon, Aijazuddin Syed, Ozge Ceyhan-Birsoy, Maksym Misyura, Panieh Terraf, David B. Solit, Marc Ladanyi, Kenneth Offit, Zsofia K. Stadler, Diana L. Mandelker, Yonina R. Murciano-Goroff, Charles M. Rudin, Michael F. Berger, Chaitanya Bandlamudi. *Memorial Sloan Kettering Cancer Center, New York City, NY*

Large case-control and familial studies have established clear cancer-specific risk profiles for several key cancer predisposition genes (CPGs). For example, germline pathogenic variants (PVs) in *BRCA1/2* (*gBRCA*) are associated with increased risk for developing breast, ovarian, pancreatic, and prostate cancers. However, the extent to which *gBRCA* mutations are involved in mediating the tumorigenesis of other cancer types remains challenging to characterize. We hypothesized that integrating orthogonal features such as selection for biallelic inactivation of the PVs and depletion of canonical somatic drivers among the carriers can enrich the signal for identifying novel gene and cancer type associations. We then extend this framework to identify novel CPGs as well as to understand how tumors arise in patients with PVs in oncogenes.

To study this, we leveraged the prospective MSK-IMPACT matched tumor-normal sequencing cohort of 49,291 patients across 77 major cancer types. We study 90 well-known CPGs as well as >300 cancer genes not previously associated with cancer predisposition.
Overall, 8% (N=3,964) of patients harbored a PV in high or moderate penetrance CPGs. We identified 90 gene and cancer type associations with enrichment for biallelic inactivation (q<0.05), including 19 novel findings among clinically actionable genes. For example, we find enrichment for biallelic inactivation of *BRCA1/2* in unexpected lineages such as hepatobiliary, endometrioid, and ampullary cancers. These tumors were also significantly depleted for somatic gain-of-function driver alterations. Hepatobiliary cancers with *gBRCA1* mutations were also enriched for somatic loss of *NF1*.
Among carriers of PVs in oncogenes, we observe two possible mechanisms of first somatic hit towards malignant transformation. We find enrichment for copy number gain or copy neutral loss of heterozygosity of the germline PV in thyroid cancers with a PV in *RET*. We also find that lung cancers with a germline PV in *EGFR* frequently developed additional somatic point mutations located *in cis* with the PV.
Investigating genes with no prior association with germline predisposition to cancer, we find evidence for *KEAP1* and *CIC* as likely novel CPGs. Lung (n=8) and thyroid (n=4) cancers with deleterious germline variants in *KEAP1* were characterized by loss of the wild-type allele, co-occurring somatic *STK11* mutations, and depletion of canonical drivers such as *EGFR*. We also found biallelic loss of *CIC* in two patients with Neuroblastoma, each carrying a different germline loss-of-function mutation in *CIC*. Both tumors were also negative for *MYCN* and *ALK* defects.
Collectively, our findings expand our understanding of cancer predisposition in cancer, shed new insights into how tumors arise in germline carriers, and provide a framework for identifying new CPGs using population scale tumor-normal paired clinical sequencing data.

Clinical features of Li-Fraumeni syndrome in Korea
Ran Song, Seeyoun Lee, Jai Hong Han, Jae Yeon Woo, Min Jung Lee, Han-Sung Kang, Sunhwa Park, Eun-Gyeong Lee, Sun Young Kong, So-Youn Jung. *National Cancer Center, Goyang, Korea, Republic of*

Purpose: Li-Fraumeni syndrome (LFS) is a rare autosomal dominant hereditary disorder caused by a germline mutation in the TP53 gene. Because of the rarity of the disease, there were limited data on the types of the mutation, clinical features and treatment outcomes. The aim of this study is to evaluate the clinical characteristics and prognosis in Korean patients with germline TP53 gene mutation.
Methods: Patients who underwent genetic counseling and confirmed with TP53 gene mutation in National Cancer Center in Korea between 2011 and 2022 were reviewed retrospectively. Data on family history with pedigree, types of mutation, clinical features and prognosis were collected.
Results: Fourteen patients with LFS were included in the study. Missense mutations were shown in 13 cases and nonsense mutation in 1 case. The repeated mutations were p.Arg273His (n=2), p.Ala138Val (n=2) and pPro190Leu (n=2). A sister with breast cancer had the same mutation of p.Ala138Val. The median age at diagnosis of first tumor in 14 LFS patients was 32 (1-67) years. Seven patients (50%) had multiple primary cancers. Breast cancer was most frequently observed (n=9) and other types of tumor included sarcoma (n=5), thyroid cancer (n=3), pancreatic cancer (n=2), ovarian cancer (n=1), endometrial cancer (n=1), colon cancer (n=1), brain tumor (n=1), adrenocortical carcinoma (n=1), vaginal cancer (n=1), skin cancer (n=1) and leukemia (n=1). The median follow-up period was 51.5 (6-188) months. There were two cases of local recurrence and

four cases of distant metastasis during the periods. Two patients died from leukemia and pancreatic cancer at three months and 23 months after diagnosis, respectively.
Conclusion: As known in other countries, many Korean patients with LFS also had an early onset and multiple primary tumors. And patients showed various types of mutation, clinical features and prognostic outcomes. Further large-scale studies are required for proper screening and management in Korean patients with LFS. Grant: This study was supported by National cancer center, Korea, Grant no. 2110181

The effect of polymorphisms in *DAT1* and *DRD4* on dietary intake during chemotherapy for childhood leukemia

Jing Wen[1], Arul Duggimpudi[2], Shengguo Li[3], Elena Ladas[4], Kara M. Kelly[5], Peter D. Cole[3].
[1]Goryeb Children's Hospital, Morristown Medical center, Morristown, NJ,[2]Rutgers, The State University of New Jersey, New Brunswick, NJ,[3]Division of Pediatric Hematology/Oncology, Rutgers Cancer Institute of New Jersey, Rutgers, The State University of New Jersey, New Brunswick, NJ,[4]Division of Pediatric Hematology/Oncology/Stem Cell Transplant, Columbia University Medical Center, New York, NY,[5]Department of Pediatric Oncology, Roswell Park Cancer Institute and University at Buffalo School of Medicine and Biomedical Sciences, Buffalo, NY

Outcomes of acute lymphoblastic leukemia (ALL) are associated with both host and environmental factors. We hypothesized that there is also an interaction between them, with genetic variants influencing dietary choices. The dopamine transporter 1 (*DAT1*) and D4 subtype of the dopamine receptor (*DRD4*) genes are polymorphic, with a variable number of nucleotide repeats (VNTR) that affect dopaminergic neurotransmission, and reward circuitry for food cravings. Specifically, the 9-tandem repeats (9R) allele of DAT1 and the 7-tandem repeats (7R) allele of DRD4 are risk factors for eating disorders or undereating behavior in children. The goal of this study was to determine whether these polymorphisms are associated with altered dietary intake during therapy for childhood ALL. DNA was isolated from peripheral blood mononuclear cells collected from 439 children being treated on Dana Farber Cancer Institute ALL Consortium Protocol 05-001 (NCT00400946). Target alleles in DAT1 and DRD4 were determined using PCR product length analysis. Each subject was classified as having either zero or at least one copy of the target alleles. Dietary intake was previously determined using food frequency questionnaires collected at three timepoints: time of diagnosis, end of induction, and continuation therapy. As previously published dietary composition in fat and carbohydrate differed significantly among three timepoints. There was no significant difference between those with or without the target alleles in DAT1 or DRD4 in percent from fat or percent from carbohydrate at any of the three timepoints. However, significant differences were observed when dietary intake was compared to the Dietary Reference Intake (DRI). Notably, a greater portion of male participants with DAT1 9R polymorphism had fat consumption below the DRI at the time of diagnosis. On the contrary, significantly decreased portion of females with DAT1 9R had fat consumption below the DRI during continuation therapy. When compared to normative values, a significantly increased number of children had total calorie consumption below DRI during induction therapy. The DRD4 7R polymorphism was associated with fat intake below DRI during induction therapy in males. However, neither DAT1 nor DRD4 polymorphisms were related to variation in carbohydrates consumption. In addition, a greater portion of participants that carry both DAT1 and DRD4 polymorphism exhibited a trend toward undereating behavior in fat intake compared to the controls. Our results are the first to indicate that DAT1 and DRD4 polymorphisms are associated with altered dietary intake during chemotherapy

for childhood ALL. Future study will further elucidate whether this modulation is associated with changes in their body weight, BMI, glucose level, and disease relapse.

Genome-wide interactions of processed and red meat intake on colorectal cancer risk

Joel Sanchez Mendez[1], Mariana C. Stern[1], Andre Kim[1], John Morrison[1], Juan P. Lewinger[1], Li Hsu[2], Eric Kawaguchi[1], Ulrike Peters[2], William J. Gauderman[1], on behalf of GECCO, CCFR and CORECT. *[1]Population and Public Health Sciences, University of Southern California, Los Angeles, CA,[2]Public Health Sciences Division, Fred Hutchinson Cancer Research Center, Seattle, WA*

Introduction: Colorectal cancer (CRC) is the third most common cancer, and second cause of cancer death worldwide. High red meat and/or processed meat consumption are established risk factors for CRC. Genome-wide association studies have identified over 200 genetic variants that explain ~20% of the variability in CRC risk. However, few large studies have evaluated genome-wide gene by environment (GxE) interactions with meat in CRC. Using the largest CRC pooled dataset available to date we conducted a genome-wide GxE analysis to identify possible interactions between common variants and red meat and/or processed meat intake and CRC risk.
Methods: A pooled sample of 29,912 CRC cases and 39,704 unaffected controls of European (EUR) ancestry from 27 studies was analyzed. Sex- and study-specific quartiles for red meat and processed meat intake were constructed from harmonized questionnaire data on meat consumption. Genotyping arrays were imputated to the Haplotype Reference Consortium. To identify novel CRC interaction loci we used the two-step EDGE method, standard GxE analyses and a 1-3 degrees of freedom (DF) test . We removed previously known GWAS hits and SNPs in high linkage disequilibrium with them.
Results: Our Meta-analyses confirmed a positive association between quartile consumption increase of red meat and processed meat with CRC risk (Red meat OR = 1.30; 95%CI = 1.21-1.41; Processed meat OR = 1.40; 95% CI = 1.20 -1.63). Greater magnitude in point estimates were observed for case-control studies compared to cohort studies, for processed meat consumption among men compared to women, and for red meat consumption and distal colon localization compared to proximal colon or rectum. Two DF GxE tests of red meat consumption revealed two SNPs in chromosome (Chr) 8 (rs4871179 & rs75212442) and a SNP in Chr10 (rs117674361) that map downstream HAS2, COLEC10 and downstream CCSER2. In addition, the two-step EDGE GxE method identified the rs35352860 SNP that maps to the SMAD7 gene in Chr18. Genotype-stratified analyses showed that the red meat and CRC risk association was restricted to homozygous carriers of major alleles for rs4871179, rs75212442 & rs117674361. Moreover, we observed dose-response increase in the red meat and CRC risk association with additional copies of the T allele of the SNP in Chr18, with homozygous carriers of the T allele having 46% higher chance of developing CRC associated with high red meat intake; this in contrast to homozygous carriers of the reference C allele, that had an 18% higher risk of developing CRC. No statistically significant GXE interactions with processed meat intake were found.
Conclusion: In this large-scale genome-wide GxE analysis we identified interactions between 4 SNPs and red meat consumption affecting CRC risk. The interaction with the SMAD7 rs35352860 SNP provides supportive evidence for a role of heme iron in the carcinogenic pathway of red meat intake in CRC development.

#5218

Genome-wide association study of African Americans reveals new susceptibility loci contributing to lung cancer and mechanisms of population-specific etiology

Jinyoung Byun[1], Younghun Han[1], Xiangjun Xiao[1], Christine Lusk[2], Hoda J. Badr[1], Rayjean Hung[3], Ann G. Schwartz[2], Christopher I. Amos[1], INTEGRAL Consortium. *[1]Baylor College of Medicine, Houston, TX,[2]Wayne State University School of Medicine, Detroit, MI,[3]University of Toronto, Toronto, ON, Canada*

Lung cancer incidence and mortality in the U.S. have substantial ethnic disparities. African Americans of both sexes have the high incidence rate at 56.8 and the highest death rate at 38.1 per 100,000 people from 2015 to 2019. Non-Hispanic black men have the highest incidence at 73.9 and the highest death rate at 56.3 per 100,000 people. While many genome-wide association studies (GWAS) of lung cancer have discovered ~45 putative risk loci, a large proportion of the heritability of lung cancer remains unexplained. To date, most single population-based GWAS have been performed in Europeans while there are a few Asian ancestry-specific genetic studies and two cross-ancestry studies. Non-European GWAS of lung cancer has been underrepresented. Although African Americans have higher lung cancer incidence and poorer lung cancer survival rate, and smoke fewer cigarettes per day compared to Europeans, few comprehensive GWAS of lung cancer in African Americans has been conducted. This study aims to decipher the genetic component of predisposition to lung cancer among African Americans. This study aims to decipher the genetic component of predisposition to lung cancer among African Americans. We conducted an African-ancestry GWAS comprising 2,280 lung cancer cases and 4,301 controls to comprehensively characterize common and low-frequency lung cancer genetic susceptibility loci using HRC imputed lung cancer data. The novel variants in or near VWF on 12p13.31 (OR=1.29, $P=6.93\times10^{-9}$) for overall lung cancer and GACAT3 on 2p24.3 (0.65, 1.24×10^{-9}), TRIP13 on 5p15.33 (3.49, 1.00×10^{-8}), ERC1 on 12p13.33 (4.64, 6.08×10^{-9}), LMAN1L (near CYP1A1) on 15q24.1 (4.25, 8.71×10^{-9}) for lung squamous cell cancer were identified at a genome-wide significance level. Our GWAS of lung cancer identified five novel genetic susceptibility associations and confirmed several variants on 15q25 and 19q13. Further works are required to elucidate the possible biological mechanisms underlying these associations among lung cancer and histological subtypes in African Americans.

#5219

Telomere length distribution, metabolic trait association, and genome-wide association study among Singaporean cohorts

Trang Nguyen[1], Penny Chan[2], Ives Lim[3], Brian Kennedy[4], Neerja Karnani[2], Rajkumar Dorajoo[5], Joanne Ngeow[1]. *[1]Nanyang Technological University Singapore, Singapore, Singapore,[2]Singapore Institute for Clinical Sciences, Singapore, Singapore,[3]Bioinformatics Institute, Singapore, Singapore,[4]National University of Singapore, Singapore, Singapore,[5]Genome Institute of Singapore, Singapore, Singapore*

Leukocyte telomere length (LTL) is known as a heritable marker of cellular aging and is a risk factor for several chronic diseases. LTL distribution and association studies are essential in providing insights into telomere homeostasis, its relationship with different metabolic traits, and age-related conditions. Such studies have been underperformed in Asian population groups. Here we estimated LTL using whole-genome sequencing data in 8,045 Singaporean samples across three major ethnic groups - Chinese, Indian, and Malay divided into six cohorts: GUSTO, HELIOS, MEC, PRISM, SEED, and TTSH. LTLs were measured using TelSeq, with normalized LTL as

phenotype in subsequent analyses. We demonstrated that average LTL was robustly longer in the childhood cohort (GUSTO) compared to the adult cohorts ($P<1.19\times10^{-195}$). We observed ethnicity differences in LTL where adult Singaporean Chinese samples had the longest LTL (5.08kb) as compared to Malay (4.87kb) and Indian (4.65kb) samples in our datasets ($P<4.98\times10^{-12}$). Our genetic association analyses replicated multiple variants previously reported to be associated with LTL (binomial $P<0.00001$) in Asian population groups, providing added confidence in the methodologies used. At the same time, we identified a novel East-Asian-specific novel variant beyond genome-wide association levels (meta $P=2.05\times10^{-08}$) at the *COL28A1/MIOS* gene loci to be associated with LTL in our study. Individual analysis of the GUSTO childhood dataset highlighted a second novel genome-wide hit at *RAD17* gene locus to be associated with LTL in our study and indicated that the previously reported variant at the *TINF2* locus may have significantly opposing effects (compared to adults) during early developmental stages. Gene-level burden analysis for rare variants (MAF <5%) in adult Chinese cohorts revealed potential cancer association with *RET* gene (SKAT, $P=5.22\times10^{-03}$) and *MLH1* gene (SKAT, P=0.037), as well as telomere biology condition association with *RECQL4* gene (CMC, P=0.0399, and VT, P=0.0379). Our findings have broadened the understanding of LTL distribution and the underlying associated genetic characteristics in both childhood and adult Singaporean populations.

Prediagnostic vitamin D status and colorectal cancer survival by vitamin D-binding protein isoforms in the US cohorts

Hanseul Kim[1], Chen Yuan[2], Long H. Nguyen[3], Kimmie Ng[2], Edward L. Giovannucci[4].
[1]Massachusetts General Hospital and Harvard Medical School, Boston, MA,[2]Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA,[3]Division of Gastroenterology, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[4]Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, MA

Background: Lower levels of 25-hydroxyvitamin D [25(OH)D], a major form of circulating vitamin D, have consistently been associated with higher mortality among colorectal cancer (CRC) patients, though the dose-response relation is not well characterized {Ng 2008; Fedirko 2012; Wesa 2015; Zgaga 2014}. A study showed a strong effect modification (*P* for interaction = 0.0002) {Gibbs 2020} by Gc2 (or, vitamin D-binding protein) isoform where patients with the isoform had significantly higher mortality if they had deficient vitamin D levels. However, it is unknown whether this association differs by Gc isoforms in other populations.
Methods: We examined the association between prediagnostic 25(OH)D levels and overall and CRC-specific mortality among CRC patients within the two ongoing prospective US cohorts: Nurses' Health Study and Health Professionals Follow-Up Study. Cox proportional hazards regression model was used to estimate the hazard ratios (HRs) and 95% confidence intervals (CIs). We evaluated potential nonlinear association using the restricted cubic splines and assessed effect modification by Gc2 isoform with stratified analyses. Individuals with the Gc rs4588 CC, CA and AA genotypes were classified as having Gc1-1, Gc1-2, and Gc2-2 isoforms, respectively. Participants with a minor allele at Gc rs4588 (rs4588*CA or rs4588*AA genotypes) were defined as having the Gc2 isoform.
Results: A total of 588 patients were observed until the date of death or last follow-up in 2018, whichever came first. Deficient versus sufficient 25(OH)D concentrations (<30 vs ≥50 nmol/L) were associated with higher overall mortality (HR, 2.06; 95% CI, 1.34-3.18) and suggestively with higher CRC-specific mortality (HR, 1.51; 95% CI, 0.75-3.07). Spline results showed that the potential beneficial role of vitamin D plateaued around 50 nmol/L (*P* for nonlinearity = 0.04). The

HRs for overall mortality comparing deficient versus sufficient concentrations were 2.43 (95% CI, 1.26-4.70) for patients with Gc1-1 isoform (rs4588 CC) and 1.63 (95% CI, 0.88-3.02) for patients with Gc1-2 or Gc2-2 (rs4588 CA or AA) isoforms (*P* for interaction = 0.54). The HRs for CRC-specific mortality were 1.18 (95% CI, 0.27-5.14) for patients with Gc1-1 isoform and 1.41 (95% CI, 0.62-3.24) for patients with Gc1-2 or Gc2-2 isoforms (*P* for interaction = 0.94).
Conclusions: We found that lower 25(OH)D levels up to 50 nmol/L were associated with higher overall mortality, but this association did not differ by Gc isoforms in the two US cohorts.

#5221

Identifying acute lymphoblastic leukemia risk loci in latino children via admixture mapping

Jalen Langie[1], Soyoung Jeon[1], Xiaomei Ma[2], Catherine Metayer[3], Adam J. de Smith[1], Joseph L. Wiemels[1], Charleston W. K. Chiang[1]. *[1]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, CA,[2]Department of Chronic Disease Epidemiology, Yale University, New Haven, CT,[3]School of Public Health, University of California Berkeley, Berkeley, CA*

Acute lymphoblastic leukemia (ALL) is the most common childhood cancer and accounts for 25% of malignancies before the age of 20. Despite decades of inquiry into ALL causes, Latino children have up to 1.4 times the rate of ALL compared to their non-Latino White counterparts. The etiology of ALL is complex and this disparity in risk has not been fully explained by social factors alone, suggesting the role of genetic variants and ancestry. Previous literature has implicated variants in *IKZF1, ARID5B, GATA3*, *PIP42KA*, and *ERG* with greater risk allele frequencies or population-specific risk effects in Latinos. Indigenous American ancestry has also been previously associated with ALL risk, relapse, and poor prognosis. To elucidate the genetic and ancestral etiology of ALL, we conducted the first admixture mapping analysis of 1930 childhood ALL cases and 8520 controls of self-identified Latino ethnicity. We uncovered putative admixture associations on chromosomes 2, 7, 10, and 15 ($P = 3.21 \times 10^{-5}$ to 7.32×10^{-8} among top associations across the four loci). Two of the four loci, on chromosomes 2 and 15, were previously not known to be associated with ALL. Following imputation with the TOPMed reference panel, we fine-mapped each putative locus by testing the ALL risk association of each variant with a minor allele frequency greater than 1%. The top associated variants at each locus showed substantial frequency differences between ancestries from the gnomAD or 1000Genomes project. For example, the top associated variant on chromosome 2 has a risk allele frequency of 43% in Native Americans from the Human Genome Diversity Panel, but a frequency of 0.10% in Non-Finnish Europeans in gnomAD. Including these variants in the admixture mapping model greatly attenuated the admixture signals at each locus, suggesting that they are likely the causal SNPs or close proxies of the causal SNPs. The top associated variants from three out of the four loci passed regional multiple testing burden and mapped to genes MGAT5, *IKFZ1* and *ARID5B* on chromosomes 2, 7 and 10, respectively. The top two SNPs on chromosome 15, which narrowly missed the regional threshold, mapped to genes RAB11A and MEGF11. We are pursuing replication of putative novel loci on chromosomes 2 and 15 in additional Latino GWAS datasets. Our results suggest that ALL risk variants with higher frequencies in individuals with Native American ancestry may contribute to the observed increased risk of ALL in Latino children. Investigation of such risk loci can contribute to the identification of new target genes for ALL prediction and therapeutics and new insights for precision medicine, which will reduce the burden of ALL.

Low count (LC) MBL is characterized by a circulating population of clonal B-cells and is a precursor state to CLL. Most individuals with LC MBL do not progress to CLL and never come to clinical attention. An active area of research is to identify factors that distinguish those individuals with MBL who progress from those who do not. Currently, 41 single nucleotide polymorphisms (SNPs) are known to be associated with CLL risk, and a portion of these SNPs have also been found to be associated with MBL risk. We hypothesize that these CLL-susceptibility SNPs associated with both MBL and CLL risk are SNPs associated with developing a B-cell clone; whereas the remaining SNPs found not to be associated with MBL risk are associated with progression of the B-cell clone (i.e., progression from MBL to CLL). To test this hypothesis, we evaluated the association of these 41 SNPs with risk of progression to CLL using a case-control study of 1,911 CLL cases and 1,579 individuals with MBL from Mayo Clinic.

Individuals with MBL were identified through screening using 8-color flow cytometry assay. Individuals with LC MBL (defined by having a clonal B-cell population with the percent clonal B-cells out of total B-cell count <85%) who had an immunophenotype consistent with CLL were included as controls. CLL cases were obtained through the Mayo Clinic hematology practice. DNA was genotyped from whole blood. We analyzed the 41 CLL susceptibility SNPs with risk of progression to CLL using logistic regression and estimated odds ratio (OR) and 95% confidence interval (CI), adjusting for sex and age. We evaluated the CLL polygenic risk score (CLL-PRS), comprised of a weighted average of the 41 SNPs, with risk of CLL.

Out of the 41 established CLL susceptibility SNPs, 15 were associated with CLL progression from MBL to CLL (all P<0.05). Nine of these 15 significant SNPs were not previously found to be associated with risk of MBL. The most significant SNPs were rs9880772 (OR=1.23, CI: 1.11-1.36, $P=6.1x10^{-5}$), rs888096 (OR=1.25, CI: 1.12-1.38, $P=3.0x10^{-5}$), and rs305065 (OR=1.28, CI: 1.14-1.43, $P=1.5x10^{-5}$). One SNP (rs77551289) had a suggestive association (OR=1.21, P=0.069). The remaining 25 SNPs had no evidence of association with progression (ORs ranging between 0.9-1.1 and all P>0.1). The CLL-PRS was also associated with CLL risk (continuous OR = 1.25, CI: 1.15 - 1.35, $P = 6.7 X 10^{-8}$).

In our study accounting for the presence of B-cell clonal population, we identified 15 out of 41 CLL-susceptibility SNPs to be significantly associated with progression from LC MBL to CLL. The remaining 25 non-significant CLL-SNPs were not associated with progression and may instead be associated with development or initiation of the B-cell clone. These findings suggest that the established CLL susceptibility SNPs may play differing role (i.e., development or progression of the clone) in the etiology of CLL.

Circulating lipoprotein lipids and colorectal cancer risk: A Mendelian randomization analysis from the GECCO consortium

Lili Liu[1], Wanqing Wen[1], Jirong Long[1], Themistocles L Assimes[2], Luis Bujanda[3], Stephen B Gruber[4], Sébastien Küry[5], Brigid Lynch[6], Conghui Qu[7], Minta Thomas[7], Emily White[7], Michael O. Woods[8], Ulrike Peters[7], Wei Zheng[1]. *[1]Vanderbilt University, Nashville, TN,[2]VA Palo Alto Health Care System, Palo Alto, CA,[3]Universidad del País Vasco, San Sebastian, Spain,[4]City of Hope National Medical Center, Duarte, CA,[5]Centre Hospitalier Universitaire (CHU) Nantes, Nantes, France,[6]Cancer Council Victoria, Melbourne, Australia,[7]Fred Hutchinson Cancer Research Center, Seattle, WA,[8]Memorial University of Newfoundland, St. John's, NH, Canada*

Background Conventional observational studies have reported conflicting results regarding the association between low density lipoprotein cholesterol (LDL-C) and risk of colorectal cancer (CRC). We conducted a Mendelian randomization analysis to address this association.
Methods Single-nucleotide polymorphisms (SNPs) associated with five blood lipids (total cholesterol, HDL-C, high-density lipoprotein cholesterol [HDL-C], non-HDL-C, and triglyceride) were obtained from a genome-wide association study (GWAS) meta-analysis of European ancestry in the Global Lipids Genetics Consortium (GLGC, N ≤ 1 319 982), and two lipids (apolipoprotein A1 and apolipoprotein B) from a GWAS in the UK Biobank (UKB, N ≤ 441 016). Summary statistics were obtained for these SNPs from a GWAS of CRC in the Genetics and Epidemiology of Colorectal Cancer Consortium (GECCO) including 34,869 cases and 29,051 controls. Associations with CRC risk per one standard deviation increase in the genetically predicted lipids level were generated using inverse-variance weighted random-effects models.
Results No overall association was observed between genetically predicted levels of blood lipids and CRC risk. However, increased risks were observed for all LDL-C related traits among women, including total cholesterol (OR = 1.10; 95%CI = 1.02, 1.18), LDL-C (1.07; 1.00, 1.14), non-HDL-C (1.09; 1.02, 1.16), and apolipoprotein B (1.11; 1.02, 1.21); whereas no significant association was found among men. Similar but ostensibly stronger associations of these traits were seen with distal colon cancer cases, with no significant association showing on proximal colon or rectum cancer cases. We also observed similar positive associations of LDL-C related traits among those having CRC before their 50 years. Of note, risk reduction was found for apolipoprotein A1, a major component of HDL-C, in these early-onset cases (0.87; 0.78, 0.98).
Conclusion Results from this study suggest that high circulating LDL-C levels may increase the risk of CRC, particularly cancer of the distal colon, and the association may differ by sex and age at CRC onset.
Key words: Blood lipids; colorectal cancer; Mendelian randomization.

Genome-wide interaction study of smoking and bladder cancer risk: results from the COBLAnCE cohort

Maryam Karimi[1], Sebastian Mendez-Pineda[2], Hélène Blanché[3], Anne Boland[4], Jean-François Deleuze[4], Xiang-Yu Meng[5], Karine Groussard[2], Thierry Lebret[6], Julia Bonastre[1], Yves Allory[7], François Radvanyi[8], Simone Benhamou[2], Stefan Michiels[1]. *[1]Bureau de Biostatistique et d'Epidémiologie (BBE), Gustave Roussy, Villejuif, France,[2]Oncostat U1018, INSERM, Villejuif, France,[3]Biological Resources Center, CEPH-Fondation Jean Dausset, Paris, France,[4]Centre National de Recherche en Génomique Humaine, Evry, France,[5]Curie Institute, Paris, France,[6]Urology, Foch Hospital, Suresnes, France,[7]Department of Pathology, Curie Institute, Saint-Cloud, France,[8]CNRS UMR444, Curie Institute, Paris, France*

Introduction: Bladder Cancer (BC) is the 6th most common cancer and the 9th leading cause of cancer death among men worldwide. Tobacco smoking is the main risk factor for BC. Accumulating evidence has found that genetic variants are also associated with the risk of BC. More insights into the biological mechanism of the disease have been gained through candidate gene-environment interaction studies, with the most known examples of the interactions between cigarette smoking and NAT2 and GSTM1 gene variants. Our objective was to perform a genome-wide association case-only study using the French national prospective COBLAnCE cohort (COhort to study BLAdder CancEr), while focusing on three important smoking behavior characteristics.
Materials and Methods: The COBLAnCE cohort comprises 1,800 BC patients included within 14 centers in France between 2012 and 2018. Peripheral blood samples and complete history of tobacco smoking were collected at enrollment and genotyping was performed using the Illumina Global Screening Array with a Multi-Disease drop-in panel. After the quality control and imputation, 9,719,614 Single Nucleotide Polymorphisms (SNPs) were investigated. Genotyping data of 1,674 , 1,283 and 1,342 patients were analyzed for smoking status, average tobacco consumption and age at smoking initiation, respectively. Genome-wide association study (GWAS) was conducted using logistic (for smoking status) and linear (for age at smoking initiation and average tobacco consumption, both log-transformed) regression models with each of the imputed SNPs as the independent variable adjusting for gender, age and first ten genetic principal components.
Results: For smoking status, none of the SNPs reached the GWAS significant threshold of 5e-08, but results are suggesting tentative loci at 1p31.3 (rs114073636: OR [95%CI] = 0.31 [0.20-0.47], p = 8.68e-08; rs116571608: OR = 0.31 [0.20-0.47], p = 8.87e-08) and 4q22.1 (rs542541627: OR = 1.69 [1.39-2.06], p = 1.81e-07; rs1533294: OR = 1.63 [1.34-1.98], p = 1.01e-06). Analyses of age at smoking initiation revealed three significant SNPs: rs531756449, rs77186197 and rs78947799 with positive interaction associations (β (SE) = 0.3 (0.05), p = 8.26e-09; β = 0.29 (0.05), p = 3.74e-09; β = 0.31 (0.06), p = 3.97e-08, respectively). Only one SNP at 11q24.1, reached the significant threshold for the average tobacco consumption analyses: rs2714069 (β = 0.63 (0.11), p = 1.35e-08). The locus 16p13.3 seems to have protective variants for the interaction with average tobacco consumption: rs113683380 (β = -0.66 (0.12), p = 6.44e-08) and rs113590624 (β = -0.64 (0.12), p = 2.74e-07).
Conclusion: Our study suggests new candidate loci interacting with smoking behavior for the risk of BC. Based on a case-only approach, our results need to be validated in a case-control or cohort study. A large-scale meta-analysis GWAS would be needed to identify SNPs with small Minor Allele Frequencies.

#5225

Expression- and splicing-based multi-tissue transcriptome-wide association studies identified multiple genes for estrogen receptor-negative breast cancer

James L. Li, Julian C. McClellan, Guimin Gao, Dezheng Huo. *University of Chicago, Chicago, IL*

Although several transcriptome-wide association studies (TWAS) have been performed to identify genes associated with overall breast cancer risk, few genes were found to be associated with estrogen receptor-negative (ER-) breast cancer. These studies were based on gene expression prediction models trained mainly in breast tissue, and they did not account for alternative splicing of genes. In this study, we utilized two approaches to perform multi-tissue TWASs of ER- breast cancer: 1) an expression-based TWAS that combined TWAS signals for each gene across multiple

tissues and 2) a splicing-based TWAS that combined TWAS signals of all excised introns for each gene across tissues. To perform these two TWASs, we first obtained gene expression prediction models that were trained in 11 tissues from the Genotype-Tissue Expression including breast, ovary, uterus, vagina, EBV-transformed lymphocytes, whole blood, spleen, liver, subcutaneous adipose, visceral adipose, and cell-cultured fibroblasts. Furthermore, we obtained GWAS summary statistics for ER- breast cancer by performing a meta-analysis of 21,468 ER- cases and 105,974 controls from the Breast Cancer Association Consortium and 9414 BRCA1 mutation carriers who were breast cancer cases and 9494 BRCA1 mutation carriers who did not have breast cancer from the Consortium of Investigators of Modifiers of BRCA1 and BRCA2. For our expression-based TWAS, we utilized the Aggregated Cauchy Association Test (ACAT) to collate TWAS signals across all 11 tissues for each gene using equal weights for each tissue, while for our splicing-based TWAS, we utilized ACAT to collate TWAS signals for all excised introns in all tissues for each gene. Overall, we identified 63 genes in 29 loci that were significantly associated with ER- breast cancer, including 23 genes that were identified using both approaches, 27 that were uniquely identified in the expression-based TWAS, and 13 that were uniquely identified in the splicing-based TWAS. Of the 63 genes, 50 genes have not been previously reported in TWAS studies of breast cancer. Using a weighted ACAT method, in which breast tissue was given a 5-fold higher weight, we obtained similar results. In summary, our joint, multi-tissue TWAS corroborated previous GWAS loci for both ER- and overall breast cancer while highlighting how incorporating TWAS signals from multiple tissues and alternative splicing allowed us to discover new susceptibility genes for ER- breast cancer.

Exome-wide association study identifies coding variant in IL17RA associated with survival in cancer patients treated with immunotherapy

Sam O. Kleeman, Michael Chan, Matthew Chvasta, Tobias Janowitz. *Cold Spring Harbor Laboratory, Cold Spring Harbor, NY*

Immune checkpoint inhibitors (ICI) targeting PD-1/PD-L1 and CTLA4 are effective treatments in multiple cancer types, but durable responses are seen only in a minority of patients. Resistance to ICI is likely to reflect a combination of tumor-intrinsic, such as tumor mutational burden, and tumor-extrinsic factors, such as systemic immune suppression and host genetics. With the advent of large-scale germline genotyping studies, there is emerging evidence that host-specific genetic factors can substantially modify both disease risk and responsiveness to therapy. There has been limited characterization to date of the interaction between host genetics and response to ICI. Here, we perform harmonized mutation calling in available normal exome sequencing from 668 metastatic cancer patients treated with ICI (derived from n=7 studies, spanning n=3 cancer types and PD-1/PD-L1/CTLA4-directed therapy) and performed exome-wide association studies in European ancestry patients. For each cancer type (melanoma, renal cell carcinoma, urothelial carcinoma), we conducted exome-wide Cox regression (with PC1-4 and sex as covariates) to identify coding single-nucleotide polymorphisms (SNPs) associated with overall survival (OS). On fixed-effect meta-analysis, we identified a single coding variant (rs140221307, C allele, MAF 0.5% in European populations) that met genome-wide significance ($p=1.11x10^{-15}$, HR=4.86, 95% CI 3.30-7.15). This SNP causes a substitution of Trp to Arg at amino acid 320 at the interface between the transmembrane and extracellular domains of interleukin 17 receptor A (IL17RA). While the secretion mechanism is uncharacterized, soluble IL17RA can be readily detected in plasma and the survival-reducing variant is associated with substantially elevated plasma IL17RA ($p=1.90x10^{-9}$, beta=1.01, Sun et al. 2018) as well as reduced monocyte counts in UK Biobank

($p=2.20x10^{-308}$, beta=-0.60). We have established a prime editing strategy to induce this variant in cultured human monocytes to investigate its biochemical and functional consequences, and are performing validation studies in independent patient cohorts. Soluble IL17RA would be expected to function as a decoy receptor to antagonize IL17/IL17RA signaling, and so these data suggest that activation of IL-17 receptor signaling might improve responsiveness to ICI therapy.

Cross-trait genome-wide association meta-analyses of clonal hematopoiesis and solid tumor risk

Victoria Gray[1], George Richenberg[1], Pedro Quirós[2], Matthew Freedman[3], Paul Pharoah[4], Simon Gayther[4], Michelle Jones[4], George Vassiliou[5], Kate Lawrenson[4], Siddhartha Kar[1]. *[1]University of Bristol, Bristol, United Kingdom,[2]Instituto de Investigación Sanitaria del Principado de Asturias, Oviedo, Spain,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Cedars-Sinai Medical Center, Los Angeles, CA,[5]University of Cambridge, Cambridge, United Kingdom*

Clonal hematopoiesis (CH) is an age-related phenomenon where hematopoietic stem cells and their progeny acquire specific somatic mutations in a small, well-defined set of leukemogenic genes conferring them with fitness advantage leading to clonal proliferation. Mosaic chromosomal alterations (mCAs) are somatic structural variants that are manifestations of genomic instability and a sign of CH when they occur in blood. The recent availability of large-scale cohorts with blood exome sequence and genotype data has powered genome-wide association studies (GWAS) investigating the germline genetic contribution to CH and mCA risk. However, phenotypes of somatic mutation acquisition in driver genes, clonal selection and expansion, and chromosomal mosaicism are processes that are not confined to blood and contribute to neoplastic transformation across tissue types. GWAS of solid tumor susceptibility have so far identified hundreds of germline variants associated with cancer risk and it is likely that a subset of these variants contributes to solid tumor risk by affecting these somatic phenotypes in the corresponding tissues of origin and that some of the variants exert these somatic effects across tissues. We aimed to identify this subset of solid tumor risk variants by undertaking fixed effects inverse-variance weighted meta-analyses combining breast, prostate, ovarian, and endometrial cancer GWAS (total n = 237,483 cases/317,006 controls; no UK Biobank samples included) with UK Biobank-based CH (10,203 “cases”/173,918 controls) and mCA (66,011 “cases”/378,188 controls) risk GWAS in pairs where each pair involved one solid tumor type and one of either CH or mCA (for example, breast cancer and mCA constituted a pair). These analyses collectively identified 61 independent (r^2<0.05) lead variants at combined cross-trait genome-wide significance ($P<5x10^{-8}$) across 22 genomic loci where each lead variant was associated with each trait individually at $P<10^{-3}$, had the same direction of allelic effect across traits, and little evidence of heterogeneity in effect (I^2<40%). New loci (>1 Mb away from previously reported risk loci for a given trait) counts were: 14 new loci in the context of mCA risk, 6 new loci for CH risk, 2 for breast cancer risk, and one each for prostate, ovarian, and endometrial cancer risks. *In silico* functional annotation of these loci suggested lead variant-target genes that could be assigned to the discrete pathways of mitotic spindle assembly (*INCENP*, *CENPN*, *ZWILCH*, *MAD1L1*), p53 signaling (*TP53*, *MDM4*, *SPI1*), DNA damage repair (*ATM*, *RAD51C*, *CHEK2*, *USP28*, *PARP8*), and myeloid oncogenesis (*WT1*, *HOXA9*, *L3MBTL3*). Our novel approach combining the latest and largest blood somatic genomic trait GWAS with large-scale solid tumor risk GWAS thus yielded clear mechanistic insights into the shared inherited genetic basis of solid tumor risk and somatic genomic traits.

Genome-wide association study and LD score regression analysis for cholangiocarcinoma

Younghun Han[1], Katherine A. McGlynn[2], Jinyoung Byun[1], Matthew A. Cooley[3], Manal M. Hassan[4], Christopher I. Amos[1], Lewis R. Roberts[3], The International Consortium for the Genetics of Biliary Tract Cancers. *[1]Baylor College of Medicine, Houston, TX,[2]National Cancer Institute, Rockville, MD,[3]Mayo Clinic, Rochester, MN,[4]The University of Texas MD Anderson Cancer Center, Houston, TX*

Cholangiocarcinoma (CCA) is a rare and aggressive cancer of the bile ducts, with a poor prognosis and limited treatment options. CCA are classified as intrahepatic and extrahepatic based on anatomical location. CCA are often diagnosed at an advanced stage because there are no effective tools for early detection. Although genome-wide association studies (GWASs) have discovered many genome-wide significant contributing risk loci, the genetic underpinning of cholangiocarcinoma remains poorly understood. To date, there is no cholangiocarcinoma-specific GWAS. We conducted GWAS of cholangiocarcinoma in 9,648 individuals of European ancestry using TOPMed reference panel. The putative associations in or near THSD7A on chromosome 7 (OR=2.61, $P=7.13\times10^{-8}$), ZBTB16 on 11 (OR=0.16, $P=6.02\times10^{-8}$) for non-PSC-related CCA, PUM3 on 9 (OR=10.74, $P=6.12\times10^{-8}$), AGBL1 on 15 (OR=2.08, $P=5.67\times10^{-8}$) for PSC-related CCA, and LINC02506 on 4 (OR=0.16, $P=8.83\times10^{-9}$) for extrahepatic CCA. We also implemented linkage disequilibrium score regression (LDSR) analysis to quantify the genetic correlation between phenotypes using publicly available GWAS summary statistics. Our study aimed to identify possible clinical and epidemiological traits associated with CCA. We identified numerous biomarkers, medical conditions, environmental and behavioral traits, and physical measurements showing high heritability, which is the proportion of phenotypic variance explained by all SNPs included in the analysis, and pairwise genetic correlation with CCA and other CCA subtypes. Elevations of selected biomarkers such as alkaline phosphatase, cystatin C, HbA1c, monocyte count, and white blood cell count show a positive genetic association with CCA in European-ancestry population. Also, autoimmune-mediated conditions show a strong positive genetic association with CCA, non-PSC related CCA, and intrahepatic CCA. The GWAS of CCA and CCA subtypes revealed potential genetic susceptibility associations and will allow us to compare the genetic architecture underlying CCA and other diseases of the bile ducts such as primary sclerosing cholangitis and liver cancer. LDSR provided an improved understanding of the genetic architecture between CCA and potential comorbid conditions and biomarkers. Mendelian randomization analysis will be needed to elucidate the causal relationship between CCA and traits of interest.

Pathogenic germline mutations and risk of multiple myeloma

Michael T. Conry[1], Nicola Camp[2], Celine Vachon[3], Michelle Hildebrandt[4], Elizabeth E. Brown[5], Steven M. Lipkin[6], Judy Garber[7], Susan L. Slager[8], Samantha Stokes[7], Aaron D. Norman[9], Aalin Izhar[1], Sita Dandiker[1], Kylee Maclachlan[1], Kenneth Offit[1], Saad Usmani[1], Vijai Joseph[1]. *[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[3]Department of Health Sciences Research, Mayo Clinic, Rochester, MN,[4]Department of Lymphoma/Myeloma, MD Anderson Cancer Center, Houston, TX,[5]Department of Pathology, Heersink School of Medicine, University of Alabama at Birmingham, Birmingham, AL,[6]Department of Medicine, Weill Cornell Medical College, New York, NY,[7]Department of Medical Oncology, Dana Farber Cancer Institute, Boston, MA,[8]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[9]Mayo Clinic, Rochester, MN*

BACKGROUND: Multiple Myeloma (MM) is an incurable disease with no known germline high penetrant risk gene. The higher risk of MM among affected relatives suggests a genetic contribution to the etiology. To date, 24 common risk variants with low effect sizes were identified using genome-wide association studies, which account for 17% of heritability. However, a systematic analysis of the known rare alleles in cancer predisposition genes has not been undertaken so far in MM. We collaborated with six other academic centers across the United States to identify and select cases for analysis of germline predisposition of MM.
METHODS: We performed whole exome, next-generation sequencing of 2,387 familial or early onset germline MM cases from the myeloma sequencing consortium (MMSEQ). We called 1.5 million variants and performed standard quality control of the data. We also obtained exome data on 1,285 cases from UK Biobank (UKBB) and 344,513 non-cancer controls (total=3,672 cases). We analyzed the ultra-rare, coding variants in 90 clinically relevant or putative candidates for cancer predisposition. We then used the automated variant curator PathoMAN to annotate and assert pathogenicity of each variant. We contrasted our results with assertions of pathogenicity from ClinVar and tested for gene association with MM.
RESULTS: Overall, we observed several pathogenic or likely pathogenic variants, both singleton and recurrent founder mutations. In the MMSEQ, 8.7% of MM cases harbored a pathogenic variant in these known/putative cancer predisposition genes. Predominant group of pathogenic variants were observed within CHEK2 (19%), TP53 (8%), and ATM (5%). A case-control analysis revealed strong association with TP53 and weakly with ATM. In the familial/early onset MMSEQ cases, TP53 mutations were enriched 68 times more than in the UKBB controls. Our

preliminary results suggest that known genes of cancer susceptibility such as TP53 and ATM may also play a role in myeloma risk.
CONCLUSION: In a large study of multi-center MM cases, we identified a significant proportion of individuals who are carriers of known (solid) cancer predisposition genes. This study suggests that these known cancer predisposition genes may be relevant in a subset of MM cases.

Comprehensive genetic analysis using clinical specimens of gastric adenocarcinoma and proximal polyposis of stomach

Chihiro Matsumoto[1], Masaaki Iwatsuki[1], Koshi Mimori[2], Hideo Baba[1]. *[1]Department of Gastroenterological Surgery, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan,[2]Department of Surgery, Kyusyu University Beppu Hospital, Oita, Japan*

Background and Purpose: Gastric adenocarcinoma and proximal polyposis (GAPPS) is an autosomal dominant genetic disorder that causes gastric carcinoma from fundus gland polyposis. Although germline mutation of APC promoter 1B was reported as a pathogenic variant in 2016, there are still many unknowns about the carcinogenesis. In this study, we performed a comprehensive Next generation sequencing (NGS) analysis of GAPPS clinical specimens to investigate the molecular profile characteristic of carcinogenesis.
Patients and Methods: Seven cases from three GAPPS families experienced in our department were included in this study. In each case, tissues were collected from normal mucosa, polyps, and carcinoma,
and FFPE and fresh-frozen samples were prepared. After pathological diagnosis was performed on each sample, RNA and DNA were extracted and analyzed based on data obtained by next generation sequence (NGS).
Results: In the RNA sequence, gene expression analysis was performed on 45 pathologically diagnosed samples, which were classified into four clusters by K-means clustering. Gene Set Enrichment Analysis (GSEA) of the four clusters showed that cancer-related genes such as p53 and KRAS were significantly enriched in the cluster of cancer, and genes related to immune response were significantly enriched in the cluster of cancer compared to the and clusters of polyp and normal. Gene mutation analysis using whole-exome sequence (read depth/coverage>20) confirmed mutation of APC promoter 1B in all samples. On the other hand, in tumor samples (N=10), the percentage of mutation of genes previously suggested to be associated with GAPPS (TP53, FBXW7, GNAS, and KRAS) were 50%, 0%, 30%, and 60%, respectively.
Conclusion: Comprehensive gene expression analysis by RNA sequence and whole-exome sequence was performed using clinical samples of GAPPS. In the future, we plan to identify specific gene-pathways involved in carcinogenesis.

Whole genome sequencing reveals significant genetic admixture in multiple myeloma patients, impacting assessment of etiology

Kylee H. Maclachlan[1], Patrick Blaney[2], Dylan Gagler[2], Eileen M. Boyle[2], Benjamin Diamond[3], Urvi A. Shah[1], Neha Korde[1], Sham Mailankody[1], Malin Hultcrantz[1], Hani Hassoun[1], Carlyn Tan[1], Faith E. Davies[2], Alexander M. Lesokhin[1], C. Ola Landgren[3], Saad Z. Usmani[1], Francesco Maura[3], Gareth J. Morgan[2]. *[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]New York University Langone Health, New York, NY,[3]Sylvester Comprehensive Cancer Center, Miami, FL*

Background: In the U.S. population, having African ancestry (AA) conveys a higher risk of multiple myeloma (MM) than white ancestry (WA), however, published whole genome sequencing (WGS) data is predominantly from WA populations. The Polyethnic-1000 (P1000) is a multi-institutional WGS initiative together with the New York Genome Center, investigating cancers having a higher prevalence in AA populations. We are extending on the P1000 in MM precursor disease; prospectively defining genomic, immune and microbiome factors driving progression, focused on the impact of racial origin.
Hypothesis: Self-described race, according to proscribed categories, is insufficient to delineate biological contribution to MM development. We propose that unique biological insights first require a comprehensive definition of genetic origin, considering heterogeneity within historical groups.
Methods: For collaborative large-scale analysis, we've developed a comprehensive cross-institutional bioinformatic pipeline (https://github.com/pblaney/mgp1000). We've included admixture; a composition profile

based on SNPs with genotypes corresponding to reference samples from 23 geographic populations. AA is divided into 5 populations (Esan, Luhya, Mende, Gambian and Yoruba), and 3 American populations are defined (Peruvian, Columbian and Puerto Rican). WGS was performed on blood mononuclear cells from 44 patients with MM or precursor disease, 29 self-identified as AA and 18 as Hispanic.
Results: Estimating directly from WGS data, complexity hidden by self-reported race was revealed by genetically determined admixture. Filtering to ≥1%, 43/44 patients had contribution from >1 of the 23 reference populations. Patients varied widely in their genetic diversity; 3 had ≥90% from a single population, 21 had ≥25% from at least 2 populations (consistent with grandparents) and 37 had ≥12.5% from different populations (consistent with great-grandparents). Within those 37, 18 patients had contributing populations within the same superfamily (i.e., all African), while 19 were across superfamily's (i.e., African + East Asian). Hierarchical clustering produced 5 main clusters, with samples in 2 clusters having predominantly Esan and Mende contribution, while differing in contribution from other AA / non-AA populations. All samples in one cluster contained American contribution >60%, another had predominantly European and American contribution, and the final cluster had AA <10%, and heterogenous population contributions.
Conclusion: Self-reported race does not consider the significant variability of genetic admixture demonstrated by this analysis, and likely has insufficient granularity regarding inherited risk. Ongoing studies will incorporate genetic admixture alongside somatic genomic assessment to accurately investigate progression risk from precursor disease to MM.

#5232
Differential expression of stress-survival pathway genes related to Hispanic colorectal cancer disparities
Urbashi Basnet[1], Aditi Kulkarni[1], Frances A. Rangel[1], Abhijeet R. Patil[1], Sourav Roy[2]. *[1]The University of Texas at El Paso, El Paso, TX,[2]Biological Sciences, The University of Texas at El Paso, El Paso, TX*

Colorectal cancer (CRC) is one of the most life-threatening gastrointestinal cancers, with around 1.9 million new cases and 935,000 deaths in the year 2020 worldwide. It accounts for 12% and 8% of all estimated new cases of cancer and 11% and 9% of all cancer deaths in Hispanic men and women, respectively. Long-term cumulative exposure to environmental factors such as reactive oxygen species (ROS) has been implicated to cause molecular damage and DNA modifications that are critical for CRC pathogenesis through stress-survival pathway genes. However, limited number of studies related to the role of these pathways have not been conducted for the Hispanic population. The identification and validation of new ethnicity-specific transcriptomic markers within the stress-survival pathways is important for improving treatment, prognosis, and detection strategies. In this study, we have explored the role of stress-survival pathway genes in Hispanic and Non-Hispanic White (NHW) CRC tissues. In one of the previously published studies from our lab we used microarray and RNA-seq datasets obtained from the gene expression omnibus (GEO), the cancer genome atlas (TCGA), and the oncomine databases to identify 28 genes associated with CRC. These genes were screened for transcript level expressions in six CRC cell lines and a normal colon cell line, and in cDNA arrays containing the tumor (n=40) from different CRC stages, and control (n=8) samples by qRT-PCR. The protein level expressions were evaluated by immunohistochemistry (IHC) in CRC tissue microarrays (TMAs) containing different stages of tumor (n = 108) and control (n = 12) tissues. All 28 genes were also analyzed for their transcript-level expressions in Hispanic (n=10) and NHW (n=10) tumors and corresponding non-tumor adjacent (NATs; n=3) tissues. The stress-survival pathway genes associated with cell cycle regulation such as *CHEK1, MCM10, PDCD2L, CCNB1, CDK1* and *CDK4*, and an oxidative stress marker *PRDX4* were upregulated at both transcript and protein levels when compared to its normal counterparts. Additionally, the genes *CHEK1*, *MCM10, BCL2L1, CSE1L, ESPL1, GLA, GPX2, RRM2B, SH3GLB1, TNFRSF12A, TRAF5 and TRIB3* were observed to be upregulated whereas *GPX1, NOXA, NQO1, SLC7A11, BCL2L12, CCNB1, CDK1, CDK4, FOXM1, PDCD2L* and *SOD2* were found to be downregulated in Hispanic tumor tissues when compared to NHWs. Only *CDK1, CHEK1, FOXM1* and *NQO1* were seen to be differentially expressed in the Hispanic and NHW NATs; however, their expression patterns were different from that observed in the respective tumor tissues. Overall, our current findings evaluate the expression of stress-survival pathway genes across different CRC cell lines, stages, and Hispanic and NHW tissues. The genes identified to be differentially expressed in Hispanic tissues may be used as potential biomarkers or as therapeutic targets specific to the Hispanic population in future.

Germline CHEK2 variants and risk of lymphoma

Nicholas J. Boddicker[1], Raphael Mwangi[1], Dennis P. Robinson[1], Allison C. Rosenthal[2], Thomas M. Habermann[1], Andrew L. Feldman[1], Lisa M. Rimsza[3], Rebecca L. King[1], Melissa C. Larson[1], Brianna J. Gysbers[1], Stephen M. Ansell[1], Jithma P. Abeykoon[1], Grzegorz S. Nowakowski[1], Thomas E. Witzig[1], Anne J. Novak[1], Susan L. Slager[1], James R. Cerhan[1]. *[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Phoenix, AZ,[3]Mayo Clinic, Scottsdale, AZ*

Lymphoma is the sixth most commonly diagnosed cancer in the US. Genome-wide association studies have identified common variants associated with risk of specific lymphoma subtypes, but less is known about the contribution of rare inherited variants in the genetic architecture of lymphoma risk. *CHEK2* is important to DNA repair and 2 small studies have found evidence of an association between *CHEK2* variants and risk of lymphoma. Here, we investigated loss of function (LoF) variants in *CHEK2* with risk of lymphoma (overall and subtypes). The study population included newly diagnosed lymphoma cases from Mayo who were enrolled in the Lymphoma SPORE Molecular Epidemiology Resource (MER). Controls were from the Mayo Clinic Biobank, from which we excluded a prior hematologic malignancy. Whole exome sequencing was performed by Regeneron on an Illumina NovaSeq panel (mean coverage of 48X). Variants were called using GATK v4 and variant annotation was performed using BioR. All LoF variants (nonsense, frameshift and consensus splice sites) in *CHEK2* with a minor allele frequency < 0.5% were included in the analyses. Logistic regression was used to estimate odds ratio (OR) and 95% confidence intervals (CI) for the association between *CHEK2*mutation status and risk of lymphoma overall, and by lymphoma subtypes that had more than 5 mutation carriers, which included diffuse large B-cell (DLBCL), follicular (FL), and T-cell lymphoma (TCL). All analyses were adjusted for age (at diagnosis for cases and at enrollment for controls) and sex. A total of 4,852 lymphoma cases and 49,724 controls were included in this analysis. Median age for both cases and controls was 62 years (range 18-99 years). Males accounted for 57.5% (n=2,789) of the cases and 40.6% (n=20,186) of the controls. The DLBCL (23.6% of cases) and FL (23.3% of cases) subtypes were the most common; 7.6% of cases had TCL. A total of 407 (0.7%) individuals had a LoF variant. The frequency of LoF variants was 1.2% in lymphoma cases and 0.7% in controls. LoF variants were associated with increased risk of lymphoma overall (OR=1.77; 95%CI: 1.32-2.33), DLBCL (OR=2.07; 95%CI: 1.20-3.13), and TCL (OR=2.78; 95%CI: 1.178-5.50), but not FL (OR=1.31; 95%CI: 0.65-2.34). CHEK2 c.1100delC was the most frequently mutated variant in this population, accounting for 76% of all LoF variants. Individuals with a c.1100delC variant had an increased risk of lymphoma overall (OR=1.90; 95%CI: 1.37-2.58), DLBCL (OR=2.06; 95%CI: 1.09-3.54), and TCL (OR=3.17; 95%CI:1.24-6.58), but not FL (OR=1.05; 95%CI: 0.41-2.15). When restricted to cases, there was no significant difference in age at diagnosis (P=0.62) or sex (P=0.53) between LoF variant carriers and non-carriers. In this large lymphoma case-control study, *CHEK2* LoF variants were associated with increased risk of lymphoma, demonstrating that rare inherited variants may play an important role in the etiology of lymphoma. Additional work is needed to investigate missense variants in *CHEK2* and risk of lymphoma.

Novel predictive biomarker SNPs and polygenic risk scores of immune-related genes for colorectal cancer survival in Korea

Dabin Yun[1], Nan Song[1], Jin-Ah Sim[2], Min Jung Kim[3], Ji Won Park[3], Seung Yong Jeong[3], Aesun Shin[4]. *[1]School of Pharmacy, Chungbuk National University, Cheongju, Korea, Republic of,[2]School of AI Convergence, Hallym University, Chuncheon, Korea, Republic of,[3]Department of Surgery, Seoul National University College of Medicine and Hospital, Seoul, Korea, Republic of,[4]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of*

Background: One of the major topics about colorectal cancer (CRC) is the core role of various immune cells against cancer cells. To comprehensively understand genetic basis of immune system underlying CRC progression, association of single-nucleotide polymorphisms (SNPs) and polygenic risk scores (PRS) of immune-related genes were investigated with colorectal cancer survival.
Methods: CRC patients enrolled in the Seoul National University Hospital with prospective follow-up were included in the study. From blood-derived DNA from CRC patients, genome-wide SNPs were genotyped by using the Korea Biobank Array (KoreanChip). 2,729 immune-related genes were selected from Ensembl, Gene Ontology (GO), and KEGG database and 37,398 mapped SNPs were extracted. SNP or PRS-based Cox proportional hazard models were fit for events of overall survival (OS) and progression-free survival (PFS) estimating effect sizes with hazard ratios (HRs). PRS was calculated as effect size weighted sum of risk alleles of individual patients and

categorized into tertiles. To investigate enriched pathways, protein-protein interaction networks analysis was conducted. Bonferroni-corrected *p*-value (1.3×10^{-6}) was used as statistically significance threshold.
Results: Among 960 CRC patients, 154 (16.0%) occurred events of death and 245 (25.5%) of progression during the follow-up (median=1,698 days, range=7-2,563 days). For OS, a statistically significant associations were mapped to *ACTR3B* , *ST6GAL1*, *COTL1*, *PRKCZ*, and *CAMK1D* genes with the strongest SNP rs14808985 (HR=3.07, P=1.87×10^{-7}). For PFS, marginal association was mapped to *MECOM* gene with the strongest SNP rs16854234 (HR=1.48, *P*=6.13×10^{-6}). In PRS analysis, the highest tertile group showed the prominently increased risk for OS (HR=25.0, *P*<2.0×10^{-16}) and PFS (HR=5.88, *P*<2.0×10^{-16}) compared with the lowest group for a reference. In protein-protein interaction networks analysis, the strongest enrichments were shown in Th17 cell differentiation pathway for OS and in adherences junction for PFS.
Conclusions: We identified novel predictive biomarker genetic variants in *ACTR3B* and *MECOM* genes associated with OS and PFS, respectively, among CRC patients. Additionally, we presented PRS as a useful biomarker for survival outcomes and suggested enriched biological pathways involved in CRC progression. These knowledges can promote the understanding of CRC survival and the development of immune-related therapeutic interventions for CRC patients in the future.

Transcriptome-wide study of tumor samples from Peruvian women identifies dysregulated pathways in luminal tumors typically associated with more aggressive disease

Chenghuiyun Xu[1], Valentina A. Zavala-Cordero[2], Xiaosong Huang[2], David M. Rocke[2], Sandro Casavilca-Zambrano[3], Jeannie M. Navarro-Vásquez[3], Carlos A. Castañeda[3], Guillermo Valencia[3], Zaida Morante[3], Monica Calderón[3], Julio E. Abugattas[3], Henry Gómez[3], Hugo A. Fuentes[3], Ruddy Liendo-Picoaga[3], Jose M. Cotrina[3], Silvia P. Neciosup[3], Katia Roque[3], Jule Vásquez[3], Luis Mas[3], Marco Gálvez-Nino[3], Jovanny Zabaleta[4], Tatiana Vidaurre[3], Laura Fejerman[2]. *[1]Graduate Group of Biostatistics, Univerisity of California, Davis, Davis, CA,[2]Department of Public Health Sciences, Univerisity of California, Davis, Davis, CA,[3]Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru,[4]Department of Pediatrics and Stanley S. Scott Cancer Center LSUHSC, Louisiana State University Health Sciences Center, New Orleans, LA*

Purpose: Breast cancer incidence and outcomes differ by US census racial/ethnic category. Since large-scale genetic studies of human disease are predominately focused on populations of European ancestry, little is known about breast cancer molecular biology in Hispanic/Latinos which can widen cancer health disparities due to suboptimal translation of discoveries into clinical practice or public health policy. We aim to describe relevant pathways in breast cancer subtype differentiation in breast cancer patients from Peru.
Patients and Methods: Formalin fixed paraffin embedded tumor tissues samples were whole exome sequenced for a total of 271 patients, recruited by the Peruvian Breast Cancer Genomics Study (PEGEN-BC) from the Instituto Nacional de Enfermedades Neoplásicas (INEN) in Lima, Peru. Quality control was conducted to remove genes with low counts. Intrinsic tumor subtypes were classified using the PAM50 method using genefu package in R. Differential gene expression between subtypes was performed by DEseq2 R package and statistical significance was determined using FDR<0.05 for samples with at least log2 1.5-fold change. Pathway analyses were performed to explore differences among the subtypes using GSEA with fgsea package in R. Indigenous American ancestry proportions for participants were estimated using germline genome-wide genotypes and the program Admixture.
Results: The mean age of patients was 50 and the median Indigenous American ancestry was 79%. PAM50 classification of the sequenced samples defined 20.2% of tumors as LumA, 27.9% as LumB, 27.1% as HER2, 22.5% as Basal and 2.3% as Normal. Transcriptomic pathway analysis showed that most of the significantly changed pathways were similar to those previously described such as upregulation of high proliferation pathways in LumB, HER2E and Basal tumors, and a strong dependency on the estrogen pathway for LumA. Top 10 significantly changed pathways show some unique findings: the epithelial-mesenchymal-transition (EMT) pathway is downregulated in Basal, comparing to LumA and HER2 tumors, which is unexpected given that the EMT is associated with stem cell features and poor outcomes. The E2F-targets pathway is upregulated in LumA when comparing to HER2 tumors, but downregulated when compared to Basal tumors.
Conclusions: We identified novel pathways associated with breast cancer subtypes in individuals with high Indigenous American ancestry from Peru and are working on testing the robustness of these findings. If our findings are confirmed, results would suggest a more aggressive profile of Luminal subtypes in the studied samples from Peru, with implications for treatment and survival.

Functional analysis of variants of uncertain significance of the *MSH6* mismatch repair gene

Elizabeth Szabo[1], Emily Blackburn[1], Patrick Pagano[2], Abhijit Rath[1], Christopher Heinen[1]. *[1]University of Connecticut Health Center, Farmington, CT,[2]University of Connecticut, Storrs, CT*

Lynch syndrome (LS) is a hereditary condition that increases patients' lifetime risk of cancer, primarily colorectal cancer. LS is caused by germline mutations in mismatch repair (MMR) genes, *MLH1, MSH2, MSH6*, and *PMS2*. Identification of these mutations is important in LS diagnosis in order to guide treatment plans and preventative care for patients' and their families. However, the consequences of some variants in these genes are not immediately obvious, granting them classification as variants of uncertain significance (VUS). Half of known variants in the MMR gene *MSH6* are VUS and, thus, the goal of my project is to provide evidence to help better determine their pathogenic significance. Laboratory functional analysis to determine whether these variants disrupt MMR function in human cells can provide such evidence toward this goal. We have previously used CRISPR gene editing to recreate variants in the endogenous loci for the MMR genes *MSH2* and *MLH1* in human embryonic stem cells (hESC) in order to test their effects on MMR function in a cellular environment. We will now use test whether this approach can be used to study *MSH6* VUS. Using these edited hESC lines we are examining the impact of the variants on RNA and protein stability, repair of DNA microsatellites, which is a hallmark of normal MMR function, and induction of the MMR-dependent DNA damage response. Using a panel of known *MSH6* pathogenic and benign controls, we will calibrate these functional assays in order to associate functional performance with likelihood of pathogenicity. We will next test a separate panel of known controls to validate these assays. Finally, we will examine up to 35 VUS. With this compilation of data, we will convert the results into a quantitative Odds of Pathogenicity value. This Odds of Pathogenicity score can be used by expert variant interpretation committees to help readily reclassify these variants, and provide a clearer diagnosis for these suspected Lynch syndrome patients.

Regulation of genes located in 6q25 by an Indigenous American genetic variant in breast cancer patients from Peru

Valentina A. Zavala[1], Xiaosong Huang[1], Sandro Casavilca-Zambrano[2], Jeannie Navarro-Vásquez[2], Carlos A. Castañeda[2], Guillermo Valencia[2], Zaida Morante[2], Monica Calderon[2], Julio E. Abugattas[2], Henry Gómez[2], Hugo Fuentes[3], Ruddy Liendo-Picoaga[2], Jose M. Cotrina[2], Katia Roque[2], Jule Vásquez[2], Luis Mas[2], Marco Gálvez-Nino[2], Jovanny Zabaleta[4], Tatiana Vidaurre[2], Laura Fejerman[1]. *[1]UC Davis, Davis, CA,[2]Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru,[3]UC Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru,[4]LSUHSC, New Orleans, LA*

Genetic studies in women of Hispanic/Latina origin identified a single nucleotide polymorphism (SNP) in the 6q25 region, rs140068132, that correlates with Indigenous American (IA) ancestry and is protective against BC. The underrepresentation of Latin American populations in public databases has hindered the study of the mechanisms by which this SNP confers a protective effect. We aimed to identify IA germline variants associated with BC risk and to test their association with tumor gene expression in this region.

We performed a case-control fine-mapping analysis in the 6q25 region. BC patients part of the PEGEN-BC Study (N=1809) were included as cases and women from a pregnancy outcomes study in Peru as controls (N=3334). Genome-wide genotype data were available and missing genotypes were imputed using the TOPMED Imputation Server. Logistic regression was used to test the association between each SNP and BC risk. We exome-sequenced 247 breast tumors of PEGEN-BC patients. Tumor subtype was assigned by the pam50 method. We excluded patients diagnosed with stage IV disease, with tumors classified as normal-like or as uncertain, and carriers of the GG genotype for rs140068132, leaving 242 samples. Association between rs140068132 and gene expression of genes in the 6q25 region was tested adjusting by age at diagnosis and IA ancestry.

The strongest signal corresponded to rs140068132 (odds ratio (OR)=0.53, p=1.9e-21). The model adjusted by rs140068132 revealed three additional independent variants that correlate with Indigenous American ancestry: rs184135739 (OR=0.8, p=0.006), rs141057867 (OR=0.87, p=0.006) and rs140125124 (OR=1.23, p=0.015). Gene expression analysis stratified by subtype revealed that among HER2+ tumors (N=63), rs140068132 was associated with ARMT1 (fold change comparing AA to AG (FC)=1.6, p<0.01), CCDC170 (FC=1.8, p<0.01), MTHFD1L (FC=0.7, p<0.01) and RMND1 (FC=1.4, p=0.013). Among Luminal-B (N=68) tumors, there was an association with ARMT1 (FC= 1.9, p=0.001), ESR1 (FC=1.4, p=0.04) and MTHFD1L (FC= 0.8, p=0.02). Only ESR1 was

associated with the SNP (FC= 0.5, p= 0.03) among basal tumors (N=56). No association was identified among Luminal-A tumors (N=55). rs141057867 showed evidence of cis-association with CLDN20 (FC=1.4, p=0.014) among HER2+ subtypes and rs184135739 with ZC3H12D (FC=2.1, p=0.02) and SUMO4 (FC=1.8, p=0.023) among Lumina-A tumors.
Two of the three novel IA SNPs are protective against BC and show association with gene expression. The rs140068132-G variant regulates the expression of genes in the 6q25 region in a subtype-specific manner. A possible mechanism explaining the protective effect of the rs140068132 polymorphism might be linked to the lower expression of MTHFD1L among G-allele carriers in some subtypes. This gene is deregulated in cancer and its expression is negatively associated with cancer survival, including BC.

#5238

The functional role of promoter germline variants in breast cancer susceptibility genes

Nelly Arlene Arroyo[1], Lenin J. Godoy[2], Julie Dutil[1]. *[1]Ponce Health Sciences University, Ponce, PR,[2]Basic Sciences, Ponce Health Sciences University, Ponce, PR*

It is estimated that inherited deleterious or pathogenic germline variants in high- to moderate- penetrance breast cancer (BC) susceptibility genes such as *BRCA1*, *BRCA2*, *STK11, CDH1*, *ATM*, *PALB2*, and *CHEK2* may explain up to 27% of the BC cases. For the remaining cases, BC develops as a result of the complex interaction between environmental and lifestyle risk factors as well as inherited familial predisposition. While low penetrance genetic variants have limited impact on BC risk when taken individually, their combined effect on polygenic risk scores may provide a risk elevated enough to justify clinical actions. Most of the previous work in hereditary breast cancer research has focused on variants located in the coding region of the genes and as a result, there is an abundance of information on the functional interpretation of such variants, while information on regulatory variants remains limited. The goal of this study was to assess the functional impact of germline variants in the promoter region of BC susceptibility genes on gene expression level. Genes evaluated include *CDH1*, *STK11*, and bidirectional promoter genes *ATM*/*NPAT* and *PALB2*/*DCTN5*. A bioinformatics approach was developed to identify and prioritize variants based on conservation level and predicted binding of transcription regulatory proteins. Selected variants will be introduced into pGL3 constructs harboring the promoter of interest using site-directed mutagenesis followed by transfection into HEK293T cells. Dual-glo luciferase expression assays are used to measure levels of promoter activities. Expression levels from promoters containing genetic variants are compared with those from constructs containing the reference sequence. The reference constructs for *STK11* and *CDH1* containing the genes complete promoters demonstrated functional activity. For bidirectional promoters, forwards and reverse construct were tested. Forward *ATM*/*NPAT and PALB2*/*DCTN5* constructs showed luciferase expression under the influence of ATM and *DCTN5* respectively. Work is on the way to assess promoter activity of the reverse complement sequence of those promoters and determine the impact of 13 candidate variants on the strength of these promoters. At the clinical level, identifying germline variants that contribute to BC risk could help better define BC risk in women with negative hereditary cancer genetic test results.

#5239

Integrative analysis of 3D chromatin organization at GWAS loci identifies *RAPGEF1* as a melanoma susceptibility gene

Rohit Thakur[1], Mai Xu[1], Alexandra Thornock[2], Hayley Sowards[1], Epring Long[1], Thomas Rheling[1], Karen Funderburk[1], Jinhu Yin[1], Rebecca Hennessey[1], Raj Chari[3], Tongwu Zhang[1], Lea Jessop[1], Timothy Myers[1], Matthew E. Johnson[4], Andrew D. Wells[4], Alessandra Chesi[4], Struan F. A. Grant[4], Mark I. Iles[5], Maria T. Landi[1], Matthew Law[6], Melanoma Meta-Analysis Consortium, Mitchell Machiela[1], Jiyeon Choi[1], Leonard I. Zon[2], Kevin M. Brown[1]. *[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[2]Harvard Medical School, Harvard Department of Stem Cell and Regenerative Biology, Boston, MA,[3]Frederick National Lab for Cancer Research, National Cancer Institute, Frederick, MD,[4]Divisions of Human Genetics and Endocrinology, University of Pennsylvania, Philadelphia, PA,[5]Leeds Institute for Data Analytics, University of Leeds, Leeds, United Kingdom,[6]Statistical Genetics, QIMR Berghofer Medical Research Institute, Brisbane, Australia*

Many GWAS loci occur in non-coding regions and often overlap with gene regulatory elements such as distant enhancers, making functional interpretation and target gene discovery challenging. The 3D chromatin organization brings enhancers in spatial proximity with a promoter to regulate target gene expression. Therefore, to map

chromatin interactions between GWAS variants and target gene promoters we performed region-focused chromatin conformation capture assay (Capture-C) in primary human melanocytes. We baited the entire region of association for all 68 independent signals from the recent melanoma GWAS, and Capture-C interactions were called using CHiCAGO tool. Integrative analysis of Capture-C interactions with melanocyte- and melanoma-specific ATAC-sequencing, massive-parallel reporter assay (MPRA), ROADMAP chromatin imputed state model, and gene expression datasets helped prioritize target genes for functional follow-up.
Capture-C assays identified physical chromatin interactions between fine-mapped risk variants and candidate causal gene (CCG) promoters at 90% of the GWAS loci; For 84% of the 68 loci, we observed at least one variant-to-gene promoter interaction longer than 100 kb, and for 20% of loci we found interactions beyond 1 Mb. For 76% of the 68 loci, the CCG-interacting variant was in annotated melanocyte or melanoma enhancer regions consistent with CCG regulation via an enhancer-promoter interaction. We observed at least one CCG-interacting variant in 63% and 51% of the 68 loci with distinct allele specific transcriptional activity in melanocyte and melanoma MPRA datasets respectively. A majority of the loci (60%) harbored CCG-linked risk variants in accessible chromatin regions in melanocytes and melanoma. Pathway enrichment analyses of Capture-C-nominated CCGs identified embryonic development, aryl hydrocarbon receptor signaling, and DNA repair pathways. Notably, we observed chromatin interactions between risk variants located near the 3' of Rap Guanine Nucleotide Exchange Factor 1 (*RAPGEF1*) to the *RAPGEF1* and *UCK1* promoter regions. The risk allele of the lead variant (rs3780269) at this locus was associated with higher *RAPGEF1* mRNA expression and was not associated with *UCK1* expression in melanocytes. We performed a CRISPR knockout proliferation screen in immortalized melanocytes and identified *RAPGEF1* as an essential gene for melanocyte growth or survival. Further, we validated the results of this screen by overexpressing *RAPGEF1* in immortalized melanocytes and found that it leads to increased cellular growth. We are now characterizing its function in melanoma tumor incidence and progression in a zebrafish model. In summary, mapping GWAS loci chromatin interactions to target gene promoters and integrative analysis using cell-type specific datasets identified *RAPGEF1* as a melanoma susceptibility gene.

Validation of research cohort based penetrance estimates for multiple cancer types and multiple primary cancers on clinically ascertained families

Nam H. Nguyen[1], Elissa B. Dodd-Eaton[1], Jessica L. Corredor[2], Jacynda Woodman-Ross[2], Nathaniel D. Hernandez[2], Angelica M. Gutierrez Barrera[3], Banu K. Arun[3], Wenyi Wang[1]. *[1]Department of Bioinformatics and Computational Biology, MD Anderson Cancer Center, Houston, TX,[2]Department of Clinical Cancer Genetics, MD Anderson Cancer Center, Houston, TX,[3]Department of Breast Medical Oncology, MD Anderson Cancer Center, Houston, TX*

Age-at-onset penetrance is the probability of developing disease by a certain age given a patient's characteristics. Accurate penetrance estimates are important for cancer screening and diagnosis, and for policy making in public health. We developed two Bayesian semi-parametric models: a model that estimates cancer-specific penetrances to the first primary (CS), and a model that estimates penetrances to the second primary without distinguishing between the cancer types (MPC). Model training requires a dataset that is enriched with enough MPC cases, as well as with competing risks from a variety of cancer types. Thus, we trained our models using data from families affected by the Li-Fraumeni Syndrome (LFS), a genetic disorder characterized by germline mutation in the gene *TP53*. This dataset consists of 189 families, all of which were ascertained via probands who were diagnosed with pediatric sarcoma at MD Anderson Cancer Center (MDACC) between 1944 and 1983. We have validated our penetrance estimates on independent LFS datasets with different ascertainment criteria, namely a patient cohort prospectively collected from high-risk clinics at MDACC, and another cohort from the National Cancer Institute (NCI). These datasets were meticulously collected for research purposes. However, clinical datasets, which resemble the data that genetic counselors encounter in counseling sessions, are severely impacted by missing data, most commonly missing ages at diagnosis and ages at last contact, and only represent a snapshot of family history without extended follow-up. To investigate the utility of our research-based risk prediction models in real-world clinics, we evaluated our penetrance estimates on clinically ascertained LFS families that were collected through the Clinical Cancer Genetics (CCG) program at MDACC in the past 10 years. The CCG dataset consists of 3,275 individuals across 124 families, of which 645 were diagnosed with at least one primary and 127 tested positive for *TP53* mutation. Our CS model showed good performance when making cancer-specific predictions of the first primary, with Areas Under the Curve (AUCs) of 0.76, 0.81, and 0.68 for breast cancer, sarcoma, and all other cancer types combined. Our MPC model showed an AUC of 0.7 when predicting patients with MPC versus those with a single primary. Both the CS and MPC models perform better than the Chompret criteria when predicting

TP53 mutation, with AUCs of 0.75 and 0.77 respectively. These results suggest that our models can be utilized for personalized risk predictions in clinical settings, despite being trained on a research-based dataset. Given that the Chompret criteria tends to predict *TP53* mutation more conservatively, the ability of our models to cast a wider net is especially meaningful in the identification of potential carriers, which assists efficient genetic testing and screening.

Association of polygenic risk scores with breast cancer risk among women with benign breast disease

Stacey J. Winham[1], Mark Sherman[2], Robert Vierkant[1], Bryan McCauley[1], Christopher Scott[1], Mia Gaudet[3], Melissa Troester[4], Sandhya Pruthi[1], Derek Radisky[2], Amy Degnim[1], Kristan Aronson[5], Rachel Murphy[6], Pascal Guenel[7], Therese Truong[8], Jenny Chang-Claude[9], Heiko Becher[10], Montserrat Garcia-Closas[11], Stephen Chanock[11], Thomas Ahearn[12], Xiaohong Yang[11], Doug Easton[13], Manjeet Bolla[13], Celine Vachon[1], Breast Cancer Association Consortium. *[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Jacksonville, FL,[3]National Cancer Institute, Bethesda, MD,[4]University of Norh Carolina, Chapel Hill, NC,[5]Queens University, Kingston, ON, Canada,[6]University of British Columbia, Vancouver, BC, Canada,[7]Research Center for Epidemiology and Population Health, Villejuif, France,[8]Center for Research on Epidemiology and Population Health, Villejuif, France,[9]German Cancer Research Center, Heidelberg, Germany,[10]University Medical Center, Hamburg, Germany,[11]National Institutes of Health, Bethesda, MD,[12]National Institute of Health, Bethesda, MD,[13]University of Cambridge, Cambridge, United Kingdom*

Over one million biopsies are performed annually in the U.S. to evaluate suspicious breast lesions. Most biopsies lead to a diagnosis of benign breast disease (BBD) and these women have a 1.5- to fourfold increase in subsequent breast cancer (BC) risk compared with the general population. A polygenic risk score (PRS) including 313 common variants was developed to predict BC risk in the general population and has improved performance when added to existing BC prediction models. However, the value of PRS in risk prediction models among women with BBD has not been evaluated.

To evaluate the role of the established PRS, BBD, and BC risk, we pooled data from 15,194 white women (6,706 BC cases and 8,488 controls) participating in five Breast Cancer Association Consortium case-control studies. BC risk associations were evaluated by self-reported BBD history and combinations of PRS expressed in tertiles using odds ratios (OR), considering the lowest category of PRS among women without BBD as the referent. Associations were also assessed in an independent case-cohort study (831 BC cases and 1,845 controls) using hazard ratios (HR).

Among the case-control studies, the PRS was strongly associated with BC risk (OR=2.50 per standard deviation increase), and associations were similar in women with (OR=2.60) and without a history of BBD (OR=2.44, p-interaction=0.23). Women with BBD have a higher risk of BC than those without BBD within each level of PRS. Compared to women without BBD and in the lowest PRS category, those with BBD and PRS in the highest tertile had 5-fold increased odds of BC (OR = 5.38; 95% CI 4.73-6.13). Associations were similar in an independent case-cohort study.

These findings indicate that BBD history and PRS are independent contributors to BC risk, and consideration of both simultaneously could improve breast cancer risk prediction. Future studies are needed to integrate PRS with other risk measures to refine absolute BC risk prediction among BBD patients.

Associations of BC risk with combinations of PRS (tertiles) and history of BBD in five case-control studies and a case-cohort study from the Breast Cancer Association Consortium.

		Case-control studies			Case-cohort study		
PRS score range	History of BBD	n BC cases	n controls	OR (95% CI)[1]	n BC cases	n controls	HR (95% CI)[2]
Tertile 1 (≤ -0.57)	No	1009	2692	1.00 (Ref)	117	584	1.00 (Ref)
	Yes	508	902	1.54 (1.35-1.76)	69	163	2.05 (1.45-2.89)
Tertile 2 (-0.58, -0.03)	No	1469	2001	1.97 (1.78-2.17)	181	475	1.93 (1.48-2.51)

Do polygenic risk scores add to clinical data in predicting pancreatic cancer? a scoping review

Louise Wang[1], Alyssa Grimshaw[2], Catherine Mezzacappa[1], Navid Rahimi Larki[3], Yu-Xiao Yang[4], Amy Justice[5].
[1]Section of Digestive Diseases, Department of Internal Medicine, Yale School of Medicine, New Haven, CT,[2]Harvey Cushing/John Hay Whitney Medical Library, Yale School of Medicine, New Haven, CT,[3]VA Connecticut Healthcare System, West Haven, CT,[4]Division of Gastroenterology, Department of Internal Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[5]Section of General Medicine, Department of Internal Medicine, Yale School of Medicine, New Haven, CT

Background: Individual susceptibility to pancreatic ductal adenocarcinoma (PDAC) is determined by both genetic and clinical factors. Polygenic risk scores (PRS) represent a summation of an individual's risk associated alleles across their genome but it is unclear whether PRS improve prognostic assessments beyond available clinical data.
Specific Aims: To evaluate the characteristics of studies examining PRS discrimination for PDAC before and after accounting for clinical factors.
Methods: Following the PRISMA extension for scoping reviews (DOI: osf.io/97hxw), we performed a comprehensive literature search in conjunction with a professional librarian to identify preprint and published research studies evaluating PDAC PRS.
Results: Nineteen studies (of 392 reviewed citations) examined associations between a PDAC-specific PRS and PDAC. The majority were conducted among the UK Biobank (n= 8) and pancreatic cancer consortia (n=4). The rest were institutional biobanks or hospital-based studies. Thirteen studies used a case-control design, and 7 adjusted for clinical risk factors (Table). Only 3 studies (15.8%) evaluated the change in discrimination with the addition of PRS to clinical factors vs. clinical factors alone, and 2 of these reported small but statistically significant improvements in discrimination (ΔAUC: 0.030, 0.039). Source populations were younger/healthier (n=9) than those at risk for PDAC, exclusively European (n=14), or drew controls without relevant exposures such as pancreatic diseases (n=2).
Conclusions: Most PDAC-specific PRS studies do not account for well-established clinical factors or evaluate changes in discrimination with the addition of PRS to clinical factors. Of the 3 studies that did, only 2 showed a modest improvement in discrimination. For PRS to be clinically useful, they must demonstrate more substantial improvements in discrimination beyond established risk factors.

Functional characterization of genetic loci in basal cell carcinoma

Mingyue Li[1], Constance Turman[2], Peter Kraft[3], Jiali Han[4]. *[1]Department of Epidemiology, Indiana University Richard M. Fairbanks School of Public Health, Indianapolis, IN,[2]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[3]Program in Genetic Epidemiology and Statistical Genetics, Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA,[4]Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN*

Background**:** Genome-wide association studies (GWAS) have identified over 30 loci associated with basal cell carcinoma (BCC) susceptibility. However, the causal variants and mechanisms at these loci remain unknown. We performed statistical fine mapping and functional enrichment to identify credible causal variants at 31 established BCC risk loci.

Methods: We performed statistical fine mapping by applying the sum of single effects (SuSiE) method to a previously published GWAS from 12,945 BCC cases and 274,252 controls. To identify genomic annotations enriched for BCC-associated variants, we compared high Posterior Inclusion Probability (PIP) variants from SuSIE to low PIP variants: we performed multivariable logistic regression of high-PIP status on 17 variant annotations from the Functional Annotation of Variants Online Resources (FAVOR) database, including sequence-contextual and functional annotations.

Results: We identified 6 variants with PIP>0.99: rs1126809 (*TYR*), rs1805007 (*MC1R*), rs78378222 (*TP53*), rs12203592 (*IRF4*), rs35407(*SLC45A2* a.k.a. *MATP*), rs12916300 (*HERC2*). Five of these six variants are in pigmentation genes; the sixth is in the tumor suppressor *TP53*. At a seventh region, the 95% credible set contained two variants in or upstream of *RALY*, which has previously been shown to be associated with pigmentation traits and multiple non-skin cancers. Another four regions had fewer than 10 variants in the credible set; the median size of the credible set was 11 (range: 1-76). After adjusting for sequence context (including location relative to exons, introns, UTRs; GC content; local mutation density, and nucleotide diversity) variants in active chromatin regions (as determined from multi-tissue methylation marks), variants in transcription factor binding sites, and skin eQTLs were significantly more likely to be high-PIP variants.

Conclusions: Our results identify candidate variants, genes, and mechanisms for further study in BCC carcinogenesis.

Breast cancer diagnosis and treatment associated with acceleration of biological aging over time in a racially diverse cohort of women

Jacob K. Kresovich[1], Katie M. O'Brien[2], Zongli Xu[2], Clarice R. Weinberg[2], Dale P. Sandler[2], Jack A. Taylor[2]. *[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]National Institute of Environmental Health Sciences, Research Triangle Park, NC*

Leukocyte DNA methylation (DNAm) at individual sites across the genome can be used to construct measures of biological age. Positive age acceleration—when biological age is older than chronological age—is associated with higher risk of age-associated diseases. Recent adjuvant therapy is reported to increase age acceleration, but the longer-term effects of a breast cancer diagnosis and treatment on age acceleration remain unknown. Here, we use blood samples collected at two timepoints to examine changes in age acceleration over time comparing women who did and did not develop breast cancer. Paired whole blood samples were drawn an average of 8 years apart (range: 5-11 years) in a sample of non-Hispanic White and Black (Hispanic and non-Hispanic) women. DNAm was profiled using Infinium MethylationEPIC BeadChips. Approximately half the women were diagnosed and treated for breast cancer between blood draws (cases; n= 190, baseline mean age= 57) whereas the other half remained breast cancer-free (controls; n= 227, baseline mean age= 56). Longitudinal changes in three age acceleration metrics were compared to determine whether an intervening breast cancer diagnosis and treatment was associated with trajectories in biological aging. On average, the cases were diagnosed with breast cancer 3.5 years after the initial blood draw and 4 years before the second blood draw. Among the cases, 36% were treated with chemotherapy, 65% with radiation therapy, and 70% with hormonal therapies; 45% of the cases received two types of therapy, and 13% received all three. Compared to women who remained cancer-free, women diagnosed and treated for breast cancer had increases in age acceleration over time as measured by PhenoAgeAccel (adjusted standardized mean difference (β)= 0.13, 95% CI: 0.00, 0.26), GrimAgeAccel (β= 0.13, 95% CI: 0.03, 0.24), and DunedinPACE (β= 0.35, 95% CI: 0.23, 0.48). The associations did not vary by timing of diagnosis between the blood draws or race; however, women diagnosed with estrogen receptor (ER) negative tumors appeared to experience faster increases in age acceleration than women diagnosed with ER positive tumors (GrimAgeAccel; ER negative β= 0.27, 95% CI: 0.07, 0.47; ER positive β= 0.10, 95% CI: -0.01, 0.21; P-interaction= 0.14). To investigate the impact of different types of breast cancer therapies, associations were examined using a case-only design. In models that simultaneously included chemotherapy, radiation therapy and hormone therapy, radiation therapy had the strongest associations with accelerated biological aging as measured by PhenoAgeAccel (β= 0.38, 95% CI: 0.18, 0.58), GrimAgeAccel (β= 0.27, 95% CI: 0.09, 0.45), and DunedinPACE (β= 0.25, 95% CI: 0.03, 0.47). We find that years after the initial diagnosis, breast cancer survivors have significantly accelerated biological aging; treatment modalities may differentially influence these rates.

Regular aspirin use, breast tumor characteristics and long-term breast cancer survival

Cheng Peng[1], Michelle D. Holmes[1], Wendy Y. Chen[2], Tengteng Wang[1], Kristen D. Brantley[1], Yujing Jan Heng[3], Pepper J. Schedin[4], Bernard A. Rosner[1], Walter C. Willett[5], Meir J. Stampfer[1], Rulla M. Tamimi[6], A. Heather Eliassen[1]. *[1]Brigham and Women's Hospital, Boston, MA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Beth Israel Deaconess Medical Center, Boston, MA,[4]Oregon Health and Science University, Portland, OR,[5]Harvard T. H. Chan School of Public Health, Boston, MA,[6]Weill Cornell Medicine, NY, NY*

Compelling epidemiologic data, supported by experimental evidence, suggest aspirin may improve survival in breast cancer patients. However, recent clinical trials showed a lack of protective effect, though length of intervention (18 months to 4.7 years) and follow-up (20 months to 4.7 years) were limited. We sought to examine the association between post-diagnostic aspirin use (frequency, dose, and duration), timing and age of initiation on breast cancer-specific mortality. Our study included 10,493 women diagnosed with stage I, II, or III invasive breast cancer. Participants were enrolled in the large, prospective Nurses' Health Study (NHS) and NHSII in 1980 and 1989 prior to diagnosis and followed up through June 1, 2017. We collected information on frequency, dose and

duration of aspirin use. Regular aspirin use was defined as using aspirin (standard- and low-dose) ≥2 days per week, and non-regular aspirin users were those who reported use of aspirin <2 days per week. We used Cox proportional hazard models to calculate multivariable adjusted hazard ratios (HRs) for breast cancer-specific mortality. After a median follow-up of 10 years, there were 2,506 total deaths and 1,221 breast cancer-specific deaths among 10,493 stage I to III breast cancer patients over 32 years of follow-up. In multivariable models, regular use of aspirin (n=3,523; 34%) was associated with a 38% lower risk of death from breast cancer compared with non-regular users (including nonusers) (HR=0.62, 95% CI: 0.54-0.71). The association was independent of pre-diagnostic aspirin use. Associations between aspirin use and breast cancer-specific mortality were stronger with longer time since diagnosis (HRs for <5 years since diagnosis: 0.73 (95% CI: 0.59-0.90), 5-<10 years: 0.63 (95% CI: 0.49-0.80), and ≥10 years: 0.53 (95% CI: 0.41-0.69)). The relations between aspirin use and breast cancer survival were similar across categories of dose (compared to non-users, HRs for 0.5-5 tablets per week: 0.59 (95% CI: 0.51-0.68); ≥6 tablets per week: 0.60 (95% CI: 0.48-0.74)) and appeared stronger with longer duration (compared to non-users, HRs for <5 years: 0.80 (95% CI: 0.57, 1.10); ≥5 years: 0.61 (95% CI: 0.51, 0.72)). For women who initiated regular aspirin use after age 70, regular aspirin use was associated with worse survival (HR=1.74, 95% CI: 1.16-2.63); on the other hand, initiation of regular aspirin use at age ≤60 (HR=0.72, 95% CI: 0.54-0.95) or 60-≤70 (HR=0.69, 95% CI: 0.50-0.95) was associated with improved survival (p-interaction=0.02). Regular aspirin use after diagnosis of nonmetastatic breast cancer was associated with improved long-term survival over 32 years. Although the associations between post-diagnostic regular aspirin use and improved survival did not differ by BMI, smoking or tumor characteristics, women who initiated regular aspirin use >70 years of age had increased risk of death due to breast cancer.

Accelerated cardiac aging in adolescent and young adult cancer survivors previously treated with cardiotoxic therapy

Michelle A. T. Hildebrandt[1], Cole J. Bernstein[1], Sairah Ahmed[1], J. Andrew Livingston[1], Efstratios Koutroumpakis[1], Michael E. Roth[1], Jose Banchs[2]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Colorado - Anschutz Medical Campus, Aurora, CO*

Cancer in adolescents and young adults (AYA) is defined as cancer occurring between the ages of 15-39 years. Although cancer is the most common disease-related cause of death in this age group world-wide, the highly favorable overall 5-year survival rate for AYA cancer patients is creating a large and growing segment of the cancer survivorship population. Young cancer survivors have rates of comorbidities, frailty, and other phenotypes that are in line with that of individuals decades older, suggesting that cancer and/or treatment exposures accelerate the aging process in these survivors. Cardiotoxicity due to anthracycline and/or radiation exposure is a major contributor to poor cardiovascular health in AYA cancer survivors, yet the presence and the potential impact of accelerated cardiac aging remains unclear. We hypothesized that hearts in AYA cancer patients exposed to cardiotoxic treatment modalities have a functional phenotype that mirrors heart function in non-treatment exposed individuals who are decades older. In this cross-sectional study, 424 echocardiograms from 127 AYA Hodgkin lymphoma (N=98) and sarcoma (N=29) survivors who were treated with anthracyclines and/or radiation were reviewed for eight functional measures (left ventricular ejection fraction, A-wave, E-wave, E/A ratio, E'-wave, posterior wall thickness, mitral deceleration time, and left ventricular end-diastolic dimension). The median anthracycline dose received for the population was 291.0 mg/m^2 (SD: 133.7) and 44.9% were exposed to radiation to the chest. At last follow-up, 8.3% were taking cardiac medications and 15.8% had been diagnosed with a cardiovascular disease during an average follow-up period of 5.6 years. Echocardiograms were obtained on average 1.3 years post-diagnosis (range: 0-14) and were grouped based at AYA survivor age at procedure (20-29 years, 30-39 years, and 40-49 years). Left ventricular ejection fraction (LVEF) and E'-wave were significantly lower than controls in all three age groups (P<0.001), with four other measures being significant in both of the two younger age groups (P<0.05). Strikingly, 90% of the population had more than one functional measure that was indicative of hearts at least two decades older than the patient at time of echocardiogram with AYA survivors having an average of 4.2 measures displaying evidence of accelerated cardiac aging. These results suggest that AYA cancer survivors exposed to cardiotoxic treatment modalities have a high burden of poor cardiac function and that accelerated cardiac aging may responsible.

#5760

Molecular, immune, and microbial profiles of early-onset, intermediate-onset, and later-onset CRCs

Tomotaka Ugai[1], Yasutoshi Takashima[1], Andressa Dias Costa[2], Daniel Buchanan[3], Jeroen Huyghe[4], Li Hsu[4], Conghui Qu[4], Claire Thomas[4], Steve Gallinger[5], Robert Grant[6], Ulrike Peters[4], Amanda I. Phipps[4], Jonathan Nowak[1], Shuji Ogino[1]. *[1]Brigham and Women's Hospital, Boston, MA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]University of Melbourne, Melbourne, Australia,[4]Fred Hutchinson Cancer Center, Seattle, WA,[5]Ontario Institute for Cancer Research, Toronto, ON, Canada,[6]Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Despite heightened interest in early-onset CRC, little is known about the tumor molecular, immune, and microbial characteristics of early-onset CRC. It is also unclear whether CRCs diagnosed at or shortly after age 50 are similar to early-onset CRC. We hypothesized that tumor molecular, immune, and microbial characteristics in CRC tissue might show differential heterogeneity patterns between three age groups (<50 "early-onset", 50-54 "intermediate-onset", ≥55 "later-onset").
Methods: We examined 3,395 CRC cases with available tissue data, including 660 early-onset and 243 intermediate-onset cases in the Nurses' Health Study, Health Professionals Follow-up Study, and Ontario Familial Colon Cancer Registry. We profiled the *in situ* T-cell landscape of 959 cases using digital imaging, machine learning, and a customized 9-plex multiplexed immunofluoresence panel with antibodies directed against CD3, CD4, CD8, CD45RA, CD45RO, FOXP3, and MKI67 (Ki-67). Using chi-squared test or Spearman's correlation test, we assessed differences in tumor characteristics including microsatellite instability, CpG island methylator phenotype (CIMP), *KRAS*, and *BRAF* mutations, LINE-1 methylation levels, *pks*$^+$ *E. coli* and *Fusobacterium nucleatum* positivity, histopathologic lymphocytic reaction, and T-cell densities between early-onset, intermediate-onset, and later-onset cases.
Results: Compared to later-onset CRC (21%), early-onset (4.8%) and intermediate-onset CRCs (5.1%) exhibited a lower prevalence of CIMP-high status (P<0.001). The mean tumor LINE-1 methylation level increased with increasing age [59 (SD, 12) in early-onset, 61 (SD, 10) in intermediate-onset, and 64 (SD, 9.8) in later-onset CRC (P<0.001)]. Early-onset CRC (4.1%) had fewer *BRAF* mutations than intermediate-onset (10.4%) and later-onset CRC (15%) (P<0.001). Compared to later-onset CRC, early-onset CRC tended to show lower levels of tumor-infiltrating lymphocytes (P=0.013), and intratumoral periglandular reaction (P=0.025). Compared to later-onset CRC, early-onset CRC had a lower density of memory (both CD4$^+$ and CD8$^+$) T-cells (median 21 vs. 48 cells/mm^2; P=0.002) and a higher density of MKI67$^+$ immune cells (median 50 vs. 19 cells/mm^2; P=0.003) in tumor epithelial areas but not in the surrounding stroma. No significant differences in other tested characteristics were identified.
Conclusions: Compared to later-onset CRC, early-onset and intermediate-onset CRCs tended to have aggressive tumor phenotypes such as LINE-1 hypomethylation, lower lymphocytic immune reaction, and a higher density of MKI67$^+$ immune cells. These findings highlight the importance of the tumor microenvironment in the etiology of early-onset and intermediate-onset CRCs.

Bayesian estimation of a semi-parametric recurrent event model with competing outcomes for personalized risk prediction among cancer survivors

Nam H. Nguyen[1], Elissa B. Dodd-Eaton[1], Seung Jun Shin[2], Jing Ning[3], Wenyi Wang[1]. *[1]Department of Bioinformatics and Computational Biology, MD Anderson Cancer Center, Houston, TX,[2]Department of Statistics, Korea University, Seoul, Korea, Republic of,[3]Department of Biostatistics, MD Anderson Cancer Center, Houston, TX*

Multiple primary cancer (MPC) is becoming more common in the general population, accounting for approximately 20% of incidence cases in the United States. Epidemiological studies indicate a strong dependence of the subsequent primary on the characteristics of the first primary. For example, there is evidence that individuals with a first primary breast cancer is more likely to develop a second primary lung cancer. These observations highlight the need to develop a statistical model that characterizes age-to-onset of cancers beyond the first primary, while accounting for the complex relationships between the cancer occurrences. Such a modeling framework was previously lacking. We hereby propose a Bayesian semiparametric framework, where the occurrences of each cancer type follow a non-homogeneous Poisson process. The time-varying intensity of this process is conditioned on genetic and demographic covariates, such as status of genetic mutation and sex, as well as on a patient's cancer history, such as type and timing of the first primary, thus allowing our model to capture the heterogeneity in cancer risks across individuals. Since our model requires a dataset that is enriched with MPC cases, we utilize data collected from families affected with Li-Fraumeni Syndrome (LFS), which is a genetic disorder characterized by

germline mutations in the tumor-suppressor gene *TP53*. People with LFS are at higher risks of certain cancer types, and many cancer survivors develop additional primary malignancy. We train and cross-validate our model on a patient cohort selected according to clinical LFS criteria at MD Anderson Cancer Center from year 2000 to 2015. The cohort consists of 11,186 individuals across 429 families, out of which 2,286 were diagnosed with at least one primary cancer and 335 were tested positive for germline mutations in *TP53*. Upon model training, we construct cancer-specific penetrance curves for the second primary cancer, which vary considerably among patients with different covariates and cancer history, thus highlighting the utility of our model for personalized risk prediction. Our penetrance estimates display good performance when being used to make cancer-specific predictions of the second primary among cancer survivors, achieving AUCs (Areas under the Receiver Operating Characteristic curves) of 0.91, 0.76 and 0.68 respectively for sarcoma, breast cancer, and all other cancers combined. While we apply our model to an LFS dataset, the statistical framework is general, and can be tailored to analyze any time-to-event datasets with suitably selected sets of covariates. Future applications include population-based characterization of specific cancer type combinations over time to impact public health policy making.

New perspective on racial disparities in prostate cancer: identification of new molecular subsets using whole-mount radical prostatectomy

Wei Zhao[1], Pin Li[1], Shannon Carskadon[1], Craig Rogers[1], James Peabody[1], Mani Menon[2], Dhananjay Chitale[1], Sean Williamson[3], Nilesh Gupta[1], Nallasivam Palanisamy[1]. *[1]Henry Ford Health System, Detroit, MI,[2]Mount Sinai Health System, New York City, NY,[3]Cleveland Clinic, Cleveland, OH*

Introduction: Prostate cancer is a heterogenous multifocal disease. We hypothesize that different tumor foci may harbor distinct driver molecular aberrations, making it a more complex disease and difficult to manage. To avoid overlooking smaller tumor foci with clinical and biological significance, we used an innovative approach to understand the genetic underpinnings of each tumor foci based on the molecular analysis of whole-mount radical prostatectomy specimens rather than a systematic sampling of dominant nodules alone. Our study aimed to identify distinct molecular subsets of prostate cancer, if any, and correlate them with clinical outcomes in Caucasians (CA) and African Americans (AA).

Method: We randomly selected 834 whole-mount radical prostatectomy tissues including 463 (56%) CA and 371 (44%) AA. We used combined dual immunohistochemistry (IHC) for ERG and SPINK1 and dual RNA in-situ hybridization (ISH) for ETV1 and ETV4. The racial disparity in aberrant oncogene expression was analyzed by the Chi-squared test. The recurrence-free survival (RFS) of patients with distinct molecular subsets of prostate cancer was examined by the Kaplan-Meier method and cox-ph models. The Gleason's grades of prostate biopsies were summarized by spaghetti plot and compared by linear mixed models.

Results: Patients with localized prostate cancer expressing none, one, two, and three of four oncogenes were 16.4%, 58.4%, 21.7%, and 3.5%, respectively. The expression of ERG and SPINK1 was negatively correlated (odds ratio (OR)=0.38, 95% CI 0.29-0.51, p<.001). Compared with CA, AA had a lower incidence of ERG (38.8% vs 60.3%), a higher incidence of SPINK1 (63.3% vs 35.6%), and similar incidences of ETV1 (9.4% vs 9.3%) and ETV4 (4.6% vs 3.9%). Importantly, ETV1 expression was associated with a worse RFS in CAs (hazard ratio (HR)=2.49, 95% CI 1.15-5.38, p=.02). ETV4 expression was associated with a worse RFS in AA (HR=3.11, 95% CI 1.32-8.04, p=.01). In addition, ETV4 expression was associated with lymph node metastasis in AA (OR=4.0, 95% CI 1.06-12.44, p=.02) but not in CA (OR=0.56, 95% CI 0.03-2.85, p=.57). For those who had multiple biopsies before radical prostatectomy, Gleason's grade increased with time in AA (0.23 per year, p<.001) but was unchanged in CA. ERG expression was associated with a lower Gleason grade (-0.20, p=.03). ETV4 was associated with a higher Gleason grade (0.50, p=.02).

Conclusion: Our findings showed the molecular heterogeneity between CA and AA who had localized prostate cancer, and supported ETV1 and ETV4 as prognostic markers that can be incorporated into clinical practice to better predict prostate cancer recurrence after radical prostatectomy in CA and AA, respectively.

#5763

Risk factors, trends, and disparities in HPV-associated subsequent malignant neoplasms among adolescent and young adult cancer survivors

Judy Y. Ou, Natalie Bennion, Kellee Parker, Douglas Fair, Heidi A. Hanson, Deanna Kepka, Echo L. Warner, Joemy M. Ramsay, Heydon K. Kaddas, Anne C. Kirchhoff. *Huntsman Cancer Institute at the University of Utah; Social & Scientific Systems, Inc., a DLH Holdings Company, Salt Lake City, UT*

Background: Subsequent malignant neoplasms (SMN) are a leading cause of premature mortality among adolescent and young adult (AYA) cancer survivors, who have unique health needs. Human Papillomavirus-related second cancers (HPV-SMN) are generally preventable through screenings and vaccination. We identified disparities in HPV-SMN among AYA survivors by demographics and first cancer therapy, and examined temporal trends in incidence of HPV-SMN.
Methods: We identified diagnoses of any HPV-SMN, oropharyngeal-SMN, and cervical-SMN among AYA survivors in the SEER 9 1976-2015 registries starting two months after the first cancer. Standardized incidence ratios (SIR) compared risk between AYA survivors and general population. We used Fine and Gray competing risk models to estimate hazard ratios (HR) of therapy on risk for HPV-SMN while controlling for cancer site and demographic confounders. Age-period-cohort (APC) models identified temporal trends in HPV-SMN incidence.
Results: Of 374,408 survivors diagnosed with a first primary cancer ages 15-44, a total of 1,369 had an HPV-SMN occurring on average five years after the first cancer. Compared to the general population, AYA survivors had increased risks of 70% for any HPV-SMN (95%CI=1.61-1.79) and 117% for oropharyngeal-SMN (95%CI=2.00-2.35). Cervical-SMN risk was generally lower in survivors (SIR=0.85, 95%=CI 0.76-0.95). Hispanic AYA survivors had a significant increase in cervical-SMN relative to the general population (SIR=1.46, 95%CI=1.01-2.06). AYAs who were uninsured or on Medicaid at diagnosis had significant increases in HPV-SMN risk relative to the general populations (Uninsured SIR=5.23, 95%CI=2.26-10.31; Medicaid SIR=5.95, 95%CI=4.07-8.40). AYAs first diagnosed with Kaposi sarcoma, leukemia, Hodgkin, and Non-Hodgkin lymphoma had increased risk for HPV-SMN relative to the general population. Among survivors with HPV-related first primary cancers, radiation was associated with increased risk for HPV-SMN (HR=1.35, 95%CI-1.03-1.77). Among survivors whose first primary cancer was not HPV-related, chemotherapy was associated with increased risk for HPV-SMN (HR=1.20, 95%CI=1.00-1.44) but the general effect of treatment was not significant (p=0.16). In APC models, incidence of oropharyngeal-SMN significantly declined over time.
Conclusion and Impact: While the overall risk is low, AYA survivors are at higher risk for HPV-SMNs than the general population, largely driven by oropharyngeal-SMN. Hispanic survivors are the only group at higher risk for cervical-SMN than the general population suggesting a need to improve their cervical cancer screening. Uninsured/Medicaid AYA survivors also face higher HPV-SMN risks. Improving access to screening and HPV vaccination is needed to reduce the burden of HPV-SMN in AYA survivors.

Promoter DNA methylation patterns in oral, laryngeal, and oropharyngeal anatomical regions are associated with tumor differentiation, nodal involvement, and survival in Latinos

BIanca Rivera-Peña[1], Oluwasina Folawiyo[2], Nitesh Turaga[2], Rosa J. Rodríguez-Benítez[3], Marco E. Felici[4], Jaime A. Aponte-Ortiz[5], Francesca Pirini[6], Sebastián Rodríguez-Torres[7], Roger Vázquez[1], Ricardo López[1], David Sidransky[8], Rafael E. Guerrero-Preston[9], Adriana Báez[10]. *[1]Department of Biology, University of Puerto Rico, Río Piedras, Puerto Rico,[2]Department of Otolaryngology-Head and Neck Surgery, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Department of General Social Sciences, University of Puerto Rico, Río Piedras, Puerto Rico,[4]Puerto Rico Department of Health, San Juan, Puerto Rico,[5]Department of General Surgery, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico,[6]IRCCS Instituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, Italy,[7]University of Pittsburgh School of Medicine, Pittsburgh, PA,[8]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[9]LifeGene BioMarks, Baltimore, MD,[10]Department of Otolaryngology-Head and Neck Surgery, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico*

Hispanics/Latinos, Black Americans, and poor Non-Latino Whites in the United States are at higher risk of developing head and neck squamous cell carcinoma (HNSCC). The incidence of HNSCC in Puerto Rico is 2.5 higher than for Hispanics/Latinos living in the United States. These health disparities are a serious public health concern due to HNSCC high mortality and morbidity rates, higher treatment costs, and significant quality of life burden. We hypothesized that the discovery of actionable targets for HNSCC early detection, diagnosis, prognostication. Differentially Methylated Regions (DMRs) can be used as HNSCC diagnostic, prognostic, and therapeutic targets in precision medicine workflows. DNA from 23 HNSCC samples and 10 healthy oral tissue

samples from patients in Puerto Rico were hybridized to a genome-wide tiling array to identify DMRs in a discovery cohort. Downstream analyses identified differences in promoter DNA methylation patterns in oral, laryngeal, and oropharyngeal anatomical regions associated with tumor differentiation, nodal involvement, and survival. Genome-wide DMR analysis showed 2,565 DMRs common to the three subsites. We identified 738 DMRs unique to laryngeal cancer (n=7), 889 DMRs unique to oral cavity cancer (n=10), and 363 DMRs unique to pharyngeal cancer (n=6). Based on the genome-wide analysis, and a gene ontology analysis, we selected 10 candidate genes to test for prognostic value and association with clinicopathological features. *TIMP3* was associated with tumor differentiation in oral cavity cancer (p =0.039), *DAPK1* was associated with nodal involvement in pharyngeal cancer (p = 0.017), and *PAX1* was associated with tumor differentiation in laryngeal cancer (p = 0.040). We selected 5 candidate genes, *DAPK1, CDH1, PAX1, CALCA,* and *TIMP3*, for a prevalence study in a larger validation cohort: 42 oral cavity; 25 pharyngeal; and 52 laryngeal cancer samples. *PAX1* hypermethylation differed across HNSCC anatomic sub-sites (p= 0.029), and predominantly detected in laryngeal cancer. Kaplan-Meier survival analysis (p=0.043) and Cox regression analysis of overall survival (p=0.001) showed that *DAPK1* methylation is associated with better prognosis in HNSCC. Our findings show that HNSCC sub-sites (oral cavity, pharynx, and larynx) display substantial differences in aberrant DNA methylation patterns among Hispanic/Latinos HNSCC patients in the US. These data suggest further research may lead to the development of diagnostic medical devices, prognostic biomarkers and novel therapeutic targets that may lead to a reduction in HNSCC disparities among Hispanic/Latinos in the US.

Prospective evaluation of cell-free DNA fragmentomes for lung cancer detection

Peter J. Mazzone[1], Kwok-Kin Wong[2], Jun-Chieh J. Tsay[2], Harvey I. Pass[2], Anil Vachani[3], Allison Ryan[4], Jacob Carey[4], Debbie Jakubowski[4], Tony Wu[4], Yuhua Zong[4], Carter Portwood[4], Keith Lumbard[4], Joseph Catallini[4], Nicholas C. Dracopoli[4], Tara Maddala[4], Peter B. Bach[4], Robert B. Scharpf[5], Victor E. Velculescu[5]. *[1]Cleveland Clinic, Cleveland, OH,[2]NYU Langone Health, New York, NY,[3]University of Pennsylvania School of Medicine, Philadelphia, PA,[4]Delfi Diagnostics, Baltimore, MD,[5]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Less than 10% of eligible persons undergo annual lung cancer screening by low-dose computed tomography (LDCT). Greater uptake of LDCT is hampered in part by its cost, inaccessibility, and balance of benefit to risk. A blood-based, low-cost, widely available initial blood test could boost screening participation and improve the net benefit of screening, if it were sensitive for cancer detection and affordable. The DELFI (DNA evaluation of fragments for early interception) technology uses low-coverage, whole-genome sequencing and machine learning to identify patterns of circulating cell-free DNA (cfDNA) fragmentation indicative of cancer. We report initial results of the cfDNA analysis from DELFI-L101 (NCT04825834), a prospective, observational, national case-control study to train and test DELFI classifiers for lung cancer detection.
Methods: Eligible participants were adults ≥50 years old with current or previous smoking histories of ≥20 pack-years and recent or planned thoracic CT imaging. At enrollment, medical history was recorded and blood samples were collected for DELFI analysis. A classifier for lung cancer detection was developed using repeated 10-fold cross-validation. A split study approach for the purposes of independent validation of the classifier is forthcoming.
Results: The study cohort included 242 patients with lung cancer and 652 individuals without cancer. Study participants largely represented those of a lung cancer screening population, with 45% stage I/IA. Most participants were ≥65 years old with roughly equal proportions of men and women. There was broad representation across lung cancer risk factors among both cases and controls. The cross-validated area under the receiver operator characteristic curve (AUC) was 0.81 for lung cancer detection. AUCs for adenocarcinoma and squamous cell carcinoma were not significantly different, but the AUC for small cell lung cancer was significantly higher than that for adenocarcinoma (p<.001) and squamous cell carcinoma (p=.02). Clinically meaningful sensitivity to detect all stages of disease was achieved.
Conclusions: A classifier developed using samples collected prospectively distinguished between lung cancer cases and controls with robust cross-validated performance across all stages and lung cancer subtypes. A cfDNA DELFI fragmentome test could represent an affordable, high-performing blood test that may improve lung cancer screening.

Pan-viral response in African Americans and European Americans with hepatocellular carcinoma

Theressa Ewa, Whitney L. Do, Limin Wang, Marshonna Forgues, Xin W. Wang. *Laboratory of Human Carcinogenesis, National Cancer Institute, Bethesda, MD*

Hepatocellular carcinoma (HCC) is often diagnosed at late-stages, with African Americans (AA) being diagnosed at a later stage with worse prognosis and high mortality rates. The poor screening and diagnosis of HCC and differences between racial/ethnic groups show a disproportion in mortality rates. Examining an individual's viral exposure history might serve as a useful biomarker of early disease that could address and, potentially, alleviate this disparity. We aim to investigate whether viral features can be used to identify HCC and individuals at high risk (HR) of HCC. Additionally, we examine the racial/ethnic differences in viral exposures and whether viral exposure history accounts for epidemiological disparity described previously. Herein we use a technique called VirScan, which conjugates Phage Immunoprecipitation sequencing (PhIP-seq) and DNA sequencing, to profile an individual's epitope antibody repertoire upon viral exposure. We performed VirScan on serum and plasma samples from 199 AA (130 HR and 79 HCC) and 260 European Americans (EA) (210 HR and 50 HCC) participants from the NCI-UMD cohort (NCT00913757; clinicaltrials.gov). We used a machine-learning XGBoost model to classify viral features that can discriminate HCC or HR. A composite viral score was generated using the SHAP value of the most significant viral features from the model with a higher score more predictive of HCC. Secondary analyses using Wilcoxon-Rank sums tests and Cox proportional hazard analysis revealed that while race/ethnicity did not differentially predict HCC in this cohort, the viral score was significantly higher in AA compared to EA in the HR group ($p = 0.027$). XGBoost search identified 235 important viral features which distinguish HCC from HR. Out of the 235 viral features, 20 viruses were different between AA and EA (FDR < 0.05). We also found the viral score was positively associated with incident mortality in HCC group over the study period of 8 years ($p=0.03$). Thus, we demonstrate that the viral history of an individual might be useful in early detection of HCC. This approach could be used to account for the disparities we see in both incidence and mortality of HCC between AA and EA.

McAllister[3], T'Nita S. Walker[3], Katie L. Kunze[4], Vanda Lindpere[4], Michael A. Golafshar[4], Margaret Klint[1], Richard J. Presutti[5], William V. Bobo[6], Aleksander Sekulic[7], Jolene M. Summer Bolster[3], Cheryl L. Willman[8], Konstantinos N. Lazaridis[9]. *[1]Clinical Genomics, Mayo Clinic Arizona, Phoenix, AZ,[2]Cancer Center, Mayo Clinic Arizona, Phoenix, AZ,[3]Mayo Clinic Rochester, Rochester, MN,[4]Biostatistics, Mayo Clinic Arizona, Phoenix, AZ,[5]Family Medicine, Mayo Clinic Florida, Jacksonville, FL,[6]Psychiatry, Mayo Clinic Florida, Jacksonville, FL,[7]Dermatology, Mayo Clinic Arizona, Phoenix, AZ,[8]Cancer Center, Mayo Clinic, Rochester, MN,[9]Center for Individualized Medicine, Mayo Clinic, Rochester, MN*

Two inherited autosomal dominant cancer predisposition conditions - *BRCA* related hereditary breast and ovarian cancer (HBOC) and Lynch syndrome (LS) - are termed Centers for Disease Control and Prevention Tier 1 (CDCT1) genetic conditions, for which early identification and intervention have a positive impact on public health. Selection of individuals for genetic testing for these conditions is based on personal and family history. The goal of this study was to evaluate whether screening in a tertiary medical center using exome sequencing could efficiently identify carriers of HBOC and LS and to determine the frequency of incremental carriers identified outside of traditional clinical practice guidelines.

Participants from three geographically diverse Mayo Clinic practices in the USA (Rochester MN, Phoenix AZ, Jacksonville FL) consented to clinical "Exome+" sequencing (Helix, San Mateo, CA; Mayo GeneGuide, Rochester, MN) in the TAPESTRY study (NCT05212428), which links sequencing data with electronic health records and the return of CDCT1 genetic findings. For this study we focused on two inherited cancer predisposition conditions: BRCA-related HBOC *(BRCA1* and *BRCA2*) and LS (*MLH1, MSH2, MSH6, PMS2* and *EPCAM*). Detailed chart review to collect demographic information, personal and family history, and assessment of clinical practice guidelines for genetic evaluation (National Cancer Control Network 2021).

To date, 44,306 patients have enrolled and sequenced in TAPESTRY. Annotation and interpretation of all variants in 7 genes for HBOC and LS resulted in identification of 550 carriers (prevalence 1.24%) which included 387 with

HBOC (27.2% *BRCA1*, 42.8% *BRCA2*) and 163 with LS (12.3% *MSH6*, 8.8% *PMS2*, 4.5% *MLH1*, 3.8% *MSH2* and 0.2% *EPCAM*). Demographics of the cohort included: 62.7% female, mean age 55.2 years, non-white race 9.6% and 3.8% Hispanic/Latino ethnicity. A personal history of cancer was present in 46.4% of test positive patients, including 22.5% of HBOC patients with breast or ovarian cancer and 20.9% of LS patients with colorectal or uterine cancer. More than half of the patients (52.1%) were newly diagnosed with HBOC and LS based on the results of this study. Overall, 39.2% of HBOC/LS carriers identified through Exome+ sequencing did not satisfy NCCN criteria for genetic evaluation, this was higher for LS (56.2%) compared to HBOC (32%). Amongst those newly diagnosed with HBOC/LS (n=286), NCCN criteria were not satisfied in 60% of cases (78% for LS and 51% for HBOC). Of the pathogenic germline variant carriers who met NCCN guidelines for testing, 34.2% were not aware of their diagnosis prior to participation in this study.
Our results emphasize the need for wide genomic screening for CDCT1 cancer predisposition syndromes. Such screening could identify at-risk carriers of HBOC and LS, who would not otherwise be identified through clinical practice guidelines.

Disparities in uptake of levonorgestrel-releasing intrauterine system (LNG-IUS): implications for uterine cancer primary prevention

Paul G. Yeh[1], Iakovos Toumazis[2], Charlotte Sun[2], Karen Lu[2], Larissa A. Meyer[2]. *[1]University of Texas Health Science Center At Houston, Houston, TX,[2]University of Texas MD Anderson Cancer Center, Houston, TX*

Introduction: Levonorgestrel-releasing intrauterine system (LNG-IUS) is associated with ~50% risk reduction for uterine cancer incidence and can be an effective primary prevention strategy. We aimed to understand current patterns of LNG-IUS use and identify disparities that could inform implementation strategies for more effective and equitable uterine cancer primary prevention.
Methods: We analyzed LNG-IUS use among U.S. women aged 18-50 with the 2017-2019 National Survey of Family Growth. Statistical analysis was stratified by race, sociodemographic, and health factors. Predictors of LNG-IUS use were assessed through weighted multivariable logistic regression using the Wald chi-square test.
Results: Current LNG-IUS use was significantly lower in Hispanic women compared to White women (AOR 0.65, *P*=0.049). Compared to women with up to a high school education, LNG-IUS use was higher for women with a college degree or higher in the overall sample (AOR 1.86, *P*=0.009), White women (AOR 1.91, *P*=0.04), and Black women (AOR 4.54, *P*=0.007), but not for Hispanic women (AOR 0.79, *P*=0.64). All racial/ethnic subgroups had lower odds of LNG-IUS for non-parous women than parous women (all *P*<0.002). Although a known uterine cancer risk factor, obesity was not associated with LNG-IUS use.
Conclusions: Hispanic women, women with lower educational levels, and nulliparous women have disproportionately low LNG-IUS use despite being at increased uterine cancer risk. Community-based educational interventions for high-risk women and their providers on the benefits of LNG-IUS on uterine cancer prevention are needed to mitigate uterine cancer disparities.

Cardiorespiratory fitness and BMI in youth and five-year mortality after site-specific cancer in men: a population-based cohort study with register linkage

Aron Onerup[1], Kirsten Mehlig[2], Agnes af Geijerstam[2], Elin Ekblom-Bak[3], Hans-Georg Kuhn[2], Lauren Lissner[2], Mats Börjesson[2], Maria Åberg[2]. *[1]St. Jude Children's Research Hospital, Memphis, TN,[2]University of Gothenburg, Gothenburg, Sweden,[3]The Swedish School of Sport and Health Sciences, Stockholm, Sweden*

Aim: Our aim was to assess the associations between cardiorespiratory fitness (CRF) and body mass index (BMI) in youth and five-year mortality following the diagnosis of 18 site-specific cancers in men.
Methods: We collected data on all men who underwent military conscription at ages 16-25 from 1968 through 2005 in Sweden. CRF was assessed as maximal aerobic workload on a cycle ergometer test and was classified as low, moderate, or high. BMI (kg/m2) was classified as underweight (<18.5), normal weight (18.5-24.9), overweight (25-29.9), or obesity (>30). Data was cross-linked on individual level through the Swedish unique identification number with follow-up data from national registers with high validity containing information on cancer diagnosis and mortality. Follow-up started at diagnosis and continued until death, emigration, five years after diagnosis, or end of follow-up (2019-12-31), whichever happened earliest. Time-to-event multivariable Cox regression analyses included CRF and BMI as well as age, year, and site of conscription and age at diagnosis. For CRF, primary analyses tested linear trends with categorical comparisons for interpretation while categorical comparisons were primary analyses for BMI.
Results: 84,621 cancer cases were included in the main analyses. The mean age at diagnosis of any cancer was 53 years and follow-up data were available during a mean of 6.5 years. Lower CRF and higher BMI were independently associated with higher mortality for several cancer sites (table 1).
Conclusion: We report clinically relevant, dose-dependent associations between CRF and BMI in youth and 5-year mortality after diagnosis of 18 site-specific cancers in men. The associations with mortality may be due to both direct cancer inhibition and an improved tolerance to withstand cancer treatment. These results further strengthen the incentive for promoting a healthy lifestyle during the whole lifespan of the population.

The vaginal microbiome as a mediator in the relationship between Black/White race and high grade cervical intraepithelial neoplasia

Katherine Y. Tossas[1], Stephanie Sullivan[2], Myrna Serrano[3], Jerome Strauss[1], Robert A. Winn[4], Gregory Buck[3]. *[1]Health Behavior and Policy, Virginia Commonwealth University School of Medicine and Massey Cancer Ctr., Richmond, VA,[2]OB/Gyn, Virginia Commonwealth University School of Medicine, Richmond, VA,[3]Microbiology, Virginia Commonwealth University School of Medicine, Richmond, VA,[4]Massey Cancer Center, Virginia Commonwealth University School of Medicine, Richmond, VA*

The vaginal microbiome (VMB) is implicated in the development of high-grade squamous intraepithelial lesions (HSIL). The VMB is taxonomically diverse, immunomodulatory, and racially differentiated. The VMB of Black women exhibits increased microbial diversity (associated with HPV tumorigenesis) and lower prevalence of taxa such as *Lactobacillus* (inversely associated with severity of cervical abnormalities) compared to white counterparts. Black women also have more persistent HPV infections and higher incidence of HSILs than whites. Our prior publication suggests the relationship between the VMB and HSIL might be differential by self-reported race. Herein we explore the underlying mechanisms by which race may lead to risk of HSIL through the VMB. We used 16S-rRNA VMB taxonomic profiles of 1,168 consented women receiving their annual routine exam between 2009-2013. Of these, 74 (6%) developed HSIL after the VMB sample collection (followed through 10/2020). The VMB profiles were categorized into three subgroups, based on *a priori* knowledge, by taxonomic abundance as "*Lactobacillus crispatus"* (including *L. crispatus*,

L. gasseri and *L. jensenii*, all generally associated with gynecologic health), "*L. iners"* (considered a transitional state), and "Other" (including taxa, such as *Gardenerella vaginalis*, *Atopibium vaginae*, *Lachnocurva vaginae* and others often associated with adverse gynecologic outcomes). HPV status was obtained by sequencing a fragment of the L1 gene. We used self-reported health histories, confirmed by electronic health records where available, and other socio-demographic information. HIV-positive women were excluded. We used structural equations modeling, following a normal theory maximum likelihood approach with robust errors to estimate the proportion of the association between race and HSIL mediated by the VMB, using STATA version 13.1. The cohort was predominantly Black (72%), with VMB prevalence by subgroup of 18%, 29% and 52% for *L. crispatus*, *L. iners*, and Other, respectively. Blacks had a higher prevalence of the "Other" VMB subtype, compared to nL-whites (59% vs. 49%). Forty-five percent of the sample tested positive for HPV, with no significant difference by race (p=0.9). The incidence of HSIL was nearly double for Blacks compared to whites (7% to 4%). Women with HSIL exhibited a higher prevalence of the "Other" VMB (68% vs. 51%) and were more likely to be HPV positive (73%vs. 44%) than their healthy counterparts. In SEM, only the following path was statistically significant at $p<0.05$: raceàVMBàHSIL, with an estimated proportion mediated by this path of 36%. Findings suggest the VMB is a mediator that might explain some of the underlying mechanisms of the relationship between race and risk of HSIL. If confirmed, this might have potential prophylactic and therapeutic implications as the VMB is amenable to pre and probiotics.

Replacing red and processed meat with legumes modulates gut microbiome and microbiota-related metabolites linked to gut health and cancer prevention in healthy working-aged men

Tuulia Pietilä[1], Isabell Schreck[1], Tiina Pellinen[1], Johanna Vauhkonen[1], Essi Päivärinta[1], Mikko Neuvonen[2], Mikko Niemi[2], Anne Salonen[3], Anne-Maria Pajari[1]. *[1]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland,[2]Department of Clinical Pharmacology, University of*

Helsinki, Helsinki, Finland,[3]Human Microbiome Research Program, University of Helsinki, Helsinki, Finland

Background **and Aim:** Changing dietary habits have great potential for colorectal cancer (CRC) prevention. Regardless of the accumulated evidence on the relationship between dietary protein sources and CRC, the explaining mechanisms remain not well established. Diet-delivered microbial metabolites such as secondary bile acids (BA), N-nitroso compounds (NOC), trimethylamine N-oxide (TMAO), short-chain fatty acid (SCFA), and branched-chain fatty acids (BCFA) have been suggested to mediate the relationship. The aim of this study was to examine the effects of partial replacement of red and processed meat (RPM), associated with higher CRC risk, with legumes on the fecal microbiota composition and metabolite profiles in healthy men.

Methods: The study was a partly controlled 6-wk parallel design randomized clinical trial (n=102, age 37 y (range 21 - 61 y), BMI 25.5 ± 3.3 kg/m^2) with two groups following either a diet supplemented with RPM (meat group) or a diet supplemented with legumes and RPM (legume group). The amount of RPM (200 g/wk) in the legume group was based on the maximum amount recommended by the EAT-Lancet Commission whereas the amount in the meat group (760 g/wk) corresponded the average intake of Finnish men. Fecal SCFAs (μg/ml) and BCFAs (μg/ml) were analyzed with GS-MS, BAs (arbitrary, analyte/standard ratios) with UHPLC-MS/MS, and NOCs (pmol/mg) with selective de-nitrosation and chemiluminescence-based detection. Urine TMAO was quantified by NMR and fecal microbiota composition was analyzed using 16S rRNA amplicon sequencing techniques. Dietary intakes were analyzed with 4-day food records.

Results: At the baseline, no significant differences ($p > 0.05$) were reported in age, BMI, dietary intake of total fiber (g/d), protein (E%), fat (E%), or in the fecal metabolites. The legume group had more pronounced effects on the gut microbiota community level, indicating ecosystem level differences. Total NOCs ($p < 0.0001$) and heme-originated NOCs (FeNO; $p < 0.0001$) were smaller in the legume group than in the meat group. Significant differences between the groups were observed in intake of total fiber ($p < 0.001$), cholesterol (mg/d, $p < 0.001$), saturated ($p < 0.005$), and polyunsaturated fat ($p < 0.001$). Although not significant ($p > 0.05$), total,

secondary and unconjugated BAs, and total BCFA were higher in the meat group, whereas primary and conjugated BAs and total SCFAs were higher in the legume group. The concentration of total SCFA and individual SCFA decreased in both groups during the intervention period. Overall, a large sample-to-sample variation was observed.
Conclusions: The results indicate that partial replacement of RPM with legume products can potentially change microbiota activity and gut metabolites, suggesting a protective gut metabolic profile against colorectal cancer.

Differential impact of rice bran based dietary interventions during inflammation-associated colorectal cancer on distinct immune infiltrates and their spatial distribution signature
Robin Kumar[1], Akhilendra K. Maurya[2], Lakshmi S. P. Bugata[3], Md. I. Kabir[3], Munendra Tomar[2], Rajesh Agarwal[2], Elizabeth P. Ryan[4], Komal Raina[3]. *[1]Dept. of Pharmaceutical Sciences, South Dakota State Univ., Brookings, SD,[2]Univ. of Colorado Anschutz Medical Campus, Aurora, CO,[3]South Dakota State Univ., Brookings, SD,[4]Colorado State University, Fort Collins, CO*

Modulating the immune cell infiltrates in the colonic tissue *via* dietary intervention or modulation of the gut microbiota and its crosstalk with the components of the diet is now recognized as an effective strategy to protect against inflammation-associated colorectal cancer (CRC). In this regard, we recently reported, both gut microbiota-dependent and independent mechanisms for dietary rice bran (RB) meditated protective efficacy against inflammation-associated azoxymethane /dextran sodium sulfate (AOM/DSS)-induced CRC. We also reported that *ex vivo* fermentation of RB with beneficial microbe '*Bifidobacterium longum'* did not exhibit similar protective benefits as RB in damaged colonic tissues in the absence of gut microbiota [germ-free (gf) mice]. The role of rice bran (RB) constituents as prebiotics and in preserving gut barrier and a healthy gut microbiota led to in-depth investigation into the protective efficacy of RB against CRC. Accordingly, in the present study, we performed multiplex imaging (9 color panel) to assess immune sub-typing and spatial phenotypic signature of the colonic tissue/tumor microenvironment in the AOM/DSS^{gf}

mice [following RB and fermented RB (FRB) dietary intervention]. Briefly, we determined the presence of T cells [$CD3^+$], cytotoxic T cells [$CD3^+$ $CD8^+$], helper T cells [$CD3^+$ $CD8^-$], regulatory T (Treg) cells [$CD3^+CD8^-$ $FoxP3^+$), natural killer (NK) cells [$CD49b^+$], NKT cells [$CD3^+CD49b^+$], macrophage (MΦ) [F4/80 $^+$], M1 [$F4/80^+iNOS^+CD206^-$] and M2 [$F4/80^+CD206^+$] subtypes and B cells [$B220^+$]. Results indicated an overall high infiltration of immune cells in female AOM/DSS^{gf} mice on control diet compared to males, which was positively correlated with severe pathological changes observed in the female colon tissues. Notably, RB and FRB diets showed a differential impact on the sub-type of immune cells and their spatial localization. Protective efficacy of RB was associated with decrease in infiltration of T cells (including their subtypes). Interestingly, while cytotoxic T cells were lower in FRB (AOM/DSS^{gf}) female mice, there was a significant increase in pro-inflammatory M1 MΦ sub-types in colon tissue of mice marred by epithelial erosion which compromised FRB potential. Spatial distance analysis also indicated that immune cells were distantly spaced in RB intervention groups compared to FRB and AOM/DSS^{gf} controls. Though, M2 MΦ were relatively higher in number in AOM/DSS^{gf} controls, their presence did not have influence on protective efficacy or lack thereof. In general, it was inferenced that the protective efficacy of the RB diets in the absence of gut microbiota was positively correlated with modulation of T cell infiltration while inflammation-associated CRC and epithelial erosion in FRB diet groups were associated with skewed MΦ sub-types-with increased presence of M1MΦ.

Transcriptomic evaluation of exercise-induced suppression of prostate cancer aggressiveness

Darpan I. Patel, Paul Rivas, Yidong Chen, Zhao Lai, Robert L. Reddick, Yuji Ikeno, Rita Ghosh, A. Pratap Kumar. *The University of Texas Health Science Center at San Antonio, San Antonio, TX*

Previous studies from our laboratory have showed that aerobic exercise significantly reduced the number of aggressive poorly differentiated tumors in the transgenic adenocarcinoma of the mouse prostate (TRAMP) model. Despite these encouraging data the underlying mechanism of how exercise

reduces tumor aggressiveness remains undefined. We aimed to fill this scientific gap by utilizing a transcriptomics approach to identify potential mechanisms by which aerobic exercise suppresses prostate tumor aggressiveness.
Methods: Twelve TRAMP mice, 8-10 weeks of age, were equally randomized to exercise or control group. Mice in the exercise group were singularly housed in cages with running wheels for 12 weeks. Mice in the control group maintained normal group housing and activity conditions for 12 weeks. At euthanasia, prostate tumors were excised, weighed and processed for immunohistochemistry and transcriptome analysis. Two independent pathologists, blinded to the interventions, performed histological analysis of the genitourinary mass. Outputs of sequencing data were assessed for quality and accuracy. Counts for all known mRNA, differential expression, and heatmap were prepared. Differential expression was filtered to identify genes that had a ≥2-fold change with an adjusted $p<0.05$. Gene ontology and pathway analyses was performed to reveal selective pathways activated.
Results: No significant difference in genitourinary mass, body mass or tumor free body mass was found between groups. Pathology revealed majority of the tissue from the control group exhibited moderate to poorly differentiated tumors (3/6). On the other hand, none of the animals in the exercise intervention group showed such pathology. Four out of five showed well differentiated tumors including prostatic intraepithelial neoplasia (PIN) lesions in one animal. Transcriptomic analysis coupled with gene set enrichment identified pathways associated with triglyceride catabolic process, lipid homeostasis, lipid metabolic process, triglyceride metabolic process to be most impacted. Differentially expressed genes of interest include haptoglobin (HP) and hormone sensitive lipoprotein lipase (Lipe) were significantly lower in the exercise group.
Conclusion: Our preliminary findings provide novel evidence suggesting that exercise suppresses prostate tumor aggressiveness, in part, through transcriptomic modulation and altered cellular pathways associated with intratumoral energy metabolism. This project was supported by the National Center Institute designated Mays Cancer Center at UT Health San Antonio.

The anti-cancer effects of vitamin D are blocked postpartum due to suppression of vitamin D metabolism in the liver

Sarah M. Bernhardt, Pepper Schedin. *Oregon Health & Science University, Portland, OR*

Postpartum breast involution is a physiologic inflammatory process that associates with increased risk of postpartum breast cancer (PPBC). In rodents, involution promotes breast cancer progression, and treatment with anti-inflammatory agents is protective. These data provide rationale for targeting the pro-tumor window of involution with anti-inflammatory agents for PPBC prevention. Vitamin D is another anti-inflammatory agent with a good safety profile. In postpartum women, vitamin D deficiency is prevalent, suggesting vitamin D supplementation during involution may prevent development of PPBC.

To model vitamin D deficiency and supplementation, BALB/c mice were fed diets deficient or supplemented with vitamin D for 4 weeks. Blood was then collected from nulliparous (never-pregnant) and 2 days post-wean (involution) mice, and serum vitamin D (i.e. 25(OH)D) measured. As expected, nulliparous mice fed a vitamin D supplemented diet showed a >2-fold increase in serum 25(OH)D (67.4±8.1nmol/L) compared to mice fed a vitamin D deficient diet (28.7±11.7nmol/L, $p<0.01$). In contrast, involution mice fed a vitamin D supplemented diet did not show increased serum 25(OH)D (supplemented 46.6±8.7nmol/L vs deficient 33.7±8.5nmol/L, $p>0.05$).

Activation of dietary vitamin D requires hydroxylation in the liver, producing both circulating (25(OH)D) and active ($1,25(OH)_2D$) forms. Thus, reduced serum 25(OH)D in vitamin D supplemented involution mice could be due to impaired vitamin D hydroxylation in the post-wean liver. Analysis of livers collected from involution and nulliparous mice found reduced expression of genes involved in vitamin D hydroxylation (*Cyp2r1*, *Cyp27a1*) during involution. Further, liver concentrations of $1,25(OH)_2D$ were reduced 3-fold in involution mice (0.31±0.29ng/g) compared to nulliparous mice (0.90±0.37ng/g, $p=0.04$). Together, these findings suggest that impaired metabolism of vitamin D in the postpartum liver may reduce bioavailability of active vitamin D, and provide corroborative evidence for weaning-induced liver involution.

To understand how suppressed vitamin D metabolism in the postpartum liver affects the anti-cancer activity of dietary vitamin D, mammary cancer cells (D2A1, 2×10^4 cells, 20μL) were injected into mammary fatpad of involution or nulliparous BALB/c mice, and tumor growth tracked for 4 weeks. In nulliparous mice, vitamin D supplementation associated with a 3-fold reduction in tumor growth (p=0.03); whereas no anti-cancer effects were observed in involution mice. Together, these findings suggest the anti-cancer effects of vitamin D are blocked postpartum, likely due to suppression of vitamin D metabolism in the liver. Understanding how postpartum liver metabolism influences efficacy of preventative agents that require liver metabolism (such as vitamin D) is required to optimize cancer prevention strategies that target this window.

Dairy product consumption across the life course and breast cancer risk

Emily Riseberg[1], Wai Ching Lam[2], You Wu[3], A. Heather Eliassen[1], Molin Wang[4], Xuehong Zhang[1], Stephanie Smith-Warner[1], Walter C. Willett[1].
[1]Nutrition, Harvard T.H. Chan School of Public Health, Boston, MA,[2]Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[3]Institute for Hospital Management, School of Medicine, Tsinghua University, Beijing, China,[4]Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA

Previous literature on dairy products and risk of breast cancer is inconsistent, and the relationship may depend on the life period of the dietary assessment and menopausal status. We aimed to prospectively investigate dairy product consumption during adolescence, pre-menopause, post-menopause, and lifetime in relation to risk of breast cancer overall and by tumor subtypes. We analyzed data from 59,655 women in the Nurses' Health Study (NHS) collected from 1980 to 2016. Average intake of dairy products during adulthood was assessed by validated semi-quantitative food frequency questionnaires (FFQ) assessed every 2 to 4 years throughout follow-up. Participants reported recalled adolescent dietary intake in 1986. Premenopausal intake was calculated as the cumulative average intake from the 1980 FFQ to the last FFQ completed prior to premenopausal breast

cancer diagnosis or menopause. Postmenopausal intake was calculated as the intake from the first FFQ after menopause to postmenopausal breast cancer diagnosis or end of follow-up. Lifetime intake was calculated as the average of adolescent, premenopausal, and postmenopausal intake. Cox proportional hazards models were used to estimate hazard ratios (HRs) relating dairy product consumption to breast cancer risk overall and by subtype. Models were adjusted for age, race, height, body mass index, alcohol intake, energy intake, and other breast cancer risk factors and lifestyle factors. We documented 5,549 incident cases of invasive breast cancer during 30 years of follow-up (N=5,128 postmenopausal). Adolescent total dairy intake was modestly associated with higher breast cancer risk (HR for a 1 serving/d increment=1.03; 95% confidence interval [CI]=1.00, 1.07). Similar results were found for adolescent milk intake (HR=1.04; 95% CI=1.02, 1.08). In contrast, adolescent cheese intake was associated with a lower risk of breast cancer (HR=0.83; 95% CI=0.70, 0.98). All three associations were more apparent for postmenopausal compared to premenopausal breast cancer. For lifetime intake, only the association with cheese intake was maintained (HR=0.83; 95% CI=0.73, 0.93). Observed inverse associations between lifetime and adolescent cheese intake and breast cancer appeared stronger among estrogen receptor negative and luminal B (adolescent only) subtypes. These findings suggest that adolescent and lifetime cheese intake may be associated with reduced risk of breast cancer and adolescent milk intake may be associated with increased risk.

The anti-genotoxic function of *Lactobacillus* species in the context of bile-mediated DNA damage and inflammation in experimental models of GERD

Joshua Bernard, Divya Joshi, Claudia Andl. *College of Medicine, University of Central Florida, Orlando, FL*

Lactobacillus species are commensal organisms with probiotic characteristics found in the human oral cavity and gastrointestinal tract. It has been shown that gram-positive organisms, including lactobacilli, make up the majority of the microbiome in the healthy human esophagus. The general consensus is that the microbiome shifts from gram-positive to

gram-negative bacteria during gastroesophageal reflux disease (GERD). In patients suffering from GERD, the esophageal tissue is injured by the low pH and bile acids present in the refluxate, resulting in Barrett's esophagus if untreated. Interestingly, it has been reported that there is a proportional increase in gram-positive lactobacilli within the esophagus during the progression from GERD to Barrett's esophagus, and finally esophageal adenocarcinoma. To investigate how lactobacilli are able to colonize and survive in a bile-rich environment of the esophagus during GERD, we first exposed three *Lactobacillus* species (*L. acidophilus, L. plantarum, and L. fermentum*) to cholate/deoxycholate bile salts or ox-bile as a more physiological model for human reflux. All three species exhibited bile resistance, in addition to bile adaptation after pre-exposure to sub-lethal concentrations. When assessed for changes in bacterial cell surface hydrophobicity, an indicator for bacterial adhesion to various surfaces, both bile types led to an increase of hydrophobicity in *L. plantarum* and *L. fermentum*, while *L. acidophilus* remained high. This provides mechanistic insight into how *Lactobacillus* species' attachment and colonization remain during reflux-related diseases. Next, we assessed the host-microbe interactions between lactobacilli and esophageal cells and the role these probiotic organisms may have in disease prevention. Acidic bile salts can induce inflammation and DNA damage to esophageal tissue through ROS during GERD, yet we found that the presence of lactobacilli co-cultured with bile-treated esophageal epithelial cells aids in the repair of bile-induced DNA damage in addition to NFKB reductions. To further investigate the host-microbe interactions, we supplemented epithelial cells with lactobacilli postbiotic metabolites and assessed cell viability during 48 hours of growth. Our current preliminary data show that postbiotic supplementation increases cell viability, providing insight into why lactobacilli are present within the normal and diseased human esophagus. This study demonstrates how the colonization of the esophagus during GERD with lactobacilli is based on their adaptability and survival due to changes in hydrophobicity thereby sustaining attachment. Furthermore, the anti-genotoxic and anti-inflammatory effects these organisms exhibit make them of significant interest in the prevention of Barrett's esophagus and esophageal adenocarcinoma in patients with GERD.

Effects of age-diet interactions on colorectal cancer (CRC) progression in mice

Jae Ho Lo[1], Shivani Soni[1], Yan Yang[2], Goar Smbatyan[1], Junxiang Wan[3], Joshua Millstein[2], Kelvin Yen[3], Hemal H. Mehta[3], Brendan Miller[4], Francesca Battaglin[1], Pooja Mittal[1], Lesly Torres Gonzalez[1], Wu Zhang[1], Pinchas Cohen[3], Heinz Josef Lenz[1]. *[1]Medical Oncology, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, CA,[3]Leonard Davis School of Gerontology, University of Southern California, Los Angeles, CA,[4]Salk Institute for Biological Studies, La Jolla, CA*

Background**.** CRC is the third leading cause of cancer related deaths worldwide with age and diet are among the strongest risk factors. CRC characteristics appear to be distinct between younger and older patients. We evaluated the effects of age on CRC tumor biology using syngeneic mice models with a focus on a) specific differences in tumor growth patterns and the role of the tumor microenvironment (TME) in young versus old mice harboring CRC allografts; b) differential dietary effects in young versus old hosts.

Methods. $1X10^6$ MC38 cells were subcutaneously implanted into the right flank of young (6 weeks) or old (24 months) C57BL/6 male mice. Mice were randomized into 3 diet groups: A. Standard Chow (SC); B. Calorie Restriction (CR: 30% reduction in total calories); C**.** High Fat (HF). Parameters studied were daily food intake, body weight, tumor growth and survival. Once endpoint reached, tumors were isolated and processed for RNA sequencing. Cytokine analysis was done on plasma using multiplex immunoassays on the Meso Scale Discovery platform.

Results. Both old and young mice showed significant reduction in tumor growth while on the CR protocol when compared to other dietary groups. Young mice fed with HF diet had increased tumor growth as compared to old. Cytokine analysis showed that the pro tumorigenic IFNγ, TNF α, IL10, IL-12p70, and 1L6 were higher in old mice relative to young. Caloric restriction irrespective of age led to significant reductions in IFNγ, TNFα, and 1L6 compared to other diets. Irrespective of diet, IL10, known for its immunosuppressive role in CRC, was significantly lower in young versus

old mice. Proinflammatory IL-5 was significantly higher in young fed a HF diet compared to the other groups. RNA sequencing of the allograft tumors at the end of the study revealed that differentially expressed genes (DEGs) between young and old mice tumors were dramatically influenced by diet. The most affected gene expression pathways were antigen processing and presentation, MHC-II complex assembly and T cell activation. Diet affected the tumor expression of key oncogenes associated with immune escape, cell proliferation, invasion, metastasis, chemotaxis, ECM remodeling and chemosensitivity which were upregulated in old mice and HF diet. **Conclusion.** Based on transcriptomic profiles and comprehensive cytokine analysis, our data shows that age-diet interactions significantly influence the host TME leading to differential gene expression in the tumor. Our findings will advance current understanding of the mechanisms by which aging and diet impact CRC onset, progression, metastasis, and therapeutic response but warrants further investigation.

Obesity drives inflammation and metabolic reprogramming in an orthotopic mouse model of early colon cancer

Elaine M. Glenny[1], Babak Mirminachi[2], Tori L. McFarlane[3], Jatin Roper[4], Stephen D. Hursting[1]. *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Medicine, Duke University, Durham, NC,[3]Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Medicine and Pharmacology and Cancer Biology, Duke University, Durham, NC*

Obesity is strongly associated with colon cancer incidence and, in animal models, promotes colon cancer growth and progression. Mounting evidence indicates that circulating growth factors and chronic inflammation are procancer factors likely mediating this relationship. While obesity blunts antitumor immunity in many cancer types, how obesity-driven inflammation and reduced antitumor immunity may cooperate to promote colon cancer progression is not yet clear. Here we used a murine syngeneic orthotopic transplantation model of colon cancer to profile changes driven by diet-induced obesity (DIO) in the immune and cancer cell compartments of the tumor using digital spatial profiling and RNA sequencing. 7-9-week-old male and female C57BL/6 mice remained on either a 10 kcal% fat diet (control, n=34) or a 60 kcal% fat diet (DIO, n=27) for at least 19 weeks.

700 *Apc-null;KrasG12D/+;Trp53-null;Smad4-null;tdTomato* (i.e., AKPS) organoids were transplanted into the colonic wall of control and DIO mice via colonoscopy-guided injection. Tumors were excised after four weeks of growth, an early time point to assess changes between diet groups independent of tumor size differences or weight loss associated with tumor growth. RNA sequencing was performed on RNA extracted from tumoral CD45+ and EpCAM+ cell fractions isolated using Milltenyi MicroBeads. DIO mice weighed more than controls (males: controls 37.0 g ± 5.1 *vs.* DIO 47.4 g ± 4.3; females: controls 26.4 g ± 3.7 *vs.* DIO 45.9 g ± 9.7) and had more mesenteric fat surrounding the colon (males: controls 388 mg ± 217 *vs.* DIO 577 mg ± 185; females: controls 201 mg ± 143 *vs* 1176 mg ± 589). Leptin, resistin, and plasminogen activator inhibitor-1 were significantly elevated in the serum of DIO mice relative to control mice. Tumor weight did not differ between groups. Gene set enrichment analysis demonstrated that tumor cells from DIO mice were significantly enriched for pathways related to inflammation (INFLAMMATORY_RESPONSE, IL6_JAK_STAT3_SIGNALING), glucose and lipid metabolism (GLYCOLYSIS, FATTY_ACID_METABOLISM), and proliferation (E2F_TARGETS, G2M_CHECKPOINT). Within the CD45+ transcriptomic profiles, Tumor Immune Estimation Resource (TIMER2.0) indicated an increase in M0- and M1-like macrophages and B cells in tumors from DIO compared with control mice. Analysis of whole tumor sections from DIO mice showed significantly reduced CD3+ cells by immunofluorescence and more Ki67+ CD45+ immune cells by digital spatial profiling relative to tumors from control mice. Taken together, obesity drives an inflammatory profile in both the immune and epithelial cell populations of AKPS murine tumors, which is associated with increased markers of proliferation. Future studies will address whether inflammatory signals from the mesenteric fat adjacent to the colon tumors may contribute to obesity-driven tumor inflammation, and thereby to colon cancer progression.

Obesity-associated endometrial cancer: Identifying the contributions of TMEM205 expression to the pathogenesis of disease

Takahiko Sakaue[1], Roman Zingarelli[1], Wafa Khadraoui[1], Uksha Saini[1], John Wallbillich[1], Muralidharan Anbazhakan[2], Ross Warner[1], Kalpana

Deepa Priya Dorayappan[1], Deepika Kalaiyarasan[1], Molly Morton[1], Casey Cosgrove[1], Adrian Suarez[1], Larry J. Maxwell[3], David O'Malley[1], David E. Cohn[1], Karuppaiyah Selvendiran[1]. *[1]The Ohio State University Wexner Medical center, Columbus, OH,[2]Tulane University, New Orleans, LA,[3]Inova Schar Cancer Institute, Fairfax, VA*

Background & Objective: Endometrial cancer (EC) is the most common gynecologic malignancy in the US. EC is more strongly associated with obesity than any other cancer type, with 57% of cases linked to obesity. As rates of obesity increase, the incidence of EC is also rising with worsening prognosis. The objective of this study is to identify the molecular mechanisms of TMEM205 expression that regulate exosome secretion, and the oncogenic proteins that underlie this transformation. Our findings are critical to understanding the pathways of obesity mediated EC and essential for developing novel strategies for preventing and treating EC.
Methods: The exosomes were then quantified using nanoparticle tracking analyzer (NTA) and their size measured by Transmission electron microscopy (TEM). TMEM205, STAT5, FAS and PIAS3 expression was confirmed by IHC, WB and RT-PCR in patient and high fat diet treated mouse tissue. Endometrial hyperplasia was developed in immunocompetent mice using high fat diet (HFD; 45 kcal% fat diet) for 16 weeks.
Results: To examine the effect of a continuous HFD (45 kcal% fat diet) on adipose, uterine and endometrial tissue, we first investigated body weight and uterine morphology in mice after 24 weeks of treatment. As expected, mice fed a HFD had a significantly higher body weight and increased adipose tissue when compared to control. In addition, mice in the HFD group showed marked enlargement in uterine horn size (hyperplasia) and inflammation with increased cell proliferation in the endometrial layer. The HFD treated mice were associated with increased exosome secretion and expression of the oncogenic proteins TMEM205 and STAT5. Expression of the tumor suppressor gene PIAS3 wasdownregulated in adipose and uterine tissues. L-2265 is a small molecule inhibitor that selectively inhibits TMEM205 and exosome secretion in EC cancer cells. To examine the effect of L-2263 in the context of obesity, we fed mice a HFD and treatment with L-2263 (2mg/kg/) weekly for 3 doses. L-2263 treatment resulted in significantly decreased body weight (BW) and decreased accumulation of adipose tissue relative to control HFD treated mice. Mice in the HFD group

showed marked enlargement in uterine horn size (hyperplasia), whereas mice that received L-2263 treatment had normal uterine morphology of mouse age. L-2263 treated mice also demonstrated a significant decrease in the expression of proteins involved in exosome secretion (e.g., TMEM205 and STAT5) and those found in exosomes.
Conclusion: This study provides fundamental insight into the mechanism of obesity-mediated TMEM205 expression and exosome secretion and their contribution to the pathogenesis of EC. This study is also provides pre-clinical evidence for the development of the first in-human studies of exosome-targeted therapies to prevent obesity-mediated EC.

#4237

Social isolation induces gut dysbiosis, mitochondrial metabolic dysfunction, and infiltration of tumor immunosuppressive cells: Do they explain enhanced mammary tumorigenesis?

Fabia de Oliveira Andrade[1], Maddie McDermott[1], Lu Jin[1], Vivek Verma[1], Karla Andrade de Oliveira[1], Christopher Staley[2], Leena Hilakivi-Clarke[1].
[1]The Hormel Institute, University of Minnesota, Austin, MN,[2]University of Minnesota, Minneapolis, MN

Social isolation (SI), are associated with increased mortality from many diseases, including breast cancer. Up to 41% of breast cancer patients are estimated to feel socially isolated when assessed between 6 months and 2 years following their cancer diagnosis. Since socially isolated breast cancer survivors are at a 64% higher risk of breast cancer-specific mortality than socially integrated survivors, the biological mechanisms which mediate the effects of SI need to be identified to prevent increased mortality. In a preclinical model, we found that SI caused recurrence of mammary cancers which had been treated with hormone therapy and thus led cancer cells to emerge from dormancy. We further found that mammary glands of SI rats exhibited upregulation of IL6/JAK/STAT3 signaling pathway and impaired oxidative phosphorylation (OXPHOS), compared with group housed (GH) rats. We investigated if these changes could be mediated through the gut-brain-axis. Stress can affect the gut microbiota, and the gut microbiota is critical for regulating the host immunity. In four separate experiments, the effect of SI on the gut microbiota composition was assessed in C57BL/6 mice that were either group housed or housed singly in SI for 4 weeks. In

each study replicate, several differences in the gut microbiota composition were seen, but these differences were mostly unique to each experiment. Beta-diversity was increased in three of the four experiments in SI mice. Nevertheless, at the genus level, SI suppressed the abundance of *Akkermansia* in all four replicates and increased *Acetatifactor* in three of the four replicates. These two bacterial changes are expected to disrupt OXPHOS, perhaps by resulting a suppression in short-chain fatty acid production. Further, low *Akkermansia* and high *Acetatifactor* are expected to increase inflammation. Thus, it is possible that the changes in the composition of the gut microbiota of SI animals explain an increase in IL6 signaling and a suppression in OXPHOS in their mammary gland. We also have studied immune cells in the spleen in SI and GH mice. SI increased the frequency of pro-inflammatory CD4+RORy+ cells, and the immunosuppressive Treg cells (CD4+Foxp3+) and myeloid derived suppressor cells (PMN-MDSCs). SI also increased PD1 expression in Foxp3+ cells. In an on-going study, we found that fecal microbiota transplant (FMT) from SI mice increased E0771 mammary tumor growth in antibiotic treated GH recipient mice, compared with mice receiving FMT from GH mice. Whether the FMT also altered IL6 and OXPHOS signaling in the mammary glands and tumors of recipient mice is currently being investigated. Our findings suggest that social isolation may increase breast cancer through inducing gut dysbiosis.

Specific oral microbiome is closely associated with oral potentially malignant disorders and oral squamous cell carcinoma

Mitomu Kioi, Hiroshi Isono, Shintaro Nakajima. *Oral and Maxillofacial Surgery, Yokohama City Univ. Graduate School of Med., Yokohama, Japan*

Background: Bacterial and virus infection may cause pre-malignant and malignant disorder such as hepatocellular carcinoma and cervical cancer. Recent studies reported that oral bacterium is associated with gastric and colon cancer. However, it is not clear yet if the oral microbiome affects the development of pre-malignant disorder in oral cavity and oral cancer. Thus, this study aims to identify the periodontal pathogen candidates involved in the onset and progression of oral squamous cell carcinoma (OSCC).

Materials and Methods: Saliva was collected from 112 patients without oral mucosal diseases (OMDs) as control, 36 patients with oral potentially malignant disorders (OPMDs), and 104 patients with OSCC, and DNA was extracted in each sample. Periodontal examinations were performed on all patients. Endpoint-PCR was performed on seven species of oral pathogens using the extracted DNA. 16S ribosomal RNA (rRNA) was utilized for analysis of oral microbiome with 20 samples in each group. 4-nitroqquinoline-1-oxide (4-NQO)-induced tongue tumor model in mice was analyzed with or without endotoxin of one of the oral bacteria, *Porphyromonas gingivalis* (*P. gingivalis*).
Results: From the statistical analysis of the clinical parameters, periodontal disease tended to worsen in the OMPD and OSCC groups compared to the control group. The number of oral bacteria was significantly higher in the OSCC group than those in other groups. From PCR results, the detection rates of *P. gingivalis*, *Aggregatibacter actinomycetemcomitans*, and *Treponema denticola* were significantly higher in the OSCC group than those in the control group. From 16S rRNA analysis, the relative abundance of *Prevotella buccae* and *intermedia* was significantly higher in OSCC groups than in the control group. Furthermore, the relative abundance of *P. gingivalis* was higher in the OSCC group compared to other groups, regardless of age and the number of teeth. In mouse model, mice treated with *P. gingivalis*-derived endotoxin developed oral leukoplakia at earlier time points and tumors significantly higher lesions compared to control group.
Conclusion: These results suggest that specific periodontal pathogens are present in the oral cavity of OPMDs and OSCC patients and those changes in the bacterial flora due to their presence may contribute to the onset and progression of OMDs.

Alternate-day fasting enhances the activity of anti-androgen therapy in prostate cancer models

Ricardo Cordova[1], May Elbanna[1], Angela Klunk[1], Christopher Rupert[2], Li Shen[2], Yanqing Wang[3], David Goodrich[3], Ron Wek[1], Kirk Staschke[1], Luigi Fontana[4], Roberto Pili[5]. *[1]Indiana University, Indianapolis, IN,[2]University at Buffalo, Buffalo, NY,[3]Roswell Park Cancer Institute, Buffalo, NY,[4]Sydney*

Medical School, Sydney, Australia,[5]Medicine, University at Buffalo, Buffalo, NY

Prostate cancer (PCa) is the most common cancer diagnosed in men in the Western countries. Epidemiological studies have suggested that environmental factors such as the Western diet, characterized by the consumption of high caloric food containing large amounts of animal protein and fats, play a key role in the pathogenesis of PCa. We propose that dietary intervention, by reducing caloric or protein intake, may be beneficial for the treatment of PCa. Our previous data suggests that dietary protein restriction reduces tumor growth in a LuCaP23.1 patient-derived xenograft (PDX) model of PCa. Thus, we tested the hypothesis whether caloric restriction induced by alternate-day fasting has a similar effect. Interestingly, caloric restriction had antitumor activity in the LuCaP23.1 model but only alternate-day fasting reduced the expression of androgen receptor (AR), a major driver of PCa growth. Therapies targeting AR activity, termed androgen deprivation therapies including the AR antagonist enzalutamide (ENZ), are the current standard of care for PCa. To address the therapeutic potential of combining alternate-day fasting with anti-androgens, we utilized the syngeneic mouse PCa xenograft models MyC-CaP and PTEN$^{-/-}$ RB$^{-/-}$, and the human LuCaP23.1 PDX model. These AR-positive xenograft models harbor the oncogenic drivers most frequently found in PCa (i.e., MYC amplification and loss of the tumor suppressor PTEN). Here, we show that alternate-day fasting enhances the activity of ENZ in these PCa xenograft models. Interestingly, the combination of alternate-day fasting with ENZ treatment reduced AR expression and signaling, and decreased proliferation and tumor growth as compared to either single treatment alone. Consistent with these findings, the reduction of AR activity by the depletion of endogenous androgens following surgical castration was enhanced with alternate-day fasting. Conversely, dietary protein restriction had no effect in combination ENZ *in vivo*, suggesting that modulation of AR by alternate-day fasting enhances the effect of anti-androgens. Transcriptomic analysis of tumors from fasted mice confirmed decreased AR transcriptional activity and revealed that several nutrient sensitive pathways were reduced by this dietary regimen, including PI3K/AKT signaling, mTORC1 signaling, and glycolysis. Additionally, we observed that several known factors induced by fasting were upregulated in

tumors from fasted mice, including SIRT1 which has been suggested to modulate AR transcriptional activity. In conclusion, we demonstrate that alternate-day fasting reduces AR signaling and enhances the activity of ENZ in several PCa xenograft models. Overall, this study suggests that caloric restriction may improve the efficacy of anti-androgen therapy in PCa patients.

Tumor PD-L1 induction associated with dietary protein restriction is modulated by PERK activation

Ricardo Cordova[1], Sean Colligan[2], Chris Rupert[2], Ronald Wek[1], Kirk Staschke[1], Roberto Pili[2]. *[1]Indiana University, Indianapolis, IN,[2]University at Buffalo, Buffalo, NY*

Tumor cells rely on the Integrated Stress Response (ISR) to adapt to different environmental and physiological stresses. The ISR is comprised of four eIF2 kinases that sense different stresses and catalyze phosphorylation of the alpha subunit of eIF2. This results in inhibition of global translation initiation, but at the same time results in preferential translation of select mRNA transcripts in order to relieve stress. Recent work has suggested that programmed death-ligand 1 (PD-L1), a cell surface protein commonly upregulated by tumors to evade the immune system, may be translationally regulated by the ISR in cancer. PD-L1 interaction with immune-checkpoint receptor programmed death-1 (PD-1) leads to the negative regulation of T cell activation and inhibitors that block the PD-L1/PD-1 interaction are widely used to treat different cancers. The ISR may serve as a novel therapeutic target to modulate PD-L1 protein levels and treat immune-evasive cancers. Our group has previously reported that dietary protein restriction increases the anti-tumor effect of PD-1 inhibition in the RENCA kidney cancer mouse model. Here, we show that in the RENCA model, phospho-PERK and phospho-eIF2α protein levels correlate with PD-L1 induction associated with dietary protein restriction. This is supported by TCGA data that shows a correlation between PERK and PD-L1 mRNA levels in different genitourinary cancers. *In vitro*, activation of the eIF2 kinases PERK and GCN2 by ER stress and amino acid starvation, respectively, in both RENCA cells and prostate cancer cells, leads to induction of PD-L1 protein without changing mRNA levels, suggesting

preferential translation under stress conditions. Inhibiting PERK using selective inhibitors blocked ER stress-induced induction of PD-L1. These data support the notion that PD-L1 is induced by dietary protein restriction and is translationally regulated by the ISR. Modulating PD-L1 protein levels in immune-evasive tumors by targeting the ISR in the context of dietary protein restriction may enhance the anti-tumor response to immune checkpoint inhibitors.

Reducing your risk cancer-focused health events to meaningfully engage the medically underserved and diminish future cancer disparities

Melinda Butsch Kovacic[1], Susan Gertz[2], Lauren Bates[3], Susan Hershberger[2], We Engage 4 Health Community-Academic Partnership.
[1]University of Cincinnati, Cincinnati, OH,[2]Miami University, Oxford, OH,[3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Lack of access to cancer prevention education, early screening, and timely treatment, particularly in low socioeconomic, underserved communities, are cited as substantial barriers to improving survivorship. Outreach educational efforts with on-site screenings offered in partnership with community groups are known to be valuable in encouraging community members' uptake of healthy behaviors and adherence to screening recommendation. To create more engaging events, a community-academic partnership, We Engage 4 Health (WE4H), co-created 11 unique 4-panel comic-style stories designed to be read aloud together as attendees visit each event table. These colorful stories are shared on boards that stand on each table and are offered in both English and Spanish at this time. Many tables also have an accompanying hands-on activity. Together, they lead to meaningful "low stakes" discussions which support understanding of seemingly complex health information. Story topics include the cause of cancer (Cells Gone Wrong), cancer risk factors (Reducing Your Risk), the role of primary care in cancer screening (Primary Care for Prevention), the purpose of research (short Research Ready) and details about specific cancer types (Combatting Colon Cancer, Blocking Breast Cancer, Looking for Lung Cancer, Silencing Skin Cancer, Hindering HPV, and Professional Prostate Protection) and COVID-19 (Take Your Best Shot FAQs). A health

passport is used to facilitate table visitation and survey collection at each table enables meaningful evaluation of the event as well as provides the community hosts and their partners baseline cancer data to inform future programing. In 2022, WE4H and the University of Cincinnati Cancer Center partnered with three different communities to co-host pilot events that served over 100 adult residents. Community, research interns and university students volunteered to work the tables at the event and received training prior. Post event surveys and discussions indicated that community partners appreciated the different take on a health fair event. Most volunteers indicated that they would enjoy volunteering again. Attendees indicated that they liked the graphic-style story format used and most preferred it to text and text with graphics approaches. Taken together, the data indicates that Reducing Your Risk events are useful in meaningfully engaging hard to reach, at risk attendees. Additional in-person and virtual events are being planned for 2023 as an approach to reach the medically underserved throughout our region.

High sugar food consumption and breast cancer risk in a prospective cohort study

Woo-Kyoung Shin, Dan Huang, Katherine De la Torre, Sukhong Min, Aesun Shin, Jong-koo Lee, Wonshik Han, Jung Eun Lee, Daehee Kang.
SNU Medicine, Seoul, Korea, Republic of

Background**:** The association between excessive sugar intake and the risk of breast cancer has been considered in epidemiologic studied, however, the results are unclear. This study examined to evaluated between high-sugar food intake and breast cancer in a prospective cohort study.
Methods: This prospective cohort study included a total of 71,266 women aged 40-69 years from the Health Examinees-Gem (HEXA-G) study between 2004 and 2013. Information on cancer diagnosis was retrieved from the Korea Central Cancer Registry until 31 December 2018. Multivariate hazard ratios (HRs) and 95% of confidence intervals (CIs) for the risk of gastric cancer according to the consumption of high-sugar food were estimated using Cox proportional hazards models with age as the time scale.

Results: A total of 713 incident cases of breast cancer occurred over an average follow-up period of 9.20 years. The top food contributing to total sugar intake was fruit (42.89%). We found that increased consumption of sugary cereal was associated with increased risk of breast cancer; HR for sugary cereal consumption of more than one servings/two months vs. almost never consumed was 1.34 (95% CI: 1.08, 1.65; p for trend = 0.01). Also, consumption of loaf bread (p for trend = 0.03), ice cream (HR for ice cream consumption of more than one servings/week vs. almost never consumed = 1.26; 95% CI: 1.00, 1.58; p for trend = 0.03), and added sugar food (HR for all sugary food groups consumption of more than two servings/week vs. less than one serving/month consumed =1.28; 95% CI: 1.02, 1.61; p for trend = 0.05) was associated with increased risk of breast cancer.
Conclusion: Our results suggest that a high-sugar food consumption was associated with an increased risk of breast cancer among Korean women.
Key words: Sugar, High-sugar foods, Breast cancer, the Health Examinees (HEXA) study, prospective cohort study.

#4243

Dietary flavonoids prevent colon tumor formation in $Apc^{Min/+}$ mice in a microbiome- and sex-dependent manner

Beckey DeLucia, Jan Claesen. *Cleveland Clinic Lerner Research Institute, Cleveland, OH*

Background: A diet rich in colorful fruits and vegetables is effective for the prevention of various inflammation-induced cancer types. Mechanistically, this effect has been attributed to the potent antioxidant properties of flavonoid molecules. However, contrary to observations in mice, the success of flavonoids in human dietary cancer prevention trials is often dampened due to large interpersonal variation. Antioxidant activity alone does not explain this variability, suggesting there is an additional important variable that has not been accounted for. Since flavonoids have a poor bioavailability and predominantly passage into the large intestine, we hypothesize that gut microbial metabolism is essential for flavonoid bioactivity in colon cancer prevention.
Goals and Objectives: The goal of this study was to evaluate the impact of microbiota composition on the efficacy of dietary flavonoids in preventing

intestinal tumorigenesis.
Methods: We used the adenomatous polyposis coli - multiple intestinal neoplasia ($Apc^{Min/+}$) mouse model, which is genetically predisposed to develop adenomas along its gastrointestinal tract. Development of these adenomas and eventual adenocarcinoma formation is further influenced by factors such as inflammation, dietary input and the gut microbiota. Animals were fed a control high fat diet (HFD) or prevention diets consisting of 1% berry extract, 1% purified flavonoid or 1% microbial catabolite, all on the HFD background. The contribution of the microbiota was modelled by including experimental groups that received an antibiotic cocktail in their drinking water throughout the course of the experiment. For these animals, microbiota community composition was determined by 16S rRNA sequencing, plasma was collected for histological profiling and metabolomics analysis and end-point measurements of intestinal tumor numbers and size were performed.
Results: Supplementation with berry extract significantly reduced colon tumor numbers and incidence in male, but not in female mice. This effect was negated in mice on antibiotic drinking water, implicating the involvement of the gut microbiota. Community analysis revealed a relative increase in *Erysipelotrichaceae*, *Clostridia* and *Akkermansia* in the berry supplemented versus HFD control mice. In addition, their systemic monocyte counts were reduced. Dietary supplementation with a major gut microbial flavonoid catabolite, did not reduce colon tumor formation, suggesting the functional involvement of different microbial metabolites.
Conclusions: Our study demonstrates the involvement of the mouse gut microbiota in dietary prevention of colon tumor formation. These effects impact circulating monocytes and are linked to changes in the plasma metabolome. We are currently elucidating the microbial actors and associated molecular pathways involved.

Black soybean seed coat extract suppress intestinal tumorigenesis in APCmin mice
Yasuyuki Shimizu[1], Shunta Hirano[1], Yoko Yamashita[2], Tsuyoshi Fukumoto[3], Naritoshi Mukumoto[1], Ai Nakaoka[1], Namiko Hoshi[4], Takeaki Ishihara[1], Daisuke Miyawaki[1], Ashida Hitoshi[2], Ryohei Sasaki[1]. *[1]Division of Radiation Oncology, Kobe University Graduate School of Medicine,*

Kobe, Japan,[2]Department of Agrobioscience, Kobe University Graduate School of Agricultural Science, Kobe, Japan,[3]Division of Dermatology, Kobe University Graduate School of Medicine, Kobe, Japan,[4]Division of Gastroenterology, Kobe University Graduate School of Medicine, Kobe, Japan

Background: Colorectal cancer (CRC) is a major cause of cancer-related deaths in Japan and worldwide. Since CRC has been reported to have close relationship with diet, it seems significant to identify dietary constituents that might suppress occurrence of CRC. Recently, an epidemiological investigation for cancer incidence in Japan revealed that consumptions of black soybeans seem to reduce incidence of several cancers, especially colorectal cancer. Black soybeans coat extract (BE) is known to contain rich procyanidins which have many beneficial physiological activities such as anticancer effects. Therefore, we hypothesized that BE may have inhibitory effects to intestinal tumorigenesis and investigated using $APC^{min/+}$ mice models.

Materials and Methods: $APC^{min/+}$ male mice in the C57BL/6 genetic background were obtained from Jackson Laboratories. $APC^{min/+}$ genotypes of each mouse were confirmed by polymerase chain reaction analysis (PCR) using DNA extracted from the tip of mouse tails. Mice were weighed weekly once and monitored regularly for any signs of weight loss. APC min/+ mice at 4 weeks of age were randomly divided into three groups with 5 mice, and fed by either AIN-76A diet, AIN-76A diet containing 0.05% or 0.05% BE for 8 weeks. At 12 weeks of age, intestines were removed from each mouse and then sliced longitudinally. The small intestine was cut into three equally parts: proximal, middle, and distal. Numbers and sizes of intestinal polyps in each portion were evaluated under Video-Zoom-microscope XV-440. Intestinal polyps were categorized by size into 1-2 mm, 2-3 mm and >3 mm. Other parts of the intestines were placed in 10% phosphate-buffered formalin for histopathology and immunohistochemical (PCNA, β-catenin, and MUC2) analyses.

Results: Numbers of polyps in mice fed with containing 0.05% or 0.5% BE diet were significantly smaller than in mice fed without BE ($P < 0.05$). As for size of polyps, the number of polyps of 1 to 3 mm in size was decreased in mice with BE, however, there were no significant difference for numbers of polyps more than 3 mm in size regarding diets with or without BE. With

0.05% BE diet, reduction rates for occurrence of polyps were 81% for proximal, 48% for middle, and 47% for distal positions, while in with 0.5% BE diet, those reduction rates were 71% for proximal, 59% for middle, and 58% for distal positions, respectively. From these results, the BE, either 0.05% or 0.05% concentration, showed inhibitory effects for tumorigeneses in the small intestine of APC min/+ mice. In histological analyses, the BE was induced higher expression of MUC2-positive cells in normal intestinal lesions and lower expression of β-catenin in tumor sites
Conclusions: The BE showed inhibitory effects in occurrence and growth of intestinal polyps in $APC^{min/+}$ mice models. With further evaluation of mechanisms, the BE could be a promising nutrition for prevention of CRC in human.

#4245

Effects of black raspberries extract on DNA repair capacity and metabolic activation/detoxification of the tobacco carcinogen dibenzo[*def,p*] in human oral cells

Yuan-Wan Sun[1], Kun-Ming Chen[2], Ana H. Sales[3], Nicholas Geacintov[3], Karam El-Bayoumy[2]. *[1]Biochemistry @ Molecular Biology, Penn State College of Medicine, Hershey, PA,[2]Penn State College of Medicine, Hershey, PA,[3]New York University, New York, NY*

We previously reported that black raspberries (BRB) powder inhibits dibenzo[*def,p*]chrysene (also known as dibenzo[*a,l*]pyrene; DBP)-induced DNA damage, mutagenesis and carcinogenesis in the mouse oral cavity. The effects of BRB on the capacity of DNA repair was investigated in an established *in vitro* system using HeLa cells to assess the DNA repair capacity. We found that pre-treatment of Hela cells with BRB extracts (BRBE) can enhance the nucleotide excision repair (NER) of a bulky DNA adduct derived from the tobacco oral carcinogen benzo[a]pyrene by ~24% and this effect is correlated with the enhanced expressions of NER factors XPA and XPB. The NER activity of guanidinohydantoin (Gh), an oxidatively-derived non-bulky DNA lesion, is also enhanced by ~24%, while its base excision repair activity is enhanced by only ~6%. Using human oral leukoplakia (MSK-Leuk1) and oral squamous cell carcinoma SCC1483, we demonstrated that BRBE can inhibit DNA damage induced by DBP through the induction of GSH synthesis and enhancing GSH

conjugates thereby inhibiting DNA damage. The effects of BRBE in MSK-Leuk1 and SCC1483 cells were further investigated on the DNA excision repair protein ERCC1 at 1, 6 and 24 h. ERCC1 forms the ERCC1-XPF enzyme complex that participates in several DNA repair pathways. Western blot analyses revealed that BRBE induced higher ERCC1 expression in SCC1483 than those observed in MSK-Leuk1 cells in a time-dependent manner. The results of our study demonstrate that BRBE is capable of inhibiting the metabolic activation, enhancing the detoxification pathway and DNA repair capacity which are consistent with its chemopreventive activity *in vivo*. Supported by NIH grant #CA173465.

#4246

Synergistic inhibition of prostate tumor growth and progression by the combination of curcumin and ursolic acid in HiMyc mice

Chelsea A. Friedman, Achinto Saha, John DiGiovanni. *Division of Pharmacology and Toxicology, UT Austin College of Pharmacy; Center for Molecular Carcinogenesis and Toxicology, Austin, TX*

Prostate cancer (PCa) is the second leading cause of cancer death among men in the United States. According to the World Health Organization, approximately one-third of all cancer deaths could be prevented through an increased consumption of natural compounds. Through the use of a two-tiered screening method in PCa cells (depletion of cellular ATP level followed by glutamine uptake) of a phytochemical library, curcumin and ursolic acid were selected for further investigation. Twenty-four hour treatment of LNCaP, 22Rv1 and HMVP2 cells with the combination resulted in significant decreases in expression of members of the miR-17-92 and miR-106b-25 clusters, which are upregulated in PCa and have been shown to be involved in tumorigenesis, cell survival, and metastasis. In the HiMyc mouse model, where mice spontaneously develop primary PCa, supplementing diets with the combination of curcumin (1%) and ursolic acid (0.2%) resulted in significant inhibition of tumor growth and progression compared to diets containing either compound alone. There were no differences in body weight or food consumption in any of the diet groups during the tumor experiment. The current data suggests that the combination of curcumin and ursolic acid synergistically inhibits PCa growth and progression in HiMyc mice, which may be in part due to their

effects on microRNA expression. Ongoing studies are further examining the role of specific miRNAs as well as oncogenic signaling pathways potentially involved in the mechanism of synergistic chemopreventive action of this combination. The current data suggest that this novel combination could be a valuable therapeutic option for prevention and/or treatment of PCa. Funding: This work was supported by NIH Grant CA228404.

Impact of 70% ethanol intraductal injections in MNU rat models for breast cancer prevention

Erin K. Zaluzec[1], Mohamed Ashry[1], Elizabeth Kenyon[1], Elizabeth G. Phelps[1], Legend Kenney[1], Katherine Powell[1], Maximilian Volk[1], Shatadru Chakravarty[2], Jeremy M.L. Hix[1], Matti Kiupel[1], Erik Shapiro[1], Lorenzo F. Sempere[1]. *[1]Michigan State University, East Lansing, MI,[2]TechInsights Inc., Nepean, ON, Canada*

Breast cancer (BC) is the leading cancer diagnosis in women. While many BC treatment options exist, only two methods are approved for prevention. Prophylactic mastectomy is an invasive surgery that removes the breast, thereby removing the targeted epithelial ductal tree cells, where most BC arises. Despite a 90% risk reduction, recovery time, risk of infection, pain management, and mental health toll on women deter them from this surgery. Hormonal preventatives, tamoxifen and raloxifene, reduce BC risk by up to 50%. However, increased risk of uterine cancer and intolerable sides effect deter women from this option. Therefore, new preventative methods are needed to maintain BC risk reduction while minimizing current BC prevention deterrents. Intraductal (ID) injection is a technique that can circumvent systemic toxicity by inserting a needle directly into the ductal tree opening. We study BC prevention using 70% ethanol (EtOH) as a cell killing, ablative solution for ID injections and have shown its effectiveness of ablation in an aggressive genetically engineered mouse model with minimum collateral tissue damage. EtOH is a safe, inexpensive reagent clinically used as a sclerosing and ablative agent. We introduced ethyl cellulose (EC), a gelling agent which further minimized damage outside the ductal tree. To confirm successful ductal tree filling without animal sacrifice, we introduced Tantalum Oxide (TaOx), a nanoparticle-based

contrast agent for real time and long-term visualization of ductal tree filling. TaOx showed remarkable local retention, without impeding 70% EtOH ablative effects or EC compared to other contrast agents. Despite our refined ablative solution, ID injection is a difficult technique to perform with limited ability to confirm success of a fully filled ductal tree. To elucidate any impact of partial ductal tree filling, we utilized a Methyl-N-Nitrosourea (MNU) rat model. Rat models improve scalability toward clinical trials and increase ductal tree filling volume and control to study the impact of partial ductal tree filling. Our MNU rat model provides a time frame between carcinogen exposure and tumor formation optimal for prevention studies. Two weeks after intraperitoneal MNU injections, rats received full or half volume (partial) injections, fat pad (partial), or no injection into individual mammary glands. Rats were monitored for tumor formation from 2 weeks post injection until reaching euthanasia criteria. Fully injected glands had the highest tumor latency increase by 1 month (130 days, $p < 0.0001$) compared to non-injected controls (95 days). Partial and fat pad tumor latency also improved compared to control (122 days, $p < 0.01$ and 110 days, $p < 0.05$ respectively). No iatrogenic effects of EtOH were observed. Here, we show that ID injection of 70% EtOH is a safe, effective, and scalable technique for BC prevention, which can be enhanced with TaOx and EC for visualization and retention.

Epithelial ovarian cancer causes cardiac dysfunction and myofilament dysregulation

Leslie M. Ogilvie[1], Madison Pereira[1], Kathy Matuszewska[1], Bridget Coyle-Asbil[1], Luca J. Delfinis[2], Shivam Gandhi[2], Keith R. Brunt[3], Christopher G. R. Perry[2], W. Glen Pyle[1], Jim Petrik[1], Jeremy A. Simpson[1]. *[1]University of Guelph, Guelph, ON, Canada,[2]York University, Toronto, ON, Canada,[3]Dalhousie Medicine New Brunswick, Saint John, NB, Canada*

Introduction: The intersections between cancer and cardiovascular disease (CVD) have become increasingly relevant in the care of both patient populations. To date, the cardio-oncology field has largely focused on how cancer treatment influences long-term cardiac health. Indeed, many cancer therapeutics show various toxic effects to the cardiovascular system. However, studies have also shown cardiac deficits in therapy-naïve cancer

patients. This suggests that these two disease states interact through similar signaling pathways, yet the mechanisms underlying cancer-induced cardiac dysfunction remain unknown. Thus, we investigated cardiac structure and function throughout the progression of epithelial ovarian cancer (EOC).
Methods: We used an orthotopic, syngeneic mouse model of ovarian cancer. Briefly, transformed murine ovarian surface epithelial cells from C57BL/6 mice (ID8; $1.0x10^6$), or saline for surgical controls, were injected under the ovarian bursa of syngeneic mice. In this model, 60 days after tumor induction, mice form large ovarian masses, numerous peritoneal lesions, and develop abdominal ascites - consistent with the clinical features of stage III (advanced) EOC. To determine whether cardiac abnormalities precede the presence of advanced disease, at 45 days post-tumor induction, mice were anesthetized, and left ventricular (LV) structure and function were assessed by echocardiography and invasive hemodynamics, respectively. Myofilament activity was measured with an actomyosin MgATPase assay and protein phosphorylation was determined by SDS-PAGE with Pro-Q Diamond phosphoprotein staining.
Results: EOC mice showed systolic (i.e., reduced contraction rate) and diastolic dysfunction (i.e., reduced relaxation rate, elevated diastolic filling pressure), with no evidence of hypertrophy or atrophy (i.e., no change in LV wall thickness or dimension). While there were no observed differences in myofilament ATPase activity, phosphorylation of regulatory myosin light chain 2 (MYL2) and cardiac myosin binding protein C (cMyBP-C) decreased, and tropomyosin (Tpm) phosphorylation increased in EOC mice.
Conclusion: Together, these data demonstrate that ovarian cancer impairs cardiac function and alters the regulation of myofilament proteins critical for contraction and relaxation. Interestingly, the observed dephosphorylation of MYL2 and cMyBP-C and hyperphosphorylation of Tpm are consistent with features of heart failure. The findings build upon our current understanding of the interactions between cancer and CVD and show that deficits in the heart precede the development of advanced malignancy. Future work further will investigate the tumor-heart axis to identify how tumor development disrupts normal cardiac physiology.

Dietary Derivatives and Repurposed and New Drugs for Cancer Prevention

The effect of aspirin on the transcriptional landscape of the colon

Jonathan M. Downie[1], Connor M. Geraghty[1], Thaddeus S. Stappenbeck[2], Ömer H. Yilmaz[3], David A. Drew[1], Andrew T. Chan[1]. *[1]Gastroenterology, Harvard Medical School/Massachusetts General Hospital, Boston, MA,[2]Inflammation and Immunity, Cleveland Clinic, Cleveland, OH,[3]Pathology, Harvard Medical School/Massachusetts General Hospital, Boston, MA*

Colorectal cancer (CRC) remains the second leading cause of cancer mortality in the United States. Aspirin is the most promising CRC prevention agent with significant data supporting long-term use with a reduction in the incidence of adenomatous polyps and colorectal cancer. The adoption of aspirin as a preventive agent has been limited by an incomplete understanding of aspirin's mode of action in humans. To elucidate the mechanism of aspirin prevention, we sought to identify aspirin-associated transcriptional changes within the colon. To accomplish this objective, we performed RNA sequencing of biopsy-derived colonic epithelial cells from participants enrolled (N=180) in our ongoing aspirin randomized placebo-control trial (RCT) program, "ASPirin Intervention for the REDuction of colorectal cancer risk" (ASPIRED). Individuals with a recent resection of an adenoma were eligible. Participants for whom epithelial cells from rectosigmoid mucosal biopsies were successfully obtained at both pre- and post-treatment timepoints (n=130) were included in this analysis. Participants were randomized to once-daily placebo (n=45), low-dose aspirin (81 mg) (n=46), or standard-dose aspirin (325 mg) (n=39) for 8-12 weeks. For each timepoint, we performed Illumina RNA 100-bp paired-end sequencing of 4,000 fluorescence-activated cell-sorted (FACS) colonic epithelial cells (CD45-; EpCAM+). Transcriptomic read alignment and read counts per gene were obtained using *STAR* and *Salmon*. Quality control measures removed 52 participants (20 placebo, 18 low-dose aspirin, and 14 standard-dose aspirin) from the analysis. No significant differences in age, gender, ethnicity, or BMI were observed between placebo and aspirin-treated participants. We then identified genes whose expression is modulated by aspirin exposure (low and standard dose aspirin) while controlling for baseline gene expression differences between placebo and aspirin-exposed patients and for intra-sample gene expression variability

using *Dream*. We found 57 genes were significantly differentially expressed in aspirin-treated participants at an FDR < 0.10. *AGR2*, which is a CRC oncogene that is upregulated by prostaglandin E2 (PGE2), was significantly downregulated by aspirin treatment suggesting aspirin modules the expression of PGE2 responsive genes in the colonic epithelium. Gene enrichment analysis found aspirin significantly downregulated scaffold proteins (e.g. *KRT8*, *KRT18*, and *ACTB*) and structural ribosomal RNA binding proteins. These pathways are critical processes in epithelial cell differentiation. This finding supports previous *in vitro* evidence that aspirin results in cell composition changes within the colonic epithelium favoring stem-like cell states, which may underlie its preventive effect.

#5248

The use of reverse phase protein array (RPPA) to identify new tumor vulnerability and actionable drug targets against human cancer cell lines

Andrew Howell[1], Julia Wulfkhule[2], Rosa Gallagher[2], Jonathan Baker[1], Ashleigh Hannah[1], Emanuel F. Petricoin[2], Amy H. Tang[1]. *[1]Eastern Virginia Medical School, Norfolk, VA,[2]George Mason University, Manassas, VA*

Introduction: The EGFR/K-RAS pathway is a major tumor driver whose hyperactivation is associated with malignant tumor growth, multidrug resistance, early tumor relapse, chemo-resistance, and metastasis. Despite more than 40 years of research, oncogenic K-RAS activation remains an undruggable target in clinical oncology. Seven-In-Absentia (SINA) homologues (SIAH) are conserved E3 ubiquitin ligases that play a critical gatekeeper role downstream of the EGFR/K-RAS pathway. Our prior studies have shown that tumor growth was abolished in human tumor cell lines following SIAH inhibition; however, the underpinning molecular mechanisms that give rise to this anti-EGFR/K-RAS and anticancer phenotype remain unclear.
Specific Objectives: to delineate the molecular mechanism(s) of why anti-SIAH2PD targeted therapy is so effective in impeding growth, we conducted reverse-phase protein array (RPPA)-based kinomic analysis to discover how major cancer signaling pathways and K-RAS-dependent signaling networks are remodeled in response to SIAH2 inhibition.

Ongoing studies aim to identify and validate dysregulated phospho-proteins identified by RPPA-based kinomic analysis.
Methods: 300 proteins/phosphoproteins were quantitatively measured by the RPPA platform to identify new tumor vulnerabilities, actionable targets, and compensatory signaling network alterations in response to anti-SIAH targeted therapies in five cancer cell lines in triplicate. Doxycycline (DOX)-inducible Tet-ON MiaPaCa, MDA-MB-231, MDA-MB-468, HeLa, and A459 cell lines were generated from a single cell, and DOX-induced SIAH2PD expression was confirmed. Reverse Phase Protein Array (RPPA) was conducted to quantify fold-changes of proteins whose expression was significantly ($p<0.05$) altered in response to SIAH inhibition. Ongoing Western Blot and Immunofluorescence (IF) studies are being used to validate our key RPPA findings.
Results: Supported by statistical analyses, we identified 6 unique proteins that were significantly up-or down-regulated in response to SIAH inhibition. These proteins play a role in controlling and regulating cell growth, cell death, NFκB signaling, stress response, DNA damage, immune function, and cell attachment pathways. Thus, our data provide additional evidence supporting our tumor eradication phenotype observed in these human cancer cell lines lacking functional SIAH. Western Blot and IF validation studies have yielded further supporting evidence to confirm our RPPA results.
Conclusion: Validation studies are being conducted to gain insight into pathway alterations and dynamic rewiring in order to uncover SIAH as a major tumor vulnerability in multiple malignant cancers. Our data supports the explanation as to why anti-SIAH targeted therapy works so effectively to shut down malignant tumor growth, as reported in the literature.

Polyphenon E effects *MXD1* and *RGS4* gene expression in PC-3 prostate cancer cells

L. Michael Carastro[1], Ethan J. Vallebuona[1], Ricardo Cordova[2], Ashley N. Gannon[1], Corrine M. Costello[1], Ricardo A. Declet-Bauzo[3], Seung Joon Kim[4], Nagi Kumar[5], Jong Y. Park[5]. *[1]Department of Chemistry, Biochemistry and Physics, The University of Tampa College of Natural and Health Sciences, Tampa, FL,[2]Department of Biochemistry and Molecular Biology, Indiana University School of Medicine, Indianapolis,*

IN,[3]Department of Radiology, Louisiana State University School of Medicine, New Orleans, LA,[4]The Catholic University of Korea, Seoul, Korea, Republic of,[5]Moffitt Cancer Center, Tampa, FL

Polyphenon E (Poly E) is a standardized, caffeine-free green tea extract with defined polyphenol content. Oral Poly E administration confers chemoprotective activity against prostate cancer (PCa) progression in the TRAMP model of human PCa. Poly E has limited activity against human PCa, but only in those previously diagnosed with atypical small acinar proliferation or high-grade prostate intraepithelial neoplasia. The molecular mechanisms underpinning Poly E chemopreventive activities against PCa are not fully understood. We hypothesized Poly E treatment of PCa cells induces gene expression changes, which could involve molecular mechanisms underpinning the limited Poly E chemoprevention activity against PCa. PC-3 cells were cultured in complete growth media supplemented with varied Poly E concentrations (0, 100, 200, or 300 mg/L) for 24 hr. RNA was isolated for comparative DNA microarray (0 vs. 200 mg/L Poly E) and subsequent qRT-PCR analyses for validation. Microarray data for 54,613 genes were filtered for > 2-fold expression level changes, with 8,319 increased and 6,176 genes decreased. Seven genes (*CASP8, CBLB, CCNB1, HDAC4, MXD1, RGCC, RGS4*) involved in key cellular signaling pathways and with > 2-fold expression level changes, as well as a control gene (*RB1*), were selected for qRT-PCR analyses. These eight genes are listed with corresponding fold-change gene expression values for each microarray probe set (Table 1). The qRT-PCR analyses identified two genes with significantly increased expression, *MXD1* (13.98-fold; p=0.0003) and *RGS4* (21.98-fold; p=0.0011), between poly E treatment levels. The significantly increased *MXD1* and *RGS4* gene expression in Poly E-treated PC-3 cells, and the Poly E-dose dependence of *MXD1* gene expression increases, could implicate *MXD1* and *RGS4* in the PCa chemopreventive activity of Poly E. Future experimental directions include cell cycle profile and Annexin V analyses, immunoblotting analyses, and including other established PCa cell lines in these studies.

Effect of the β-blocker carvedilol in preventing DMBA-induced mammary gland tumor growth

Pabitra Kumar Sardar[1], Steven Yeung[2], Ayaz Shahid[2], Bradley T. Andresen[2], Ying Huang[2]. *[1]Western University of Health Sciences, Pomona, CA,[2]Pharmaceutical Sciences, Western University of Health Sciences, Pomona, CA*

According to global cancer statistics, breast cancer has now become the most diagnosed cancer and has become the fifth leading cause of cancer-related deaths worldwide. A promising method of retarding cancer-related mortality is cancer chemoprevention. However, there is no drug available that can be used routinely as a breast cancer-preventative agent. As carvedilol (CAR), an FDA-approved beta-adrenergic receptor blocker,

reduces breast cancer mortality, we hypothesized that CAR might act as a breast cancer preventative agent. Three protocols were utilized to evaluate the ability of CAR to prevent 7,12-Dimethylbenz(a)anthracene (DMBA)-induced mammary tumors in rats. In protocol 1, two doses of CAR (2 and 10 mg/kg) were administered in drinking water as a 7-day pretreatment and throughout the study. In protocol 2, 10 mg/kg tamoxifen and 10 mg/kg carvedilol were provided as a 7-day pretreatment, and treatment was halted after six weeks. In protocol 3, CAR and the non-β-blocking enantiomer R-carvedilol (10 mg/kg) were given as a 7-day pretreatment and throughout the study. In all studies, animals were palpated weekly beginning at week 5 to detect the presence and location of mammary tumors. Tumors were measured using a caliper, and the experiments terminated at week 13. In protocol 1, only 10 mg/kg CAR was effective in delaying DMBA-mediated tumor occurrence ($p = 0.0002$); the first appearance of tumors and median tumor appearance in CAR-treated rats were separated from rats receiving DMBA alone by 2 and 4 weeks, respectively. However, tumors that did form grew at the same rate in all groups. In protocol 2, tamoxifen served as a control to prevent DMBA-mediated tumors; only one tamoxifen-treated rat developed a tumor at the end of the study. The tamoxifen-treated rats tumor formation was not statistically different than negative controls; however, the CAR group was not statistically different from the DMBA group. In protocol 3, CAR and R-CAR treatment showed delayed tumor formation and growth compared to the DMBA-only group, although not statistically significant. Combining all DMBA and 1-week pretreatment CAR data (n = 58 and 40, respectively), CAR effectively prevents DMBA-induced tumor incidence ($p = 0.001$), with a 3-week differential in the median tumor formation between the two groups. Therefore, continuous CAR treatment is essential to achieve the observed chemopreventive effects. As carvedilol is a clinically used beta-blocker, the results provide significant implications in breast cancer chemoprevention.

Skeletonema marinoi algae extract and carotenoid fucoxanthin are endowed with potential chemopreventive and angiopreventive properties for prostate cancer

Adriana Albini[1], Luana Calabrone[2], Douglas M. Noonan[3], Marco Festa[2], Cinzia Ferrario[2], Valentina Carlini[2], Debora Macis[1], Luigi Pistelli[4],

Christophe Brunet[4], Clementina Sansone[4]. *[1]Istituto Europeo di Oncologia (IEO), Milano, Italy,[2]IRCSS MultiMedica, Milano, Italy,[3]University of Insubria, Varese, Italy,[4]Stazione Zoologica Anton Dohrn, Napoli, Italy*

Background: Research and production of natural anti-oxidants is growing and is developed both in experimental laboratories and in nutraceuticals and pharmaceutical industries. Marine microorganisms represent underestimated sources of bioactive compounds endowed with anti-oxidant, anti-inflammatory, cardiovascular protective and anti-angiogenic properties, all beneficial effects on human health.
Methods: Chemopreventive and anti-angiogenic activities of extracts from the marine coastal diatom *Skeletonema marinoi* (*Sm*) and carotenoid fucoxanthin, that is present in *Sm*, were evaluated in prostate cancer (PCa) and endothelial cell lines in *in vitro*. Morphogenesis assay was carried out to evaluate effects on HUVEC ability to form capillary-like structure on Matrigel. Gene expression analysis was performed by qPCR, measuring different inflammation and angiogenesis gene expression in cells treated with *Sm* extract and fucoxanthin. Membrane antibodies arrays were used to see alterations at protein level of pro- or anti-angiogenic factors.
Results: *Sm* extract and fucoxanthin were able to decrease cell viability, in MTT and Crystal violet assays. Furthermore, we observed that fucoxanthin enhanced the effects of chemotherapeutic drugs, 5-Fluorouracil (5-FU) and cisplatin (Cis-Pt), two of the most commonly used anti-cancer drugs. *Sm* extract and fucoxanthin hindered vascular mimicry of PCa cells and also inhibited capillary structure formation in endothelial cells. Finally, *Sm* extract and fucoxanthin shown a down-regulation of inflammation and angiogenesis associated genes.
Conclusions: Our study suggests promising potential chemopreventive and angiopreventive activities of *Skeletonema marinoi* extract and fucoxanthin for prostate cancer. Microalgae derived drugs can be a potential and relevant source of novel nutraceutical and preventive compounds, which can be considered as dietary supplements or in combination treatments in cancer prevention approaches.

Salsolinol suppresses the STAT3-EMT axis in liver carcinogenesis

Hyeon Jeong Oh[1], Seah Park[1], Hong-Kyung Yang[1], Hoon Ryu[2], Young-Joon Surh[3], Dae-Yong Kim[4], Hye-Kyung Na[1]. *[1]Sungshin Women's Univ., Gangbuk-gu, Seoul, Korea, Republic of,[2]Brain Science Institute, Korea Institute of Science and Technology, Seoul, Korea, Republic of,[3]College of Pharmacy, Seoul National University, Seoul, Korea, Republic of,[4]College of Veterinary Medicine, Seoul National University, Seoul, Korea, Republic of*

Liver cancer is one of the most common malignancies and a leading cause of death worldwide. However, it is still very difficult to treat and prevent liver cancer. Salsolinol (SAL) is an endogenous catechol isoquinoline generated by the condensation of dopamine with acetaldehyde, a major metabolite of ethanol. In the present study, we found that SAL inhibited the phosphorylation, dimerization, and subsequent nuclear translocation of STAT3 in a concentration-dependent manner in SK-Hep1 cells, a hepatic carcinoma cell line. SAL suppressed the expression of Cdk 4 and Cyclin D1, the major target protein of STAT3, and induced the cell cycle arrest at Go/G1 phase. However, SAL induced the expression of STAT1 in SK-Hep1 cells. In addition, SAL enhanced the expression of the cell cycle regulators such as p53 and p21 in SK-Hep1 cells. Epithelial-mesenchymal transition (EMT) promotes tumor invasion and metastasis in malignancies through STAT3 activation. SAL induced the expression of E-cadherin while suppressing the expression of Snail, N-cadherin, and Slug, which are related to EMT. SAL inhibited the migration of SK-Hep1 cells by suppressing the expression of MMP-9 and MMP-2. Furthermore, intraperitoneal injection of SAL reduced the number of tumors in the diethylnitrosamine (DEN)-induced liver carcinogenesis model without affecting the body weight change. Proliferative markers PCNA and KI-67 and p-STAT3 were down-regulated in the SAL-injected mice liver cancer tissue. The plasma level of alpha-fetoprotein, a tumor marker in the blood, was also reduced in the SAL-injected mice. Interestingly, SAL injection significantly reduced the anxiety-like behavior without affecting the locomotive activities in the DEN-induced hepatocellular carcinoma mouse model. Moreover, SAL injection recovered tyrosine hydroxylase, a key enzyme for producing dopamine from tyrosine in the substantia nigra compacta of DEN-treated mice. Together, SAL inhibits STAT3 signaling, thereby suppressing the cell cycle progression and EMT in SK-Hep1 cells, which may account for its

anti-depressant and anti-carcinogenic activity in DEN-induced liver carcinogenesis.

Topical inhibition of UV-induced PD-L1 expression and inflammatory signaling by the small molecule inhibitor BMS-202

Prajakta Vaishampayan[1], Jana Jandova[2], Yuchen (Ella) Ai[1], Viktoria Kirschnerova[1], Clara Curiel-Lewandrowski[3], Georg T. Wondrak[2], Sally E. Dickinson[4]. *[1]University of Arizona Cancer Canter, University of Arizona, Tucson, AZ,[2]R. Ken Coit College of Pharmacy, Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ,[3]College of Medicine, Division of Dermatology, University of Arizona, Tucson, AZ,[4]Pharmacology, University of Arizona, Tucson, AZ*

Immune evasion is a molecular hallmark of cancer, and overexpression of the immune checkpoint protein PD-L1 (CD274) has been documented in several tumors including cutaneous squamous cell carcinoma (cSCC). Notably, while baseline levels of PD-L1 in normal human epidermis are low, acute solar-simulated light (SSL) exposure increases the expression of this protein in epidermal keratinocytes, an effect which can be replicated in cultured keratinocytes and in mouse models. While current immunotherapies targeting the PD-1/PD-L1 axis using monoclonal antibodies are providing therapeutic benefits in many cancers including cSCC, small molecule inhibitors are also being developed to target PD-L1 which may be amenable for topical formulation and therefore early intervention with reduced systemic exposure. We have recently tested one such molecule, BMS-202, *in vitro* and *in vivo*. BMS-202 application to keratinocytes in culture inhibits UV-induced PD-L1 RNA and protein expression. Notably, exposure to this inhibitor also reduced UV-induced stress signaling as measured by AP-1 luciferase assay in cultured keratinocytes. Topical application of BMS-202 to immunocompetent SKH-1 mouse skin resulted in significant inhibition of SSL-induced epidermal PD-L1 as determined by immunoblot analysis. NanoString nCounter Pathway™ transcriptomic analysis of full-thickness SKH-1 mouse skin shows strong inhibition of SSL-induced inflammatory responses, chemokine activity, innate immune response and NF-κB activation in BMS-202 treated samples compared to SSL-only controls. Our results indicate

that early intervention against PD-L1 expression/activity could be a viable target for skin cancer photochemoprevention. Topical application of small molecule PD-L1 inhibitors such as BMS-202 may provide novel treatment options for populations at high risk for cSCC.

Effect of STAT3 inhibitors, TTI-101 and SH5-07, against bladder cancer in preclinical 3D tumor models

Surya P. Singh[1], Gopal Pathuri[1], Adam Asch[2], Brian Cholewa[3], Robert Shoemaker[4], Chinthalapally V. Rao[1], Venkateshwar Madka[1]. *[1]Medicine, Center for Cancer Prevention and Drug Development, Stephenson Cancer Center, Hem-Onc Section, University of Oklahoma HSC, Oklahoma City, OK,[2]Medicine, Stephenson Cancer Center, Hem-Onc Section, Oklahoma City, OK,[3]Division of Cancer Prevention, Chemopreventive Agent Development Research Group, National Cancer Institute, Rockville, MD, OK,[4]Division of Cancer Prevention, Chemopreventive Agent Development Research Group, National Cancer Institute, Rockville, MD, MD*

Bladder cancer (BC) is a lethal genitourinary malignancy associated with frequent recurrence and poor survival due to metastatic potential. Identification of key cancer cell signaling networks and developing promising agents is critical for effectively inhibiting tumor growth and progression. In many cancers, including bladder cancer (BC), signal transducer and activator of transcription 3 (STAT3) has emerged as an important molecular pathway due to its role in promoting proliferation, invasion, and chemoresistance. Thus, developing STAT3 targeting, orally bioavailable small molecule inhibitors may be helpful for the prevention of BC progression and improving the survival rate of patients with muscle invasive BC. Monolayer culture has limitations for drug testing. Therefore, spheroid and organoid culture are used extensively as they may mimic in-vivo drug response more accurately. The aim of our study is to examine the preclinical anticancer efficacy of STAT3 inhibitors [TTI-101 (C188-9) and SH5-07] in 3D (spheroid and tumoroid) invitro models of BC. We optimized the spheroid growth using various BC cell lines [human (J82), rat (NBT-II), and mouse (MB49) BC cells]. Similarly, tumoroids from rat (BBN-induced bladder tumors) and transgenic mice (UPII-SV40T) bladder tumors were developed. These spheroids and tumoroids were treated with

various concentrations (0 - 50 μM range) of STAT3 inhibitors and evaluated for their viability [Calcein AM (CA) and EtBr staining], ATP production (CellTiter-Glo™ 3D), and ROS production (MitoSOX^{TM}). Effect of drug treatment on biomarkers of cell proliferation, apoptosis, stemness, STAT3 signaling, and immune modulation was determined using western blotting and immunofluorescence. Treatment with TTI-101 (0 - 50 μM or SH5-07 (0 - 50 μM) for 144 hrs resulted in significant reduction in the spheroids size (39-45% smaller Vs untreated; $p<0.0001$), along with decreased ATP levels (20%-40%, $p<0.05$). MitoSOX^{TM} staining suggested that STAT3 inhibitors treatment increased ROS production in BC cells. CA and EtBr staining revealed that TTI-101 and SH5-07 treatment resulted in increased cell death in BC spheroids compared to control. Decreased spheroids and organoids size also correlated with increased apoptotic marker (cleaved caspase-3) along with decreased cyclin D1, PCNA, and pSTAT3 protein expression. Drug treated BC spheroids/tumoroids also showed reduction in CD44 (BC stemness and invasion marker) and induction of cGAS-STING pathway (cGAS, STING, TBK1, and IRF3) in comparison to the control. These findings indicate that STAT3 inhibitors, TTI-101 and SH5-07, could inhibit bladder cancer by suppressing STAT3 pathway activation and therefore warrant further study in vivo. Understanding HPV vaccine confidence and conspiracy beliefs across the US: Opportunities to increase cancer prevention through HPV vaccine education

Josheili Ymar Llavona-Ortiz, William A. Calo. *Public Health Sciences, Penn State College of Medicine, Hershey, PA*

Purpose: The purpose of this study was to compare HPV vaccination confidence and HPV vaccination conspiracy beliefs across the US. By characterizing vaccine confidence and conspiracy beliefs by HPV vaccine initiation status and sociodemographic variables, opportunities to develop HPV vaccine education as a cancer prevention measure can be identified. **Methods:** Four questions measuring vaccine confidence and seven questions measuring vaccine conspiracy beliefs were adapted from validated scales. All questions were assessed utilizing a Likert scale ranging

from 1 (strongly disagree) to 5 (strongly agree). Participants were a sample of US parents of adolescents ages 11-17 (n=1,109). Participants were recruited online through a market research panel maintained by Qualtrics. To define HPV vaccine initiation status, parents were asked about the number of HPV shots their child had received. Parents that reported their child receiving at least one HPV shot were categorized as initiators while parents that were unsure or reported no HPV shot were defined as non-initiators. Boxplots were created for each category (confidence and conspiracy beliefs) by child's vaccination status and parent age group, sex, and racial/ethnic identity utilizing Stata/BE. T-tests and ANOVA models were used to assess statistical significance of overall mean scores (MS).
Results: Vaccine safety MS was lower among parents that had not initiated the HPV vaccination series for their child compared to parents that had initiated the HPV vaccination series for their children (3.69 vs 4.12, respectively). Across individual vaccine conspiracy beliefs by vaccination status, differences were observed regarding the belief that vaccine-related data is fabricated or covered up. For racial/ethnic comparisons, overall MS for vaccine confidence statements was lowest among Non-Hispanic Black (NHB) parents (MS=3.81). Concurrently, the overall MS for vaccine conspiracy beliefs was highest among NHB parents (MS=3.31). ANOVA models were statistically significant for overall confidence and conspiracy beliefs' scores by vaccination status, parent age group, and parent racial/ethnic identity ($p<0.05$).
Conclusions: Although parents that have initiated HPV vaccination for their children are more confident about vaccines than those that have not, conspiracy beliefs are still common among both groups. Additionally, NHB parents had lower confidence surroundings vaccines and higher report of belief in vaccine conspiracies, while trends have shown that NHB have higher overall risk of dying due to HPV-related cancers. The need to address HPV vaccination education for both vaccinated and unvaccinated communities, additionally tailored by racial/ethnic group, is essential to empower communities with knowledge they can feel certain about and increase protection against HPV-related cancers.

Activation of NRF2-mediated oxidative stress response pathway by curcumin analog FLLL12: Implication for chemoprevention

Raji Lukmon, Adeoluwa A. Adeluola, A.R.M. Ruhul Amin.
Pharmaceutical Sciences, Marshall University, Huntington, OH

Purpose: Carcinogenesis is a multi-step complex process initiated with irreversible genetic mutation due to endogenously derived or carcinogen-induced oxidative stress. Activation of the antioxidant pathways ameliorates oxidative stress, protects cells from carcinogenic insults, and plays a pivotal role in chemoprevention. We have previously reported that FLLL12 is a potent curcumin analog, possesses in vitro and in vivo anticancer activity, and has better pharmacokinetic profiles than curcumin. The purpose of the current study is to identify novel pathways activated by FLLL12 using RNASeq analysis.
Methods: MDA686, a head and neck cancer cell line, were treated with 2 μM FLLL12 for 24h. Total RNA was isolated and used for RNASeq analysis. 2-fold differentially expressed genes were used for Ingenuity Pathway Analysis to identify the most significantly affected pathways. Real-time qPCR and western blotting were used to confirm the expression of the genes associated with the most significantly affected pathways and their protein products respectively in normal, premalignant, and malignant cell lines.
Results: Whole transcriptome analysis using RNASeq identified 641 genes that were either upregulated or downregulated by 2-folds after FLLL12 treatment. Enrichment of this gene set with Ingenuity Pathway Analysis identified the ferroptosis signaling pathway, the tumor microenvironment pathway, and the NRF2-mediated oxidative response pathway as the top three most significantly affected pathways by FLLL12. We confirmed the activation of HMOX-1, NQO1, SLC7A11, and GCLC mRNA and proteins in HOK (normal), MSK-LEUK1 (premalignant), and MDA686TU (malignant) cells. Although these genes are common for the ferroptosis signaling pathway and the NRF2-mediated oxidative response pathway, treatment of cells with ferroptosis inhibitors, ferrostatin 1, and deferoxamine, had no effect on FLLL12-induced cell death suggesting that these genes are associated with oxidative stress response pathway.
Conclusions: Our results strongly suggest that FLLL12 activates the oxidative stress response pathway in normal, premalignant, and malignant head and neck cancer cell lines and has strong promise for chemoprevention.

Preclinical testing of CD73 inhibitor AB680 for pancreatic cancer immunoprevention

Lincoln N. Strickland[1], Erika Y. Faraoni[1], Nicolette R. Mardik[1], Lana Vornik[2], Michelle I. Savage[2], Shizuko Sei[3], Mark S. Miller[3], Holger K. Eltzschig[1], Powel H. Brown[2], Florencia McAllister[2], Jennifer M. Bailey-Lundberg[1]. *[1]Anesthesiology, Critical Care and Pain Medicine, University of Texas Health Science Center At Houston, Houston, TX,[2]Clinical Cancer Prevention, University of Texas MD Anderson Cancer Center, Houston, TX,[3]Cancer Prevention, National Cancer Institute, Rockville, MD*

Introducti**on:** Pancreatic ductal adenocarcinoma (PDAC) is characterized by a profoundly immunosuppressive microenvironment. Innovative therapeutic strategies are urgently needed to stop the progression of precancerous lesions into aggressive PDAC, which remains a lethal malignancy. The goal of this research project is to test immunopreventive strategies by targeting the 5' ectonucleotidase enzyme, CD73, one of the gatekeeper enzymes responsible for conversion of adenosine monophosphate (AMP), to an immunosuppressive metabolite, adenosine, in the tumor microenvironment (TME). We hypothesize that inhibition of CD73 will prevent pancreatic intraepithelial neoplasia (PanIN) formation and progression to PDAC by reversing adenosine directed immunosuppression. This research explores immunopreventive strategies aimed to restore tumor immune surveillance to prevent cancer initiation or progression.

Materials and methods: We used two models: a syngeneic model of PDAC using cells derived from *Kras^{G12D};Trp53$^{R172H/+}$;PdxCre* (KPC) mice and a *Kras^{G12D};PdxCre* (*KC*) genetically engineered mouse model (GEM) of PDAC. Oral gavage of AB680 (small molecule CD73 inhibitor) was given three days/week at 10mg/kg starting the day after KPC injections and tumor sizes were measured weekly. In the GEM model, the same treatment regimen began when the mice were between 6 and 9 weeks old and were euthanized either between 15 and 20 weeks of age or around 27 weeks of age, and pancreas tissue was harvested. Histology was analyzed and 6 fields per mouse were quantified using ImageJ.

Results: As we have described (*Singh, et al, bioRxiv*), in the syngeneic model, there was a significant reduction in tumor growth and significant increase in activated CD8-positive T cells, dendritic cells, and macrophages from AB680 treated mice. The intratumoral adenosine levels were significantly decreased in AB680 treated mice compared to vehicle treated mice. In the *KC* GEM model, we quantified significantly fewer early PanIN lesions ($p=0.0328$), a trend in decreased advanced PanIN ($p=0.0641$), and significant decrease in PDAC ($p=0.0058$) in the AB680 treated mice when compared to the vehicle treated mice. We quantified abundance of collagen deposition as a marker of fibrosis and observed significantly decreased collagen ($p<0.0001$) in AB680 treated *KC* mice. In addition, we quantified abundance of CK19+ lesions and observed a significant decrease in CK19+ lesions in AB680 treated mice ($p=0.0061$) compared to vehicle treated mice.
Conclusion: Inhibiting CD73 restructures TME and reduces PanIN incidence and progression to PDAC. CD73 inhibition may be a candidate immunoprevention strategy in pancreatic cancer. [Supported by NCI 75N91019D00021/75N91020F00002]

Bazedoxifene plus conjugated estrogen improves metabolic health and reduces mammary gland epithelial proliferation in an ovary intact rat model of obesity and breast cancer risk
Ramsey M. Jenschke[1], Karen A. Corleto[1], Carol J. Fabian[2], Stephen D. Hursting[3], Bruce F. Kimler[4], Danilo Landrock[1], Tara N. Mahmood[1], Katherine L. Cook[5], Erin D. Giles[6]. *[1]Texas A&M University, College Station, TX,[2]Department of Medicine, University of Kansas Comprehensive Cancer Center, Kansas City, KS,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]University of Kansas Comprehensive Cancer Center, Kansas City, KS,[5]Wake Forest University School of Medicine, Winston-Salem, NC,[6]University of Michigan School of Kinesiology and Rogel Cancer Center, Ann Arbor, MI*

Background**:** The majority of women risk eligible for primary breast cancer prevention with tamoxifen or aromatase inhibitors refuse uptake due to concerns about side effects, especially vasomotor symptoms. Tamoxifen

may also have detrimental metabolic effects in overweight/obese women. Duavee™, a complex of bazedoxifene (BZA) and conjugated estrogen (CE), is FDA approved for relief of hot-flashes and prevention of osteoporosis. Preclinical studies suggest favorable metabolic effects in ovariectomized animals and potential for breast cancer risk reduction. A single arm clinical trial found reduction in Ki-67 and mammographic density such that BZA+CE is being further evaluated in a Phase IIB trial of peri and early postmenopausal women with vasomotor symptoms who are at high risk for breast cancer. Here, in a companion study, we assessed the effect of BZA+ CE on metabolic health and cancer risk in a rat model of carcinogen induced ER+ tumors and high fat diet induced obesity.

Methods: Rats received 50 mg/kg N-methylnitrosourea at 7 weeks to increase mammary tumor risk and were fed a high fat diet (46% kcal fat) to promote obesity. At 16 weeks lean and obese rat were selected based on % body fat and were then randomized to 8 weeks of daily oral vehicle control or 3mg BZA + 0.07mg CE/kg body weight. Systemic metabolic variables were measured at 16 and 24 weeks, and RNA from mammary glands analyzed by gene expression microarray (Affymetrix).
Results: BZA+CE resulted in systemic as well as mammary changes indicative of improved metabolic health, including: reduction in total and visceral fat ($p<0.01$), glucose ($p<0.05$), cholesterol ($p<0.001$), and triglycerides($p=0.08$), as well as an increase in the adiponectin:leptin ratio ($p<0.01$). BZA+CE vs control increased the ratio of small (insulin sensitive) to large adipocytes in the mammary gland. Gene set enrichment analysis (GSEA) showed BZA+CE downregulated proliferation-associated pathways which had been upregulated in obese rats, consistent with anti-cancer effects. Obese rats treated with BZA+CE also had upregulation of metabolic pathways, including adipocyte differentiation, fatty acid metabolism, and inflammatory response pathways.
Conclusions: Unlike tamoxifen, BZA+CE improved whole body and mammary gland metabolic health, particularly in obese rats. Transcriptional profiling and GSEA demonstrated a blunting of cell cycle and proliferation and enrichment of metabolic and immune-related pathways. Together this supports BZA+CE (Duavee) as an agent to be explored for breast cancer risk reduction in obese individuals.

#5260

Chemopreventive efficacy of everolimus and naproxen combination against carcinogen induced bladder cancer in F344 rats

Venkateshwar Madka[1], Gopal Pathuri[1], Surya P. Singh[1], Anil Singh[1], Anh Bao[1], Nicole Stratton[1], Stanley Lightfoot[2], Clinton J. Grubbs[3], Jennifer Fox[4], John L. Clifford[5], Brian Cholewa[5], Shizuko Sei[5], CV Rao[1]. *[1]OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]formerly VA medical Center, Oklahoma City, OK,[3]Formerly University of Alabama, Birmingham, AL,[4]National Institute of Aging, NIH, Bethesda, MD,[5]Division of Cancer Prevention, NCI, Rockville, MD*

Bladder Cancer (BC) is the second common genitourinary cancer with high recurrence and mortality rate due to metastatic muscle invasive BC (MIBC). Since majority of BCs are non-invasive at diagnosis, developing agents that effectively block BC progression may be beneficial for clinical translation. In this study, clinically approved agents, everolimus, mTOR inhibitor, [0.19mg/kg;7x/week (low dose, LD) or 1.33mg/kg;1x or 2X/week (high dose, HD)] at various dosing schedules alone or in combination with naproxen, an NSAID (30mg/kg body weight) intermittent dosing (3 Wks ON/OFF) were tested for efficacy in an N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN)-induced BC rat model. Female F344 rats (8 weeks age; N=30) were gavaged 16 doses of BBN (150mg/dose). Either one-week (early intervention) or 12-weeks (late intervention) after BBN treatment, rats in each group received respective drug treatments by gavage. At 50 weeks age, rats were euthanized, and tissues were analyzed. Results suggest that BBN-exposed rats developed high number of Non-MIBC (NMIBC) and MIBC and had significantly large bladders (430±57mg, Mean±SEM; $p<0.0001$) compared to normal bladders in vehicle group (68.8±1.3mg). Importantly, there was significant reduction in tumor growth and progression of hyperplasia/papilloma with naproxen alone (3 weeks intermittent dosing) by 70% (129.7±7.7mg; $p<0.0001$) and 58% (180.8±27.6mg; $p<0.001$) at early and later interventions respectively compared to untreated BBN-exposed rats. Continuous LD or HD everolimus regimens during early intervention showed significant inhibitory

effect on papilloma progression, whereas its delayed administration had modest to insignificant inhibitory effect of papilloma progression to NMIBC/MIBC. Intermittent dosing of naproxen alone inhibited large tumors (>200mg) incidence by 90% ($p<0.0001$) and by 75% ($p<0.0001$) with early and late interventions respectively. Early treatment with combinations led to >72% reduction in tumor weight (120.8±7.8mg, 121.8±11.5mg, and 118.6±5.2mg; $p<0.0001$) while late intervention had 58%-65% tumor reductions (179.6±14.4mg, 150.6±12.6mg, and 172.5±15.6mg; $p<0.0005$) with the combination dosing regimens. Notably, all 3 regimens of naproxen plus everolimus combinations significantly inhibited large tumor incidence at both early intervention (90%-100%; $p<0.0001$) and late intervention (60%-70%; $p<0.0005$), with significant suppression of papilloma progression to NMIBC and MIBC, including squamous cell carcinoma (SCC). Protein biomarker analysis suggested decrease in markers of proliferation, inflammation and mTOR signaling with an increased apoptosis. In summary, our study indicated that naproxen and everolimus combination can prevent bladder cancer progression and warrants further evaluation. (Supported by NCI-PREVENT program 75N91019D00020-75N91020F00003)

Prostate specific sustained anti androgen delivery to delay early stage prostate cancer progression

Pujan Desai[1], Maithili Rairkar[2], Nela Pawlowska[1], Scott Thomas[1], Pamela N. Munster[1]. *[1]UCSF - University of California San Francisco, San Francisco, CA,[2]Alessa Therapeutics, San Carlos, CA*

Prostate cancer is the most common cancer in men. Commensurate with risk, current approaches to localized prostate cancer include prostatectomy, prostate radiation with or without radiation therapy or active surveillance. Recent data suggest that systemic anti-androgen therapy with enzalutamide reduced the risk of prostate cancer progression in men on active surveillance but was associated with considerable side effects. We developed a novel polymer-based drug delivery method to provide sustained localized drug administration of anti-androgens selectively to the prostate. In vitro and in vivo mouse and canine studies show that this drug eluting implant delivers sustained high prostate to plasma therapeutic anti-

androgen levels for an anticipated range of 2 years while preventing accumulation of anti-androgens in the liver, lungs, heart and brain. We performed a proof of concept study in a canine prostate model implanting an 15mm x 1mm bicalutamide eluting implant into each lobe of the prostate. Bicalutamide levels in the prostate measured near the implant at 6 months were 3250 ± 1622 ng/g, n = 3 compared to 3809 ± 638 ng/g, n = 3 to those achieved at steady-state oral administration. Plasma and other off target levels were over 1000-fold lower in the implant cohort compared to oral administration: Plasma: 5.9 ± 0.2 ng/ml, liver: 11.3 ±4.3 ng/g, and brain: 5.4 ±0.8 ng/g versus plasma: 18170 ± 3820 ng/ml, liver: 35407 ±8510 ng/g, and brain: 8870 ±1797 ng/g. The implants were well tolerated without local toxicity and imaged easily with ultrasound. The design characteristics of the implant facilitates minimally invasive surgical implantation under standard image guidance and withstands the concomitant use of prostate radiation. This novel technology warrants future clinical exploration of prostate specific anti-androgen therapy for (neo)adjuvant therapy or in active surveillance.

Tissue	**Bicalutamide oral (2m) (ng/g)**	**Bicalutamide implant (6m) (ng/g)**
Plasma	18,170 (3820)	5.9 (0.2)
Prostate	3,809 (638)	3,250 (1622)
Liver	35,407 (8510)	11.3 (4.3)
Cerebrum	8,870 (1797)	5.4 (0.8)
Cerebellum	8,737 (1550)	6.2 (1.3)

Avasimibe abolishes the breast cancer preventative efficacy of statin in a spontaneous mouse model of breast cancer

Anjana Bhardwaj, Zhenlin Ju, Alexander Koh, Rhea Bhala, Jing Wang, Isabelle Bedrosian. *UT MD Anderson Cancer Center, Houston, TX*

Background**:** The cholesterol biosynthesis pathway plays a central role in the normal cellular development and carcinogenesis. Relevant to breast cancer prevention, the breast epithelium in women with atypical hyperplasia has been shown to have increased in cholesterol levels and oxidative products of cholesterol. Additionally, cholesterol pathway genes such as HMGCR and HMGCS1 are known to be upregulated during progression of breast cancer in patients. We have previously shown in SV40C3TAg mice that the cholesterol lowering drug-fluvastatin reduces breast tumor incidence and burden by 50% and have noted that the efficacy of statin is reduced due to the tight regulation of the cholesterol biosynthesis pathway through multiple restorative feedback loops, thus bypassing the effect of statin blockade.
Hypothesis: We hypothesize that fluvastatin efficacy can be improved by co-targeting the restorative feedback pathways that are involved in resistance to statins.
Methodology: RNA seq data from statin resistant MCF10.AT1-R cell clones was compared to the statin sensitive parental MCF10.AT1 cells in order to identify pathways and targets involved in statin resistance. Genes that were also found to be upregulated in the statin non-responders mice mammary tumors relative to responders mice were tested for dual targeting. Efficacy of avasimibe, an ACAT inhibitor, to sensitize MCF10.DCIS cells to statin therapy was studied by the colony formation assay. In vivo validation of the statin + avasimibe dual therapy was performed in SV40C3TAg mice that spontaneously develop triple negative breast cancer.
Results: We found ACAT1 and ACAT2 to be overexpressed in statin resistance cell clones and non-responder mouse breast tumors. ACATs are involved in cholesterol esterification that is required for storing cholesterol in lipid droplets. Cholesterol esterification in conjunction with cholesterol synthesis and export constitute key mechanisms involved in maintaining cholesterol homeostasis. Thus, we tested if avasimibe treatment potentiates the fluvastatin efficacy to inhibit colonizing ability. Avasimibe and fluvastatin combination completely abolished the ability of MCF10.DCIS cells to form colonies. Next, we tested the efficacy of combination treatment to prevent breast tumors in SV40C3TAg mice. The treatments started at the age of 6 weeks, prior to the onset of cancer and continued until 22 weeks of age. We found fluvastatin and avasimibe combination to

be completely ineffective and 90% mice developed tumors. In addition, tumor burden was not reduced with dual treatment.
Conclusions: We postulate that avasimibe enhanced metabolism of fluvastatin in mouse system and thus completely abolishing the chemopreventive effects of statin. Genomically derived rationale drug combinations may result in unanticipated interactions and/or ancillary effects that limit efficacy in vivo/ in patients.

Licochalcone A is a candidate for breast cancer prevention through its reprogramming of metabolic and antioxidant pathways

Atieh Hajirahimkhan[1], Elizabeth Bartom[1], sriram Chandrasekaran[2], xiaoling xuei[3], Susan Clare[1], Seema Khan[1]. *[1]Northwestern University, Chicago, IL,[2]University of Michigan, Ann Arbor, MI,[3]Indiana University, Indianapolis, IN*

Background: Increased adiposity is a risk factor for postmenopausal breast cancer. It is accompanied by protumorigenic effects: chronic low-grade inflammation and elevated levels of reactive oxygen species. Breast cancer risk reducing drugs with proven efficacy have adverse side effects, significantly minimizing their uptake and impact. Effective alternative strategies with lower toxicity are needed. We have shown that licochalcone A (LicA) suppresses aromatase expression and activity, enhances the activity of detoxifying enzymes, and reduces estrogen genotoxic metabolism in cell lines and animal models. However, no previous data exist on the breast tissue of women at substantial risk of breast cancer. We hypothesize that LicA creates a tumor preventive environment in the breast by modulating antioxidant/anti-inflammatory responses in the breast and adipogenesis leading to decreased proliferation.
Methods: We prepared microstructures from the fresh tissue of contralateral unaffected mastectomy specimens of 6 postmenopausal women with incident unilateral breast cancer. After exposing them to DMSO (control) and LicA (5 μM), we performed total RNA sequencing. Differentially expressed genes were identified, and analyzed by gene ontology and pathway membership. The RNA-seq data was utilized also to conduct metabolism flux analysis. Combined enrichment scores > 4 and FDR < 0.05 was considered significant. The NanoString metabolism panel was

employed in 6 additional subjects. We performed live cell imaging to monitor proliferation of pre-malignant DCIS.COM, DCIS.COM/ER+ PR+; and malignant MDA-MB-231 (ER- PR-), MCF-7 (ER+ PR+), MCF-7aro, and BRCA1 defective HCC-1937, and HCC3153 cells.
Results: We observed upregulation of antioxidant genes (up to 8-fold), consistent with upregulation of *NRF2* and the thioredoxin system, the major regulators of antioxidant pathways. This was accompanied with the significant downregulation of RELA- and NF-kB1-dependent inflammatory pathways. In addition, we observed decreased expression of the pro-adipogenic transcription factors *SREBF1* and *SREBF2*, which may explain the downregulation (4 to 32-fold) of cholesterol biosynthesis and transport, and lipid metabolism genes. Metabolism studies confirmed these data and demonstrated a robust increase in the pentose phosphate shunt and NAD(P)H generation without enhancing ribose 5 phosphate formation, suggesting an antioxidant and anti-proliferative environment. LicA also suppressed proliferation of pre-malignant and malignant cells, with sustained effects on aggressive cells at doses < 10 μM.
Conclusion: Our data suggest that LicA is a good candidate for breast cancer prevention through modulation of metabolic and antioxidant pathways leading to decreased proliferation. Our ongoing in vivo study will further demonstrate the efficacy of LicA for breast cancer prevention.

Cucurbitacin D modulates the Nrf2 signaling pathway and protects against benzo[a]pyrene-induced liver injury

Shabnam Malik[1], Anyssa Rodriguiez[1], Mohammed Sikander[1], Daniel Zubieta[1], Fathi T. Halaweish[2], Subhash C. Chauhan[1], Meena Jaggi[1].
[1]Immunology and Microbiology, University of Texas Rio Grande Valley, Edinburg, TX,[2]South Dakota State University, Brookings, SD

Background**:** Accumulating studies have shown strong correlation of HCC and co-morbidity factors including smoking. Tobacco smoke contains benzo[a]pyrene, which is extremely carcinogenic and contributes to liver damage. Cucurbitacin, a triterpene, has a wide range of biological activities, including antioxidant, anti-inflammatory, and anti-cancer properties. However, their hepatoprotective effects remain poorly understood. In the current study, we examined the hepatoprotective activity of cucurbitacin D,

a novel analog of cucurbitacin, against benzo[a]pyrene-induced liver injury in human HepG2 cells.
Method: To investigate the hepatoprotective effect of cucurbitacin D against benzo[a]pyrene-induced liver damage, proliferation, clonogenicity, migration, invasion, Western blotting, and qPCR analyses were performed. The DCFDA assay was performed to determine the level of intracellular reactive oxygen species (ROS) in liver cells.
Results: Functional assays showed that cucurbitacin D exhibited cytoprotective effects against dose-dependent growth inhibition by benzo[a]pyrene in human HepG2 cells. This protective effect was likely associated with antioxidant potential of cucurbitacin D, as evidenced by the attenuation of ROS observed by fluorimeter and fluorescence microscopy. Western blotting analysis demonstrated Cucurbitacin D targets Nrf-2 signaling pathway and associated effector proteins including HO-1 and LC3A in protecting liver cells against benzo[a]pyrene induce oxidative damage. Further studies are underway to understand the underlying molecular mechanism of action.
Conclusion: These findings demonstrate the hepatoprotective effects of cucurbitacin D against benzo[a]pyrene-induced liver damage, making it a promising ingredient for nutritional supplements.

Investigating the role of Desmocollin-3 and immune infiltrate in bladder cancer

Chandreshwar P. Shukla[1], Nayan K. Jain[2], Michael A. O'Donnell[3], Kapil J. Vachhani[4], Rashmi Patel[5], Aruna Vanikar[5], Rajiv I. Modi[4], Sanjay V. Malhotra[6], Bakulesh Khamar[4]. *[1]Cadila Pharmaceuticals Pvt Ltd, Dholka, Ahmedabad - Gujrat, India,[2]Department of Life science,, Gujarat University, Ahmedabad - 380009, Gujarat, India,[3]Department of Urology, Carver College of Medicine, University of Iowa, Iowa City, IA,[4]Cadila Pharmaceuticals Pvt Ltd, Dholka, Ahmedabad-Gujrat, India,[5]Civil Hospital Campus,, Institute of Kidney Diseases and Research Center, Institute of Transplantation Sciences, Asarwa, Ahmedabad - Gujrat, India,[6]Knight Cancer Institute, Oregon Health & Science University, Portland, OR*

Introducti**on:** Adhesion molecules are important for tissue integrity, its maintenance as well as communication (signaling). Desmocollin-3 (DSC3) one of the desmosomal adhesion (Desmoglein 1, 2, 3 and Desmocollin 1, 2, 3) proteins is a trans-membrane glycoprotein present in basal/suprabasal layer of normal stratified epithelium. It is a p53-responsive desmosomal cadherin protein. Cancer development and progression are associated with either additional cytoplasmic expression of DSC3 as seen with squamous non-small cell lung cancer and colorectal cancer or loss of DSC3 expression as seen in prostate and breast cancer To investigate the role of DSC3 in bladder cancer, we evaluated the expression levels of DSC3 in biopsy samples of patients with non-muscle invasive bladder carcinoma (NMIBC) and muscle-invasive bladder carcinoma (MIBC) and correlated it with the clinical staging and immune cell infiltration. Also, its relationship with immune signature genes and immune cell subsets is evaluated using TCGA dataset available on c-bioportal.

Materials and Method: DSC3 protein expression was evaluated by Immunohistochemistry. H&E stained slides were evaluated by light microscopy to identify immune cells as macrophages or lymphocytes and their location as intrastromal or intratumoral as previously described. It was correlated with the type, stage, and grade of the tumor. Spearman correlation between DSC3 and 207 immune signature genes available in TCGA data was calculated using RSEM and methylation values of each gene.

Results: The data suggests that NMIBC is more likely to be DSC3 positive than MIBC. DSC3-positive samples are more likely to have tumor-infiltrating immune cells (TIL) compared to DSC3-negative samples. *In silico* analysis of bladder cancer shows that DSC3 mRNA expression is inversely proportional to its methylation. We found that DSC3 expression is biased towards the Th1 subset of immune cells. DSC3 is not correlated with PD-1/PDL1 expression, and the macrophage subsets are negatively correlated with DSC3.

Conclusion: DSC3 expression is associated with the Basal/Squamous type of bladder cancer. Therefore, this study suggests the potential of DSC3 as a predictive biomarker for response to systemic immunotherapy and resistance/poor response to conventional therapy (chemotherapy; radiotherapy, and cystectomy) and underscores the need for studies evaluating the potential of DSC3 expression as a biomarker.

Metabolic rewiring and epigenetic reprogramming by the environmental carcinogen benzo[a]pyrene in a two-stage skin carcinogenesis mouse model and cancer interception by triterpenoid ursolic acid

Md. Shahid Sarwar[1], Christina N. Ramirez[1], Hsiao-Chen Dina Kuo[1], Pochung Chou[1], Renyi Wu[1], Davit Sargsyan[1], Ahmad Shannar[1], Rebecca Mary Peter[1], Ran Yin[1], Yujue Wang[2], Xiaoyang Su[2], Ah-Ng Kong[1].
[1]Department of Pharmaceutics, Rutgers, The State University of New Jersey, Piscataway, NJ,[2]Medicine, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ

Nonmelanoma skin cancer (NMSC) is the most common skin cancer burden on the U.S. population. Environmental exposure to chemical carcinogens is one of the major causes of NMSC initiation, promotion, and progression. Ursolic acid (UA) is a naturally abundant pentacyclic triterpenoid showing anticancer potentials against diverse cancers. In the current study, we developed a two-stage skin carcinogenesis model in SKH1 hairless mice by administering cancer-initiating agent benzo[a]pyrene (B[a]P) and promoting agent 12-O-tetra-decanoylphorbol-13-acetate to study the epigenetic, transcriptomic, and metabolic changes at different stages (5, 20, and 26 weeks) during the development of NMSC, and investigated how UA regulates B[a]P-mediated alterations for NMSC interception. We found that UA protects against B[a]P-induced tumorigenesis at different phases of NMSC. Epigenetic CpG methyl-seq showed UA abrogated B[a]P-mediated alterations in differentially methylated regions (DMRs) profiles. Transcriptomic RNA-seq data exhibited UA reversed the differentially expressed genes (DEGs) of several inflammatory genes, such as chemokine ligand 8 (*Ccl8*) and interleukin 17F (*Il17f*), and epigenetic genes, such as DNA-methyltransferase 3-like (*Dnmt3l*) and protein-l-isoaspartate O-methyltransferase domain-containing protein 1 (*Pcmtd1*) during different stages of NMSC. Association study between DEGs and DMRs showed that B[a]P promoted transcription of kallikrein-related peptidase 13 (*Klk13*) by promoter demethylation, while UA suppressed *Klk13* expression through hypermethylation in the promoter during the initiation stage, indicating the early intervention of UA.

Ingenuity pathway analysis further showed significant upregulation of macrophage-stimulating protein-recepteur d'origine nantais (MSP-RON) signaling pathway by B[a]P during the initiation stage while suppressed by UA treatment. The metabolomic study revealed UA modulated cancer-associated changes in metabolisms, including the TCA cycle and pyruvate metabolism/metabolites during the promotion phase, indicating UA plays a critical role in regulating B[a]P-regulated metabolic changes and intercepting NMSC progression. In summary, UA protects against the environmental carcinogen B[a]P-driven epigenetic, transcriptomic, and metabolic changes during the initiation, promotion, and progression of NMSC, potentially contributing to the anticancer effects of UA. (Supported by NIH R01 CA200129 to A.N.K)

Effects of polyphenon E treatment on gene expression in DU145 prostate cancer cells

Ethan J. Vallebuona[1], Ashley N. Gannon[1], Corrine M. Costello[1], Ricardo Cordova[2], Ricardo A. Declet-Bauzo[3], Seung Joon Kim[4], Nagi Kumar[5], Jong Y. Park[5], L. Michael Carastro[1]. *[1]University of Tampa College of Natural and Health Sciences, Tampa, FL,[2]Department of Biochemistry and Molecular Biology, Indiana University School of Medicine, Indianapolis, IN,[3]Department of Radiology, Louisiana State University School of Medicine, New Orleans, LA,[4]Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Korea, Republic of,[5]Moffitt Cancer Center, Tampa, FL*

One promising focus of prostate cancer (PCa) research is the chemopreventive effects of Polyphenon E (Poly E), a defined mixture of green tea polyphenols. A previous study utilizing the TRAMP model of human PCa, displayed chemopreventive activity as a result of Poly E oral administration in a dose-dependent pattern. Human clinical trials of Poly E treatment exhibited activity in PCa of those previously diagnosed with atypical small acinar proliferation or high-grade prostate intraepithelial neoplasia. The molecular mechanisms of these Poly E chemopreventive activities against PCa are not well established. Our hypothesis is that Poly E treatment influences expression of genes involved in key cellular signaling

pathways. DU145 prostate cancer cells were cultured in complete growth media supplemented with varied Poly E concentrations (100, 200, 300 mg/L) for 24 hrs. RNA was isolated for comparative microarray (0 vs. 200 mg/L Poly E) and qRT-PCR analyses. Microarray data for 54,613 genes were filtered for > 2-fold expression level changes, with 5,272 increased and 6,467 genes decreased. Nine genes, (*CASP8, CBLB, CCNB1, HDAC4, MXD1, RGCC, RGS4, TBC1D7, ZNF462*) involved in key signaling pathways with >2-fold gene expression changes were selected for subsequent qRT-PCR analyses. Microarray probe set IDs and fold change gene expression values for these nine genes analyzed are listed (Table 1). From qRT-PCR analyses, six of these genes had significant gene expression changes between Poly E treatment levels, *MXD1* (14.20-fold; $p = 0.0122$), *RGCC* (0.6748-fold; $p < 0.0001$), *TBC1D7*(0.2416-fold; $p = 0.0037$), *ZNF462* (0.7030-fold; $p = 0.0173$), *CASP8* (0.4856-fold; $p = 0.0136$), and *CBLB* (2.149-fold; $p = 0.0036$). We conclude that two thirds (6/9) of the genes selected from the microarray data for qRT-PCR analyses had significant Poly E induced gene expression changes. Future experimental directions include cell cycle profiling and annexin V apoptosis analysis, as well as inclusion of other established PCa cell lines.

Drug screening of non-small cell lung cancer patient-derived organoids in a microwell platform

Qiyue Luan[1], Ines Pulido[2], Jian Zhou[1], Takeshi Shimamura[2], Ian Papautsky[1]. *[1]Biomedical engineering, University of Illinois Chicago, Chicago, IL,[2]University of Illinois Chicago, Chicago, IL*

Patient-derived organoids (PDOs) have been widely accepted as ideal 3D tumor models for drug response prediction. However, research involving non-small cell lung cancer (NSCLC) PDOs is hampered by the compromised sample size and the lack of appropriate platforms tailored for scarce samples. Although BME2 domes show promising results in PDO maintenance and drug testing, the need for relatively large sample and the long incubation time hinder their application in drug response studies. Here, we report an agarose microwell (AMW) platform requiring miniscule sample volume for PDO rapid drug screening.

The AMWs were formed by 3D-printed molds and attached to the bottom of 24-well plates. Each well has ~400 agarose microwells with 200μm diameter, 75μm depth and U-shaped bottom. Seeded cells migrate and form spheroids in each microwell. NSCLC spheroids of H358 (KRASG12C), A549 (KRASG12S) and PDOs CK7152 (KRASG12C, obtained from NCI PDMR) were cultured in arrays and treated by KRASG12C inhibitor adagrasib.

PDOs normally grow in a BME2 dome, however large PDO size variability and consumption complicate drug evaluation. The AMWs are

biocompatible and have a smooth surface that allows single cells or PDOs to migrate into microwells within 1d. The amount of PDOs in one dome is enough for 4 wells of 24-well plate. After 7d culture, PDOs formed in AMW exhibited high viability (89%±7% in AMW vs. 89%±11%, in dome) and better size uniformity (CV 29% in AMW vs. 44% in dome).
AMWs can easily be implemented to standardize cytotoxicity evaluation. Following the exposure to adagrasib for 72h, we found that H358 spheroids were sensitive to KRASG12C specific inhibitor adagrasib in dose-dependent manner with an IC50 of 88nM; whereas A549 spheroids - without the target mutation- was not responsive. CK7152 PDOs were also exquisitely sensitive to adagrasib (34% and 21% viability reductions viability in AMWs and dome).
Drug sensitivity can be affected by several factors that maintain proliferative signals active in tumor microenvironment. We have been able to simulate the effect of the tumor microenvironment, by culturing spheroids and PDOs with fibroblast supernatant in AMWs. The IC50 of adagrasib for H358 spheroids treated with WI-38 supernatant was about 3.5× higher than that in normal medium (310nM vs. 88nM). We replicated these results with CK7152 PDOs treated with CAF supernatant that significantly decreased viability from 24% to 51% ($p<0.001$) following 72h treatment of 500nM adagrasib.
Our AMW is a convenient 3D culture platform that generates uniform spheroids from a small sample volume for highly consistent drug screening results. The adagrasib drug response observed in AMW was comparable to that in conventional dome culture. Resistance due to tumor microenvironment can be readily assessed using fibroblast supernatant in AMW platform, promising for pre-clinical drug screening and personalized medicine.

RF-1302, a novel dual inhibitor of PIM1 and FLT3 in preclinical treatment of acute myeloid leukemia

Weiwei Qi[1], Yanjun Zhang[2], Lei Zhao[3], Ailian Zhang[3], Chunze Zhang[3], Xiaoming Zhang[3], Lijuan Li[1], Huaquan Wang[1], Zonghong Shao[1], Rong Fu[1]. *[1]Hematology, Tianjin Medical University General Hospital, Tianjin, China,[2]Chinese Academy of Medical Science, Hematology Institute, Tianjin, China,[3]Ruifu Therapeutics, Inc., Beijing, China*

It was reported that PIM (Proviral Insertion site in Moloney murine leukemia virus) proteins are family kinases (PIM1, PIM2, and PIM3), which are upregulated in several cancer types, especially PIM1 is highly expressed in hematopoietic malignancies. PIM kinase family are responsible for enhancement of cell cycle, inhibition of apoptosis, activation of transcription, and cell homing/migration. Fms-like tyrosine kinase 3 (FLT3) is part of a family of receptor tyrosine kinases (RTKs), and a molecular therapeutic target of acute myeloid leukemia (AML). There are three FTL3 inhibitors, midostaurin, gilteritinib, and quizartinib have been approved for clinical treatment of AML. We have developed a novel dual inhibitor of PIM1 and FLT3, RF-1302 and evaluated its inhibition of cell proliferation *in vitro* and antitumor activity *in vivo*. RF1302 was found to have a strong inhibitory activity against target enzymes (PIM1 IC_{50} at 1.0-2.3 nM and FLT3 IC_{50} at 0.8-2.2 nM), which were more potent than the tested positive control drugs gilteritinib, quizartinib, and midostaurin. RF-1302 showed to be highly cytotoxic to cultured human acute myeloid leukemia (AML) cells (MV4-11 and Molm-13) with IC_{50} at 5.7nM and 9.5 nM, respectively. The *in vivo* antitumor activity of RF-1302 was evaluated and compared with midostaurin and gilteritinib in the treatment of the two AML xenograft models. RF-1302 at 20 mg/kg/daily x 14, oral) significantly delayed tumor growth and resulted in a tumor growth inhibition (TGI) of 95% ($p<0.001$ compared with the control group) in the Molm-13 AML model, and cured all of the tumor-bearing mice in the MV4-11 AML model. The antitumor activity of RF-1302 was superior to gilteritinib (TGI=46-55%) and midostaurin (TGI=63-75%). The treatment with RF-1302 showed very little toxicity (only 2% body weight loss) which were well below the maximum tolerated dose. These preclinical results suggest that RF-1302 represents a novel dual inhibitor of PIM1 and FLT3, which may constitute a highly efficacious modality for the treatment of FLT3 mutant AML, and is worthy of further clinical evaluation.

Silibinin modulates migration and survival pathways in bone marrow mast cells via RAC2: Implications in its anti-cancer activity in basal cell carcinoma growth and progression

Neha Mishra, Sandeep Paudel, Chapla Agarwal, Rajesh Agarwal. *Skaggs School of Pharmacy and Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, CO*

Most of the non-melanoma skin cancers are basal cell carcinoma (BCC); thus, extensive efforts to discover chemopreventive agents against BCC are ongoing. Recently, we showed that silibinin (SB) exerts strong efficacy against ultraviolet B radiation (UVB)-induced BCC growth/progression, and mast cells (MCs) are one of the targets of its efficacy. Notably, 30 days of UVB exposure in patched (Ptch)+/- mouse model of UVB-induced BCC formation increased MC numbers by ~50% that was completely inhibited by SB. Hence, understanding pathways associated with MC regulation by SB seems valuable for its efficacy against BCC and other cancers. We generated bone marrow MCs (BMMCs) in presence of interleukin (IL)-3 and stem cell factor from C57BL/6 mice (confirmed using flow cytometry dual staining: cKit/Fc€RI). They were treated with two concentrations of SB (25 μM; SB 25 and 100 μM; SB 100) or untreated (control), and proteomics was performed (liquid chromatography mass spectrometry on Fusion Lumos mass spectrometer). Total 3575 proteins were identified and 166 were found to be statistically significant (ANOVA, Fisher's posthoc analysis, $p<0.05$, FDR<0.01) amongst the three groups (n=4/group). Proteins with highest differential expression among the groups (greatest fold change expression; n=50), greatest contribution to the selection (variable importance; n=15), and common expression profiles in both SB 25 and SB 100 compared to control (n=21) were selected for further pathway analysis. Important nodes found for SB regulation of MCs were tumor necrosis factor, interferon-gamma, and IL-13; IL-13 also emerged as a key regulatory node in normal BMMCs. Furthermore, to determine the effect of SB in BCC associated MCs, a subset of proteins implicated with skin-associated MC activity (determined using IPA) was generated. Most important molecules implicated included IL-13 and Rac Family Small GTPase2 (RAC2; regulates all myeloid lineages). RAC2 was found to modulate the expression of mast cell protease4 (MCPT4), mast cell transcriptase1 (TPSAB1), and macrophage migration inhibition factor. RAC2 also activates MC proteases via JNK signaling cascade. Together, via the regulation of MCPT4, TPSAB1, and JNK signaling, RAC2 regulates inflammatory responses, and controls MC migration via actin cytoskeleton

reorganization and lamellipodia formation. Phagosome maturation was also an important pathway implicated in our analysis; MCs lyse engulfed pathogens/debris via phagosome maturation and fusion with lysosomes. In conclusion, our findings demonstrate that SB increases RAC2 expression in BMMCs, which can regulate MC migration into the tumors and effectively increase the MC protease gene expression. Thus, SB treatment shifts BMMCs towards anti-tumorigenic pathways and RAC2 can be a novel therapeutic target in BCC and other cancers as well.

Inhibition of ultraviolet B radiation-induced mast cell recruitment by silibinin in its efficacy against basal cell carcinoma in Ptch$^{+/-}$ mouse model

Sandeep Paudel[1], Neha Mishra[1], Komal Raina[2], Chapla Agarwal[1], Rajesh Agarwal[1]. *[1]Skaggs School of Pharmacy and Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, CO,[2]College of Pharmacy and Allied Health Professions, South Dakota State University, Brookings, SD*

Recently, we have reported the chemopreventive and therapeutic efficacy of topical silibinin (SB, a natural flavonolignan from milk thistle seeds) application against ultraviolet B radiation (UVB)-induced basal cell carcinoma (BCC) growth and progression. During the histopathological analyses of the skin tissues in these studies, we observed a significant decrease in mast cell (MC) numbers in SB-treated UVB-exposed groups. Although, the MCs are primarily responsible for conferring protection against diseases and pathogens, the dynamics of BCC and MCs are complex, where MCs may also contribute to tumor transformation/progression; furthermore, their role in BCC is poorly understood. To address this gap, we first assessed the course of MC recruitment in wild-type (C57BL/6) mice vs. Ptch$^{+/-}$ mice as a function of time following either a single or thrice weekly UVB (240 mJ/cm^2) exposure. Results indicated that Ptch$^{+/-}$ mice had significantly higher infiltration of MCs compared to C57BL/6 mice. MC infiltration into the epidermis/dermis was initiated as early as 30 min post single UVB exposure in Ptch$^{+/-}$ mice, and the MCs remained in the epidermis/dermis for a longer

duration in the Ptch$^{+/-}$ mice compared to C57BL/6 mice. Next, the effect of SB treatment (topical-9 mg/200 µl acetone) on MC recruitment upon UVB exposure in these mice was assessed. Notably, SB treatment significantly decreased MC numbers in both pre- and post-UVB single exposure by ~48% and ~43%, respectively, and in multiple exposure by ~55% and ~41%, respectively. Furthermore, UVB exposure for 26 and/or 46 weeks caused an increase in MC numbers by ~2.3 fold in BCC tumors, which was also decreased by both pre- (~38-39%) and post- (~20-26%) SB treatments at 26 and 46 weeks, respectively. Notably, in preformed BCC tumors (UVB 26 weeks exposure), SB treatment for 20 weeks post UVB stoppage also decreased the number of MCs by ~25%. Thus, it was evident that anti-BCC efficacy of SB was associated with its potential to decrease MC numbers. To further understand the role of SB in MC regulation, assessment of cell viability and migration (towards BCC cell lines) in *in vitro* assays were performed with/without SB exposure in bone marrow derived mast cells (BMMCs from C57BL/6 mice), which indicated that non-toxic doses of SB (25 -100 µM) at the 48-72 h timepoint were able to inhibit BMMC migration towards BCC cell lines. Furthermore, a correlation of other immune cells (T cells, macrophages, etc.) with MC recruitment and anti-BCC effect was also determined. Taken together, our results suggest that SB effectively regulates MC numbers/function in its efficacy against BCC in Ptch$^{+/-}$ mouse model; thus, further in depth-studies, deciphering the associated molecular pathways, could yield novel preventive/ therapeutic avenues targeting MCs in BCC and other cancers.

3D cell-culture strategy for screening novel agents in Fanconi anemia chemoprevention

Gretchen M. Unger[1], Beverly R. Wuertz[2], Mary E. Brown[3], Sanjana Arji[2], Janeen H. Trembley[4], Frank G. Ondrey[2]. *[1]Genesegues, Inc., St. Paul, MN,[2]Otolaryngology, University of Minnesota, Minneapolis, MN,[3]Neuroscience, University of Minnesota, University Imaging Centers, Minneapolis, MN,[4]Research Service, Minneapolis VA Health Care System, Minneapolis, MN*

Fanconi anemia (FA) patients have DNA repair mutations predisposing them to oral cancers so treatment with non-DNA damaging agents is highly desired. As cancer experimental therapeutics advance towards study paradigms that more carefully mimic physiology, e.g. organoids and spheroids. Presently, we are using a 3D cell culture method emphasizing layers of extracellular matrix (ECM) as FA premalignant lesions retain epithelial architecture. We conducted 3D screening studies using 2 layered geometries: 1) nanofibers coated with 1 ng/mL 2:1 Collagen III/IV (C3C4) then 100 pg/mL 2.75:1 Tenascin C/Fibronectin (TNFN) and 2) polystyrene layered with 50 ug/mL C3C4 then 3.5 ug/mL TNFN. We developed these coatings to maximize lipid raft recovery, a drug transport feature lost in 2D culture. The ECM impact on FA cell drug transport was characterized by comparing effective nuclear delivery of a 20nm nanoencapsulated FITC-labeled RNAi compound (s50-TBG-RNAi3UTR), known to require lipid rafts, to the same oligo formulated with Dotap in a FA HNSCC cell line (FA1). Using confocal microscopy and IMARS software to segment delivery at maximal nuclear intensity into nuclear or endolysosomal compartments, we found, for FA1 cells on ECM, nuclear oligo signal colocalization with nuclear compartment ± coefficient of variation was 62 ± 2.2% for the capsule vs 9.8 ± 8.5% for Dotap oligo. On glass, nuclear delivery was 10 ± 52% for s50 capsule vs 25 ± 32% for Dotap. Endolysosomal compartment sequestration was respectively 28 ± 12, 62 ± 10, 44 ± 19 and 51 ± 15%. This illustrates a relevant decrease in variation in FA cell biology from ECM addition. Next, we studied metformin (Met) and pioglitazone (Pio)(agents in current oral cancer prevention studies) combined with G2/M blockade inhibitors, MK1775 (Wee1 kinase inhibitor) and GSK461364 (PLK inhibitor) in FA1s. Inhibiting G2/M blockade, already induced by FA-derived DNA damage, could promote inappropriate cell division, mitotic catastrophe (MOC) and death. In initial 2D FA1 growth studies, increased death was observed with Met plus MK1775. 3D studies, in contrast, showed increased cell death for FA1s treated with Pio plus either MK1775 or s50-TBG-RNAiCK2 (RNAiCK2). Confocal mechanistic studies in cells plated on ECM and treated for 18 hours, indicated Pio + MK1775 inhibited Survivin and ß-catenin upregulation and FA1 cells did proceed into MOC and death. For Pio (PPARg agonist) + RNAiCK2, RXRa was dephosphorylated at S260, enabling its escape from cytosolic sequestration to bind nuclear PPARg, initiating differentiation.

Differentiation was indicated by upregulation panKeratin and Transglutaminase-3. We conclude combination therapies with high interest agents in FA-associated oral cancer can be performed in 3D culture systems and might confirm drug mechanisms of action, thus augmenting other standard methods of cancer drug evaluation and screening (e.g. cell proliferation and clonogenicity).

The E3 ubiquitin ligase SIAH2 promotes clear cell renal cell carcinoma epithelial-mesenchymal transition via regulation of SETD2 stability

Mengxue Yu[1], Lingao Ju[1], Gang Wang[2]. *[1]Zhongnan Hospital of Wuhan University, Wuhan, China,[2]Department of Urology, Zhongnan Hospital of Wuhan University, Wuhan, China*

Introduction & Objective: SETD2, a major histone H3K36 trimethyltransferase, has been shown to play an important role in multiple biological processes. Mutations in *SETD2* have been evidenced in several types of cancer, including clear cell renal cell carcinoma (ccRCC). Previous studies reported the potential involvement of SETD2 in driving ccRCC tumorigenesis. However, the mechanism by which SETD2 causes cell metastasis remains poorly understood.
Methods: Genome-wide CRISPR-Cas9-based screens and immunoprecipitation-mass spectrometry were used to identify candidates for regulating SETD2 stability. Immunohistochemistry staining of the ccRCC tissue array and bioinformatics analysis of TCGA database were used to investigate the clinical relevance of SETD2 in ccRCC. The gene expression was detected by qRT-PCR, and the protein level was detected by western blotting. Wound healing and transwell migration assay were used to explore the cell migration ability. SIAH2 was deleted from ccRCC cell lines using CRISPR/Cas9-mediated gene editing. Furthermore, we used BALB/c-nude mice to construct xenograft mouse models and pulmonary metastasis models. Moreover, RNA-seq, H3K36me3 CUT&Tag and RNA N^6-methyladenosine-IP were performed to uncover the mechanism.
Results: SETD2 mutant or low expression was correlated with poor prognosis in patients with ccRCC based on TCGA data and tissue array. Through the CRISPR/Cas9 screening system and immunoprecipitation-mass spectrometry, we identified the E3 ubiquitin ligase SIAH2 that

regulates the stability of SETD2. Then, we verified that the protein stability of SETD2 was downregulated by SIAH2 in a dose-dependent manner and further confirmed that the SIAH2 promotes SETD2 degradation in a proteasome-dependent pathway. In addition, we constructed a dominant negative mutant of SIAH2 and proved the degradation dependent on its enzymatic activity. Moreover, we showed that SIAH2 knockout increased the protein level of SETD2. In SETD2 stable knockdown ccRCC cell lines, loss of *SETD2* enhanced the capability of cell migration, while knockdown of *SIAH2* resulted in the rescue of *SETD2* deficient effect. Moreover, *SETD2* ablation significantly decreases H3K36me3 peaks of E-cadherin, further reducing the m^6A signal and stability of *E-cadherin* mRNA. Conclusion: In this study, we firstly revealed the mechanism that E3 ubiquitin ligase SIAH2 interacted with SETD2 and promoted the ubiquitination degradation of SETD2. Moreover, *SETD2* ablation in ccRCC cells enhanced EMT through impaired epigenetic regulation of *E-cadherin*, suggesting SIAH2/SETD2/E-cadherin axis as a potential therapeutic target for ccRCC.

Assessing efficacy and immune-stimulatory effects of tumor-derived dendritic cell reprogramming using immuno-competent 3D tumor spheroid model

Irina Agarkova[1], Nadezhda Rotankova[1], Michal Rudnik[1], Silvan Strebel[1], Olga Zimmermannova[2], Andre Rosa[3], Fabio F. Rosa[3], Wolfgang Moritz[1], Carlos-Filipe Pereira[2], Christiana F. Pires[3]. *[1]InSphero AG, Schlieren, Switzerland,[2]Molecular Medicine and Gene Therapy, Lund Stem Cell Centre, Lund University, Lund, Sweden,[3]Asgard Therapeutics, Lund, Sweden*

Immunotherapy has brought hope for cancer treatment, but its clinical success remains limited. Recently, overexpression of the transcription factors PU.1, IRF8 and BATF3 (PIB) was shown to induce direct reprogramming of tumor cells into antigen-presenting type 1 conventional

dendritic cells (cDC1s), a rare subset of immune cells with pivotal role in anti-cancer immunity. This strategy might open avenues to enhance cancer cell recognition and elimination by the immune system. However, currently existing in-vitro and in-vivo testing platforms do not qualify to reproduce all complex cell interactions essential for the approbation of this hypothesis. Here, we report the development of the InSphero 3D InSight™ Oncology Platform for in-vitro assessment of efficacy and immune-stimulatory effects of this novel cancer immunotherapy approach. The feasibility of 3D spheroid formation for several GFP-expressing tumor cell lines was evaluated by varying seeding conditions in AKURA 96 well plate. We have measured the growth (ATP content) and GFP signal overtime and analyzed the morphology of the spheroids by IHC. With this, we have established spheroid models of T98G (glioblastoma), PK59 (pancreatic cancer), and A375 (melanoma) cell lines that are growing and viable for at least 10 days. In parallel, using 2D cultures, we have identified the optimal multiplicity of infection of a lentiviral vector encoding for PIB and mCherry to enable high transduction (mCherry+ cells), reprogramming efficiency (mCherry+CD45+HLA-DR+ cells), and cell viability, quantified by flow cytometry and IHC. Then, we have demonstrated that cDC1 reprogramming progresses in the context of 3D cancer spheroids and tumor cells acquire expression of CD45+ and HLA-DR+ cells using IHC and confocal microscopy analysis. We developed an algorithm enabling automated analysis of confocal images and quantification of cDC1 reprogramming efficiency from individual image stacks calculated as a ratio of mCherry+, CD45+ and HLA-DR+ cells versus the number of DAPI+ nuclei. Using the new algorithm we have evaluated the reprogramming efficacy of the different virus dosages in all three types of 3D tumor spheroids. Lastly, we have cocultured tumor spheroids transduced with PIB with naïve or activated HLA-matched PBMCs and evaluated cytokine secretion as a readout of immune cell activation. We observed that reprogramming induces activation of T cells and correlated it to the number of reprogrammed cells in the tumor spheroid, evaluated by the HC imaging. In summary, we developed the InSphero 3D InSight™ Oncology Platform that allowed us to demonstrate the effects of direct reprogramming of tumor cells into immunogenic dendritic cells. Combined with high-content imaging analysis, this platform offers a powerful solution for preclinical translational research.

Reconstructing the metastatic tumor microenvironment of high grade serous ovarian cancer: understanding the contribution of malignant cells

Beatrice Malacrida, Samar Elorbany, Eleni Maniati, Florian Laforets, Ranjit Manchanda, Frances R. Balkwill. *Barts Cancer Institute, London, United Kingdom*

Following a 'deconstruction' of the metastatic tumor microenvironment (TME) of high grade serous ovarian cancer (HGSOC), we developed 3-dimensional (3D) human multicellular in vitro models using patient-derived primary cells and HGSOC malignant cell lines. In this study, we used these 3D in vitro human models to study how malignant cells influence the surrounding TME. Using patient-derived primary adipocytes, fibroblasts and mesothelial cells isolated from macroscopically normal omentum (the primary site of metastasis in HGSOC) from women undergoing gynaeco-oncology surgery, we built multicellular models combining those cells with different high grade serous malignant cell lines and monocytes isolated from healthy individuals. We found that peripheral blood monocytes were able to differentiate and polarize to macrophages in our pentacultures (i.e., five different cell types) with phenotypes also found in HGSOC omental metastases. In addition, the cells in our pentaculture models self-rearranged in ways that were dependent on the HGSOC malignant cell lines used in the culture. Macrophage phenotype and cytokine secretion from the multicellular cultures was also influenced by the different malignant HGSOC cell lines used in the model. RNAseq analysis of the pentacultures showed that the cultures clustered according to the malignant cell line used. In addition, we were able to identify some gene expression clusters in the macrophages and fibroblasts of the pentacultures that matched those found by single cell RNAseq analysis of human HGSOC biopsies. These human 3D in vitro multicellular models allow us to define the contribution of each cell type to tumor growth and spread, and also provide us a semi-high throughput platform to investigate antibody or drug targets.

3D-EXplore platform of fresh patient tumoroids with intact TME allows assessment of the efficacy of drugs targeting the tumor stroma on *ex vivo* tumor immunotherapy

Seth Currlin, Brittney Ruedlinger, Sharon Camacho, Angie Rivera, Jasmin D'Andrea, Jared Ehrhart, Soner Altiok. *Nilogen Oncosystems, Tampa, FL*

Introducti**on:** Cancer associated fibroblasts (CAFs) are a major component of the tumormicroenvironment (TME) and exhibit diverse tumorigenic functions such as immunosuppressionand extracellular matrix (ECM) remodeling. Treatment of solid tumors is often hindered by acomplex TME, which persists despite effective tumor-cell directed therapies. Therefore,treatment of solid tumors in combination with stromal-targeting therapies is essential toovercome CAF-facilitated tumor growth, and immunosuppression. Herein we interrogate theimpact of tumor stroma targeting therapeutics, in combination with nivolumab, on the efficacy oftumor cell killing (TCK) in a 3D human tumoroid *ex vivo* culture model (3D-EXplore). Resultingdata suggests that impairing the recruitment and activation of CAFs within the TME leads toenhanced TCK when combined with immune checkpoint blockade therapy.

Materials and Methods: All patients tumor samples were collected with patient consent andrelevant IRB approval. 3D tumoroids measuring 150 microns in size were generated from freshpatient tumors including endometrial, ovarian, and colorectal cancer tissues. Tumoroids werethen treated with stromal targeting strategies for TGF-beta (galunisertib), the FGF pathway(Dovitinib), FAK inhibitors (defactinib), and cell adhesion modulators (plerixafor) alone or incombination with nivolumab for 72-hours *ex vivo*. Tumor responses to *ex vivo* treatments wereassessed using a proprietary tumor cell killing assay and 21-color flow cytometry analysis.

Results and Summary: Here we evaluated the impact of stromal targeting therapeutics onCAFs and associated tumor cell killing as well as overcoming immune evasion mechanismspreserved in the tumoroid models. Furthermore, we used a multicolor flow panel to analyzewhether combination of stromal targeting drugs enhances nivolumab's effect on the activation oftumor resident CD4, CD8 T-cells, NKT, and NK cell populations as well as on macrophagepolarization. Treatment-mediated changes in the tumor immune microenvironment was furthercorroborated by a multiplex cytokine release assay detecting GM-CSF, sCD137, IFNγ,

sFas,sFasL, Granzyme A, Granzyme B, IL-2, IL-4, IL-5, IL-6, IL-10, IL-13, MIP-1α, MIP-1β, TNF-α,Perforin in tumoroid culture media and correlated with clinicopathologic findings and PD-L1expression for individual tumnors. Further, this 3D-tumoroid platform provides unique insightinto the microenvironment of both treatment responsive and non-responsive tumors and can aidin the development of patient-centered therapeutic regimens.

#4553

How do shiitake and reishi mushrooms work on lung cancer? : A high throughput screening of 3D cell culture

Mihi Yang[1], Hee-Kyung Jang[2], Huiwon Kang[1]. *[1]Sookmyung Women's University, College of Pharmacy, Seoul, Korea, Republic of,[2]Natural Dream, Goesan, Korea, Republic of*

Shiitake (*Lentinula edodes*) and reishi mushrooms (*Ganoderma sichuanense*) have been noticed for desirable chemoprevention, such as improving immunity, overcoming anticancer drug resistance, etc. Particularly, beta-glucans have been mostly mentioned as the active component of the mushrooms. However, the right preparation and effective usage of the mushrooms for cancers are unclear, yet. Thus, we screened various extractions of the two mushrooms and combinations of the extracts, using a high throughput screening of 3D cell culture system on 384-pillar plates with various cancer cells and Cell Titer-Glo 3D cell viability assay kit (Promega). We also quantified the beta-glucans in all extractions with the Megazyme Mushroom and Yeast Beta-Glucan kit (K-YBGL) by excluding the alpha-glucans content from the total-glucans. As results, most of the extracts showed cytotoxicity on the lung cancer cells, A549 cells, rather than on the other cells, such as HepG2 (N=9 for each treatment). The extracts of reishi mushroom in 60% of methanol (dose range, 0.21-2.3 mg/ml) showed the strongest cytotoxicity on the lung cells, IC50=0.90 +/- 0.01 mg/ml, among the extracts of different methanol contents (10-60%) or different temperatures (50-90 °C) of hot water. However, the 60 % of methanol reishi extracts included relatively low levels of beta-glucans, compared to other extracts (18.57 +/- 0.31 vs. 22.42 +/- 5.56 % w/w). In addition, the levels of beta-glucans in all of reishi mushroom extracts were lower than those in all of the shiitake extracts (17.70 +/- 1.89 % vs. 27.05

+/- 4.21 % w/w: $p<0.01$). Moreover, there was no association between the levels of beta-glucans and IC50 in A549 cells. Interestingly, the combination (1:1) of the above 60% of methanol extracts of reishi mushroom and the 30% methanol extracts of shiitake (dose range, 0.30-3.26 mg/ml) showed synergic effects, i.e., 2-7 fold stronger effects (average of IC50=0.40 mg/ml) than every single treatment (average of IC50=0.90-2.63 mg/ml). Taken together, the reishi mushroom may have other strong chemopreventive materials rather than beta-glucans, while the shiitake may have a potentiation effect, when combined with the reishi mushroom. In conclusion, our 3D cell culture system showed high throughput performance to find the right preparation and effective usage of the two mushrooms and provided useful information for the next clinical studies for lung cancer.

Head and neck cancer HuBiogel-embedded microtumor assay system for therapeutic efficacy testing of patient tumor specimens

Christopher D. Willey[1], Yedeh P. Ying[2], Anthony B. Morlandt[2], Hope M. Amm[2], Patricia H. Hicks[1], Joshua C. Anderson[1], Andee M. Beierle[1], Carissa M. Thomas[3], Jason M. Warram[3], Jingsong Chen[4], Jeffrey A. Thomas[4], Katie Banko[4], Raj K. Singh[4]. *[1]Radiation Oncology, O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL,[2]Oral & Maxillofacial Surgery, O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL,[3]Otolaryngology, O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL,[4]LifeNet Health, Virginia Beach, VA*

Head and neck (HN) cancer recurrence is common, and selecting effective salvage systemic therapy remains difficult, particularly for oral cavity cancers. Developing a rapid, robust and predictive therapeutic testing system could support clinical decision-making and improve patient outcomes. We developed a Patient Therapy Evaluation System (PTES) that employs a three-dimensional (3D) fully human microtumor drug testing assay using tissue specimens collected during surgery of HN cancers. Remnant fresh tumor tissue from patients is dissociated into single-cell suspension that is embedded using a novel HuBiogel-cell encapsulation technology (3D microtumors). This high-throughput assay platform allows

morphologic, functional, and molecular evaluations in parallel by real-time imaging, cell proliferation, and biomarker protocols. Microtumor viability, growth profiles, and drug screening data are captured at multiple time points up to 14 days. Our initial cohort included 57 patient specimens (53 squamous cell carcinomas, 1 verrucous carcinoma, 1 osteosarcoma, 1 ameloblastoma, and 1 non-cancerous lichenoid mucositis). HuBiogel-embedded tumor cells formed numerous multicellular colonies exhibiting distinct organization and growth patterns in 14-day microtumor cultures. Interestingly, epithelial, stromal and stem-cell like populations were preserved in HN microtumor models based on marker expression. Treatment with single (cisplatin, 5FU, docetaxel) drugs and their combinations resulted in tumor inhibitory responses (IC50) evaluated by CellTiter-Glo assay, and residual surviving cells were also recorded by Calcein-AM staining of 3D Microtumors. While patient-derived HN microtumors were produced with high success rates, factors associated with lower microtumor yield included smaller tumor specimens and low viability after dissociation. In conclusion, our new all human microtumor assay models replicating phenotypic, functional, and molecular properties ex vivo provide a potential theranostic tool for rapidly predicting drug sensitivity and improving treatment strategy for HN cancer patients.

#4555

Aryl-hydrocarbon receptor inhibitors in combination with anticancer agents, especially proteasome pathway inhibitors, in a complex spheroid screen using patient-derived cell lines can result in greater-than additive cytotoxicity

BEVERLY A. TEICHER[1], Jeffrey A. Moscow[1], Joel Morris[1], James H. Doroshow[1], Thomas S. Dexheimer[2], Nathan P. Coussens[2], Thomas Silvers[2], Rene Delosh[2], Zahra Davoudi[2], Russel Reinhart[2], Chad Ogle[2], Eric Jones[2].
[1]DCTD, National Cancer Institute, Bethesda, MD,[2]Applied and Developmental Research Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD

Three aryl-hydrocarbon receptor (AhR) selective inhibitors, BAY-2416964, GNF351 and CH-223191, were assayed alone and in combination with 25 approved or investigational anticancer agents in complex spheroids including tumor cells, endothelial cells, and mesenchymal stem cells. The

tumor cell lines were from the National Cancer Institute's Patient-Derived Models Repository (PDMR) collection (https://pdmr.cancer.gov/models/database.htm). The AhR is a ligand-activated helix-loop-helix transcription factor of the bHLH-PAS family. It is involved in the regulation of responses to planar aromatic hydrocarbons by activating the transcription of xenobiotic-metabolizing enzymes such as cytochrome P450 or by acting as an E3 ligase. Thus, the AhR activates detoxification pathways that dispose of small molecule toxins and damaged proteins. In the absence of xenobiotics, the AhR is located within the cytoplasm in complex with two Hsp90 molecules and co-chaperones. Upon xenobiotic binding, the AhR translocates to the nucleus and binds to the AhR nuclear translocator protein to form an active transcription factor complex and promote gene transcription. As single agents, the three AhR inhibitors showed little cytotoxicity at concentrations up to 10 μM. Combinations of AhR inhibitors with anticancer agents including doxorubicin, cisplatin, SN38, venetoclax, selinexor, and etoposide (https://dtp.cancer.gov/organization/dscb/obtaining/default.htm) produced primarily additive cytotoxicity in complex spheroids after a 7-day exposure. However, unexpected greater-than-additive effects were observed with AhR inhibitors in combination with proteasome pathway inhibitors. Bortezomib, a direct inhibitor of the chymotrypsin-like protease of the 26S proteasome, and pevonedistat, a NEDD8-activating enzyme inhibitor, produced additive or greater-than-additive cytotoxicity in some complex spheroids. However, the combination of BAY-2416964 with TAK-243, a ubiquitin activating enzyme inhibitor, produced profound greater-than-additive cytotoxicity in more than half of the 28 PDMR cell lines tested as complex spheroids. The combination resulted in an increase of 1- to 3-logs of excess cytotoxicity in malignancies including bladder cancer, pancreatic cancer, colon cancer, NSCLC, SCLC and glioblastoma. In vivo studies are under discussion. This project was funded in part with federal funds from the NCI, NIH, under contract no. HHSN261201500003I.

Matrix properties regulate 3D tumor spheroid growth and cancer drug response

Jaxson R. Libby, Linqing Li, Sarah R. Walker. *University of New Hampshire, Durham, NH*

3D cancer spheroids are vital in vitro models for cancer drug discovery. The current cancer spheroid generation utilizes low-adhesion plates or forced aggregation of single cells. However, certain cancers do not form stable spheroids in these protocols, nor do pre-formed tumor spheroids recapitulate in vivo development and progression. This project aims to overcome this limitation with the use of a biomimetic hydrogel system to mimic in vivo cancer cell growth and tumor development and use it as an in vitro platform for 3D cancer drug screening. The biocompatible and tunable hydrogel permits independent control of key biochemical and biophysical cues such as matrix degradation, cell adhesion, and stiffness; leading to systematic investigation of matrix parameter contribution to regulating in vitro tumor growth and treatment response. We modified a homo-polysaccharide dextran with methacrylate groups and generated dextran macromers (Dex-MA) containing ample reactive methacrylates per polymer. Cell adhesion is mediated by thiol-terminated RGD peptide added to the methacrylates, followed by crosslinking with di-thiolated MMP-labile peptides through Michael-type addition reaction. Varying the sequence of the crosslinker furthermore gives access to a range of degradability, independent of matrix stiffness. Our experiments showed that Dex-MA supported robust growth of SK-BR-3 breast cancer cells from single cell to 3D tumor spheroids, whereas the cell line failed to form tumor aggregates in low-adhesion plates. Alteration of hydrogel stiffness further revealed stiffness dependence of tumor growth, invasion, and response to treatment, suggesting the importance of matrix properties on regulating cell behavior. This dextran-based tunable hydrogel system provides key insights into how engineered matrix properties control tumor growth, critical for screening novel therapy compounds, and may reveal mechanisms for 3D tumor development, invasion, metastasis, and drug resistance.

3D-EXpress platform utilizing tumoroids from patients with MSS and MSI-H tumors allows rapid assessment of anti-tumor activity of immune checkpoint inhibitors and development of clinically relevant biomarkers of treatment response

Brittney Ruedlinger, Seth Currlin, Sharon Camacho, Alliyah Humphrey, Jared Ehrhart, Soner Altiok. *Nilogen Oncosystems, Tampa, FL*

Introducti**on:** Recent studies showed that patients with deficient mismatch repair(dMMR)/microsatellite instability-high (MSI-H) tumors, have higher sensitivity to immune checkpointinhibitors (ICIs) compared to patients with microsatellite-stable (MSS)/microsatellite instability-low(MSI-L) tumors. However, the mechanisms of treatment responsiveness and resistance is not wellunderstood. Here, we used a novel 3D-EXpress *ex vivo* fresh patient tumoroid platform to assess theefficacy of nivolumab/ipilimumab combination therapy in tumors with known MSS/MSI-H status andperformed correlative studies.

Materials and Methods: All tumor samples were obtained with patient consent and relevant IRBapproval. Tumoroids measuring 150 μm in size retaining tumor cell heterogeneity, tumor-residentimmune cells, stromal components, and cell-extracellular matrix interaction were prepared frompatients with endometrial and colorectal tumors among others. Tumoroid aliquots were cryopreservedin Nilogen's tumoroid Biorepository for future studies. For the 3D-EXpress studies cryopreservedtumoroids were selected based on MSS/MSI-H status and treated *ex vivo* with nivolumab andipilimumab alone and in combinations for 72h. Tumor responses to treatments were evaluated by aproprietary tumor cell killing assay and changes in tumor immune microenvironment. Furthermore,tumor PD-L1 expression levels were analyzed on the associated TMA slides.

Results: Treatment-induced tumor cell killing activity in intact tumoroids was assessed by a 3D high-content confocal imaging technique using a proprietary algorithm for data analysis. The impact of *exvivo* treatment by nivolumab and/or ipilimumab on tumor resident immune cell populations wasmonitored by a multiplex cytokine release assay analyzing release of GM-CSF, sCD137, IFNγ, sFas, sFasL,Granzyme A, Granzyme B, IL-2, IL-4, IL-5, IL-6, IL-10, IL-13, MIP-1α, MIP-1β, TNF-α, and Perforin usingculture supernatants isolated from treated tumoroid samples. Based on the *ex vivo* responses tumorswere assigned to treatment sensitive and resistant groups and correlative analyses were performed withindividual tumors' innate and adaptive immune cell populations detected by a 21-color flow cytometrypanel, in addition to tumor MSS/MSI-H and p53 status, and detailed clinicopathologic data readilyavailable for the tumors cryopreserved in the Biorepository.

Conclusion: The 3D-Express platform, using cryopreserved 3D tumoroids with intact TME is an effectivetool for the assessment of rational combinations which may prove relevant in the treatment of solidtumors. Furthermore, we believe this platform is a useful tool for the pre-clinical assessment of specifictherapeutic regimens designed for individualized patient care.

High-throughput, high content Imaging assay for assessing solid tumor phagocytosis in 3D spheroid model

Michal Rudnik, Özlem Yavaş Grining, Nadezhda Rotankova, Silvan Strebel, Francesca Chiovaro, Olivier Frey, Irina Agarkova, Wolfgang Moritz. *InSphero AG, Schlieren, Switzerland*

Emerging studies have demonstrated that innate immune checkpoints, regulating Tumor-associated Macrophage (TAM) phagocytic activity, play a crucial role in immune escape and survival of cancer cells. CD47-SIRPα axis is the best studied example of the “don’t eat me” signal, frequently overexpressed on cancer cell. Targeting of CD47 protein has shown impressive results in clinical trials in hematologic malignancies but remained challenging for solid tumors therapy. Therefore, tools facilitating the development of novel innate immune checkpoint inhibitors are of great interest. To address that unmet need, we established a high-throughput, 384-well-format assay for efficacy assessment of compounds inducing macrophage phagocytosis. As a model of solid tumor, we employed 3D spheroids aggregated of human cancer cell lines (A375, HCT116, MCF7, SKOV3) expressing GFP or PDX material (LXFA1647 lung adenocarcinoma, MEXF2106 melanoma) and cancer associated fibroblasts, as well as Monocyte-Derived Macrophages (MDMs) which altogether were co-aggregated to form spheroids mimicking the tumor microenvironment and immune-competence. In parallel MDMs were co-cultured with matured spheroid to emulate tumor infiltration. Both models were cultured in automation and High Content imaging compatible Akura™ 384-well plate. To evaluate our system, we targeted CD47-SIRPα axis by treatment of 3D spheroid models with αCD47 antibody (H6D12) in combination with atezolizumab (αPD-L1 antibody). Tumor viability and growth were assessed by fluorescence measurements and ATP level. Phagocytosis of

fluorescently labeled tumor cells was imaged by confocal microscopy and quantified by inhouse developed analysis pipeline. Immune cell activation was evaluated by a cytokine bead array. The treatment of cell line-based 3D models with αCD47 antibody resulted in an increased number of phagocytic macrophages followed by a decrease of fluorescence and size of tumor spheroids in a dose-dependent manner. Moreover, we observed an induced secretion of TNFα, IL-6, IL-10 and IL-RA after 48h. Similarly, in PDX-based models, we observed decreased spheroid size and ATP level at day 7. Notably, αCD47 antibody-induced level of cytokines was further increased in combination with atezolizumab. To conclude, we have developed a human disease relevant, high-throughput assay for the evaluation of novel therapeutic modalities targeting phagocytosis. Due to compatibility with microscopy and most of the biochemical assays, it represents a powerful tool for clinical candidate development.

Evaluation of T cell cytotoxicity, PD-L1 expression and phenotypic features in novel automated 3D microfluidic breast cancer co-culture platform

Ekaterina Moroz Nikolov[1], Anthony Thai[1], Lila Cooper[1], Mahomi Suzuki[2], Arvonn Tully[3], Rashmi Rajendra[1], Evan F. Cromwell[1]. *[1]Protein Fluidics, Inc., Burlingame, CA,[2]Yokogawa Electric Corporation, Ishikawa, Japan,[3]Yokogawa Corporation of America, Sugar Land, CA*

Immunotherapy is now recognized as a powerful therapeutic approach to treat and cure cancer. However, the objective response rates for most solid tumors are low (below 30%). Accumulating evidence has shown that chemotherapy can increase the efficacy of immune checkpoint blockade and improve cancer outcomes. We have investigated if chemotherapy can modulate anti-PDL1 enhanced T cell cytotoxicity in breast cancer using novel *in vitro* 3D co-culture assay system. 3D co-culture of cancer and immune cells is a powerful platform for disease modeling and therapies testing because it can mimic the tumor micro-environment and complex cellular interactions. In this study we evaluated the immunomodulatory effect of chemotherapy on spheroid-T cells interactions in response to PD-L1 inhibition in triple-negative breast cancer. MCF7 and MDA231 cell lines with differential PD-L1 status were formed into spheroids and used as a

tumor model. T cells were activated from PBMCs using ImmunoCult CD3/CD28 T cell Activator. Co-culture assays were performed over 72 hr in a Pu·MA System. The Pu·MA System is an automated microfluidic platform that enables phenotypic and functional assays using physiologically relevant 3D cell models. Cancer spheroids and T cells were cultured, manipulated, and measured in a single well of a microfluidic flowchip. The platform integrates 1) 3D cell model with delivery of immune cells, 2) drug delivery, 3) imaging of phenotypic features and 4) functional profiling for cytokine secretion and viability. T cells-spheroid interaction, invasion and cell viability was assessed using high-content fluorescence imaging CellVoyager CQ1 system. IL2, IFN-γ and TNF-α secretion was measured in collected supernatants using Lumit immunoassays. After viability determination, co-cultures were fixed and stained for cancer and T cell markers (E-Cadherin, F-Actin, CD3, CD8) using automated IF staining protocol and then imaged. Image analysis revealed colocalization and infiltration of the T cells into the spheroids. Disintegration of spheroid, loss of circular shape, and increased number of dead cancer cells indicated T cell mediated cancer cell death. To evaluate the immunomodulatory effect of chemotherapy on spheroid-T cells interactions in response to PD-L1 inhibition, co-cultures were exposed to PD-L1 inhibitor Atezolizumab in the presence or absence of Cisplatin/Pemetrexed. We have analyzed a shift in T cell-mediated killing activity and function in the presence or absence of chemotherapeutics. The proposed co-culture platform can be further extended to a more complex patient-derived 3D models using different cell types. Our functional immune-oncology 3D platform allows to study the crosstalk between immune, cancer and other cell interactions, evaluate new drug candidates and assess individual therapeutic approaches to advance precision medicine.

Assay-ready tissue-engineered cancer microspheres for high-throughput screening

Yuan Tian[1], Yongwoon Kim[2], Wen J. Seeto[1], Shantanu Pradhan[3], Dmitriy Minond[4], Rock Pulak[2], Elizabeth A. Lipke[1]. *[1]Chemical Engineering, Auburn University, Auburn, AL,[2]Union Biometrica, Holliston, MA,[3]Department of Biotechnology, Indian Institute of Technology Madras,*

Chennai, India,[4]Department of Pharmaceutical Sciences, Nova Southeastern University, Ft. Lauderdale, FL

For drug discovery, new *in vitro* cancer models are needed to obtain more translatable study outcomes in a low-cost and high-throughput manner. For this purpose, 3D cancer spheroids have been established as more effective than 2D models. Current commercial techniques, however, rely heavily on self-aggregation of dissociated cells and cannot replicate key features of the native tumor microenvironment, particularly due to a lack of control over extracellular matrix components and heterogeneity in size and aggregate-forming tendencies. Also, current spheroidal techniques are typically limited to one spheroid per well, therefore providing a narrow range of cell numbers per well, disadvantageous for assay development in drug screening. Here, we overcome these challenges by coupling tissue engineering toolsets with microfluidic technologies to create engineered cancer microspheres and sorting desired numbers of microspheres into assay-ready well-plate format. To form the engineered cancer microspheres, MCF7 (non-metastatic) and MDA-MB-231 (metastatic) breast cancer cells were encapsulated within poly(ethylene glycol)-fibrinogen hydrogels using our previously developed microfluidic platform. Highly uniform cancer microspheres (intra and inter-batch coefficient of variation $\leq 5\%$) with high cell densities (over 20×10^6 cells/ml) were produced rapidly, which is critical for use in drug testing. The microspheres supported the 3D culture of both breast cancer cell lines over at least 14 days in culture. Encapsulated cells displayed cell type-specific differences in morphology, proliferation, metabolic activity, ultrastructure, and overall microsphere size distribution and bulk stiffness. To prepare assay-ready pre-plated microspheres, a COPAS FP flow cytometer was used for its ability to analyze and sort large sample particles such as tumor spheroids and hydrogel cancer microspheres generated in this study. When using a 96-well plate, the sorting rate varied from 2.5 - 6 microspheres per second, depending on the sample concentration. When sorting a desired number of microspheres per well, the accuracy was greater than 95% as verified visually by microscopy. Viability of sorted microspheres was verified 24 hours post-sort. Shipping conditions were established that maintained cell viability for remote use in drug testing. Methods for compound addition by pinning and imaging were tested and optimized. Using these approaches, the microsphere system was

shown to be compatible with an automated liquid handling system for administration of drug compounds; MDA-MB-231 microspheres were distributed in 384 well plates and treated with chemotherapeutic drugs. Expected responses were quantitated using CellTiter-Glo® 3D and detected using automated imaging. Overall, our results demonstrate initial applicability for the tissue-engineered cancer microspheres for drug screening.

#4561

3D Reconstructed Pancreas: A model capturing the unique tumor microenvironment and stromal architecture of pancreatic cancer

Arnat Balabyev[1], Justin D. Phillips[1], Michael Steffey[2], Eleanore J. Kirshner[1], Aayushi Ahlawat[1], Arlette H. Uihlein[1], Daniel Saims[2], Scott Wise[2], David Draper[2], Julia Kirshner[1]. *[1]Predictive Oncology Inc, Eagan, MN,[2]Labcorp, Drug Development, Ann Arbor, MI*

As it is rarely discovered early, the prognosis for people with pancreatic cancer is poor, with an average 5-year survival rate of 10% and only 3% for those with metastatic illness. Pancreatic cancer patients have few therapeutic options and innovative therapies are sorely needed to improve treatment of the disease. This is mainly due to the late diagnosis and partially due to the biology of the disease. Capturing the components of the tumor microenvironment, which serve as both a physical barrier and a source of stromal-driven resistance to therapeutics, is one of the issues faced by drug developers searching for agents to combat pancreatic cancer. We have created a 3D model of the pancreatic tumor microenvironment, the *Reconstructed Pancreas* (r-Pancreas), using Mia PaCa-2, PANC-1, and BxPC-3 pancreatic tumor cell lines embedded in an extracellular matrix (ECM) that was formulated to recapitulate the typical ECM of pancreatic tumors. We have shown that gemcitabine was effective against pancreatic tumor cells cultured in r-Pancreas (IC_{50}=0.4-0.8μM), while 5-fluorouracil was ineffective (IC_{50} not reached), mimicking clinical response. In nude mice, subcutaneous PANC-1 tumors exhibited similar responses to gemcitabine and 5-fluorocurcil. Treatment with gemcitabine resulted in a Day 63 median ΔT/ΔC of 37% while 5-fluorouracil resulted in a Day 63 median delta ΔT/ΔC of 102%. Incorporating a collagen-rich capsule

increases the physiological relevance of the r-Pancreas model because it has been shown that human pancreatic tumors have an outer layer of stiff ECM that functions as a physical barrier and prevents drugs from penetrating the tumor. Recently, we showed that, at least in the Mia PaCa-2 and BxPC-3 tumor cell lines, introducing such a collagen capsule dramatically reduced sensitivity to gemcitabine. Disrupting the collagen capsule with MMP-9 restored the sensitivity of the tumor cells to gemcitabine demonstrating that the capsule provides a physical barrier to drug entry. Additionally, creating a co-culture of primary activated pancreatic stromal cells and pancreatic tumor cell lines produces a more complete 3D model that permits the testing of potential therapeutic agents inside the pancreatic tumor microenvironment. Hence, we have created a 3D model where pancreatic tumor cells were co-cultured with human pancreatic fibroblasts. According to our results, the IC_{50} values for pancreatic tumor cell lines treated with gemcitabine increased by twofold when co-cultured with activated pancreatic fibroblasts compared to control sets of tumor cells alone (IC_{50}=1-3μM). Together, these data imply that, to be clinically relevant, *in vitro* models of pancreatic cancer must integrate tumor-specific components of the microenvironment, including the collagen capsule and activated fibroblasts.

Measuring immunotherapy responses *ex vivo* using novel 3D culture platform: E-slice

Thomas D. Gallup[1], Jose A. Maldonado[2], Corina Margain[1], Min P. Kim[2], David F. Gallup[1], Kyuson Yun[2]. *[1]EMPIRI, Inc, Houston, TX,[2]Houston Methodist Research Institute, Houston, TX*

Immunotherapies have provided dramatic and life-saving results in some patients; however, their effectiveness varies greatly in different tumors, even among patients with the same clinical diagnosis. Clearly, a better system to evaluate the personalized response to immunotherapies will greatly benefit the patients and reduce the cost of care. In addition, due to their theoretical and demonstrated benefits in providing durable responses, new immunotherapies are avidly sought after by most major pharmaceutical companies, numerous biotech companies, and academic laboratories. However, preclinical evaluation of new immunotherapy efficacy is

challenging and inaccurate using most experimental model systems.E-slice is a faithful model of an individual cancer patient's tumor. It is a proprietary 3D tissue slice culture platform, and E-slices are generated by making thin sections of intact, fresh tumor tissues from patients. As such, immune components and the TME in E-slices are native to each patient's tumor. E-slice overcomes many of the limitations of other experimental systems for multiple reasons. The E-slice platform: 1) uses chemically defined, serum-free medium; 2) measures viability changes upon treatment longitudinally, from the same tissue, which allows both absolute and relative responses for as short as 4 days or as long as over 4 weeks ex vivo; 3) can be generated from any solid tumor tested thus far (breast, lung, colorectal, pancreas, brain, head 7 neck, and others) from patient tumors directly or from PDX and genetically engineered mouse models; 4) retains the native TME and tissue architecture because E-slices are never dissociated or otherwise reconstituted; 5) is compatible with biopsies as well as surgical samples; 6) has been shown to accurately predict individual patient treatment responses to chemotherapies and targeted therapies in 4-12 days, paving the way for evidence-based personalized treatment selections in a clinically actionable time frame.Specifically for immunotherapy response measurements, key differentiators of the E-slice platform from other ex vivo systems for immunotherapy responses are: 1) E-slice is generated from fresh patient tumor tissues with tumor-trained and resident immune cells and not artificially introduced PBMCs used in most other systems; 2) serum-free, chemically defined medium and does not artificially activate or suppress the immune system; 3) E-slice has been validated by single-cell RNA-sequencing to maintain immune cells in their native state up to 8 days ex vivo; 4) E-slices can be used to detect secreted protein and metabolic biomarkers in the conditioned media pre- and post-treatment; 5) E-slice can measure immunotherapy responses ex vivo in 8 days. In summary, we present a novel ex vivo 3D human tumor tissue drug sensitivity platform that can enhance immunotherapy development pipelines and clinical deployment.

Liquid-phase-based cell culture platform that enables polymer surface stimuli-induced generation of patient-specific glioma stem cell-like tumor spheroids

Junhyuk Song[1], Yoonjung Choi[1], Yumi Lee[1], Hyo E. Moon[2], Changjin Seo[1], Hyung W. Park[2], Dohyeon Kim[1], Chang W. Song[3], Daeyoup Lee[1], Sun H. Paek[2], Sangyong Jon[4]. *[1]Department of Biological Sciences, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of,[2]Department of Neurosurgery, Cancer Research Institute and Ischemic/Hypoxic Disease Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Department of Radiation Oncology, University of Minnesota Medical School, Minneapolis, MN,[4]Department of Biological Sciences, Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of*

Despite the rapidly growing interest on cancer stem cells (CSCs) from cancer biologists, oncologists and the clinic because of their crucial role in recurrence and metastasis due to resistance in solid cancers, including GBM, there is still a lack of robust, effective *in vivo*-like 3D CSC models from cancer cells or patient-derived tumor tissues. In this sense, we developed a novel functional polymer thin film (Poly-X-PTF) via a streamlined liquid-phase synthesis, a more facile and advanced version than previous lab-made vapor-deposited poly(2,4,6,8-tetravinyl-2,4,6,8-tetramethyl cyclotetrasiloxane) called pV4D4-PTF. Emerging from a previous success with pV4D4, the new platform, Poly-X, could also simply stimulate surface stimuli-guided, rapid transformation of differentiated cancer cells to a number of ECM-enriched, similar-sized 3D CSC-like tumor spheroids from both commercialized cancer cell lines and patient-derived primary GBM cells. Varied GBM patient-derived cancer spheroids demonstrated a variety of phenotypes and transcriptomic profiles known about glioma stem cells (GSCs) in common. Notably, respective sensitivities of different patient-based 3D GSC spheroids to irradiation with or without temozolomide were retrospectively associated with the individual therapeutic outcome and overall survival, as a result of clinically relevant concurrent chemoradiation treatment (CCRT) regimens proposed in a fast Poly-X-spheroids-based 3D viability assay format. Ultimately, this versatile platform may serve to study fundamental CSC biology. Furthermore, it may translate into a powerful preclinical *ex vivo* tool in glioma medical settings both to aid in on-site prospective prediction of the patient-specific prognosis via CCRT viability responses within around 10

days and assess a patient-tailored, promising drug candidate or combination treatment.

#4565

Drug screening by layered 3D co-cultured tumor model including vascularized stromal tissue

Yuki Takahashi[1], Yumi Nomura[1], Yuma Yokokawa[1], Shiro Kitano[1], Satoshi Nagayama[2], Eiji Shinozaki[2], Ryohei Katayama[3], Naoya Fujita[3]. *[1]Toppan Inc., Saitama, Japan,[2]Cancer Institute Hospital of JFCR, Japanese Foundation for Cancer Research, Tokyo, Japan,[3]Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo, Japan*

Introduction: *In vivo*, tumor microenvironments consist of not only cancer cells but also extracellular matrix and stromal tissues, such as fibroblasts, blood vessels, and so on. The interactions between cancer cells and stromal tissue have been reported to affect the behavior of cancer cells. So that *ex vivo* model recapturing the tumor microenvironment is needed to evaluate the efficacy of drugs under the condition mimicking the patient tumor tissue. Here, we developed the unique tissue engineering technique, which easily enables the construction of cell - stacked three dimensional (3D) tissue, and co-culture of 3D stromal tissues and patient-derived cancer cells (PDCs). We investigated drug sensitivity in conventional 2D culture, our 3D co-cultured model and *in vivo* tumor.
Methods: Fibroblasts and vascular endothelial cells were suspended in a buffer solution containing heparin and collagen to support cell aggregation. The heparin/collagen-treated cells were seeded in culture-inserts in over-confluent manner, and 3D layered stromal tissue called were constructed. PDCs established from colorectal cancer (CRC) and non-small cell lung cancer (NSCLC) patients in the Cancer Institute Hospital of JFCR were co-cultured with the 3D stromal tissue. The 3D co-cultured model applied to drug screening, and the results were compared with those of 2D culture model. *In vivo* drug evaluations were performed with the compounds in which marked differences were observed between 2D and 3D models.
Results: In our 3D model, drug sensitivities to most of the tested compounds tended to be decreased in comparison with those in 2D culture condition. Interestingly, a part of drugs did not effective in 2D showed marked tumor growth inhibition in our 3D model. The compounds that

showed favorable efficacy in 3D rather than 2D in multiple PDCs were accounted for about 5% of tested compounds. At least half of these drugs showed significant tumor growth suppression or tumor regression *in vivo*. On the contrary, in the case of drug sensitivities were considerably fallen in our 3D model, most of the evaluated compounds represented almost no anti-tumor effect *in vivo*. Results from gene and protein expression analyses supported that cancer cells co-cultured in our 3D stromal tissue have some similar profiles to in vivo tumor rather than 2D culture condition. Conclusion: Our study proposed the unique 3D co-cultured tumor model. The model may enable more accurate drug screening reflecting the *in vivo* circumstances. Further studies are needed to confirm the model's predictability of clinical outcomes.

#4566

3D cancer cell-fibroblast heterospheroids forming tumor-like microenvironments are valuable tools to study immune cell infiltration and as pre-clinical drug testing models

Boye Schnack Nielsen, Natasha H. Madsen, Jesper Larsen, Hjalte M. Larsen, Monika Gad, Kim Holmstrom. *Cellular Engineering & Disease Modelling, Bioneer A/S, Hørsholm, Denmark*

3D cancer cell cultures have enabled new opportunities for replacing compound testing in experimental animals and provide a basis for high content work-flows for drug testing. Here we present data obtained from 3D multicellular tumor spheroids (MCTS) composed of cancer cell lines, fibroblasts and macrophages. We cultured HT29 and SW480 CRC cell lines (as well as others) with fibroblasts and obtained heterospheroids that could be evaluated in cell viability and apoptosis assays, by flow cytometry and high content imaging (HCI). In addition, mature MCTS were embedded in paraffin and used for traditional biomarker characterization using immunohistochemistry and in situ hybridization. The cancer cell x fibroblast interactions promoted a tumor-like microenvironment that recruited monocytes isolated from primary donors. FACS analysis indicated that the infiltrating monocytes polarized into CD163-positive M2 macrophages in HT29 MCTS, and in pancreatic MIA PaCa-2 MCTS, using Pexidartinib and anti-CSF1R mAb, we found that monocyte infiltration was strongly CSF1R dependent. Preliminary data suggest that also infiltration of

T cells into the heterospheroids is possible, thus making the models useful for the study of immune cell infiltration. Whole transcriptomic analysis of mono-cultures of SW480 cancer cells and fibroblast spheroids and co-cultures (MCTS) identified traditional cell-type-related transcripts as well as a group of *de novo* expressed genes induced by co-culturing, such as serpin peptidase inhibitor clade A1 (serpinA1) and inhibin-β A (INHBA). The NGS analysis as well as immunohistochemical staining also showed that SW480 expressed high levels of P-glycoprotein (P-Gp, MDR1) in contrast to the fibroblasts. On the other hand, the HT29 MCTS were negative for P-Gp. Histological analysis and the apoptosis assay showed that the fibroblasts were more sensitive to 5FU and cisplatin treatment than the cancer cells. We are currently testing if the P-Gp inhibitor, PSC-833, can re-sensitize the cancer cells to 5FU and cisplatin. In conclusion, we have developed 3D multicellular heterospheroids mimicking tumor-like microspheres that can be used for drug testing of traditional drug compounds, biologics and even immunotherapeutic agents.

#4567

Transcriptomic analysis of a 3D engineered cancer model recapitulating stage-dependent heterogeneity in colorectal PDX tumors

Yuan Tian[1], Iman Hassani[1], Benjamin Anbiah[1], Bulbul Ahmed[2], William Van Der Pol[3], Elliot J. Lefkowitz[4], Peyton C. Kuhlers[2], Nicole L. Habbit[1], Martin J. Heslin[5], Elizabeth A. Lipke[1], Michael W. Greene[2]. *[1]Chemical Engineering, Auburn University, Auburn, AL,[2]Nutritional Sciences, Auburn University, Auburn, AL,[3]Center for Clinical and Translational Science, University of Alabama at Birmingham, Birmingham, AL,[4]Department of Microbiology, University of Alabama at Birmingham, Birmingham, AL,[5]Mitchell Cancer Institute, University of South Alabama, Mobile, AL*

Colorectal cancer (CRC) is the third-most leading cause of cancer-related deaths in the United States. To advance the understanding of CRC tumor progression, models which mimic the tumor microenvironment (TME) and have translatable study outcomes are urgently needed. CRC patient-derived xenografts (PDXs) are promising tools for their ability to recapitulate tumor heterogeneity and key patient tumor characteristics, such as molecular characteristics. However, as in vivo models, CRC PDXs are costly and low-

throughput, which leads to a need for equivalent in vitro models. To address this need, we previously established an in vitro model using a tissue engineering toolset with CRC PDX cells. However, it is unclear whether tissue engineering has the capacity to maintain patient- and/or cancer stage-specific tumor heterogeneity. To address this gap, we employed three PDX tumor lines, originated from stage II, III-B, and IV CRC tumors, in the formation of 3D engineered CRC PDX (3D-eCRC-PDX) tissues and performed an in-depth comparison between the 3D-eCRC-PDX tissues and the original CRC-PDX tumors. To form the tissues, CRC-PDX tumors were expanded in vivo and dissociated. The isolated cells were encapsulated within poly(ethylene glycol)-fibrinogen hydrogels and remained viable and proliferative post encapsulation over the course of 29 days in culture. To gain molecular insight into the maintenance of PDX line stage heterogeneity, we performed a transcriptomic analysis using RNA seq to determine the extent to which there were similarities and differences between the CRC-PDX tumors and the 3D-eCRC-PDX tissues. We observed the greatest correspondence in overlapping differentially expressed human genes, gene ontology, and Hallmark gene set enrichment between the 3D-eCRC-PDX tissues and CRC-PDX tumors in the stage II PDX line, while the least correspondence was observed in the stage IV PDX line. The Hallmark gene set enrichment from murine mapped RNA seq transcripts was PDX line-specific which suggested that the stromal component of the 3D-eCRC-PDX tissues was maintained in a PDX line-dependent manner. Consistent with our transcriptomic analysis, we observed that tumor cell subpopulations, including human proliferative (B2M+Ki67+) and CK20+ cells, remained constant for up to 15 days in culture even though the number of cells in the 3D-eCRC-PDX tissues from all three CRC stages increased over time. Yet, tumor cell subpopulation differences in the stage IV 3D-eCRC-PDX tissues were observed starting at 22 days in culture. Overall, our results demonstrate a strong correlation between our in vitro 3D-eCRC-PDX models and the originating in vivo CRC-PDX tumors, providing evidence that these engineered tissues may be capable of mimicking patient- and/or cancer stage-specific heterogeneity.

Evaluating response of renal cell carcinoma to tyrosine kinase inhibitor and immune checkpoint inhibitor using a human histo-culture

platform

Satish Sankaran[1], Kowshik Jaganathan[1], Gowri Shankar K[1], Saurabh Bhargav[2], Ganesh MS[3], Amritha Prabha[3], Prakash BV[4], Syamkumar V[1], Biswajit Das[1], Vasanth K[1], Manimaran A[1], Chandan Bhowal[1], Rajashekar M[1], Oliyarasi M[1], Ritu Malhotra[1], Govindraj K[1], Nandini Pal Basak[1].
[1]Farcast Biosciences, Bangalore, India,[2]Mazumdar Shaw Medical Centre, Bangalore, India,[3]Vydehi Multi Specialty Hospital, Bangalore, India,[4]Sri Lakshmi Multi Specialty Hospital, Bangalore, India

Tyrosine Kinase Inhibitors (TKIs) and Immune checkpoint inhibitors (ICIs) are used in first line treatment of clear cell renal cell carcinoma (ccRCC). Identifying patients who truly benefit from these treatments remains a challenge. Developing newer and better therapy options that fail in the clinical phase is yet another unmet need. Both these limitations could be addressed by employing testing platforms that best capture the heterogeneity and complexity of the tumor within the patient. Farcast™ TruTumor is a near native human histo-culture platform which retains the tumor and stroma along with the intra-tumoral immune compartment post culture that holds promise to improve treatment outcomes in patients. In this study, we developed a ccRCC platform using surgical excess specimens from consented patients and compared its immune profile with the head and neck squamous cell carcinoma (HNSCC) platform. ccRCC samples (n=10) were processed to generate explants and cultured for 72h and interrogated for response to treatment with Sunitinib (TKI :27.7ng/ml) or Nivolumab (anti-PD1:132µg/ml). On comparison of immune profiles between HNSCC and ccRCC at baseline, we observed a significantly lower total immune content in ccRCC. ccRCC showed comparatively higher variation in myeloid (70%CV) and lymphoid compartments (30%CV) as compared to HNSCC. Live tumor and immune cell population was found to be well preserved post-culture in ccRCC. Presence of various T cell sub-populations, monocyte and macrophage population post culture were confirmed using flowcytometry. Sunitinib treatment significantly increased caspase-3 expression (8/10 samples, p value<0.01), along with decrease in tumor content in 4/10 samples (average drop 23%). Two samples which did not respond to Sunitinib treatment showed an increase in Interferon gamma (IFNg) ($Log_2FC \pm SD$, 2.7± 0.7) and Granzyme B ($Log_2FC \pm SD$, 1.05±

0.85) secretion, in response to Nivolumab treatment. Of these, in one sample we observed an increase in CD8+ Granzyme B, CD8+ Ki67 and decrease in CD4+ FoxP3 population, with concomitant decrease in Pan CK+ population by flowcytometry. In this sample, we observed a decrease in tumor content indicating anti-tumor response to Nivolumab treatment. In summary, the TruTumor platform potentially offers personalized treatment choices to patients improving their chances of recovery. In addition, this platform could provide powerful insights into the mechanisms of a wide range of therapy molecules in development to predict their efficacy better than other simplistic and non-human testing models.

Expanding the 3D ex vivo patient tissue platform toolbox for (immuno)-oncology drug testing

Nataliia Beztsinna[1], Sander Basten[1], Ezgi Kaya Aksoy[1], Niels Meesters[1], Stefanos Timiliotis[1], Donny van der Meer[2], Kuan Yan[1], Emma Spanjaard[1], Willemijn Vader[2], Leo S. Price[1]. *[1]Crown Bioscience Netherlands B.V., Leiden, Netherlands,[2]Vitro Scan B.V., Leiden, Netherlands*

Introduction: The fast-paced (immuno)-oncology drug development pipeline requires sophisticated and reliable in vitro models to accurately represent all players of complex human tumor microenvironment (TME). Our 3D *Ex Vivo* Patient Tissue (EVPT) platform is a short-term 3D ex vivo culture system utilizing ultra-fresh human tumor material processed to preserve the rich TME with high content image (HCI) analysis for higher throughput screening. The EVPT platform has previously been validated for standard of care (SoC) and immunological drug testing, including immune checkpoint inhibitors (ICI), in ovarian and non-small cell lung cancer (NSCLC) samples. Here, we present the expansion of the EVPT platform to other cancer indications, including resections from bladder, prostate, breast cancer, melanoma, glioblastoma (GBM) and hepatocellular carcinoma (HCC).

Methods: Tumor tissues from NSCLC, ovarian, bladder, prostate, breast cancer, melanoma, GBM and HCC patients were processed within 24 hours. Freshly isolated tumor clusters were embedded in a protein-rich hydrogel and exposed to panels of (immuno)-oncology treatments at various doses in a 384-well format for 5-7 days. Phenotypic effects of treatment on

morphological features, such as tumor cell killing, growth arrest, and immune cell proliferation, were measured using our proprietary automated HCI platform. Whole blood samples were also collected and PBMCs were isolated for autologous co-culture assays with selected cancer samples. Additionally, biomarkers analysis, including IHC, FACS and cytokine measurements, was performed.
Results: At least two patient samples per new indication were processed. The success rate of the assay (30-40%) was primarily dependent on the sample quality, and the absence of necrotic, healthy, or fibrotic tissue within the sample. Panels of SoC drugs, targeted therapies, immunotherapies, and control compounds established for each indication were profiled per patient sample. For example, prostate cancer samples responded to Paclitaxel and Crizotinib, and one of GBM samples showed sensitivity to Regorafenib and Bevacizumab. Overall, similarly to clinical findings, about 20% of NSCLC and bladder cancer samples responded to ICI treatment, while 60-70% of the samples have responded to immunostimulatory controls (SEA and CD3/CD28).Although TME composition varied between NSCLC samples, IHC and FACs analysis showed a rich representation of immune compartment - T Cells (CD3+CD4+, CD3+CD8+), NK cells (CD16+), myeloid cells (CD14+, CD68+) alongside with EpCAM+ tumor cells.
Conclusion: Despite tissue quality remaining a challenge for many primary ex vivo assays, the gentle processing and short-term 3D culturing in our EVPT platform preserves the rich TME in a wide range of tumors. This makes our EVPT platform an innovative and translational tool for complex (immuno)-oncology drug testing in multiple cancer indications.

A novel *ex vivo* platform, 3D-EXpress, to rapidly assess the efficacy of KRAS targeting drugs alone and in combination with nivolumab using a biorepository of fresh patient tumoroids with intact tumor microenvironment

Jared Ehrhart, Brittney Ruedlinger, Angie Rivera, Romanus Ezeoke, Sharon Camacho, Seth Currlin, Soner Altiok. *Nilogen Oncosystems, Tampa, FL*

Introduct**on:** 3D-EXpress is a novel *ex vivo* drug testing platform using a Biorepository of neverdissociated, propagated, or reassembled fresh patient tumoroids with intact tumor microenvironment.Tumoroids measuring 150

μm in size retain tumor cell heterogeneity, tumor-resident innate andadaptive immune cells, stromal components, and cell-extracellular matrix interaction allowing to rapidlytest the efficacy of drugs and drug combinations targeting various components of the TME includingtumor cells, stroma, and immune cell populations. Here we employed the 3D-EXpress platform tocompare the efficacy of different drugs and drug combinations targeting KRAS and PD-1/PD-L1 immunecheckpoint *ex vivo.*
Materials and Methods: All tumor samples were obtained with patient consent and relevant IRBapproval. Cryopreserved tumoroids with known KRAS mutation status, PD-L1 expression, detailedimmune profiles and clinicopathologic data were selected from Nilogen's tumoroid Biorepository for the*ex vivo* assays. 3D tumoroids were treated with vehicle only, a SOS1::KRAS inhibitor, BI 1701963, apotent, selective, and covalent KRASG12C inhibitor, MRTX849, and a KRAS G12C inhibitor, sotorasib,alone and in combination with nivolumab for 72h. Treatment-mediated changes in tumor cell killing andtumor immune microenvironment were analyzed.
Results: To quantify treatment-mediated tumor cell killing activity we employed 3D high-contentconfocal imaging using a proprietary algorithm for data analysis. To monitor how *ex vivo* drugtreatments affect the tumor immune microenvironment culture supernatants isolated from treatedtumoroid samples were used for multiplex cytokine detection including GM-CSF, sCD137, IFNγ, sFas,sFasL, Granzyme A, Granzyme B, IL-2, IL-4, IL-5, IL-6, IL-10, IL-13, MIP-1α, MIP-1β, TNF-α, and Perforin.We observed a significant difference in tumor responses among patient samples to *ex vivo* tested drugsand drug combinations, which were further correlated with tumor resident innate and adaptive immunecell populations detected by a 21-color flow cytometry panel in addition to tumor KRAS mutation status,patient smoking history, tumor characteristics as well as PD-L1 expression levels analyzed on theassociated TMA slides.
Conclusion: Our data demonstrate that the 3D-Express platform, using cryopreserved 3D tumoroidswith intact TME, is an effective tool to assess the efficacy of KRAS and immune checkpoint inhibitorstargeting drugs to identify rational combination therapies and to develop clinically relevant biomarkersfor individualized patients in the future.

#4572

3D-EXpress ex vivo platform using a biorepository of characterized fresh patient tumoroids allows development of rational combinations with drugs targeting DNA damage response and immune checkpoint blockade

Jared Ehrhart, Seth Currlin, Sharon Camacho, Samantha Hoffman, Angie Rivera, Soner Altiok. *Nilogen Oncosystems, Tampa, FL*

Introducti**on:** Nilogen Oncosystems' 3D-EXpress platform allows for the detailed characterization offreshly resected patient tumor tissue for inclusion in studies investigating rational combinations of IOtherapeutics. Incorporating data on immune cell composition, tumor cell target expression, mutationalstatus, and HPV infection within tumoroids generated from HNSCC tissues provides tremendous input toidentify candidate tissues for therapeutic testing. The 3D-EXpress platform employed here providesdetailed observations investigating tumor cell viability using confocal microscopy and immune cellactivation indicated by increases in cytokine release.

Materials and Methods: 3D tumoroids measuring 150 microns in size were generated from fresh patientHNSCC resection samples collected with proper patient consent and relevant IRB approval. Tumoroidswere never enzymatically dissociated, propagated, or reassembled to maintain the intact tumormicroenvironment (TME). The resulting tumoroids were cryopreserved in the Biorepository, where eachsample had associated patient demographic data, tumor grade, stage, mutational and HPV status inaddition to a detailed tumor immune profile and a FFPE representative sample in TMA format for targetselection. Pooled tumoroids for each patient tumor were treated ex vivo both singly with a selectiveWEE1 inhibitor, AZD1775 and an ATR blocker AZD6738 alone and in combination with a PD-1 immunecheckpoint inhibitor antibody nivolumab for 72h.

Results and Summary: To quantify treatment-mediated tumor cell killing we used 3D high-contentconfocal imaging and a proprietary algorithm for data analysis. Additionally, culture supernatantsisolated from treated tumoroids were used for multiplex cytokine detection to monitor changes in theTME upon *ex vivo* treatment. Responses to treatments were further correlated with the composition ofinnate and adaptive TIL populations within each tumor as assessed by 21-color flow cytometry inaddition to

tumor mutational status, HPV infection, smoking status, as well as EGFR and PD-L1expression levels analyzed by multiplex IF on associated TMA slides.
Conclusion: These results demonstrate that targeting DNA damage response and immune checkpointblockade may provide a potential combination strategy for the treatment of HNSCC. Furthermore, weshowed that our 3D-EXpress *ex vivo* tumoroid model provides a unique platform to rapidly assess theefficacy of drugs and drug combinations in fresh patient tumor samples with intact TME. Correlation of*ex vivo* drug responses with characteristics of each tumor's immune microenvironment and detailedclinicopathological data may allow to identify clinically relevant biomarkers to enable the most effectivetreatment strategies for individual patients in the clinic.

#4573
Evaluation of tumor treating fields (TTFields) effects at 200 kHz on a glioblastoma, an anaplastic ependymoma and an oligodendroglioma sample in a patient-derived *ex vivo* organoid model
Vera Nickl[1], Ellina Schulz[1], Ellaine Salvador[1], Laureen Trautmann[1], Leopold Diener[1], Almuth F. Kessler[1], Camelia M. Monoranu[2], Ralf-Ingo Ernestus[1], Mario Löhr[1], Carsten Hagemann[1]. *[1]Department of Neurosurgery, Section Experimental Neurosurgery, University Hospital Wuerzburg, Wuerzburg, Germany,[2]Institute of Pathology, Department of Neuropathology, University of Wuerzburg, Wuerzburg, Germany*

TTFields are alternating electric fields of low intensity (1-3 V/cm) and intermediate frequency (100-500 kHz), which are effective and approved for the treatment of glioblastoma (GBM) using 200 kHz frequency. However, there is a lack of *ex vivo* models to evaluate effects on patients' tumor biology or to screen patients for treatment efficacy. Therefore, we adapted patient-derived three-dimensional GBM tissue culture models to be compatible with TTFields application and recently published the feasibility of such an approach (Nickl, et al., 2022, doi: 10.3390/cancers14215177). Here, we applied one of those models, i.e. tumor-organoids cultured as microtumors on murine organotypic hippocampal slice cultures (OHSCs), to additional brain tumor entities, namely a sample of an anaplastic ependymoma (AE) patient and an oligodendroglioma patient. Organoids

were generated from fresh intra-operatively obtained tumor tissue and cultured for 2 weeks. OHSCs were prepared by slicing the brains of mice 5-8 days postpartum to sections with a thickness of 350 µm using a vibratome, and culturing them for 2 weeks as well. Subsequently, organoids were placed onto the OHSCs. The inovitro™ laboratory research system was used for TTFields administration at 200 kHz and 1.5 V/cm for 72 h. Microtumor growth was evaluated on fluorescence images. Viable organoids formed from the GBM, AE and oligodendroglioma sample and grew to microtumors when placed onto OHSCs. Application of TTFields at 200 kHz led to a significant decrease of microtumor size of the GBM and AE (both $p<0.0001$), but not the oligodendroglioma sample. This proof-of-principle investigation proved that the application of patient-derived organoids cultured on OHSCs is feasible to investigate the effects of TTFields on different kinds of brain tumors. To our knowledge, this is the first evaluation of TTFields efficacy on patient derived AE and oligodendroglioma tissue cultures. While TTFields at 200 kHz led to a decrease in the microtumor size of the AE sample, the non-responsiveness of the oligodendroglioma sample may be due to different inter-patient sensitivity to TTFields or a suboptimal TTFields frequency.

#4574

Long-term drug efficacy evaluation using stiffness-tunable scaffolds colonized by a three-dimensional tumor microenvironment

Elly De Vlieghere, Olivier De Wever. *Ghent University Hospital, Gent, Belgium*

Long-term drug evaluation heavily relies upon rodent models. Methods to reduce animal models in oncology may include three-dimensional cellular systems that take into account tumor microenvironment (TME) cell types and biomechanical properties. Innovative translational research is needed in low-grade serous ovarian cancer (LGSOC) in which the presence of oncogenic mutations in the RAS pathway likely suggest the opportunity to test targeted treatments. To address all these needs this study reports on an elastic polymer, to print a scaffold that mimics tissue relevant stiffness. Introduction of single cell suspensions from LGSOC patient-derived early passage cultures of cancer cells and cancer-associated fibroblast form heterocellular spheroids mimicking the growth ratio and spatial

organization of the LGSOC TME. The resulting scaffold allows long-term (>40 days) follow-up and targeted compound evaluation confirmed the durable response to a drug combination. The drug-response results from this long-term *in vitro* model are compared with drug responses in an orthotopic LGSOC xenograft mouse model. In conclusion, the stiffness-tunable scaffolds colonized by a three-dimensional LGSOC TME allow long-term drug evaluation and can be considered as a valid alternative to reduce, replace and refine animal models in drug discovery.

High-throughput method to analyze the cytotoxicity of CAR T cells in a 3D tumor spheroid model using image cytometry

Samir Patel[1], David Zurowski[2], Daniel Hui[2], Mignane Ka[2], Charles Hernandez[1], Andrea Love[1], Bo Lin[1], Andrea Moore[2], Leo Li-Ying Chan[1].
[1]Nexcelom Bioscience, Lawrence, MA,[2]Resilience, East Norriton, PA

Chimeric antigen receptor (CAR)-T cell therapy is an antigen-dependent cellular therapy that has gained considerable traction in the field of cancer immunotherapy. CAR-T cell therapy involves specifically engineering T cells to attack tumor cells by binding a tumor antigen and inducing T cell activation resulting in intracellular signaling and cytokine release. Currently, there are six FDA-approved CAR-T cell therapies, which all target the CD19 or BCMA antigens for hematologic B cell malignancies. In the recent years, a strong focus has been placed on CAR T cell therapy discovery for solid tumors, which may better recapitulate physiological conditions, thereby potentially improving the selection of CAR construct candidates. Immune cell trafficking and immunosuppressive factors within the tumor microenvironment increase the relative difficulty in developing a robust CAR-T cell therapy against solid tumors. Therefore, it is critical to develop novel methodologies for high-throughput phenotypic and functional assays using 3D tumor spheroid models to better assess CAR-T cell therapies against solid tumors. Recently, plate-based image cytometry has emerged as a method to investigate and characterize CAR T cell functions in a high-throughput manner. Image cytometry has demonstrated capabilities in
analyzing transduction efficiency, cell proliferation, and cytotoxicity for CAR T cell therapy. With the development of 3D spheroid models, image

cytometry may provide the necessary tools and applications for CAR T cell therapy discovery geared towards solid tumors. In this work, we discuss the use of CAR-T cells targeted towards PSMA, an antigen that is found on prostate cancer tumor cells, the second most common cause of cancer deaths among men worldwide. Herein, we demonstrate the use of high-throughput plate-based image cytometry to characterize PSMA CAR-T cell-mediated cytotoxic potency against 3D prostate tumor spheroids and simultaneously monitor location of the T cells *in vitro*. We were able to kinetically evaluate the efficacy and therapeutic value of PSMA CAR-T cells by analyzing the cytotoxicity against prostate tumor spheroids. Furthermore, the T cells are fluorescently labeled with a tracer dye to visually locate the cells on the tumor spheroids. The proposed image cytometry method can overcome limitations placed on traditional methodologies to effectively assess cell-mediated 3D tumor spheroid cytotoxicity and efficiently generate time- and dose-dependent results.

3D *in vitro* models uncover malignant cell intrinsic and extrinsic mechanisms of CAR-T cell resistance in high grade serous ovarian cancer

Joash Dominic Joy[1], Beatrice Malacrida[1], Florian Laforêts[1], Panoraia Kotantaki[1], Eleni Maniati[1], Sarah Hopkins[2], Ianire Garrobo-Calleja[2], Julien Gautrot[3], Frances Balkwill[1]. *[1]Barts Cancer Institute, London, United Kingdom,[2]GSK Medicines Research Centre, Stevenage, United Kingdom,[3]Institute of Bioengineering Queen Mary University, London, United Kingdom*

Chimeric antigen receptor (CAR)-T cell therapies have promising outcomes in hematologic malignancies but limited activity in solid tumors. We used 3-dimentional (3D) *in vitro* human cell models of increasing complexity to investigate resistance to CAR-T cell therapy in high grade serous ovarian cancer (HGSOC), a disease with poor response to immunotherapy. We identified mucin-1 (MUC1) and TnMUC1 as target antigens in HGSOC omental metastasis and the HGSOC cell lines, OvCAR3 and G164. We then generated CAR-T cells against these targets and tested them in spheroids, collagen gels and microfluidic models. In spheroids, OvCAR3 cells were killed by CAR-T cells whereas, G164 cells were resistant to CAR-T cell

cytotoxicity. RNA sequencing suggested that the impaired apoptotic signaling in G164 cells caused malignant cell-intrinsic resistance to CAR-T cell cytotoxicity. Treating G164 spheroids with birinapant, an antagonist of cellular inhibitor of apoptosis protein, induced CAR-T cell cytotoxicity. Moreover, when resistant cells were co-cultured as spheroids with primary omental fibroblasts from ovarian cancer patients, CAR-T cells were activated and cytotoxic. G164 spheroids cultured in fibroblast-conditioned medium also induced CAR-T cell cytotoxicity due to C-C motif chemokine ligand 2 (CCL2) produced by fibroblasts. CCL2 activated CCR2/4+ CAR-T cells to induce cytotoxicity in an antigen-dependent manner. We then investigated CAR-T cell migration and cytotoxicity in malignant cell/fibroblast co-culture collagen gels. CAR-T cell migrated into OvCAR3 gels and were cytotoxic against the malignant cells. However, a dense extracellular matrix (ECM) produced primarily by fibroblasts prevented CAR-T cell migration and cytotoxicity in G164 gels. Treating G164 gels with transforming growth factor beta (TGFβ) receptor inhibitor SB431542 reduced ECM content and altered ECM structure, thus stimulating CAR-T cell penetration and restoring cytotoxicity against G164 cells. We also developed an ovarian cancer-on-a-chip model which involved culturing cell-seeded collagen gels in vascularized tri-channel microfluidic devices. CAR-T cells successfully penetrated and killed malignant cells in co-culture collagen gels when delivered through vascularized microfluidic devices. To our knowledge, this is the first report to use microfluidic tumor models to successfully deliver CAR-T cells. Using these different human 3D *in vitro* models, we uncovered malignant cell-intrinsic factors and novel mechanisms involving fibroblasts which may influence CAR-T cell activity. Complex human cell models may accelerate preclinical research into CAR-T cell therapies in solid tumors.

#4577

An innovative platform to mimic the tumoral vascular microenvironment (TME) of patients with metastatic colorectal cancer (mCRC) using bioprinted hydrogel microfluidics

Nadia Saoudi González[1], Francesc Salvà Ballabrera[1], Ariadna García[1], Javier Gonzalo-Ruiz[1], Iosune Baraibar[1], Javier Ros[1], Marta Rodriguez[1], María García Díaz[2], Marta Falcó Fusté[2], Melika Parchehbaf Kashani[2], Carlos Honrado[3], Alar Ainla[3], Josep Tabernero[1], Lorena Diéguez[3], Elena

Martínez Fraiz[2], Elena Élez[1]. *[1]VHIO Vall D'Hebron Institute of Oncology, Barcelona, Spain,[2]Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain,[3]International Iberian Nanotechnology Laboratory (INL), Braga, Portugal*

Introduction: Metastasis involves a set of complex events that finally result in malignant cells from primary tumors invading distant tissues by the pass of circulant tumor cells (CTC) through the blood circulation. To authentically comprehend the complex chain of events and even enable new therapeutic approaches in mCRC patients, ex-vivo functional models are an unmet research need.
Experimental Plan: PROMISE project is combining bioengineering solutions such as bioprinting biomaterials and microfluidics to mimic the tumor microenvironment (TME) of metastatic sites in mCRC. In this project, we are developing a bioprinted hydrogel-based microfluidic device that recapitulates this TME. Then, CTCs are isolated from mCRC patients, cultured, and characterized by microdroplet technology. Those CTCs are then infused on the biodegradable polymer that mimics vascular channels and surrounding stromal cells, through microfluidic connection, in order to mimic CTC-endothelial interactions, study the procedures of extravasation (the invasiveness potential of extravasated patient-derived CTCs into TME) and intravasation (the process of CTCs-derived and biopsy-derived tumor spheroids from the TME to the vascular channel).
The photopolymerizable hydrogel mimics vascular structures, supporting the growth of HUVEC cells, and is printed in a cost-effective manner (30 minutes) using a semi-direct printing method with visible light. The CROSS chip is used for fast and efficient isolation of CTCs from unprocessed blood of mCRC patients. In parallel, multi-omics of mCRC are done in circulant tumor DNA (ctDNA) and tumor biopsy of mCRC, therefore correlating the phenotypic and genetic profile of the patient cohorts studied.
A first pilot test has been carried out successfully obtaining blood from mCRc refractory patients, and excellent coordination between the multidisciplinary consortium has been achieved to draw blood from the patient, isolate CTCs and infuse them into the hydrogel. Extravasation and intravasation studies are ongoing.
Conclusion: This multidisciplinary project, which brings together bioengineering, microfluidic, and oncology experts' teams, is developing a

successful ex-vivo, in vitro, and dynamic model that will permit a better study and understanding of the metastatic process in mCRC, from the process of intravasation to extravasation of CTCs, passing thought the better multi-omic characterization of CTCs and ctDNA.

#4578

Miniaturized and multiplexed evaluation of NK cell cytotoxicity and infiltration in patient-derived sarcoma spheroids using a novel multichambered microwell chip

Valentina Carannante[1], Niklas Sandström[1], Karl Olofsson[1], Shi Yong Neo[2], Patrick Albert Sandoz[1], Hanna Van Ooijen[1], Quentin Verron[1], Jacopo Fontana[1], Damien Toullec[1], Elisabeth Moussaud-Lamodière[2], Brinton Seashore-Ludlow[2], Thomas Frisk[1], Madoka Takai[1], Päivi Östling[2], Felix Haglund[2], Andreas Lundqvist[2], Martin Wiklund[1], Björn Önfelt[1]. *[1]KTH Royal Institute of Technology, Stockholm, Sweden,[2]Karolinska Institutet, Stockholm, Sweden*

Tumor diversity and rarity of patient tumor material negatively contribute to the development of new effective treatments for sarcomas. As a high proportion of sarcoma patients presents inherent or acquired chemo-resistance, immune checkpoint inhibitors could represent an alternative for these cases. However, only a small fraction of sarcoma patients seem to respond to immune checkpoint therapy, suggesting the existance of heterogenous immune-suppressive mechanisms across individuals and sarcoma subtypes. Therefore, new strategies to boost the immune system, together with tools predicting which patients could benefit from therapy, are needed for sarcoma patients. There is still a lack of methods that take advantage of benefits, such as low consumption of patient material or reagents, offered by miniaturized *in vitro* analysis systems. In this work, we used a novel multichambered microwell chip for testing personalized immunotherapy on patient-derived sarcoma spheroids. We derived multiple primary sarcoma spheroids from various sarcoma subtypes and grades, which were used to test NK cell cytotoxicity in combination with anti-TIGIT, anti-PD-L1, anti-EGFR treatment. Using this combinatorial strategy, we could boost NK-mediated killing significantly. We analyzed immune cell infiltration in the original tumor and found PD-1^{+} and TIGIT^{+} cytotoxic

lymphocytes in both peripheral and central tumor tissues, suggesting that anti-TIGIT and anti-PD-L1 therapy could be appropriate in some sarcoma patients. In addition, high levels of pro-inflammatory cytokines were found in plasma from sarcoma patients, together with high levels of soluble PVR. This work provides a better understanding of immune surveillance of sarcoma and shows an important implementation of patient-derived spheroids. The miniaturized format allowing long-term cell culture, efficient screening and high-quality imaging of small sample volumes makes this methodology promising for personalized immunotherapy.

#4579

A three-dimensional model of glioblastoma for discovery of novel therapeutics

Viktoriia Kriuchkovskaia[1], Brendan A. C. Harley[2], Rebecca B. Riggins[3].
[1]Chemical and Biomolecular Engineering and Institute for Genomic Biology, University of Illinois Urbana-Champaign, Champaign, IL,[2]Chemical and Biomolecular Engineering, University of Illinois Urbana-Champaign, Champaign, IL,[3]Georgetown University, Washington, DC

Statement of Purpose: Glioblastoma (GBM) is the most common and lethal form of brain cancer. Despite an aggressive treatment strategy, including surgical resection followed by radio- and chemotherapy, GBM has one of the highest mortality rates among all human tumors. The leading causes of this devastating prognosis are rapid recurrence and therapeutic resistance; current chemo- and immunotherapies fail to control tumor growth and progression. Temozolomide (TMZ) remains the gold standard for GBM treatment since its FDA approval for GBM in 2005. Subsequently, GBM treatment strategy has seen no significant advancement, despite TMZ providing only minimal benefit to most patients. Recent efforts to develop novel therapies for GBM have primarily involved *in vivo* animal models and conventional 2D cell cultures. However, animal models do not allow for elucidating specific interactions between cancer cells and tumor microenvironment (TME), while 2D models fail to depict the complex tumor architecture. *In vitro* biomaterial models offer an opportunity to evaluate aspects of cell-cell and cell-matrix driven responses within the complex TME. Here, we construct and validate a 3D hydrogel platform to

evaluate drug response in GBM and to examine the role of TME in drug response, resistance, and local invasion.
Results: Our model departs from most biomaterial platforms by assessing a wide range of TMZ concentrations and further validating drug response at low doses. Moreover, we use a set of GBM cell lines with defined shifts in TMZ response. These lines are an ideal candidate to model TMZ response & resistance—a unique set of isogenically matched GBM cells (8MGBA vs. 8MGBA-TMZres; 42MGBA vs. 42MBGA-TMZres). This set exhibits TMZ responsiveness or resistance along with disparate proliferative and invasive patterns. Here, we analyze these cell models in GelMA hydrogels to elucidate mechanisms underlying the acquired TMZ resistance in GBM tumors. We validate our platform by using physiologically relevant TMZ doses, showing the possibility to study TMZ response in 3D at low, physiologically relevant (< 100 μM) concentrations. We determine the growth-rate (GR) inhibition, GR50, IC50, and metabolic activity to benchmark detection limits for acquired TMZ resistance in the engineered GelMA GBM model. Subsequently, we use WT and TMZres variants of 42MGBA and 8MGBA lines to determine the upper and lower bounds of detectable TMZ response in 3D GelMA hydrogels. These quantified shifts in TMZ-induced GR inhibition are a key benchmark for studies of the efficacy of novel therapeutics in patient-derived GBM models. Furthermore, we assess the effect of acquired drug resistance on local invasion of GBM. Ongoing experiments aim to adapt our platform for phenotypic drug screening and target validation of novel small-molecule therapeutics.

Advances in Angiogenesis

An essential role for Cmtr2 in endothelial cell function and vascular development

Alena Yermalovich[1], Zarin Mohsenin[1], Bruno Giotti[2], Douglas Wheeler[1], Kelly Xu[1], Alexander Tsankov[2], Matthew Meyerson[3]. *[1]Dana-Farber Cancer Institute, Boston, MA,[2]Icahn School of Medicine at Mount Sinai, New York, NY,[3]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Cancer genome sequencing studies have identified multiple novel tumor suppressor genes, including the FTSJD1 or CMTR2 gene that is subject to statistically significant levels of both nonsense and frameshift mutations in lung adenocarcinoma. However, these analyses are insufficient to determine the importance and modes of action of the gene in the disease. Follow-up functional studies are essential to elucidate these gene functions. The protein product of CMTR2 has been described as an mRNA cap methyltransferase, which O-methylates the ribose of the second guanine residue of the 5' cap, likely serving to modify efficiency of transcript processing, translation and stability, but the details of how and why specific transcripts undergo methylation by the enzyme, as well as its role in oncogenesis, remain to be elucidated. In this study we report the first comprehensive analysis of the physiologic consequences of Cmtr2 deficiency in knockout (KO) mice and primary human cells. Constitutive deletion of Cmtr2 results in embryos that die in midgestation with defects in embryo size, placental malformation and yolk sac vascularization. Endothelial-specific deletion of Cmtr2 in mice also results in vascular defects and perinatal lethality, suggesting that vascular development is a key function of Cmtr2 in animals. In summary, our study reveals that Cmtr2 plays a critical role in vascular development, maturation and remodeling. Further studies of CMTR2 function may provide insight not only into lung cancer biology but also to its broader roles in ontogeny.

Genetic disruption of vascular endothelial profilin-1 impacts tumor microenvironment supressing tumorigenicity of renal cancer

David M. Gau[1], Abigail Allen[1], Andrew Daoud[1], Jessica Kunkel[1], Stefan Duensing[2], Partha Roy[1]. *[1]Bioengineering, University of Pittsburgh, Pittsburgh, PA,[2]Universitätsklinikum Heidelberg, Heidelberg, Germany*

Renal cell carcinoma (RCC) is estimated to result in 79,000 new cases and 13,920 deaths in 2022. Clear cell renal cell carcinoma (ccRCC) is the most common subtype of RCC and is characterized by a highly vascularized tumor microenvironment (TME). While current anti-angiogenic therapies targeting VEGF signaling are initially effective, almost all patients develop resistance to these therapies. Therefore, there is a need to identify clinically relevant alternative molecular targets to suppress tumor angiogenesis and

progression in ccRCC. We previously discovered transcriptional upregulation of actin-binding profilin1 (Pfn1) in tumor-associated vascular endothelial cells (EC) in ccRCC and higher expression of Pfn1 correlated with adverse clinical prognosis. The goal of the present work was to further explore whether genetic manipulation of Pfn1 specifically in EC has therapeutic benefit in kidney cancer. We found that triggering vascular endothelial Pfn1 gene deletion, either in a widespread manner or locally in a kidney-restricted manner, suppresses tumor initiation and/or growth progression of pre-established kidney tumors in syngeneic mouse models. Loss of endothelial Pfn1 dramatically impacts the TME characterized by prominent suppression of tumor angiogenesis with massive tumor cell death and reduction of tumor-infiltrating immune cells. By performing cytokine array and Luminex assays of tumor lysates, we further identified Pfn1-dependent downregulation of several pro-angiogenic cell-secreted factors and pro-inflammatory cytokines that are major drivers of tumor progression in RCC including VEGF, endothelin-1, Cyr61, Macrophage Inflammatory Protein, G-CSF and IL6 *in vivo*. As a clinical correlate for mouse model data, we performed multiplexed quantitative immunohistochemistry analyses of human ccRCC specimens constructed on tissue microarray which also showed a positive correlation between Pfn1 expression (either in endothelial cells or tumor cells) and tumor infiltration of predominantly macrophages. Furthermore, through small molecule screening, we identified a novel inhibitor of the Pfn1-actin interaction (Pfn1i) and showed its ability to inhibit tumor angiogenesis and growth aggressiveness of tumor cells resembling various genetic landscapes of human ccRCC. Collectively, these findings establish endothelial Pfn1 as a critical regulator of TME and tumor progression in RCC, and provide a proof-of-concept for targeting Pfn1 as a potentially novel therapeutic strategy in RCC.

#4585

Tumor lymphangiogenesis sensitizes melanomas to the immunological effects of radiotherapy but also disrupts the local lymphatic vasculature

Anish Mukherjee[1], Nikolaos Mitrousis[1], Mari Stella Sasso[1], Margo MacDonald[1], Ainhoa Arina[2], Phillip Ang[3], Ariana Baginski[1], J. Emiliano G. Medellin[1], Ralph R. Weichselbaum[3], Melody A. Swartz[1]. *[1]Pritzker School of Molecular Engineering, University of Chicago, Chicago,*

IL,[2]Department of Radiation and Cellular Oncology, University of Chicago, Chicago, IL,[3]Pritzker School of Medicine, University of Chicago, Chicago, IL

Tumor lymphangiogenesis is typically associated with cancer progression and metastasis. However, recent studies from our group have demonstrated that tumor lymphangiogenesis promotes intratumor T cell infiltration and potentiates the efficacy of a wide range of immunotherapies in melanoma-bearing mice as well as patients undergoing checkpoint blockade. Radiotherapy (RT) can also induce immunogenic tumor cell death, so we investigated whether lymphangiogenic tumors would yield more immunogenic responses to RT than non-lymphangiogenic tumors. Here, we compared effects of RT in mice bearing B16-F10 melanomas expressing either a control vector (B16-Ctrl) or overexpression the lymphangiogenic factor VEGF-C (B16-VC), where lymphatic vessels were significantly increased in number and size compared to B16-Ctrl tumors. First, we find that B16-VC regress faster than B16-CT after RT (either a single 20 Gy dose or two 15 Gy doses), and that this regression was correlated with enhanced CD8+ T cell activity. On the other hand, lymphatic endothelial cells (LECs) can be more sensitive to damage from RT if they are undergoing lymphangiogenesis. We found that irradiated B16-VC tumors showed higher levels of intra-lymphatic fibrin. Consistent with this, LECs in the irradiated B16-VC tumors expressed higher levels of tissue factor and caspase-3, which correlated with the degree of lymphatic clotting. Fibrin clotting was also observed in the subcapsular sinus of the draining lymph nodes of irradiated B16-VC tumors. These findings highlight the complex role of tumor lymphangiogenesis in radiotherapy responses, where they may potentiate acute anti-tumor immune responses but may also cause localized damage of the vasculature, potentially leading to increased metastasis. Further studies are needed to investigate therapeutic targets to inhibit lymphatic coagulation and look at its effects on cancer immunotherapy and metastasis.

#4586

To define how the uvel melanoma-liver environment crosstalk shapes metastasis growth and therapeutic response

Sathya Neelature Sriramareddy[1], Zhihua Chen[1], Jiannong Li[1], Ann Chen[1], Jonathan D. Licht[2], J William Harbour[3], Keiran Smalley[1]. *[1]Tumor Biology, H lee Moffitt Cancer Center and Research Institute, Tampa, FL,[2]Department of Medicine, University of Florida Health Cancer Center, University of Florida, Gainesville, FL,[3]Department of Ophthalmology, University of Texas Southwestern Medical Center, Dallas, TX*

BACKGROUND: Uveal melanoma (UM) is derived from melanocytes of the eye. Up to 50% of individuals with primary uveal melanoma will eventually develop liver metastases through mechanisms that remain poorly described. At this time there are no systemic therapies that are effective against the majority of UM liver metastases. The goal of this study is to better understand the role of tumor-host cell crosstalk in the progression and therapeutic response of UM liver metastases.
METHODS: We used UM liver metastatic mouse models to study bidirectional cell-cell communication. Mice were treated with MEKi (trametinib, daily),HDACi (panobinostat, 3 times a week), or the combination for the period of 21 days.The tumor progression was monitored using MRI. Single cell RNA-Seq (scRNA-seq) was performed to delineate the host-tumor crosstalk and mechanisms of therapy response. Similarly, scRNA seq was conducted *in vitro* with mono- and co-cultures of hepatic stellate cells (HSCs) and uveal melanoma cells. Human cytokine arrays were carried out between mono and co-culture to identify and confirm unbiased growth factors released between HSCs and UM. ELISA assays were conducted to quantify the cytokine IL8 in mono and coculture cell culture supernatant. A vascular tube formation assay was carried to study the angiogenesis in presence of IL-8 and GDF15.
RESULTS: Our scRNA-Seq analyses of UM liver mets revealed a large infiltration of HSCs, along with myeloid derived suppressor cells, macrophages, dendritic cells and hepatocytes. As HSCs were the major host cell type in UM liver mets we performed scRNA-Seq on UM monocultures and UM-HSC co-cultures to determine the patterns of cell-cell interaction upon co-culture and in response to drug. Singlecell SignalR analysis identified key interactions between UM-HSC mediated through FGFR2 and RPS27A associated with increased IL-6, FOS/JUN, STA3, & NFκB signaling in the UM cells. Further studies showed that Class 2 UM cells secreted GDF15 that activated the HSCs resulting in the secretion of

multiple growth factors, including MMPs, VEGFA, TGF-β1, IL8 and multiple ECM genes.As many of the identified growth factors were associated with angiogenesis, we performed co-culture assays with UM, HSC and endothelial cells and noted increased vascular network formation in the presence of activated HSCs. Addition of exogenous IL-8 was found to mimic the effects vascular network formation *in vitro*, suggesting this to be a potential mediated of HSC-driven angiogenic response in UM mets. Treatment of established UM liver mets with the MEKi+HDACi combination significantly decreased angiogenesis in UM liver mets, an effect associated with inhibition of IL-8 and GDF15 release.
CONCLUSION: Bidirectional communication between hepatic stellate and UM cells induces angiogenic pathways in UM both in *in vitro* and *in vivo*, leading to vascular network formation and tumor progression in the liver.

Vascular-derived signature imprinted by tumor microenvironment-dependent transcriptional memory predicts colon cancer prognosis

Elisabeth Naschberger, Maximilian Fuchs, Nicholas Dickel, Meik Kunz, Charles G. Anchang, Richard Demmler, Bernt Popp, Arif B. Ekici, Steffen Uebe, Carol I. Geppert, Claudia Günther, Susanne Merkel, Vera S. Schellerer, Michael Stürzl. *University Hospital of Erlangen, Erlangen, Germany*

Background: Antiangiogenic therapy is part of the guideline therapy of colorectal cancer (CRC). Surprisingly, the impact of the tumor microenvironment (TME) on tumor vessel endothelial cells (TECs) is largely unclear. The aim of this study was to investigate the presence of a TME-dependent transcriptional memory in TECs isolated from patients and to exploit it to retrieve signatures that characterize TECs in different intratumoral TMEs with impact on patient outcome.
Methods: ECs from tumor and normal colon tissues, PBMCs and tumor cells were isolated from CRC patients with different prognostic TMEs. Cells were analyzed by qPCR, immunocytochemistry and multi-omics (transcriptomics, EPICmethylation chips, exome sequencing). Integrative bioinformatics was used to identify TME-dependent memory genes predicting prognosis and scRNASeq to validate endothelial gene expression in CRC tissues.

Results: Ultrapure TECs were isolated from CRC with different prognostic TMEs (Th1 vs. non-Th1) and systematically compared by multi-omics. A transcriptional memory differentiating the respective TEC groups was identified. This *in vivo* imprinted transcriptional memory was preferentially regulated by epigenetic DNA methylation but not by genomic alterations and was different from an *in vitro* primed transcriptional memory to IFN-γ. Moreover, it was specific for TECs and not observed in CAFs. With integrative bioinformatics a TME-dependent memory signature was extracted and its expression in TECs in CRC tissues was confirmed by scRNASeq. Notably, the identified signature predicted the prognosis of CRC patients.
Conclusion: We identified a tumor vessel-derived TME-dependent transcriptional memory signature that was manifested by epigenetic mechanisms and allowed tumor vessel-based prediction of CRC patients prognosis.

Vascular regulation of T-cell exclusion in melanoma

Ha-Ram Park[1], Anahita Shiva[1], Portia Cummings[1], Richard Carvajal[1], Gavin Thurston[2], Joon-Yong An[3], Amanda W. Lund[4], Hee Won Yang[2], Minah Kim[1]. *[1]Columbia University Irving Medical Center, New York, NY,[2]Regeneron Pharmaceuticals, New York, NY,[3]Korea University, Seoul, Korea, Republic of,[4]NYU Langone Health, New York, NY*

T-cell position in the tumor microenvironment determines the probability of target encounter and tumor killing. $CD8^+$ T-cell exclusion from the tumor parenchyma is associated with poor response to immunotherapy and yet the biology that underpins this distinct pattern remains unclear. Here we show that the vascular destabilizing factor angiopoietin-2 (ANGPT2) causes compromised vascular integrity in the tumor periphery, leading to impaired T-cell infiltration within tumor. We analyzed the spatial regulation of ANGPT2 in whole tumor cross-sections and its impact on $CD8^+$ T-cell position, vascular integrity, and response to immunotherapy using syngeneic murine melanomas. We found that T-cell exclusion was associated with peritumoral expression of ANGPT2 and elevated vascular leakage in human and murine melanomas. Both pharmacological and

genetic blockade of ANGPT2 promoted $CD8^+$ T-cell infiltration to the tumor core, exerting antitumor effects. Importantly, the reversal of T-cell exclusion following ANGPT2 blockade not only enhanced response to anti-PD-1 therapy in immunogenic, therapy responsive mouse melanomas, but also rendered non-responsive tumors susceptible. Therapeutic response after ANGPT2 blockade, driven by improved $CD8^+$ T-cell infiltration, coincided with TIE2 signaling activation and increased vascular integrity in the tumor periphery, indicating that maintenance of vascular integrity within tumors is necessary for robust response to immunotherapy. These data highlight ANGPT2/TIE2 signaling as a key mediator of T-cell exclusion and a promising target to potentiate checkpoint inhibitor efficacy in melanoma.

Deciphering collagen-responsive mechanism in pancreatic tumor progression and immunology at single-cell resolution

Yang Chen. *Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX*

A hallmark feature of PDAC is its desmoplastic stroma. However, clinical trials of generic strategies targeting PDAC stromal components have mostly failed or, in some cases, even accelerated tumor progression. These findings prompt us to re-evaluate the functional heterogeneity and selective targeting of the tumor stroma. Tumor stroma involves the prominent accumulation of type I collagen (Col1), the most abundant protein in PDAC and the human body. However, the precise molecular and mechanistic contributions of Col1 to PDAC remain unknown, due to the lack of mouse models for precise knockout of Col1. I have established a variety of novel transgenic mouse models that allow specific genetic deletion of Col1 in various cell populations including fibroblasts or cancer cells of spontaneous PDAC (Chen et al., Cancer Cell, 2022; Chen et al., Cancer Cell, 2021; Chen et al., Nature Communications, 2021). In addition, my prior studies underscore the importance of deciphering the functional heterogeneity of tumor microenvironment with both tumor-restraining and tumor-promoting functions (McAndrew, Chen, Darpolor et al., Cancer Discovery, 2022; Chen et al., Nature Reviews Clinical Oncology, 2021; Chen et al., EMBO Molecular Medicine, 2018; Chen et al., PLoS Biology, 2018). Specifically,

my recent studies identified that Col1 deletion in fibroblasts significantly aggravates tumor progression and immune suppression, with enriched myeloid-derived suppressor cells (MDSCs) and inhibited T/B cells (Chen et al., Cancer Cell, 2021). On the contrary, Col1 deletion in cancer cells inhibited PDAC progression and immunosuppression, leading to beneficial intra-tumoral microbiome and enhanced efficacy of immunotherapy (Chen et al., Cancer Cell, 2022). In contrast to the normal Col1 heterotrimer (α1/α2/α1) produced by fibroblasts, pancreatic cancer cells produce abnormal oncogenic Col1 homotrimer (α1/α1/α1). Col1 homotrimers produced by cancer cells exhibits potent tumor-promoting functions, in contrast to the tumor-restraining functions of Col1 heterotrimers produced by fibroblasts. These findings, as validated in both transgenic mouse models and pancreatic tumor patient datasets, identify the distinct impact of various Col1 subtypes on tumor progression, immune landscape, and microbiome profile. Furthermore, my results underscore the need for new therapeutic strategy preferably targeting Col1 homotrimer-specific oncogenic effects in cancer cells via cancer-specific receptors, without disturbing Col1 heterotrimer-induced tumor-restraining functions. My current studies aim to dissect the cancer cell-intrinsic response and immune response to Col1 homotrimer versus Col1 heterotrimer, which may unravel the fundamental collagen-responsive mechanism by which cancer cells survive in the desmoplastic microenvironment, revealing potential vulnerabilities of PDAC.

Anti-angiogenic mAb, anti-human VEGFR2(Cyramza) retards tumor growth in KDR (VEGFR2) humanized mice engrafted with syngeneic vs. xenograft solid tumors

Daniel He. *Shanghai Model Organisms Center, Inc., Shanghai, China*

Blood vessels is required for the growth of solid tumors and cutting off the blood supply to tumor is a potential novel strategy to retard tumor growth, although which may consequently result in pan-hypoxia and metastasis paradoxically. VEGFA is identified as the major angiogenic factor and VEGFR2 binds to all VEGFA isoforms and VEGFR2 (KDR) is a dominant mediator in regulating the angiogenic and permeability-enhancing effects of VEGFA. Importantly, in numerous solid tumors, VEGFA and VEGFR2 are

overexpressed to promote intratumoral angiogenesis to support local tumor survival, tumor growth and distant metastasis. Given that VEGFA/VEGFR2 interaction plays a crucial role in promoting intratumoral angiogenesis and tumor growth, it is appealing to develop novel potent anti-angiogenic agents for cancer treatment by direct against VEGFA-VEGFR2 interaction. However, the preclinical assessment of anti-angiogenesis agents are limited due to lack of suitable preclinical models for human-specific therapeutic antibodies which usually don't cross-bind to mouse targets. To this end, we developed the KDR (VEGFR2) humanized mouse model (hKDR model), in which the extracellular regions of mouse VEGFR2 corresponding to exons 4-15 are replaced by human counterparts via ES cell-based homologous recombination. As a result, hKDR humanized mouse expresses a chimeric VEGFR2 receptor containing the human extracellular domain plus mouse trans-membrane and intracellular domains. Firstly, we characterized the chimeric h/m KDR expression on the endothelial cells as well as in intratumoral blood vessels derived from hKDR knockin mice. Subsequently, we investigated the anti-tumor responses of anti-human VEGFR2 antibody (Cyramza, Ramucirumab) in hKDR mice bearing B16-F1 and MC38 syngenic solid tumors and we observed that Cyramza inhibited the tumor growth in vivo remarkably in a dose-dependent way, indicating the binding of anti-human VEGFR2 antibody to the chimeric h/m KDR receptor. Notably, we further generated hKDR knockin model in Rag2 knockout background (hKDR/Rag2^{KO}) by crossbreeding which lack mature T cells and B cells. The female hKDR/Rag2^{KO} mice were subcutaneously inoculated with human hepatocellular carcinoma LI0612 PDX model and human gastric cancer GA2419 PDX model to assess the anti-tumor effects of anti-angiogenic agents in xenograft solid tumors. The data suggested that Cyramza displayed moderate tumor growth inhibition (TGI) in LI0612 model at 10 mg/kg and weak TGI in GA2419 model at 10 mg/kg, respectively. Our findings support the notion that normalization of tumor vasculature is critical for tumor inhibition based on anti-angiogenic therapy and may synergize the anti-tumor effects with the immune checkpoint blockade or promote the cancer immunotherapy of immunomodulators in the future trials.

Mechanisms of tumor-mediated endothelial cell proliferation independent of VEGF

Kevin L. Sheng, Jude Raj, Kris C. Wood. *Duke University, Durham, NC*

A hallmark of cancer is dysregulated angiogenesis and blood vessel co-option, which are often driven by vascular endothelial growth factor (VEGF). Despite the key role of VEGF signaling in promoting endothelial cell (EC) proliferation, survival, and migration, the clinical use of VEGF inhibitors has modest success and faces many challenges. In particular, patients demonstrate variable initial responses to anti-VEGF therapy, and many of those who respond to treatment subsequently develop resistance. These challenges suggest that there may be VEGF-independent mechanisms driving EC proliferation in the tumor microenvironment. To study these mechanisms, we established an *in vitro* model using a dual-reporter system in a co-culture model of ECs and tumor cells. Specifically, we used an immortalized endothelial cell line (SVEC4-10) expressing GFP and *Renilla* luciferase and a mouse renal carcinoma cell line (RENCA) expressing Tomato and Firefly luciferase. This model allowed us to independently evaluate the growth rates and cell viabilities of both ECs and tumor cells in direct co-culture. Our preliminary data revealed that ECs exhibit increased growth rates when directly co-cultured with tumor cells. Interestingly, this EC proliferation is VEGF-independent and not impacted by VEGF-A knockout in tumor cells or with treatment of a pan-VEGFR small molecule inhibitor (axitinib). To further characterize if our phenotype was due to other tumor secreted factors, we used a transwell setup to eliminate direct contact between ECs and tumor cells and found that EC growth rates were substantially mitigated. These results revealed that tumor cells induced EC proliferation through a physical cell-to-cell interaction that is independent of VEGF. Further characterizing this unknown mechanism may inform therapeutic interventions to overcome the clinical challenges of anti-VEGF therapies for cancer. To expand our understanding of this VEGF-independent EC proliferation, we aim to characterize the cell surface proteome from tumor-conditioned ECs using cell surface mass spectrometry. We will validate hits from this study using our *in vitro* model and translate these findings to *in vivo* mouse models. We expect that our current and future research will reveal new insights into tumor co-option of

the vascular system and identify novel targets for developing therapies to effectively treat cancer.

In vivo efficacy evaluation of anti-human VEGFR2 antibodies in humanized B-hVEGFR2 mice

Lei Zhao[1], Chengzhang Shang[1], Rebecca Soto[2], Chonghui Liu[1], Zhaoxue Yu[2]. *[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Biocytogen Boston Corp, Wakefield, MA*

Angiogenesis, vascular development, vascular permeability, and embryonic hematopoiesis is partly regulated by VEGF binding to VEGFR2, which forms receptor dimers and activates downstream signaling pathways. In addition to developmental cues, VEGFR2 is also associated with disease progression for psoriasis, rheumatoid arthritis, diabetic retinopathy, and more significantly, tumor growth and drug resistance. Given this, inhibition of VEGFR2 signaling is actively being studied, and multiple VEGFR2 inhibitors have entered various phases of clinical studies and have shown promising results. To evaluate *in vivo* efficacy of anti-human VEGFR2 antibodies, we generated a human *VEGFR2* knock-in (B-hVEGFR2) mouse model by replacing the murine *Vegfr2* extracellular domain sequence with the corresponding human sequence. We validated human VEGFR2 gene and protein expression in B-hVEGFR2 mice by RT-PCR and flow cytometry, respectively. Furthermore, we observed an anti-tumor effect with anti-human VEGFR2 antibodies in homozygous B-hVEGFR2 mice subcutaneously implanted with MC38 colon cancer cells. Taken together, we established a novel preclinical B-hVEGFR2 mouse model for evaluation of VEGFR2-targeted immunotherapy.

Glioblastoma tumors that respond poorly to bevacizumab therapy show upregulation of an angiogenesis gene set

Roshan Lodha, Gaelle Muller-Greven, Lydia Guo, Candece Gladson. *Cleveland Clinic Lerner Research Institute, Cleveland, OH*

Glioblastoma (GBM) is the most common primary brain tumor in adults with a 15-month median survival, despite surgical-resection and radio-

chemotherapy, and a recurrence rate of 90%. Despite improving survival in only a small percentage of patients, bevacizumab, a monoclonal antibody toward vascular endothelial growth factor-A, is frequently used to treat recurrent-GBM. To find predictors of poor-response to bevacizumab, we performed RNA-sequencing on multiple GBM patient-derived xenograft (PDX) tumors after orthotopic propagation in athymic nude mice. The study was repeated, and once PDX-tumors were established, mice were treated with bevacizumab and grouped based on survival. Bioinformatic-analysis of RNA-sequencing data demonstrated differential gene expression in tumors that were poor-responders to bevacizumab (no survival change) as compared to tumors that were good-responders (longer survival), along with upregulation of an angiogenesis gene set in poor-responders. Within this gene set, multiple genes known to be regulated by the early growth response 1 (*EGR1*) transcription factor were identified; *CHRNA7* (cholinergic-receptor-nicotinic-α7-subunit) was selected for further study based on the reported role in promoting cancer cell migration and proliferation. Results were validated at the protein level using immunohistochemical staining. Additionally, Sry-box transcription factor-10 (*SOX10*) showed upregulation in poor-responders, potentially driven by impaired proteosome degradation. *SOX10* is known to promote mural-cell coverage of neovasculature, cancer cell migration, and glioma development when cooperating with platelet-derived growth factor-B (*PDGFB*). In summary, GBM PDX-tumors with upregulated expression of an angiogenesis gene set and of two transcriptional regulators (*EGR1* and *SOX10*) demonstrated a poor response to bevacizumab; upregulation of these genes could be used to predict bevacizumab response.

STAT-3 chemical inhibition modulates decidual-like polarization in NK cells from PCa patients and restore their anti-tumor activities

Matteo Gallazzi[1], Maria Teresa Palano[1], Martina Cucchiara[2], Federico Dehò[3], Paolo Capogrosso[3], Francesca Franzi[4], Fausto Sessa[4], Angelo Naselli[1], Lorenzo Mortara[2], Antonino Bruno[2]. *[1]IRCCS MultiMedica, Milano, Italy,[2]University of Insubria, Varese, Italy,[3]ASST Settelaghi, Ospedale di Circolo e Fondazione Macchi, Varese, Italy,[4]ASST Sette-Laghi, University of Insubria, Varese, Italy*

Introducti**on.** Natural Killer (NK) cells are innate lymphoid cells involved in tumour recognition/elimination. NK cells are altered in their phenotype and functions in diverse tumors, including prostate cancer (PCa). We demonstrated that PCa circulating NK cells (TANKs) acquire the pro-angiogenic/decidual-like $CD56^{bright}CD9^{+}CD49a^{+}$ phenotype, release IL-8 and MMP-9, functionally support endothelial cell activation and secrete monocyte-recruiting/M2-like macrophage-polarizing factors.

Materials and methods. Here, we characterized the phenotype of tumour infiltrating NKs (TINKs) and tumour-associated (TANKs) in PCa patients and evaluated the contribution of STAT3, as possible driver of NK cell polarization. PCa TINKs and TANKs were characterized by multicolour flow cytometry (FC) for decidual-like surface markers (CD9, CD49a) and degranulation capabilities (CD107a). STAT3 activation, was investigated in circulating PCa NK cells, by FC. Using a drug-repurposing approach with the antipsychotic agent Pimozide (a chemical inhibitor of STAT3), we modulated STAT3 activation, *ex vivo*, in PCa TANKs and monitored their secretome changes, by commercially available protein membrane arrays together with their capability to degranulate and produce perforin/GranzymeB.

Results and discussion. We observed that PCa TINKs acquire the same $CD9^{+}CD49a^{+}$ decidual-like NK cell phenotype, as found in PCa TANKs. We detected the presence of $CD56^{bright}CD9^{+}CD49a^{+}$ decidual-like NK cell also in peripheral blood of subjects with benign prostatic hyperplasia (BPH), but in a lower frequency, compared to those from PCa TANKs. Sera from PCa patients were enriched in IL-4, IL-6, IL-8 and IL-10, all cytokines able to activate STAT3 signalling. We detected increased phosphorylation of STAT3 in PCa TANKs, compared to NK cells from healthy controls, that was reduced following 24 hours of stimulation by Pimozide. This treatment resulted in decreased capabilities of PCa TANKs to secrete pro-angiogenic factors (IL-8, IL-6), molecules involved in monocytes recruitment/M2-like macrophage polarization (CCL-2, CCL5, GM-CSF, IL-10), together with increased degranulation, augmented secretion of (IFN-γ and TNF-α) and increased production of Perforin and Granzyme.

Conclusions. Our results suggest that STAT3 inhibition can be envisaged as a potential strategy to limit the generation of pro-angiogenic/decidual-like NKs, while contributing to NK cell re-education in PCa.

BIOhabitats clinical study (NCT05375318): Histopathological analysis of vascular habitats in glioblastoma defined by perfusion MRI

María del Mar Álvarez-Torres[1], Rebeca Burgos-Panadero[1], Jaime Agustí Martínez[2], Carlos Irles Vidal[3], Jaime Font de Mora[4], Elies Fuster-Garcia[1], Juan Miguel García-Gómez[1]. *[1]Biomedical Data Science Laboratory, ITACA., Universitat Politècnica de València, Valencia, Spain,[2]Pathology Department, Hospital Clínico Universitario of Valencia, Valencia, Spain,[3]Neurosurgery Department, Hospital Clínico Universitario of Valencia., Valencia, Spain,[4]Laboratory of Cellular and Molecular Biology, Instituto de Investigación Sanitaria La Fe, Valencia, Spain*

Tumor heterogeneity is a key hallmark and a major cause of therapeutic resistance in glioblastoma (GBM) patients. To characterize this heterogeneity, the automatic method ONCOhabitats delineate four habitats within the lesion using artificial intelligence analysis of perfusion magnetic resonance imaging (MRI): high angiogenic tumor (HAT), low angiogenic tumor (LAT), infiltrated peripheral edema (IPE), and vasogenic peripheral edema (VPE).

BIOhabitats has been successfully implemented in two Spanish hospitals, with the purpose of describing the vascular habitats at histopathological level. To collect samples from each habitat during the standard surgeries, the habitats masks were included in the neuronavigators. Posterior histopathological analyses of each sample were performed.

In this preliminary study, we present data from 37 samples from 9 GBMs. Neoplasic cellularity and density of mitosis were evaluated using Mann-Whitney test. In addition, we analyzed the proportion of samples of each habitat from the entire cohort with the presence of necrosis, reactive gliosis, microvascular proliferation (MVP), and glomeruloid vessels.

Table 1 includes results analyzing differences among habitats. Our results underline that HAT and LAT are characterized by more proliferative and vascular profiles compared to the edema habitats. However, the IPE habitat presented the highest value of reactive gliosis, which is associated with inflammatory processes and can be related to tumor infiltration. Higher proportions of necrosis, MVP, and glomeruloid vessels were also found in this habitat compared to VPE.

Despite this is a preliminary study, we found significant differences among tumor and edema habitats. We highlight the particular histopathological profile of the IPE habitat, different from the active tumor habitats but also from the VPE. BIOabitats is currently in progress including more patients for characterizing the habitats in depth.

Table 1. Histopathological analysis among vascular habitats.A) Mann Whitney results of analyzing ne

TIMP1 is a major contributor of the angiogenic priming of tumor associated fibroblasts in lung adenocarcinoma

Natalia Isabel Diaz Valdivia[1], Paula Duch[1], Rafael Ikemori[1], Eduard Monso[2], Noemi Reguart[3], Jordi Alcaraz[1]. *[1]Unit of Biophysics and Bioengineering, Universitat de Barcelona, Barcelona, Spain,[2]CIBERES, Hospital Parc Taulí de Sabadell, Sabadell, Spain,[3]Medical Oncology, Hospital Clinic, Barcelona, Barcelona, Spain*

Background**:** Lung adenocarcinoma (ADC) and squamous cell carcinoma (SCC) are the most common histologic subtypes in lung cancer. Intriguingly, ADC and SCC exhibit distinct responses to the multi-tyrosine kinase inhibitor nintedanib and other antiangiogenic drugs, suggesting that angiogenesis may depend on the histologic subtype in lung cancer. In addition, tumor-associated fibroblasts (TAFs) are known regulators of angiogenesis, and we have recently reported that TAFs exhibit enhanced fibrosis and response to nintedanib in ADC compared to SCC, owing to the stronger epigenetic repression of SMAD3 in SCC-TAFs caused by excessive exposure to cigarette smoke particles. However, how the histotype-dependent fibrotic phenotype in TAFs impacts their pro-angiogenic functions remains unknown.

Methods: A panel of angiogenesis markers was assessed in patient samples using publicly available databases. The pro-angiogenic function of the conditioned medium of TAFs from ADC and SCC patients pre-activated with TGF-β1 was analyzed *in vitro* using migration and network formation assays of endothelial cells. The secretion of pro-angiogenic factors in TGF-β1-activated TAFs was analyzed using an angiogenesis antibody blot array. Selected factors were functionally validated *in vitro* and *in vivo* using genetic models.

Results: All angiogenesis markers were consistently upregulated in ADC compared to SCC concomitantly with a lower necrosis in ADC, unveiling a larger angiogenesis in ADC. We also observed that the conditioned medium of TGF-β1-activated TAFs elicited a larger endothelial cell network formation and migration in ADC than SCC, revealing that ADC-TAFs exhibit enhanced angiogenesis. Our immunoblot array analysis identified a subset of pro-angiogenic factors that were selectively overexpressed in ADC-TAFs compared to SCC-TAFs, including TIMP-1. Notably, TIMP-1 overexpression in ADC-TAFs was SMAD3-dependent and knocking down

TIMP-1 by siRNA in ADC-TAFs impaired angiogenesis *in vitro* and in tumor xenografts *in vivo*.
Conclusions: Our results reveal a larger angiogenesis in ADC compared to SCC, and implicate the TGF-β1/SMAD3/TIMP-1 pathway in the enhanced angiogenesis of ADC-TAFs. Our findings identify a biological process underlying the poor response of SCC to antiangiogenic therapies like nintedanib, and provide a rationale for the earlier metastasis of ADC patients compared to SCC patients based on the enhanced pro-angiogenic role of ADC-TAFs.

Vitamin b1 derivative, benfotamine, prevents VEGF-induced angiogenesis
Kieran V. Allowitz, Trevor J. Plowman, Kota V. Ramana. *Noorda College of Osteopathic Medicine, LLC, Provo, UT*

Several studies have indicated that thiamine, and more specifically its lipid soluble derivative benfotiamine, exerts an anti-oxidative and anti-inflammatory effect on the body. However, its effect in preventing cancer cell proliferation, migration, invasion, and metastasis is not yet clearly understood. It is known that angiogenesis plays a significant role in the growth and spread of many cancers but the role of benfotiamine in neovascularization is not yet known. Therefore, in this study, we hypothesized that benfotiamine would prevent VEGF-induced angiogenesis in vitro and in vivo. To examine this, we have treated human umbilical vein endothelial cells (HUVECs) with VEGF (Vascular Endothelial Growth Factor; 10 ng/ml) in the absence and presence of benfotiamine (0-100 uM) in a time and dose-dependent manner. We then examined the cell viability by MTT assay and apoptosis by Annexin-V staining and found that benfotiamine alone had minimal effect on cell viability and it prevents VEGF-induced cell proliferation. In vitro angiogenesis assay indicates that benfotiamine prevented the VEGF -induced tube formation of HUVECs. Further, benfotiamine regulated the expression of VEGF-induced growth factors such as VEGF, PIGF, IGFBP-1, ECGF, FGF-1 and 2, anti-angiogenic enzymes such as Serpin E1, TIMP-1, MMP-8, TSP-1, PTX3 and uPA and cytokines such as IL-8, Prolactin, ET-1, Endostatin, and CCL3. We will next examine how benfotiamine prevents in vivo

angiogenesis by utilizing a rat Matrigel plug model of angiogenesis in rats. The Matrigel sections will be stained with CD36, vWF, and other angiogenic markers to visualize the effect of benfotiamine on VEGF-induced angiogenesis. In conclusion, our current results indicate that benfotiamine has anti-angiogenic potential via inhibition of various pro-angiogenic growth factors and promoting anti-angiogenic factors in vitro and in vivo. Thus, our studies demonstrate that benfotiamine could be further developed as a novel therapeutic agent to prevent cancer growth and metastasis.

Blood and lymphatic endothelial cell contractility-mediated vessel permeability regulates interstitial fluid pressure and T cell infiltration in the tumor microenvironment

Yansong Peng, Esak Lee. *Nancy E. and Peter C. Meinig School of Biomedical Engineering, Cornell University, Ithaca, NY*

Solid tumors such as breast and pancreatic cancer are characterized by poor prognostic outcomes with high interstitial fluid pressure (IFP), which promotes tumor progression by modulating angiogenesis, matrix metalloproteinase activity, and cancer cell motility and compromises immunotherapies by keeping immune cells (e.g., T cells) from infiltrating into the tumor. To reduce tumor IFP, researchers tried to decrease solid stress and normalize hyperpermeable blood vessels (BV) in tumors, but how lymphatic vessels (LV) are impaired in the tumor microenvironment is poorly understood. Several studies reported that vascular endothelial growth factor C (VEGFC) treatment defeated tumors by promoting lymphangiogenesis and boosting T cell recruitment, while it has also been recognized to promote lymph node metastasis. Given the controversial roles of VEGFC, the main goals of this study are to control LV permeability and promote drainage by identifying currently unappreciated roles of rho-associated protein kinase 1 and 2 (ROCK1/2) in regulating lymphatic endothelial cell (LEC) contractility, junctions, and drainage in tumors. We will have blood endothelial cells (BEC) as controls to understand how ROCK1/2 and cell contractility affect LEC/BEC junctions and permeability differently. Here, we created a three-dimensional (3D) bioengineered model of vascularized pancreatic and breast tumors to study vessel junctions,

permeability, and IFP formation. The device consisted of a LEC or BEC lined, perfusable channel and a tumor-filled ECM chamber. We observed impaired barrier function of tumor BV/LV with increased permeability and loss of tight junctions compared to healthy vessels. To quantify the contractility of LEC/BEC, we employed traction force microscopy (TFM) by creating a 2D biomimicry of the endothelial monolayers using micropatterned polyacrylamide gel substrates with tunable stiffness. Using TFM, we showed that the combination of tumor-secreted factors and elevated matrix stiffness increased the traction of LEC/BEC, resulting in their loss of tight junctions. Using Rho kinase blockade to inhibit ROCK1/2 reduced the contractility of endothelial cells, reconstructed vessel structural integrity and functionality, and reduced intratumoral IFP in animal models. We expect that a decrease in the tumor IFP due to the restoration of lymphatic drainage would increase T cell infiltration, suppress tumor growth, and improve the survival of tumor-bearing mice combined with the anti-PD-1 or anti-PD-L1 therapy in our future studies. Together, our study provides new insights into understanding the physical interaction of endothelial, tumor, and immune cells, evidence of rho-kinases as a target for cancer immunotherapy, as well as a promising way to increase the efficacy of immunotherapies in cancer patients.

Phenotypic & functional diversity of tumor associated neutrophils in murine breast tumor models

Hasan Korkaya, Elayne Benson, Fulya Koksalar Alkan, Justin Wilson, Tulshi Patel, Hilmi K. Alkan, Virginia McEvoy, Nika Shekastehband, Nate Francois, Huidong Shi, Catherine C. Hedrick. *Augusta University, Augusta, GA*

Despite the advances in early diagnostics and therapeutics, women with metastatic breast cancer have limited treatment options. Women with TNBC, who constitute 15-20% of breast cancer patients, are often diagnosed with aggressive/metastatic disease. Advanced studies implicated immunosuppressive tumor microenvironment (TME) in aggressive/metastatic properties of TNBC subtype. Alternatively activated immature myeloid cells including tumor-associated macrophages (TAM), tumor-associated neutrophils (TAN), tumor-associated dendritic cells

(TADC) and myeloid derived suppressor cells (MDSC) constitute a major component of TME. However, anti-tumorigenic microenvironment is also reported and that may have clinical relevance in early TNBC patients. Therefore, our hypothesis is that myeloid cells polarize to become immunosuppressive and infiltrate tumors and pre-metastatic niches in patients with advanced disease, while patients with early TNBCs may elicit anti-tumor immune response eliminating disseminated tumor cells (DTC). The utilization of syngeneic immunocompetent mouse models has contributed to our current understanding of immunosuppressive or immunomodulatory TME. Using these models, we have demonstrated that tumor dissemination and growth at metastatic sites is facilitated by MDSC's. Emerging technologies; single cell RNA sequencing (scRNA-Seq), mass cytometry (CyTOF) or cellular indexing of transcriptomes and epitopes sequencing (CITE-Seq) has been powerful platforms for detailed characterization of tumors and TME compartments. We performed scRNA-Seq and CyTOF analyses of the myeloid cell populations of tumors and spleens from metastatic 4T1 and non-invasive EMT6 tumor-bearing mice. Tumors and spleens from 4T1 tumor-bearing mice exhibited a marked expansion of myeloid cell subsets that are characterized by the expression of immunosuppressive as well as progenitor markers. On the contrary, indicated tissues from EMT6 mice were enriched in NK cells, T and B lymphocytes and they were lacking immunosuppressive myeloid cell subsets. Furthermore, we identified a distinct differentiation pattern of immature myeloid cell subsets from neutrophil progenitors (NP) in 4T1 tumor-bearing mice. Using the murine TNBC models in syngeneic mice, we provide evidence that early TNBC tumors may elicit anti-tumor immune responses and thus the survival outcome in those patients is substantially increased after complete surgical resection of the primary tumors. Whereas immunosuppressive tumor microenvironment contributes to the poor overall survival in patients with advanced TNBCs. Therefore, identifying an anti-tumor immune signature in early TNBC patients may be utilized as a clinical biomarker before surgical intervention as well as improve the survival outcome.

Vitamin D supplementation attenuates resistance to anti-angiogenic therapy in colorectal cancer liver metastases

Miran Rada, Lucyna Krzywon, Audrey Kapelanski-Lamoureux, Stephanie Petrillo, Anthoula Lazaris, Peter Metrakos. *McGill University Health Centre, Montreal, QC, Canada*

Colorectal cancer liver metastasis (CRCLM) is one of the deadliest cancers. CRCLM tumours have two distinct histopathological growth patterns (HGPs) including desmoplastic HGP (DHGP) and replacement HGP (RHGP). The DHGP tumours are angiogenic, while their RHGP counterparts are vessel co-opting. The patients with RHGP tumours showed poor response to anti-angiogenic agents, as well as a worse prognosis. Herein, we conducted a retrospective cohort study that comprised 106 CRCLM patients to examine the effect of vitamin D supplementation on the HGPs of the tumours and the 5-year overall survival (OS). Interestingly, we found an inverse correlation between vitamin D supplementation and the presence of RHGP tumours in CRCLM patients. Additionally, the population who used vitamin D supplementation had significantly better 5-year OS. Moreover, our in vivo results suggested that vitamin D supplementation significantly improves the response of CRCLM tumours to anti-angiogenic therapy. Mechanistically, we found that vitamin D can suppress cancer cell motility, which is essential for the development of vessel co-option tumours and resistance to anti-angiogenic therapy. Collectively, this study suggests vitamin D supplementation is a promising way to attenuate resistance to anti-angiogenic therapy and improve the prognosis of CRCLM patients.

Differences in tumor vascular density between smoker and non-smoker cancer patients

Shubhangi Singh[1], Mohammad Aslam Khan[2], Elba T. Herrera[3], Seema Singh[2], Ajay P. Singh[2], Santanu Dasgupta[2]. *[1]International Studies, University of South Alabama, Mobile, AL,[2]Pathology, University of South Alabama, Mobile, AL,[3]Mitchell Cancer Institute, University of South Alabama, Mobile, AL*

Smoking is among the most significant preventable risk factors associated with cancer and other benign diseases. Cancer development is a multi-step process in which transforming cells gradually gain malignant properties

through a series of oncogenic genetic alterations. Successful cancer progression also depends on the remodeling of the surrounding stroma, which feeds the cancer cells in a host-parasite interaction. Tumor angiogenesis, the process of blood vessel formation, is an essential feature of solid tumors that ensures that they have the needed supply of food and oxygen to sustain their proliferative growth. We previously demonstrated that nicotine, an addictive component of tobacco smoke, promoted tumor angiogenesis by impacting the growth of endothelial cells. In the present work, we examined the differences in tumor vasculature between smoker and non-smoker patients to find clinical support for our laboratory findings. After searching the available tumor cases in the repository for the patient's smoking history, I selected 27 smokers (12 lung and 15 prostate adenocarcinomas) and 19 non-smokers (4 lung and 15 prostate adenocarcinomas) cases. The tissue blocks were sectioned and subjected to hematoxylin and eosin staining and immunohistochemistry using an antibody against CD31, a biomarker for endothelial cells. Following digital scanning, all slides were reviewed to identify tumor areas and $CD31^+$ tubular structures (blood vessels). We observed that lung and prostate tumor tissues from smoker patients had a significantly higher number of blood vessels than those from non-smoker patients. Thus, increased tumor vascularization appears to be a common feature of smoking cancer patients providing clinical support for a novel mechanism by which smoking may contribute to tumor pathobiology.

Effect of CDK 4/6 inhibition on anti-angiogenesis effect in gastric cancer

Sang Woo Cho[1], Woo Sun Kwon[2], Tae Soo Kim[2], Juin Park[2], Eun Seo Kim[1], Hyun Cheol Chung[3], Sun Young Rha[4]. *[1]Songdang Institute for Cancer Research, Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Songdang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Songdang Institute for Cancer Research, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University Health System, Seoul, Korea, Republic of,[4]Songdang Institute for Cancer Research, Brain Korea 21 PLUS Project for Medical Science, Division of Medical Oncology,*

Department of Internal Medicine, Yonsei Cancer Center, Yonsei University Health System, Seoul, Korea, Republic of

Angiogenesis, a hallmark of cancer, is a phenomenon in which new blood vessels are created from existing blood vessels. As the tumor grows, they secrete ligands such as vascular endothelial growth factor (VEGF). Therefore, anti-tumor effect could be achieved by preventing tumor-associated angiogenesis. In previous reports, CDK4/6 has been acknowledged to regulate VEGF transcription in addition to cell cycle regulation. There are few studies explaining the angiogenesis-related effects of CDK4/6 inhibitors in gastric cancer (GC). In this study, we aim to verify the anti-angiogenesis effect through CDK4/6 inhibition. First, we confirmed proliferation and angiogenesis in endothelial cells. Next, the change in VEGF expression induced by CDK4/6 inhibitor in GC cell lines was investigated. *In-vitro* angiogenesis research was conducted using human umbilical vein endothelial cells (HUVEC). Abemaciclib was used as a CDK4/6 inhibitor. To determine the efficacy of abemaciclib, HUVEC was treated with abemaciclib for 3 days and cell viability was assessed by CCK-8 assay. IC_{50} value was determined by the CalcuSyn software. Furthermore, tube formation assay, wound healing assay, cell cycle analysis and SA-β-gal assay were performed to explore effect of abemaciclib on HUVEC. VEGF-A expression was evaluated by ELISA. First, we identified direct anti-angiogenesis effect of abemaciclib on HUVEC. The IC_{50} value was 1.28 μM. At clinically achievable concentrations of abemaciclib (Cmax, 0.5 μM), HUVEC only showed a 20% growth inhibition. Abemaciclib did not suppress tube formation and migratory potential of HUVECs. However, abemaciclib induced a G1 arrest in HUVEC after 0.5 μM abemaciclib treatment for 24hr. To ensure whether the increase in the number of G1 phase cells is due to senescence, SA-β-gal assay was performed. The levels of SA-β-gal-positive cell staining in abemaciclib-treated group were higher than control, suggesting that abemaciclib induced cell senescence on HUVEC. While our results suggested that CDK4/6 inhibitor did not show direct anti-angiogenic effect on endothelial cells, we studied indirect anti-angiogenesis effect of abemaciclib in GC cell lines through regulation of VEGF transcription. Conditioned media of 49 GC cell lines had a wide range of VEGF secretion ranged from 0.146 to 22.676 ng/mL. (ave. 4.07 ng/mL). We have set the cut off of secreted VEGF as 10 ng/mL, at which

angiogenesis can be induced. There were four cell lines (4/49, 8.2%) whose VEGF concentrations were more than the angiogenesis-inducing VEGF concentration (10 ng/mL). Interestingly, 3 of these 4 GC cell lines demonstrated a decrease in VEGF secretion, following 0.5 μM abemaciclib treatment. In conclusion, we did not observe inhibition of angiogenesis in HUVEC. However, CDK4/6 inhibition can cause senescence in HUVEC, inhibit tumor growth, and indirectly induce anti-angiogenic effects in gastric cancer.

Chronic VEGF-C signaling exacerbates the progression of non-alcoholic steatohepatitis and hepatocarcinoma through endothelial VEGFR2 and VEGFR3

Seock-Won Youn[1], Jason W.-L. Eng[2], Bhairavi Swaminathan[1], Pamela Teneqexhi[1], Rahul Vadakath[1], Jan K. Kitajewski[1]. *[1]Department of Physiology and Biophysics, College of Medicine, University of Illinois at Chicago, Chicago, IL,[2]Division of Gastroenterology and Hepatology, Department of Medicine, University of Illinois at Chicago, Chicago, IL*

Obesity, aging, and metabolic diseases contribute to non-alcoholic fatty liver disease (NAFLD) that can progress to non-alcoholic steatohepatitis (NASH) due to ongoing inflammation and pathological angiogenesis. At present, NASH is a leading cause of cirrhosis, hepatocarcinoma cancer (HCC) and liver transplant within the United States. Pathological angiogenesis of liver sinusoidal endothelial cells (LSECs) is one of the hallmarks of liver injury that disrupt normal LSEC physiology. Therefore, strategies which target factors involved in LSEC dysregulation may improve the progression of hepatic diseases. Examination of a human tissue microarray identified increased levels of vascular endothelial growth factor-C (VEGF-C) in NASH livers compared with healthy individuals. Additionally, single nuclei RNA sequencing and immunofluorescent staining revealed that the receptors for VEGF-C, VEGFR2 and VEGFR3, are primarily expressed by the LSECs. Using murine models of NASH, we further investigated the role of VEGF-C during disease progression. Chronic over expression of VEGF-C by adeno-associated viral (AAV) infection in mice fed a western diet with carbon tetrachloride injections increased NASH progression compared with control AAV infected NASH

mice. Interestingly, overexpression of VEGF-C C156S, a variant of VEGF-C which exclusively binds to VEGFR3, resulted in significantly increased hepatic steatosis, but only minimal fibrosis. To determine whether blockade of VEGF-C signaling would delay disease progression, we administered lenvatinib, a tyrosine kinase inhibitor which primarily blocks VEGFR2 and VEGFR3 at low doses, to NASH mice. We discovered that low dose lenvatinib resulted in significantly decreased amount of fibrosis, steatosis, and tumor formation. Analysis of vehicle treated and lenvatinib treated livers by single nuclei RNA sequencing uncovered significant changes in endothelial cell genes associated with extracellular interactions and inflammation, as well as hepatocyte genes involved in lipid synthesis and metabolism. Taken together, these findings indicate that chronic VEGF-C production in NASH plays a role in promoting liver fibrosis and steatosis as well as HCC development, and that blockade of the downstream receptors for VEGF-C, VEGFR2 and VEGFR3, may be a promising therapeutic strategy to mitigate disease severity.

Heat shock proteins in immunosuppressive tumor microenvironment

Fulya Koksalar Alkan[1], Justin Wilson[1], Elayne Benson[1], Tulshi Patel[1], Virginia McEvoy[1], Nate Francois[1], Emma Nguyen[1], Hilmi Kaan Alkan[1], Ahmed Chadli[1], Jason Gestwicki[2], Hasan Korkaya[1]. *[1]Augusta University, Augusta, GA,[2]Pharmaceutical Chemistry, University of California, San Francisco, San Francisco, CA*

We previously demonstrated that upregulation of A20 in TNBC subtype in response to TNFα protects these cells from cytotoxic cell death by upregulating HSP70 protein and maintaining EMT/CSC phenotype. In contrast, luminal MCF7 or ZR75-1 cells display approximately 70% apoptosis when treated with TNFα. Overexpression of A20 in luminal cells not only protected them from TNFα-induced cytotoxicity by upregulating HSP70 and EMT/CSC phenotype, but also exhibited aggressive metastatic properties in mouse xenograft models.
We determined that TNFα-induced HSP70 upregulation in TNBC cell lines was dependent on A20 de-ubiquitinase activity that protected its degradation. Interestingly, our preliminary findings also suggested that A20 protein upregulation may be dependent on HSP70 chaperone activity. We

show significant overexpression of HSP70 and A20 proteins in 4T1 cell line when treated with TNFα or chemotherapeutic agents. However, A20 expression is significantly reduced when we block HSP70 activity in cells treated with TNFα or chemotherapeutic agents (Docetaxel-DTX or Doxorubicin-DOX). We proposed that A20 transcriptional upregulation upon TNFα stimulation leads to suppression of E3-ligase and accumulation of HSP70 which then stabilizes A20 with chaperone activity. Based on our reasoning, we performed the LIMBO chaperone binding assay which predicted A20 being the potential HSP70 client protein.
Furthermore, we show that A20/HSP70 pathway attracts tumor-infiltrating lymphocytes (TILs) while inducing the accumulation of immunosuppressive MDSCs in syngeneic mouse models. Interestingly, pulmonary DTCs as well as the immune infiltrates from 4T1 tumor-bearing mice exhibited significantly higher HSP70 expression. Therefore, targeting HSP70 will have a dual activity on tumors and MDSCs and thus it may potentiate the efficacy of immunotherapy in preclinical models of breast cancer. As previously reported, murine 4T1 tumors fail to respond to check point inhibitors. We reasoned that this may be an appropriate model to test the efficacy of HSP70 inhibitor, JG-231. Expectedly, there was no difference in tumor growth and metastasis between control and anti-PDL1 treated animals, however, combination of anti-PDL1 antibody with JG-231 and chemotherapy (cyclophosphamide-CTX) significantly reduced primary tumor growth (>10 fold) and eliminated metastasis. Collectively, our pilot experiments provide a strong rationale for testing our hypothesis and may lead to a rapid translation into the clinical utility.

TRPS1 inhibits angiogenesis in triple negative breast cancer down regulating JAG1 and TYMP genes involved in angiogenesis pathways
Liliana Guzman. *Breast Oncology, Houston Methodist Research Institute, Houston, TX*

Background**.** Triple-negative breast cancer (TNBC), the most difficult subtype to treat, is defined as estrogen receptor, HER2, and progesterone receptor negative. TNBC constitutes 10-20% of all breast cancer and has a higher rate of distal recurrence and a poorer prognosis than other breast cancer subtypes. Less than 30% of women with metastatic TNBC survive 5

years and almost all die from their disease despite adjuvant chemotherapy. Angiogenesis is a critical factor in the development of tumors and metastases in numerous cancers. Clinical trials with anti-angiogenic drugs showed to be inadequate, with moderate response rates and insignificant survival gains for patients. To understand the genetic forces involved in TNBC, we performed a transposon mutagenesis screen in Pten mutant mice that identified several candidate trunk drivers and progression genes. A major finding of our screen was the discovery and functional validation of, Trichorhinophalangeal syndrome type 1 (TRPS1), a GATA-like transcription factor, which functions as a transcriptional repressor or activator, depending on cell type, stage of development, or pathological conditions. Based on this data, we explored the role of TRPS1 in angiogenesis.
Methods and Results. Tube formation and sprouting assays were performed using overexpression and inactivation of TRPS1 in MDA-MD-231 and HCC70 cells, respectively. Interestingly, inactivation of TRPS1 expression accelerates tube formation structures compared to the vector control as well as cell branching in the sprouting assay. Overexpression of TRPS1 prevents tubing and branching formation in vitro assays. Moreover, immunohistochemistry staining of CD31 detected a reduced number of blood vessels in MDA-MB-231 tumor xenografts overexpressing TRPS1, and an increase of angiogenic vasculature in HCC70 TRPS1-shRNA tumor xenografts. In vitro and in vivo assays demonstrate the role of TRPS1 in tumor angiogenesis. Furthermore, human ChIP qPCR angiogenesis array identified 10 top candidate genes potentially regulated by TRPS1 transcription factor. Of these candidates, JAG1 and TYMP showed to have a higher fold enrichment compared to other angiogenic related genes. Finally, we validated its direct functional binding by using luciferase reporter assay, such demonstrated that TRPS1 is a direct transcriptional regulator of JAG1 and TYMP.
Conclusion. TRPS1 is a tumor suppressor involved in the mechanisms regulating tumor angiogenesis by repressing the expression of JAG1 and TYMP genes in TNBC.

Evaluating Tumor Progression via 3D and Spatial Approaches

Leveraging organotypic brain slice models to enhance adoptive cellular therapies

Alexandra Reid[1], Dan Jin[2], Bayli DiVita-Dean[2], Laura Falceto-Font[2], John Figg[2], Connor Francis[2], Catherine Flores[2]. *[1]University of Florida, Gainesville, FL,[2]Neurosurgery, University of Florida, Gainesville, FL*

Glioblastoma (GBM) is an incredibly aggressive and prevalent primary CNS tumor with dismal survival outcomes. GBM's intra-tumor heterogeneity and lack of anti-tumor immune cell infiltration have proved to be formidable challenges to the development of effective therapies. These hurdles may be overcome by garnering a better understanding of the cell-cell interactions occurring within the tumor microenvironment (TME). Accounting for the complexity and the spatial orientation of the components within the TME may offer insight into the multitiered layers of immunosuppression capitalized on by GBM tumors, thus elucidating the factors responsible for poor response to therapy and uncovering potential therapeutic targets that may offer more favorable therapeutic results for immunotherapies. Current in vitro and in vivo models, however, sorely limit our ability to probe these distinct attributes while preserving the intricate nature of the TME. To bridge this gap, we have devised a novel organotypic brain slice culture (BSC) model using tumor-bearing C57BL/6J mice, allowing us to characterize the tumor milieu in situ. We have identified infiltration of myeloid-derived suppressor cells (MDSC) and microglia polarized to the M2 anti-inflammatory phenotype within the TME. Leveraging this platform, we sought to define further the factors contributing to the dynamic impacts of GBM immunosuppression, such as the tolerogenic response in dendritic cells (DC) upon interaction with the TME. We have demonstrated outcomes similar to those seen in vivo following the introduction of DCs to tumor-bearing BSCs, further supporting the physiological relevancy of this model, and have since worked to unravel elements responsible for this response.

Microphysiological vascularized solid liver tumor model for drug and cell therapy

Jyothsna Vasudevan[1], Ragavi Vijayakumar[2], Jose Antonio Reales-Calderon[2], Maxine Sin Yee Lam[2], Jin Rong Ow[2], Joey Aw[2], Damien Tan[2],

Giulia Adriani[3], Andrea Pavesi[2]. *[1]Mechanobiology Institute, National University of Singapore (NUS), Singapore, Singapore,[2]Institute of Molecular and Cell Biology, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore,[3]Singapore Immunology Network, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore*

Development of efficacious therapeutic strategies against solid tumors is limited by the lack of pre-clinical models that can reliably predict treatment outcomes in patients. This is primarily because models often do not accurately reflect the complexity of the tumor microenvironment (TME). The TME consists of vasculature, stromal cells and immune cells that can promote tumor resistance or prevent targeted drug and cell therapy. Here, we developed an in vitro vascularized liver tumor model in a microfluidic device to evaluate drug delivery and immunotherapy approaches. The model consists of a tumor spheroid surrounded by a perfusable self-organized vasculature bed with physiologically relevant permeability. Sorafenib (Nexavar) efficacy was evaluated by assessing tumor spheroid viability, quantified by the loss of fluorescence signal. The presence of vasculature showed enhanced cytotoxicity, highlighting the importance of tumor-vascular interactions for testing therapeutic efficacy. Engineered immune cells (chimeric antigen receptor (CAR) T-cell and transiently expressing T-cell receptors (TCR)) were introduced into the model to demonstrate immunotherapy validation. Our results showed that the engineered immune cells were more effective at infiltrating the tumor spheroid without a vasculature but were more cytotoxic in the presence of the vasculature. By removing the cultured microtissue from the device and performing digital spatial transcriptomics on standard paraffin-embedded sections, we identified known and novel genes involved in creating a pro-tumorigenic microenvironment. This platform can be utilized to model critical features of the in vivo TME, providing better predictability of drug responses, with potential applications towards personalized medicine.

#4613

Inhibition of myosin II in triple-negative breast cancer cells limits macrophage recruitment in a 3D environment

Youngbin Cho, Ruxuan Li, Ioannis Zervantonakis. *Bioengineering, University of Pittsburgh, Pittsburgh, PA*

Among all breast cancer subtypes, triple-negative breast cancer (TNBC) exhibits the least favorable outcomes with a complex tumor microenvironment that facilitates metastatic progression. Remodeling of the extracellular matrix at the tumor invasive front is associated with increased cancer cell motility and poor outcomes. Myosin II, a key cytoskeletal regulator, plays a central role in cancer cell metastatic potential. In the clinic, high expression of myosin II in breast tumors has been associated with distant metastasis and lower survival rates. Interestingly, breast tumors overexpressing myosin II exhibited a higher density of tumor-associated macrophages and an immunosuppressive microenvironment. However, the relationship between myosin II activation in TNBC cancer cells and macrophage recruitment remains poorly understood. Here we employed a novel 3D microfluidic model of tumor-macrophage co-culture to study macrophage infiltration toward cancer cells with high spatiotemporal resolution. Using a panel of TNBC cell lines we found that high myosin II expression in cancer cells correlated with higher macrophage recruitment in a 3D matrix. Pharmacologic or genetic inhibition of myosin II reduced macrophage recruitment. Furthermore, using our microfluidic devices, we controlled the spatial distribution of cancer cells in a 3D matrix and separated the role of cancer cell-secreted paracrine factors from cancer cell-mediated matrix remodeling on macrophage recruitment. Analysis of matrix remodeling over time revealed that targeting myosin II in cancer cells limited the establishment of migratory tracks that facilitated macrophage recruitment. In sum, our studies revealed the critical role of cancer cell-driven matrix remodeling in promoting macrophage infiltration that can be therapeutically targeted to reverse the establishment of an immunosuppressive microenvironment.

Investigating lymphatic vessel remodeling and anti-tumor immunity in pancreatic cancer using tumor-on-chip and mouse models

Anna Maria Kolarzyk, Conor Loy, Renhao Lu, Iwijn De Vlaminck, Deborah Fowell, Esak Lee. *Cornell University, Ithaca, NY*

Pancreatic ductal adenocarcinoma (PDAC) remains one of the deadliest tumors in humans. PDAC has an immunosuppressive tumor

microenvironment, constituting for poor immunotherapy outcomes. Lymphatic vessels (LVs) transport leukocytes and antigens from tumor peripheries to draining lymph nodes (dLNs) for activation of anti-tumor immune responses. It is believed that impairment of the lymphatic function may result in delayed and ineffective immune activation against tumors. In this study, we created a three-dimensional (3D) tumor-on-chip model to examine phenotypical and functional changes in 3D engineered LVs, composed of human primary lymphatic endothelial cells (LECs) in co-culture with PDAC cells. Our *in vitro* studies revealed that PDAC cells induce lymphangiogenesis and tighten cell-cell junctions in LECs, forming "zipper-like" LEC junctions, compared to control LECs with "button-like" junctions. We introduced 70kDa dextran into the LV lumens and showed PDAC-induced zippering of junctions decreased vessel permeability. These results led us to hypothesize that altered LEC junctions may affect fluid drainage into the LVs *in vivo*. We inoculated PDAC cells into the mouse ear pinnae and performed whole-mount immunostaining and lymphatic drainage experiment by injecting Evans blue into the ears and measured the remained Evans blue in the ears. In the ear experiments, inoculated PDAC cells affected host LVs with originally button-like junctions to become zipper-like and impede lymphatic drainage. To identify a potential signaling pathway that may be responsible for LEC junction zippering, we used phospho-kinase arrays and discovered that PDAC cells induced LECs to increase phosphorylation of GSK3-β, JNK kinases, and enhanced the total protein level of β-catenin, implying that PDAC cells turned on the WNT signaling in LECs. In preliminary screening, we treated LECs co-cultured with PDAC cells with WNT-C59, an WNT inhibitor that blocks secretion of all WNT ligands, which resulted in decreased number of LV sprouting and less contractile actin-cytoskeleton in LECs. It is critical to know which molecules were secreted by PDAC cells and influenced the WNT signaling in LECs. With that in mind, we plan to perform mass spectrometry with PDAC-conditioned media to identify PDAC-specific secretome; and run RNA-seq with LECs isolated from mouse ears with or without PDAC to investigate molecular basis of the WNT activation in LECs and LV remodeling. Finally, we plan to examine the egress of leukocytes from primary PDAC tumor site, T cell activation in tumor-dLNs, and PDAC tumor growth with or without WNT inhibition in Kaeda mice. The identity and function of PDAC-egressed immune cells, and those which stayed

within the primary tumor will enhance our understanding of the roles of LVs in orchestrating anti-tumor immunity in PDAC.

Differential immune characteristics and anti-PD-1-induced reinvigoration capacity of tumor-infiltrating lymphocytes according to ProMisE classifier in endometrial cancer

Jung Chul Kim[1], Junsik Park[2], Yong Jae Lee[1], Sunghoon Kim[1], Sang Wun Kim[1], Jung-Yun Lee[1]. *[1]Obstetrics and Gynecology, Yonsei University College of Medicine, Seodaemun-gu, Korea, Republic of,[2]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seodaemun-gu, Korea, Republic of*

Endometrial cancer (EC), one of the most common gynecological malignancies, has been gradually increasing worldwide. The Cancer Genome Atlas endometrial collaborative project discovered 4 distinct prognostic genomic subtypes, and the Proactive Molecular Risk Classifier for Endometrial Cancer (ProMisE) was developed: *POLE*-mutated, mismatch repair deficiency (MMR-D), non-specific molecular profile (NSMP), and p53-abnormal (p53abn). In the era of immunotherapy, immune checkpoint inhibitors (ICIs) become a definite management of EC, both as single agent or in combination with other targeted agents. However, the characteristics of the tumor immune microenvironment according to molecular classification in EC are not well known. This study was conducted to identify distinct immune properties of tumor infiltrating lymphocytes (TILs) according to molecular classification in EC and find optimal therapeutic targets in each molecular subtypes. We isolated peripheral blood mononuclear cells (PBMCs) and TILs from 81 patients with EC. The expression of immune checkpoint receptors and T-cell transcription factors of TILs were examined using flow cytometry. Sixty-six patients were evaluated according to the ProMisE algorithm based on sequencing for the presence of *POLE* mutations, immunohistochemistry for MMR proteins and p53 (*POLE*-mut, n=6; MMR-D, n=17; p53abn, n=20; NSMP, n=23). Tumors were categorized into one of the four molecular subtypes. TILs were *ex vivo* stimulated with anti-CD3 in the presence of anti-PD-1, and their proliferation was assessed to predict ICI-induced reinvigoration capacity of CD8 TILs. Comparing T-cell transcription factors

(TCF-1 and TOX), CD8 TILs showed higher expression of TOX, and lower expression of TCF-1. When comparing the immune characteristics of TILs according to molecular subtypes, Tregs of *POLE*-mut showed significantly lower expression of CTLA-4 and Ki-67 than that of MMR-D. In addition, CD8 TILs of MMR-D showed higher expression of immune checkpoint receptors, including PD-1, CTLA-4, and TIM-3, and lower expression of TCF-1 than those of p53abn. $CD8^+$TILs of p53abn showed significantly higher expression of CD226 than those of MMR-D. In particular, the frequency of antigen reactive $CD39^+CD103^+$CD8 T cells significantly lower in p53abn than in MMR-D. CD8 TILs of NSMP showed higher expression of TOX than those of MMR-D. In *ex vivo* T cell proliferation assay (n=49), 80.0% POLE-mut (4 of 5), 46.2% MMR-D (6 of 13), 35.7% p53abn (5 of 14) and 35.36% NSMP (6 of 17) showed enhanced proliferation of CD8 TILs upon anti-PD-1 treatment. In endometrial cancer, TILs showed distinct immune properties according to ProMisE classification. Further study is needed to develop optimal treatment targets for the p53abn and NSMP subtype, which is non-immunogenic and hardly reinvigorated by ICIs.

#4616

Automated multiplex immunofluorescence enables single cell analysis of tumor stroma

François Rivest[1], Victor de Gautard[1], Vytautas Navikas[1], Nadine Nelson[2], Bastian Nicolai[1], Joanna Kowal[1], Saska Brajkovic[1]. *[1]Lunaphore Technologies SA, Tolochenaz, Switzerland,[2]Abcam, Cambridge, United Kingdom*

Background**:** The tumor microenvironment (TME) consists of malignant cells and supporting non-malignant cellular and non-cellular components that form the tumor stroma. The tumor stroma plays an important role in tumor progression and has emerged as a modulator of anti-tumor immunity (Salmon et al., Nat Rev Cancer 2019) and responses to therapy (Hirata and Sahai, Cold Spring Harb Perspect Med 2017). As such, several therapeutic approaches have recently been developed to target stromal cells as anti-cancer treatments (Valkenburg et al., Nat Rev Clin Oncol 2018, Bejarano et al., Cancer Discov 2021). In addition, the composition of the TME has been recognized as a prognostic factor for survival in cancer patients (Pagès et

al., Oncogene 2011). Current protein-based approaches to characterize and better understand the cell composition of the tumor stroma face many limitations such as reagent availability and lengthy protocols. In this study, we identified a list of 22 markers to characterize non-tumoral immune cells, fibroblasts and endothelial cells in the TME, in a single tissue slide. We propose an approach that overcomes reagent incompatibility and opens new avenues of research of tumor stroma.
Method: Multiorgan Tumor Microarray (TMA) was interrogated with a sequential immunofluorescence (seqIF™) panel encompassing protein markers enabling characterization of TME. A 22-plex panel was created based on expanding an already established 13-plex panel (CD3, CD4, CD8, CD11c, CD20, CD45, CD56, CD68, aSMA, FoxP3, Ki67, PD1, PD-L1) by adding 9 additional antibodies (CD11b, CD14, CD31, CD47, CK, FAP, LaminB1, SIRPα, Vimentin). Hyperplex immunofluorescent staining was performed using automated staining-imaging COMET™ platform generating ome-tiff images containing 25 layers: DAPI, 2 autofluorescent and 22 marker channels. Postprocessing of images was done with HORIZON™ image analysis software.
Results: We established a panel of 22 markers that can be analyzed simultaneously on a single tissue slide despite limited variability in primary antibody species. Using seqIF™ protocol allowed the study of colocalization and co-expression of markers not compatible to study simultaneously in the traditional immunofluorescence approach. Our hyperplex data revealed distinct composition of the stromal compartment between different tumor types, highlighting high heterogeneity in the tissue composition and stromal architecture.
Conclusion: COMET™ platform enabled studying in detail TME components and highlighted heterogeneity of tumor stroma across different tissue types. SeqIF™ protocol lifted the limitation imposed by same species antibodies and allowed simultaneous interrogation of markers' expression preserving their spatial relationship.

#4617

A complete pipeline for high-plex spatial proteomic profiling and analysis on the cosmx^{tm} spatial molecular imager and atom^{tm} spatial informatics platform

Tien Phan-Everson, Zachary Lewis, Giang Ong, Yan Liang, Emily Brown, Liuliu Pan, Aster Wardhani, Mithra Korukonda, Carl Brown, Dwayne Dunaway, Edward Zhao, Dan McGuire, Sangsoon Woo, Alyssa Rosenbloom, Brian Filanoski, Rhonda Meredith, Kan Chantranuvatana, Brian Birditt, Hye Son Yi, Erin Piazza, Jason Reeves, John Lyssand, Vik Devgan, Michael Rhodes, Gary Geiss, Joseph Beechem. *NanoString Technologies, Inc., Seattle, WA*

Detecting and analyzing large numbers of proteins using whole-slide imaging is critical for a comprehensive picture of immune response to cancer. Many existing approaches for high-plex proteomics face issues around simplicity, speed, scalability, and big data analysis. Here, we present an integrated workflow from sample preparation through downstream analysis that addresses many key concerns around high plex proteomics. The CosMx Spatial Molecular Imager (SMI) and AtoMx Spatial Informatics Platform (SIP) comprise of a turnkey, end-to-end workflow that efficiently handles highly multiplex protein analysis at plex sizes exceeding 110 targets. We demonstrate an extension of our commercially available 64-plex human immuno-oncology panel to higher numbers of targets and show how the cloud computing-enabled AtoMx SIP allows flexible construction of analytic pipelines for cell typing and spatial analyses.

The CosMx protein assay uses antibodies conjugated with oligonucleotides, which are detected using universal, multi-analyte CosMx readout reagents. The CosMx Human Immuno-oncology panel was optimized to comprehensively profile lymphoid and stromal lineages within the tumor microenvironment as well as markers of cancer signaling and progression. Each CosMx SMI antibody was validated on multi-organ FFPE tissue microarrays covering prevalent solid tumor types with matched controls, and 52 human FFPE cell lines, including overexpression lines for key targets such as GITR, CD278, PD-L1, and PD-1. CosMx SMI uses a deep learning algorithm to segment whole cells and a semi-supervised algorithm to classify cell types. The AtoMx SIP provides full analysis support, including a whole-slide image viewer, and methods for performing built-in or fully customizable analyses for cell typing, ligand-receptor analysis, neighborhood analysis and spatial differential expression.

Within the cancer sample profiled, we performed in-depth single-cell proteomic profiling across different cell populations. We detected TLS,

characterized TLS maturation, and identified immune interactions with the tumor microenvironment. The CosMx SMI assay profiled the composition and spatial organization of infiltrating immune cells within and around the tumor microenvironment. We found that markers of T cell activation and exhaustion varied across the tumor landscape.
CosMx SMI is a high-plex spatial multi-omics platform that enables detection of more than 110 proteins at subcellular resolution in real-world FFPE tissues. The extensibility of the CosMx protein assay to large numbers of protein targets and our flexible, scalable bioinformatic platform provides a straightforward and robust solution for comprehensive immune phenotyping with full spatial context.
FOR RESEARCH USE ONLY. Not for use in diagnostic procedures.

Biomarkers of functionally active tertiary lymphoid structures in human breast cancer

Doïna Sofronii[1], Francine Padonou[1], Mireille Langouo[1], Noemie Thomas[1], Anais Boisson[1], Alexandre De Wind[2], Denis Larsimont[2], Ahmad Awada[3], Soizic Garaud[4], Karen Willard-Gallo[1]. *[1]Molecular Immunology Laboratory, Jules Bordet Institute, Free University of Brussels (ULB), Brussels, Belgium,[2]Department of Pathology, Jules Bordet Institute, Free University of Brussels (ULB), Brussels, Belgium,[3]Department of Medical Oncology, Jules Bordet Institute, Free University of Brussels (ULB), Brussels, Belgium,[4]B Lymphocytes, Autoimmunity and Immunotherapies, Inserm U1227, Brest, France*

The clinical relevance of tumor infiltrating lymphocytes (TIL) in breast cancer (BC) is now widely accepted and being implemented in clinical practice. Our lab previously demonstrated that 60% of BC organize some of their TIL in tertiary lymphoid structures (TLS). TLS have been detected in a wide variety of solid tumors with their prognostic value and importance in the response to immunotherapy increasingly accepted. Reliable biomarkers to identify and characterize TLS and their immune activities in tumors are needed. The specific aim of this project was to perform a comprehensive analysis across the spectrum of TLS states to identify biomarkers associated with active and inactive TLS, where the former are associated with functional anti-tumor immunity and improved responses to treatment and

long-term survival. This study analyzed FFPE tissues from 38 primary untreated HER2+ and triple negative (TN) BC patients. Patients were divided into two groups based on a TLS score evaluating CD3/CD20 and PD-1/Ki-67 dual IHC-stained tumor tissues: 1) BC containing a majority of active TLS (tumors with only active TLS have never been observed), defined by the presence of a germinal center (GC^{pos} ; $Ki\text{-}67^{+}$ follicular B cells) and 2) BC with only inactive TLS (GC^{neg} ; $Ki\text{-}67^{-}$ follicular B cells). Controls included normal breast tissues, BC without TLS and lymphoid tissues (reactive tonsils for GC^{pos} and spleens for GC^{neg} TLS). RNA extracts from microdissected tissues (N=100), including active TLS, inactive TLS and lymphoid B follicles, were sequenced. DESeq2 and CIBERSORT were employed to quantify differentially expressed genes and immune cell subpopulations, respectively. Gene Set Enrichment Analysis was used for additional data interpretation and pathway identification. Tumors from patients with active TLS were characterized by increased naïve and plasma B cell TIL compared to tumors with only inactive TLS. Preliminary analysis of the differentially expressed genes in active TLS (vs inactive TLS) revealed upregulation of key B cell differentiation, somatic hypermutation and class switch recombination genes, which paralleled their respective lymphoid controls. These gene upregulations were linked with a GC presence in active TLS. A specific set of immunoglobulin genes were also differentially expressed in active TLS. Continued analysis of the TLS data, including their cellular composition, location, maturation and functionality, along with data confirmation (RT-PCR and multiplex IHC), and assessment of their functional and clinical relevance is ongoing. Our preliminary results suggest that active B cell differentiation and Ig production contribute to TLS functionality. In lymphoid tissues, the GC plays important roles in orchestrating the molecular and cellular programs of humoral immunity. Our data suggest that active GC-containing TLS foster an immune microenvironment in BC that favors positive clinical outcomes.

Spatial analysis of the immunosuppressive tumor microenvironment in brain cancer applying a novel multiplex immunofluorescence panel

Yvonne Reiss[1], Jadranka Macas[1], François Rivest[2], Victor de Gautard[2], Saska Brajkovic[2], Bastian Nicolai[2], Tatjana Starzetz[1], Kathleen Sommer[1], Pinar Cakmak[1], Jonathan Schup[1], Jennifer H. Lun[1], Karl H. Plate[1].
[1]Institute of Neurology (Edinger Institute), Goethe University, Frankfurt, Germany,[2]Lunaphore Technologies, Tolochenaz, Switzerland

Glioblastoma (GBM) and brain metastases (BM) account for >70% of all brain cancers. The annual incidence averages to 10-17 cases per 100.000 person (~ 3 cases for GBM and 7-14 for BM), resulting in 45.000-77.000 new cases in the European Union alone. The standard of care for GBM includes maximal surgical resection followed by radiation and chemotherapy with temozolomide, whilst whole brain irradiation or surgical removal with or without chemotherapy are used for BM. In spite of therapy, the median overall survival remains < 6 months for BM, and 16 months for GBM, suggesting brain cancers as one of the most therapy-resistant tumors. Despite the emergence of novel therapeutic strategies, such as anti-angiogenic therapy, targeting myeloid cells or checkpoint immunotherapy, no significant improvement in overall survival of brain cancer patients was observed. Several studies have suggested the resistance to therapy in brain cancers is largely attributed by the presence of an immunosuppressive brain tumor microenvironment.
To investigate the spatial architecture of the tumor microenvironment in BM derived from lung and breast cancers, we employed the Lunaphore 13-plex immune-oncology (IO) Core Panel, consisting of clinically relevant IO biomarkers (CD3, CD4, CD8, CD45, FoxP3, PD1, PD-L1, CD11c, CD20, CD56, CD68, aSMA and Ki-67) for multiplex immunofluorescence (mIF) assays. These findings were then compared to isocitrate dehydrogenase-wildtype glioblastoma, which is a T-cell-poor cancer that is also characterized by an immunosuppressive tumor microenvironment. Further, the IO Core Panel was expanded with previously established antibodies targeting myeloid, blood-brain barrier and tumor cell markers in a proteomic workflow on COMET™, a fully automated, sequential immunofluorescence (seqIF™) platform.
Comprehensive mapping of the GBM microenvironment and BM confirmed previous observations obtained by bulk and single cell RNA sequencing analysis that described profound differences in the tumor microenvironment of BM versus GBM. In contrast to GBM, anti-tumor

immunity in BM was increased, whereas immunosuppressive cells remained unchanged between the two. Of note, T- and B-cells were not evenly distributed within the tumor tissue, providing an additional level of spatial information that would have been missed by bulk RNA or proteomic analyses.
Our study is the first to demonstrate a successful application of Lunaphore's IO core panel on GBM and BM samples. This highlights potential future use in the development of tools for personalized medicine for GBM and other tumor types.

Automated multiplex immunofluorescence workflow to interrogate the cellular composition of the tumor microenvironment

Vytautas Navikas, Quentin Juppet, Samuel Aubert, Benjamin Pelz, Joanna Kowal, Diego Dupouy. *Lunaphore Technologies SA, Tolochenaz, Switzerland*

Background**:** The tumor microenvironment (TME) is a constantly changing niche due to dynamic interactions between tumor cells and their surroundings. Recently, it became evident that a better understanding of the TME is needed to target the disease more accurately (Binnewies et al., Nat Med 2018; Vitale et al., Nat Med 2021). Spatial hyperplex immunofluorescence enables the visualization of cellular and non-cellular tissue components simultaneously. However, the increasing number of biomarkers detected by spatial proteomics quickly escalates the complexity of images and renders their interpretation challenging. Extracting quantitative data from images remains a challenge as it requires extensive training and experience in data analysis. Additionally, inferring cellular interactions and dependencies from spatial assays is an important milestone that needs to be overcome with image analysis approaches. Here, we present an end-to-end solution that combines automated hyperplex execution with image data extraction to study the spatial composition of TME.
Methods: Sequential hyperplex immunofluorescence was performed on COMET™ on an FFPE Breast Tissue Microarray (TMA), generating images containing 42 layers: nuclear DAPI, tissue autofluorescence, and 39 single layers for biomarkers. All layers were delivered as a single ome.tiff

file and processed using HORIZON™ image analysis software in combination with downstream statistical analysis. The tissue composition was interrogated with the use of an in-house trained nuclei detection algorithm (Schmid et al., MICCAI 2018; Weigert et al., WACV 2020), in-house developed image artifact exclusion approach, and spatial analysis based on a Squidpy workflow (Palla G. et al., Nat Meth 2022).
Results: We interrogated the composition of breast tumor tissues (n=9). Our in-house developed pipeline allows for filtering out both autofluorescent objects and segmentation artifacts based on the tissue autofluorescence and morphological features. Once the quality of segmented cell detection was assured, over 20 different cell phenotypes were identified by unsupervised Leiden clustering and visualized using UMAP dimensionality reduction method. It revealed several myeloid cell subsets highlighting their heterogeneous phenotypes including, but not limited to, immunosuppressive neutrophils and macrophages. Contrastingly, the uniform presence of T regulatory lymphocytes was detected in majority of cores and their co-occurrence with CD14+CD163+ macrophages was observed.
Conclusion: Here, we showcased an innovative automated workflow that highlights the ease of adoption of multiplex imaging to explore TME composition at single-cell resolution using simple workflow: slide in-data out. This workflow is easily transferrable to various cohorts of specimens to provide a toolset for spatial cellular dissection of the cancer milieu.

Distinct spatial and molecular maps in the tumour microenvironment of resistant melanoma patients treated with checkpoint inhibitor immunotherapy

Camelia Quek[1], Aditya Pratapa[2], Ines Pires da Silva[1], Ghamdan Al-Eryani[3], Aaron Mayer[4], Nenad Bartonicek[5], Kate Harvey[3], Oliver Braubach[2], Robyn P.M. Saw[1], Jonathan Stretch[1], Kerwin F. Shannon[1], Alexander M. Menzies[1], Richard A. Scolyer[1], Georgina V. Long[1], Alexander Swarbrick[3], James S. Wilmott[1]. *[1]Melanoma Institute Australia, Sydney, Australia,[2]Akoya Biosciences, California, CA,[3]Garvan Institute of Medical Research, Sydney, Australia,[4]Stanford University, California,*

CA,[5]Melanoma Institute Australia, Garvan Institute of Medical Research, Australia

Background: Checkpoint-based immunotherapies can achieve durable clinical responses in a variety of advanced cancers, including melanoma. However, clinical responses are not universal and there is still a substantial gap in understanding the mechanistic insights of immunotherapy resistance. This study aims to better understand patients' resistance to immune checkpoint therapies by dissecting and tracing individual tumour and immune cell clones.
Methods: Melanoma tumour dissociates and lesion matched formalin-fixed paraffin-embedded tissue samples were collected from patients with advanced melanoma receiving ipilimumab in combination with nivolumab; 2 patients were long-term responders, 2 had innate resistance and 1 acquired resistance. The molecular characteristics and spatial cellular relations associated with tumour and immune subsets in response to treatment were identified using single-cell indexing of transcriptomes and epitopes by sequencing and CODEX (CO-Detection by indEXing) multiplexed tissue imaging. Integration of spatial and molecular information was performed by combining reference-based phenotyping, Louvain clustering, and a mutual nearest neighbours-based transfer learning algorithm.
Results: Pre-treatment melanoma biopsies from 5 patients (3 responding and 2 non-responding) along with a subsequent acquired resistance biopsy from an initially responding patient were analysed. Comparisons of cellular phenotypes identified higher proportions of gamma delta T cells (1.98% versus 0.2%) and enriched memory T cell profiles (CD3E, CD44, CD45RO, CD8) in responding compared to non-responding pre-treatment biopsies. Fibroblast from non-responding lesions overexpressed stromal related cytokine, IL1A (log2 fold change (FC) = 3.3) and CXCL1 (log2 FC = 1.4), which were enrichment at the tumour margin compared to responding lesions. Comparisons of a patient's pre-treatment biopsy that initially responded to a subsequent progressing biopsy with acquired resistance had altered expression of transcript factor, ZFX (log2 FC = -1.59; adjusted p = 0.0119), and MBD2 (log2 FC = -1.5; adjusted p = 0.0225) within the patient's memory T-cells.

Conclusion: The combination of high dimensional single cell transcriptomics and spatial tissue imaging are effective tools to identify specific changes in cell phenotypes, intracellular signalling, and spatial location. This analysis identified reduced memory T cells, increased fibroblast, and altered cellular signalling were associated with resistance to immunotherapies.

Tumor microenvironment differences between lung cancer subtypes revealed by spatial transcriptomics

Matthew D. Wilkerson[1], Savannah Kounelis-Wuillaume[1], Camille Alba[2], Teri J. Franks[3], Martin L. Doughty[1], Robert L. Kortum[1], Robert F. Browning[1], Clifton L. Dalgard[1], Craig D. Shriver[1]. *[1]Uniformed Services University, Bethesda, MD,[2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD,[3]Joint Pathology Center, Department of Defense, Silver Spring, MD*

Lung cancer is a leading cause of cancer deaths worldwide and has complex underlying genetic drivers, subtypes and immune cell types. Molecular analysis of bulk tumors has repeatedly identified key somatic driver genes and subtypes in lung cancer. However, these key molecular strata of bulk lung tumors still contain significant heterogeneity which if characterized in finer detail may reveal new tumor microenvironment factors and lead to improved patient prognostication and therapy options. Here, we sought to compare the tumor microenvironments of lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC) through spatial transcriptomics. Using four frozen lung tumors and three with replicated sections (n = 7), we sequenced spatial transcriptomes using the 10X Visium platform and illumina sequencing to measure up to 5,000 latticed-spots throughout 6.5 mm^2 of the tumor surface area. Data analysis revealed a large number of latticed-spots per tumor (median 3,486) with a large number of genes detected per median spot (tumor median 4,427). Through unsupervised clustering of spots in each tumor, we found between 8 and 10 clusters per tumor with distinct pathway activities, including multiple immune-enriched clusters per tumor (range: 3-5). Immune-enriched clusters in one LUAD tumor displayed a spatial shape consistent with tertiary lymphoid structures (TLS). Concordantly, this cluster overexpressed both B cell and T cell

pathways and as well as a TLS signature from liver cancer. Interestingly by bulk tumor RNA analysis, this TLS+ tumor was classified to be in the terminal respiratory unit expression subtype, which is an immune-mild bulk subtype. This supports that the TLS signal can be a unique property of spatial expression in lung cancer that may be unobservable by bulk tumor RNA sequencing. Then to compare global spatial heterogeneity among tumors, we calculated an index of expression spatial continuity and found LUSC tumors to have more contiguous expression patterns than LUAD tumors (mean 0.60 vs 0.54). We also quantified expression diversity across all tumor latticed-spots and found that LUSC tumors had greater values compared to LUAD tumors (mean 0.37 vs 0.27). Together, our results suggest that LUSC has a more contiguous and heterogeneous tumor expression microenvironment than LUAD. TLS are predictive of immune checkpoint inhibitor response in many other tumor types, and our results suggest that spatial transcriptomics may also identify this responsiveness in lung cancer. Future, larger cohorts of lung tumors are needed to determine recurrent spatial properties associated with patient outcome and treatment response. The views expressed in this abstract are solely of the authors and do not reflect the official policy of the Departments of Army/Navy/Air Force, Department of Defense, USUHS, HJF, or U.S. Government.

Single-cell spatial proteomic analysis of the tumor microenvironment in treatment-naive NSCLC samples with immunotherapy treatment and response data

Marie Cumberbatch[1], Geoffrey Ivison[2], Amy Lam[2], Aaron Mayer[2], Milan Bhagat[1]. *[1]TriStar Technology Group LLC, Washington DC, DC,[2]Enable Medicine, Menlo Park, CA*

The tumor microenvironment (TME) represents a complex network comprising a variety of cell types including immune, stromal, and extracellular elements in addition to malignant tumor cells. Growing evidence suggests that the spatial relationships of these components influence tumor progression and response/resistance to immunotherapeutic agents. However, the precise mechanisms driving this relationship to clinical outcomes remains poorly understood. This is in part because generating comprehensive spatial datasets has only recently been made

possible due to innovations in instrumentation, laboratory techniques, and data storage and processing. Thus, there has been little integration between various types of -omics datasets with spatial data. Here, we present a workflow for analyzing multi-omic data of the TME with the aim of providing mechanistic insights into signatures of response to immunotherapy. The workflow starts with data generation and proceeds through cell segmentation, quality filtering, phenotype assignment through unsupervised clustering, analysis of pairwise interactions and higher order multicellular structures (i.e., "neighborhoods"), and finally association with patient clinical and molecular data allowing for meaningful comparisons to be made. This analysis can be performed through the Enable Medicine Cloud Platform, a framework that facilitates the association of a multitude of data types to samples, rapid processing of multiplex images to deliver single cell spatial proteomic data, and graphical interfaces for each analysis step. To demonstrate the utility of this workflow, we generated spatial proteomic data for a tissue microarray (TMA) comprising a cohort of treatment naïve NSCLC samples (n=42) with second-line immune checkpoint inhibitor-treatment and clinical follow-up information. The spatial proteomics data was generated with the Akoya PhenoCycler-Fusion multiplexed tissue imaging platform, with an optimized panel of 51 oligonucleotide-conjugated antibodies covering a wide variety of immune, epithelial, stromal, and malignant cell markers developed by Enable Medicine. This proteomic data was then integrated with GeoMX DSP, bulk RNAseq, and clinical information using the Enable Platform. This framework for analysis allows for the comprehensive integration of both clinical and biological parameters to enable biomarker discovery and insight into signatures of response to immunotherapy. Deciphering the tumor microenvironment at single-cell resolution using a workflow combining RNA transcript and protein detection with Brightplex®, a sequential chromogenic multiplex assay

Alex Trinh, Marion Olive, Aurélie Collignon, Maité Chamourin, Georgia Culley, Clemence Jaume, Vanina Leca, Assil Benchaaben, Giovanni

Bussotti, Alboukadel Kassambara, Jerome Galon, Jacques Fieschi.
Veracyte, Inc., Marseille, France

Tumor-infiltrating immune cells play an important role against cancer and are critical to control tumor growth and spread. Immunotherapy and immune checkpoint blockade, which aim to reinvigorate exhausted T cells have revolutionized cancer therapy. Despite inducing long-term response in many cancer types, these therapies remain ineffective for a majority of the patients. A better understanding of the tumor microenvironment, and in particular the characterization of immune cells and other stromal cells, along with their abundance and distribution, may help to better stratify patients and understand mechanisms of resistance to immunotherapy. Brightplex® is a chromogenic multiplex technology allowing the detection of several biomarkers on a single FFPE slide to identify and quantify complex cell populations such as T-cells expressing immune checkpoints, M1 and M2 macrophages, Treg cells and myeloid-derived suppressor cells. However, the exquisite characterization of some cell types within the tumor microenvironment or their activation status may require the identification of soluble proteins that cannot be detected by IHC. For example, the detection of secreted proteins such as cytokines or activation factors would allow one to determine the activation status of immune cells or cancer-associated fibroblasts (CAF). In that case, the detection of RNA transcripts corresponding to soluble biomarkers by In-Situ hybridization can be used as a substitute to protein detection.Here, we propose a new multiplex platform combining In Situ Hybridization (ISH) and immunohistochemistry (IHC) using Brightplex® technology. This platform allows the detection of several biomarkers that can be either RNA transcripts or proteins on a single FFPE tissue section. Thanks to that technique it is possible to: 1) detect and quantify TGFb in cancer associated fibroblasts, or IL-10 in immunosuppressive cells, 2) Quantify the level of RNA expression by individual cells, 3) assess the spatial distribution of activated cells based on complex phenotypes within the tumor or other regions of interest. This new workflow combining RNA transcript detection and proteins detection using Brightplex® is automated on Bond RX platform. Following staining and slide digitization, images are fused to create a virtual multi-channel image where cells of interest are detected by digital pathology (DP). Following cell detection, their densities and spatial distribution are obtained using R-

studio software.Integrated into an Immunogram, an analytics platform which integrates multi-omics datasets from Veracyte Biopharma Atlas, this new tool could be a powerful solution to understand the tumor landscape and predict response to immunotherapy and patient outcome.

#4625

A comprehensive guided workflow for highplex imaging, tissue segmentation, and multiplex cellular phenotyping for tumor microenvironment analysis

Brenna O'Neill[1], Smriti Kala[2], Sam Lim[2], Clinton Hupple[2], Nina Lane[2], Rasmus Norre Sorensen[1], Rasmus A. Lyngby[1], Alessandro Massaro[1], Andreas Hussing[1], Jeppe Thagaard[1], Johan Dore-Hansen[2], James Robert Mansfield[1]. *[1]Visiopharm, Horsholm, Denmark,[2]Standard BioTools, South San Francisco, CA*

The growth in cancer immunotherapy agents requires an understanding of the immune contexture of the tumor microenvironment (TME). Understanding immune contexture requires multiplex staining, imaging, and analysis to obtain multi-marker phenotypes of specific cells and analyze their biodistribution in the TME. Imaging Mass Cytometry™ (IMC) is the method of choice for single-step staining and highplex imaging of FFPE tissues. FFPE tissue is autofluorescent, which limits the utility of immunofluorescence methods. Lung and colorectal tissue (and bone, skin, etc) are highly autofluorescent, and therefore good targets for IMC. However, developments in analysis software for highplex imagery have not kept pace with imaging advances. We present a comprehensive workflow designed specifically for highplex image analysis, covering tissue segmentation, cell segmentation based on IMC DNA images, cellular phenotyping, and spatial analyses.
Lung and colorectal tissue sections with a 30-marker IMC panel of structural, tumor, stroma, immune cell, and immune activation markers were imaged (Hyperion+™, Standard BioTools). Highplex image analysis (Phenoplex™, Visiopharm) was performed as a multi-step workflow in a single software package that includes: conversion of IMC images to pyramidal format; easy visualization methods for displaying different marker subsets; a paint-to-train algorithm for tissue segmentation (into tumor, stroma, blood vessels, etc.); deep-learning-based nuclear

segmentation pre-trained on IMC DNA channels; cellular phenotyping based on thresholds based on visual assessment of positivity; spatial biodistribution metrics for cell populations; and a flexible set of outputs for downstream analysis. Tissue segmentation was used to divide the tissue into tumor, stromal, and tumor margin regions, and these regions were used to compare the immune contexture through a series of t-SNE images partitioned by spatial region.
We demonstrate that a simple analysis workflow can be used for highplex images of different tissue types by users with no programming knowledge. Visualization templates for the marker subsets and the pre-trained IMC nuclear segmentation are reusable. A new tissue segmentation algorithm for each tissue type is required, as are new thresholds for biomarker positivity. Spatial biodistribution metrics, heatmaps and partitioned t-SNE plots were generated for each tissue type with a minimum of work.
Highplex IMC imaging of lung and colorectal tumor samples is a simple and effective means of obtaining high-parameter images without interfering autofluorescence. Having a comprehensive workflow for the analysis of this complex data makes obtaining useful results from highplex images more accessible to biologists and immunologists by circumventing the requirement for expert programming for each specific application.

Spatial profiling of the tumor microenvironment in head and neck cancer identifies immune checkpoints and proteins involved in cell death signaling biomarkers of immunotherapy response

Habib Sadeghirad[1], Ning Liu[2], James Monkman[1], Chin Wee Tan[2], Caroline Cooper[3], Jeni Caldera[4], Sarah Church[5], Fabian Schneider[4], James Robert Mansfield[4], Ken O'Byrne[3], Melissa Davis[2], Brett Hughes[6], Arutha Kulasinghe[1]. *[1]The University of Queensland, Brisbane, Australia,[2]The Walter and Eliza Hall Institute, Melbourne, Australia,[3]The Princess Alexandra Hospital, Brisbane, Australia,[4]Visiopharm, Horsholm, Denmark,[5]Nanostring, Seattle, WA,[6]The Royal Brisbane and Women's Hospital, Brisbane, Australia*

Immune checkpoint inhibitors (ICIs) Pembrolizumab and Nivolumab have shown promising results in patients with recurrent or metastatic (R/M) head

and neck squamous cell carcinoma (HNSCC). Nonetheless, only up to 20% of patients may benefit from them. Next generation predictive biomarkers of response to ICI therapies are currently needed.
This retrospective study profiled pre-treatment tissue samples collected from R/M HNSCC patients (n=30) treated with Pembrolizumab or Nivolumab. Targeted spatial proteomics profiling was performed using NanoString's GeoMx® Digital Spatial Profiler (GeoMx). To develop an informed region-of-interest (ROI) selection strategy for the GeoMx, we analyzed H&E images from serial sections and performed Oncotopix® Discovery software, which considered pathology inputs and machine learning to analyze H&E imagery and 4-channel GeoMx visualization inputs. We profiled 80 proteins simultaneously using the GeoMx across modules in cell death, immune activation, immune cell typing, immuno-oncology drug target, immune profiling, PI3K/AKT signaling, and pan-tumor markers. . Next, we performed differential expression (DE) analysis of the proteins localized in the tumor and stromal compartments against response to therapy parameters of complete, partial, stable and progressive disease (according to RECIST criteria).
Four-channel GeoMx immunofluorescence images provided per-ROI cell counts (total and phenotyped based on 3 markers), and these data were used to aid in area and cell count normalization within the tumor and stromal compartments. We found that patients responsive to immunotherapy had higher expression levels of PD-L1, Bcl-2, BCLX, and BIM in the tumor, whereas VISTA, FOXP3, and CD66b were downregulated. In the stromal compartment, it was found that responders had higher expression levels of B7-H3, CD40, and SMA, but lower expression of PARP, S100B, and NY-ESO-1 in comparison to non-responders. In terms of best response analysis, patients with PR (n=5) had higher levels of PD-L1, ER-alpha, and CD68 expression, but lower levels of VISTA, CD27, and CD95/Fas in tumor regions than patients with PD (n=8). In the stroma, PD-L1, CD68, and HLA-DR were upregulated, while VISTA, BIM, and BAD were downregulated in patients with PR versus those with PD.
We found that informed ROI selection strategy aided in defining key features in the tumor microenvironment for comparative analysis across samples, and for data normalization methods. Moreover, we found that immune checkpoints and proteins involved in cell death signaling play

important roles in the immune responsive tumor microenvironment of HNSCC based on response to immunotherapy.

Immune profiling of immunotherapy and adjuvant chemotherapy pretreatment NSCLC tissues by CODEX

James Monkman[1], Afshin Moradi[1], Connor O'Leary[1], Zhenqin Wu[2], Steven Hamel[2], David Mason[3], Fabian Schneider[3], James Robert Mansfield[3], Aaron Meyer[2], Ken O'Byrne[4], Arutha Kulasinghe[1]. *[1]The University of Queensland, Brisbane, Australia,[2]Enable Medicine, Menlo Park, CA,[3]Visiopharm, Horsholm, Denmark,[4]The Princess Alexandra Hospital, Woolloongabba, Australia*

Non-small cell lung cancer (NSCLC), including adenocarcinoma and squamous cell carcinoma subtypes, is a leading cause of cancer deaths worldwide. Treatment of NSCLC has advanced from chemotherapy modalities to the use of immunotherapy, namely immune checkpoint inhibitors (ICIs) which enhance the adaptive immune response against tumour cells. Thus, while the immune cell composition of tumours and its influence on treatment outcomes is poorly understood, it likely holds the key to effective, personalized treatment regimens.

Here we profiled an adjuvant chemotherapy (n=61) as well as a second line immunotherapy (n=42) NSCLC cohort by the Phenocycler CODEX technology (highplex spatial proteomics) to investigate the association between immune composition and patient outcome. We applied a panel of 38 markers to delineate naïve, memory, cytotoxic and hyperactivated T cell states, as well as B cells, Tregs and myeloid lineage innate immune cell types. Our study sought to understand the heterogeneity of tumour-immune composition across patients and investigate the spatial neighbourhoods and clusters that these cells inhabit within TMA cores. We used Phenoplex™ software for tissue segmentation (into classes for tumor, stroma, artifacts, blood vessels, etc.), cellular segmentation, and cellular phenotyping based on thresholds for each marker, and then performed spatial analyses (distances, interactions, neighborhoods) using SpatialMap[1] to identify cellular motifs associated with clinical phenotypes.

Our study has identified spatial features associated with immune contexture linked to therapy outcome in both chemotherapy and immunotherapy

modalities. Taken together, our study demonstrates the utility of spatial proteomics to identify cellular features associated with outcome to therapy in lung cancer.

Profiling the tumor microenvironments of triple- and quadruple-negative breast cancers

Geetanjali Saini[1], Manali Rupji[2], Mahak Bhargava[1], Sunil Badve[3], Ritu Aneja[1]. *[1]Department of Clinical and Diagnostic Sciences, School of Health Professions, University of Alabama at Birmingham, Birmingham, AL,[2]Emory University, Atlanta, GA,[3]Department of Pathology and Laboratory Medicine, Emory University School of Medicine, Atlanta, GA*

Triple-negative breast cancer (TNBC) is a heterogeneous breast cancer subtype that lacks expression of estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2. Approximately 15%-20% of breast cancers are triple-negative. Based on expression of the androgen receptor (AR), TNBC can be categorized as AR-positive (AR+ TNBC) or AR-negative (quadruple-negative breast cancer, QNBC). Studies have reported that the loss of AR expression is associated with poor prognoses. Recent evidence suggests that QNBCs disproportionately affect women of African descent and contributes to poor overall survival. QNBC is a more aggressive disease compared to TNBC, and patients with QNBC currently have no treatment options beyond chemotherapy. Data from interrogating public databases such as TCGA indicates that QNBC is distinct from TNBC in molecular makeup, particularly in immune tumor microenvironment. Currently, QNBC is not considered distinct from the broader TNBC subtype, hence a comprehensive molecular characterization is lacking. We aim to examine differences between the TNBC and QNBC tumor microenvironments that consist of both immune and stromal components. We analyzed RNA expression data from the METABRIC (TNBC= 11, QNBC= 185) and TCGA (TNBC= 29, QNBC= 103) datasets. Based on AR transcript expression, patients with TNBC were stratified into AR-low (considered QNBC) and AR-high (deemed ‘true’ TNBC) groups. The analytical immune tools - CIBERSORTx and xCELL were used to analyze

the RNA-Seq data. CIBERSORTx can distinguish 22 mature human hematopoietic populations and provides abundance of member cell types in a mixed cell population, from gene expression data. xCELL is a gene signature-based method that can perform cell type enrichment analysis from gene
expression for 64 immune and stromal cell types. Thus, xCell can discriminate between closely related cell types. Using these immune tools, the tumor microenvironments of the TNBC and QNBC groups were compared. Correlations between individual immune and stromal components with patient survival probability were assessed. Significant differences (p-value <0.05) in several immune and stromal cell types were noted when comparing the TNBC and QNBC groups within these datasets. CIBERSORTx and xCELL yielded both unique and common sets of cell types. Notably, significant differences in the stroma score (a composite score of stromal cell types provided by xCELL) were observed between TNBC and QNBC in both the METABRIC and TCGA datasets. These immune tools are based on different methodologies and our results show that they can provide complementary information. Our data suggest that QNBC and TNBC have distinct tumor microenvironments, and that QNBC should be considered as an independent breast cancer subtype that warrants comprehensive characterization.

Heterogeneity in glioblastoma tumor microenvironment: Opportunities for new therapies

Sandra Delebecq, Adele Ponzoni, Richard Ruez, Corinne Ramos, Jonathan Stauber. *ImaBiotech, Loos, France*

Background: Glioblastoma (GBM) is the most common and aggressive form of brain tumor, characterized by a poorly accessible microenvironment that render it notoriously hard to treat. The insufficient treatment success is, in large parts, due to its tremendous molecular heterogeneity, which affects the overall prognosis and response to therapies. The significant intra- and inter-tumor microenvironment (TME) composition heterogeneity plays a crucial role in GBM progression. Mostly due to this high, multifactorial immunosuppression occurring in the microenvironment, the efficacy of immunotherapy in GBM is low. Focusing on characterizing the components

of different TMEs to evaluate their molecular and cellular component heterogeneity has a significant advantage to target group of cancer patients that would normally be resistant to immunotherapy.
Methods: Deep spatial transcriptomics profiling was performed on non-treated glioblastoma human tissue microarrays (TMA) using NanoString's *GeoMx* Digital Spatial Profiler (*DSP*). 6 tumor tissues from 6 different patients were hybridized and analyzed with the Whole Transcriptomic Atlas (WTA) panel that includes 18,000 genes. Three regions of interest (ROIs) were selected per tissue sample. All the statistical analysis were performed with GeoMx® DSP Analysis Suite. Cell deconvolution using the SpatialDecon® algorithm (Nanostring®) was then performed to estimate mixed cell type abundance in the spatially-resolved gene expression defined segments.
Results: Spatial transcriptomic analyses revealed that glioblastoma tumors varied dramatically in their global gene expression profiles and suggested the existence of differential gene expression among the tumors highlighting the inter-tumors heterogeneity of glioblastoma. Interestingly, different areas of the same tumor did not display distinct molecular profiles. Upregulation of stromal collagen genes was significantly detected in some patient specifically the fibrillar collagens type I, III and VI. Those findings indicated excessive collagen depositions in the surrounding of the tumor for some patient characteristic of tumor progression and involvement of cancer associated fibroblasts (CAFs) in the dysregulated collagen turnover leading to tumor fibrosis.
Conclusion: As a cold tumor, malignant glioma has strong immunosuppression and immune escape characteristics. The TME provides the “soil” for the survival of malignant tumors, and recent studies have highlighted a major role for cancer-associated fibroblasts (CAFs) in promoting immunotherapy resistance by excluding T cells from tumors in the TME. Here the spatial transcriptomic analyses allowed a better phenotypical stratification of the cancer patient. In some, targeting CAFs would improve the TME and enhance the efficacy of immunotherapy.

Deep Immuno-profiling of syngeneic tumor mouse models for preclinical studies

Anais Joachim[1], Emilie Maturin[1], Marielle Mello[2], Lillia Hadjem[2], Magali Grange[2], Olivier Deas[3], Ana Zarubica[1], Bernard Malissen[1], Hervé Luche[1].
[1]Immunomics, JC DISCOVERY, Marseille, France,[2]Immuno-Phenotyping Module, CIPHE, Marseille, France,[3]R&D Lab Head, Xentec, Evry, France

Identification of major cellular players involved in progression of cancer is key to success of new immunotherapies. It is however a daunting challenge due to the complex interplay between tumor cells and the immune system. Component of innate and adaptive immunity may be directed to a pro- or anti-tumor function. In order to cope with the complexity of the tumor microenvironment (TME), it is necessary to use an experimental approach characterizing the heterogeneity of cell types, the evolution of their relative proportion and their fine-tuned functional specificity. This approach should lead to the identification of new cellular biomarkers characteristics of different stages of tumor cancer progression.
To decipher the impact of immunotherapy treatments, cellular phenotyping of leukocytes infiltrating TME but also those present in peripheral organs is necessary. In order to increase our understanding in the precise mode of action of anti-PD1 treatment at the cellular level in sensitive and unsensitive syngeneic models, we investigated immunophenotypes and responses to immune checkpoint inhibitor (ICI) of several hallmark tumor models (MC38, CT26, B16F10, B16-OVA, RENCA, EMT6) in immunocompetent mouse models by flow and mass cytometry. We compared growth kinetics and profiled the immune cell composition of tumor microenvironment (TME), draining lymph node (dLN) and blood in order to establish immune-phenotypic cell signatures that correlates with treatment efficacy. Supervised, unsupervised and integrative data analysis arewere used to identify significant changes across different experimental settings. Our results indicate that each model possesses a unique tumor-immune infiltrate profile that can be modulated with immunotherapies. Overall, these studies provide an important resource of highly well-characterized syngeneic tumor model and highlight the importance of tumor immune landscape changes across models that will drive selection of the most appropriate model to test novel immunotherapeutic agents and enhance our translation of knowledge from syngeneic models to human tumors.

Multiplex IHC assay to explore regional heterogeneity of FAP and inflammatory cell density in localized prostatic adenocarcinoma

Fernanda Caramella Pereira[1], Alan K. Meeker[2], Kenneth Pienta[3], Qizhi Zheng[1], Tracy Jones[1], Srinivasan Yegnasubramanian[4], Jessica L. Hicks[1], Sujayita Roy[1], Angelo M. De Marzo[2], W. Nathaniel Brennen[3]. *[1]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Departments of Pathology, Oncology, and Urology, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins and the James Buchanan Brady Urological Research Institute., Baltimore, MD,[3]Departments of Oncology, and Urology, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins and the James Buchanan Brady Urological Research Institute., Baltimore, MD,[4]Departments of Pathology, Oncology, and Urology, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins and the James Buchanan Brady Urological Research Institute, Baltimore, MD*

Cancer-associated fibroblasts (CAFs) expressing FAP promote tumor growth, invasion and immune suppression. FAP is a molecular imaging target in cancer and its protease activity is a potential anti-cancer drug target. While FAP expression was associated with biochemical recurrence after prostatectomy using tissue microarrays (TMAs)(DOI:10.1158/2767-9764.CRC-21-0183), its expression has not been comprehensively correlated with morphological features of disease aggressiveness beyond grade. 48 cases of localized prostatic adenocarcinoma were used for a multiplex immunohistochemical assay that included FAP, CD45, CD163, p63 and Keratin 8. Each of these markers were individually optimized by single-plex staining and were then performed as an iterative IHC assay (PMID:35188986) and quantification was performed using the HALO image analysis platform (Indica Labs). We developed a second multiplex assay including FAP, vimentin, smooth muscle actin, desmin, CD31, S100, keratin 8 and p63. FAP IHC staining was analytically validated using a series of positive and negative cell lines. In normal appearing (non-inflamed) prostate regions, FAP expression was negative. By contrast, upregulation of FAP was observed in the stromal compartment in regions of chronic inflammation and some proliferative inflammatory atrophy (PIA) lesions. In tumor regions, only 1 case was totally negative for FAP. Except for 2 cases, in which there was focal weak tumor cell staining, all FAP

expression was present in the tumor stromal compartment (TSC). The vast majority of FAP expression was associated with Vim+/Des- fibroblasts, which at times were also positive for SMA (Vim+/Des-/SMA+), indicating they are myofibroblasts. There was very infrequent FAP expression associated with M2 macrophages, endothelial cells, nerves and vimentin-negative smooth muscle cells, indicating that the majority of FAP expression occurs in fibroblasts. Preliminary quantitative data using visual estimations of the fraction of TSC expressing FAP (range, 0-80%, mean=35.8%, median=30%, SD=23.7) was not associated with the overall GS/grade group, but was associated with non-organ confined disease. Furthermore, there was a trend towards increased FAP expression in cases showing intraductal carcinoma and large cribriform formation. Ongoing studies are in process to obtain quantitative data by image analysis and to correlate FAP expression with the presence of overall inflammatory cell density and the density of M2 macrophages. Additionally, we will characterize the cases in terms of molecular features including TMPRSS2-ERG status and PTEN genomic status. Future use of these panels will facilitate studies of associations of FAP with clinical outcome, MRI and PET imaging, response to specific treatments and to help characterize FAP as a predictor of response to emerging FAP inhibitors and FAP-targeted prodrugs.

#4632

Spatial whole transcriptome analysis of differential expression for biomarker discovery in colorectal cancer

Elim Cheung, Vidyodhaya Sundaram, Baowen Zhang, Lutong Zhang, Tong Lu. *BioChain Institute, Inc., Newark, CA*

Background**:** Colorectal cancer (CRC) is one of the leading causes of cancer death, which is frequently caused by genetic or epigenetic changes. The study of tumor microenvironment (TME) profiling may provide a better knowledge of spatial gene expression patterns of known CRC markers, visualize the cell composition and localization, and serve to aid the understanding of the mechanisms of tumor formation. BioChain Institute, Inc. is currently investigating the TME profiling of CRC through tissue-wide, whole transcriptome analysis for the ability to discover potential therapeutic targets.

Methods: BioChain's formalin-fixed paraffin-embedded (FFPE) tissue samples from 3 primary colon adenocarcinoma tumors (PT), and their matched adjacent normal tissues (PN), were used to investigate the TME. The images of Hematoxylin and Eosin (H&E)-stained tissue sections were annotated by our pathologist. The spatial whole transcriptome was analyzed using 10x Genomics Visium Spatial Gene Expression for FFPE. This assay provided about 5,000 spatially barcoded spots with mRNA-binding oligonucleotides to capture the gene expression. The integration of the imaging and sequencing data enabled a spatially resolved transcriptome of CRC heterogeneity.
Results: The annotations of both PT and PN tissue samples were found to be correlated with the spatial gene expression clustering. With the overlaying of total gene counts for each spot on the H&E-stained tissue image, about 16,000-17,000 genes were detected in each sample. The median of ~5,500 and ~1,600 genes per spot were expressed in PT and PN samples respectively. The study of gene expression levels revealed the overexpression of several well-known CRC markers (APOE, SCD, IGFBP3, TIMP1, SPARC) and the down-regulation of numerous markers (DES, CA1, KLF4) in PT samples significantly.
Conclusion: Our spatial analysis results provide insight into tumor heterogeneity, spatial organization of cells within the TME and biomarker identification. BioChain is in a unique position to facilitate researchers with a plethora of oncologic and other diseased tissue types, as well as the spatial whole transcriptome analysis. Our study enables the understanding of the TME, discovery of potential diagnostic and prognostic targets, especially for the development of personalized therapy.

#4633

Quantitative spatial profiling of NSCLC subtypes across tumor stages using 6-plex multiplex imaging technology and AI-powered phenotyping analysis

Lorcan Sherry[1], Nicole Couper[1], Bethany Remeniuk[2], Karen McClymont[1], Bei Hopkins[2], Natalie Monteiro[2], Gabriel Reines March[1], Darren Locke[2].
[1]OracleBio Ltd, Glasgow, United Kingdom,[2]Akoya Biosciences, Marlborough, MA

Non-small cell lung cancer (NSCLC) is a complex disease with varying pathological subtypes including adenocarcinomas and squamous cell carcinomas. After diagnosis, tumor staging provides important information about the extent of cancer in the body and anticipated response to treatment. NSCLC patients can have impaired immune responses within the tumor microenvironment (TME), leading to a progression of tumor growth and poorer prognosis. Accurate cell phenotyping combined with spatial profiling of the immune contexture and checkpoint expression, can provide a deeper understanding of complex cellular interactions underpinning the tumor-immune response. The aim of this study was to utilize spatial multiplexed imaging technology and associated data analysis methods to profile the immune contexture, as well as their spatial interactions with the tumor, in a set of tissue cores covering a range of NSCLC subtypes and tumor staging. Formalin-fixed paraffin-embedded (FFPE) NSCLC tissue microarrays (TMA), comprised of n=41 cores containing a range of carcinomas and pathological Tumor-Node-Metastasis (pTNM) stages (I-IV), were stained on a Leica Bond RX™ using the Akoya PhenoCode™ Signature Immuno-contexture Human Protein Panel, which includes markers for CD8, CD68, PD-1, PD-L1, FoxP3, and PanCK as a tumor indicator. Stained TMAs were scanned at 20x magnification on a PhenoImager HT multispectral imaging system. Image analysis was performed using Visiopharm software. Deep learning algorithms were applied to segment tumor and stroma regions of interest (ROI) and to accurately detect and classify specific cell phenotypes. Cell object data files *per* core were exported for spatial and neighborhood analysis using OracleBio's proprietary python-based program, PhenoXplore. Immune cell counts, phenotypes and spatial interactions were generated within tumor and stroma ROI *per* core. Data included total and negative cell phenotype counts, cell density in tumor and stroma, as well as cell distance and neighborhood spatial interactions *per* core across NSCLC subtypes and stages in the TMA set. The combination of high-quality staining provided by the PhenoCode™ panel, coupled with deep learning quantitative phenotyping and spatial pattern analysis enables detailed characterization of the complex cellular interactions, at both the functional and spatial level, within the TME of NSCLC tissue. Data generated will support a greater understanding of the complex cellular interactions that can contribute to

progression of NSCLC and may help guide future precision medicine strategies.

#4634

Identifying and analyzing tumor subtypes using custom morphology markers for NanoString® GeoMx® Digital Spatial Profiler

Jessica Runyon[1], Vijay Baichwal[2], Weston Stauffer[2], Christian Nievera[1].
[1]Canopy Biosciences, St. Louis, MO,[2]Canopy Biosciences, Hayward, CA

Molecular subtyping studies have allowed the allocation of cancer into groups based on similar molecular, morphological, and clinical characteristics. Such studies are critical to help researchers identify actionable targets for drug design and biomarkers to predict therapeutic response. Based on multi-omics data, various approaches have been used to identify and analyze tumor subtypes and their correlation with tumor immunity and immunotherapy success. The NanoString GeoMx Digital Spatial Profiler is one approach that combines morphological context with spatial transcriptomics on a single tissue specimen. A critical step in this approach involves staining with morphology markers to identify relevant regions of interest (ROIs) for analysis. Yet, widespread adoption of GeoMx DSP has revealed a significant limitation, namely that researchers base transcriptional analysis of thousands of RNA targets on the spatial information provided by only a few morphology markers. Recent efforts have greatly expanded the availability of morphology markers to facilitate cell type-specific analyses. To evaluate the ability of this technology to selectively enrich specific cell types, we developed custom morphology markers to stain non-small-cell lung cancer (NSCLC) tissue specimens of various subtypes. Focusing on squamous cell carcinoma and adenocarcinoma, we stained with P40 and TTF-1 and transcriptionally profiled cell type-specific ROIs with the Cancer Transcriptome Atlas panel. Differential gene expression analysis of the whole transcriptome was performed using GeoMx DSP Analysis Suite software. The data reveal differences in gene expression in several key cancer pathways between tumor subtypes are correlated with the presence or absence of specific cell types. The data support the use of custom morphology markers for cell type stratification in tumor subtypes, providing more meaningful gene expression analysis. Ongoing work continues to explore the utility of this

technology for cell type-specific gene expression analysis within different tumor subtypes.

Single cell definition of the immunogenic synapse between the tumorigenic schwann cells and tumor associated macrophages in Plexiform Neurofibroma

Thomas J. On, Xiyuan Zhang, Shahroze Abbas, John Shern. *Pediatric Oncology, NIH-NCI, Bethesda, MD*

Background**:** Patients with Neurofibromatosis Type 1 (NF1) frequently develop benign tumors called Plexiform neurofibromas (PN). Macrophages compose 30-50% of the total cellular composition of PNs and have previously been shown to play a critical role in the PN development and growth. This study defines components of the immunogenic synapse between the neoplastic Schwann cell and the tumor associated myeloid compartment and investigates alterations of the synapse during treatment with MEK inhibition (MEKi). The IL34-CSF1R axis is nominated as a key node in the maintenance of the tumor associated macrophages in PN.
Methods: In this work, we applied single cell RNA sequencing (scRNAseq) to human primary tumor PN samples to comprehensively evaluate tumor cellular populations and their interactions. Resulting cellular populations were compared to a single cell atlas of tumor associated immune cells taken from a panel of tumor types. Ligand and receptor interactions were informatically extracted from scRNAseq data and immunohistochemistry was used to validate scRNAseq observations. scRNAseq was also used on pre and post treatment samples taken from three patients receiving the MEKi Selumetinib. Human primary macrophage cell cultures and qPCR were used to interrogate the roles of the IL34-CSF1R signaling and MEKi in PN.
Results: scRNAseq generated data on 45101 PN myeloid cells. Integration of these cells with a publicly available tumor atlas of 11 different tumors containing a total of 52195 cells discovered correlation of cell populations between the PN as compared to other tumor types. Tumor-promoting (M2) macrophages represented the largest portion (48%) of the PN myeloid population. Receptor-ligand analysis using cellphoneDB highlighted IL34-CSF1R ($p<.0001$), TNF-TNFRSF1A ($p<.0001$) and SIRPA-CD47

(p<.0001) as significant interactions between the neoplastic Schwann cell and macrophages. IL34 and CSF1R protein expression was confirmed in human PN tumors with immunohistochemistry. scRNAseq data from NF1 patients PN tumors taken pre and post MEK inhibitor treatment, demonstrated decreased M2 macrophage gene expression of CD163(p<.001), MRC1(p<.001), TREM2(p<.001) after treatment. Finally, IL34 stimulated primary human monocytes produced macrophages with an M2-like phenotype. MEKi treatment of these macrophages resulted in increased expression of inflammatory macrophage genes CXCL9 (p<.05), CXCL10(p<.001), IDO1(p<.001).
Conclusions: PN myeloid populations contain large amounts of M2 macrophages with expression profiles consistent with TAM seen in a variety of malignant tumors. We postulate that IL34 expression by the neoplastic Schwann cell leads to expansion and maintenance of this TAM population. MEKi treatment on human PNs reduces number of macrophages in PNs and shifts macrophage gene expression towards inflammatory genes.

High-plex co-detection of RNA and protein to explore tumor-immune interactions utilizing RNAscope with Imaging Mass Cytometry
James Pemberton[1], Smriti Kala[1], Anushka Dikshit[2], Clinton Hupple[1].
[1]Standard BioTools, Markham, ON, Canada,[2]Advanced Cell Diagnostics, Inc., Newark, CA

Purpose The next breakthroughs in immuno-oncology will be driven by high-plex tools that decipher the spatial arrangement of different cell types within the tumor microenvironment (TME). Imaging Mass Cytometry™ (IMC™) is a proven tool for the study of complex cellular interactions in the TME. It utilizes CyTOF® technology for simultaneous assessment of 40-plus protein markers at subcellular resolution without spectral overlap or background autofluorescence, thus providing unprecedented insight into the organization and function of the TME. Despite this, some protein targets are challenging to include in IMC as they have very few or no commercial antibodies available. Moreover, although cellular identity can easily be deciphered through detection of protein targets, knowledge of the cell's transcriptome improves understanding of cellular function and activation

state. Here, we present a robust and reliable workflow that combines the highly sensitive and specific RNAscope™ technology for RNA detection with the multiplexing capability of IMC to visualize key RNA and protein markers in the same tumor samples.
Methods The RNAscope HiPlex v2 assay was combined with protein detection on the Hyperion+™ Imaging System to evaluate expression of both RNA and protein targets in formalin-fixed, paraffin-embedded (FFPE) tumor tissue microarray (TMA). The RNAscope assay was used with 12 target RNA marker probes and associated metal-labeled detection probes, suitable for use in IMC. The RNAscope HiPlex v2 assay workflow was followed as recommended up until applying the fluoros. Instead of using the fluoros, metal-conjugated probes were used for RNA detection. Metal-conjugated antibodies were used for protein detection in the same tissue.
Results Target protein markers identified a range of immune cells, tumor cells, stromal cells, endothelial cells, and extracellular matrix. Co-detection of RNA and protein allowed visualization of several cytokines and chemokines, such as *CXCL13, CXCL9, CXCL10, IFNγ, IL10, IL8*, and *IL1B*, enabling the identification of the cellular source of these secreted factors. Additionally, immune cell subpopulations and their activation states were visualized using marker-specific antibodies. Immune cell hubs associated with anti-tumor immune responses were detected in tumor niches across the TMA.
Conclusions Overall, combining RNAscope with protein co-detection on the IMC platform allowed simultaneous visualization of RNA and protein targets to interrogate the tumor microenvironment. The single-cell resolution offered by the RNAscope assay provides superior sensitivity for RNA detection in addition to the existing protein-detection capability of the IMC platform. This workflow can be applied to FFPE tissues to study therapeutic efficacy, stratify patients based on inflammatory signature, and study cell-cell interactions within the TME.

Integrative spatial analysis of paired IHC and H&E images identifies Foxp3 enriched tumor-infiltrating lymphocytes associated with disease-free survival in human papillomavirus (HPV)-related oropharyngeal squamous cell carcinoma

Sumanth Reddy Nakkireddy[1], Inyeop Jang[2], Minji Kim[2], Linda X. Yin[3], Michael Rivera[4], Joaquin J. Garcia MD[4], Kathleen R. Bartemes[3], David M. Routman[5], Eric J. Moore[2], Daniel J. Ma[5], Kathryn M. Van Abel[6], Tae Hyun Hwang[7]. *[1]1Department of Artificial Intelligence and Informatics, Mayo Clinic Florida, Jacksonville, FL,[2]Department of Artificial Intelligence and Informatics, Mayo Clinic Florida, Jacksonville, FL,[3]Department of Otolaryngology-Head and Neck Surgery, Mayo Clinic, Rochester, MN,[4]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[5]Department of Radiation Oncology, Mayo Clinic, Rochester, MN,[6]1Department of Artificial Intelligence and Informatics, Mayo Clinic, Jacksonville, FL,[7]Department of Artificial Intelligence and Informatics, Mayo Clinic, Jacksonville, FL*

Background: Recent studies support that high levels of tumor-infiltrating lymphocytes (TILs) were associated with better prognosis in HPV(+) oropharyngeal squamous cell carcinoma (OPSCC). While these studies provide a potential role for TILs as a prognostic biomarker, the analyses were relied on manual quantification performed by pathologists, resulting in inter-observer variability. Deep Learning (DL)-based whole slide hematoxylin and eosin (H&E) image analyses may overcome these challenges. However, this analysis only provides the presence of cell types without consideration for the functional roles of each cell within the tumor immune microenvironment (TME). In this work, we develop a computational pipeline to integrate paired H&E and immunohistochemistry (IHC) images to functionally characterize TILs and investigate their prognostic utility.
Methods: We analyzed 88 patients: 42 stage I, 39 stage II, and 7 stage III. Our data contain both H&E and IHCs examining FoxP3, CD3, PD-L1, CD20, etc. on serial sections of the tissue. In-house DL-based H&E analysis used to identify TILs, tumors, and stroma in each tumor, then performed registration between adjacent H&E and IHC images from the same tissue. The patients were then classified into three basic immune phenotypes: immune inflamed (IN; high TILs in the tumor region), immune excluded (EX; TILs are mostly localized in stroma), and immune desert (ID; few/no TILs) based on TIL enrichment in the TME. To functionally characterize TILs, we quantified protein expression from the adjacent IHCs.

For example, we further classified each patient into different subtypes based on enriched protein expression (e.g., FoxP3 high IN, FoxP3 low IN). We used the Kaplan-Meier method and multivariate Cox analysis to evaluate the prognostic value of different subtypes enriched with different proteins to predict disease-free survival (DFS).
Results: The IN group with 43 patients was significantly associated with good prognosis. Interestingly, further stratification of the IN subgroup based on Foxp3 quantification on TIL regions (i.e., high FoxP3 IN and low FoxP3 IN) showed that high protein expression of FoxP3 in TILs in the IN subgroup is significantly associated with a better prognosis compared to other immune subgroups (HR, 0.16; p-value, 0.003). Multivariate analysis, including other clinical covariates showed that the immune subtypes associated with high FoxP3 are independently associated with DFS. These results demonstrate that DL-based integrative IHC and H&E image analysis could be used to identify subgroups with distinct clinical outcomes. Furthermore, our results reveal unknown roles for Foxp3 expression in the TILs in HPV(+) OPSCC as a prognostic biomarker, a finding which should be evaluated in a larger cohort.

Single-cell immunoprofiling and spatial analysis of hormone receptor subtypes in HER2+ and HER2low breast tumors using multiplexed immunofluorescence

Anna Juncker-Jensen[1], David Tallman[2], Harry Nunns[1], Heather Lefebvre[2], Karen Yamamoto[1], Katharine A. Collier[2], Mark Vater[2], Ava Strahan[2], Ava Willoughby[2], Olivia Bouchard[2], Madison Kingsbury[2], Mathew Cherian[2], Ashley C. Pariser[2], Preeti K. Sudheendra[2], Bhuvaneswari Ramaswamy[2], Margaret Gatti-Mays[2], Ainura Kyshtoobayeva[1], Zaibo Li[2], Daniel G. Stover[2]. *[1]NeoGenomics, Aliso Viejo, CA,[2]The Ohio State University, Columbus, OH*

Background: Breast cancer is characterized by distinct molecular subtypes based on expression of estrogen and progesterone hormone receptors (ER and PR), and epidermal growth factor receptor 2 (HER2). To investigate presence and location of distinct immune cell populations on single cell level we utilized the multiplexed immunofluorescence (mIF) platform MultiOmyx to investigate the tumor immune microenvironment (TME) in

HER2+ breast cancer. We have built on growing data implicating distinct immunophenotypes in the breast cancer TME with breast cancer outcomes by profiling 1) prevalence; 2 location (e.g. intratumoral, stromal); 3) phenotype (e.g. activated, exhausted) of infiltrating immune cells.
Methods: We optimized a custom 26-marker MultiOmyx panel interrogating HER2 IF expression, HER2 signaling, and immune markers. This mIF platform leverages serial IF image capture to allow concurrent profiling of all 26 markers on a pathologic section at single cell resolution. We applied the 26-marker panel to a tissue microarray of 208 unique patients with matched tumor/normal tissue cores (1-4 cores/patient; total 333 tumor and 307 normal cores). HER2-positive was defined via ASCO/CAP guidelines; HER2-low was defined as HER2 immunohistochemistry (IHC) 1+/2+ but HER2 in-situ hybridization (ISH) negative.
Results: The 208 unique tumors profiled included 88.9% (185/208) HER2-positive and 11.1% (23/208) HER2-low; 62.5% (130/208) hormone receptor (HR) positive and 37.5% (78/208) HR negative. Median follow-up from diagnosis was 143 months. Among HER2-positive patients, 98.9% (n=183/185) received HER2-directed therapy in the (neo)adjuvant or metastatic setting or were diagnosed prior to FDA approval of trastuzumab for early stage disease. In sum, from 1166 regions of interest in 640 total cores, a total of 1,076,700 single cells were profiled via the 26-marker panel. Tumors categorized based on HR and HER2 reflected distinct immunophenotype. Relative to HR+HER2low, HR-HER2low tumors had a significant increase in the density of T cells (CD3) and tumor-associated macrophages (TAMs) (CD68). The increase in T cells was observed for T helper (CD3+CD4+), T regulatory (CD3+CD4+FoxP3+), as well as T cytotoxic cells (CD3+CD8+). Observed increases in pro-tumorigenic M2 TAM density (CD68+CD163+) were observed for both HR negative subtypes when compared to HR+HER2+ and HR+HER2low groups, indicating a negative correlation between M2 TAM infiltration and ER/PR status. HER2low tumors had significantly lower tumor PDL1+ than HER2+ tumors. Additionally, 18 of the 208 patients with equal distribution across the hormone-receptor subtypes underwent whole slide multiplexed analysis to perform a deeper spatial analysis.
Conclusions: In a large, clinically annotated cohort of breast cancers distinct immunophenotypes are evident among HR and HER2+ subsets.

CAF contributes to cancer progression through its immunomodulatory role within the tumor microenvironment

Muriel Antonieta Núñez[1], Oreste Corrales[1], Victoria Velasquez[1], Daniel Ernst[2], Montecinos Viviana[3], Francisco Nualart[4], María Isabel Yuseff[1], Javier Cerda-Infante[5]. *[1]Department of Cellular and Molecular Biology, Pontifical Catholic University of Chile, Santiago, Chile,[2]Institute of Science and Innovation in Medicine, University for Development, Santiago, Chile,[3]Department of Hematology-Oncology, Pontifical Catholic University of Chile, Santiago, Chile,[4]University of Concepción, Santiago, Chile,[5]Environ Spa, Santiago, Chile*

Introduction: Cancer progression and metastatic spread is modulated by the tumor microenvironment. Cancer-associated fibroblasts (CAF) are the most abundant cell type within the tumor microenvironment. Little is known about the specific mechanisms by which CAF would exert its cancer progression, through the high secretory capacity of soluble pro-tumorigenic molecules and remodeling of the extracellular matrix. Recent studies in our laboratory have shown for the first time that CAF derived from patients without metastasis express a different genetic profile than those with metastases (mCAF). This study seeks to evaluate the contribution of mCAF to tumor progression through its immunomodulatory role.
Methodology: mCAFs were obtained from patients with metastatic disease and BAF from benign patients. The fibroblasts were functionally characterized by the generation of fibroblast-derived matrices (FDM) and secretory profiles by cytokine array. CD8 T lymphocytes were obtained from healthy patients and treated with fibroblast-secretome. Markers were studied by flow cytometry: activation (CD25 and CD69) and repression (LAG3 and PD1). The migration of CD8 T lymphocytes was studied by transwell and agarose drop migration assay.
Results and conclusion: FDM of mCAF are different in their composition and organization. Furthermore, the secretome of each type of fibroblast presents a differential effect on the activation of CD8 T cells according to the markers highlighted. Regarding migration, it has been observed that the mCAF-secretome can attract lymphocytes. However, it would lead them to

apoptosis. Our results suggest that mCAF, within the tumor microenvironment, has an immunomodulatory role on CD8 T lymphocytes.

Modeling the effects of niche specific microenvironmental changes on patient-derived organoids
Jennifer von Schlichting, Leona Simon, Stefan Peidli, Markus Morkel, Nils Blüthgen. *Charité - Universitätsmedizin Berlin, Berlin, Germany*

Here, we present an approach to study the effects of microenvironmental changes on inter- and intratumoral heterogeneity using colorectal cancer (CRC) patient-derived organoids. We identified relevant paracrine interactions between stromal and tumor cells based on the expression of ligand-receptor pairs in single cell-RNAseq data of 12 colorectal cancer patients. Physiological relevance was tested by adding CRC stroma-derived ligands to patient-derived organoids. A systematic screening of different conditions was enabled by multiplexed mass cytometry and scRNAseq analysis. We also aimed to model the effects of a changing extracellular matrix composition, by supplementing the laminin/collagen IV rich environment with other known ECM proteins such as collagen I to identify the impact of a changing substrate on cell plasticity. We found that ECM parameters as well as niche specific paracrine factors affect proliferation, differentiation, and developmental trajectories of colorectal cancer patient-derived organoids. We hypothesize that supplementing patient-derived organoids in vitro with physiologically relevant factors and substrates may expand the phenotypic space in which organoid cells differentiate, resulting in a more versatile preclinical model system.Our data provide insights into non-genetic sources of inter- and intratumoral heterogeneity resulting in differential drug responses. Additionally, they can serve as guidelines to improve existing patient-derived colorectal cancer models and provide a feasible approach to address common limitations in organoid culture.

Identification of conditionally active antibodies that selectively block CD39 activity in the acidic tumor microenvironment

Aiping Bai, Elise Renahan, Kanam Malhotra, Thomas Thisted, F. Donelson Smith, Robert H Pierce, Edward H van der Horst. *Sensei Bio, Boston, MA*

Background CD39 expression is upregulated in the tumor microenvironment (TME), which is characterized by high levels of extracellular ATP (eATP) and low pH. CD39 catalyzes the rate-limiting degradation step of this immunostimulatory ATP, leading to a rise in immunosuppressive adenosine (ADO). CD39 displays broad expression on endothelial cells and macrophages, which represents a significant peripheral sink for CD39 targeting antibodies. Our strategy aims to circumvent this problem through delivery of pH-selective anti-CD39 blocking antibodies that will achieve a high target occupancy in the tumor, maintaining eATP and inhibiting ADO generation to enhance anti-tumor immunity.

Methods Anti-CD39 antibodies were generated through a yeast-based screening platform and characterized for efficacy of blocking CD39 activity. Cell lines (HEK293 stably overexpressing CD39, parental HEK293, $CD39^{+}$ SK-MEL28, and $CD39^{high}$ ARH77) or soluble CD39 protein were incubated with candidate antibodies. CD39 enzymatic activity was determined using CellTiter Glo 2.0 assay (Promega) and EnzCheck Phosphate Assay (Thermo Fisher).

Results Monovalent affinity of 83 candidate antibodies was measured; K_Ds ranged from $1x10^{-9}$ - $5X10^{-7}$M under both physiological (pH 7.4) and acidic (pH 6.0) conditions. All 83 antibodies bound CD39-overexpressing HEK293 cells at pH 6.0; 76 bound CD39-overexpressing HEK293 cells at pH 7.4. We identified 30 antibodies (100 nM) that block CD39 activity on HEK293-CD39 cells (threshold: > 5% inhibition) under either pH 7.4 or pH 6.0 conditions. 26 antibodies inhibit CD39 activity at pH 7.4, whereas 22 antibodies block CD39 at pH 6.0. Among these 30 antibodies, ten (at 200 nM) inhibit CD39 activity on SK-MEL28 cells (moderate CD39 expression) at both pH 7.4 and pH 6.0; 5 of these preferentially inhibit CD39 at pH 6.0 (threshold: > 7.5% inhibition). The 30 antibodies selected above were tested on ARH77 cells (high CD39 expression). Among them, 16 antibodies inhibited CD39 enzymatic activity beyond 10% at pH 6.0 (maximal inhibition: 43%) and > 6.5% at pH 7.4 (maximal inhibition: 35%). All 16 suppressed soluble CD39 activity under both pH conditions. A

set of 8 antibodies demonstrating higher efficacy of CD39 inhibition on both cell lines at pH 6.0 versus pH 7.4 were prioritized for lead optimization.
Summary and conclusions A panel of 83 antibodies were identified and characterized for inhibition of CD39 enzymatic activity at neutral and acidic pH. The 8 most promising antibodies in terms of pH-selective CD39 binding and inhibition are currently undergoing lead optimization. This pH-dependent TME targeting strategy may alleviate undesirable properties of on-target/off-tumor binding such as target-mediated drug disposition (that results in suboptimal pharmacokinetic properties) and effectively bolster the specific blocking of CD39 in the local tumor environs.

Relative contribution of tumor infiltrating B cells to the tumor microenvironment assessed using an immuno-oncology focussed multi-tumor tissue microarray
Milan Bhagat, Leorenzo Memeo, Christopher Womack, Woo Hoo Kim, Marie Cumberbatch. *TriStar Technology Group LLC, Washington DC, DC*

Although cancer immunotherapy approaches have focused primarily on driving T cell mediated immunity, attention has turned to other immune cell types within the tumor microenvironment (TME) to improve efficacy. Growing evidence supports a role for tumor-infiltrating B cells in complementing T cell-mediated immunity and contributing to the immunomodulation of cancer. Analyses of RNA sequencing data from The Cancer Genome Atlas (TCGA) have correlated high expression of B cell genes with improved patient survival in a range of cancer types. However, it is likely that effective anti-tumor immunity involves interactions between both B and T cells. To investigate the relative contribution of B cells to the overall TME across multiple tumor types simultaneously, we have examined a multi-tumor tissue microarray (TMA) comprising 29 different cancer types represented by approximately 12 unique donors per indication and duplicate 1mm cores per donor (1 from invasive margin [IM] and 1 from tumor center [TC]). Serial sections were stained by single-plex immunohistochemistry for CD20, CD3, CD4 and CD8, and immune cells enumerated by digital image analysis (CellProfiler^{TM}). Analysis of overall immune infiltration regardless of core location (IM and TC combined)

revealed tumor indications such as NSCLC, gastric, TNBC, cutaneous SCC and cervical to be most highly infiltrated, and GIST, GBM and prostate to exhibit the fewest tumor-infiltrating immune cells. B cell frequencies correlated with T cell densities for most tumor types with some notable exceptions including, for example, ER+ BC and gallbladder cancer where the proportion of B cells was higher relative to T cells, and TNBC where the converse pattern was evident. Spatial analyses revealed increased B cell frequencies in IM compared with TC, correlating with the distribution of T cells in the TME for the majority of tumor indications. However, a contrasting expression pattern was observed for ER+ BC, NSCLC SCC and cutaneous SCC where B cell frequencies were greater in TC. Clear evidence for presence of B cells in tertiary lymphoid structures (TLS) was observed for some tumor donor cores (e.g. gastric cancer). Taken together, we describe the relative distribution of B cells in the TME across multiple tumor types simultaneously. This approach demonstrates the benefits of utilizing an immuno-oncology focussed multi-tumor TMA to interrogate B cell biology and to dissect how heterogeneity of this cell population may contribute to anti-tumor immunity.

Potential of TIMP3 regulating the versican status in the colorectal cancer tumor microenvironment

Anna Field[1], Sean Kraus[1], Kristina Matkowskyj[2], Dustin Deming[3], Cheri A. Pasch[1], Wei Zhang[1]. *[1]University of Wisconsin-Madison, Madison, WI,[2]Human Pathology, University of Wisconsin-Madison, Madison, WI,[3]Hematology/Oncology, University of Wisconsin-Madison, Madison, WI*

Background: In colorectal cancer (CRC), versican (VCAN) accumulation has been found to negatively correlate with CD8+ tumor infiltrating lymphocyte (TIL) abundance and its proteolysis into versikine (Vkine) positively correlates with TIL abundance. TIMP3 has demonstrated the ability to inhibit several ADAMTS proteases able to cleave VCAN to Vkine. Here we investigate the correlation of TIMP3 accumulation in CRCs with the VCAN status and CD8+ T cell infiltration.
Methods: Matched primary and metastatic CRC samples from 156 patients who had resected oligometastatic CRC were stained for VCAN, Vkine, TIMP3, and CD8+ TILs. VCAN, Vkine, and TIMP3 were scored using an

intensity binning system ranging from 0-3+ and T cells in the epithelium were reported per high power field (HPF). Tumors were designated as high (2 or 3+) or low (0 or 1) for both VCAN and Vkine and positive (+; 1-3) or negative (0) for TIMP3. Tumors designated VCAN low and Vkine high are considered VCAN proteolytic predominant (VPP) and all other combinations are considered VCAN proteolytic weak (VPW).
Results: Across the whole dataset, 52% of cancers were VCAN high and 24% were VPP. TIMP3 was detected in 33% of cancers. The frequency of TIMP3 was similar between primary and metastatic tumors (39% and 29%, respectively). Of the VCAN high cancers, 42% were TIMP3+ whereas 61% of the TIMP3+ samples are VCAN high. Of the Vkine high cancers, 44% were TIMP3+ and 36% of VPP cancers were TIMP3+. The prevalence of the VPP phenotype was similar between the TIMP3+ and negative cancers. Additionally, among the TIMP3+ samples 68% were Vkine high versus 46% in TIMP3 negative cancers (p=0.001). VCAN proteolysis correlates with higher CD8+ TIL abundance, thus we assessed the number of CD8+ TILs in TIMP3+ and negative tumors. The TIMP3+ cancers had a median of 2 CD8+ TILs/HPF and the TIMP3 negative cancers has a median of 3 CD8+ TILs/HPF. For VPP cancers, those that were also TIMP3+ had a median of 3 CD8+ TILs/HPF compared to TIMP3 negative cancers which had a median of 6 CD8+ TILs/HPF (p=0.2).
Conclusions: TIMP3 correlates with higher levels of VCAN accumulation but does not correlate with lower levels of proteolysis. Future studies are needed to better clarify the impact of TIMP3 and other mediators in regulating VCAN accumulation and proteolysis in the tumor microenvironment.

How inherited mutations affect single cells within the tumor microenvironment in breast tumors stratified by receptor status

Dana Pueschl[1], Derek A. Oldridge[2], Jonathan Belman[1], William Chandler[1], Anupma Nayak[1], Bradley Wubbenhorst[1], John Pluta[1], Michael Feldman[1], E. John Wherry[1], Heather Thorne[3], Georgia Chenevix-Trench[4], Kathleen Cuningham Foundation Consortium for Resea kConFab[5], Susan M. Domchek[1], Katherine L. Nathanson[1]. *[1]University of Pennsylvania, Philadelphia, PA,[2]Children's Hospital of Philadelphia, Philadelphia,*

PA,[3]The Peter MacCallum Cancer Centre, Melbourne, Australia,[4]QIMR Berghofer Medical Research Institute, Brisbane, Australia,[5]kConFab, Melbourne, Australia

The tumor microenvironment (TME) plays important roles in tumor progression, therapy response and patient survival. In this comprehensive study, we performed a detailed multiomic single cell analysis of breast cancers with inherited mutations in different genes (*BRCA1*, *BRCA2*, *PALB2*, *ATM*, *CHEK2*), and wild type mutation negative (WT) patients, stratified by hormone receptor status, to understand the relationship between inherited mutation and immunogenicity. Using spatial tissue multiplexing (PhenoCycler), single cell RNAseq (10X Genomics) and bulk RNAseq, we evaluated cellular markers within the TME associated with DNA damage as well as phenotypes with tumor suppressive (M1, CD8 T cells, NK cells) or tumor promotive (M2, Treg, CAF) properties. We developed a 43-plex antibody panel and characterized eight tissue microarrays containing 443 patient samples from mutation carriers (*BRCA1*: n=142, *BRCA2*: n=118, *CHEK2*: n=2, *TP53*: n=3, *PALB2*: n=7) and WT tumors (n=171). We addressed how the TME differs in mutation carriers versus WT tumors stratified by receptor status. To further investigate immune cell function (cytolytic function, exhaustion, immune checkpoint) as well as pathways involved in immune suppression and/or promotion, we performed scRNA sequencing using isolated single cells from fresh collected BC samples (WT ER: n=3, *BRCA2* ER: n=1, *CHEK2* ER: n=1, *VUS* ER: n=1) and bulk RNA (*BRCA1*: n=17, *BRCA2*: n=9). To determine immune cell (IC) frequency, we analyzed CD45+ cells detectable in each cohort and their co-expression of markers to determine specific phenotypes. Our data suggest that within *BRCA* mutation-associated BC, there are two groups: 1) with increased tumor infiltrating lymphocytes (TILs) including CD8+ cytotoxic T cells with high cytolytic function; and 2) with decreased TILs and cytolytic function. The frequency of CD8+ T cells is significantly decreased in breast cancers with *BRCA2* mutations compared to *BRCA1*. Characterizing ER+ *CHEK2* BC reveals T cell exhaustion compared to WT ER+ BC. Furthermore, preliminary scRNA results reveal increased fibroblast markers in ER+ *CHEK2* and ER+ WT compared to ER+ *BRCA2* tumors. Interestingly, cancer associated fibroblast (CAFs) markers (*ACTA2, COL1A1, FAP, PDGFRA, PDGFRB, PDPN,*

THY1) as well as TAMs (*CCL2, CD163, CD206, CD68, IL10, LOX, PLOD2, SIGLEC1*) are increased in ER+ CHEK2 tumors compared to ER+ WT. These data could provide insights into how the TME associated with ER+ *CHEK2* mutations might be driven by CAFs and TAMs with a frequency much higher than in ER+ WT. The detection of immune suppressive (Treg, M2) and immune promotive (M1) phenotypes differs in *BRCA1* compared to *BRCA2* mutated and WT TNBC. Our findings could decipher the role of DNA repair gene mutations and their effect on cells within the TME that might influence the design of treatment options in patients with inherited mutations based on their receptor status.

Design and validation of ultrahigh-plex discovery panels for immuno-oncology and oncology

Yan He, Shannon Berry, Olive Shang, Michael McLane, Nicholas Ihley, Yi Zheng. *Akoya Biosciences, Marlborough, MA*

Introducti**on** Ultrahigh-plex single-cell spatial phenotyping is revolutionizing cancer research through deeper interrogation of cellular and protein-level co-expression, localization, and arrangements within cancer tissues. To enable in-depth characterization of the tumor microenvironment (TME), we have developed and validated pre-optimized antibody panels on cancer tissues to reveal key cell types and cellular architecture using the PhenoCycler™-Fusion system. Here, we present our methodology for the development and validation of multiplex spatial phenotyping panels for oncology and immuno-oncology.

Methods We designed panel modules such that each module answers specific biological questions about the TME and can be multiplexed together for a more comprehensive view of the structure and function of the tumor and TME. The resulting PhenoCode™ Discovery panel modules include markers that identify key immune cell types, immune activations and checkpoints, mediators of proliferation, and other hallmarks of cancer. Each antibody in the panel module was conjugated to an oligo barcode and stained on human formalin-fixed paraffin-embedded (FFPE) tissue. The slide was imaged on a PhenoCycler™-Fusion platform, where dye-labeled oligo reporters (complementary to the barcodes) are hybridized to the barcode to visualize the antibody. The results were compared serial sections

run with a 3,3'-Diaminobenzidine (DAB) chromogenic immunohistochemistry assay to ensure specificity of the antibody was retained. Antibody concentration, exposure time, and corresponding dye were further optimized, verified, and validated as a whole module using tonsil and cancer tissues based on image analysis and intensity analysis, to achieve an ultrahigh-plex detection.
Results and Conclusions In this study, we showcased the rigorous process used for development and validation of PhenoCode™ Discovery panel modules and demonstrated how they can seamlessly work together to collect more data out of one tissue sample. The introduction of these pre-optimized antibody panel modules mark a pivotal point in the evolution of ultrahigh-plex spatial phenotyping. They not only simplify experimental design and assay set up, with panels that make it easier for researchers to answer important questions with this technology, but also save precious time and resources, while reducing overall costs.

High intratumoral levels of Notch3 increase tumorigenesis and promote an immunosuppressive TME in EGFR-mutant NSCLC
Shankar Suman, Jacob Kaufman, Rajeswara Arasada, Sanjay Varikuti, Nastaran Navari, Shuxiao Guan, Joseph Amann, Mikhail Dikov, David Carbone, Regan Memmott. *The Ohio State University, Columbus, OH*

Activating mutations in the Epidermal Growth Factor Receptor (EGFR) are one of the most common driver mutations in non-small cell lung cancer (NSCLC). They are present in the tumors of ~15% of Caucasian patients and in up to 50% of Asian patients. Notch3 is a member of a family of transmembrane receptors that has been shown to increase cell proliferation and inhibit cell death and differentiation. Notch3 also promotes the formation of cancer cells with stem-like properties. Studies have shown that a high level of Notch3 in tumors is associated with poor prognosis of patients with NSCLC. However, its role in EGFR-mutant NSCLC tumorigenesis has not been specifically evaluated. We analyzed the TCGA, Moffit, and ORIEN datasets, which include tumor samples from patients with EGFR-mutant lung cancer. We found that high levels of Notch3 were associated with decreased overall survival (HR=2.0, p=0.04). Interestingly, analysis of two additional datasets derived from the phase 3 clinical trials

OAK and POPLAR showed that patients whose EGFR-mutant tumors had the highest levels of Notch3 had worse clinical outcomes when treated with immunotherapy (HR 18.6, p=4e-04) but not chemotherapy. This could suggest that Notch3 promotes EGFR-mutant lung tumorigenesis by creating an immunosuppressive tumor microenvironment (TME). To test this, we generated a novel mouse model, c/EGFR^{L858R}Notch3, that expresses tetracycline-inducible Notch3 and mutant EGFR under the control of the Clara cell-secretory protein (CCSP) promoter. CT-based imaging showed that mice whose tumors harbored high levels of Notch3 had significantly increased lung tumor burden at eight weeks. These mice also had worse overall survival (HR 2.3, p=0.04). To determine if increased Notch3 expression in tumors promotes a more immunosuppressive TME, we did immunophenotyping analysis that revealed a significant increase in regulatory T cells and a decrease in cytotoxic CD8+T cells. Furthermore, T cells in the TME expressed higher levels of markers of exhaustion, specifically, PD-1 and Tim-3. We also found that mice whose tumors had high levels of Notch3 had a greater density of immunosuppressive macrophages in the TME, which was associated with elevated levels of TNF-α. Overall, our data suggest that patients with EGFR-mutant NSCLC whose tumors harbor high levels of Notch3 may have worse clinical outcomes and response to immune checkpoint inhibitors due to Notch3 promoting an immunosuppressive TME.

#4651

Comparison of the tumor and lymph node immune microenvironment in early non-small cell lung cancer through multimodal single cell sequencing

Zhanhao Xi[1], Yusuke Koga[1], Shannon McDermott[2], Jennifer Beane[1], Sarah A. Mazzilli[1], Kei Suzuki[3], Joshua D. Campbell[1]. *[1]Computational Biomedicine, Boston University, Boston, MA,[2]Boston University, Boston, MA,[3]Department of Surgery, INOVA, Falls Church, VA*

Background/**Purpose:** Previous studies have analyzed the tumor and local immune microenvironments in lung cancers and suggest immune modulation is associated with worse clinical outcome. However, the tumor-immune microenvironment in early stage lung tumors and lymph nodes (LNs) have not been fully described. We aim to compare cell states in the

immune microenvironments between lung tumors and LNs through multi-modal profiling of the transcriptome and surface proteins.
Methods: Needle biopsy samples were taken from 10 treatment-naive early stage lung cancer patients undergoing lung cancer resections. Tissues were obtained from normal lung, lung tumor, and multiple mediastinal LNs, and processed for scRNA-seq including labeling with Total-Seq C CITE-seq panel to quantify the levels of 130 cell surface proteins. In total, 76,721 cells (4,462 normal lung; 39,019 tumor; 33,240 LN) were identified with a median of 1,673 genes and 92 protein features detected per cell. Protein expression was decontaminated through the decontX algorithm. Weighted-Nearest Neighbor analysis from the *Seurat* R package was applied to integrate the CITE-seq and RNA-seq level data for clustering cells into subpopulations.
Results: Six broad cell populations were identified including T/NK, myeloid (CD14+), B (CD19+), mast (TPSAB1+), pDC (IRF8+), and epithelial (EPCAM+) cells. Among 8 CD4+ T lymphocyte subpopulations and 11 CD8+ T lymphocyte subpopulations observed through clustering, a naïve CD4+ and a CD8+ T subpopulation (LEF1+, TCF7+) was observed respectively. These naïve T lymphocyte populations displayed increased proportions in LNs in comparison to tumors. In addition, 5 of the 8 observed CD4+ T lymphocyte populations were enriched in LNs. Immune populations enriched in LNs were largely shared and uniform across different patients. In contrast, a single CD4+ and CD8+ T lymphocyte subpopulation displayed expression of T lymphocyte exhaustion markers (TIGIT+, LAG3+, PD-1+) and were enriched in tumors. 6 of the 11 observed CD8+ T lymphocyte populations were enriched in tumor samples in comparison to LNs. Two alveolar macrophage populations (MARCO+) were enriched in normal lung tissue, in which one showed a heightened stress response.
Conclusion: Single-cell profiling reveals diversity in immune cell populations between LNs, tumor, and adjacent normal tissue in early-stage LUAD. The results suggest the composition of immune cell type is fairly consistent across LNs but more heterogeneous in the tumor and adjacent normal tissue in early-stage patients. In the future, we aim to determine if these immune subpopulations are associated with survival, recurrence, aggressiveness, and predict responses for neoadjuvant treatments, which could improve prognosis and patient quality of life.

A cellular and transcriptomic dissection of the human breast for studying mechanisms of cell and tissue function

Katelyn Del Toro[1], Rosalyn W. Sayaman[2], Kate Thi[3], Yamhilette Licon-Munoz[1], William C. Hines[1]. *[1]Biochemistry and Molecular Biology, Univ. of New Mexico School of Medicine - Albuquerque, Albuquerque, NM,[2]Department of Laboratory Medicine, University of California, San Francisco, San Francisco, CA,[3]Life Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA*

A fundamental question in biology, central to our understanding of cancer and other pathologies, is determining how different cell types coordinate to form and maintain tissues. Recognizing the distinct features and capabilities of the cells that compose these tissues is critical. Unfortunately, the complexity of tissues often hinders our ability to distinguish between neighboring cell types and, in turn, scrutinize their transcriptomes and generate reliable and tractable cell models for studying their inherently different biologies. A lack of comprehensive methods to identify, isolate, and culture each cell type from many tissues have impeded progress. Here, we will describe such a method for the breadth of cell types composing the human breast. Furthermore, we have sequenced mRNAs from each purified population and investigated transcriptional patterns that reveal their distinguishing features. These analyses have exposed differentially expressed genes and enriched biological pathways that capture the essence of each cell type, along with transcripts that display intriguing expression patterns. These data, analytic tools, and transcriptional analyses form a rich resource whose exploration provides remarkable insights into the inner workings of the cell types composing the breast, thus furthering our understanding of the rules governing normal cell and tissue function.

Spatial architecture of tumor-infiltrating macrophagesorchestrates tumor immunity and therapeutic response

Yuanyuan Zhang, Fuduan Peng, Guangsheng Pei, Yunhe Liu, Guangchun Han, Linghua Wang. *UT MD Anderson Cancer Center, Houston, TX*

Tumor-infiltrating macrophages, a major cellular component in the tumor microenvironment (TME), have been proven to be linked with tumor progression and immunotherapy resistance. Tremendous heterogeneity has been revealed for tumor-associated macrophages (TAMs) in different cancer types, however, how these TAM subtypes are localized and interact with tissue ecosystems remains poorly understood. Here, we perform an integrative analysis of TAMs, malignant and non-malignant cells from 10 cancer types, based on single-cell RNA-seq and spatial transcriptomic data. By interrogating the spatial distributions of different TAM subtypes in situ, we reveal spatially restricted developmental, regulation, and functional heterogeneity of TAMs in TME. Different cancer types show distinct TAM subtype enrichments with specific interface architectures, which is potentially shaped by the cellular compositions and spatial niches of tumor cells. Furthermore, the compartmentalized TAM subpopulations can reflect the spatial architecture of surrounding stromal and immune cells, and thus orchestrate tumor immunity and therapeutic response. Our study demonstrates the cellular and molecular underpinnings of TAM heterogeneity and stochastic regulations of TAMs for TME architecture, tumor progression and immunotherapy responses, which will assist in the identification of possible therapeutic targets.

Differential immunomodulation following checkpoint blockade in the orthotopic ID8-luc ovarian model

Sheri Barnes, Anita Zaitouna, Lauren Kucharczyk, Scott Wise. *Laboratory Corporation of America, Ann Arbor, MI*

Syngeneic tumor models for ovarian cancer are limited in preclinical research. One of these models, ID8-luc, is established intraperitoneally with disease progression resulting in the accumulation of ascites fluid. Treatment efficacy can be determined by non-invasive bioluminescence imaging (BLI), but solid ID8-luc tumors do not form in the peritoneal cavity, making assessment of immunomodulation challenging. To this end, we have developed the ID8-luc model as a tool to investigate immuno-modulatory drug candidates by utilizing tissues in the peritoneal cavity of diseased animals for ex vivo analyses. Specifically, flow cytometry of diseased ovaries was employed to examine the effects of checkpoint inhibition on T

cell phenotypes and NK cell infiltration. To identify tumor deposits in organs from mice bearing ID8-luc disease for analysis tumor infiltrate, the model was established in untreated C57BL/6 albino mice, and ovaries, liver, peritoneal wall, pancreas, and spleen were evaluated pathologically. Progressive establishment of tumor deposits were seen in the ovaries, pancreas, and peritoneal wall of untreated mice, but not in naïve mice. Further, immune infiltration in ovaries were markedly higher compared to naïve mice. To assess immunomodulation, disease was established in a second cohort of mice, and mice were treated with anti-mPD-1, anti-mPD-L1, and anti-mCTLA-4. Disease progression was monitored by BLI, and following treatment, ovaries containing tumor deposits were collected and lymphoid infiltrate was analyzed by flow cytometry. Checkpoint blockade did not result in efficacy under the conditions tested. However, differences in T cell infiltration were notable with treatment of anti-PD-1 and anti-mPD-L1. Particularly, a marked increase of five to ten fold CD8+ and CD4+ T cells by absolute counts was seen with anti-mPD-1 and anti-mPD-L1 treatment compared to control. Further, the percentage of CD8+ T cells expressing the activation markers CD69 and ICOS as well as PD-1, TIM-3, and LAG-3 checkpoint proteins increased with anti-mPD-1 treatment. Less prominent yet similar trends in this biomarker expression were seen with anti-mPD-L1 treatment. NK and NKT infiltration also increased five to eight fold in ovaries following anti-mPD-1 treatment. Interestingly, anti-mCTLA-4 treatment did not result in any remarkable changes in infiltration or activation marker dynamics. Taken together, these findings are suggestive of a mounting immune response following PD-1 and PD-L1 blockade, but not CTLA-4 blockade, characterized by changes in the lymphocyte compartment in the ovaries. This response is seen in the absence of efficacy, suggesting the potential that this immunomodulation can be exploited in rational combination strategies with checkpoint blockade for immune-oncology drug candidates using the ID8-luc ovarian tumor model.

The prognostic significance of a 12-chemokine tertiary lymphoid structure (TLS) gene signature in uveal melanoma (UM)

Hassan Mohammed Abushukair[1], Ayah Al-Bzour[1], Andrew Knight[2], Walter J. Storkus[3], John M. Kirkwood[4], Lilit Karapetyan[5]. *[1]Jordan University of*

Science & Technology, Irbid, Jordan,[2]Department of Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA,[3]Departments of Dermatology, Immunology, Pathology and Bioengineering, University of Pittsburgh Medical Center, Pittsburgh, PA,[4]Department of Medicine, Division of Hematology/Oncology, UPMC Hillman Cancer Center, Pittsburgh, PA,[5]Department of Cutaneous Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

Introducti**on** Lymphoid aggregates are commonly associated with better prognosis and enhanced response to immune modulators in several cancers. Considering the immune-privileged status of the eye we sought to investigate the immune, genomic and prognostic significance of 12-chemokine TLS gene signature in UM patients.

Methods A previously validated 12-chemokine gene signature established in cutaneous melanoma was used (*CCL2-5, CCL8, CCL18, CCL19, CCL21, CXCL9-11, CXCL13*). Clinical, genomic and transcriptomic data was retrieved from The Cancer Genomic Atlas UM cohort (n = 80) and the GSE22138 dataset (n = 63) from the gene expression omnibus. The signature was constructed using principal component (PC) analyses based on the first PC1. Patients with a PC1 score > +4 or < -4 were considered gene expression profile (GEP) high and low, respectively. The CIBERSORT algorithm was used to estimate the immune composition in tumor tissue. Gene Set Enrichment Analysis (GSEA) was conducted using the Hallmarks gene sets. A cytotoxic T cell (CTL) score was calculated based on the coordinate expression of *CD8A, CD8B, GZMA, GZMB* and *PRF1*.

Results The 12-chemokine score was higher among epithelioid vs. spindle cell or mixed histology (mean: 7.84 vs -4.91 vs 1.22, p = 0.038) and there were no differences across different tumor sites or stages. GEP low patients had significantly better overall survival (HR: 0.10, 95% CI: 0.03-0.36, p < 0.001) and disease-free survival (HR: 0.23, 95% CI: 0.06-0.88, p = 0.031) compared to GEP high. Metastasis-free survival was not significantly different in the second cohort (0.47, 95% CI: 0.16-1.42, p = 0.182). The EIF1AX and SF3B1 driver mutations were significantly more frequent among GEP low (22.5% and 35%) compared to GEP high patients (3.7% and 7.4%). Tumor mutational burden and other driver mutations (BAP1, GNA11, GNAQ) were similar between both groups. GSEA revealed

significant enrichment of inflammatory response (IFN-α/γ, TNF-α signalling via NF-κB, IL2-STAT5, IL6-JAK-STAT3 signalling), Epithelial Mesenchymal Transition (EMT), reactive oxygen species, and angiogenesis pathways in GEP high patients. GEP low patients had lower CTL scores compared to GEP high patients (31.3 vs 11.4, $p < 0.001$). M1 macrophages, CD8+ and regulatory T cells were enriched in GEP high patients whereas CD4+ memory T cells and activated dendritic cells were more prevalent in GEP low patients.
Conclusion Uveal melanoma patients with a high GEP score had inferior survival and were enriched for inflammatory, angiogenic, and EMT pathways, while patients with a low GEP score were more likely to express prognostically favourable driver mutations (EIF1AX, SF3B1). Our results suggest a variable prognostic role of lymphoid aggregates in the setting of UM compared to other solid tumors, warranting further investigation for their differential underlying mechanisms.

#4656
Targeting macrophage PI3KGamma in aggressive prostate cancer
Kenneth M. Adusei[1], Thomas R. Nirschl[1], Alex J.-E. Lee[1], Fan Shen[1], Xiaoxu Wang[1], Jade Alvarez[1], Tamara L. Lotan[1], Judith Varner[2], Jelani Zarif[1]. *[1]Johns Hopkins University, Baltimore, MD,[2]University of California San Diego, San Diego, CA*

The phosphatidylinositol-4,5-bisphosphate 3-kinase (PI3K) family of lipid kinases play key roles in cancer biology by promoting cell motility, growth, and survival. Of the four class I PI3K isoforms, PI3Kα,β,δ,γ, the PI3Kγ isoform is primarily expressed by myeloid cells. Studies from the Varner lab have established that the macrophage lipid kinase, PI3Kγ, selectively promotes myeloid cell trafficking and immune suppressive transcription in tumor associated monocytes and macrophages, thereby inhibiting T cell recruitment, activation, and tumor eradication. We hypothesized that antagonism or deletion of PI3Kγ would induce tumor growth inhibition *in vivo* in prostate cancer (PCa) models. To test our hypothesis, we implanted syngeneic murine prostate cancer tumors (B6CaP) into global PI3Kγ knock out mice and preliminary studies show severe tumor growth inhibition. Using a publicly available single cell RNA sequencing database of metastatic PCa (mPCa) tumors from bone, we calculated regulon scores for

transcription factors C/EBPβ and NFκB which are up and down-regulated by PI3Kγ signaling in myeloid cells respectively. This analysis indicated that a notable proportion of monocytes in mPCa have active PI3Kγ signaling based on C/EBPβ activity and a lack of NFκB activity. Finally, we tested the significance of eganelisib treatment on monocytes and found that this pathway was essential for monocyte survival during macrophage differentiation and adhesion. Altogether, our proposed research delineates the mechanistic roles of PI3Kγ in the regulation of prostate cancer tumor growth and support PI3Kγ as a target to sensitize PCa to immune checkpoint inhibitors.

Topological data analysis reveals pan-cancer immune phenotypes with immune-related survival differences

Kevin A. Murgas[1], Jung H. Oh[2], Joseph O. Deasy[2], Allen R. Tannenbaum[3].
[1]Biomedical Informatics, Stony Brook University, Stony Brook, NY,[2]Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Applied Mathematics & Statistics, Stony Brook University, Stony Brook, NY

Cancer immune phenotypes present a wide range of heterogeneity across cases, with individual tumors displaying unique patterns of infiltrating immune cell types. Deconvolutional methods allow for scoring of various immune cell types in bulk tumor RNA as a quantification of immune phenotype. Understanding how immune phenotype relates to clinical outcome remains limited. Here, we demonstrate an approach applying topological data analysis to investigate differences of immune phenotype in a pan-cancer cohort (TCGA; n=11,373 tumors). We first define an Immune Activation Score based on relative abundance of activator and suppressor immune cell types and find this score depends on cancer type and distinguishes overall survival outcomes. We then implement a robust Mapper-based algorithm to delineate clusters of immune phenotypes of tumor samples across pan-cancer and within cancer types. Our method identifies immune-activated and immune-suppressed phenotypes with distinct survival outcomes and molecular features.

Flexible multiplexed immunofluorescent panels for accelerated identification of spatial signatures for immunotherapy checkpoint investigations

Jacob Circelli, Rachel Schaefer, Oscar Perez, Linying Liu, Michael McLane, Yi Zheng. *Akoya Biosciences, Marlborough, MA*

A fundamental step in the characterization of the tumor microenvironment (TME) is the identification of the distinct immunologic phenotypes in various cancer types. The spatial arrangement of these cells and their co-expression patterns serve as an increasingly important tool for the identification of a novel class of highly predictive biomarkers for immunotherapy response knows as spatial signatures. To study the complex biological processes within the TME and develop clinically useful spatial signatures, it is imperative to take an approach that combines relevant content with flexibility, speed, and throughput. We recently introduced PhenoCode^{TM} Signature Panels that offer researchers the ability to stain for multiple biomarkers including their marker of choice at a single cell resolution on a single tissue in a scalable end-to-end automated workflow. Incorporating Akoya's novel barcoded antibody labeling chemistry, these panels enable all primary antibodies to be applied as a cocktail in a single incubation step, followed by the sequential amplified detection of each marker via Opal fluorescent dye technology. Previously, we have presented data on 3 panels that address key questions for the characterization of the TME, including whether the tumor is "hot" or "cold," the identity of the immune cells comprising the TME, the proliferative state of tumor cells and the activation state of the immune cells. Here we showcase two new PhenoCode Signature panels that allow researchers to further characterize the TME by examining immune cell exhaustion and macrophage polarization, key events that contribute to an immunosuppressive TME. In this study, staining was performed using all five PhenoCode Signature panels and DAB on the Leica BOND RX^{TM} automated stainer. Human formalin-fixed, paraffin embedded (FFPE) lung cancer tissues were stained and whole slide multispectral scans were acquired on the PhenoImager HT® platform. Image analysis was performed with a phenotyping algorithm in inForm® and staining intensities were analyzed in R using Phenoptr and PhenoptrReports. The fluorescent staining of each marker was benchmarked to the DAB staining. Each panel was proven to be both highly

accurate and reproducible. Together these five PhenoCode Signature panels provide researchers a rapid and robust method for characterizing the TME to aid the development of spatial signatures which have been shown to be highly effective at predicting therapeutic outcomes.

Depicting ONC201/Delta-24-RGD combination for the treatment of pHGGs and DMGs reveals a therapeutic benefit and a proinflammatory tumor microenvironment remodelation

Daniel de la Nava[1], Virginia Laspidea[1], Iker Ausejo-Mauleón[1], Marc García-Moure[1], Sabine Mueller[2], Javad Nazarian[2], Joshua E. Allen[3], Oren Becher[4], Juan Fueyo[5], Candelaria Gomez-Manzano[6], Ana Patiño-Garcia[1], Carl Koschmann[7], Marta M. Alonso[1]. *[1]Department of pediatrics, University of Navarra, Pamplona, Spain,[2]Department of Oncology, University Children's Hospital Zürich, Zürich, Pamplona, Switzerland,[3]Chimerix, Durham, NC,[4]Department of pediatrics, Icah School of Medicine at Mount Sinai, New York City, NY,[5]Department of Neuro-Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Department of pediatrics, University of Navarra, Houston, TX,[7]Department of pediatrics, University of Michigan, Ann Arbor, MI*

Purpose of the work: Pediatric High Grade Gliomas (pHGGs) and Diffuse Midline Gliomas (DMGs) are two of the most aggressive tumors developed during childhood. Its poor overall survival emphasizes the need of alternative treatments. ONC201, an imipiridone small molecule, and the oncolytic virus Delta-24-RGD have shown safety and effectiveness in preclinical and clinical settings for these diseases. In this work, we set to characterize the antitumor effect of these two agents combined for the treatment of pHGGs and DMGs.
Experimental procedures: A panel of human pHGG (CHLA-03-AA, SF188, SJ-GBM2), DMG (SU-DIPG IV, SF8628, TP-54, HSJD-DIPG-007, UMPED83), and murine DMG cell lines (XFM, NP-53) were used. We assessed viral replication by hexon titration, protein expression by immunoblotting/immunohistochemistry, and oxygen consumption by Seahorse analyses. Viability was measured by MTS. Mitochondrial DNA (mtDNA) were measured by qPCR. CHLA-03-AA/XFM were

orthotopically engrafted in athymic nude/Balb/c mice. For *in vivo* experiments, animals were treated with PBS/Delta-24-RGD (10^7 pfu/mice) intratumorally, followed by ONC201 oral gavage administration (125 mg/kg/twice/weekly). The tumor microenvironment immune infiltration was evaluated by flow cytometry.
Results: We checked the potential negative interaction between both agents *in vitro*. Adenovirus replication was not affected by ONC201 cotreatment, indicating the suitability of this combination. *In vitro* citotoxycity analyses showed the cotreatment is either synergistic or additive in 80% of the cells evaluated. Then, we set to characterize the mechanistic effects of the combination. Analysis of mitochondria status showed the decrease in oxygen consumption previously reported as ONC201 effect is maintained with Delta-24-RGD presence. Confirmation of higher mitochondria damage was assessed by a reduction of mtDNA in the combination. Independently, endoplasmic reticulum stress (ERS) previously described in both agents was found potentiated in cotreatment via ATF4. Altogether, these data suggest an improved response in the combination by mitochondria and ERS perturbation. *In vivo*, cotreatment led to a significant increase in the median OS (Control: 48 days; ONC201: 54.5 days; Delta-24-RGD: 62 days; Delta-24-RGD/ONC201: 95 days (P=0.0008)) in CHLA-03-AA bearing mice, leading to 20% long-term survivors, free of disease. Of importance, a reshaping of the tumor microenvironment towards a proinflammatory phenotype were described (increases of lymphoid (T and NK cells) and myeloid (macrophages, granulocytes, monocytes, denditric cells and microglia) linage.
Conclusions: Our data support the combination ONC201/Delta-24-RGD leads to a superior therapeutic effect due to the generation of a proinflammatory microenvironment in pHGG and DMGs preclinical models.

Novel Targets, Biomarkers, and Models for Cancer

A forward genetic screen identifies SIRT1 as a driver of neuroendocrine prostate cancer

Francisca Nunes de Almeida[1], Alessandro Vasciaveo[2], Min Zou[1], Matteo Di Bernardo[1], Andrea Califano[2], Cory Abate-Shen[1]. [1]*Department of*

Molecular Pharmacology and Therapeutics, Columbia University Irving Medical Center, New York, NY,[2]Department of Systems Biology, Columbia University Irving Medical Center, New York, NY

Neuroendocrine prostate cancer (NEPC) is a deadly variant of prostate cancer for which no cure is yet available. Up to 20 percent of the patients with castration resistant prostate cancer (CRPC), will progress to NEPC after treatment with standard-of-care therapies, such as abiraterone and enzalutamide, that target the androgen receptor (AR) pathway. However, the molecular mechanisms that drive the emergence of NEPC are largely unknown, contributing to a lack of treatment options for patients with NEPC. We implemented a forward genetic approach to identify novel drivers of NEPC, by using the *Sleeping Beauty* (SB) transposon-based forward genetic mutagenesis screening system in our *Pten-, Trp53*-deficient mouse model that is primed to develop NEPC at a low frequency. We generated a mouse strain (*NPp53-SB*) in which the *Nkx3.1* promoter regulates the expression of tamoxifen-inducible *Cre* specifically in the mouse prostate epithelium, resulting in transposition of the *T2Onc2* transposable element and conditional deletion of *Pten* and *Trp53* in mouse prostate epithelium. We observed an increased NEPC incidence in our *NPp53-SB* mouse model compared to control mice without the transposon *T2Onc2*, suggesting that the SB-mediated insertional mutagenesis events are driving the development of NEPC. To elucidate the genetic events that are driving the observed NEPC phenotype, we identified the common insertion sites (CISs) of the transposon insertions, which revealed a total of 330 CIS-associated genes. We further performed an integrative analysis using RNA-seq data from our SB cohort, a second mouse dataset and a metastatic CRPC patient cohort, which allowed us to identify the Master Regulator (MR) proteins that are associated with NEPC, as well as the upstream genomic events that modulate these MRs and the emergence of NEPC. Our integrative analysis identified the deacetylase Sirt1 as a candidate driver of NEPC. Using CRISPR activation (CRISPRa) technology *in vivo* we observed that SIRT1 activation induced an NEPC-like phenotype in the adenocarcinoma LNCaP cell line, while Sirt1 drug-mediated inhibition in an NEPC cell line resulted in less aggressive tumors.In summary, we have developed a *Sleeping Beauty* forward genetic screen in our mouse model of CRPC, which not only accelerates disease progression, but also increases the incidence of NEPC. Our integrative analysis identified a panel of CIS-associated genes that are likely to be functionally involved in progression to NEPC. In particular, Sirt1 was

shown to be a promising candidate, which may shed light on mechanisms that this aggressive disease uses to evade treatments and may inform the development of novel therapies.

Small cell lung cancer subtype plasticity is regulated by KDM6A

Leslie Duplaquet[1], Yixiang Li[1], Matthew A. Booker[1], Yingtian Xie[1], Radhika A. Patel[2], Deli Hong[1], Thomas Denize[3], Emily Walton[3], Yasmin N. Laimon[3], Roderick Bronson[4], Jackson Southard[1], Shuqiang Li[1], Sabina Signoretti[3], Michael Y. Tolstorukov[1], Paloma Cejas[1], Henry W. Long[1], Michael C. Haffner[2], Matthew G. Oser[1]. *[1]Dana-Farber Cancer Institute, Boston, MA,[2]Fred Hutchinson Cancer Research Center, Seattle, WA,[3]Brigham and Women's Hospital, Boston, MA,[4]Harvard Medical School, Boston, MA*

Small cell lung cancer (SCLC) is a high-grade neuroendocrine cancer that accounts for ~15% of lung cancers. While nearly all SCLCs are genetically driven by near universal loss of function (LOF) mutations in *RB1* and *TP53*; several recent studies show that there are different phenotypic SCLC molecular subtypes characterized by expression of lineage transcription factors. These include the neuroendocrine ASCL1 and NEUROD1 subtypes which together comprise ~70-80% of SCLCs. Initially subtypes were thought to be mutually exclusive, but recent evidence shows intra-tumoral subtype heterogeneity and plasticity between subtypes. A recent study found that 35-40% of human SCLCs express both ASCL1 and NEUROD1, but the mechanisms driving ASCL1 and NEUROD1 intra-tumoral heterogeneity are not well understood. My laboratory previously developed an autochthonous CRISPR-based SCLC genetically-engineered mouse model (GEMM) generated by intratracheally injecting adenoviruses encoding Cre recombinase and sgRNAs targeting *Rb1*, *Trp53*, and *Rbl2*. Cre turns on Cas9 expression and allows for CRISPR/Cas9 editing of *Rb1*, *Trp53*, and *Rbl2* in somatic cells in the lungs. The unique advantage of this model is that it allows the inclusion of sgRNAs targeting additional genes of interest in the same adenovirus. Using this CRISPR-based autochthonous SCLC GEMM approach, we studied the consequences of inactivating the epigenetic modifier KDM6A during SCLC tumorigenesis. KDM6A

functions as an H3K27 histone demethylase and also exists in the COMPASS complex with KMT2C/D to promote H3K4 mono-/di-methylation at enhancers. KDM6A along with its protein binding partner KMT2D are mutated in SCLC and KDM6A has been implicated in controlling differentiation in other lineages. Strikingly, we found that KDM6A inactivation in SCLC GEMMs induced plasticity from ASCL1 to NEUROD1 resulting in SCLC tumors that expressed both ASCL1 and NEUROD1. ATAC-sequencing showed open chromatin at the promoters of NEUROD1 and NEUROD1 target genes in KDM6A inactivated tumors. Interestingly, KDM6A inactivated tumors showed a spectrum of ASCL1 to NEUROD1 heterogeneity where some KDM6A inactivated tumors completely lost ASCL1 and solely expressed NEUROD1, some tumors expressed ASCL1 and NEUROD1 in a mutually exclusive manner, while others primarily expressed ASCL1 with very few NEUROD1 positive cells. Mechanistically, KDM6A binds and maintains ASCL1 target genes in an active chromatin state with its loss increasing H3K27me3 near both promoters and enhancers, and decreasing H3K4me1/2 at enhancers together leading to a cell state primed for ASCL1 to NEUROD1 subtype switching. This work identifies KDM6A as an epigenetic regulator that controls ASCL1 to NEUROD1 subtype plasticity and provides an autochthonous SCLC GEMM to model ASCL1 and NEUROD1 subtype heterogeneity, which is found in 35-40% of human SCLCs.

#5775

GLIS3 drives a neural-like malignant state enriched after neoadjuvant treatment in pancreatic cancer

Jimmy A. Guo[1], Jennifer Su[2], Carina Shiau[3], Ananya Jambhale[1], Annan Yang[4], Westley Wu[1], Junning Wang[4], Connor Hennessey[4], Patrick Yu[1], Brendan Parent[4], Giselle Uribe[4], Julien Dilly[4], Laleh Abbassi[4], Qijia Yu[4], Arnav Mehta[1], David Ting[3], Brian Wolpin[4], William Freed-Pastor[4], Joseph Mancias[4], Tyler Jacks[2], William L. Hwang[3], Andrew J. Aguirre[4]. *[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]MIT, Cambridge, MA,[3]Massachusetts General Hospital, Boston, MA,[4]Dana Farber, Boston, MA*

Pancreatic cancer is a challenging disease which lacks a robust precision oncology framework. Prior work has demonstrated that transcriptional subtypes in pancreatic cancer can stratify patients by response to chemotherapy and overall survival. These include classical and basal-like as the predominant subtypes in untreated disease, as well as a transdifferentiated neural-like malignant subtype enriched after standard-of-care chemotherapy. Nonetheless, our understanding of transcriptional subtypes remains critically limited by genetic and culture-based confounders in preclinical models. Furthermore, most murine pancreatic cancer models do not fully reflect the classical *vs.* basal-like divide observed in humans, preventing faithful *in vivo* investigation. Collectively, these challenges have hindered the study of and development of therapeutic strategies against these transcriptional subtypes. To enable systematic study of the classical, basal-like and neural-like subtypes, we developed isogenic KP (*Kras*$^{G12D/+}$;*Trp53*$^{FL/FL}$) organoids and leveraged CRISPR activation to endogenously overexpress state-specific transcription factors. Our data revealed that *Gata6* and dN*Trp63* drove classical and basal-like identity, respectively, supporting prior studies. Furthermore, through *in silico* approaches, we identified candidate drivers of the neural-like state, including *Glis3*, a zinc finger protein that mediates neuroendocrine fate during pancreatic development. We confirmed that *Glis3* overexpression results in neural-like transdifferentiation in cancerous organoids through RNA-seq and proteomics, and that *GLIS3* knockout abrogates neural-like identity in human cell lines. To study their malignant potential *in vivo*, we performed orthotopic transplants into murine pancreata, and observed that *Glis3* and dN*Trp63* accelerated tumor formation and progression, corresponding to clinical outcomes observed in patients. These models may therefore provide a means for *in vivo* interrogation of subtype biology and vulnerabilities. Finally, to model and predict therapeutic sensitivities, we performed *ex vivo* treatment assays with chemotherapy and emerging KRAS^{G12D} inhibitors. A selection assay showed that basal-like and neural-like organoids were starkly enriched by multi-agent chemotherapy, while classical organoids were depleted. Finally, we learned that the neural-like subtype exhibits differential sensitivity to KRAS^{G12D} inhibition through an RTK-associated mechanism. Taken together, we provide a foundational system for interrogating subtype-specific vulnerabilities in pancreatic cancer.

Advancing a screening platform with panels of patient-derived organoid models for drug discovery and development

Annamaria Rapisarda[1], Eric Jones[1], Curtis Hose[1], Erik Harris[1], Petreena S. Campbell[1], Mariaestela Ortiz[1], John Connelly[1], Nanda Mahashetty[1], Thomas Silvers[1], Zahra Davoudi[1], Penny Sellers Brady[1], Tiffany Nikirk Rohrer[1], Julie Grams[1], Karen Martin[1], Patricia Ramsey[1], Lori Bowles[1], John R. Britt[2], Ralph E. Parchment[3], Thomas S. Dexheimer[1], Beverly A. Teicher[4], James H. Doroshow[4], Nathan P. Coussens[1]. *[1]Molecular Pharmacology Laboratories, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Natural Products Support Group, Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Clinical Pharmacodynamic Biomarkers Program, Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

High-throughput screening (HTS) offers the potential to rapidly evaluate the activities of anticancer single agents and combinations in many types of cell-based tumor models; however, successful translation of the findings to patients requires tumor models with high biological relevance. The National Cancer Institute's Patient-Derived Models Repository (PDMR, https://pdmr.cancer.gov) continues to develop a collection of highly characterized patient-derived organoid models representing a variety of cancer types including rare and recalcitrant malignancies and tumors from patients of diverse ancestry. More than 230 publicly available organoid models are undergoing characterization of their suitability for incorporation into HTS panels based on their recovery from cryopreservation, reproducible growth and expansion capacity, and assay performance metrics in a 384-well format with a CellTiter-Glo 3D viability endpoint. Organoid models with suitable characteristics are being screened with a library of 166 FDA-approved oncology drugs (https://dtp.cancer.gov/organization/dscb/obtaining/default.htm). Over a 7-day period, the organoids are exposed to five concentrations of each drug with a 1-log dilution series ranging from 0.01 μM to 100 μM. The concentration-response profiles of patient-derived organoids will provide

reference data for the organoid screen and will eventually include data from all approved and most investigational oncology agents (approximately 1,000 small molecules). NCI-60 cell lines were screened as monolayers in a 384-well format with a CellTiter-Glo viability endpoint after a 3-day exposure to the same oncology drug concentrations. Both monolayer and 3D tumor models were tested using a custom designed fully automated screening system and data analysis software platform. A comparison of the FDA-approved drug responses of a panel of 3D colon cancer organoids and a corresponding panel of 9 colon carcinoma NCI-60 cell lines elucidated similarities and differences attributable to the assay methodologies as well as the tumor model characteristics, such as the presence of a BRAF V600E variant or other clinically relevant genetic alterations (APC, ARID1A, BRCA2, etc.). As the characterization of PDMR organoid models for HTS continues, these pharmacological datasets will be made available as a resource for the cancer research community. This project was funded in part with federal funds from the NCI, NIH, under contract no. HHSN261201500003I.

Race as a predictive confounder in the rate of transdifferentiation and drug response in human pancreatic acinar ductal metaplasia

Corey Melissa Perkins[1], Jinmai Jiang[1], Hesam Hakimjavadi[2], Jason Brant[3], Zhongyue Zhang[3], Ji-Hyun Lee[3], David Quashie[4], Yating Mao[4], Jamel Ali[4], Sarah Kim[1], Martha Campbell-Thompson[2], Thomas Schmittgen[1].
[1]Pharmaceutics, University of Florida, Gainesville, FL,[2]Pathology, Immunology, and Laboratory Medicine, University of Florida, Gainesville, FL,[3]Biostatistics, University of Florida, Gainesville, FL,[4]Chemical & Biomedical Engineering, Florida Agricultural & Mechanical University, Tallahassee, FL

Pancreatic diseases (chronic pancreatitis, type 2 diabetes, pancreatic cancer) disproportionately affect the Black/African American (AA) community in comparison to non-White Hispanics and Whites. Acinar to ductal metaplasia (ADM), the process by which pancreatic acinar cells transdifferentiate into ductal epithelial cells, is believed to be an initiating event of pancreatic ductal adenocarcinoma. Our lab has developed a 3D organoid assay to display ADM using primary, human pancreatic acinar

cells to study the rate of transdifferentiation amongst these three different races. Preliminary data shows that the rate of ADM is occurring significantly faster ($p < 0.05$) in Blacks/AAs (White=16, Hispanic=11, Black/AA=5), which may explain the disproportionately behind the incidence and mortality rates for this race in pancreatic cancer. A sigmoid Emax function best captured the longitudinal changes in the percentage of ADM in nonlinear mixed effects modeling analysis performed in Monolix. Covariate analysis on top of the selected model demonstrated that race was the only covariate affecting the individual trajectories in the percentage of ADM. We additionally use nanoparticles to study the biomechanical properties (I.e., viscoelasticity, storage modulus) of the ADM microenvironment which shows a stiffer microenvironment in Blacks/AAs than for the other races (White=4,Hispanic=4, Black/AA=1). Furthermore, we have used a histone deacetylase (HDAC) inhibitor in reversing the process of ADM, which has consequently shown race-related outcomes, with Blacks/AAs displaying a significant chemoresistance ($p < 0.05$) to HDAC treatment (White=6,Hispanic=6, Black/AA=3) by utilizing an ADM reversal index (ADMRI). Through further analysis, the plan is to continue procuring human samples from these three races to isolate an ADM-specific biomarker in relation race and drug reversal by studying the expression/activity of pancreatic associated genes by bulk-RNA and single-cell sequencing.

#5778

Breast cancer mutations HER2^{V777L} and PIK3CA^{H1047R} activate the p21-CDK4/6 -Cyclin D1 axis driving tumorigenesis and drug resistance

Xiaoqing Cheng[1], Yirui Sun[1], Maureen Highkin[1], Nagalaxmi Vemalapally[1], Xiaohua Jin[1], Brandon Zhou[1], Julie L. Prior[1], Ashley R. Tipton[1], Shunqiang Li[1], Anton Iliuk[2], Samuel Achilefu[1], Ian S. Hagemann[1], John R. Edwards[1], Ron Bose[1]. *[1]Washington University in St. Louis, St. Louis, MO,[2]Tymora Analytical Operations, West Lafayette, IL*

In metastatic breast cancer, HER2 activating mutations frequently co-occur with mutations in the *PIK3CA*, *TP53*, or E-cadherin genes. Of these co-occurring mutations, *HER2* and *PIK3CA* mutations are the most prevalent gene pair, with approximately 40% of *HER2* mutated breast cancers also having activating mutations in *PIK3CA*. To study the effects of co-

occurring *HER2* and *PIK3CA* mutations, we bred genetically engineered mice with the (loxP-STOP-loxP) $HER2^{V777L}$; $PIK3CA^{H1047R}$ transgenes (HP mice) and studied the resulting breast cancers both *in vivo* as well as *ex vivo* using breast cancer organoids. HP mice rapidly developed invasive mammary adenocarcinoma at a median time of 2.1 weeks after adenoviral Cre injection into the mammary gland. Organoids from these breast cancers showed increased number of buddings in branching morphogenesis assay and increased migration and invasion *in vitro*. *In vivo*, HP breast cancers are resistance to the pan-HER tyrosine kinase inhibitor, neratinib, but are effectively treated by the combination of neratinib plus trastuzumab deruxtecan (T-DXd). *Ex vivo*, we found strong synergy between neratinib and T-DXd in HP organoids. Proteomic and RNA-seq analysis of HP breast cancers showed increased gene expression of *CCND1* (cyclin D1) and *CDKN1A* (which encodes p21WAF1/Cip1) and changes in cell cycle markers. An increase in p-p53, p-p27, and p-PDK1 in HP organoids was seen. The GSEA analysis showed that the mTOR pathway and the MYC target signature were significantly upregulated in the HP organoid group. As p21 stabilizes the cyclin D1-CDK4/6 complex to further activate CDK4/6, we found CDK4/6 inhibitors inhibit cell proliferation in HP mice-derived organoids. Combining neratinib with CDK4/6 inhibitors was another effective strategy for HP breast cancers with neratinib plus palbociclib showing a statistically significant reduction in mouse HP tumors as compared to either drug alone. We validated both the neratinib plus T-DXd and neratinib plus palbociclib combinations using a human breast cancer patient-derived xenograft that has HER2 and PIK3CA mutations very similar
to our transgenic mouse. This study provides valuable preclinical evidence for these drug combinations, which are being tested in phase 1 clinical trials.

A platform utilizing high-grade serous ovarian cancer organoids for prospective patient stratification in functional precision medicine

Wojciech Senkowski[1], Laura Gall-Mas[1], Matias M. Falco[2], Yilin Li[2], Kari Lavikka[2], Mette C. Kriegbaum[1], Jaana Oikkonen[2], Daria Bulanova[1], Elin J. Pietras[1], Karolin Voßgröne[1], Yan-Jun Chen[1], Erdogan P. Erkan[2], Mia K. G. Høg[3], Ida M. Larsen[3], Tarja Lamminen[4], Katja Kaipio[4], Jutta Huvila[4], Anni

Virtanen[2], Lars H. Engelholm[3], Pernille Christiansen[3], Eric Santoni Rugiu[1], Kaisa Huhtinen[4], Olli Carpén[2], Johanna Hynninen[5], Sampsa Hautaniemi[2], Anna Vähärautio[2], Krister Wennerberg[1]. *[1]University of Copenhagen, Copenhagen, Denmark,[2]University of Helsinki, Helsinki, Finland,[3]Rigshospitalet, Copenhagen, Denmark,[4]University of Turku, Turku, Finland,[5]Turku University Hospital, Turku, Finland*

High-grade serous ovarian cancer (HGSC) is the most prevalent and lethal ovarian cancer type. While HGSC usually responds well to primary treatment, most cases eventually relapse. Functional precision medicine - tailoring individualized treatments based on functional in vitro assays on patient-derived cells - has been recently employed in cancer clinical trials. Cancer organoids - three-dimensional, self-organizing, self-renewing cell cultures that recapitulate original tissue structure and function - have been applied as cellular models in these trials. However, in case of HGSC, organoid derivation has proven time consuming and inefficient, hindering their application in functional precision medicine due to a short time window, in which therapy for each patient needs to be selected.
To address this problem, we aimed to establish whether drug vulnerabilities at HGSC relapse could be predicted using organoids derived from the primary disease cells. We derived sequential organoid models from material sampled during primary treatment and at relapse. Then, for organoid pairs (primary-relapse), we performed large-scale drug response profiling of a library of 370 compounds (approved drugs or drugs in clinical development), in 384-well microplate format, alone or in combination with a standard HGSC chemotherapeutic agent carboplatin. First, we found that HGSC organoid responses to standard chemotherapeutics retrospectively correlated to observed clinical treatment outcomes. But further, for each patient we identified compounds with pronounced cytotoxicity both in the primary and in the relapsed model, amounting to 66% of all hits (7% were primary-specific and 27% relapse-specific). We then focused on identifying patient-specific hits rather than compounds displaying general toxicity in all patient models. Based on a potential clinical applicability, for three patients we selected compounds for validation in organoid outgrowth assay, with prolonged (>1 month) drug-free period post-treatment. In two patients, AZD4573, a selective CDK9 inhibitor in clinical development for hematological malignancies, at nanomolar concentrations caused

eradication of organoids when combined with carboplatin. Organoids from the third patient were vulnerable to nitazoxanide, an approved anti-helminthic agent and an inhibitor of mitochondrial oxidative phosphorylation. Importantly, the selected final hits were identified solely based on screening in organoid models from primary disease.
In summary, we here demonstrate that HGSC organoids derived from primary disease material predict a majority of patient-specific drug vulnerabilities of organoids derived from the relapsed HGSC lesions. This indicates that patient stratification in functional precision medicine for treatment of HGSC relapse could be prospectively performed at the primary disease stage.

Patient-Derived Xenograft Models

MatchR a preclinical platform of models resistant to innovative therapies

Ludovic Bigot[1], Catline Nobre[1], Francesco Facchinetti[1], Loic Poiraudeau[1], Floriane Braye[1], Jonathan Sabio[1], Naoual Mensourri[1], Olivier Deas[2], Claudio Nicotra[3], Maud Ngo-Camus[3], Lambros Tselikas[4], Jean Yves Scoazec[5], Karim Fizazi[6], Siantiago Ponce[3], Benjamin Besse[6], Luc Friboulet[1], Yohann Loriot[1]. *[1]INSERM U981 (Gustave Roussy), Villejuif, France,[2]Xentech, Evry, France,[3]Drug Development Department (DITEP), Gustave Roussy, Villejuif, France,[4]Department of Interventional Radiology, Gustave Roussy, Villejuif, France,[5]Experimental and Translational Pathology Platform, Gustave Roussy, Villejuif, France,[6]Department of Medical Oncology, Gustave Roussy, Villejuif, France*

Introduction: In the last 20 years, the advances in molecular oncology and cancer genetics allowed the identification of an increasing number of actionable oncogenic drivers and the development and clinical use of specific inhibitors. Despite these successes, it is now well established that tumour cells adapt and develop acquired resistance. It is crucial to understand these mechanisms of acquired resistance to develop overcoming therapeutic strategies. At Gustave Roussy, a prospective clinical trial MATCH-R (NCT02517892) is conducted to study the acquired resistance

mechanisms and to find new therapeutic approaches for patients. . In parallel, of genetics analysis from patients biopsies, we develop Patient Derived Xenograft (PDX) to deepen our understanding of the resistance mechanism and to investigate new therapeutic approaches.
Material and Method: Fresh tumor biopsy specimens were obtained prospectively from patients through a prospective single-institution clinical trial (MATCH-R, NCT02517892). Patient derived xenografts (PDX) in NOD Scid Gamma (NSG) mice as well as patient derived organoids from PDX (PDXO) and Patient derived cell lines were developed and characterized. Extensive molecular profiling including whole exome sequencing (WES), RNA sequencing (RNAseq) and immunohistochemistry were performed on human samples; PDX; Patient derived cells lines and PDXO.
Results and Discussion: As of November 2022, 145 PDX models have been successfully obtained from 371 biopsies (global take rate of 39%). Our focus is the development of models from different cohorts: Androgen receptor inhibitors in castration-resistant prostate cancer, (18 PDX), ALK inhibitors in lung cancers (16 PDX including 3 post brigatinib, 7 post Lorlatinib and 6 Alectinib), *EGFR* inhibitors in lung cancers (33 PDX includind 24 post osimertinib), FGFR inhibitors in urothelial carcinoma and cholangiocarcinoma (29 PDX including 14 post erdafitinib, 4 post pemigatinib, 4 post futibatinib) and KRAS inhibitors in lung cancer and pancreatic cancers (20 PDX). The PDX models recapitulate the genetics, the phenotype and the pharmacology of the original biopsies. Novel mechanisms of resistance to tyrosine kinase inhibitors (TKI) in solid tumors were identified. Adaptive treatment with novel TKI or combinatorial strategies were evaluated to restore the sensitivity in PDX (readout: mean tumor growth). These results confirmed that PDX models are crucial to study the resistance mechanism and to develop new therapeutic strategies.
Conclusion: Overall, the MATCH-R study provides a unique preclinical platform to identify resistance mechanisms to innovative therapies and to develop next generation therapeutic strategies.

Enhancing preclinical testing of agents in patient-derived pediatric solid tumor orthotopic xenografts with pharmacokinetics

Burgess B. Freeman[1], Kaley Blankenship[2], Michael A. Dyer[3], Elizabeth Stewart[2]. *[1]Preclinical Pharmacokinetics Shared Resource, St. Jude Children's Research Hospital, Memphis, TN,[2]Department of Oncology, St. Jude Children's Research Hospital, Memphis, TN,[3]Department of Developmental Neurobiology, St. Jude Children's Research Hospital, Memphis, TN*

Understanding a potential therapeutic agent's in vivo pharmacokinetics (PK) is important in translating findings from preclinical murine efficacy models to patients. In consideration of this, PK evaluations play a prominent up-front role in our pediatric solid tumor testing pipeline. The aim of such PK studies is to define an agent's PK under our experimental conditions – i.e. our mouse strain, husbandry, chow, source and lot of agent, and formulation. We ultimately relate our mouse plasma exposures to the known or anticipated exposures in humans or children, thereby deriving a clinically relevant dose (CRD). Preclinical testing of novel agents and combinations are performed simultaneously with the testing of standard of care agents using the CRD and schedule to allow for more unbiased assessment of efficacy. To date, our group has studied the PK of over 35 agents, predominantly investigational new drugs, in both normal and patient-derived orthotopically xenografted (PDOX) immuno-deficient mice. When possible, rhabdomyosarcoma and neuroblastoma PDOXs were destructively sampled over time to evaluate an agent's intra-tumor exposure. All samples were quantified using sensitive, specific, and research- or qualified-tier LC-MS/MS assays. Roughly 70% of the agents had adequate tumor penetration, approaching or exceeding concentrations in the plasma. This was unsurprising, given that many test agents had reportedly high volume of distribution (V_d) values. While most of our mouse PK exposure parameters (e.g. C_{max}, AUC) were in line with available previous reports, several agents varied appreciably, generally trending lower. We speculate that this may be due to differing study conditions, test agent physical forms, or formulations. CRD estimates were based upon unbound (when available) steady-state plasma AUC equivalencies between mice and humans for a defined clinical dosage regime. Some latitude was permitted in the recommended CRD, and being within two-fold of clinical target was generally considered acceptable. The

resultant mouse CRDs and updated PK results for studied agents will be presented, with this information also being openly available upon request and/or at http://cstn.stjude.cloud. In conclusion, we have found that PK-driven, clinically relevant dosing enhances the efficiency and rigor in our in vivo efficacy testing program. Such an approach minimizes false positive signals arising from supra-clinically relevant doses and exposures in mouse models, allowing us to focus on efficacious agents and regimens for rapid clinical translation.

PDX, mini-brain co-cultures and patient-derived tumor organoids: Preclinical models to study the prion protein in glioblastoma biology

Maria Clara da Silva Souza[1], Barbara P. Coelho[1], Camila F. L. Fernandes[1], Tiago G. Dos Santos[2], Stefan Knorst[3], Cibele Masotti[3], Maria Rita S. Passos-Bueno[4], Marilene H. Lopes[1]. *[1]Cell Biology and Developmental, Institute of Biomedical Sciences (ICB), University of Sao Paulo, Sao Paulo, Brazil,[2]International Research Center, Hospital A.C.Camargo Cancer Center, Sao Paulo, Brazil,[3]Institute of Teaching and Research Sírio-Libanês Hospital, Sao Paulo, Brazil,[4]Institute of Biosciences, University of Sao Paulo, Sao Paulo, Brazil*

Glioblastoma (GBM), supported by a subpopulation of glioblastoma stem cells (GSCs), stands among the most harmful tumors. Its invasive and aggressive behavior has been correlated with poor therapy outcomes and reduced patient survival, which remains difficult to model and treat due to its cellular and molecular heterogeneity. GSCs are responsible for the malignant features of this cancer, including increased recurrence rates and resistance to therapy. Efforts have been employed to understand the molecular and cellular mechanisms underlying GSCs biology. The cellular prion protein (PrP^C), encoded by the *PRNP* gene, is a key player in GBM biology, and our group has proposed PrP^C as a scaffold protein that integrates signaling platforms involved in GSCs maintenance. A deeper understanding of the intracellular pathways modulated by PrP^C is essential to identify novel targets for GBM treatment. We have analyzed bulk-RNA sequencing (RNA-seq) data from patient-derived xenografts (PDX) and *in vitro* preclinical experimental models. RNA-seq analyses identified

differentially expressed genes (DEGs) associated with adhesion and migration signaling pathways in PDX cells with high PRNP expression (PRNP^{-HIGH}). Morphological characterization of PDX samples with PRNP^{-HIGH} levels showed an increase in morphologically undifferentiated cell groups, that are more commonly found in younger GBM patients. Furthermore, molecular profiling using Exome data showed that groups PRNP^{-HIGH} present enhanced global patterns of gene mutations. Due to the importance of experimental models to translate basic science into clinical applications, we are establishing emerging models to study PrP^{C} function in GBM biology: glioblastoma organoids (GBO) from patient's surgically resected GBM tumors; and brain organoids derived from human-induced pluripotent stem cells. We noticed a morphological and molecular reproducibility of the cytoarchitecture of brain organoids and GBO, similar to that described in the literature, indicating consistency in 3D structures, despite the variability between patients. Furthermore, brain organoids will be co-cultured with GSCs, providing platforms for studying the interaction between tumor cells and brain parenchyma. The establishment of these models will improve our comprehension of the role of PrP^{C} in GSCs maintenance and provide additional tools to understand GBM biology and predict tumor progression and response to treatment.

Establishment of patient-derived human cell lines using PDX mouse model for intrahepatic cholangiocarcinoma

Takashi Matsumoto. *Kumamoto Univ Graduate School of Medical Sci, Kumamoto, Japan*

Background: In recent years, patient tumor transplant models (PDX models) have attracted method that can predict the effects of anticancer drugs on patients. The PDX model is a technique in which the patient's tumor tissue is directly transplanted into immunodeficient mice. Tumors can grow three-dimensionally in a living mouse, so compared to culturing in petri dishes, the situation is like the growth of tumors in the patient's body. In addition, there are reports that the efficacy of anticancer drugs in patients and the results of administration of anticancer drugs in PDX show a high concordance rate, and it is attracting attention as a model that can predict efficacy in patients. In this time, we report on the establishment of

cell lines using PDX mice for resected cases of intrahepatic cholangiocarcinoma in our hospital.
Methods: Twelve patients who underwent surgical resection between September 2019 and December 2021 were included. After resected the tumor, the tumor was transplanted into up to 10 PDX mice, and cell lines were established from the formed tumor tissue.
Results: Of the 12 cases, tumors formed in PDX mice after transplantation in 6 cases, and the median time to engraftment after the first transplantation was 133 days (75-188). Furthermore, among the 6 cases, 3 cases achieved the establishment of cell lines.Case1:moderately differentiated adenocarcinoma, tumor diameter 50mm, single, vascular invasion positive, no lymph node metastasis, Stage IIIA (UICC 8^{th})Case2:well differentiated adenocarcinoma, tumor diameter 60mm, single, vascular invasion negative, no lymph node metastasis, Stage II (UICC 8^{th})Case 3:moderately differentiated adenocarcinoma, tumor diameter 55mm, single, vascular invasion positive, no lymph node metastasis, Stage IIIA (UICC 8^{th})
Conclusion: The cell line we established this time is a case of advanced cancer, and we would like to continue to increase the number of cases and continue to establish cell lines, which will lead to future research.

***In-vitro* modeling of tumor-associated macrophages in glioblastoma**

Hasan Alrefai, Andee M. Beierle, Taylor L. Schanel, Lauren C. Nassour, Joshua C. Anderson, Patricia H. Hicks, Christopher D. Willey. *Radiation Oncology, University of Alabama at Birmingham, Birmingham, AL*

BACKGROUND**:** The Glioblastoma (GBM) tumor microenvironment (TME) is comprised of a plethora of cancerous and non-cancerous cells that contribute to GBM growth, invasion, and chemo- and radio-resistance. In-vitro models of GBM typically fail to incorporate multiple cell types. Some groups have addressed this problem by employing 3D bioprinting to incorporate macrophages, astrocytes, and other parenchymal cells in an extracellular matrix. However, these models also use serum-containing media, which has been shown to cause GBM brain-tumor initiating cells to lose their stem-like properties, and IL-4/13 polarized macrophages (M2), even though tumor-associated macrophages (TAMs) do not adhere to the traditional M2 phenotype. Taken together, these observations highlight a

critical need to develop physiologically accurate in-vitro model systems for GBM.
METHODS: THP-1 monocytes were transitioned from serum-containing RPMI 1640 to serum-free CTS™ AIM V™ SFM and TheraPEAK™ X-VIVO™-15 Serum-free Hematopoietic Cell Medium. Monocytes were stimulated towards a macrophage-like state with PMA and polarized by co-culturing them with GBM patient-derived xenograft (PDX) lines, using transwell inserts. dPCR, a cytokine array, and a phagocytosis assay were used to characterize macrophages polarized by this method relative to classically polarized resting (M0), pro-inflammatory (M1), and anti-inflammatory (M2) macrophages.
RESULTS: There was no significant difference in proliferation rates up to 48 hours for THP-1 monocytes grown in serum-free CTS AIM V or X-VIVO-15 media compared to serum-containing RPMI 1640. At 72 hours, both serum-free alternatives had slightly decreased proliferation relative to the serum-containing RPMI 1640; however, the X-VIVO-15 had higher proliferation relative to the CTS AIM V ($p<0.0001$). THP-1 macrophages polarized towards a tumor-supportive phenotype by the GBM PDX cell line, JX39P-RT, did not recapitulate the cytokine expression profile of any other polarization group. M2 macrophages had significantly higher phagocytic capacity (25%) of JX39P-RT relative to M0, M1, and TAMs (<15%, $p<0.01$).
CONCLUSIONS: We have demonstrated a serum-free method by which we can polarize macrophages towards a GBM-supportive phenotype. This high-fidelity method of modeling TAMs in GBM will aid in the development of innate immunomodulatory therapeutics that may one day enter the clinic in hopes of improving GBM outcomes.

#4669
A patient derived xenograft model for lung adenocarcinoma using Obagel®, a human derived hydrogel
Cecilia Sanchez[1], Jonathan Nakashima[2], Kristein King[2], Trivia Frazier[1].
[1]Obatala Sciences, Inc., New Orleans, LA,[2]Certis Oncology Solutions, San Diego, CA

Patient Derived Xenografts (PDXs) are valuable disease models as they preserve the tumor microenvironment's structure, providing the most

clinically relevant in vivo testing platform. Nevertheless, most of those models still use animal derived hydrogels as scaffolds for patient derived cells, reducing the potential to fully mimic the physiological microenvironment of the disease and human condition. ObaGel® is a human-derived hydrogel successfully deployed for supporting 3D cell culture, organoid, perfusion bioreactor, and/ microphysiological system development for studying obesity, type II diabetes, and various forms of related cancers. Here we are investigating the use of Obagel® in the in-vivo development of a PDX-derived culture of lung adenocarcinoma and compare its performance to currently used animal derived hydrogels. *Methods:* 3 X 10^6 CRT00295 Non-small cell lung adenocarcinoma cells in 100ul 50:50 indicated Gel in PBS per injection site; the study used 10 NOG mice per condition. *Results:* The results indicated that ObaGel® performed similarly in terms of engraftment and tumor kinetics compared to animal derived hydrogels such as Cultrex, Geltrex, and Matrigel, using a patient-derived xenograft culture of lung adenocarcinoma. *Conclusions:* Our data supports the use of a human-derived hydrogel for PDX models, ObaGel® performs equivalently to animal derived hydrogels to support tumor volume over time. The use of a human derived hydrogels as scaffolds for PDX models provide a better humanized local microenvironment for lung adenocarcinoma. Obagel® can also be adapted for use as xenografts in other tissue/disease models

True bench-to-bedside science: An international pilot study modeling hard-to-cure pediatric cancers to prioritize therapeutic intervention

Nadine Azzam[1], Nicole Melong[1], Lissandra Tuzi[1], Lisa Pinto[1], Jamie I. Fletcher[2], Alvin Kamili[2], Biljana Dumevska[2], Loretta Lau[3], Jennifer A. Chan[4], Donna L. Senger[5], Stephanie A. Grover[6], Michelle Haber[2], David Malkin[6], Jason N. Berman[1]. *[1]CHEO RI - Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada,[2]Children's Cancer Institute, Sydney, Australia,[3]Sydney Children's Hospital, Sydney, Australia,[4]Arnie Charbonneau Cancer Institute, Calgary, AB, Canada,[5]Lady Davis Institute for Medical Research, Montreal, QC, Canada,[6]The Hospital for Sick Children, Toronto, ON, Canada*

There has been dramatic improvement in treatment outcomes for many pediatric cancers over the last three decades. However, for the 20% of young people with relapsed or refractory cancer, the prognosis remains grim. Canada's PRecision Oncology For Young peopLE (PROFYLE) and Australia's Zero Childhood Cancer (ZERO) programs, leverage nation-wide scientific and clinical oncology expertise to provide personalized precision medicine to children, adolescent and young adult (CAYA) cancer patients who lack treatment options. Beyond improving the lives of young cancer patients nationally, PROFYLE and ZERO have partnered to create an international pipeline for knowledge sharing and sample acquisition.
A key component of both programs is the use of mice for patient-derived xenografts (PDXs). However, long lead times for mouse PDX generation make the timely return of preclinical drug response data challenging. PROFYLE has uniquely incorporated zebrafish larval xenografts, which have the potential to provide comparable information in a clinically actionable timeframe. In a pilot study, we compared retrospective matched ZERO patient and mouse PDX therapeutic response data with prospective zebrafish larval PDX data as a proof-of-principle that drug efficacy signals were maintained across model systems. Three ZERO avatars: high-risk neuroblastoma, Ewing's sarcoma, and anaplastic large cell lymphoma were shipped from Australia to Canada and transplanted into 48h *casper* zebrafish. Following dose optimization, zebrafish PDXs were treated with targeted single and combination drug treatments by immersion therapy. Strikingly, in as little time as a week, cell proliferation rates and drug responses to single agents and combinatorial therapy in zebrafish PDXs recapitulated mouse and patient data. To expand on this pilot project, we tested additional patient samples, including multiple subtypes of sarcomas, T-cell acute lymphoblastic leukemia and an embryonal tumor with multilayered rosettes. Results further validated the practical utility of the zebrafish larval PDX model and in fact provided drug response data when mouse PDX data were unavailable. This study demonstrates the robustness and feasibility of the zebrafish larval PDX model as a preclinical tool for personalized precision therapeutic decision-making and highlights the value of international collaboration in improving outcomes of rare childhood cancers.

MAO A, MAO B inhibitors and NMI for colon cancer therapy

Shivani Soni[1], Hui Ju Tseng[2], Yan Yang[3], Goar Smbatayan[1], Unnati Hemant Shah[2], Jae Ho Lo[1], Joshua Millstein[3], Francesca Battaglin[1], Pooja Mittal[1], Lesly Torres Gonzalez[1], Wu Zhang[1], Jean Chen Shih[2], Heinz Josef Lenz[1]. *[1]Medical Oncology, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Pharmacology and Pharmaceutical Sciences, University of Southern California, Los Angeles, CA,[3]Department of Population and Public Health Sciences, University of Southern California, Los Angeles, CA*

Background**:** Mitochondrial MAO A and MAO B isoenzymes catalyze oxidative deamination of neuroactive and vasoactive monoamines in CNS and peripheral tissues. MAO A inhibitors have been used as antidepressants; MAO B inhibitors have been used for Parkinson's disease. Recently, we and others have shown MAO inhibitors can be repurposed for cancer therapy. This study focused on the MAO inhibitors as a novel therapeutic strategy for CRC utilizing patient derived xenograft (PDX) platform which recapitulates the patient's molecular characteristics.
Methods and Results: CRC PDX models were selected from our repository based on MAO A and B expression and activity. To establish two PDX models with high or low MAO A / B activity we implanted patient's tumor samples (F0 generation) with high MAO A/B activity (MAO high) or low MAO A/B activity (MAO low) in 8 weeks NSG mice (F1 generation). F1 MAO low PDX model showed substantially slower tumor growth rates as compared to MAO high PDX model (200 days vs 65 days), suggesting the role of MAOs in CRC growth. For each PDX model trial, tumors were pooled from 6 F1 PDX mice and implanted in 30 NSG mice (F2 generation). There were five mice in each of experimental groups: one control arm (vehicle: 67% PEG 400, 33% saline) and treatment arms (i.p. for 21 days): 1. MAO A inhibitors: clorygyline: 50mg/kg; 2. Near infrared dye conjugated MAO A inhibitor (NMI): 5 mg/kg; 3. MAO B inhibitor: deprenyl 10mg/kg;4. MAO A & B inhibitor: phenelzine (30mg/kg). MAO high PDX cohort showed significant reduction in tumor volume in mice treated with MAO A inhibitors clorygyline ($p=0.009$); NMI ($p=0.053$) and MAO B inhibitor deprenyl ($p=0.022$), phenelzine ($p= 0.097$) when compared to control. Angiogenesis marker CD31 staining of tumor tissues showed significant reduction in mice treated with clorygyline and NMI.

Additionally, Ki 67 staining demonstrated considerable decrease in cell proliferation and TUNEL assay exhibited increase in apoptosis in tumor treated with clorygyline and NMI. RNA sequencing revealed 50 differentially expressed genes (DEGs) between clorygyline treated tumors and control, 171 between NMI treated and control group (padj <0.05, |fold change| >=1.5). Ingenuity Pathway Analysis showed alterations in pathways including oxidative phosphorylation, sirtuin pathway, estrogen receptor signaling, and mitochondrial dysfunction. NMI showed same efficacy with no toxicity compared to clorygyline even at 10 times lower dose in MAO high PDX model. No significant difference in tumor size was found among treatment groups in MAO low PDX cohort.
Conclusion: Our CRC PDX studies showed both MAO A and B are important for tumor growth and are potential target for therapy. Both MAO A and B inhibitors and NMI (NIR-conjugated MAO an inhibitor, clorgyline) reduced tumor growth. IHC and RNA seq data shows MAO A inhibitor and NMI has similar mechanisms, though NMI is more effective than clorygyline and also can be used for diagnosis.

In-vivo tumor implantation site exhibits differential immune response in solid tumors

Rajeev Shrimali[1], Jasmine Borroel[1], Carmen Sunico[2], Bridget Corcoran[2], Bianca Carapia[3], Rowan Prendergast[4], Jantzen Sperry[5], Jonathan Nakashima[5]. *[1]Immuno-Oncology R & D, Certis Oncology Solutions, San Diego, CA,[2]In-vitro R & D, Certis Oncology Solutions, San Diego, CA,[3]In-vivo operations, Certis Oncology Solutions, San Diego, CA,[4]Study Director, Certis Oncology Solutions, San Diego, CA,[5]Operations R & D, Certis Oncology Solutions, San Diego, CA*

Successful discovery and development of cancer targeted therapeutics depends on testing these agents in the clinically most relevant translational models. Emerging evidence highlights the importance of the local tumor microenvironment in evaluating the efficacy of new therapeutics, especially for immunotherapies. Historically, patient-derived xenograft (PDX) modeling involves subcutaneous implantation which minimally represents the actual human tumor site. Here, we use PBMC humanized PDX models to demonstrate differences in the tumor microenvironment, overall immune

response, and the pharmacological outcome, between subcutaneous and orthotopic PDX models. These findings highlight the importance of testing cancer therapeutics in the most physiologically relevant setting for greater translation into clinical success.

#4673

Therapeutic potential of polatuzumab vedotin for the treatment of diffuse large B-cell lymphoma

Hui Qi, Fuyang Wang, Bingrui Han, Xiaomin Wang, Xiangnan Qiang, Zhixiang Zhang, Qiangyang Gu. *WuXi AppTec, Shanghai, China*

Background Diffuse large B-cell lymphoma (DLBCL) is typically treated with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP). Although most patients can be cured with R-CHOP, up to one-third of them relapses with a dismal outcome in most cases. Numerous approaches have been attempted to improve the treatment outcomes with R-CHOP. Polatuzumab vedotin is an antibody-drug conjugate targeting CD79b, which is ubiquitously expressed on over 90% of B-cell NHL malignancies, including DLBCL. To determine the potential of polatuzumab vedotin as a therapeutic agent, we evaluate its potency across a series of DLBCL patient derived xenograft (PDX) models.
Method We established and characterized a series of DLBCL lymphoma PDX models. Eight DLBCL PDX models were selected for polatuzumab vedotin efficacy study, of which three are GCB DLBCL. Gene expression analysis of these lymphoma PDX models was performed using an Illumina NovaSeq 6000 system following Illumina-provided protocols for 2x150 paired-end sequencing. The expression status of CD79b on these DLBCL PDX models was also evaluated by IHC.
Conclusion Our data showed that a single dose of polatuzumab vedotin at just 2 mg/kg could reached a comparable effect with R-CHOP and no significant body weight loss was observed. Our result showed that there is no apparent correlation between polatuzumab vedotin responses (TGI) and the CD79b expression (IHC Score). Although polatuzumab vedotin demonstrated encouraging activity in the treatment of DLBCL, some of the PDX models are also resistant to polatuzumab vedotin treatment. To further investigate the molecular parameters of the relative sensitivity of polatuzumab vedotin. Gene expression profiling of those PDX models and

their sensitivity to polatuzumab vedotin were conducted, we found that the expression level of BCL-XL was correlated with reduced sensitivity to polatuzumab vedotin.

#4674

Patient-derived xenograft (PDX) and corresponding cell line models from glioblastoma for drug development, immuno-oncology and translational research

Joshua Alcaniz[1], Lars Winkler[1], Maria Stecklum[1], Hagen Wieland[2], Antje Siegert[1], Michael Becker[1], Bernadette Brzezicha[1], Wolfgang Walther[3], Jens Hoffmann[1]. *[1]EPO GmbH, Berlin, Germany,[2]PromoCell, Heidelberg, Germany,[3]Charité Universitätsmedizin, Berlin, Germany*

Background**:** Glioblastoma (GBM) is the most common malignant brain tumor in adults, with about 90% of tumors developing *de novo*. Their heterogeneity, aggressiveness and infiltrative growth limit success of current standard of care (SoC) therapy and efficacy of new therapeutic approaches. For drug development a large panel of patient-derived tumor cell models is needed to generate most comparable *in vitro* and *in vivo* platform reflecting the complex biology of glioblastoma. Glioblastoma cell lines from patient-derived xenografts (PDX) preserve many patient specific characteristics and to perform the essential steps of pre-clinical drug development from *in vitro* screening to orthotopic *in vivo* approaches under conditions, which closely resemble the clinical situation. Further, GBM PDX models are useful for immune oncology research.
Methods: A panel of 26 glioblastoma PDX models was established on immunodeficient mice (15 out of these established orthotopically). All models were characterized for drug sensitivity and molecular profile using panel and transcriptome sequencing. From these, three corresponding tumor cell lines were successfully established and characterized. Quality and identity of the models was performed by FACS and PCR analysis. Expression profile, drug sensitivity and growth behavior was determined and compared *in vitro* and after re-transplantation *in vivo* with the original PDX glioma model. In addition, we employed GBM PDX models for checkpoint-inhibitor sensitivity in humanized mouse settings.
Results: Drug testing was performed in s.c. and orthotopic models revealed, that best treatment responses in s.c. models (tumor growth

inhibition > 50%) were observed for SoC temozolomide (TMZ), irinotecan and bevacizumab. Molecular characterization identified all our models as IDH-wt (R132) with frequent mutations in PARP1, EGFR, TP53, FAT1, and within the PI3K/AKT/mTOR pathway. Their expression profiles resemble proposed *mesenchymal*, *proneural* and *classical* GBM molecular subtypes. Further, treatment of GBM PDX with ipilimumab, nivolumab or pembrozolumab generated minor growth delay.
Conclusions: In drug sensitivity screening, irinotecan or bevacizumab were identified as alternative treatment options in TMZ resistant GBM PDX models. Our data demonstrate, that the established platform of s.c. and orthotopic GBM PDX is valuable for drug development and can well be complemented by a PDX-derived cell lines for *in vitro* screens. Furthermore, these models can be used for the evaluation of new immune-oncology therapies.

#4675
Chemoresistant patient-derived xenografts to identify treatment options in breast cancer patients not responding to standard chemotherapy
Eivind Valen Egeland, Kotryna Seip, Geir Frode Øy, Eleni Skourti, Solveig J Pettersen, Siri Juell, Mads Haugland Haugen, Olav Engebraaten, Lina Prasmickaite, Gunhild M Maelandsmo. *Institute for Cancer Research, Oslo University Hospital, Oslo, Norway*

Resistance to chemotherapy is a major clinical challenge in breast cancer (BC), and patients developing resistance need treatment alternatives. In this project we utilize patient-derived xenografts (PDXs) from triple negative BC (TNBC), as these models better reflect the human tumor complexity and heterogeneity, compared to cell line-based- and transgene animal models. An in-house established orthotopically growing PDX, MAS98.12, has gained resistance to chemotherapy due to prolonged exposure to paclitaxel (MAS98.12-PR), a microtubule-targeting chemotherapeutic agent. As the resistance was obtained in animals, we also have the paclitaxel sensitive equivalent (MAS98.12-PS). By utilizing the pair of sensitive and resistant tumors we can study the corresponding mechanism evolving in patients who initially respond to chemotherapy before resistance and disease progression. This model will aid in identifying key

mechanisms of survival in the resistant tumors, and eventually in identifying targets for use as novel therapeutic opportunities in TNBC patients resistant to standard therapy. Finally, we have samples collected early and late after resistance development, allowing us to characterize mechanisms involved in stepwise progression of paclitaxel resistance. We are currently performing molecular profiling to reveal the mechanisms involved in development of resistance. Data from bulk RNAseq, immune profiling of myeloid cells, exome sequencing, secretome profiling and reverse-phase protein array (RPPA) allow for characterizing the isogenic pair of tumors on multiple levels. Preliminary observations include aberrant expression of *ABCB1*/MDR1, normally involved in translocating drugs across membranes, and previously described as a mechanism involved in pertaining resistance in tumor cells. As multiple attempts to target MDR1 itself has failed, we hypothesize that our PS and PR pair will identify vulnerable/targetable signaling axis in the resistant tumors. Additionally, both PDX models have been assessed for their sensitivity to various chemo-/targeted-drugs and their combinations, revealing alternative means of treating the resistant tumors. Altogether, the molecular profiles and the sensitivity data will give novel knowledge and treatment options for patients failing to respond to standard chemotherapy.

#4676

Deconvolution of extrinsic and intrinsic factors influencing tumor growth in solid cancer PDX models to support design, analysis and application of PDX-based pharmacology studies

Mathew Clark[1], Kanstantsin Lashuk[2], Edward McGowan[3], Julia Schueler[2].
[1]Charles River Laboratories, Inc., Wilmington, MA,[2]Charles River Laboratories, Inc., Freiburg, Germany,[3]Discovery Charles River, Chesterfield Park, United Kingdom

PDX models are one of the gold standard models in preclinical drug development. Their intra- and intertumoral heterogeneity is accepted as a model immanent feature. However, the model performance directly impacts the study design as well as the interpretation of experimental data using those models. To discriminate between intrinsic and extrinsic factors driving heterogeneous tumor growth of PDX models we investigated the model performance of >500 subcutaneously growing PDX models of solid

cancer by examining growth curves of control arms run in the framework of > 5000 independent experiments. The relative tumor volume (RTV) over time was correlated with the number of passages in mice, the respective mouse strain, and the applied control vehicle per model as well as across tumor types. The analysis of ten different colon cancer PDX models revealed statistically significant differences between RTV on a specific day across different passages in a specific model as well as across all ten models (Kruskall-Wallis test). However, neither the variance nor the doubling time of the tumor correlated with the number of passages in mice. Based on these results we extended the analysis across six different tumor types with 33 distinct models in six different mouse strains. Again, an influence of the passage number on the tumor volume on a specific experimental day was depicted. The range of mean RTV related to a specific passage were least pronounced on day 7 (71% - 1626%), most notable on day 14 (65% - 4543%) and decreasing again on day 21 (34% - 3633%). In this larger cohort a subset of data points was more similar in performance to each other than any other set. The clustering was based on performance on experimental day 7. This subset received either saline or was untreated. This demonstrates that non-saline ingredients have an evident effect on tumor progression. Due to limited size of the dataset the influence of the mouse strain was evident only on a descriptive level. Whereas the use of different nude mouse strains, such as CD1-, athymic, or NMRI nude, did not affect tumor volume over time, the use of more immunodeficient mice such as SCID, NSG or NOG led to a faster tumor growth in some of the models across different passages. In the next iteration we will analyze the full dataset overcoming current limitations due to small subsets in a specific condition. The actual aim of this project is to better understand and measure tumor heterogeneity in PDX models. Based on these analyses the output of PDX-based studies will be optimized, as we get a better understanding how extrinsic factors (mouse strain and vehicle) and intrinsic factors (passage number) influence tumor growth. In a longer perspective the ability to model tumor volume over time in a specific model will reduce the need of control animals in future experiments, thereby actively supporting the concept of 3R.

#4677

A preclinical platform of breast cancer PDX and derived cellular models as a tool for pharmacological screening and functional studies

Delphine Nicolle[1], Aurore Gorce[1], Marie Tavernier[1], Elisabetta Marangoni[2], Didier Decaudin[2], Christophe Ginestier[3], Emmanuelle Charafe-Jaufret[3], Judith Passildas[4], Nina Robin[4], Robert Clarke[5], Erwan Corcuff[6], Anaïs Joachim[7], Bernard Malissen[8], Ana Zarubica[8], Hervé Luche[8], Jean-Gabriel Judde[1], Olivier Déas[1]. *[1]XenTech SAS, Évry-Courcouronnes, France,[2]Institut Curie, Paris, France,[3]CRCM, Marseilles, France,[4]Centre Jean Perrin, Clermont-Ferrand, France,[5]University of Manchester, Manchester, United Kingdom,[6]Janvier Labs, Laval, France,[7]JC Discovery, Marseilles, France,[8]Centre d'Immunophenomique, Aix Marseille Universite, Inserm, CNRS / JC Discovery, Marseilles, France*

Despite considerable progress in understanding the biology and genetics of breast cancer, the development of effective therapies needs physiological and predictive preclinical models. In this context, breast cancer (BC) patient-derived xenograft (PDX) models have become a standard tool as they reproduce the biology of tumors of origin, in term of histology, genotype and response to chemotherapy. They have proven their relevance in the study of pathways leading to the development and progression of cancer, to the mechanisms linked to tumor resistance and to the identification of novel effective therapies. We present a preclinical platform of over 60 fully characterized BC PDX models and their *in vitro* cell derivatives for preclinical evaluation of new treatment modalities. Our platform consists of a PDX collection of 43 TNBC, 6 ER+, 4 HER2+ , 6 Luminal B models (ER+ HER2+) and 14 cellular models derived from these PDXs, representing the variety of BC. PDX models were obtained by transplantation of post-surgery tumor specimens either by grafting of tumor fragments in the interscapular region of nude mice or by injection of tumor cells into the fat pad of NOD-Scid mice. Molecular analyses were done included gene expression, gene copy number, whole exome sequencing and IHC markers staining. *In vivo* drug efficacy assays were performed with standards of care as single agent or in combinations. This PDX panel mostly reflects the molecular heterogeneity of breast cancer and reproduce accurately the molecular and drug response profile of human tumors. It provides an invaluable tool for translational research. It is widely used to

performed standard drug evaluation but also “Mouse Clinical Trials” (MCT) *in vivo* screens to provide more predictive preclinical data on single-agent or combination drug efficacy. Engrafted on highly immunodeficient mice humanized with human PBMCs or CD34+ cells, these PDX models allow bispecific T-Cell engager antibody testing or immune-checkpoint inhibitors evaluation. In addition to these PDX panel, we derived cellular models (PDXDCs) to offer a time- and cost-effective preclinical screening tool. PDXDCs were obtained from dissociated PDX tumors cultured under different media and matrix conditions. They were characterized by comparison with the parental PDX by Short Tandem Repeat (STR) profiling before performing a master bank. WES and RNASeq molecular analyses were done and *in vitro* drug sensitivity was compared with their parental PDX *in vivo* drug response. Overall, the results show that this PDXDC panel reproduced *in vitro* the *in vivo* drug response profile of the original PDXs with various therapies. This BC PDX panel and *in vitro* cell derivatives provide a powerful preclinical platform to improve our knowledge on BC biology and to rapidly evaluate response to new treatments and translate this knowledge to the clinic.

Characterization of a PDX panel covering molecular diversity of non-small cell lung cancer to accelerate the development of precision therapy

Delphine Nicolle[1], Laura Brulle-Soumare[1], Katell Mevel[1], Ludovic Bigot[2], Tala Tayoun[2], Benjamin Besse[2], Françoise Farace[2], Luc Friboulet[2], Didier Decaudin[3], Erwan Corcuff[4], Anaïs Joachim[5], Bernard Malissen[6], Ana Zarubica[6], Hervé Luche[6], Jean-Gabriel Judde[1], Olivier Deas[1]. *[1]XenTech SAS, Évry-Courcouronnes, France,[2]Gustave Roussy, Villejuif, France,[3]Institut Curie, Paris, France,[4]Janvier Labs, Laval, France,[5]JC Discovery, Marseilles, France,[6]Centre d’Immunophenomique, Aix Marseille Universite, Inserm, CNRS / JC Discovery, Marseilles, France*

Lung cancer remains the first cause of cancer-related deaths worldwide, of which Non-Small Cell Lung Cancer (NSCLC) represents more than 80% of patients with advanced disease at the time of diagnosis. NSCLC is a highly heterogenous disease, and the identification of its main actionable

oncogenic drivers (i.e. EGFR, ALK, PI3K/AKT/mTOR, RET, MET, BRAF and NTRK/ROS1) and the development of specific inhibitors against these targets has transformed therapeutic care. In addition, immune-checkpoint therapy has emerged as an indispensable treatment modality, especially for patients lacking actionable oncogenic drivers, although biomarkers for predicting response to immune-checkpoint inhibition have remained elusive. Despite these new therapeutic options, NSCLC remains a lethal disease in the majority of patients due to tumor plasticity and selection leading to frequent resistance development and disease progression. Efforts are therefore needed to identify drugs and drug combinations that can prevent or overcome these resistance pathways. Patient-Derived Xenografts (PDX) models developed in immune-compromised mice recapitulate the disease more faithfully than any other in vivo model in terms of histopathologic and genomic features. They have proven their relevance in the study of pathways leading to the development and progression of cancer, to the mechanisms linked to tumor resistance and to the identification of novel effective therapies, facilitating the translation of preclinical results in the clinical setting. We describe a platform of over 35 NSCLC PDX models covering most of the molecular diversity of the disease, that have been fully characterized at the molecular level and for their response to a panel of cytotoxic chemotherapies and targeted therapies. These NSCLC PDX models have been established in immune-deficient mice from tumor biopsies collected in treatment-naïve patients or in patients having acquired resistance following an initial objective response to a variety of targeted inhibitors (EGFRi, ALKi, ROSi, BRAFi,⋯) in the MATCH-R clinical trial. In addition, 4 PDX models were established from circulating tumor cells (CTC) isolated from the blood of advanced NSCLC patients. Finally, some of these NSCLC PDX models were established in highly immunodeficient mice humanized with human PBMCs or CD34+ cells allowing testing of efficacy of bispecific T-Cell engager antibody or immune-checkpoint inhibitors. This panel of NSCLC PDX models provides a powerful preclinical platform to improve our knowledge on the mechanisms underlying resistance to treatment and to rapidly evaluate response to new treatments and translate this knowledge to the clinic.

Molecular pathology and BTKi pharmacology of DLBCL-PDXs

Jingjing Wang[1], Yueying Wang[1], Wubin Qian[1], Jia Xue[1], Sheng Guo[1], Likun Zhang[1], Henry Qixiang Li[2]. *[1]Crown Bioscience, Inc., San Diego, CA,[2]Hanx Biopharmaceuticals Inc., Oceanside, CA*

Diffuse large B-cell lymphoma (DLBCL), the largest subtype of non-Hodgkin's lymphoma (NHL, ~40%), is a heterogeneous disease with diverse pathogenesis, represented by different subtypes/genotypes based on lymphoma related specific gene expression profiling according to cell-of-origin (COO) and/or mutation profiles, likely influencing their responses to drug treatment. Patient derived xenografts (PDXs) represent powerful experimental system to investigate heterogeneous molecular pathology, and their corresponding pharmacology of DLBCLs. We created a unique cohort of 19 PDXs representative of diverse subtypes of *de novo* DLBCL patients, along with 15 EBV transformed DLBCLs during xenografting, followed by comprehensive molecular pathological analysis, using "EBV scan", COO and LymphGen algorithm. The 19 *de novo* DLBCL-PDXs were classified into activated B cell-like (7/19 ABC, including 2 EBV^+), germinal center B-cell-like (4/19 GCB) and unclassified (8/19 including 4 EBV^+); the 15 EBV transformed DLBCL include two ABC, one GCB and 12 unclassified. The *de novo* DLBCL-PDXs were also annotated as MCD, BN2, N1, A53, ST2, and unknown genotypes. Clustering and principal component analysis (PCA) clearly separated EBV^+ DLBCL-PDXs (regardless of *de novo* DLBCL, EBV-associated, or EBV transformed DLBCLs) from the EBV^- *de novo* DLBCL-PDXs, suggesting distinct molecular pathogenesis, while no apparent difference between the two EBV^+ DLBCLs suggested the similar pathogenesis. The expanded mouse clinical trial of BTKi using drinking water administration of ibrutinib (0.16mg/ml) showed: 1) EBV^- MCD and BN2 genotype are largely sensitive, suggesting these models' dependency of chronic BCR signaling; 2) all EBV^+ DLBCLs, regardless of the origin or genotypes, are all insensitive; 3) there are some cases of EBV^- non-MCD/BN2 models being sensitive, likely due to the presence of certain related activating mutations. Molecular pathology analysis also demonstrated EBV^+ PDXs, including significantly elevated BCL2 and down-regulated BCL6, in contrast to EBV^- DLBCL-PDXs, implicating possible sensitivity to respective treatments. In summary, these observations

in PDXs, some of which are consistent with the retrospective analysis of clinical trials, can be used to help develop BTKi and other treatment for DLBCLs.

#4680

Intracranial breast cancer brain metastases (BCBM) models - stereotactic vs. intracarotid inoculation

Sigrid Cold[1], Moritz Braig[2], Trine Bjoernbo Engel[2], Maria Zeiler Alfsen[2], Maria Nikoline Baandrup Kristiansen[2], Lotte Kellemann Kristensen[2], Andreas Kjaer[3], Carsten Haagen Nielsen[2]. *[1]Department of Biomedical Sciences, University of Copenhagen, Minerva Imaging ApS & Cluster for Molecular Imaging, Oelstykke & Copenhagen, Denmark,[2]Minerva Imaging ApS, Oelstykke, Denmark,[3]Department of Clinical physiology, Nuclear Medicine and PET & Department of Biomedical Sciences, Nuclear Medicine and PET & Cluster for Molecular Imaging, Copenhagen, Denmark*

Breast cancer is the most prevalent cancer in women worldwide. 30% of breast cancer patients develops metastases at distant organs, with 10-20% of these patients developing brain metastases. The median survival time for patients with brain metastases is only 7.2 months and there is an urgent need for effective therapies. Development of novel therapies relies on good translational animal models. Subcutaneous tumors are technically easy and highly reproducible but lacks the natural tumor environment and the impact of the blood brain barrier. Breast cancer brain metastasis (BCBM) models are most often established by stereotactic intracranial inoculation. However, this leads to formation of single tumors and does not take the extravasation and seeding part of the metastatic cascade into account and resembles primary tumors to a larger extend. Intracarotid inoculation incorporates extravasation and seeding of micro metastases making it a better suited translational animal model for BCBM. A panel of intracranial BCBM was established through stereotactic and intracarotid inoculation of breast cancer cell lines with high survival and take rates (>85%). The panel included the ST941 PDX model, an estrogen receptor positive model harbouring the ESR1-Y537S mutation and exhibiting resistance to fulvestrant. The panel also included the triple negative breast cancer cell line MDA-MB-231 as well as HER2+ models. Tumor establishment and progression were

evaluated using bioluminescence and magnetic resonance imaging (MRI). Whole brain and tumors were isolated, and paraffin embedded for histological evaluation of tumor establishment, invasiveness, and infiltration. Intracranial tumor establishment was evident early after inoculation using bioluminescence imaging and tumor growth was later confirmed by MRI. Tumor growth rate were dependent on inoculation method with rapid tumor growth observed with stereotactic inoculation. While stereotactic inoculation led to single tumor establishment with defined tumor borders, intracarotid inoculation led to micro seeding with multiple foci established throughout the brain. At early timepoints, the metastases consisted of <150 cells per metastases, but at later timepoints larger metastases were formed. Tumor infiltration was more diffused in brains with multiple metastases and the blood brain barrier integrity was different when comparing the models and inoculation methods. A panel of BCBM was successfully established using both stereotactic and intracarotid inoculation. While bioluminescence allowed the earliest tumor imaging, MRI provided additional information on tumor establishment such as location, numbers, and blood brain barrier permeability. The models showed varying tumor establishment, infiltration, and marker expression. The established panel can be used as a platform for testing novel anti-cancer therapies targeting BCBM.

Human Cancer Models Initiative (HCMI): A community resource of next-generation cancer models and associated data

Eva Tonsing-Carter[1], Rachana Agarwal[2], Cindy W. Kyi[1], Julyann Perez-Mayoral[1], Conrado T. Soria[2], Jean Claude Zenklusen[1]. *[1]National Cancer Institute, Bethesda, MD,[2]Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Rockville, MD*

The Human Cancer Models Initiative (HCMI) is an international consortium founded by National Cancer Institute (NCI), Cancer Research UK, Wellcome Sanger Institute, and the foundation Hubrecht Organoid Technology. The initiative has generated patient derived Next-generation Cancer Models (NGCMs) from diverse tumor types and subtypes including rare adult and pediatric cancers as a community resource. HCMI addresses deficiencies in traditional cell lines models by collecting patients' clinical

data, as well as the genomes and transcriptomes of the parent tumor, case-matched normal tissue, and the derived next-generation cancer model. NCI's Center for Cancer Genomics (CCG) sponsors four Cancer Model Development Centers (CMDCs) who are managed by Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc. CCG also supports the downstream model development pipeline. The CMDCs are tasked with generating HCMI NGCMs. The model-associated clinical data are submitted to the Clinical Data Center. The models, their associated tumor, and normal samples are processed at the Biospecimen Processing Center (BPC). The nucleic acids isolated at BPC are sent to the Genomic Characterization Centers for molecular characterization. All biospecimen, clinical, and molecular characterization data are quality controlled and submitted to NCI's Genomic Data Commons (GDC) for the research community. The HCMI models and culture protocols are made available to the research community through a single third-party distributor. The HCMI Searchable Catalog (https://hcmi-searchable-catalog.nci.nih.gov/) is an online resource that allows users to query and identify available models using various data elements including clinical and molecular characterization data, including WGS, WXS, RNA-seq, and methylation array. To date, over 250 HCMI models are available to query on the Searchable Catalog and are available to the research community through the NCI designated model distributor, ATCC. These models have been derived from several cancer types including glioblastoma, colorectal, pediatric, gastroesophageal, pancreatic, and more. Biospecimen, clinical, and molecular characterization data are available for over 100 models at NCI's GDC, with additional cases released as the data completes the HCMI pipeline. Data, tools, and resources generated by CCG initiatives are made publicly available via the CCG website and GDC. The CCG website also provides available data types, data usage policies and guides to access data (https://www.cancer.gov/about-nci/organization/ccg).

PDCM Finder: an open global research platform for patient-derived cancer models

Zinaida Perova[1], Mauricio Martinez[1], Tushar Mandloi[1], Federico Lopez Gomez[1], Csaba Halmagyi[1], Alex Follette[1], Jeremy Mason[1], Steven Neuhauser[2], Dale A. Begley[2], Debra M. Krupke[2], Carol Bult[2], Helen

Parkinson[1], Tudor Groza[1], Marcelo P. Rios Almanza[1]. *[1]European Bioinformatics Institute, Hinxton, United Kingdom,[2]The Jackson Laboratory, Bar Harbor, ME*

PDCM Finder (www.cancermodels.org) is a cancer research platform that aggregates clinical, genomic and functional data from patient-derived xenografts, organoids and cell lines. Currently, the portal has over 6300 models across 13 cancer types, including rare pediatric models (17%) and models from minority ethnic backgrounds (33%), making it the largest free to consumer and open access resource of this kind. The PDCM Finder standardizes, harmonizes and integrates the complex and diverse data associated with PDCMs for the cancer community and displays over 90 million data points across a variety of data types (clinical metadata, molecular and treatment-based). PDCM Finder was launched in April 2022 and has been recently enhanced with new functionality and an updated user interface. Users can search for models of interest by either (1) exploring molecular data summaries for models of specific cancer types, or (2) using the intuitive search and faceted filtering options of the web user interface or (3) accessing resource database via REST API to run their own analysis. The data includes gene expression, gene mutation, copy number alteration, cytogenetics, patient treatment and drug dosing studies. We link external resources like publication platforms and cancer-specific annotation tools enabling exploration and prioritization of PDCM variation data (COSMIC, CIViC, OncoMX, OpenCRAVAT). PDCM Finder builds on the success of the PDX Finder resource (PMID:30535239). Critical PDCM attributes, such as diagnosis, drug names and genes, are harmonized and integrated into a cohesive ontological model based on the PDX Minimal information standard (PDX MI, PMID: 29092942). PDX MI has become established in the community for data exchange, adopted by the PDX providers, consortia and informatics tools integrating PDX data. We are driving the development of and promoting the use of descriptive standards to facilitate data interoperability and promote global sharing of models. PDCM Finder data is FAIR and underpins the generation and testing of new hypotheses in cancer mechanisms and personalized medicine development. We provide expertise and software components to support several worldwide consortia including PDXNet, PDMR and EurOPDX. PDCM Finder is freely available under an Apache 2.0 license (https://github.com/PDCMFinder). This work

is supported by NCI U24 CA204781 01, U24 CA253539, and R01 CA089713. We welcome feedback on the resource and are looking for participants for usability studies - please get in touch if interested.

Developing human Ewing sarcoma *in vitro* models to prioritise new treatments

Elizabeth A. Roundhill[1], Elton J. R. Vasconcelos[2], David R. Westhead[3], Sarah Grissenberger[4], Martin Distel[5], Susan A. Burchill[6]. *[1]University of Leeds, Leeds, United Kingdom,[2]Leeds Omics, University of Leeds, Leeds, United Kingdom,[3]Faculty of Biological Sciences, University of Leeds, Leeds, United Kingdom,[4]St. Anna Children's Cancer Research Institute, Vienna, Austria,[5]Zebrafish platform Austria for preclinical drug screening, Vienna, Austria,[6]Leeds Institute of Medical Research, University of Leeds, Leeds, United Kingdom*

Models that more accurately reflect Ewing sarcoma (ES) will enable the prioritization of novel targeted agents from bench to clinic. To date, development of an ES mouse model have been unsuccessful[1] and engraftment of human ES in mice is variable[2]. Coupled with a moral obligation to minimize the use of mammals, we have established and characterized models using patient-derived ES cultures *in vitro* and in larval zebrafish. The transcriptomes of ES cell lines and patient-derived ES cultures[3] were analyzed and compared using total RNAseq followed by DESeq2 and Gene Set Enrichment analysis. Cells in 2D, as 3D spheroids, in combination with cells of the tumor microenvironment and in larval zebrafish (*Danio rerio*) were characterized. Six cell lines clustered independently from patient-derived ES cultures (n=20), reflecting differential expression of 15,709 RNAs ($p<0.01$). Interrogation of the differentially expressed genes using Reactome, KEGG and Gene Ontology identified up regulation of genes associated with mitotic spindle and G2/M G1/S DNA damage spindle checkpoints, homologous recombination and the cell cycle in the cell lines compared to patient-derived cultures ($p<0.01$). These data are consistent with the quicker doubling time (DT) and increased sensitivity of ES cell lines to chemotherapy (actinomycin D, doxorubicin, vincristine, etoposide; DT range=19-33h, EC50 range=4-

34nM) compared to patient-derived cultures (DT range=55-197h, EC50>10μM, $p<0.05$). All patient-derived ES cultures formed spheroids of similar diameter (range 105-258μm) at 96h ($p>0.05$), although there was heterogeneity in spheroid weight (range 205-3639ng, $p<0.05$) and migration index (MI; range 30-170, $p<0.05$). Treatment with actinomycin D (1-10 μM) significantly increased spheroid diameter ($p<0.05$), whereas 4-hyperoxyifosfamide (active metabolite of ifosfamide, 7-30μM) decreased spheroid diameter ($p<0.05$). Doxorubicin did not significantly change the diameter of spheroids. When propagated in combination with mesenchymal stem cells there was a 2-fold increase in viable cell number ($p<0.0001$) compared to ES cultures alone. Patient-derived ES cultures in zebrafish were observed at the injection site (perivitelline space). Some cells were detected in circulation 3 days post injection. This is consistent with heterogeneity and the high MI of patient-derived ES cultures. The transcriptome of ES cell lines is significantly different from that of ES patient-derived cultures and is associated with increased doubling times and response to chemotherapies. This highlights the importance of developing preclinical models using patient-derived ES cultures. Patient-derived ES cultures in 2D and 3D models *in vitro* and in zebrafish may provide a reliable cost-effective preclinical pipeline. [1]Minas *et al.* 2017.Oncotarget,8(21):34141-34163.[2]Nanni *et al*. 2019.Sci Rep,9(1):12174. [3]Roundhill *et al.* 2021.Cell Oncol,44(5):1065-1085.

Genomic and transcriptomic analysis of a diffuse pleural mesothelioma patient-derived xenograft library

Triparna Sen. *Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Despite recent treatment advances, malignant pleural mesothelioma (MPM) is an aggressive, recalcitrant malignancy. Currently, the histologic subtype (epithelioid/non-epithelioid/biphasic) is the primary prognostic factor; other potential biomarkers to guide therapeutic strategies remain elusive. Even with multimodality therapies, recurrence is high in early-stage disease. In the unresectable/metastatic setting, there are only two FDA-approved regimens, both in the first-line setting: cisplatin/pemetrexed and ipilimumab/nivolumab. Unfortunately, most who respond to first-line treatment experience disease progression within a year.

Therapeutic and diagnostic advances in DPM are hindered by a paucity of well-annotated preclinical models which can faithfully recapitulate the complex genomic interplay of the disease.
Methods: We established a library of patient-derived xenografts (PDX) from patients with DPM. We performed multi-omic analyses on available PDX and patient samples to deconvolute the mutational landscapes, global expression profiles, and molecular subtypes. Targeted next-generation sequencing (NGS; MSK-IMPACT), immunohistochemistry, and histologic subtyping were performed on all available samples. RNA-sequencing was performed on all available PDX samples. Clinical outcomes and treatment history were annotated for all patients. Platinum-doublet progression free survival (PFS) was determined from the start of chemotherapy until radiographic/clinical progression and grouped into $<$ or $\geq$ 6 months.
Results: The mutational landscapes of PDX models strongly correlated with paired tumor samples. There were some differences in *CDKN2A/B* mutations and relative enrichment of *NF2* with fewer *BAP1* alterations, the significance of which is being investigated. When compared by histological subtype, we observed an upregulation of genes involved in NOTCH and EMT signaling in the epithelioid models. Models derived from patients with shorter overall survival or poor response to platinum doublet had higher expression of WNT/β-catenin signaling, hedgehog pathway, and epithelial-mesenchymal transition signaling as well as downregulation of immune-activation pathways, including type I and II interferon signaling and inflammatory response pathways.
Conclusions: This library of MPM PDXs, the largest to date, effectively mimics human disease and provides unprecedented insight into the genomic, transcriptomic, and protein landscape of MPM. These PDX models will inform future clinical investigations and provide an important new preclinical resource.

Pediatric Cancer 2: Biology and Therapeutics

CCND2 promotes proliferation in *Drosha* and *DICER1* driven tumors

Claudette R. Fraire[1], Uma Obalapuram[1], Patricia D. B. Tiburcio[1], Kavita Desai[2], Kenneth S. Chen[1]. [1]*Pediatrics, UT Southwestern Medical Center,*

Dallas, TX,[2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA

Mutations in microRNA processing genes such as *DROSHA* and *DICER1* consist of 1.5-2% of pediatric cancers including a brain tumor called pineoblastoma. We developed a genetically engineered mouse model of Drosha- and Dicer1- driven pineal tumors. These tumors develop without microRNAs and express early pineal developmental markers. Gene set enrichment analysis revealed E2F target genes to be highly expressed in these tumors. One of the most upregulated genes in these tumors is cyclin D2 (Ccnd2). Additionally, these tumors stain positively for Rb phosphorylation. In a Wilms tumor cell line (WiT49) with Drosha knocked down, RNA sequencing revealed that *CCND2* was the most upregulated gene. Similarly, in patient-derived xenografts (PDXs) of DICER1-related tumors such as pleuropulmonary blastoma (PPB), we observed high expression of CCND2 and positive staining for Rb phosphorylation. To test the dependence of Rb phosphorylation in Drosha and Dicer tumors, we next treated a Drosha pineal tumor allograft with a CDK4/6 inhibitor, palbociclib, and observed tumor growth suppression. Additionally, treatment of *DICER1* mutant PPB PDXs with palbociclib had similar results. These experiments suggest that CDK4/6 is important for tumor proliferation in *Drosha* and *DICER1* driven cancers.

#3522

DICER1 Platform domain missense variants led to tumor susceptibility via failure of precursor miRNA binding

Dylan Pelletier, Anne-Laure Chong, Sophie Albert, Marc Fabian, William Foulkes. *Lady Davis Institute at Jewish General Hospital, Montreal, QC, Canada*

DICER1 is a key protein in the micro(mi)RNA biogenesis pathway responsible for cleaving precursor (pre)-miRNA stemloops with its RNase IIIa and IIIb domains into mature single stranded miRNAs. DICER1 syndrome is a pleiotropic tumor predisposition syndrome in which clinical manifestations are normally first seen during childhood. This genetic disorder is defined by the presence of inherited or *de novo* germline pathogenic variants (GPVs) in the *DICER1* gene. While many germline loss

of function variants fail to generate DICER1 protein, a subset of patients has germline missense variants that are predicted to produce full-length DICER1 protein that cluster in the DICER1 Platform domain, a region that plays a role in binding to the 5' phosphate of pre-miRNA stemloops. Due to the uncertainty surrounding the pathogenicity of missense variants in DICER1 syndrome, clinical actionability can be limited. To determine how Platform mutations predispose to DICER1 syndrome we characterized a number of these variants using *in vitro* pre-miRNA binding and cleavage assays. Interestingly, four of these variants displayed impaired pre-miRNA binding and processing, with three of them localizing to a hydrophobic pocket in the Platform domain. In keeping with *in vitro* results, DICER1 mutants displayed impaired miRNA processing when introduced into mesenchymal stem cells. Furthermore, we identified a second somatic hit in the RNase IIIb domain of DICER1 in thyroid nodular hyperplasia DNA from a patient affected by one of these variants. Taken together, these results identify a key region in the DICER1 protein that is essential for pre-miRNA processing and help the classification of these germline variants as pathogenic to ensure proper clinical management of affected patients. Additionally, these results provide insight on the molecular basis involved in DICER1 syndrome predisposition.

A systematic comparison of molecular features shared by H3K27-altered diffuse midline gliomas and posterior fossa A ependymomas

Matthew Pun[1], Drew Pratt[2], Patricia R. Nano[3], Piyush K. Joshi[4], Li Jiang[5], Bernhard Englinger[5], Arvind Rao[1], Marcin Cieslik[1], Arul M. Chinnaiyan[1], Kenneth Aldape[2], Stefan Pfister[4], Mariella G. Filbin[5], Aparna Bhaduri[3], Sriram Venneti[1]. *[1]University of Michigan Medical School, Ann Arbor, MI,[2]National Cancer Institute, Bethesda, MD,[3]Department of Biological Chemistry, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA,[4]Hopp Children's Cancer Center (KiTZ) Heidelberg, Division of Pediatric Neurooncology, German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, Germany,[5]Dana Farber Cancer Institute, Boston, MA*

In children, brain tumors account for the highest mortality rates of all malignancies, and in contrast to adult brain cancers, pediatric tumors often arise in infratentorial regions. Two tumors in particular, H3K27-altered diffuse midline gliomas (DMGs) and group-A posterior fossa ependymomas (PFAs) arise from structures around the fourth ventricle, and strikingly, both tumors exhibit a global decrease in the histone mark histone 3, lysine 27 tri-methylation (H3K27me3) that is associated with transcriptional repression. H3K27-altered DMGs primarily are found primarily in the pons and exhibit by lysine-to-methionine mutations at H3K27 (H3K27M). This missense mutation results in inhibition of the catalytic activity of the polycomb repressive complex 2 (PRC2) which mediates H3K27me3 deposition. PFAs are found in the lateral recess of the fourth ventricle and the cerebellum and demonstrate overexpression of EZH inhibitory protein (EZHIP). EZHIP contains a domain with striking resemblance to the mutant H3K27M histone tail and similarly blocks PRC2 activity. Although H3K27me3 levels are dramatically reduced in both areas, select genes retain H3K27me3 in both tumor types. Increasingly, data have emerged demonstrating that cases of PFAs actually harbor H3K27M mutations and cases of H3-wildtype DMGs in fact overexpress EZHIP. The neighboring origins and overlapping recurrent H3K27me3-modulating alterations observed in these two pediatric brain tumors suggest certain populations of cells in the developing hindbrain may be particularly prone to malignant transformation in the setting of PRC2 inhibition. A systematic comparison of genomic, transcriptomic, and epigenomic datasets for both tumors identified key molecular similarities between subsets of DMGs and PFAs and highlighted how developmental signatures may be preserved in tumor expression profiles. Specifically, these analyses identify shared copy-number profiles between PFAs and different subtypes of DMGs and demonstrate that the Activin A Receptor Type 1 (ACVR1), a gene with recurrent activating mutations in H3K27-altered DMGs, is overexpressed in a subset PFAs with worse survival outcomes. Additionally, interrogation of the H3K27me3 and enhancer landscapes identified critical genes with similar chromatin profiles and revealed heterogeneity in repression of H3K27me3-marked genes that correlated with patterns of inferred anatomic origins for each tumor. Moreover, one of these genes, cellular retinoic acid binding partner 1 (*CRABP1*) showed enrichment in progenitor cell types in single-cell transcriptomic datasets. Together, these analyses characterize the

common and unique molecular features of H3K27-altered DMGs and PFAs and shed light on the cellular contexts of the developing hindbrain that lead to development of each tumor.

#3524

Pharmacological characterization of pediatric brain tumor PDX models in a single mouse trial format

Eva Oswald[1], Dorothee Lenhard[1], Kanstantsin Lashuk[1], Stefan Pfister[2], Louis Stancato[3], Julia Schueler[1]. *[1]Charles River Laboratories, Inc., Freiburg, Germany,[2]DKFZ, Heidelberg, Germany,[3]Eli Lilly and Company, Indianapolis, IN*

Cancer remains the leading cause of disease-related death in children. Preclinical drug testing to identify promising treatment options for relapsed patients or those with poor prognosis is hindered by the lack of well characterized and annotated preclinical models. In the framework of the ITCCP4 consortium (www.ITCCP4.eu) our group determined the pharmacological profile of 47 orthotopically implanted pediatric brain PDX models. The panel comprised 21 high grade glioma (HGG), 13 medulloblastoma (MB), eight ependymoma (EP), three non-classified brain tumors (XT), one atypical teratoid/rhabdoid tumor (AT/RT) and one neuroblastoma (NB).. Depending on the tumor type the models were screened in an eleven or twelve arms single mouse trial study layout. Three treatment arms comprised standard of care cytotoxic compounds and radiation, whereas the other arms covered targeted therapies, mostly small molecules. Tumor load was determined using a fluorescent based in vivo imaging technology based on the lentiviral transient transduction of the PDX cells with iRFP713 prior to implantation into the brain. In addition, body weight and neurological scoring was applied to determine the overall condition of the animals. At the end of the study brain tissue was harvested and tumor load confirmed by immunohistochemistry. The mean overall survival of the orthotopic implanted animals on study was 48 days with a minimum of 7 days and a maximum of 132 days. Overall, the treatment was well tolerated in the tumor bearing animals as determined by body weight measurement. However, the combination of two cytotoxic drugs in some of the arms needed dose adjustments due to increased toxicity. Across all tumor types at least one of the cytotoxic arms improved overall survival of

the tumor bearing animals markedly: Temozolomide and Lomustine for HGG (43d and 50d, respectively vs 28d in the control arm), Lomustine and Endoxan for MB (99d and 73d, respectively vs 61d in the control arm), and Actinomycin D for EP (64d vs 52d). However, several of the targeted agents showed a distinct efficacy profile: Cobimetinib was efficacious in 50% of the HGG (47d vs 28d in the sensitive subset) and Idanasutlin in 80% of the EP models (79d in the sensitive subset vs 52d). The optical imaging signal over time confirmed tumor engraftment at the start of treatment. The most efficacious treatment arms induced growth delay or partial remission. This preclinical validation set gains even more importance using the accompanying molecular profiling data that are available not only for the PDX but also for the donor patient. Together with the breadth and depth of the still growing PDX collection, a unique preclinical platform for the development of drugs as well as companion diagnostics specifically for pediatric brain cancers is now available to the scientific community.

Clinical sequencing efforts are rapidly identifying sarcoma gene fusions that have not been functionally validated for their transformation capacity and biological activity. An example is the new fusion of transcriptional coactivators, VGLL2-NCOA2, found in infantile rhabdomyosarcoma. To delineate VGLL2-NCOA2 tumorigenic mechanisms and identify

therapeutic vulnerabilities, we implemented a cross-species comparative oncology approach with zebrafish, mouse allograft, and patient samples. We found that in our transgenic zebrafish and mouse allograft models, VGLL2-NCOA2 is sufficient to generate mesenchymal tumors that display features of immature skeletal muscle. Zebrafish and mouse VGLL2-NCOA2 tumors are consistent with the human disease histologically and transcriptionally, and express diagnostic rhabdomyosarcoma markers. We found a shared molecular feature of these tumors was a suppression of myogenic differentiation pathways and reactivation of developmental programs. To identify impacted developmental programs, we transcriptionally clustered zebrafish VGLL2-NCOA2 tumors with the trajectory of early zebrafish development. A subset of VGLL2-NCOA2 zebrafish tumors cluster with embryonic somitogenesis and pinpoint VGLL2-NCOA2 developmental targets, including a RAS family GTPase, ARF6. In VGLL2-NCOA2 zebrafish, mouse allograft, and patient tumors, ARF6 is highly expressed and is absent from mature skeletal muscle. ARF6 knockout in our C2C12-VGLL2-NCOA2 cell culture model suppresses VGLL2-NCOA2 soft agar colony formation capacity, suggesting a genetic cooperating event in the disease. Our data indicate that VGLL2-NCOA2 is an oncogene which leverages developmental programs for tumorigenesis, and that the reactivation or persistence of ARF6 could represent a therapeutic opportunity.

The transcription factor ZEB1 shapes osteosarcoma aggressiveness by affecting tumor cell differentiation and stemness features

Caterina Cascini[1], Daniele Lecis[1], Laura Botti[1], Chiara Ratti[1], Valeria Cancila[2], Katia Scotlandi[3], Claudio Tripodo[2], Mario Paolo Colombo[1], Claudia Chiodoni[1]. *[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[2]University of Palermo, Palermo, Italy,[3]IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy*

Osteosarcoma (OS) is a mesenchymal bone tumor affecting mainly children and young adults, characterized by a particularly aggressive behavior, with 20% of patients showing lung micro metastasis already at diagnosis. To date, treatment options for OS are still based on multi-drug chemotherapy and prognosis for metastatic patients is dismal, making urgent the

identification of new therapies. OS is considered a differentiation disease, because of the incapability of mesenchymal stem cells or osteoblastic progenitors to proceed toward terminal differentiation. We tested the effects on OS cells of targeting ZEB1, a transcription factor known to be critical for the maintenance of mesenchymal and stemness features in cancer. We inhibited ZEB1 expression in a murine OS cell line by lentiviral vectors based on CRISPR-Cas9 technology. We firstly tested the effects of ZEB1 deficiency in vitro, evaluating OS cell stemness potential by sarcosphere forming assay and osteogenic differentiation by alkaline phosphatase (Alp) staining. Gene expression profile (GEP) comparing ZEB1 KO clones and control ones was also performed to investigate the transcriptional changes induced by ZEB1 deletion and potentially identify alternative, more easily druggable, therapeutic targets. We also investigated in vivo the effect of ZEB1 inhibition. ZEB1 KO clones showed decreased stemness potential and increased Alp staining, both features suggestive of a more differentiated phenotype. Preliminary GEP analysis showed 849 down-regulated genes and 1093 up-regulated genes in ZEB1 KO clones versus ZEB1-competent controls. Gene set enrichment analysis indicated a down-modulation of pathways related to cellular proliferation and survival such as MTORC1 signaling, MYC targets, GM2 checkpoint, E2F targets and oxidative phosphorylation in ZEB1 KO clones. In vivo we observed a reduced tumor growth in ZEB1 KO clones that were also characterized by a more differentiated morphology in comparison to controls. Interestingly, the absence of ZEB1 in tumor cells affected also the immune infiltrate, as tumors derived from ZEB1 KO clones were significantly less infiltrated by pro-tumoral CD206+ M2-like macrophages. Moreover, we observed a reduced metastatic potential in ZEB1 KO clones than controls when we inject the cells intravenously. Taken together, these results support the hypothesis of ZEB1 as a key factor in OS aggressiveness, affecting tumor cell differentiation, stemness ability and in vivo growth capability.

WNT5B drives osteosarcoma stemness, metastasis and chemoresistance

Rachel S. Perkins, Sarocha Suthon, Gustavo A. Miranda-Carboni, Susan A. Krum. *University of Tennessee Health Science Center, Memphis, TN*

Osteosarcoma is a pediatric bone cancer that has no targeted therapy and has had no treatment advances for the last three decades. Osteosarcoma frequently metastasizes to the lungs, reducing patient survival with metastatic disease to 20% after 5 years. The goal of this study is to describe the function of WNT5B and its signaling pathway in osteosarcoma stem cells, metastasis and chemoresistance and its potential as a therapeutic target. Using RNA sequencing from publicly available datasets and immunohistochemistry on tumor microarrays, we reveal that WNT5B is the most expressed WNT in osteosarcoma patients and correlates with both metastasis and survival. Osteosarcoma is thought to result from a block in differentiation, and based on WNT5B's role in inhibiting osteoblast differentiation of mesenchymal stem cells from normal bone, we hypothesized a role for WNT5B in osteosarcoma stem cells. In spheroids, we show that both protein and mRNA levels of WNT5B are enhanced in the stem cell population compared to adherent cells. We found that WNT5B upregulates the expression of the stemness gene *SOX2* and directs stemness phenotypes, such as sphere forming efficiency, proliferation and migration. We show a reduction in sphere forming efficiency with 143B-WNT5B-knockdown cells compared to parental control cells which can be rescued with re-introduction of WNT5B. Additionally, we show that WNT5B drives proliferation and migration of osteosarcoma stem cells through increasing sphere size and capability to migrate on collagen matrix. Further, WNT5B enhances osteosarcoma chemoresistance to methotrexate. Through revealing a novel role for WNT5B in osteosarcoma cancer stem cells and therapy resistance, we present the WNT5B pathway as a candidate for therapeutically targeting osteosarcoma stem cells in patients.

ALKBH5 promotes cancer growth by regulating ER homeostasis via UPR, autophagy, and mitochondrial function

Panneerdoss Subbarayalu[1], Daisy Medina[2], Pooja Yadav[1], Santosh Timilsina[1], Kunal Baxi[2], Ratna Vadlamudi[3], Yidong Chen[1], Manjeet Rao[2].
[1]Greehey Children's Cancer Research Institute, UT Health San Antonio, San Antonio, TX,[2]Greehey Children's Cancer Research Institute, UT Health San Antonio, San Antonio, TX,[3]UT Health San Antonio, San Antonio, TX

Background**:** N6-methyladenosine (m^6A) RNA methylation is a dynamic reversible epitranscriptomic modification that includes methyl transferases (writes m^6A), demethylases (erases m^6A) and reader proteins, which proofreads m^6A marks of a specific site of transcripts. Recent studies have suggested that RNA methylation affects several fundamental cellular and molecular functions including mRNA splicing, stability, export, stem cell fate, circadian rhythms, DNA repair and cell survival. The objective of this study is to establish the mechanisms by which RNA demethylase ALKBH5 (AlkB homolog 5) facilitates tumor growth and progression.
Methods: To establish the significance of RNA methylation in children's cancers, we performed siRNA screen targeting m^6A writers, erasers, and readers in osteosarcoma (OS). We used several OS cell lines including 143B, MG63, SaOS2, U2OS and multiple patient derived OS cell lines. Mechanistic studies were conducted using ALKBH5 KO and knockdown cells and by measuring the status of Autophagy and UPR associated proteins using Western blot analysis, confocal and electron microscopy.
Results: Our results revealed that depletion of ALKBH5, a demethylase that erases the m^6A mark from the target gene, altered the autophagy in OS cells. Interestingly, we found that level of LC3, which is the universal marker for autophagy, was significantly increased in OS cells. RNA seq analysis showed that depletion of ALKBH5 significantly altered several autophagy related genes in the OS cells. To better understand the molecular mechanism by which ALKBH5 regulates autophagy, we investigated the Endoplasmic Reticulum (ER) stress-induced Unfolded Protein Response (UPR) pathway, which is a known activator of autophagy. We discovered that ER stress induced UPR signaling pathway is highly activated in ALKBH5 depleted cancer cells. Further, mechanistic studies suggested that ALKBH5 promoted ER homeostasis by controlling the expression of ER lipid raft associated 1 (ERLIN1), which binds to the activated inositol 1, 4, 5,-triphosphate receptor and facilitates its degradation via ERAD to maintain calcium flux between ER and mitochondria. Using functional studies and electron microscopy, we show that ALKBH5-ERLIN1-IP3R-dependent calcium signaling modulates the activity of AMP kinase, and consequently mitochondrial biogenesis. These findings thus reveal that ALKBH5 serves an important role in maintaining ER homeostasis and cellular fitness.

Conclusion: These findings provide novel insight into how m^6A may promote cancer cell growth by regulating the crosstalk among ER signaling, UPR, autophagy, and mitochondrial function. Our study is the first to show that RNA methylation plays an important role in osteosarcoma by regulating autophagy via UPR.

EWSR1-WT1 isoform selectivity, DNA binding, and druggable targets: unpacking the biology of desmoplastic small round cell tumor

Justin W. Magrath[1], Ilon A. Goldberg[1], Alifiani B. Hartono[2], Sean B. Lee[1].
[1]Tulane University School of Medicine, New Orleans, LA,[2]Canary Center at Stanford, Palo Alto, CA

Desmoplastic small round cell tumor (DSRCT) is a rare pediatric cancer caused by the *EWSR1-WT1* fusion gene. No targeted therapies have been established and multimodal therapy is ineffective with a 5-year survival rate of 15-25%. Many questions about the biology of DSRCT remain unanswered including the critical genes regulated by the *EWSR1-WT1* fusion gene, the role of the - and +KTS fusion gene isoforms produced by alternative splicing, and the relationship between *EWSR1-WT1* binding and gene expression alterations. To address these questions, we established four doxycycline-inducible DSRCT cell lines that selectively knockdown the expression of *EWSR1-WT1*. RNA-seq analysis on these cell lines with or without *EWSR1-WT1* knockdown identified commonly altered genes and pathways. To illuminate the role of the *EWSR1-WT1* -KTS and +KTS isoforms, the -KTS, +KTS, or both isoforms were overexpressed in a mesothelial cell line, a hypothesized cell of origin for DSRCT. Remarkably, different gene expression alterations were observed between the -KTS and +KTS isoforms. While overexpression of the -KTS isoform upregulated 765 genes and downregulated 366 genes, overexpression of the +KTS isoform upregulated 203 genes and downregulated 25 genes. Gene set enrichment analysis showed *EWSR1-WT1* regulated gene signatures are recapitulated by overexpression of the -KTS isoform or both +/-KTS isoforms, but not the +KTS isoform alone, suggesting the -KTS isoform predominantly regulates gene expression in DSRCT. To interrogate the influence of direct and indirect gene regulation by *EWSR1-WT1*, ChIP-seq and CUT&RUN data were integrated into our RNA-seq analysis. Across

each of our four DSRCT cell lines, approximately 25% of *EWSR1-WT1* bound peaks led to upregulation, 10% led to downregulation, and 65% led to no gene expression alteration. *EWSR1-WT1* binding accounted for 33% of *EWSR1-WT1* commonly upregulated genes but only 4.2% of commonly downregulated genes. Upregulated *EWSR1-WT1* bound genes were more likely to be bound in the promoter or first intron and coincide with Znf263 or Hoxb4 motifs. To evaluate the functional role of *EWSR1-WT1* targets in DSRCT biology, a screen of the 24 druggable *EWSR1-WT1* targets was conducted and a number of novel and known target genes were identified as important for DSRCT survival. Current work is verifying these targets with gene knockdown and evaluating their function *in vivo*.

Mechanisms underlying Ewing sarcoma-induced osteolysis

James J. E. Williams, Joanna B. Kitlinska. *Biochemistry and Molecular Biology, Georgetown University, Washington D.C., DC*

Ewing Sarcoma (ES) is an aggressive pediatric tumor, which often arises in bones and forms osseous metastases, both of which present as osteolytic lesions. Our previous studies indicated that neuropeptide Y (NPY), which is secreted from ES tumors, stimulates tumor-induced bone degradation via its effect on macrophage recruitment and their subsequent osteoclastic differentiation. This effect was dependent on the autocrine activation of the NPY Y5 receptor (Y5R) expressed by ES cells. However, the exact mechanisms of the osteolytic activity induced by the NPY/Y5R axis remained unknown. To identify the osteolytic factors released from ES cells due to the NPY/Y5R autocrine loop activity, we used shRNA to silence NPY or Y5R in SK-ES-1 ES cells and compared concentrations of known factors involved in the regulation of bone homeostasis in their conditioned media by an antibody array. Four secreted factors were found to be significantly decreased after silencing of NPY signaling: interleukin 8 (IL-8; $p<0.005$), matrix metalloproteinase 9 (MMP-9; $p<0.05$), intercellular adhesion molecule 1 (ICAM-1; $p<0.005$), and monocyte chemoattractant protein 1 (MCP-1; $p<0.05$). Among these proteins, IL-8 and MMP-9 were selected as the main candidates for mediators of NPY-induced osteolysis. To test their role in ES-mediated stimulation of osteolysis, we co-cultured mouse RAW 264.7 cells, that represent monocyte/macrophage lineage, with

SK-ES-1 cells in the presence or absence of the MMP-9 inhibitor (JNJ-0966; 10-7M-10-5M) or anti-IL-8 neutralizing antibody (0.1-0.4µg/ml) and tested their effect on osteoclast differentiation detected by TRAP staining. Inhibiting MMP-9 activity significantly decreased osteoclastogenesis of RAW264.7 cells in dose-dependent manner, while blocking IL-8 had no significant effect on the number of formed osteoclasts. These findings implicate MMP-9 as the mediator of NPY osteolytic activity. Further studies are required to understand the exact mechanisms underlying these effects, as well as potential role of NPY-induced release of MCP-1 in macrophage recruitment to ES tumors.

Discrete extracellular matrix-secreting tumor cell subpopulations remodel the Ewing sarcoma tumor microenvironment to promote invasion

Emma D. Wrenn[1], April A. Apfelbaum[1], Shireen Ganapathi[1], Erin R. Rudzinski[2], Xuemei Deng[2], Nicolas Garcia[1], Katherine Braun[1], Trisha Lipson[3], Shruti Bhise[4], Sami B. Kanaan[4], Olivia Waltner[4], Erika Newman[5], Scott Furlan[4], Elizabeth R. Lawlor[1]. *[1]Ben Towne Center for Childhood Cancer Research, Seattle Children's Research Institute, Seattle, WA,[2]Seattle Children's Research Institute, Seattle, WA,[3]University of Washington, Seattle, WA,[4]Fred Hutchinson Cancer Center, Seattle, WA,[5]University of Michigan, Ann Arbor, MI*

Ewing sarcoma (EwS) cells exist along a neuro-mesenchymal transcriptional continuum that is largely determined by transcriptional activity of the EWS::FLI1 fusion oncoprotein. Although EWS::FLI1-low state cells are more metastatic in experimental models, the role of these cells in established EwS tumor ecosystems is unknown. Here we have leveraged multimodal single-cell sequencing, spatial transcriptomics, and immunohistochemical profiling to characterize EwS cell subpopulations in cell lines, PDX models, and patient tumors. We identify CD73 as a marker of mesenchymal-high state EwS cells and show that CD73+ tumor cells share properties of experimentally-induced EWS::FLI1-low cells including altered cytoskeletons, enhanced migration and invasion, and increased expression of EWS::FLI1-repressed genes. However, CD73+ cells retain

proliferative capacity and do not down-regulate the fusion or the EWS::FLI1-activated signature. Instead, CD73+ EwS cells selectively express a gene signature that is enriched in extracellular matrix (ECM) genes. Examination of xenograft and EwS patient biopsies confirms the existence of subpopulations of spatially and transcriptionally distinct ECM-producing tumor cells and shows them to be more prevalent in infiltrating regions. Importantly, the local tumor microenvironment (TME) surrounding these cells is rich in tumor-derived TNC, SPARC, and biglycan, ECM proteins that have been widely implicated in cancer metastatic progression. Significantly, CD73+ EwS cells also upregulate expression of ECM-sensing genes, including *ITGA5* and *ITGB1*, suggesting potential to activate autocrine feedback loops. In support of this, interrupting outside-in ECM:integrin signaling cascades, through pharmacologic inhibition of FAK or SRC pathways, strongly reduces the invasive properties of CD73+ tumor spheroids in 3D collagen. Together these studies confirm the presence and functional importance of transcriptionally distinct tumor cell subpopulations in established EwS tumor ecosystems. In particular, our data reveal that highly mesenchymal tumor cells both generate and respond to pro-metastatic ECM proteins to support invasion. Studies are ongoing to determine the role of tumor cell-derived ECM on EwS progression and treatment resistance.

Activator protein-1 (AP-1) signaling inhibits the growth of Ewing sarcoma cells in response to DNA replication stress

David Gordon, Emma Croushore, Stacia Koppenhafer, Kelli Goss, Elizabeth Geary. *Pediatrics, University of Iowa, Iowa City, IA*

Ribonucleotide reductase (RNR) is the rate-limiting enzyme in the synthesis of deoxyribonucleoside triphosphates (dNTPs) and is required for DNA replication and the repair of DNA damage. Multiple types of cancer, including Ewing sarcoma tumors, are sensitive to RNR inhibitors or a reduction in the levels of either the RRM1 or RRM2 subunits of RNR. However, the polypharmacology and off-target effects of RNR inhibitors has complicated the identification of the precise mechanisms that regulate sensitivity and resistance to this class of drugs. Consequently, we used a conditional knockout (CRISPR/Cas9) and rescue approach to target RRM1

in Ewing sarcoma cells and identified that loss of RRM1 results in upregulation of the expression of multiple members of the activator protein-1 (AP-1) transcription factor complex, including c-Jun and c-Fos. This upregulation of AP-1 is mediated, in part, by SLFN11, which is expressed at high levels in Ewing sarcoma tumor and other pediatric sarcomas. Notably, the inducible expression of c-Jun and c-Fos in Ewing sarcoma cells impairs cell growth, downregulates the expression of the stem cell factor Sox2, and upregulates markers of cellular differentiation. In addition, small-molecule inhibitors of RNR, including gemcitabine and hydroxyurea, and HDAC inhibitors, which reduce the level of the RRM1 protein, also activate this AP-1 signaling pathway in Ewing sarcoma cells. Overall, these results provide novel insight into the critical pathways activated by loss of RNR activity and the mechanisms of action of inhibitors of RNR.

Zebrafish *her3*knockout impacts developmental and rhabdomyosarcoma-related gene signatures

Matthew R. Kent[1], Delia Calderon[1], Katherine M. Silvius[1], Jack P. Kucinski[1], Collette A. LaVigne[2], Matthew V. Cannon[1], Genevieve C. Kendall[1]. *[1]Nationwide Children's Hospital, Columbus, OH,[2]UT Southwestern Medical Center, Dallas, TX*

HES3 is a basic helix-loop-helix transcription factor that regulates neural stem cell renewal during development. *HES3* overexpression is predictive of reduced overall survival in patients with fusion-positive rhabdomyosarcoma, a pediatric cancer that resembles immature and undifferentiated skeletal muscle and is most commonly driven by the fusion-oncogene *PAX3-FOXO1*. However, the mechanisms of *HES3* cooperation in *PAX3-FOXO1* driven rhabdomyosarcoma are unclear and are likely related to *her3*/*HES3's* role in neurogenesis. To investigate *HES3's* function during development, we generated a zebrafish CRISPR/Cas9 null mutation of *her3*, the zebrafish ortholog of *HES3*. Phenotypic characterization revealed that *her3* null mutation is not embryonic lethal as they are present at expected Mendelian ratios. We observed a temporary growth delay *her3* zebrafish null mutants and, rarely, eye defects in adults. Transcriptomic analysis of *her3* null mutant embryos showed early dysregulation of a known downstream target, *neurog1* and downregulation

of genes involved in organ development, such as *pctp* and *grinab*, while genes pointing toward a terminal differentiation state, such as *tmod*, are upregulated. Differentially expressed genes in *her3* null mutant embryos are enriched for HOX and SOX10 motifs, suggesting these may be key genes involved during HES3 dysregulation. Several cancer-related gene pathways are impacted, including the inhibition of matrix metalloproteinases and the tumor microenvironment pathway. To complement our zebrafish model, we are developing a double-inducible cell line model consisting of a tetracycline-inducible *HES3* and a cumate-inducible *PAX3-FOXO1* to further investigate the hypothesized cooperation between *her3/HES3* and *PAX3-FOXO1* in fusion-positive rhabdomyosarcoma. These two systems will allow us to elucidate conserved mechanisms of cooperation between *HES3* and *PAX3-FOXO1,* and identify new therapeutic opportunities for children with fusion-driven rhabdomyosarcoma.

#3534

Interrogating the immune microenvironment of a novel mouse model of fusion positive rhabdomyosarcoma

Erin E. Resch[1], Kristianne M. Oristian[2], Elizabeth Mendes[2], Corinne M. Linardic[2], Brian H. Ladle[1]. *[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Duke University Medical Center, Durham, NC*

Immunotherapies have been largely ineffective for pediatric soft tissue sarcomas, in particular for fusion-positive rhabdomyosarcoma (FP-RMS), characterized by the PAX-FOXO1 gene fusion. We are hampered by a paucity of predictive, immune-competent mouse models of this cancer with which to develop novel and effective immune-based therapies. To overcome this barrier, we analyzed the immune microenvironment of one of the few genetically-engineered mouse models (GEMM) of FP-RMS. Briefly, this model is driven by conditional knock-in expression of *Pax3:Foxo1* at the endogenous *Pax3* locus, with or without conditional loss of MST1/2 (gene name *Stk4/3*), a Hippo pathway mediator that is modulated by PAX3-FOXO1. These two genotypes demonstrate different disease penetrance and tumor location, with mice bearing loss of MST1/2 exhibiting higher tumor penetrance and favoring head and neck disease sites. We hypothesize that these models exhibit differences in tumor-immune interactions in the microenvironment that correlate with these phenotypic differences. We aim

to characterize the immune microenvironment differences between these tumors and to establish this GEMM as a predictive, syngeneic model of FP-RMS. Tumors were generated spontaneously from a GEMM of FP-RMS. Tumors expressed PAX3-FOXO1 and either carried a conditional loss of MST1/2 (MST^{null}) or native MST1/2 (MST^{wt}). We analyzed 8 formalin-fixed, paraffin-embedded (FFPE) tumors and 2 tumor-derived cell lines from these novel models. FFPE tumor samples were analyzed via immunohistochemistry (IHC) for CD3 (T cell marker) and CD11b (myeloid cell marker) and were scored for immune cell infiltration. Overall, tumors demonstrate poor $CD3^+$ T cell infiltration with significantly higher infiltration of $CD11b^+$ myeloid cells ($p=0.0002$); this trend is also seen within the individual MST^{wt} ($p=0.0286$) and MST^{null} cohorts ($p=0.0286$). There was no significant difference in $CD3^+$ T cell or $CD11b^+$ myeloid cell density between the two genotypes. The drivers of this immune phenotype and the role of Hippo pathway signaling in mediating RMS tumor immune cell infiltration warrants further investigation. Additional ongoing studies are utilizing a spatial gene expression platform to visualize the spatially-preserved transcriptome of intact tumors to reveal potential pathways mediating the immune microenvironment.

Role of Myc family proteins in fusion-positive rhabdomyosarcoma

Bishwanath Chatterjee, Salah Boudjadi, Puspa Raj Pandey, Hana Kim, Wenyue Sun, Frederic G. Barr. *Cancer Molecular Pathology Section, Laboratory of Pathology, National Cancer Institute, Bethesda, MD*

Fusion-positive rhabdomyosarcoma (FP RMS) is an aggressive pediatric malignancy characterized by the presence of a PAX3-FOXO1 (P3F) or PAX7-FOXO1 fusion gene. Previous RNA expression studies have shown that these FP RMS tumors also express high levels of MYCN and lower levels of MYC. Our recent studies of FP RMS tumors revealed an inverse relationship between MYCN and MYC RNA expression in FP RMS tumors. Western blot studies of FP RMS cell lines and patient-derived xenograft (PDX) tumors identified tumors with high level MYCN and MYC protein expression as well as tumors with high level protein expression of either MYC or MYCN. To model the interaction of P3F with Myc family proteins in FP RMS, we generated human Dbt myoblasts with

doxycycline-inducible P3F (iP3F) with or without constitutively expressed MYCN. We previously observed that doxycycline-treated human Dbt myoblasts engineered with iP3F and constitutive MYCN expression (Dbt-MYCN-iP3F) form foci *in vitro* and rapidly form tumors *in vivo*, while doxycycline-treated Dbt myoblasts engineered with only iP3F expression (Dbt-iP3F) do not form foci *in vitro* and form tumors *in vivo* at a slower rate. Western blot and qRT-PCR analysis of the parental and tumor-derived (TD) Dbt-MYCN-iP3F lines revealed high MYCN and low MYC expression. In contrast, Dbt-iP3F parental lines express moderate levels of MYC and very low levels of MYCN whereas iP3F TD lines show increased MYC and MYCN expression, though this level of MYCN expression is considerably less than that seen in Dbt-MYCN-iP3F lines. Using CRISPR-Cas9 technology to knockdown MYCN or MYC, we found a primary dependence on MYCN in both Dbt-MYCN-iP3F parental and TD lines as indicated by loss of focus formation following MYCN knockdown while MYC knockdown does not interfere with oncogenicity. In contrast, oncogenicity in Dbt-iP3F TD lines is primarily dependent upon MYC whereas MYCN knockdown results in a modest and variable effect on oncogenicity. To elucidate the role of Myc proteins on the expression of P3F target genes, we measured expression of several transcriptional targets in these parental and TD lines by RNA sequencing and qRT-PCR. Several target genes (such as FGFR4) showed comparable upregulation by P3F in both parental and TD lines with or without constitutive MYCN expression. In contrast, a few target genes (such as FGF8) were stimulated by P3F at low levels in Dbt-iP3F parental lines and were stimulated at much higher levels in Dbt-iP3F TD lines as well as in both Dbt-MYCN-iP3F parental and TD lines. This finding indicates that some P3F target genes do not require high MYCN or MYC expression whereas other P3F target genes can only be maximally stimulated by P3F in the presence of high levels of MYCN and/or MYC. We postulate that the dependence of FP RMS on high level expression of a Myc family protein may be explained by the need to stimulate expression of one or more of the P3F target genes in this latter category.

#3537

A novel orthotopic xenograft model of spontaneous metastasis for rhabdomyosarcoma using lingual intramuscular injection

Katie E. Hebron[1], Kristine Isanogle[2], Amy James[3], Simone Difilippiantonio[3], Marielle E. Yohe[1]. *[1]NCI, National Institutes of Health (NIH), Frederick, MD,[2]Laboratory Animal Services Program, National Institutes of Health (NIH), Frederick, MD,[3]Laborator Animal Services Program, National Institutes of Health (NIH), Frederick, MD*

Rhabdomyosarcoma (RMS), a cancer characterized by the defective differentiation of skeletal muscle precursor cells, is the most common pediatric soft tissue sarcoma. Despite significant efforts to characterize the transcriptomic and genetic abnormalities of the disease, the prognosis for patients with advanced or refractory disease has remained unchanged for more than four decades. Preclinically, studies have been hampered by insufficient animal models. For example, the hindlimb orthotopic model, an injection into the gastrocnemius muscle of immunocompromised mice, produces highly encapsulated, non-invasive, non-metastatic tumors. While this model has shown a reasonable recapitulation of tumor proliferation response, investigators using this model are unable to assess the effect of their investigational treatment on local invasion or distant metastasis. Moreover, transgenic mouse models of RMS, while commonly metastatic, diverge significantly from the transcriptomic signature of human tumors. With these considerations, we hypothesized that an alternative orthotopic site, the tongue, may provide a more representative xenograft model of RMS. In a proof of principal experiment, the fusion negative RMS (FN-RMS) cell line RD was injected into the skeletal muscle of the tongue, a lingual intramuscular (LIM) injection. Tongue tumors establish in approximately 60-80% of mice injected within approximately 40 days. By histopathology, the primary tumors show evidence of local invasion. Interestingly, approximately 60% of these tumors also spread to local cervical lymph nodes, a process not observed in hindlimb orthotopic models or subcutaneous models. We expanded our investigation to include additional FN-RMS cell lines: RMS-YM, SMS-CTR, and a MEK inhibitor resistant cell line CTR-557. Mice injected with RMS-YM cells established tumors in at least 60% of mice by 75 days post injection. Additionally, enlarged local and distant lymph nodes are observed in 50% of these mice. Intriguingly, mice injected with SMS-CTR or its MEK inhibitor resistant derivative, CTR-557, frequently have tumors in both local and distant lymph nodes without evidence of a primary tongue tumor. One mouse in each group also had pulmonary metastases. Taken together, this model not only demonstrates the first orthotopic xenograft model of spontaneous metastasis for FN-RMS, it also mimics the spread of disease that is observed clinically in RMS originating in the head and neck. Ongoing and future studies include 1) generating highly metastatic human FN-RMS cell lines; 2) using spatial transcriptomics to compare the tumor microenvironment of non-metastatic hindlimb tumors and invasive and/or metastatic lingual tumors; and 3) identifying drivers of FN-RMS dissemination through transcriptomic, genome accessibility, and phospho-proteomic methods.

Endogenous HiBiT-tagging of PAX3-FOXO1 identifies potent suppressors of PAX3-FOXO1 protein levels by high-throughput screening

Yong Yean Kim[1], Robert G. Hawley[2], Mehal Churiwal[1], Teresa S. Hawley[3], Christine N. Evans[4], Raj Chari[4], David Milewski[1], Ranuka Sinniah[1], Young K. Song[1], Hsien-Chao Chou[1], Xinyu Wen[1], Ying Pang[1], Jing Wu[1], Craig J. Thomas[5], Jun S. Wei[1], Michele Ceribelli[5], Javed Khan[1]. *[1]National Cancer Institute, Bethesda, MD,[2]George Washington University, Washington, DC,[3]Research Technologies Branch, National Institute of Allergy and Infectious Diseases, Bethesda, MD,[4]Frederick National Laboratory for Cancer Research, Frederick, MD,[5]National Center for Advancing Translational Sciences, Rockville, MD*

Background: Oncogenic fusion genes are attractive therapeutic targets due to their tumor-specific expression and driver roles in cancers. PAX3-FOXO1 (P3F) is the dominant oncogenic driver of fusion-positive rhabdomyosarcoma (FP-RMS) with no targeted therapy. We developed methods to directly measure endogenous P3F protein levels amenable to high-throughput drug screens to identify suppressors of P3F.
Methods: HiBiT tag, an 11 amino acid peptide of the small fragment of NanoLuc luciferase, was inserted into the endogenous P3F using CRISPR-Cas9 in FP-RMS cell lines RH4 and SCMC. Western analysis was used for HiBiT tag validation and confirmation of P3F suppression. RNA-seq and ChIP-seq were used to assess transcriptomics and DNA binding of HiBiT-tagged P3F (P3F-HiBiT) respectively. High-throughput drug screen using Nano-Glo luciferase assay was performed using the Mechanism Interrogation PlatE (MIPE 5.0) drug library, which included

2,480 drugs with known mechanisms of action. CellTiter-Glo was used to monitor cell viability. We identified drugs that suppressed P3F by Nano-Glo without acute cytotoxicity by CellTiter-Glo at an early 24-hour timepoint. Mouse xenograft model of FP-RMS was used to investigate in vivo efficacy of top hits.
Results: We validated HiBiT tagging of P3F and not the wild-type FOXO1 by Western analysis. We showed that the HiBiT tag did not change the function of P3F by transducing human fibroblasts with P3F-HiBiT versus unmodified P3F. Gene Set Enrichment Analysis (GSEA) of RNA-seq showed that P3F-HiBiT activated the same downstream target genes as unmodified P3F. ChIP-seq using HiBiT antibody in HiBiT-tagged FP-RMS cell lines RH4 and SCMC matched the genomic locations from ChIP-seq with P3F antibody in parental RH4 and SCMC. Using a cutoff of Area Under the Curve (AUC) of CellTiter-Glo - AUC of Nano-Glo > 90, in both RH4 and SCMC, identified 182 compounds. Filtering for drugs with ≥ 3 hits for the same target identified 14 drug classes that suppressed P3F protein level including HDAC inhibitors (3), mTOR inhibitors (4), CDK inhibitors (8), and BRD4 inhibitors (3). One top hit was the CDK inhibitor TG02 (Zotiraciclib), currently in human trials. TG02 suppressed P3F protein levels by Nano-Glo and Western analysis. We confirmed induction of apoptosis by PARP cleavage in a panel of FP-RMS cell lines. GSEA analysis of RNA-seq after treatment with TG02 showed marked suppression of P3F target gene sets. TG02 also significantly delayed tumor progression of established tumors in a mouse xenograft model of FP-RMS without weight loss.
Conclusion and Future Directions:By HiBiT tagging the fusion oncogene P3F, we identified 182 compounds that suppress P3F levels of which TG02 was a top hit that also showed in vivo efficacy. Drug combination studies are currently underway to identify synergistic suppressors of P3F protein levels that can be translated into clinical trials.

Indoleamine-2,3-dioxygenase 2 (IDO-2) is expressed in hepatoblastoma cells and associated with metastatic state

Lisandro Luques[1], Ashby Kissoondoyal[1], Emily De Sousa[1], Paula Quaglietta[1], David Malkin[1], Stefano Cairo[2], Emilie Indersie[3], Reto Baertschiger[1]. *[1]Genetics & Genome Biology Program, The Hospital for Sick Children, Toronto, ON, Canada,[2]Champions Oncology Inc, Rockville, MD,[3]XenTech, Evry, France*

Hepatoblastoma (HB) is the most common pediatric primary liver malignancy and represents about 1% of all pediatric tumors. Incidence of HB has been increasing in the past 10 years. Risk stratification of HB patients is established by the extent of the liver disease, patient age, levels of serum AFP and presence of metastatic disease. Currently, treatment and prognosis of HB patients relies on chemotherapy and complete tumor resection. Unfortunately, patients with high-risk HB (metastatic, unresectable, refractory and recurrent) have dismal prognosis. The molecular mechanisms underlying the aggressiveness and metastatic potential of the tumor have not been elucidated yet. Tryptophan-2,3-dioxygenase (TDO) and indoleamine-2,3-dioxygenase 1 and 2 (IDO 1 and IDO-2) are enzymes in mammals that catabolize tryptophan to kynurenine and its activity has been related with immunoregulation and tumorigenesis. While TDO and IDO-1 have been extensively studied before the discovery of IDO-2, the role of the later in tumorigenesis is still under evaluation. Expression of IDO-2 is normally found in liver, kidney, pancreas, brain and epididymis while a dysregulated expression was reported in different types of cancer. IDO-2 activity was found to affect both the immune cells activation status and also the proliferation, migration and survival of tumor cells both *in vitro* and *in vivo*. Despite being expressed in normal liver tissues, IDO-2 expression has never been assessed in HB cells. The aim of this study was to determine if IDO-2 mRNA is expressed in HB cell lines and to determine if this expression is correlated with patient risk classification. By using real-time RT-PCR, we determined the expression of IDO-2 in commercially available HepG2 cells and in three patient derived xenograft (PDX)-derived HB cell lines (HB214, HB279, HB 303) (high risk metastatic, high-risk non metastatic and-low risk, respectively). IDO-2 is expressed in both HepG2 cells and in the 3 PDX-derived cell lines. Data analysis by using linear mixed effects modelling followed by t-tests to examine specific comparisons showed significant differences between cell lines. Expression of IDO-2 in cells from the metastatic tumor (HB214) was significantly higher than in HepG2 and cells from non-metastatic disease ($p<0.05$). In conclusion, we report here for the first time that IDO-2 is expressed in HB cells. Although further investigation should be conducted in order to understand its specific role in HB, the findings in this work suggest that IDO-2 expression might be related with clinical tumor behavior.

Reduction in cell viability of hepatoblastoma cells following inhibtion of Hsp90

Ashby Kissoondoyal[1], Emily DeSousa[1], Paula R. Quaglietta[1], Emilie Indersie[2], Stefano Cairo[3], David Malkin[1], Lisandro Luques[1], Reto M. Baertschiger[1]. *[1]Genetics and Genome Biology, SickKids, Toronto, ON, Canada,[2]XenTech, Evry, France,[3]Champions Oncology, Rockville, MD*

Background: Hepatoblastoma (HB) is the most frequent liver tumor in children. While most tumors respond well to treatment with good outcomes, there are a subgroup of refractory tumors for which novel therapies are required. Emerging literature has suggested a role of Hsp90 in HB progression. One possible mechanism hypothesizes that Hsp90 helps stabilize misfolded proteins that contribute to HB progression including β-catenin. Our study aimed to investigate if inhibition of Hsp90 would affect the cell viability of hepatoblastoma cell lines in vitro.
Methods: Commercially available HEPG2, and patient xenograft-derived hepatoblastoma cell lines (HB214, HB279, and HB303) were analyzed for differences in Hsp90 gene expression by qRTPCR as well as cell viability (n = 3 replicates for each cell line) using the MTS assay. Differences in cell viability for each cell line were further examined after treatment with a 0.1μM or 0.25μM dose of 17-AAG (an HSP90 inhibitor) for 48H. We examined gene expression and the MTS assay cell viability data using linear mixed effects modelling followed by t-tests to examine specific comparisons (significance at $p < 0.05$).
Results: Hsp90 gene expression was significantly increased in HEPG2 cells ($p < 0.001$) and in HB279 cells ($p < 0.05$), but not in HB214, or HB303 cells, compared to HUVECs control cells. Examining clinically relevant characteristics, significant improvements to model fit were found with the inclusion of sex ($p < 0.01$), β-catenin deletion status ($p < 0.01$), and a higher PRETEXT stage but not from examining if cell lines were derived from metastatic parent tumors. While we observed no significant cell line viability differences between individual HB cell lines at baseline (0μM 17-AAG treatment) or overall significant differences for treatment with either 0.1μM or 0.25μM dosages of 17-AAG, there were differences in cell viability for individual HB cell lines. We observed significant decreases in cell viability in HEPG2 cells with 0.1μM ($p < 0.05$) and 0.25μM ($p < 0.05$), as well as in HB279 cells with 0.1μM ($p < 0.05$) and 0.25μM ($p < 0.05$) 17-AAG treatments but observed no effect of 17-AAG treatment on cell viability in HB214, or HB303 cells. Similar improvements in model fit were observed with the inclusion of sex ($p < 0.01$), β-catenin deletion status ($p < 0.01$), and a higher PRETEXT stage ($p < 0.001$), but not from examining if cell lines were derived from metastatic parent tumors.
Conclusion: HB cell lines express Hsp90 at levels correlated with age, β-catenin deletion status, and risk stage. Moreover, the expression levels of Hsp90 corresponded to the sensitivity of each cell line to the Hsp90 inhibitor 17-AAG, with cells more highly expressing Hsp90 having a greater reduction in cell viability. Continuing to understand the mechanisms of Hsp90 action in HB, particularly through the previously demonstrated connection with β-catenin, may identify potential targetable therapies in the care of HB.

#3541

Tumoroid-based screening platform to test focal, chemo- and combination therapy for retinoblastoma

Irina Sinenko[1], Fabien Kuttler[2], Valentin Simeonov[3], Alexandre Moulin[4], Christina Stathopoulos[4], Gerardo Turcatti[2], Adeline Berger[4], Francis Munier[5], Paul Dyson[1]. *[1]Institute of Chemical Sciences and Engineering, Swiss Federal Institute of Technology Lausanne (EPFL), Lausanne, Switzerland,[2]Biomolecular Screening Facility, School of Life Sciences, Swiss Federal Institute of Technology Lausanne (EPFL), Lausanne, Switzerland,[3]Laboratory of Environmental Remote Sensing, Swiss Federal Institute of Technology Lausanne (EPFL), Lausanne, Switzerland,[4]Jules-Gonin Eye Hospital, Foundation Asile des Aveugles, Lausanne, Switzerland,[5]Swiss Federal Institute of Technology Lausanne (EPFL), Lausanne, Switzerland*

Current treatments for retinoblastoma, the most common intraocular malignancy, rely on a limited number of drugs repurposed from other pediatric cancer therapies. Drug toxicity and relapse of the disease necessitate new therapeutic strategies. The implementation of drug candidates in the clinic is usually followed by *in vitro* validation, which requires accurate and clinically relevant *in vitro* models. We report here a robust 3D tumoroid-based platform, for testing various clinical protocols, e.g. therapeutic agents following a single or repeated exposure, alone or in combination with focal therapy (thermotherapy). The platform, generated from the Y79 retinoblastoma cell line, consists of matrix-embedded tumoroids, which retain the key features of the disease and allow prolonged culture time. Following the optimization of growth conditions, the effect of single and repeated exposure to chemotherapeutic agents has been measured by high-throughput automated fluorescence imaging followed by quantification. The clinical conditions of chemothermotherapy have been recapitulated with a setup consisting of: an infrared diode laser (810 nm, 0.3 W) that heats the tumoroids in the presence of indocyanine green (50 μg/mL); a thermal camera to enable real-time temperature measurement; and an environment-controlled

inverted microscope to ensure physiological conditions and precise focusing of the laser. Melphalan and carboplatin, two drugs currently used to treat retinoblastoma in clinical protocols of chemotherapy and chemothermotherapy respectively, have been applied to validate the system.Tumoroid viability and size progressively decreased over 4 weeks of repeated drug exposure with melphalan, reflecting the response of retinoblastoma in advanced clinical cases. Carboplatin treatment showed an activity enhancement in the tumoroid model similar to that observed in the clinic, when combined with focal therapy, demonstrating that the platform system closely recapitulates the clinical conditions. Inversely, the thermotherapy experimental protocol designed for 2D *in vitro* cell culture and commonly used to date, i.e. an incubation temperature increased to 42 ºC for 1 h, did not show an improvement of the carboplatin cytotoxicity, confirming that our laser-based thermotherapy protocol provides a more accurate and clinically relevant drug response.
Such an approach, combining physiologically relevant *in vitro* cancer models and investigation of drugs in well-established treatment modalities, can significantly reduce the number of new drug candidates that give false-positives or overestimated efficacies when evaluated in relevant *in vivo* models. It is expected that the platform will contribute to the implementation of new therapeutic strategies to treat retinoblastoma, and could also be adapted to other diseases for which repeated drug exposure and/or chemothermotherapy is relevant.

A stem cell model dissects detrimental effects of neuroblastoma-linked chromosomal aberrations on cell differentiation during neural crest development

Ingrid M. Saldana-Guerrero[1], Luis F. Montano-Gutierrez[2], Christoph Hafemeister[2], Dylan Stavish[3], Lisa E. Shaw[4], Irfete S, Fetahu[2], Andrea Wenninger-Weinzierl[2], Caterina Sturtzel[2], Celine Souilhol[3], Sophia Tarelli[3], Mohamed R. Shoeb[2], Marie Bernkopf[2], Polyxeni Bozatzi[2], Maria Guarini[5], Eva Bozsaky[2], Michelle C. Buri[2], Eva M. Putz[2], Peter W. Andrews[6], Ivana Barbaric[3], Helen E. Bryant[7], Martin Distel[2], Sabine Taschner-Mandl[2], Matthias Farlik[4], Anestis Tsakiridis[3], Florian Halbritter[2]. *[1]Centre for Stem Cell Biology, Neuroscience Institute, & Sheffield Institute for Nucleic Acids, The University of Sheffield, Sheffield, United Kingdom,[2]St. Anna Children's Cancer Research Institute (CCRI), Vienna, Austria,[3]Centre for Stem Cell Biology & Neuroscience Institute, The University of Sheffield, Sheffield, United Kingdom,[4]Department of Dermatology, Medical University of Vienna, Vienna, Austria,[5]CeMM Research Center for Molecular Medicine of the Austrian Academy of Science, Vienna, Austria,[6]Centre for Stem Cell Biology, The University of Sheffield, Sheffield, United Kingdom,[7]Sheffield Institute for Nucleic Acids (SInFoNiA), Department of Oncology and Metabolism, The University of Sheffield, Sheffield, United Kingdom*

Early childhood malignancies are driven by sparse genetic aberrations in oncogenes that often co-occur with large copy number variants (CNVs). The combination of these mutations is thought to transform developmentally pliant embryonic cells to initiate tumorigenesis. However, the mechanistic interactions between CNVs, oncogenes, and differentiation have not been systematically studied due to several obstacles: (i) CNVs cannot be engineered efficiently yet; (ii) transient embryonic progenitors are absent in full-grown tumors; and (iii) inter-species differences in lineage specification limit the applicability of animal models.
To overcome these challenges, we used isogenic human embryonic stem cell (hESC) lines carrying gains of chromosome 17q/1q, which are prevalent in the embryonal tumor neuroblastoma (NB). We differentiated these cells toward trunk neural crest (NC) and their sympathoadrenal derivatives, the putative cells-of-origin of NB, and performed single-cell RNA sequencing and cell-biological assays at key differentiation stages. We found that CNVs impaired the specification of sympathoadrenal cell types and instead potentiated early Schwann-cell-precursor-like phenotypes. Additional overexpression of the oncogene MYCN (which is frequently amplified together with CNVs in high-risk NB tumors) exacerbated these differentiation defects, enabled tumourigenic cell proliferation, and generated cell states in vitro that transcriptionally resembled NB tumor cells. Finally, using epigenome analysis, we connected these states to a stepwise disruption of gene-regulatory networks centered on developmental transcription factors.
Together, our results chart a mechanistic route to NB tumorigenesis and provide a general framework for the CNV-driven initiation of embryonal tumors, in which CNVs ‘prime’ embryonic cells for oncogenic transformation. The tumor-like cells in our model may serve as proxies to experimentally test therapeutic interventions during tumorigenesis.

Mesenchymal stromal cells and tumor-associated macrophages modulate adrenergic to mesenchymal state switching in neuroblastoma

Meng-Hua Lee, Kevin Louault, Krinio Giannikou, Xiangming Ding, Alice Yanovsky, Jin-Seok Park, Yves A. DeClerck, Shahab Asgharzadeh. *Cancer and Blood Diseases Institute, Children's Hospital Los Angeles, Los Angeles, CA*

Neuroblastoma (NB), a common solid tumor of children, can adopt a lineage-committed adrenergic (ADRN) or an immature mesenchymal (MES) tumor cell type, which differs in phenotype, epigenetic landscape, transcription factors, and core regulatory circuitries. These cell types can spontaneously interconvert, but the mechanism remains largely unknown. Here, we hypothesize that the tumor-associated macrophages (TAM) and cancer-associated fibroblast (CAF) within the tumor microenvironment contribute to pro-tumorigenic factors production and drive switching from ADRN to MES state in neuroblastoma. We first demonstrate the ADRN and MES lineage identity of NB cell lines by Western blot and compared the control and NB cell lines co-cultured with mesenchymal stromal cells (MSC), the precursor cell of CAF, and monocyte in transwell. Initial experiments demonstrated the morphology of NB cell line CHLA255 and CHLA136 showing increased spreading area and spindle shape in TAM-CAF co-cultures compared to control cells. As compared to control cells, monocytes and MSC-CAF co-culture induced the MES lineage markers SOX9 and Notch1 of NB cell lines that had low basal SOX9 expression, with a reduction in protein levels of ADRN lineage markers PHOX2B, and GATA3. Next, single-cell RNA-sequencing was utilized to analyze the expression of TAM and CAF, and MES- and ADRN-signature genes of NB cells in NB-TAM-CAF co-cultures. Single-cell analyses of TAM-CAF co-cultured CHLA255 and CHLA136 demonstrated enrichment of MES signature over time providing clear evidence of mesenchymal differentiation of NB cells within a TME-rich environment. Pathway enrichment analyses reveal enrichment of pathways associated with extracellular matrix (ECM) deposition and epithelial to mesenchymal of TAM-CAF co-cultured NB cell lines. Our results suggested that the presence of CAF and TAM in the tumor microenvironment drives neuroblastoma ADRN: MES switch akin to that observed in epithelial: mesenchymal switch in adult tumors. ADRN-MES state switching has been shown relevant for tumor relapse and therapy resistance. Our studies point to a therapeutic vulnerability by targeting cells and pathways activated in the NB-TAM-CAF axis.

ALK signaling activity stabilizes SLC3A2 protein levels in neuroblastoma tumorigenesis

Wei-Yun Lai, Tzu-Po Chuang, Marcus Borenäs, Ruth Palmer, Bengt Hallberg. *University of Gothenburg, Gothenburg, Sweden*

Background: Neuroblastoma is the most common childhood tumor that grows in the adrenal glands or sympathetic ganglia. Approximately 10% of pediatric neuroblastoma patients harbor mutations in anaplastic lymphoma kinase (ALK). In a previous study, we identified SLC3A2 as a potential interacting partner with ALK using BioID-based *in vivo* proximity labeling. SLC3A2 is a multifunctional protein that mediates integrin-dependent signaling, acts as a trafficking chaperone for amino acid transporters, and regulates polyamine transport. No previous link to ALK signaling has been reported and the underlying mechanisms and functional consequences of a SLC3A2-ALK interaction in ALK-driven neuroblastoma are unclear.
Materials & Methods: The interaction of SLC3A2 and ALK initially detected with BioID-based *in vivo* proximity labeling was validated by immunoprecipitation. The effect of ALK signaling on SLC3A2 expression and protein stability was evaluated by quantitative PCR and immunoblotting. The functional effect of SLC3A2 on cell viability were investigated by siRNA and inhibitor treatments in both human and mouse ALK-driven neuroblastoma cells.
Results: SLC3A2 was confirmed to interact with ALK in both anti-ALK and anti-SLC3A2 antibody co-immunoprecipitations from NB1 cells (ALK-wild-type) and CLB-GE (ALK-F1174V). Moreover, this interaction was decreased by ALK inhibitor (lorlatinib) treatment. Upon ALKAL2 ligand treatment, ALK signaling increased the protein levels of SLC3A2 and this was abrogated by lorlatinib treatment in NB1 cells. Furthermore, lorlatinib treatment suppressed SLC3A2 expression and significantly affected protein stability in neuroblastoma cells with different ALK mutations including CLB-BAR (ALK exon4-11 deletion), CLB-GAR (ALK-R1275Q), and CLB-GE (ALK-F1174V) during cycloheximide chase analysis. Knockdown of SLC3A2 significantly inhibited cell growth and down-regulated the amino acid transporter SLC7A5 (LAT1) expression in CLB-GE cells (ALK-F1174V). While mono treatment of either lorlatinib (ALK TKI) or AMXT-1501 (polyamine transport inhibitor) only showed moderate effects, combinatorial treatment exhibited a synergistic effect on cell growth in ALK-driven

primary-cultured mouse neuroblastoma #9883 (Th-*MYCN*; *Alk-F1178S*) and #111 (Th-*MYCN*; *Rosa26_Alkal2*) cells.
Conclusions: SLC3A2 protein stability and its interaction with ALK is dependent on ALK signaling in an ALK-driven neuroblastoma context. The synergistic effect of combined ALK and polyamine transport inhibitors suggests a potential therapeutic option for ALK-driven neuroblastoma.

#3545
The Yes-associated protein (YAP) regulates GD2 immunotherapy response in high-risk neuroblastoma
Adeiye A. Pilgrim[1], Hunter C. Jonus[1], Andrew Ho[1], Anna Cole[2], Jenny Shim[1], Kelly C. Goldsmith[1]. *[1]Emory University School of Medicine, Atlanta, GA,[2]Emory University, Atlanta, GA*

Background Patients with the pediatric solid tumor high-risk neuroblastoma (HR NB) receive intense multimodal therapy yet 50% still relapse with chemotherapy-resistant disease. Relapsed NBs harbor increased RAS/MAPK pathway mutations and increased expression and downstream activity of the transcriptional co-regulator YAP. We have previously shown that YAP mediates resistance to chemotherapy and MEK inhibitors in RAS mutant NBs (Shim *et al., Cancer Res* 2020). Patients with relapsed NB are treated with the GD2-targeting monoclonal antibody dinutuximab in combination with chemotherapy. Given the increased expression and activity of YAP in relapsed HR NB, we posited that YAP might also play a role in GD2 immunotherapy response.
Methods/Results We stably knocked down YAP in the human derived NRAS mutant SK-N-AS NB cell line with a scrambled short hairpin (sh) control or 2 YAP-targeting shRNAs to generate 3 distinct cell lines. Dinutuximab requires antibody-dependent cellular cytotoxicity (ADCC) and we have shown that gamma delta (γδ) T cells augment dinutuximab in aggressive NB models. We exposed the shYAP1, shYAP2, and control SK-N-AS cells to γδ T cells with/ without dinutuximab. YAP knockdown sensitized both SK-N-AS shYAP cell lines to γδ T cell killing both in the presence and absence of dinutuximab. To investigate the mechanism of increased dinutuximab sensitivity, we evaluated a panel of NB cell lines (*MYCN* amplified and *MYCN* single copy) for YAP protein and GD2 cell surface expression and noted an inverse relationship. That same inverse correlation was found for GD2 and YAP gene expression in primary HR NB tumor datasets. We therefore evaluated GD2 expression following YAP knockdown in SK-N-AS and show that GD2 significantly increased on the cell surface following YAP inhibition. PRRX1 is a master transcription factor that induces a mesenchymal NB phenotype which is one of high YAP expression with very low to no GD2 surface expression. Interestingly, *PRRX1* expression increased in YAP knockdown cells yet GD2 expression also increased, suggesting YAP regulates GD2 expression more directly than PRRX1. In the GD2 biosynthesis pathway, GM3 is converted into GD3 by GD3 synthase (GD3S). GD2 synthase then catalyzes GD3 into GD2. GD3S gene (*ST8SIA1*) expression significantly increased (>100-fold) upon YAP knockdown. Furthermore, shRNA stable inhibition of GD3S in shYAP NB cells reverted the phenotype and decreased GD2 cell surface expression back to baseline. We then treated established SK-N-AS control or shYAP xenografts with an 18-day course of human γδ T cells, dinutuximab, and cyclophosphamide. Pilot results show significantly extended survival in mice harboring SK-N-AS shYAP tumors.
Conclusion These results support YAP regulation of GD2 expression through transcriptional suppression of GD3 synthase and identify YAP as a therapeutic target to augment GD2 immunotherapy responses in HR and relapsed NB.

Pediatric Cancer 3: Genomes and Novel Tumor Models

The ENL YEATS domain links leukemic stem cell frequency and enhances YEATS inhibitor sensitivity in MLL-ENL leukemias
Hsiangyu Hu[1], Nirmalya Saha[1], Yuting Yang[1], Ejaz Ahmad[1], Lauren Lachowski[1], Uttar Shrestha[1], Vidhya Premkumar[1], James P. Ropa[2], Lili Chen[1], Blaine Teahan[1], Sierrah Grigsby[1], Rolf Marschalek[3], Zaneta Nikolovska-Coleska[1], Andrew G. Muntean[1]. *[1]University of Michigan Medical School, Ann Arbor, MI,[2]Indiana University School of Medicine, Indianapolis, IN,[3]Institut für Pharmazeutische Biologie, Goethe-Universität, Frankfurt am Main, Germany*

Chromosome 11q23 translocations are present in ~10% of acute leukemia, which generate the oncogenic MLL fusion (MLL-r hereinafter) proteins and drive a subset of aggressive leukemia. Mechanistic studies of MLL-r leukemias implicated several complexes involved in RNA polymerase II-mediated transcription: the Super

Elongation Complex (SEC), the DOT1L Complex (DotCom) and the Polymerase Associated Factor 1 Complex (PAF1c). These protein complexes are dysregulated in MLL-r leukemias and amplify transcription of pro-leukemic target genes. The proteins ENL and AF9 are two common MLL fusion partners and share high homology within their N-terminal YEATS domains that function as epigenetic reader domains. Recently, the importance of the wild type ENL (but not AF9) and its epigenetic reader function has been demonstrated in acute leukemias. However, the importance of the YEATS domain in the context of MLL-ENL fusions has not been explored. In patients, we found that most MLL-ENL fusions (84.1%; N=302 patients), but not MLL-AF9 fusions, retain the YEATS domain. These findings prompted us to investigate 1) how the YEATS domain contributes to MLL-ENL leukemogenesis, 2) whether the YEATS domain affects MLL-ENL fusion protein functions, and 3) if YEATS domain presence in MLL-ENL fusion exposes a vulnerability to YEATS inhibitors. Using published YEATS epigenetic reader mutations, we found that the YEATS epigenetic reader function significantly contributes to MLL-ENL leukemogenesis. Disrupting the YEATS epigenetic reader function in MLL-ENL fusion proteins significantly impacts leukemic stem cell frequency. Using an MLL-ENL construct relevant in patients (ΔYEATS hereinafter), we discovered a subset of MLL-ENL targets with altered expression. GSEA revealed several gene signatures enriched in ΔYEATS cells, most interestingly genes downregulated in leukemic stem cells. Specifically, the MLL-ENL target *Eya1* is severely disrupted in MLL-ENL YEATS epigenetic reader mutants and ΔYEATS cells. Our mechanistic data suggest that while MLL-ENL binding at *Eya1* is impacted in ΔYEATS, YEATS epigenetic reader mutants do not significantly alter MLL-ENL and PAF1c localization. However, YEATS epigenetic reader mutations severely impact epigenetic modifications associated with active transcription, including H3K4me3, H3K9ac and H3K79me2 at the *Eya1* locus. Finally, we tested the YEATS inhibitor sensitivity in AML cell lines. We found that the cell line HB1119, which is driven by MLL-ENL fusion with an intact YEATS domain, is among the most sensitive lines to the YEATS inhibitor SGC-iMLLT. Together, our study provides the biological and mechanistic characterizations of the YEATS domain in MLL-ENL leukemias and contributes to the theoretical framework for YEATS inhibitor development in the majority of MLL-ENL patients.

Single-cell characterization of pediatric T-cell acute lymphoblastic leukemia transcriptomes

Irina Pushel, Byunggil Yoo, Daniel Louiselle, Margaret Gibson, Midhat S. Farooqi, Keith August. *Children's Mercy Kansas City, Kansas City, MO*

Pediatric T-cell acute lymphoblastic leukemia (T-ALL) is a rare cancer with a diverse set of causative genomic abnormalities. The variety and limited characterization of genomic mechanisms underlying this disease presents a unique challenge for the development of improved treatments for these patients. Using the 10x Genomics Chromium system, we have generated single-cell gene expression (scRNA) and chromatin accessibility (scATAC) data for blood and/or bone marrow samples collected at diagnosis from eight pediatric T-ALL patients. We sequenced 21,669 high-confidence cells and performed normalization and downstream analysis using the Seurat v4.0.2 package in R 4.0.3. Our data show that patient cancer cells show highly individual transcriptomes and are often characterized by combinatorial expression patterns of genes including *MEF2C*, *BCL11B*, *HOXA9*, *NKX2-1*, and *LMO2*, which have been previously implicated for their roles in various T-ALL subtypes. Additionally, we observe that each patient has a unique ratio of cancer cells with a CD4+ T-cell, CD8+ T-cell, and hematopoietic stem cell-like identity, which may be linked to treatment response and patient outcome. This dataset represents one of the first forays into exploring the biology of pediatric T-ALL at the single-cell level. Our comparative analysis of patient cancer cells reveals novel insights into the transcriptional and chromatin-related for distinct subsets of pediatric T-ALL cases, paving the way for future treatment selection and drug development to improve outcomes for these patients.

#3552

YAP-TEAD2 binding mediates therapy resistance in RAS-driven neuroblastoma

Jenny Shim[1], Andrew Ho[1], Hunter C. Jonus[1], Adeiye A. Pilgrim[1], Benjamin G. Barwick[1], Tracy T. Tang[2], Lawrence H. Boise[1], Kelly C. Goldsmith[1]. *[1]Emory University, Atlanta, GA,[2]Vivace Therapeutics, Inc, San Mateo, CA*

Background/**Objectives:** Despite intensive multimodal therapy, greater than 50% of children with high-risk neuroblastoma (HR NB) relapse with incurable disease. Next generation sequencing of primary HR NB tumors identified an increase in activating mutations in the RAS/RAF/MAPK pathway. Moreover, gene set enrichment analyses showed a significant decrease in expression of genes suppressed by the Yes-Associated Protein (YAP) at

relapse, suggesting increased YAP transcriptional repression. YAP binds with TEAD family transcription factors to regulate gene expression. We have shown that YAP promotes chemotherapy and MEK inhibitor resistance in RAS-mutated NB tumors *in vivo* by suppressing the expression of Harakiri (HRK), a BH3-only pro-apoptotic protein activated in response to tumor environmental stress such as serum starvation. Our overall objective is to elucidate how YAP represses HRK and tumor suppressor genes globally, and to enhance MEK inhibitor potency by combining MEK inhibition with agents that inhibit YAP or induce HRK to restore the tumor environmental stress response and apoptosis in RAS-mutated NB.
Design/Methods: We used publicly available databases to identify TEAD binding sites on the *HRK* gene locus in NB. To assess the global state of methylation, we treated NB cells, SK-N-AS ($NRAS^{Q61K}$ mutation, *MYCN* non-amplified) and NLF (*NF1* deletion, *MYCN* amplified), with demethylating agent azacitidine and evaluated *HRK* expression. To identify the specific TEAD (1-4) binding partner to YAP, we performed siRNA and co-immunoprecipitation studies. We further tested novel YAP-TEAD small molecule inhibitors with varying TEAD1-4 inhibition specificity in SK-N-AS and NLF cells *in vitro*.
Results: We observed that TEAD binds near *cis*-regulatory regions on the *HRK* gene locus in NB. We found that *HRK* expression is restored when SK-N-AS and NLF cells are treated with azacitidine despite *YAP* expression increasing. We also identified TEAD2 as the specific binding partner to YAP in NB and found that TEAD2 is necessary for HRK regulation. Novel YAP-TEAD small molecule inhibitors affect NB cell viability under serum-deprived conditions *in vitro*, especially the inhibitor with highest specificity against TEAD2, and affect YAP-TEAD downstream targets.
Conclusions: YAP-TEAD2 binding is essential for HRK regulation in RAS-mutated NB and thus is a logical therapeutic target to restore therapy response. Further studies are ongoing to test YAP-TEAD small molecule inhibitors in combination with MEK inhibitors and *in vivo*.

Simultaneous somatic copy number alterations and single nucleotide variants detection in paired aqueous humor and tumors from retinoblastoma eyes
Liya Xu[1], Mike J. Schmidt[2], Rishvanth K. Prakabar[2], Peter Kuhn[2], James Hicks[2], Jesse Berry[1]. *[1]Children's Hospital Los Angeles, USC - University of Southern California, Los Angeles, CA,[2]Michelson Center-CSI-Cancer, USC - University of Southern California, Los Angeles, CA*

Introduction: Retinoblastoma (Rb) is the most common childhood intraocular cancer. Tissue biopsy of Rb can cause tumor spread, so it is contraindicated. We demonstrated that aqueous humor (AH), an ocular fluid, is a high-yield liquid biopsy enabling in vivo detection of tumor-derived cell-free DNA (cfDNA) thus overcoming the contraindication of biopsy. Somatic genomic alterations, including both somatic copy number alterations (SCNAs) and single nucleotide variations (SNVs) on RB1 gene, have been able to be identified in the same clinical samples but with two separate sequencing runs. In this study, we first developed a single targeted sequencing method to identify both SCNAs and RB1 SNVs. With this method, we further investigated the degree of genomic concordance between paired tumor and AH samples from the same Rb eye.
Materials and Methods: 11 paired AH and Rb tumor samples were included in the study. cfDNA of AH and tumor DNA of enucleated Rb eyes were isolated with QIAgen commercial kits. DNAs were constructed into whole genome libraries followed by hybridization target enrichment (Agilent SureSelect). The enrichment assay covers the whole length of RB1 and MycN genes, the all-exon regions of BCOR and CREBBP genes, and a whole genome CNV backbone. Libraries were submitted to Illumina HiSeq 4000 platform for fastq data generation with 2x150bp mode. The bioinformatics pipeline was optimized to generate SCNA profiles from targeted sequencing reads, along with SNV calling.
Results: For SCNA profiles, 11/11 AH samples (100%) and 8/11 tumor samples (72.72%) have positive RB-SCNA signatures. Strong concordances were observed between AH and tumor SCNA profiles (median = 90.1%) with targeted sequencing reads. In total, 9 disease-driving RB1 SNVs were identified in 6 patients (54.5%). 7/9 (77.8%) of the variants were shared between AH and tumor samples, while the AH and tumor each contained one unique SNV. In all SNVs, the AH displayed a higher allele frequency. Notably, 4/11 samples have focal RB1 gene deletion detected with SCNA profiling, which may explain the difficulties of RB1 SNV detection in some samples. Further, one case was driven by a MYCN gene amplification with no RB1 alterations.
Conclusions: This study presented highlights the utility of a single method to call both SVNs and SCNAs in a single clinical sample, with enriched tumor information detected in AH compared with tumor. This study further strengthens the utility of AH as a liquid biopsy platform for Rb eyes.

Targeting chromatin remodeling complex in pediatric cancers

Jun Qi. *Cancer Biology, Dana-Farber Cancer Institute, Boston, MA*

Chromatin accessibility plays critical roles in maintaining normal gene regulatory programs in healthy tissue. Aberrant chromatin accessibility triggered by abnormal activity of a variety of chromatin remodeling complexes is known to activate and maintain tumor proliferation. The most widely known of these complexes is the SWI/SNF (also called BAF) complex. Studies have shown that BAF regulates chromatin accessibility in a more global manner and its long-term inhibition or functional loss may lead to non-specific downstream effects in both tumor and normal tissue. Thus, there is a need to further probe understudied complexes, such as the Imitation Switch (ISWI) family of chromatin remodelers, to find more cancer specific functions that can provide mechanistic insights that pave the way for novel therapeutic discoveries. We have examined the functions of these chromatin complex in different type of pediatric cancers to estsablish the pre-clinical rationale for potential novel pediatric cancer therapy. We discovered that fusion protein positive rhabdomyosarcoma (FP-RMS), an aggressive sub-type of RMS characterized by chromosomal translocations resulting in gene fusions between PAX3/7 and FOXO1 is highly dependent on chromatin accessibility. This aggressive subtype exhibits a significant vulnerability in its dependence on the oncogenic transcription factor PAX3-FOXO1, yet like many other TFs, PAX3-FOXO1 is currently not considered a viable therapeutic candidate. We have then carefully examined the effect of chemical inhibition and chemical degradation of BAF complex function in FP-RMS and discovered that BAF complex globally regulates chromatin accessibility, is not specifically regulating FP function. We next examined the function of other chromatin remodeling complexes that might regulate FP function specifically in FP-RMS. We identified that some of other chromatin remodeling complex, such as Nuclear Remodeling Factor (NURF) complex, a member of the ISWI chromatin remodeling complex family, interacts with a critical fusion protein, PAX3/7-FOXO1, in FP-RMS. There is limited understanding surrounding the functions of NURF complex, particularly in pediatric cancer. Here, we then studied the key functions of FP regulated by variety of chromatin remodeling complex utilizing combined chemistry and biology method to elaborate the essential functions of PAX3/7-FOXO1 fusion protein. We have developed variety of chemical strategies to target these complexes, and utilize these tool compounds to delineate the chromatin remodeling complex regulated FP functions. This study showcased our approach to advance cancer research by combining the power of chemistry, chemical biology, structural biology, computational biology and cellular biology to identify novel mechanistic understanding as well as novel therapeutic approach for pediatric cancers.

Proteomic characterization of rhabdomyosarcoma-derived extracellular vesicles reveals a fusion-positive protein signature

Paula R. Quaglietta[1], Ashby Kissoondoyal[1], Ethan Malkin[2], David Malkin[1], Reto M. Baertschiger[1]. *[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, Toronto, ON, Canada*

Rhabdomyosarcoma is the most common pediatric soft tissue sarcoma. Current diagnostic methods involve imaging and tissue biopsy for staging, histology and fusion status assessment. There are presently no serum biomarkers for rhabdomyosarcoma diagnosis or surveillance. Novel approaches and identification of biomarkers are warranted for minimally invasive diagnostic/surveillance techniques. Extracellular vesicles (EVs) are recognized as critical mediators of intercellular communication and the pathophysiology of carcinogenesis and metastasis. This study aimed to characterize the proteome of rhabdomyosarcoma-derived EVs and identify proteomic signatures that correlate with clinical characteristics such as histological subtype, cancer stage, age and metastasis, using patient-derived cell lines. EVs were isolated from cell culture conditioned media by differential ultracentrifugation from four rhabdomyosarcoma cell lines (RH4, RH18, RH30, RD), each in triplicate. Liquid chromatography-tandem mass spectrometry identified EV protein cargo. Proteins identified in our samples were compared to all available EV data in the Vesiclepedia database, using the FunRich software. We identified 1,527 total proteins in our rhabdomyosarcoma-derived EVs. When comparing to Vesiclepedia, 96 unique proteins were identified from our EVs that were not previously annotated in EVs within the database. Expression of these 96 proteins was further evaluated based on clinical characteristics of the tumors the cell lines were derived from. We found a four-protein signature in the EV secretome of rhabdomyosarcoma cell lines correlated with FOXO1 fusion-positive status. This signature includes proteins involved in regulating extracellular matrix organization, regulating gene expression, protein biosynthesis and translation. Rhabdomyosarcoma cells secrete EVs with unique protein cargo based on clinical characteristics of the parent tumor such as histological subtype and FOXO1

fusion status. Further validation of these secreted EV proteins in biological fluids could prove an effective liquid biopsy technique for novel diagnostic approaches or surveillance in pediatric rhabdomyosarcoma.

Stage-restricted osteoblasts specify signatures of osteosarcoma molecular subtypes
Jianning Tao, Fang Fan, Haydee Torres. *Sanford Research, South Dakota, Sioux Falls, SD*

A challenging question in osteosarcoma research is the identity of the cell of origin, and its contribution to the molecular subtypes and signatures. We examine the potential of stage restricted osteoblasts to induce fully penetrant osteosarcoma using osteoblast stage specific Cre mice to mutate Trp53. We identified three molecularly distinct subtypes of osteosarcoma induced by the same driver mutation. Our results suggest that the three subtypes arise from different subpopulations of osteoblasts. Despite histologic identity as one entry osteosarcoma, these subtypes are separable based on molecular signatures and specific signaling pathways. These studies point to the cell of origin as a determinant of osteosarcoma molecular subtypes. Our studies may provide insights for understanding osteosarcoma heterogeneity and improving treatment of the disease.

Role of FLI portion of EWS::FLI in transcription regulation via modulation of chromatin 3D landscape in Ewing sarcoma
Ariunaa Bayanjargal, Cenny Taslim, Jesse Crow, Julia Selich-Anderson, Stephen L. Lessnick. *Nationwide Children's Hospital, Columbus, OH*

Ewing sarcoma is an aggressive bone-associated tumor currently treated with dose-intense chemotherapy, radiation, and surgery and it affects adolescents and young adults. The hallmark of Ewing sarcoma is a translocated fusion transcription factor named EWS::FLI that drives the oncogenic process. We hypothesize that FLI portion of EWS::FLI containing a crucial alpha-helix plays a novel role in transcription regulation of thousands of genes by modulating chromatin looping. The hypothesis is based on recent evidences from our lab: an alpha-helix immediately downstream of DNA binding domain as an important player in regulating transcriptional activity and that EWS::FLI has a substantial role in shaping the chromatin landscape of Ewing sarcoma cells. The ***objective*** of this study is to elucidate the mechanism underlying transcriptional regulation by FLI. We utilized knockdown/rescue experiments in which EWS::FLI was depleted with shRNA and replaced with constructs containing the ETS DNA Binding Domain (DBD) alone or DBD+ (DBD and 4th alpha-helix). The binding pattern and transcriptional regulation were assessed with CUT&Tag and RNA-Seq respectively. The extent of roles each of these construct play in organization, structure, and function of chromatin are being assessed using Micro-C technique, a variation of Hi-C with improved resolution, higher signal-to-noise ratio and more information on chromatin domain boundaries and chromatin looping. The DNA binding and genomic localization of EWS::FLI was unaltered by the deletion surrounding the DNA binding domain (which contains a 4th alpha-helix) in A673 and TTC466 cells. Despite this similarity in genomic localization and binding, the transcriptional output driven by EWS::FLI was significantly diminished by the deletion. With this current study, we hope to understand if the flanking region neighboring the DNA binding domain contributes to the chromatin architecture remodeling function of EWS::FLI and whether this function could be attributed to the transcriptional output differences in the DBD and DBD+ conditions.

Understanding Ewing sarcoma cell fate
Danh Truong, Sandhya Krishnan, Alexandar Lazar, David McCall, Joseph A. Ludwig. *UT MD Anderson Cancer Center, Houston, TX*

Like several other translocation-positive sarcomas, Ewing sarcoma (ES) exists exclusively in a high-grade, undifferentiated state. We believe that the pathognomonic EWS-FLI1 fusion protein (FP) responsible for ES is intimately linked to cell fate, differentiation, and plasticity. Over the last two decades, an emerging body of research has begun the challenging task of deciphering how the FP - via its action as an aberrant transcription factor- blocks differentiation and promotes reprogramming toward a quasi-stem-like cell with features of neuroectodermal or mesenchymal stem cells. We compared ES transcriptome data to other cancers in an unsupervised comparison between the gene expression profile of cancer cells in the Cancer Cell Line Encyclopedia (CCLE) and tumor expression datasets. While ES is traditionally classified as a bone cancer, it does not cluster

near other bone cancer subtypes (e.g., osteosarcomas) or soft-tissue sarcomas. To that end, we sought to better understand how targeting the FP affected ES differentiation and lineage. Using a CRISPR knockout (CRISPR-KO) model of A673, we targeted Exon 4 of the EWSR1 protein in the n-terminus of the FP and generated a clonal pool (EWSR1 CRISPR KO). We used single-cell RNA sequencing (scRNA-seq) to identify the transcriptional changes after FP knockout (FP KO). We identified five cell clusters in the data. We observed the expression of FP target genes (EWS-FLI1 On), *PRKCB,* and *LIPI* and saw robust expression in four of the clusters suggesting normal FP expression. Conversely, FP repressed genes (EWS-FLI1 Off), *LOX* and *IGFBP3*, were elevated in cluster 2, which contained only EWSR1 CRISPR KO cells. This suggests that the FP was successfully knocked out in cluster 2 (FP EWSR1 KO). Next, we asked how the FP KO changed the lineage/fate of A673 cells. We hypothesized that loss of the FP would induce mesenchymal/fibroblastic fate in ES cells. To answer this, we used SingleR, which compares the gene expression profile of query cells to the CCLE data set, to identify the nearest cell type. Interestingly, all clusters except the FP EWSR1 KO cluster identified closely with ES and related tumors. The FP EWSR1 KO cluster, which expressed EWS-FLI1 'off' genes, did not resemble ES. Using a granular identification with cell lines, we confirmed that the highest score was A673 since these were A673 cell lines. However, the FP EWSR1 KO resulted in a phenotype unrelated to A673 and more closely resembled cell lines with fibroblastic phenotype. Our data suggest that targeting the FP significantly changed ES lineage. While the FP KO did not lead to cell death, our results suggest a novel gene regulatory network acts to sustain ES lineage. Further perturbations in this network may lead to a better understanding of ES treatment, particularly as novel EWS-FLI1-directed therapies emerge.

Understanding alternative splicing in Ewing sarcoma progression and metastasis to inform novel therapy development

Akila S. Venkataramany, Safiya Khurshid, Anthony R. Miller, Saranga Wijeratne, Pin-Yi Wang, Timothy P. Cripe, Dawn S. Chandler. *Nationwide Children's Hospital, Columbus, OH*

Introduction: Ewing sarcoma (ES) is the second most common pediatric bone cancer, and patients with metastases have five-year survival rates of <30%. Both local and metastatic ES tumors are characterized by the EWS-FLI1 chromosomal translocation, resulting in an aberrant transcription factor that increases ES cell proliferation and metastasis. EWS-FLI1 activity and ES transformation are reliant upon increased IGF-1 signaling, so initial therapies have centered on IGF-1R inhibition. However, compensatory upregulation of insulin receptor A (*IR-A*), an oncogenic spliced isoform of *IR*, provides a viable resistance mechanism to support ES growth and progression. *IR* has two spliced isoforms formed by the inclusion or exclusion of exon 11 (*IR-B* and *IR-A* respectively), and *IR-A* is differentially expressed in cancers due to its high affinity binding to IGF-II. *We hypothesize that the pathogenesis and metastatic potential of ES is driven in part by alternative splicing of IR and other key genes. Furthermore, modulation of this splicing via antisense oligonucleotides (ASOs) aided by adeno-associated viral (AAV) delivery may be a novel therapeutic avenue for ES.*

Results: We performed long-read mRNA sequencing to identify differentially spliced isoforms between the matched ES cell lines CHLA-9 and CHLA-10 (derived from a localized and metastatic ES tumor respectively). Our analysis revealed global differences in alternative splicing between CHLA-9 and CHLA-10 and identified gene isoforms in the insulin receptor/IGF signaling pathway (*IGFBP3*) that are unique to CHLA-10. Additionally, we detected both previously reported and novel isoforms for *CD99*, *RHOA*, *RACK1*, splicing factors (*PTBP1*), and eukaryotic initiation factors, among other genes.

To further understand *IR* alternative splicing, our labs have developed an *IR* ASO targeting the CUG-BP1 regulatory site upstream of exon 11, and we have previously validated its efficacy in HeLa cells transfected with an *IR* minigene and in pediatric sarcoma cell lines. In ES cell lines, we observed significant *IR-A* upregulation in a panel of ES cell lines and patient-derived xenografts derived from local and metastatic tumors, highlighting the opportunity for intervention with our ASO. To facilitate delivery, we have explored the use of AAV vectors, a clinically approved option for gene therapy, and shown successful transduction of AAV-8 over a time-course in ES cells.

Conclusions: Our results indicate that alternative splicing is differential between local and metastatic ES and produces isoforms unique to the metastatic setting. Additionally, the oncogenic *IR-A* isoform and other spliced isoforms are viable targets for ASO therapy aided by AAV delivery. By better understanding splicing in ES, we can identify targetable interactions at the transcriptional level and develop innovative therapeutics that can improve the clinical outcomes of ES patients.

Recurrent genetic alterations in epigenetic pineoblastoma subtypes

Tobias Goschzik[1], Mathias Yuan[2], Martin Mynarek[3], Elke Pfaff[4], Evelyn Dörner[1], David T. W. Jones[5], Stefan M. Pfister[6], Stefan Rutkowski[2], Torsten Pietsch[7]. *[1]Dept. of Neuropathology, University of Bonn Medical Center, Bonn, Germany,[2]Dept. of Pediatric Hematology/Oncology, University Clinics Hamburg-Eppendorf, Hamburg, Germany,[3]Dept. of Pediatric Hematology/Oncology & Mildred Scheel Cancer Career Center HaTriCS4, University Clinics Hamburg-Eppendorf, Hamburg, Germany,[4]Department of Pediatric Oncology, Hematology and Immunology & Pediatric Glioma Research Group (B360), Hopp Children's Cancer Center Heidelberg (KiTZ) & German Cancer Research Center (DKFZ), Heidelberg University Hospital, Heidelberg, Germany,[5]Pediatric Glioma Research Group (B360), Hopp Children's Cancer Center Heidelberg (KiTZ) & German Cancer Research Center (DKFZ), Heidelberg, Germany,[6]Department of Pediatric Oncology, Hematology and Immunology & Division of Pediatric Neurooncology, Hopp Children's Cancer Center Heidelberg (KiTZ) & German Cancer Research Center (DKFZ), Heidelberg University Hospital, Heidelberg, Germany,[7]Dept. of Neuropathology and DGNN Brain Tumor Reference Center, University of Bonn Medical Center, Bonn, Germany*

Introduction**:** Genome-wide methylation analyses recently revealed novel epigenetic pineoblastoma (PBL) subtypes, but so far few data are available on recurrent cytogenetic alterations due to the rarity of these neoplasms. Therefore, our aim was to shed further light onto the molecular and genetic characteristics underlying the pathogenesis of pineoblastoma subtypes.

Experimental procedures: Cytogenetic alterations of tumor samples of 60 patients with a diagnosis of PBL confirmed by reference neuropathology and methylation array profiling (450K or EPIC BeadChips (Illumina)) were analyzed by high-resolution genome-wide molecular inversion probe analysis. 52 cases could be screened for mutations by next-generation DNA panel sequencing. Survival data of 41 patients were available. All patients had surgery and older patients (≥4y) received RT followed by maintenance chemotherapy (n=37); infants (<4y) were primarily given a RT-sparing regimen that involved intensified chemotherapy dosage.

Results: Of the recently published epigenetic consensus PBL subtypes (Liu et al., 2021), our cohort consisted of 37 PBL-miRNA1 (1A, 30; 1B, 7), 17 PBL-miRNA2, 2 PBL-MYC/FOXR2, and 4 PBL-RB1 samples. PBL-miRNA subtype tumors had characteristic alterations in microRNA-processing genes; *DICER1* mutations (n=14; 4 in Grp1A / 1 in Grp1B / 9 in Grp2) were most abundant, followed by homozygous deletions of the *DROSHA* locus (n=11; 8 / 1 / 2) and *DROSHA* mutations (n=9; 3 / 3 / 3). Most frequent cytogenetic aberrations in these subtypes were chromosome (chr.) 7 gains (n=25) and chr. 14 losses (n=20, with all but one of miRNA2 cases). *DICER1* mutations were significantly associated with chr. 14 losses ($p<0.001$). 17 cases showed gains of the chromosomal arm 14q, in 6 additional cases, focal gains were found of the *OTX2* oncogene located on chr. 14q. In the miRNA subtypes we identified cases with a tetraploid phenotype (n=11; 7 / 4 / 0). Interestingly, none of the 6 patients with tetraploid tumors and survival data had relapses, while the remaining patients of the miRNA subtypes had a 5-year PFS of 72% and 5-year OS of 68% (10 of 31 with relapse/death) after a median follow-up time of 3.9 years. However, this did not reach statistical significance. A significant impact on survival could not be demonstrated for chr. 14q gains or focal *OTX2* gains. The PBL-RB1 subtype cases had homozygous *RB1* deletions (n=3) or biallelic *RB1* mutations (n=1). Focal chromosomal aberrations were frequently found in this subtype, but rarely numerical alterations.

Conclusion: The epigenetically defined PBL subtypes were characterized by distinct cytogenetic and mutational events. Although we could not demonstrate a prognostic impact of these events, this might be due to the small sample size. A possible prognostic role for a superior (e.g. tetraploidy) or inferior outcome (e.g. *OTX2* gains) need studies in larger cohorts and ideally in prospective clinical trials.

Pfister[8], Keith L. Ligon[1], Volker Hovestadt[1], Claudia Kleinman[12], Henry Long[1], David T. W. Jones[8], Pratiti Bandopadhayay[1], Timothy N. Phoenix[4]. *[1]Dana-Farber Cancer Institute, Boston, MA,[2]Cincinnati Children's Hospital, Cincinnati, OH,[3]Broad Institute of MIT and Harvard, Cambridge, MA,[4]University of Cincinnati, Cincinnati, OH,[5]St. Jude Children's Research Hospital, Memphis, TN,[6]Lowy Cancer Research Centre, Sydney, Australia,[7]University Hospital Essen, Essen, Germany,[8]German Cancer Research Center, Heidelberg, Germany,[9]University Medical Center Göttingen, Gottingen, Germany,[10]Klinikum Kassel, Kassel, Germany,[11]University Hospital Stuttgart, Stuttgart, Germany,[12]McGill University, Montreal, QC, Canada*

Background: Diffuse midline gliomas (DMGs) are a universally fatal brain tumor of childhood. While histone mutations are a critical tumor initiating event, they are insufficient to drive gliomagenesis. Histone mutations co-occur with somatic alterations in other pathways including TP53, MAPK, and MYC signaling. However, the mechanisms through which these pathways are activated have not been fully elucidated.
Methods: We applied an integrative approach using transcriptomics, epigenetics, proteomics, *in vitro* cancer models, and *in vivo* mouse models to systematically evaluate how FOXR2 mediates gliomagenesis.
Results: We have recently found that a subset of DMGs aberrantly express *FOXR2*, a forkhead transcription factor. FOXR2 is both sufficient to enhance tumor formation, and necessary for *FOXR2*-expressing DMGs. While FOXR2 indeed enhances MYC protein stability, FOXR2 exerts oncogenesis through MYC-independent functions and specifically hijacks E26-transformation specific (ETS) transcriptional circuits and FOXR2 DNA-binding is highly enriched at ETS motifs. We have performed proteomic and phospho-proteomic analysis of *FOXR2*-expressing human neural stem cells to identify proteins and phospho-sites that are highly enriched in FOXR2-expressing cells.
Conclusion: Taken together, this study elucidates how FOXR2 interacts with ETS transcription factors to mediate oncogenesis, and further highlights a role for FOXR2 in activating ETS and MAPK signaling.

#3563

SWI/SNF-associated DPF1 is a unique transcriptional regulator of malignant peripheral nerve sheath tumors

Bega Murray, Xiyuan Zhang, Shahroze Abbas, Haiyan Lei, Hilda Jafarah, Jack F. Shern. *National Cancer Inst. - Bethesda Campus, Bethesda, MD*

Background**:** Malignant peripheral nerve sheath tumors (MPNST) are rare soft tissue sarcomas that are typically therapy resistant and associated with a poor prognosis. Genetic aberrations of the polycomb repressive complex 2 (PRC2) occur in up to 75% of MPNST cases. PRC2 functions antagonistically to SWI/SNF protein complexes, regulating expression of target loci in a dynamic relationship that is critical to normal cellular development and maintenance of cell identity. The consequences of PRC2 loss on chromatin state maintained by SWI/SNF in MPNST is unexplored. Therefore, this study used functional genomics to elucidate the role of SWI/SNF in MPNST.
Methods: To define the transcriptional regulatory role of SWI/SNF complexes in MPNST, SWI/SNF components were targeted via a CRISPR knock-out (KO) screen combined with a single cell RNA sequencing (RNAseq) readout. Genes of interest highlighted by this screen were further investigated using bulk CRISPR RNAseq. Phenotypic effects of the expression of these genes were studied using loss-of-function assays coupled with colony formation assays. SWI/SNF complex heterogeneity was characterized using glycerol gradient sedimentation, co-immunoprecipitation (co-IP), and mass spectrometry experiments.
Results: The investigation of SWI/SNF transcriptional regulation in MPNST highlighted the Double PHD Finger family proteins (DPF1,2,3) as regulating distinct downstream targets. Notably, *DPF1* had a unique transcriptional profile compared to other SWI/SNF components. Bulk CRISPR KO RNAseq confirmed these findings and highlighted a specific set of *DPF1* target genes including many long non-coding RNAs. The phenotypic role of DPF1 in MPNST was investigated using *in vitro* siRNA and CRISPR experiments, where DPF1 KO reduced proliferation and viability of MPNST cells in both 2D and 3D cell culture assays. Further, DPF1 was found contribute to anchorage independent cell growth of MPNST cells using soft agar assays. Glycerol gradient sedimentation assays demonstrated that DPF1 co-migrated with core components of a SWI/SNF complex known as canonical BAF (cBAF) and not the alternate GBAF and PBAF SWI/SNF complexes. These findings were further validated using co-immunoprecipitation assays where core the SWI/SNF ATPase, SMARCA4, pulled down DPF1, while components unique to the GBAF and PBAF complexes did not. An ATPase directed proteolysis targeting chimers (PROTAC) was used to therapeutically target cBAF in MPNST cells, reducing their growth and

viability. Combination treatment with standard of care chemotherapy synergistically increased the efficacy of this drug.
Conclusions: DPF1 was identified as a unique transcriptional regulator of MPNST cells and acts as a member of the cBAF SWI/SNF complex to play important phenotypic roles in this cancer type.

#3564
SNAI2 enhances oncogenesis in malignant peripheral nerve sheath tumors
Hilda Jafarah, Béga Murray, Jack Shern, Xiyuan Zhang. *NIH-NCI, Bethesda, MD*

Background: MPNSTs are highly aggressive soft tissue sarcomas. Recurrent genetic mutations have been linked to its tumorigenesis, including the loss of functional polycomb repressive complex 2 (PRC2). This results in an altered transcription landscape characterized by the global loss of methylation on histone H3 lysine 27 (H3K27me3) and increased super-enhancer (SE) -associated histone acetylation. We have previously identified SNAI2 as a core SE-driven transcription factor (TF) that is essential for the growth of MPNST. Although *SNAI2* is known to be critical for oncogenic processes, including epithelial-to-mesenchymal transition (EMT) and dedifferentiation, its role in maintaining MPNST survival through transcriptomic and epigenetic regulation has not been explored.
Methods: Using CRISPR mediated knockout (KO), we targeted the *SNAI2* DNA binding domain and confirmed KO via western blot, followed by *in vitro* phenotypic characterization, including 2D growth assays, anchorage-independent colony formation assays, and scratch assays. Additionally, an integrative analysis of *SNAI2* genomic distribution and the transcriptomic effect of its KO was performed using chromatin immunoprecipitation coupled with DNA sequencing (ChIPseq) and RNA sequencing (RNAseq). Finally, an inducible re-expression system was employed to examine the effects on the chromatin landscape with SNAI2 rescue.
Results: Genetic loss of *SNAI2* slowed the growth of MPNST cells by 50% in comparison to the control. *In vitro* tumorigenic assays revealed that SNAI2 KO diminished the cells' capacity in invasion but not in anchorage-independent cell growth. Analysis of the RNAseq results revealed that SNAI2 loss upregulated 790 genes and downregulated 1623 genes (log2fold change> 1, $p<0.01$), indicating a dominant transcriptional activation role. Gene Set Enrichment Analysis of these SNAI2-regulated genes revealed upregulation of hallmark Myc targets (normalized enrichment score (NES)=2.6, FDR=0.0), whilst genes involved in response to alpha interferon proteins were downregulated (NES=-1.87, FDR=0.002). Interestingly, genes defining EMT were upregulated (NES=1.6, FDR=0.006) in cells upon SNAI2 loss, contrasting its known repressive role in this biological process in other systems. Through integrative analysis of the RNAseq and ChIPseq data, we demonstrate SNAI2 binding to promoters of its regulated targets. Downstream targets of interest include CRELD1, a gene involved in cell adhesion, where SNAI2 KO caused loss of promoter binding and gene downregulation ($p<0.001$).
Conclusion: SNAI2 is an essential SE-driven TF in MPNST cells. Transcriptomic and genomic profiling of SNAI2 through loss- and gain-of-function experiments revealed that it is a critical TF that is involved in key biological processes. Future efforts will focus on designing methods to employ targeted degradation of this essential TF and test preclinical efficacy in treating MPNST.

Establishing a multimodal data warehousing platform to accelerate discoveries in pediatric brain tumors for the Children's Brain Tumor Network
Bailey K. Farrow, Nicholas Van Kuren, Nathan Young, Christopher Friedman, Meen Chul Kim, Alex Lubneuski, Jennifer Mason, Thinh (Bin) Nguyen, Zeinab Helili, Elizabeth Frenkel, Catherine Sullivan, Ariana Familiar, Yuankun Zhu, Mateusz Koptyra, Tatiana Patton, Jena Lilly, Phillip B. Storm, Adam Resnick, Allison P. Heath. *Children's Hospital of Philadelphia, Philadelphia, PA*

Brain tumors are the leading cause of disease-related death in children and young adults ages 0-19 in largely populated countries such as the United States. In one year alone, 4,000 children and young adults will be diagnosed with a brain or central nervous system tumor in the United States. Brain tumors are complex and difficult to treat in growing children, with current treatments oftentimes causing significant and lifelong side effects. Furthermore, there have only been five drugs in the last 20 years approved by the FDA to treat pediatric brain tumors. Founded in 2011, the Children's Brain Tumor Network (CBTN) is focused on accelerating the pace of translational research, the discovery of new treatments, and informing precision medicine for children diagnosed with brain tumors. CBTN comprises 32 member institutions/hospitals having over 4700 patient subjects

enrolled, spanning 30+ brain tumor diagnoses, over 66,000 biobanked samples and 150 preclinical models. Longitudinal clinical data is also collected for every subject that is enrolled in the observational protocol. Through large scale data generation efforts funded by the NCI and foundational support, CBTN has whole genome, RNA-seq and other molecular characterization for over half of the enrolled patient population. Additionally, efforts have been underway to collect all pathology and radiology imaging and reporting for the subjects. With sequencing being done by multiple vendors, imaging protocols being different across multiple hospitals, and complex clinical treatment and longitudinal follow up data being translated from EHR systems, CBTN has created a rich, but complex, data landscape that is the largest of its kind in the world. In order to accelerate the process of going from data to cures, the data needs to be centralized, organized, and easily distributable. To do this, CBTN has built a first of its kind data workflow that acts as the inventory system for its various data assets. Using a modern data stack including dbt, PostgresSQL, Meltano and AWS, combined with utilization of FHIR as an interchange standard, data from multiple disparate sources such as REDcap, EHR systems, and PAC systems flow in near “real-time” to be utilized as integrated data resources.
The result of this modern, multimodal, and multi-institutional warehouse allows CBTN to distribute data quickly and accurately to translational researchers around the world and contribute data to key research efforts such as AACR Project Genie, Kids First Data Resource Center, NCI Childhood Cancer Data Initiative, and the NCI’s Open Targets Platform.

Pediatric central nervous system (CNS) cancers are the leading disease-related cause of death in children and there is urgent need for curative therapeutic strategies for these tumors. To address the urgency, Children’s Brain Tumor Network (CBTN) has advanced an open science model to accelerate the research discovery for pediatric brain tumors. In first phase of Open Pediatric Brain Tumor Atlas (OpenPBTA) effort CBTN together with Pacific Pediatric Neuro-Oncology Consortium (PNOC) with support of Gabriella Miller Kids First Data Resource Center (KFDRC) created and comprehensively characterized over 1000 clinically annotated pediatric brain tumors.
In the second phase of the OpenPBTA effort, through resource awards and collaboration across KFDRC, the NCI Childhood Cancer Data Initiative (CCDI), NCI’s Clinical Proteomic Tumor Analysis Consortium (CPTAC), NCI Center for Cancer Research and additional partnered institutions and foundations, CBTN has expanded OpenPBTA to support high throughput molecular characterization for an additional 1900 pediatric brain tumor patients and their families. This includes the processing and characterization of over 8000 specimens across >50 brain tumor diagnoses. The cohort expansion builds on >1000 previously characterized samples with a portfolio of multimodal data including whole genome sequencing, RNA sequencing, miRNA sequencing, methylation sequencing, proteomics, lipidomics and/or metabolomics. Molecular data is linked to patient longitudinal clinical data, imaging data (MRIs and radiology reports), histology slide images, and pathology reports. To inform novel discovery and clinical implementation of genomic approaches for diagnostic/therapeutic purposes, the data is deposited the cloud-based research environment of the NCI’s CCDI and the KFDRC to provide near real-time integration, dissemination, processing, and sharing of associated petabyte-scale harmonized data. The approach leverages the DRC platform’s cloud-based computational environment in CAVATICA. Processed annotations are facilitated via CAVATICA-enabled shareable pipelines and can be explored through PedcBioPortal, a data visualization/analysis application further integrating additional public and deposited datasets. This expansion phase of OpenPBTA is released with no embargo period and provides one of the largest deeply characterized cohorts of pediatric brain

tumor samples and associated clinical data for >3000 pediatric brain tumor patients. CBTN's open-science, rapid-release model aims to advance novel biomarkers and therapeutic exploratory research, supporting new clinical trial development and accelerated discovery on behalf of changing the outcome for kids with brain tumors.

Cancer-epigenetic mouse models for medulloblastoma

Shilpa S. Dhar, Ali S. Rizvi, Lauren Reed, Calena Brown, Min Gyu Lee. *UT MD Anderson Cancer Center, Houston, TX*

Medulloblastoma (MB) is the most common childhood brain tumors (up to 20% of all childhood brain tumors) and occurs mainly in children (<15 years old. MB is located in the cerebellum in the brain and can spread to the spine or to other parts of brain. Because MB growth is very fast, MB is categorized as a type of high-grade malignant primary tumors. MB development is often associated with the dysregulation of signaling pathways, such as the wingless (WNT) and sonic hedgehog (SHH). Methylated histone H3 lysine 4 (H3K4) is a major methylation mark. Trimethyl H3K4 (H3K4me3) occupies as much as 75% of all human gene promoters. We previously reported that the H3K4 methyltransferase KMT2D (also called MLL4, MLL2, and ALR; a transcriptional coactivator, is required for neuronal differentiation of human neuron-lineage NT2/D1 stem cells. Interestingly, our analysis of several databases has shown that *Kmt2d* is the most frequently mutated epigenetic modifier (8%–10%) in medulloblastoma (MB). Recently, we showed that brain-specific knockout of *Kmt2d* alone induces spontaneous MB in mice. *Kmt2d* loss highly upregulated several oncogenic signaling programs and downregulated tumor suppressive genes. In this study, we sought to determine whether *Kmt2d* loss cooperates with another oncogenic event in MB genesis. Particularly, *PTCH* (also known as *PTCH1*) is one of the most frequently mutated genes in MB, and *KMT2D* is known to be a shared driver gene mutation in MB. For these reasons, we examined the effect of *Kmt2d* loss on of $Ptch^{+/-}$-driven MB genesis. A heterozygous loss of *Kmt2d* increased the incidence and progression of $Ptch^{+/-}$-driven MB genesis. We have shown that *Kmt2d* loss reduces epigenomic signals for super-enhancers/enhancers and broad H3K4me3 in 4-month-old cerebella. In addition, we determine the effect of heterozygous Kmt2d loss on cell proliferation by comparing the Nes-Cre $Kmt2d^{fl/+}$ $Ptch^{+/-}$ (KP) cerebella to $Ptch^{+/-}$ cerebella at 2- & 4-month-old time points using IHC staining of Ki-67 (a proliferation marker). MB's from KP mice showed two different mechanisms by activating oncogenic cellular signaling kinases (e.g., phospho [p]-AKT and p-p38) levels as well as MYCN signaling pathway. Our transcriptomic analysis revealed several tumor suppressive and transcriptional corepressor genes to be downregulated such as *Ncor2* and *Dnmt3a*. We found *Ncor2* depletion in Ptch-/+ neurospheres shows upregulation of similar oncogenic genes as in KP mice tumors. *Kmt2d* loss reduced cerebellar granule cell differentiation. Our analysis for oncogenic kinases may provide a basis for a novel MB treatment plan involving the use of cellular kinase inhibitors. As KMT2D is among the most often mutated genes in human MBs, this mouse model may be useful for future preclinical therapeutic experiments for the treatment of MB patients. KMT2D in medulloblastoma genesis using mouse models will provide epigenetic and mechanistic insights into how heterozygous KMT2D loss promotes medulloblastoma.

Developing pediatric glioblastoma microtumors with a three-dimensional bioprinter

Andee M. Beierle, Taylor L. Schanel, Hasan Alrefai, Joshua C. Anderson, Patricia H. Hicks, Lauren C. Nassour, Christopher D. Willey. *University of Alabama at Birmingham, Birmingham, AL*

Background:Glioblastoma multiforme is one of the most devastating forms of brain cancer seen in children. Children diagnosed with high-grade gliomas have poor prognosis, and there remains a need for improvement in the standard of care. In order to improve the standard of care for this condition, it is necessary to develop *in vitro* models which better recapitulate the nature of the tumors. Three-dimensional bioprinting has proven to be an effective technique in creating microtumors using adult glioblastoma cell lines but remains unexplored in pediatric glioblastoma. As such, we sought to develop a protocol which would allow for the creation of three-dimensionally bioprinted microtumors using patient-derived pediatric glioblastoma cells.
Methods:A Bio X three-dimensional bioprinter (Cellink) was utilized to create the microtumor constructs. The composition of the bioink was modified through varying concentrations of sodium alginate and gelatin, or gelatin-methacrylate (Gel-MA). The microtumor size and volume was optimized through the variation of extrusion time, nozzle pressure, and both nozzle and print bed temperature. The crosslinking technique was also optimized through the utilization of 2% calcium chloride for varying exposure times, and also a 405-nm light (for Gel-MA bioink) at varied light intensity, length of time of application to, and distance from, the printed structure.

Bioprinted pediatric XD456 brain tumor initiating cell constructs were treated with both chemotherapeutics and radiation to determine the model's capacity to respond to treatment. PamStation 12 (PamGene Inc.) Kinomic data and RNA-seq (Illumina) data were generated for the constructs. Imaging was performed using Cytation 5 imager (Agilent).
Results:Fluorescent microscopy with Calcein AM and Sytox™ Orange (ThermoFisher), along with viability assessments via CellTiter-Glo®, demonstrated expected cytotoxic effects after exposure to 10 μM Cisplatin. Additionally, PamStation 12 Kinomic and RNA-seq data indicated a difference in kinomic signaling between the bioprinted constructs as compared to the XD456 cells cultured as neurospheres.
Conclusions:The utilization of a three-dimensional bioprinter allows for the creation of microtumors using patient-derived pediatric glioblastoma cells. Future studies will investigate the microtumors' capacity as a drug screening model. The model will also be developed to further recapitulate the native tumor microenvironment of pediatric glioblastoma.

An animal model of GLI2-amplified medulloblastoma
Yanxin Pei. *Children's National, Washington, DC*

Medulloblastoma (MB) is the most common malignant brain tumor affecting children. Among the known subtypes of MB, *GLI2*-amplified SHH-MB associated with P53 mutations has the worst prognosis, and a 5-year survival rate of less than 30%. Moreover, *GLI2*-amplified MBs are non-responsive to SMO inhibitors, the only targeted treatment option available for SHH-MB. To address this treatment gap, there is an urgent need to identify novel potential therapeutic targets, an effort that requires better understanding of key cellular and molecular mechanisms underlying *GLI2*-amplified MB. To that end, we generated a mouse model of *GLI2*-amplified MB and identified *GL12* as the critical driver of tumorigenesis, and granule cell progenitors (GCPs) as the cells of tumor origin. We further found that *GLI2* specifically drives embryonic, but not neonatal, $Math1^+$ GCPs to form SHH-MB tumors. An scRNA-seq analysis revealed MAPK pathway activation specifically in embryonic $Math1^+$ GCPs. The MAPK pathway was activated in mouse and human *GLI2*-driven MB tumors, and a MEK/ERK inhibitor significantly inhibited *GLI2*-driven MB *in vivo*. Based on these findings, we hypothesize that *GLI2*-driven MB originates from a specific population of $Math1^+$ GCPs during a discrete temporal interval in cerebellar development, and that targeting MAPK/MEK/ERK pathway components represents a novel approach to treatment of *GLI2*-amplified MB.

#3570
Preservation of cellular heterogeneity in 3D and 2D cultures of pediatric solid tumors
Justina D. McEvoy, Melody Allensworth, Mariajose Franco, Natalie McDonald, Brittney Gordon, Anand Patel, Elizabeth Stewart, Michael Dyer. *St. Jude Children's Research Hospital, Memphis, TN*

Over the past 10 years, we have developed and characterized over 280 orthotopic patient derived xenografts (O-PDXs) representing 23 different types of pediatric solid tumors. The O-PDXs have undergone comprehensive characterization including genomics, transcriptomics, epigenomics, histologic review and analysis of cellular heterogeneity. All data, tissue samples and cryopreserved O-PDXs are freely available with no obligation to collaborate through the Childhood Solid Tumor Network (CSTN) at www.stjude.org/CSTN/. While these in vivo models are useful for preclinical testing of drugs and immunotherapy, researchers are limited by throughput, expense and expertise. High throughput ex vivo culture systems that more faithfully recapitulate the cellular heterogeneity and arrested differentiation in the patient tumors are urgently needed to test new drug combinations. Solid tumor cell lines have undergone extensive selection and adaptation in culture, and most have lost the cellular heterogeneity found in patient tumors. In order to overcome this barrier in the field, we have developed a 3D-to-2D workflow. Previous attempts to produce 2D ex vivo cultures from patient tumors or O-PDXs have had limited success because most cells die upon initial plating, they are difficult to cryopreserve for future studies and they lose key cell populations found in the patient tumors. Our new workflow was designed to overcome two sources of stress when adapting patient tumors or O-PDXs to culture. The first source of stress is transitioning from the in vivo environment to ex vivo in culture medium. The second source of stress is the transition from extensive 3D cell-cell contacts in vivo to a more limited cell-cell contact ex vivo. To overcome these two sources of stress, we adapted cultures to 2D in a stepwise manner. First, we dissociate O-PDX tumors into single cell suspension and then rapidly re-aggregate them in 3D spheres for ex vivo culture. After the spheres have grown for 7 days, they are transitioned to 2D by seeding cells in culture dishes coated with extracellular matrix components. Importantly, the

3D and 2D cultures preserve the cellular heterogeneity of the O-PDX and patient tumor and they can be cryopreserved. When injected back into immunocompromised mice, they recapitulate the molecular and cellular features of the original tumors. We have shown that the 3D and 2D cultures can be genetically manipulated using lentiviral vectors and can be used for high-throughput drug screening. Matched 3D and 2D cryovials are now available to the international biomedical research community for rhabdomyosarcoma through the CSTN. Neuroblastoma, osteosarcoma, Ewing sarcoma and retinoblastoma are expected to be available in late 2023. We anticipate this will accelerate the testing of oncology drugs for pediatric solid tumors in response to the RACE act through the PIVOT program.

Cancer represents a leading cause of death by disease in childhood. Pediatric tumors exhibit a high intertumoral heterogeneity, as different tumor types and subtypes have emerged with peculiar molecular and clinical features; however, compared to cancer in adults, pediatric tumors are rare and mostly present with lower mutational burden. The lack of specific therapeutic options represents the main current challenge; systematic, multi-disciplinary approaches are required to accelerate drug development and ultimately to find cures for all children with cancer. The EU funded "Innovative Therapies for Children with Cancer--Pediatric Preclinical Proof-of-Concept Project"

(ITCC-P4; www.itccp4.eu) consortium consists of a public-private partnership including academic and industrial partners with the goal of developing a large-scale platform comprising >400 patient-derived xenograft (PDX) models representing high-risk pediatric cancers. Currently, this collection of PDX models includes the most common types of pediatric tumors, such as leukemia (n=28), bone and soft-tissue sarcomas (n=154), CNS tumors (n=96) and neuroblastomas (n=38), as well as other rare childhood cancers, such as hepatoblastomas (n=20) and malignant rhabdoid tumors (n=18); PDX models have been generated either from primary (n=206) or relapse (n=118) disease. In order to: a) investigate the biology of the pediatric PDX models in a high-throughput and systematic fashion, b) assess whether they accurately reflect the molecular features of the corresponding primary tumor and, c) identify potential new suitable biomarkers, we performed a comprehensive molecular characterization (whole-exome and low-coverage whole-genome sequencing; DNA methylation profiling; RNAseq and gene expression profiling) of the PDX models, as well as their matching human tumors and germline samples. These data contributed to the stratification of the PDX models based on their mutational status and emerging molecular vulnerabilities to inform *in vivo* drug testing in all these PDX models. This proof-of-concept drug testing has been conducted defining, for each group of models, a panel of single compounds (SOC n=3; novel targeted therapies, n=6) or combinations (with each other or with chemo- or radiotherapy). All processed molecular and drug-testing data are collected in the consortium´s centralized data repository (https://r2.amc.nl) allowing data downstream analysis, visualization and interpretation. Taken together, the ITCC-P4 sustainable platform represents a validated and powerful tool to investigate the biology of pediatric cancer based on the establishment, characterization and preclinical testing of pediatric cancer PDX models, ultimately envisaged to contribute the development of innovative therapeutic options for childhood cancer patients.

Genomic profiling of subcutaneous patient derived xenograft models of solid childhood cancer

Funan He[1], Abhik M. Bandyopadhyay[1], Laura Klesse[2], Anna Rogojina[1], Erin Butler[2], Taylor Hartshorne[2], Trevor Holland[1], Luz Perez Prado[1], Anne-Marie Langevan[3], Allison C. Grimes[3], Chatchawin Assanasen[3], Zhao Lai[1], Yi Zou[1], Dias Kurmashev[1], Lin Xu[4], Yang Xie[4], Yidong Chen[1], Xiaojing Wang[1], Gail E. Tomlinson[1], Stephen X. Skapek[2], Raushan T. Kurmasheva[1], Peter J. Houghton[1], Siyuan Zheng[1]. *[1]Greehey Children's Cancer Research Institute, University of Texas Health Science Center, San Antonio, TX,[2]Department of Pediatrics, Division of Hematology/Oncology, University of Texas Southwestern Medical Center, Dallas, TX,[3]Department of Pediatrics, Division of Pediatric Hematology Oncology, University of Texas Health Science Center, San Antonio, TX,[4]Harold C. Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Cancer causes significant mortality and morbidity in children. Current therapies are effective but can cause long-term health problems for patients. Development of new therapies relies on faithful preclinical models. Patient-derived xenografts (PDXs) are an important tool for pre-clinical testing in childhood cancer research. It remains incompletely understood how well genomically PDXs recapitulate primary patient tumors (PTs), particularly in rare cancers.
Method: To characterize the fidelity of early passage subcutaneous PDXs derived from pediatric solid tumors, we established 70 early passage PDX models from 16 cancer types. The cohort comprises some very rare cancers such as hepatoblastoma (n=13), germ cell tumor (n=10), osteosarcoma (n=13), and Wilms tumor (n=14). We performed low pass whole genome, exome, and RNA sequencing on these PDXs, their matched PTs and germline samples when materials were available.
Result: Overall, we observed low somatic mutation rates in these tumors; however, prior chemotherapy was associated with higher mutation rate. Of the 25 PT/PDX pairs, 20 showed high mutation similarity. The five pairs with low mutation similarity showed evidence of clonal selection. We observed high genomic instability in osteosarcoma. Consistently, more fusions were identified in this cancer type. PTs and PDXs showed high similarity in the copy number pattern, including both broad and focal events. GISTIC analysis identified recurrently amplified or deleted genes including *MYC*, *CCNE1*, *TP53*, *PTEN*, and *BCL2*. On the transcriptional level, though PTs and PDXs were generally similar, their expression is more reflective of tissue of origin. We identified fusions that are characteristic of the cancer type such as *BCOR-CCND3* in an Ewing like sarcoma. We also identified an NTRK fusion in an osteosarcoma. In summary, we show that PDXs generally recapitulate PTs in mutations, copy number changes, and expression. The dataset represents a valuable resource for future preclinical and mechanistic studies.

PET, MRI, and CT Imaging

Molecular imaging of CD8 infiltration following combination immunotherapy in preclinical glioblastoma

Carlos A. Gallegos[1], Yun Lu[2], Alessandro Mascioni[3], Fang Jia[3], Jennifer C. Clements[4], Patrick N. Song[2], Shannon E. Lynch[2], Jason M. Warram[5], James M. Markert[4], Anna Sorace[1]. *[1]Biomedical Engineering, University of Alabama at Birmingham, Birmingham, AL,[2]Biomedical Sciences, University of Alabama at Birmingham, Birmingham, AL,[3]Imaginab Inc, Inglewood, CA,[4]Neurosurgery, University of Alabama at Birmingham, Birmingham, AL,[5]Otolaryngology, University of Alabama at Birmingham, Birmingham, AL*

Background: Novel immune-promoting therapeutics for glioblastoma multiforme (GBM), such as oncolytic herpes simplex viruses (oHSV) and immune checkpoint inhibitors (ICI), have the potential to improve overall survival and lead to long-term remission, however their clinical benefit remains inconsistent. Under standard of care imaging, assessment of immunotherapeutic response can be limited by apparent radiological tumor progression associated with treatment-induced inflammation and immune infiltration. This has led to a need for better understanding of immune cell dynamics and immunotherapy response in GBM. The objective of this study is to evaluate changes in $CD8^+$ infiltration and its relation to therapy response, through positron emission tomography (PET) imaging, in preclinical GBM.

Methods: GSC005-luc orthotopic GBM models (n= 40) were treated with saline, M002 oHSV, anti-PD1 or combination immunotherapy following three weeks of tumor growth. One-week post-treatment, [^{89}Zr]-CD8 PET imaging was performed and biologically validated through *ex vivo* PET, autoradiography and staining for H&E and CD8 immunohistochemistry (IHC). Further, longitudinal changes in CD8 infiltration were evaluated via [^{89}Zr]-CD8 PET imaging one- and three-weeks post-immunotherapy with responses monitored every three days via bioluminescence imaging (BLI). Statistical analysis involved one-way ANOVA and unpaired T-test, with $p<0.05$ considered significant.

Results: Linear correlations were seen between *in vivo* PET signal and *ex vivo* uptake ($r=0.61$, $p<0.01$), autoradiography ($r=0.46$, $p<0.01$), and IHC tumor $CD8^+$ cell density ($r=0.55$, $p<0.01$) one-week post-treatment. Immunotherapy efficacy, defined by decreased BLI signal, resembled clinical findings as only a subset of mice exhibited long-term positive response measured by BLI signal decrease (n=9/24). Response classification revealed increased $CD8^+$ cell tumor localization, as measured by peak standardized uptake value (SUV_{peak}) tumor to background ratio (TBR), in non-responders ($p<0.01$) and decreased heterogeneity in signal distribution in responders ($p<0.05$) relative to controls early in the course of therapy.

Conclusions: Early CD8 infiltration and uptake distribution from CD8-PET imaging provides potential imaging metrics of therapeutic response to oHSV immunotherapy in GBM. Development of these immune-focused imaging approaches for the assessment of positive immunotherapeutic effects in GBM is beneficial for the better understanding of immune cell dynamics and their relation to clinical outcomes.

A first assessment of CD8-PET/CT with ^{89}Zr-Crefmirlimab as predictive biomarker for response to standard of care immunotherapy in patients with solid tumors

guillaume potdevin[1], Isabelle Ayx[1], Laura Dillon[2], Emilie Mahieu[1], Hadassah Sade[1], Günter Schmidt[1]. *[1]Computational Pathology Munich / Translation Medicine, AstraZeneca Oncology, Munich, Germany,[2]Parthenon Therapeutics, Boston, MA*

Background: Elevated levels of CD8+ tumor-infiltrating lymphocytes are associated with response to immunotherapy (IoT)[1] in many indications. While immunohistochemistry (IHC) has been the method of choice to evaluate CD8+ tumor infiltration level, the utility of the CD8-PET/CT imaging method offers an attractive non-invasive alternative to biopsies, with the potential to account for both intra-patient tumor heterogeneity and lesion-specific response.

Methods: Using the data from ImaginAb's phase II trial[2], we predict response to standard of care (SOC) IoT in patients with advanced solid malignancies. Solely based on CD8-PET/CT scan data, the novel method scores each identifiable lesion by using its volume as measured in the CT data, and mean CD8-PET uptake values before and 4 to 6 weeks after treatment start. All lesion scores are aggregated to compute the patient score, to be subsequently compared to the best standard RECIST evaluation. This methodology was defined and developed using data from 14 patients, and later evaluated using the whole cohort of 40 patients.

Results: Despite the multiplicity of indications and SOC IoT in the patient cohort, the computed scores significantly identify and stratify responders (Complete or Partial Response, mean score = -0.78, 10 subjects) from non-responders (Stable or Progressive Disease, mean score = 0.088, 25 subjects): two sample t-test value = 5.378, p-value = 1e-05. RECIST evaluations remain too preliminary to report for 4 subjects. Furthermore, CD8-PET outcomes are available much earlier (median 35 days, median best of RECIST 105 days), which may facilitate important therapy decisions. In addition, the discriminative power between the response groups is reduced when restricting the method to either of the infiltration or lesion size measurements. This result highlights the complementarity of the two measurements.
Conclusions: CD8-PET offers new non-invasive opportunities in the early discrimination of responders and non-responders to IoT as well as visualization of the heterogeneity of tumor responses to IoT, supporting its use pre-IoT and early on IoT for adult solid tumors.
Acknowledgement: All the data used in this study come from clinical study [2]. These data were acquired and discussed within the frame of a pre-competitive collaboration between AstraZeneca, Takeda, Pfizer and imaginAb. We want to thank the respective parties for fruitful discussions which helped us refine our analysis methodology.

Using a novel [^{68}Ga]-radiolabeled peptide to detect cell surface expression of calreticulin in pancreatic adenocarcinoma

Rachael Guenter[1], Maxwell Ducharme[2], Brendon Herring[1], Tejeshwar C. Rao[3], Odalyz Montes[2], Tyler McCaw[1], Herbert Chen[1], Suzanne E. Lapi[2], Benjamin Larimer[2], J. Bart Rose[1]. *[1]Surgery, University of Alabama at Birmingham, Birmingham, AL,[2]Radiology, University of Alabama at Birmingham, Birmingham, AL,[3]Cell, Developmental and Integrative Biology, University of Alabama at Birmingham, Birmingham, AL*

Background**:** Pancreatic ductal adenocarcinoma (PDAC) is the 3rd leading cause of cancer related death with a 5-year survival rate at 11%. New systemic therapies for patients with PDAC are desperately needed. Upregulation or exposure of a new protein on the tumor cell surface can serve as a therapeutic or diagnostic target. Here, we highlight our recently developed strategy to induce localization of the reticular protein calreticulin (CALR) to the cell surface in PDAC cells and its subsequent detection using a novel radiolabeled peptide.
Methods: Surface translocation of CALR was detected by flow cytometry, western blot, and total internal reflection fluorescence (TIRF) microscopy in PDAC cells treated with either doxorubicin or gemcitabine. The radionuclide-binding chelator 'DOTA' was covalently linked to a CALR-specific peptide 'KLGFFKR' and then labeled with ^{68}Ga. Samples were analyzed on HPLC with an average radiolabeling efficiency of 93%. Mice bearing Panc02 allografts were treated with doxorubicin for 24h, injected with ~3 MBq (5 μg) of radiopeptide, and sacrificed after 1 hour to determine biodistribution.
Results: Using flow cytometry, we found that treating PDAC cells with doxorubicin or gemcitabine increased both the total number and the median fluorescence intensity of surface staining for live cells expressing CALR. When membrane proteins were isolated from PDAC cells treated with doxorubicin at various time points, a peak in surface CALR protein was detected at 30 minutes with persistent expression lasting for 24 hours. TIRF microscopy showed that Panc02 cells treated with doxorubicin had approximately a 2-fold higher surface CALR expression as detected by enhanced membrane fluorescence compared to controls. *In vivo*, our novel [^{68}Ga]-CALR peptide showed rapid clearance through the kidneys with no significant uptake in vital organs (n=4). In Panc02 allograft-bearing mice treated intratumorally with either vehicle or doxorubicin, biodistribution analysis after radiopeptide injection showed a significant increase in radiopeptide uptake in the treated tumors (n=6, $p < 0.05$).
Conclusions: CALR is translocated to the cell surface in PDAC cells, where it can subsequently be targeted by a novel radiopeptide agent. Future studies are needed to determine if induced CALR can be targeted for therapeutic effect.

Assessment of target-mediated biodistribution of an ^{89}Zr labeled PD-L1/4-1BB bispecific Mabcalin protein

Claudia A. J. van Winkel[1], Xiaoyu Fan[2], Danique Giesen[2], Glenn Gauderat[3], Lucia Pattarini[4], Thomas Jaquin[5], Anissa Barakat[3], Anne-Marie De La Bigne[3], Marleen Richter[5], Nicole Andersen[5], Julie Legrand[3], Helene Lelièvre[3], Elisabeth G. E. de Vries[1], Aizea Morales-Kastresana[5], Marjolijn N. Lub-de Hooge[6]. *[1]Medical Oncology, University Medical Center Groningen, Groningen, Netherlands,[2]Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, Groningen, Netherlands,[3]Institut de Recherches Internationales Servier Oncology R&D Unit, Suresnes, France,[4]Center for Therapeutic Innovation Oncology, Institut de Recherches Servier, Croissy-sur-Seine, France,[5]Pieris Pharmaceuticals, Hallbergmoos, Germany,[6]Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands*

Background: PRS-344/S095012 is a novel 4-1BB (CD137) and programmed death-ligand 1 (PD-L1) bispecific antibody-Anticalin® fusion protein (Mabcalin™ protein) designed to cluster 4-1BB on activated T cells exclusively in the presence of PD-L1 expressing cells. We aimed to study PRS-344/S095012 in vivo biodistribution and pharmacokinetics with ^{89}Zr-positron emission tomography (PET) at a dose with antitumoral activity in mice and evaluate the contribution of each targeting arm.
Methods: PRS-344/S095012 lacks cross-reactivity to murine 4-1BB and PD-L1. To explore the PRS-344/S095012 biodistribution in a humanized 4-1BB knock-in mouse model, we synthesized the surrogate ^{89}Zr-Atezo-J10 with the same 4-1BB building block and cross-reactivity to murine PD-L1. Humanized 4-1BB knock-in C57BL/6J (h4-1BB KI B6) and C57BL/6J (B6) mice (n=4-6 per group) were subcutaneously engrafted with murine wildtype MC38 colon adenocarcinoma cells. Tumors were grown to a minimum of ≥50 mm^3 (average 163 mm^3) before tracer injection. Mice received intravenously 30 µg (2.5 MBq) of ^{89}Zr-PRS-344/S095012 or ^{89}Zr-Atezo-J10 supplemented with PRS-344/S095012 or Atezo-J10 up to 10 mg/kg. Four mice groups were formed to distinguish between bispecific (Atezo-J10 in h4-1BB KI B6), monospecific PD-L1 (Atezo-J10 in B6), monospecific 4-1BB (PRS-344/S095012 in h4-1BB KI B6), and isotype (PRS-344/S095012 in B6) binding up to 4 days post-injection (pi). In addition, a fifth group (5 MBq ^{89}Zr-Atezo-J10) was studied to visualize the bispecific biodistribution up to 7 days pi. At days 1, 2, 4, or 2, 4, 7 pi, mice underwent serial PET imaging to obtain mean and maximum standardized uptake (SUVmean/max) and retro-orbital blood sampling, followed by ex vivo biodistribution.
Results: PET imaging showed ^{89}Zr-Atezo-J10 specific tumor accumulation with higher tumor-to-blood ratios of respectively 2.2-, 2.6-, and 2.4-fold ($p<0.01$) at 4 days pi compared to monospecific binding of PD-L1, 4-1BB, and isotype. The ex vivo biodistribution demonstrated the same trend with respectively 4.2-, 5.5-, and 6.8-fold ($p<0.01$) increase in tumor-to-blood uptake for ^{89}Zr-Atezo-J10 versus monospecific binding of PD-L1, 4-1BB, and isotype. ^{89}Zr-Atezo-J10 spleen uptake was comparable (ns) with monospecific binding of PD-L1 but elevated ($p<0.01$) compared to 4-1BB or isotype distribution. The uptake in lymph nodes (axillary, cervical, tumor-draining, and mesenteric) did not differ between the groups.
Conclusion: ^{89}Zr-Atezo-J10 specific accumulation in PD-L1 expressing tumors is due to both PD-L1 and 4-1BB binding and is higher than with PD-L1 and 4-1BB mono-targeting. This preclinical study supports the clinical evaluation of ^{89}Zr-PRS-344/S095012's whole-body distribution and the development of tumor-specific 4-1BB targeting bispecifics.

Noninvasive immuno-PET imaging of CD8+T cell behavior in tumor bearing mice models treated with SAR444245

Sebastion d'Heilly[1], Fabrice Tirode[1], Maxime Gaulin[1], Dudzicki Anne[1], Guillaume Bluet[1], Stéphane Guerif[1], Francis Descamps[2], Peter Casteels[2], Xiangming Li[3], Rui Wang[3], Robin Meng[3], Erwan Jouannot[1]. *[1]Sanofi, Vitry-sur-Seine, France,[2]Sanofi, Ghent, Belgium,[3]Sanofi, Cambridge, MA*

SAR444245 (formerly THOR-707) is a site-specific pegylated recombinant human IL-2 molecule which blocks IL-2R alpha-binding while retains near-native affinity for beta/gamma IL-2 receptor subunits. SAR444245 reduces B16-F10 tumor proliferation in C57BL/6 mice and induces a short transient migration of CD8+ T and NK cells from peripheral blood to lymphoid organs before a strong proliferation (Ptacin et al, Nat Commun 2021). Here we report CD8+ T cells imaging post SAR444245 as monotherapy in naive and tumor bearing mice using nuclear imaging. An anti-murine CD8+ PET probe was injected in mice 24 hours post SAR444245 administration and nuclear imaging was performed at different times over 6 days. In C57BL/6 naive and in poorly immunogenic B16-F10 tumor bearing animals, images reveal a decreased Standardized Uptake Value (SUV) within blood in treated animals at 3mg/kg compared to control ones. In parallel, blood SUV Ratio (SUVR) increases within spleen, lymph

nodes and thymus after SAR444245 injection compared to control mice. On tumor site, a stronger SUVR is measured at 144 hours post injection in SAR444245 treated group than in the control group. A dose escalation ranging from 1 to 6 mg/kg of SAR444245 was performed in highly immunogenic CT26 tumor bearing animal. Blood SUV decreases in the treated groups compared to the control group. In lymphoid organs, all SUVR increase at 144 hours post injection in the treated groups compared to the control one. In CT26 tumors, a slight increase of the SUVR is observed for groups treated at 3 and 6 mg/kg. In parallel, a pronounced reduction of tumor growth is observed in the treated group at 6mg/kg. These studies non-invasively confirm the mode of action of SAR444245 with a rapid relocation of CD8+ T cells from peripheral blood to lymphoid organs and tumor site.

Differentiation of niraparib and olaparib brain penetration in healthy rhesus macaque monkeys

Mark Reid Groseclose[1], Jeremy Barry[1], Yongle Pang[1], Jennifer Deutsch[1], Shannon Berry[1], Elaina McCormick[1], David K. Lim[1], Hoang Tran[1], Sean Maguire[1], Hasan Alsaid[1], Amine Aziez[2], Elaine Paul[3], Keyur Gada[4]. *[1]GSK, Collegeville, PA,[2]GSK, Basel, Switzerland,[3]GSK, Raleigh, NC,[4]GSK, Waltham, MA*

Purpose: There remains an unmet need to provide effective treatment therapy for patients with primary and metastatic brain tumors; lack of drug penetration across the blood brain barrier (BBB) is a key factor. Synthetic lethality is an attractive mechanism in treating brain tumors post radiotherapy. Here we investigate the brain penetration of niraparib and olaparib in healthy monkeys to understand the potential of each to cross the intact BBB.

Experimental Procedures: Four healthy male Rhesus macaque monkeys were dosed daily via oral gavage for five days with either niraparib (n=2; 6 mg/kg) or olaparib (n=2; 10 mg/kg). Pre-dose blood was collected daily and terminal blood, cerebrospinal fluid (CSF), and brain tissue was collected at necropsy. Coronal brain sections were analyzed by matrix-assisted laser desorption/ionization (MALDI) imaging mass spectrometry (IMS) to quantitatively assess the tissue distribution of the dosed compounds. Blood, CSF, and bulk homogenate of brain tissue were analyzed by LC-MS bioanalysis.

Summary of Data: Greater brain penetration was observed for niraparib when compared to olaparib in healthy Rhesus macaque monkeys following five days oral administration. The unbound brain-to-plasma partition coefficient ($K_{p,uu,brain}$) was 15x higher for niraparib compared to olaparib. Quantitative MALDI IMS of coronal brain sections from monkeys administered niraparib showed consistent concentrations distributed throughout the brain parenchyma. Olaparib was not detected by MALDI IMS in any of the coronal brain sections collected from the monkeys administered olaparib. Similar plasma and CSF concentrations were observed between the monkey's administered niraparib vs olaparib, highlighting the unique ability of niraparib to cross the intact BBB of monkeys and distribute throughout the brain.

Conclusions: Niraparib showed markedly higher brain penetration than olaparib in healthy Rhesus macaque monkeys demonstrating enhanced ability to cross intact BBB.

Differentiation of niraparib and olaparib brain penetration in a mouse brain metastatic tumor model

Mark Reid Groseclose[1], Jeremy Barry[1], Tinamarie Skedzielewski[1], Gerald McDermott[1], Chakravarthi Balabhadrapatruni[1], Bill Benson[1], Yongle Pang[1], David K. Lim[1], Hoang Tran[1], Mike Ringenberg[1], Keyur Gada[2], Amine Aziez[3], Elaine Paul[4], Hasan Alsaid[1]. *[1]GSK, Collegeville, PA,[2]GSK, Waltham, MA,[3]GSK, Basel, Switzerland,[4]GSK, Raleigh, NC*

Purpose: There remains an unmet need to provide effective treatment therapy for patients with primary and metastatic brain tumors; lack of drug penetration across the blood brain barrier (BBB) is a key factor. Synthetic lethality remains an attractive mechanism in treating brain tumors post radiotherapy. Here, we evaluated brain penetration and distribution of niraparib and olaparib in a mouse brain tumor model.

Experimental: Female mice (CrTac:NCr-Foxn1nu; 6 w/o) received 2.5E5 luciferase transfected human breast cancer line (MDA 231-BRM2-831) via intracardiac injection. Mice were imaged twice/week using bioluminescence imaging (BLI) to monitor tumor growth. On day 35, mice with brain metastases (BM) were treated via oral gavage once daily for 5 days with either niraparib (35 mg/kg, n=4 BM, n=3 control), olaparib (50 mg/kg, n=3 BM, n=3 control), or vehicle (n=3 control). Terminal blood samples and brains were collected 2 hr post final dose. Serial tissue sections were collected for MALDI-IMS, H&E and IHC staining from 5 distinct horizontal planes in the brain. Tissue collected between each imaging plane was homogenized for LC-MS bioanalysis.

Summary of Data: In vivo BLI imaging was used to identify mice with BM and tumor presence was confirmed ex vivo using IHC. Quantitative MALDI IMS of coronal brain sections collected from mice administered niraparib showed consistent concentrations distributed throughout the brain parenchyma with locally higher concentrations detected from tumor regions. Table 1 summarizes the LC-MS bioanalysis concentrations in plasma and bulk brain homogenates and brain section concentrations detected by MALDI IMS. The estimated mean unbound brain-to-plasma partition coefficient ($K_{p,uu,brain}$) was 3.0x and 5.6x higher for niraparib compared to olaparib in control and BM mice, respectively.

Conclusions: Herein, we demonstrated that niraparib has a higher brain penetration and distribution compared to olaparib in both control mice and mice with BM.

Novel MRI contrast system using halloysite nanotubes embedded with iron-platinum nanoparticles for the regulation of the CHST11 expression for cancer treatment

Ming-Hsien Chan[1], Chien-Hsiu Li[1], Yu-Chan Chang[2], Michael Hsiao[1]. *[1]Academia Sinica - Genomics Research Center, Taipei, Taiwan,[2]Department of Biomedical Imaging and Radiological Sciences, National Yang MingChiao Tung University, Taipei, Taiwan*

Topic: TB Tumor Biology (TB03) *In Vivo* Imaging.
Multifunctional nanocomposites have been a popular research target in recent years. This research aims to produce magnetic nanocomposites with high saturation magnetization (Ms) and good biocompatibility to improve the disadvantage of iron-oxide was easy decomposition in the biological environment and overcome the unclear contrast problem of T2-weighted magnetic resonance imaging (MRI) of lung adenocarcinoma. In order to fit the suitable size of iron-based nanoparticles embedded into the halloysite nanotubes (HNT), the iron-platinum (FePt) nanoparticles were chosen as the MRI's core materials. The FePt@HNT nanocomposites have low toxicity, and superparamagnetism is expected to be used in biomedical therapy and magnetic separation for disease treatment and environmental protection. Lung adenocarcinoma cancer cells grow *in situ,* usually invade, and are frequently recurrent after treatment. Since CHST11-mediated gene regulation may serve as a possible means of reducing tyrosine kinase inhibitor (TKI)-induced mitotic cell death, CHST11 modulation of integrin signaling may help lung cancer cells enhance their resistance to gefitinib. To enable the FePt@HNT nanocomposite to be effective in treating lung tumors, we designed miRNAs that inhibit CHST11 expression in an attempt to diagnose lung adenocarcinoma concurrently for treatment.
Keywords: Magnetic resonance imaging, halloysite nanotubes, FePt nanoparticles, CHST11, Lung adenocarcinoma

Early and non-invasive detection of radiation-induced cardiotoxicity in pre-clinical and clinical models
Taylor-Jade Higgins, Jayesh Sharma, Elizabeth R. Zhang-Velten, Sarah Elliott, Junjie Ma, Jun Chen, Gabriele Schiattarella, Chantal Vidal, Nan Jiang, Daniel Daou, Joseph Hill, Thomas Gillette, Craig Malloy, Vlad Zaha, Jae Mo Park, Prasanna Alluri. *UT Southwestern Medical Center, Dallas, TX*

Background**:** Nearly half of all patients receive radiation therapy as a component of their cancer care. Despite the efficacy of radiation therapy as a cancer treatment, cardiotoxicity is a major concern in patients receiving chest radiotherapy. There are currently no standardized approaches for early detection of radiation-induced cardiotoxicity as a stage that offers potential for early intervention. In this study, we employ hyperpolarized ^{13}C-pyruvate magnetic resonance spectroscopy to non-invasively characterize early metabolic changes in the heart in response to radiation.
Methods: We established a pre-clinical model of radiation induced heart disease (RIHD) by performing whole heart irradiation (8Gy x 5) in rats. Echocardiography was used characterize mechanical changes in the heart following radiation. To non-invasively detect myocardial mitochondrial dysfunction following cardiac irradiation *in vivo*, we employed hyperpolarized ^{13}C- pyruvate magnetic resonance spectroscopy (MRS) to track the fate of pyruvate, an intermediate of glucose metabolism, as it is metabolized in the heart. Hyperpolarized ^{13}C- pyruvate MRS was also employed in a patient who received thoracic radiation for treatment of thymoma to non-invasively study changes in glucose metabolism in response to radiation.
Results: We identified evidence of early cardiac mitochondrial dysfunction prior to onset of mechanical changes in the heart. Following cardiac irradiation, due to mitochondrial dysfunction, pyruvate was preferentially metabolized to lactate in the cytoplasm (as opposed to bicarbonate in the mitochondria in non-irradiated hearts). The ratio of products of ^{13}C- pyruvate metabolism in the mitochondria and cytoplasm as ascertained by hyperpolarized ^{13}C- pyruvate MRS served as a biomarker for metabolic dysfunction in the heart both in a pre-clinical rat model and in a patient who received thoracic radiation.
Conclusions: We have developed a non-invasive approach for detection of cardiac mitochondrial dysfunction, which may serve as a biomarker for early detection of radiation-induced cardiotoxicity, and shown feasibility in a human patient. Clinical adoption of this approach may enable early identification of patients who are at high risk for future cardiac complications and may benefit from mitigation strategies.

Probing the relationship between renal carcinoma perfusion, hypoxia, and metabolism during response to VEGFR inhibition and at resistance

Qianhui Dou, Patricia Coutinho de Souza, Xiaoen Wang, Aaron K. Grant, Leo L. Tsai. *Radiology, Beth Israel Deaconess Medical Center, Boston, MA*

Clear cell renal cell carcinoma (ccRCC) is the most common primary kidney cancer. VEGF-receptor tyrosine kinase inhibitors remain a second-line or concurrent (with immunotherapy) treatment option for advanced RCC, but resistance inevitably occurs. There remains a need for biomarkers predictive of response to VEGFR targeting. Anti-VEGFR therapy-induced hypoxia can result in changes to both tumor metabolism and vascularization that contribute to the aggressiveness of treatment-resistant tumors. In this study we used *in vivo* hyperpolarized ^{13}C-tert-butanol, a freely-diffusible novel MRI tracer that provides high-SNR tissue perfusion mapping, and hyperpolarized ^{13}C pyruvate MRI, which enables real-time investigation of glycolytic lactate production, to understand the evolution of RCC perfusion and metabolism in response to VEGFR targeting, while correlating to histologic measures of tumor proliferation (Ki67) and vascularization (CD34). A498, a human ccRCC cell line, was implanted subcutaneously into 12-week-old nude mice. When tumors reached 15mm, the mice were placed into three arms, untreated (UT), sunitinib sensitive (SS), and sunitinib resistant (SR). SS mice were treated with sunitinib (25 mg/kg via gavage) then the mice were imaged with MRI at 48 hours. SR mice were treated with sunitinib daily until 2mm of re-growth was detected, then MRI was performed. UT mice were imaged when tumors reached 20mm. Pimonidazole infusion immediately after MRI, then the tumors were harvested. Histology included Ki67, CD34, and pimonidazole (hypoxia) staining. Ki67 expression was greater in the UT group compared to SS (37.56±5.21 vs 26.23±3.78, p=0.004), but not compared to SR (37.56±5.21 vs 34.32±1.12, p=0.93). The UT group demonstrated greater vascularization with CD-34 vessel counting than SS (UT 6.70±1.81 vs. SS 2.39±1.16, p=0.002), while vascularization was increased in SR compared to SS (SR 3.82±1.81 vs SS 2.39±1.16, p=0.05). Ki67 expression was positively correlated with CD34 expression. MR-measured tumor perfusion of the SS group was greater than UT (0.0086±0.0056 vs 0.0035±0.0026, p=0.0001) and SR (0.0086±0.0056 vs 0.0043±0.0033, p=0.0003). Tumor lactate production in the SS group was lower than UT (0.752±0.268 vs 0.609±0.188, p=0.04) and SR (0.752±0.268 vs 0.593±0.246, p=0.006). However, tumor perfusion was negatively correlated with lactate production ratio only in the SR group. Untreated and sunitinib-resistent RCC tumors are associated with increased perfusion and vascularity, and decreased lactate production. An inverse relationship between lactate production and perfusion in SR may be attributable to vascular normalization. Analysis of the spatial relationship between tumor metabolism and perfusion will further yield additional detail on the interplay between hypoxia and metabolism.

In vivo targeted detection and imaging of ovarian cancer by SPMR and MRI using anti-folate receptor functionalized iron oxide nanoparticles

Marie Zhang, Kathirvel Kandasamy, Yamitha Perera, Dan Inglese, Eric Smith-Nguyen. *Imagion Biosystems, Inc., San Diego, CA*

Ovarian cancer is the second most common and most deadly gynecological cancer in women. Early and accurate detection is crucial in improving survival rate and quality of life of patients. Folate receptor alpha (FRα) is a folate transporter that has been reported to be overexpressed in approximately 90% of ovarian cancer, which makes it a suitable molecular target to use in developing tumor imaging methods. Iron oxide nanoparticles (NPs) have been used in a variety of cancer detection/imaging applications. Here we show that anti-FRα targeted superparamagnetic iron oxide nanoparticles (SPION) can be used for *in vivo* detection by two different imaging methods. Superparamagnetic Relaxometry (SPMR) is a highly sensitive *in vivo* detection technology that is able to differentiate the magnetic signature of nanoparticles bound to tumor cells from unbound nanoparticles. Same targeted SPIONs accumulated in tumor are able to provide molecular magnetic resonance imaging (MRI) contrast as well. Our results have shown that the anti-FRα NPs can distinguish high and low FRα expression cell lines, such as KB and A549, respectively in an *in vitro* cell based assay by SPMR, demonstrating good sensitivity, specificity and selectivity. *In vivo* study using xenograph model with KB and A549 cells implanted subcutaneously on the flank region of female athymic nude mice demonstrated higher level tumor accumulation of anti-FRα NPs in KB tumor compared to A549 tumor, measurable by *ex vivo* tumor detection using SPMR. Using a PEG NPs (without the target ligand) as control for the mice study have shown that minimum nanoparticle tumor accumulated were observed, demonstrating the specificity of the nanoparticles *in vivo*. Organ distribution study indicated that anti-FRα NPs mostly accumulated in liver and spleen as these nanoparticles were cleared through these two organs.

Other organs such as brain, heart, lung, kidney didn't show appreciable accumulation. The repeat of same type of xenograph mice model used in the SPMR study is currently under the way using MRI as an alternative *in vivo* detection method with images taken pre- and post- dosing of the nanoparticles. Based on the specificity and sufficient accumulation of nanoparticles demonstrated in the SPMR study, it is expected that MRI will show similar performance with additional anatomical information.Our anti-FRα NPs provided targeted and specific delivery to cancerous tissue and generated measurable signal by SPMR. Furthermore, demonstration of these anti-FRα NPs generating tumor specific contrast in MRI is currently under the way. These studies lay the groundwork for use of bio-safe magnetic particles as a detection and contrast agent for early ovarian cancer detection with improved accuracy to minimize the needs of invasive biopsies/surgery as well as potential utility for monitoring therapy response or recurrence.

High resolution microCT to analyze the 3D morphology of microcalcifications in benign breast disease and breast cancer biopsy tissues

Sarah E. Schrup[1], Thomas de Bel[2], Tanya Hoskin[3], Teresa Allers[4], Stacey Winham[3], Derek Radisky[5], Laura Pacheco-Spann[6], Lisa Seymour[4], Amy Degnim[4], Mark Sherman[6]. *[1]Mayo Clinic Alix School of Medicine, Rochester, MN,[2]Radboud University Medical Center, Nijemegen, Netherlands,[3]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[4]Department of Surgery, Mayo Clinic, Rochester, MN,[5]Department of Cancer Biology, Mayo Clinic, Jacksonville, FL,[6]Department of Quantitative Health Sciences, Mayo Clinic, Jacksonville, FL*

Introduction**:** We used micro-computed tomography (microCT), a high-resolution imaging option, to detect and characterize microcalcifications (MCs) in three dimensions within pathology blocks of benign and malignant breast tissues.

Methods: A set of 44 formalin-fixed, paraffin-embedded breast tissue blocks were assessed from n=22 women at two time points: benign breast biopsy and subsequent DCIS or DCIS with invasive disease breast cancer. Blocks were scanned using the Bruker Skyscan 1276 microCT at a resolution of 10 µm. SkyScan analysis CTAn software was utilized to prepare and analyze morphological parameters and multiple MCs contained within each block were averaged. Paired morphological parameters were compared between the benign and subsequent cancer samples within women using Wilcoxon signed-rank tests.

Results: Median age of patients was 53 years (range 37-77 years) at initial benign biopsy and developed breast cancer at median of 5.6 years (range: 2.3-12.8 years) later. The initial benign biopsies were for proliferative disease without atypia in the majority (59%), while 23% had non-proliferative lesions and 18% atypical hyperplasia. The average structural model index was consistent with a near rod-like shape (median 2.99, range: 2.71-3.29). Paired comparisons between benign and cancer blocks showed that the average surface area of MCs was significantly higher in the cancer samples (p=0.0467), as was the average volume of MCs (p=0.0298) (Table 1).

Conclusions: Preliminarily, we demonstrate that microCT of routinely prepared pathology blocks of breast tissues may be useful in characterizing the 3-D morphometry of MCs with suggestive differences in benign and cancer tissues. Given that MCs are a sentinel radiologic marker of DCIS but are common in benign breast disease, developing improved approaches for classifying MCs may have value in breast cancer screening and management.

Table 1: Comparison of MC parameters in biopsy tissues (IQR = Interquartile Range).

Multiplex proteomics profiling with the imaging mass cytometry (IMC) identifies immune cell phenotypes associated with high NOS2/COX2 expression in ER- negative and TNBC patients

Milind Pore[1], Lisa Ridnour[2], Paul Mallory[1], Ashley Cardamone[1], Stephen Lockett[1], William Bocik[1], David Wink[2]. *[1]Cancer Research Technology Program, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Center for Cancer Research, National Cancer Institute, Frederick, MD*

Elevated expression of Inducible Nitric oxide Synthase-2 (NOS2) occurs during acute and chronic inflammation and wound healing processes however, it is also a predictor of bad prognosis in aggressive ER-negative tumors. Overexpression of NOS2 correlates with other prognostic biomarkers making it a unique multifunctional oncoprotein. Cyclooxygenase-2 (COX2) is another enzyme associated with cancer inflammation and is overexpressed in >50% of breast cancers. In our previous studies, we have shown that NOS2/COX2 co-expression is a strong predictor of poor clinical outcome and promotes $CD8^+$ T cell exclusion from tumor epithelia in Triple-negative breast cancers (TNBC). This observation was further explored using multiplexing proteomics technologies. Imaging Mass Cytometry (IMC) has revolutionized tumor microenvironment research by allowing the interrogation of over 35 protein markers simultaneously for the elucidation of the spatial distribution of immune and tumor cells at sub-cellular resolution. Herein, we used multiplex capability IMC to explore the interactions of immune and tumor cell counterparts in ER-negative and TNBC tumors. We employed Formalin-fixed paraffin-embedded (FFPE) tissue from 26 ER-negative and TNBC samples from a clinical cohort of African American breast cancer patients in the Baltimore MD area. We developed a panel of 15 protein metal-labeled antibody markers including antibodies targeting NOS2, COX2, T cells (CD45, CD3, CD4, CD8,) endothelium (CD31), monocytes (CD14), macrophages (CD68), basal markers (α-SMA), cancer stem cells (CD44v6), cancer cells (Pan-CK, B7H4, Cadherin), and serine proteases (granzyme B) secreted by T cells or Natural Killer (NK) cells. Single section slides of 4 µm size were stained with the cocktail of metal-labeled antibodies. Multiple regions of interest (ROIs) representing the tumor and immune cells compartments and tumor-facing stromal cell areas were ablated with the Hyperion Imaging system. The data analysis was performed by the Bodenmiller lab pipeline and VisioPharm software packages. Our preliminary data suggest that patient tumors with high or low NOS2/COX2 expression showed variable levels of CD68 positive macrophage population and T cells. We are currently analyzing the remaining data to understand the cell phenotypes associated with the immunosuppressive and immune-rich clinical samples and performing neighborhood analysis of tumor cells to immune cells and vessels.

The use of a novel orthotopic xenograft model of fusion negative rhabdomyosarcoma to study the effect of ASAP1 on tumor progression and metastasis

Sarah M. Hammoudeh, Yeap Ng, Mukesh P. Yadav, Roberto Weigert, Paul A. Randazzo. *Laboratory of Cellular and Molecular Biology, Center for Cancer (CCR) Research, National Institutes of Health (NIH), National Cancer Institute (NCI), Bethesda, MD*

ASAP1 is a multidomain ADP-ribosylation factor (Arf) GTPase-activating protein (GAP) involved in the regulation of the actin cytoskeleton, focal adhesions dynamics and receptor tyrosine kinases trafficking. ASAP1 expression levels correlate with progression of solid tumors (e.g. breast, colorectal, pancreatic, ovarian, gastric, and prostate cancer). The first evidence for a role of ASAP1 in cancer progression was the discovery that the amplification of ASAP1 gene on chromosome 8 correlates with poor prognosis in uveal melanoma. A similar amplification of chromosome 8 has been reported in ~72% of fusion negative rhabdomyosarcoma (FN-RMS) tumors, suggesting a potential role for ASAP1 signaling in the progression of FN-RMS. To determine the function of ASAP1 in tumor growth, invasion and metastasis, we used a tongue orthotopic xenograft of FN-RMS which recapitulates physiologically relevant tumor progression and metastasis to lymph nodes and lungs, two of the

common metastatic sites in patients. Using intravital microscopy, we observed that injected FN-RMS cells formed elongated structures and exhibited dynamic branching, which might represent local invasion. H&E stained of fixed tissue revealed invasion into the tongue and local metastasis. Metastases to the regional lymph nodes, lower mandible and lungs were also observed. Using this system, we are now able to determine effect of knocking down and knocking out ASAP1 on the progression of the xenografts, including invasion in real time and metastasis.

Targeted detection of ovarian cancer using functionalized iron oxide nanoparticles

Marie Zhang, eric Smith-Nguyen. *Imagion Biosystems, Inc., San Diego, CA*

SuperParaMagnetic Relaxometry (SPMR) is a highly sensitive detection technology that can differentiate the magnetic signature of nanoparticles (NP) bound to tumor cells from unbound nanoparticles. Nanoparticles that reach and bind to the target cells are measurable by superconducting quantum interference device (SQUID) magnetometers (MRX instrument developed in house), while unbound nanoparticles such as those freely circulating in the bloodstream are not detected and bone and normal tissue do not produce any magnetic signal. We have developed a protocol to produce high precision 25nm$\pm$1nm (<7% dispersion) Fe_3O_4 nanoparticle core. These core nanoparticles are coated by a polymer shell functionalized with carboxylate groups. Antibody are then conjugated on the surface providing molecular targeting capabilities and PEG is also attached to the surface to reduce opsonization. In previous studies, we have demonstrated that when conjugated with anti-HER2 antibody such as Herceptin, these nanoparticles exhibited great specificity and selectivity towards HER2+ tumor cells in vitro and in vivo. In current studies, we expanded our nanoparticles applications to other type of cancers, such as ovarian cancer.

The CA125 is a tissue-specific antigen expressed in ovarian cancer. It is associated with greater than 80% of epithelial ovarian neoplasms. OC125, a murine monoclonal antibody, reacts with glycosylation-dependent antigens present exclusively in the cleaved portion of the molecule. OC125 antibody is conjugated to our nanoparticles using the same strategy developed for Herceptin nanoparticles. Each nanoparticle contains one to three OC125 antibody molecules covalently attached to the surface based on ELISA analysis. Our results have shown that OC125-NP can distinguish CA125+ and CA125- cell lines, OVCAR3 and HeyA8 respectively. Positive signal can be competed out by pre-incubation with free OC125 antibody and negative cell line produce undetectable SPMR signal, demonstrating good sensitivity, specificity and selectivity.

Antigen glypican-1 (GPC1) is a proteoglycan located on cell surface composed of a membrane-associated protein core anchored to the cytoplasmic membrane. GPC1 may play a functional role in the control of cell division and growth regulation. The expression of GPC1 has been found to be elevated in many cancer cells, including ovarian. Applying the same conjugation strategy developed for Herceptin NP, humanized anti-GPC1 antibody is conjugated to the nanoparticles with minor modification. GPC1-NP generate appreciable signal using SKOV3 cell line (GPC1+ ovarian cell lines) and the signal can be competed out by the presence of excess free GPC1 antibody. Together, these results suggest that in additional to breast cancer application, our antibody functionalized nanoparticle system can be developed for other targeted cancer detection, such as ovarian cancer.

Does the metastatic immunoenvironment determine poor immunotherapy responses?

Nicole D. Barth[1], Floris J. van Dalen[2], Camille Duran[1], Utsa Karmakar[3], Lorena Mendive-Tapia[3], Takanori Kitamura[4], Martjin Verdoes[2], John S. Condeelis[1], Maja Oktay[1], Marc Vendrell[3], Valerie Brunton[5], David Entenberg[1]. *[1]Albert Einstein College of Medicine, New York, NY,[2]Dept. Tumor Immunology and Institute for Chemical Immunology, Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Radbound, Netherlands,[3]Centre for Inflammation Research, Queen's Medical Research Institute, The University of Edinburgh, Edinburgh, United Kingdom,[4]MRC Centre for Reproductive Health, Queen's Medical Research Institute, University of Edinburgh, Edinburgh, United Kingdom,[5]Cancer Research UK Edinburgh Centre, Institute for Genetics & Cancer Research, United Kingdom, Edinburgh, United Kingdom*

Despite new treatments, cancer remains the second leading cause of death worldwide with breast cancer being the most common type. Of these deaths, the majority are due to the formation of distant metastases. While new immunotherapies have shown some success in primary tumors, their efficacy in combating metastases has been lacking. Thus we aim to investigate the hypothesis that immune responses at the metastatic site contribute to limitations of current therapies.Within the last decade, new microscopy technologies now enable real-time

visualization of immune responses at primary and secondary sites. Here, we present use of these microscope technologies, along with the development of novel probes to detect apoptotic cancer cells, to investigate the success of checkpoint inhibitors in the primary and secondary sites. We validate, in multiple in vitro and in vivo assays (including intravital imaging), that fluorescent cyclic amphipathic peptide probes specifically label cells undergoing therapy-induced cancer death. In addition, we introduce a newly developed fluorescent, enzyme-activatable, chemokine-conjugate capable of targeting defined macrophage subsets in live tumors. This chemokine-conjugate exploits the high expression of chemokine receptors (e.g. CCR2) and the activity of cysteine cathepsins in tumor associated macrophages to selectively target and eradicate them without affecting other macrophages or immune cells (e.g., neutrophils, T cells, B cells). This research will help to elucidate the role of combination therapy on the metastatic foci and will provide the first insights into the benefit and limitations of combination therapy on secondary site immune responses.

Regulation of Invasion and Migration

Epigenetic driven IL32 expression contributes to a JNK related cell stress response in breast cancer stem cells to promote cellular invasion

Megan A. Wilson[1], Elayne M. Benson[2], Emma Gray[1], Paige Cairns[1], Maria Ouzounova[3], Hasan Korkaya[4], Austin Y. Shull[1]. *[1]Biology, Presbyterian College, Clinton, SC,[2]Augusta University, Augusta, GA,[3]University of Lyon, Lyon, France,[4]Georgia Cancer Center, Augusta University, Augusta, GA*

Metastatic potential in basal-like breast cancers typically correspond with increased enrichment of EpCAM-/CD49f- cancer stem cells (CSC). With this premise in mind, it is important to better understand the mechanistic driver of these cell populations and their distinctive potential to interact with the tumor microenvironment (TME) for cancer promotion. Previous work from our lab has compared the 450K DNA methylation profile of EpCAM-/CD49f- poor breast cancer cell lines to that of EpCAM-/CD49f- enriched breast cancer cell lines and found the IL32 promoter to be hypomethylated in EpCAM-/CD49f- enriched cell lines, a result which corresponded basal-like patient samples in TCGA. By identifying IL32 being differentially regulated in CSC-enriched cell lines, we further sought to characterize IL32's role in breast cancer aggressiveness. We first were able to identify several overarching mechanisms altered in siIL32 treated SUM15PT cells by RNAseq differential expression analysis (FDR p-value <0.01). Most notable from our RNAseq results was the significant enrichment of upregulated pathways involved in extracellular matrix (ECM) organization as well as significant enrichment of downregulated pathways involved in cellular and replicative stress responses. Particular examples of transcripts differentially expressed between control and siIL32-treated SUM159PT cells included *COL6A1*, *ITGB3*, and *CD24* that were upregulated as well as *NQO1*, *HMOX1*, and *CXCL2/CXCL3* that were downregulated. Furthermore, IL32 suppression decreased SUM159PT invasion in both an ECM-matrix cell invasion assay and a chick CAM xenograft/angiogenesis model. From our RNAseq results, we then performed a multi-pathway protein phosphorylation array to determine whether any key signaling events were affected by siIL32 knockdown in SUM159PT cells. Based on this approach, we were able observe a significant decrease in phosphorylated JNK and phosphorylated NFKB in siL32-treated cells when compared to control, both of which are well-established events that can coordinate both cell stress responses and cellular invasion. Collectively, our results reflect the notion that differential IL32 expression by promoter hypomethylation in breast CSCs plays a role to mitigating intracellular stress and subsequently allowing for breast cancer cell invasion and metastasis.

#3596

EMG1 is an rRNA-modifying protein that contributes to breast cancer progression

Amr R. Elhamamsy, Heba A. Alsheikh, Rajeev S. Samant, Lalita A. Shevde. *Pathology, O'Neal Comprehensive Cancer Center at UAB, Birmingham, AL*

The ribosome, a multi-subunit RNA-protein complex, is essential for translation in all cells. Variation in ribosome composition and characteristics has been observed between cell types and under different metabolic conditions; this phenomenon is referred to as "ribosome heterogeneity." Ribosome heterogeneity has been linked to carcinogenesis and cancer progression. One of the major layers of ribosome heterogeneity is the diverse rRNA modifications. To study the impact of rRNA modifications on cancer, we performed a systematic literature search and identified 22 rRNA modifying proteins (RRMPs) that are involved in mediating different modifications of rRNA. We next examined the RRMPs' expression levels and frequency of mutation in different cancer types, with

a focus on breast cancer. We see that most malignancies show alterations in RRMPs' expression levels and frequent mutations. Our analysis of gene expression patterns and clinical outcomes in breast cancer has shown that several RRPMs are strongly linked to an aggressive phenotype and a poor prognosis. Our analysis also revealed that EMG1, a N1-specific psuedouridine methyltransferase, is a RRMP with potential roles in cancer progression and metastasis. Our findings pave the way for further research into the role of RRMPs in different cancers as well as the development of therapies that specifically target RRMPs involved in cancer progression.

SUV420H2-mediated regulation of collective invasion in triple-negative breast cancer

Emily Campbell Whitt[1], Laura M. McLane[2], Paula M. Vertino[2]. *[1]Cell Biology of Disease Graduate Program, University of Rochester Medical Center, Rochester, NY,[2]Department of Biomedical Genetics, University of Rochester Medical Center, Rochester, NY*

Breast cancer is the second most common cancer in women and metastasis is the leading cause of breast cancer-related mortality. While the factors leading to metastasis remain poorly understood, epigenetic changes in the cancer cell are likely strongly associated with the shift from primary tumor to metastasis. There are several breast cancer subtypes, the most aggressive of which is triple-negative breast cancer which is difficult to treat in part because it is prone to metastasis. In the early stages of metastasis, cells from the primary tumor invade the surrounding tissue before breaking away and seeding metastases. In some cases, tumor cells invade as clusters of cells that migrate as a group and maintain their cell-cell contacts through a process known as collective invasion. These clusters of collectively invading cells have been shown to seed circulating tumor cell clusters that are more efficient at forming metastases than single tumor cells. SUV420H2 is a histone methyltransferase that trimethylates histone H4 lysine 20 (H4K20me3), an epigenetic mark associated with transcriptional repression. Triple-negative breast cancer has lower levels of SUV420H2 and H4K20me3 levels than more luminal subtypes. Our lab and others have found that downregulation or inhibition of SUV420H2 promotes increased plasticity in the epithelial-to-mesenchymal transition, a transcriptional program associated with cancer metastasis. Our objective was to use a three-dimensional tumor spheroid system to determine the role of SUV420H2 and H4K20me3 on breast cancer invasion. We found that in immortalized non-tumorigenic breast cells grown as spheroids in an extracellular matrix, knockdown of SUV420H2 promotes invasion. Treatment of triple-negative breast cancer spheroids with an inhibitor of SUV420H2 (A196) also leads to an increase in invasion, as well as a shift in invasive phenotype from one where cells invade as single cells to a one where cells invade as collective chains emanating from the central spheroid. This suggests that reduced levels of SUV420H2 and the associated changes in histone marks and transcriptional programming in triple-negative breast cancer promote a phenotypic shift from single cell to collective invasion and may be one factor contributing to the increased metastatic potential of this subtype. Future studies will focus on characterizing the effects of SUV420H2 loss on gene and protein expression as well as chromatin in invading cells in tumor spheroids.

Cooperative NF-KappaB and Notch1 signaling promotes a macrophage-mediated metastatic phenotype in breast cancer

Camille L. Duran[1], George S. Karagiannis[2], Xiaoming Chen[1], Ved P. Sharma[3], David Entenberg[1], John S. Condeelis[4], Maja H. Oktay[1]. *[1]Pathology, Albert Einstein College of Medicine, Bronx, NY,[2]Microbiology and Immunology, Albert Einstein College of Medicine, Bronx, NY,[3]Bio-Imaging Resource Center, Rockefeller University, New York, NY,[4]Cell Biology, Albert Einstein College of Medicine, Bronx, NY*

Metastasis is a multistep process that leads to the formation of clinically detectable tumor foci at distant organs and, frequently, to patient demise. Only a subpopulation of breast cancer cells within the primary tumor can disseminate systemically and cause metastasis. To disseminate, cancer cells must express MenaINV, an isoform of the actin-regulatory protein, Mena, encoded by the *ENAH* gene that endows tumor cells with transendothelial migration activity allowing them to enter and exit the blood circulation. We have previously demonstrated that MenaINV mRNA and protein expression is induced in cancer cells by macrophage contact. Here, we report on the discovery of the precise mechanism by which macrophages induce MenaINV expression in tumor cells. We examined the promoter of the human and mouse *ENAH* gene and discovered a conserved NF-κB transcription factor binding site. Using live imaging of an NF-κB activity reporter and staining of fixed tissues from mouse and human breast cancer we further determined that, for maximal induction of MenaINV in cancer cells, NF-κB needs

to cooperate with the Notch1 signaling pathway. Mechanistically, Notch1 signaling does not directly increase MenaINV expression, but instead enhances and sustains NF-κB signaling through retention of p65, an NF-κB transcription factor, in the nucleus of tumor cells, leading to increased MenaINV expression. In mice, these signals are augmented following chemotherapy treatment and abrogated upon macrophage depletion. Targeting Notch1 signaling *in vivo* decreased NF-κB signaling and MenaINV expression in the primary tumor and decreased metastasis. Altogether, these data uncover mechanistic targets for blocking MenaINV induction that should be explored clinically to decrease cancer cell dissemination and improve survival of patients with metastatic disease.

Molecular characterization of mouse colorectal cancer cell lines with high potential of peritoneal metastasis

Haruki Mori[1], Hisanori Isomura[2], Shuang Zhou[2], Taisuke Kajino[2], Yuichi Abe[2], Takashi Kinoshita[2], Seiji Natsume[2], Yusuke Sato[2], Akira Ouchi[2], Toru Miyake[1], Waki Hosoda[2], Koji Komori[2], Yasuhiro Shimizu[2], Masaji Tani[1], Ayumu Taguchi[2]. *[1]Department of Surgery, Shiga University of Medical Science, Otsu, Japan,[2]Aichi Cancer Center, Nagoya, Japan*

Background: Peritoneal metastasis occurs in approximately 7% of colorectal cancer (CRC) patients and is associated with worse prognosis compared to non-peritoneal metastasis. In CRC patients with peritoneal metastasis, administration of systemic chemotherapy only slightly improves overall survival. Therefore, a better understanding of the biology of peritoneal metastasis and the development of new molecular therapeutics for CRC patients with peritoneal metastasis are urgently needed.
Materials and Methods: CT26 mouse CRC cell lines with low metastatic potentials (CT26-N5) and high metastatic potentials to peritoneum (CT26-P6) were established after several rounds of in vivo selection by orthotopic transplantation of CT26 cells into the syngeneic BALB/c mice. Transcriptomic and proteomic analyses were conducted on CT26-N5 and CT26-P6 cells.
Results: Orthotopic transplantation of CT26-P6 cells exhibited significantly increased peritoneal metastasis compared to CT26-N5 cells, while growth of primary tumors was not different between these CT26 sublines. In addition, CT26-P6 cells had higher cell migration and invasion potential in vitro than CT26-N5 cells. Integrated analyses of transcriptome and proteome resulted in identification of molecular signatures associated with peritoneal metastasis. An actin-binding protein Advillin, encoded by the Avil gene, was markedly increased at both mRNA and protein levels in CT26-P6 cells compared to CT26-N5 cells. Knockdown of Avil using siRNA or shRNA in CT26-P6 cells significantly reduced cell migration and invasion in vitro and occurrence of peritoneal metastasis in vivo. Gene Set Enrichment Analysis on transcriptome datasets from CT26-P6 cells and CT26-N5 cells identified interferon gamma response as the most significantly enriched pathway in CT26-cells. In addition, Immunoprecipitation coupled with LC-MS/MS identified potential interaction between Avil and a molecule X that regulates epithelial-mesenchymal transition in CRC. Consistent with the findings in mouse CT26 cells, AVIL knockdown in CRC patient-derived cells (PDCs) suppressed cell migration and invasion in vitro. While AVIL expression was induced by interferon gamma in CRC PDCs, JAK inhibitors, Momelotinib and Ruxolitinib, significantly reduced interferon gamma-induced AVIL expression, suggesting regulation of AVIL by interferon gamma.
Conclusion: Molecular characterization of mouse colorectal cancer cell lines with different metastatic potential identified AVIL as a potential therapeutic target in CRC patients with peritoneal metastasis. Regulation of AVIL expression by interferon gamma may suggest functional relevance of tumor immune microenvironment in the development of peritoneal metastasis in CRC.

#3600

MET-mediated STING activation regulates EMT and NF-KB pathway in non-small cell lung cancer

Seungchan Mun[1], Bogyeong Han[2], HyunKyung Ahn[1], Jaemoon Koh[2], Sehui Kim[2], DooHyun Chung[2], YoonKyung Jeon[2]. *[1]Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Pathology, Seoul National University College of Medicine, Seoul, Korea, Republic of*

The cyclic GAMP-AMP synthase (cGAS)-stimulator of interferon genes (STING) pathway is known to have anti-tumor activity by activating the innate immune response against cytosolic double-stranded DNA (dsDNA). The regulating mechanism of STING remains unclear, and a pro-tumorigenic effect of STING pathway was recently reported. In this study, we investigated the expression of STING by MET and a novel role of the STING pathway in non-small cell lung cancer (NSCLC). The Cancer Genome Atlas (TCGA) and Cancer Cell Line Encyclopedia

(CCLE) analysis showed that cGAS/STING pathway is enriched and STING expression is higher in MET-overexpressing tumors. Western blot for NSCLC cells and immunohistochemistry for NSCLC tumor tissues showed positive correlation between MET and STING expression in NSCLC cells. MET-overexpression and a MET agonist (HGF) treatment increased STING expression and CXCL10 and IFNβ expression and secretion, whereas MET-knockdown and a MET inhibitor (capmatinib) treatment decreased STING expression in NSCLC cells. In MET-positive and STING-positive cells, a STING agonist (poly-dAdT and diABZI) treatment led to increased activation of STING signaling pathway. In EBC-1 cells, MET knockdown decreased STING expression and STING-agonist-induced STING-pathway activation and cytokine production. To further investigate the role STING in NSCLC, EBC-1 cells were transfected with STING siRNA and submitted to RNS-seq. Gene set enrichment analysis revealed that several pathways were affected by STING expression. Epithelial-mesenchymal transition (EMT) and TNFα-signaling via NF-κB signaling were significantly downregulated in STING-knockdowned cells. In vitro experiments using EBC-1 cells, STING overexpression increased SLUG and TWIST1 expression and migration of cells, whereas STING knockdown decreased SLUG and TWIST1 expression and migration of cells. In summary, this study demonstrated that MET and STING expression were positively correlated with each other in NSCLC and MET overexpression increased STING expression and subsequent activation upon STING agonist stimulation. In addition, STING contributed to EMT in NSCLC.

#3601

Tumor MK2 signaling regulates cell migration and invasion in head and neck squamous cell carcinoma

Dakota D. D. Okwuone[1], Deri Morgan[1], Hannah M. Smith[1], Grace Millington[1], Kiersten L. Berggren[2], Christopher E. Lominska[1], Sufi M. Thomas[1], Gregory N. Gan[1]. *[1]University of Kansas Medical Center, Kansas City, KS,[2]The University of New Mexico Comprehensive Cancer Center, Albuquerque, NM*

Poor 5-year overall survival in head and neck cancer (HNC) can be attributed to high rates of locoregional and distant metastasis. We have previously demonstrated that high phosphorylation/activation of MAPK-activated protein kinase 2 (MK2), a stress-activated kinase directly downstream of p38 MAPK, in head and neck squamous cell carcinoma (HNSCC) is associated with worse overall survival and inhibition of the MK2 pathway enhances in vivo HNSCC radiosensitivity. Our prior work also demonstrates that radiotherapy-induced epithelial-to-mesenchymal transition (EMT) gene expression can be suppressed in cells when MK2 is inhibited. Several studies have shown that EMT plays a prominent role in HNSCC tumor invasion, treatment resistance, and locoregional metastases to lymph nodes. In this study, we investigate the impact of MK2 activity on HNSCC tumor progression by examining its contribution to cancer cell morphology. We used lentiviral-shRNA and the CRISPR-Cas9 system to knock down/out the MK2 gene in multiple human and murine HNSCC cell lines. We measured tumor cell migration and invasion in both classic 2D in vitro culture as well as with 3D spheroids. We performed unbiased analysis via RNAseq in human HNSCC cell lines comparing MK2 shRNA vs scramble cell lines. Substantial gene and pathway alterations were examined using a combination of immunoblot and RT-qPCR. Our data shows knocking down/out MK2 in HNSCC cells significantly diminishes cell migration and invasion in 2D and 3D in vitro culture assays. RNAseq analysis demonstrated loss of MK2 leads to a significant increase in many cell adhesion molecules, including E-cadherin, and a decrease in N-cadherin, suggesting a shift from mesenchymal to more epithelial phenotype. Furthermore, we note expression of multiple matrix metalloproteinases and EMT markers (i.e., Snail) are substantially reduced in MK2 shRNA and KO cell lines. These results indicate that the MK2 pathway is involved in HNSCC motility and invasion. We also observe the loss of MK2 contributes to a shift in the epithelial:mesenchymal ratio potentially by suppressing cancer EMT plasticity. All in all, this study provides evidence suggesting tumor MK2 activation mediates HNC progression.

The metastasis-suppressive function of intracellular galectin-3 in melanoma

Norhan B. B. Mohammed, Charles J. Dimitroff. *Translational Medicine, Florida International University, Miami, FL*

Melanoma is a relatively rare skin cancer. However, it accounts for most of all skin cancer-related deaths worldwide. Once melanoma spreads to distant sites, it confers a poor prognosis characterized by resistance to therapy and high mortality rate. Hence, a favorable clinical outcome is strongly correlated with early diagnosis. Despite the ongoing research to identify novel diagnostic, prognostic, and therapeutic targets for metastatic melanoma (MM), a reliable serum marker to predict whether melanoma is vulnerable to metastasize or has already metastasized is still lacking. Galectin-3 (Gal-3), a ß-galactoside-binding protein, is widely expressed by many

human epithelial and immune cells. High extracellular Gal-3 expression levels have been reported to be positively correlated with late-stage disease in melanoma patients, where it is theorized to bind surface glycosylated proteins to promote melanoma cell invasion and metastasis. Gal-3 is also expressed intracellularly where it participates in the regulation of many biological processes. However, intrinsic Gal-3 levels within the melanoma cell and its relationship to melanoma progression is still poorly understood. Using The Cancer Genome Atlas (TCGA) database, we analyzed the Gal-3 expression profiles of 471 tumor samples obtained from melanoma patients. To our surprise, TCGA data analysis has shown significantly higher expression of Gal-3 in primary melanoma samples compared to metastatic melanoma. We hypothesize that intracellular Gal-3 potentially negatively regulates primary melanoma progression to metastatic disease. Using several human melanoma cell lines silenced for Gal-3 expression, we investigated the corresponding malignancy-associated activities of these cells. Our results revealed that Gal-3 silencing in melanoma cells potentiated melanoma migration, invasion, and colony formation, compared with mock controls, suggesting that intracellular Gal-3 could interfere with melanoma metastatic activity. Moreover, loss of Gal-3 boosted the activation of the PI3K/AKT and MAPK signaling pathways and upregulated nuclear factor of activated T cells (NFAT1) expression and its pro-metastatic downstream target genes. Importantly, this study illuminates the apparent opposing roles of Gal-3 in melanoma progression, with intracellular Gal-3 potentially serving as a metastasis-suppressive molecule. Moreover, these studies reveal the potential of analyzing melanoma cell-intrinsic levels of Gal-3 to better predict metastatic potential and clinical outcome in melanoma patients.

Epithelial Caveolin-1 regulates lung metastasis in advanced stages of breast cancer

Dhirendra Pratap Singh[1], Rashmi Pathak[2], Abhishek Pandit[3], Philip J. Ebenezer[4], Nithya Jambunathan[1], Sanjay Kumar[5], Alexander Du Plooy[4], Joseph Francis[3], Mary E. White[6]. *[1]Cardiovascular Medicine, Indiana University Health Methodist Hospital, Indianapolis, IN,[2]Biological Sciences, Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, LA,[3]Comparative Biomedical Science, Louisiana State University, Baton Rouge, LA,[4]Louisiana State University, Baton Rouge, LA,[5]Biological Sciences, Louisiana State University, Baton Rouge, LA,[6]Department of Pathology and Population Medicine, Midwestern University, Baton Rouge, AZ*

Organotypic metastasis is a well-orchestrated sequence of events that takes place in tumors. The interplay between secretory factors from the primary tumor and the microenvironment of a distant organ determines the fate of metastasis. A significant concern in effective triple-negative breast cancer (TNBC) treatment is lung metastasis. Caveolin-1 (Cav-1), a lipid raft protein, is an important component of the metastatic interplay and is reported to be upregulated in the advanced metastatic stage of breast cancer. Although Cav-1 has been shown to have oncogenic potential, its role in TNBC lung metastasis is not fully understood. Our data illustrates, knocking out Cav-1 in the 4T1 cells (a mouse breast cancer cell line) affects cell morphology, extracellular vesicle formation, and MMP release in vitro. Furthermore, a wound healing/ cell migration assay showed reduced migration in Cav-1 KO 4T1 cells when compared to control 4T1 cells, and these findings were validated using Cav-1 siRNA. For investigating the metastatic role, we injected Cav-1 KO 4T1 and control 4T1 cells into the mammary fat pad of female BALB/c mice, a syngeneic mouse model of triple-negative breast cancer. We found no evidence of lung metastasis in Cav-1 KO 4T1 injected mice when compared to control 4T1 injected mice. This was further supported by mRNA profiling of the tumor. We observed 21 epithelial cell migration genes that are differentially expressed in Cav-1 KO tumors when compared to WT tumors. Correlation analysis from Breast Cancer Gene-Expression Miner v4.8 (bc-GenExMiner), a human database, showed a significant correlation between Cav-1 expression and several of the 21 epithelial cell migration genes, along with integrin 3 alpha (ITGα3). Interestingly, in silico protein docking predicted an interaction between Cav-1 and ITGα3, which was later confirmed by co-immunoprecipitation. The role of ITGα3 in metastasis was further corroborated by cell migration assay, which was affected when siRNA was used to silence ITGα3 gene expression. Collectively, these findings provide evidence that Cav-1 KO, along with ITGa3, plays an important role in distant lung metastasis in the 4T1 tumor-induced mice model.

#3605

Peroxiredoxin IV promotes prostate cancer malignancy through the activation of NF-kB signaling

Na Ding, Hong Jiang, Pratik Thapa, Yanning Hao, Aziza Alshahrani, Vivek Rangnekar, Xiaoqi Liu, Qiou Wei. *University of Kentucky, Lexington, KY*

Background: The peroxiredoxin (Prx) family of proteins functions as major cellular antioxidants to maintain redox homeostasis as well as mediate oxidative signaling in both physiological and pathological conditions. Our previous studies show that Prx4 is highly expressed in prostate cancer and promotes tumor growth *in vitro* and *in vivo*. But how Prx4 contributes to prostate cancer cell invasion and metastasis remains to be elucidated. The purpose of this study is to understand the oncogenic signaling pathways that are mediated by Prx4 in prostate cancer cells. Methods: Bioinformatic analysis of existing database were used to examine the expression of Prx4 in primary and metastatic prostate cancer samples. CRISPR/Cas9 technique was used to establish Prx4 knockout in cultured human prostate cancer cell lines. Matrigel invasion assays were performed to evaluate cell migration and invasion. RNAseq was performed to examine the differences of gene expression between control and Prx4KO cells. Gene Set Enrichment Analysis (GSEA) and Gene Oncology (GO) enrichment analysis were performed using RNAseq results. RT-PCR and immunoblotting were used to validate findings from RNAseq and enrichment analysis. Results: Compared with normal prostate, transcript levels of *PRDX4* are found to be upregulated in specimens of patients with prostate cancer, and those with bone metastasis show even higher levels. Knockout of Prx4 in cultured human prostate cancer cells leads to significantly reduced ability of cell migration and invasion. Gene expression profiling reveals that loss of Prx4 leads to the upregulation of epithelial as well as downregulation of mesenchymal markers, and multiple signaling pathway changes including the inhibition of cellular response to inflammatory factors such as tumor necrosis factors and interleukins. These changes are also associated with variety of cellular activities such as wound healing, interferon signaling, and antigen processing & presentation. Among known target genes downstream of NF-κB signaling, E-cadherin, vimentin and matrix metalloproteinase 14 (MMP14) were found to be significantly affected by the loss of Prx4. Therefore, Prx4 plays a critical role in human prostate cancer cell malignancy through regulation of intracellular cell signaling pathways. Conclusions: A combination of bioinformatic, cellular and molecular methods reveals that Prx4 plays a critical role in promoting prostate cancer metastasis. Prx4 is a potential therapeutic target to reduce prostate cancer metastasis.

#3606

HDAC8-mediated inhibition of EP300 drives a neural crest-like transcriptional state that increases melanoma brain metastasis

Michael Emmons[1], Richard Bennett[2], alberto riva[2], Chao Zhang[1], Robert Macaulay[1], Daphne Dupéré-Richér[2], Bin Fang[1], John Koomen[1], Jiannong Li[1], Ann Chen[1], Edward Seto[3], Jonathan Licht[2], Keiran Smalley[1]. *[1]Moffitt Cancer Center, Tampa, FL,[2]University of Florida, Gainesville, FL,[3]George Washington University, Washington DC, DC*

Melanomas are heterogeneous and adopt multiple transcriptional states that can confer an invasive phenotype and resistance to therapy. Little is known about the epigenetic drivers of these cell states, limiting our ability to regulate melanoma heterogeneity and tumor progression. Here we identify stress-induced HDAC8 activity as the driver of a neural crest stem cell (NCSC)-like transcriptional state that increased the formation of melanoma brain metastases (MBM). Exposure of melanocytes and melanoma cells to multiple different stresses led to HDAC8 activation, a switch to a NCSC gene expression signature and the adoption of an amoeboid, invasive phenotype. This cell state enhanced the survival of melanoma cells under shear stress conditions and increased the formation of metastases in the brain. Single cell RNA-seq analyses showed that HDAC8 expression was correlated with the NCSC cell state in clinical MBM specimens. ATAC-Seq and ChIP-Seq analysis showed HDAC8 to alter chromatin structure by increasing H3K27ac and accessibility at c-Jun binding sites without changing global histone acetylation. The increased accessibility of Jun binding sites was paralleled by decreased H3K27ac and accessibility at MITF binding sites and loss of melanoma-lineage gene expression. Mass spectrometry-based acetylomics demonstrated that HDAC8 deacetylated the histone acetyltransferase (HAT) EP300 leading to its enzymatic inactivation. This, in turn, led to an increased binding of EP300 to Jun-transcriptional sites and decreased binding to MITF-transcriptional sites. Increased expression of EP300 decreased invasion and increased the sensitivity of melanoma cells to multiple stresses while inhibition of EP300 function increased invasion and resistance to stress. We identified HDAC8 as a novel mediator of transcriptional co-factor inactivation and chromatin accessibility that increases MBM development.

RNA-binding proteins are essential for EGF-induced fibronectin expression and metastasis of head and neck squamous cell carcinoma

Ting-Wei Chang[1], Wen-Chang Chang[2], Ben-Kuen Chen[3]. *[1]Institute of Basic Medical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan,[2]Graduate Institute of Medical Sciences, College of Medicine, Taipei Medical University, Taipei, Taiwan,[3]Department of Pharmacology, College of Medicine, National Cheng Kung University, Tainan, Taiwan*

There is a higher expression level of epidermal growth factor receptor (EGFR) in up to 90% of advanced head and neck squamous cell carcinoma (HNSCC) tissue than in normal surrounding tissues. However, the precise mechanism involved in modulating EGF-associated metastasis in HNSCC remains unclear. In this study, we reveal that the concurrent expression of EGFR and fibronectin (FN1) was highly associated with the stages of HNSCC progression. EGF-induced fibronectin/integrin axis enhanced tumor-endothelial cell interaction and increased endothelial permeability, conferred HNSCC cell metastasis. Mechanistically, we found that ERK and NF-κB pathway activation was essential for EGF-induced fibronectin expression. In addition, EGF-enhanced mRNA stability of fibronectin occurred through the 5' untranslated region (5'-UTR) of the gene and was mediated by nucleolin (NCL) and hnRNPA2/B1, which were also involved in the regulation of epithelial-mesenchymal transition gene expression. Intriguingly, the *in vivo* study showed that depletion of NCL, hnRNPA2/B1, and inhibition of the fibronectin/integrin axis significantly inhibited EGF-promoted HNSCC metastasis in the lung. Our data suggests that the nucleolin/ hnRNPA2/B1-regulated fibronectin is essential for EGF-induced tumor-endothelial cell interactions to enhance HNSCC cell metastasis.

MLL1 regulates cytokine-driven cell migration and metastasis

Praful R. Nair[1], Ludmila Danilova[2], Estibaliz Gómez-de-Mariscal[3], Dongjoo Kim[4], Rong Fan[4], Arrate Muñoz-Barrutia[3], Elana Fertig[2], Denis Wirtz[1]. *[1]Johns Hopkins University, Baltimore, MD,[2]Johns Hopkins School of Medicine, Baltimore, MD,[3]Universidad Carlos III de Madrid, Madrid, Spain,[4]Yale University, New Haven, CT*

Cell migration, particularly in three-dimensional (3D) environments, is a critical requirement for metastasis - the spread of cancer cells from a primary tumor to distant sites. Despite causing the vast majority of cancer-related deaths, targeting metastasis remains challenging clinically. Cancer cell migration can be triggered and maintained by elevated levels of cytokines, which are presumed to be predominantly secreted by immune cells in the tumor microenvironment. However, recent work has highlighted the importance and impact of cytokine production by cancer cells themselves. While the signaling cascades that regulate cell migration have been studied extensively, the epigenetic regulation of cell migration is still poorly understood. MLL1 is a histone methyltransferase, which along with its scaffold protein Menin, is integral to methylation at the histone 3 lysine 4 (H3K4) site. Here, we show that the MLL1-Menin interaction is essential for the migration of cancer cells and that the disruption of this interaction impairs cell migration and metastasis. MLL1 depletion reduces 3D cell migration *in vitro* and led to lesser metastatic burden and prolonged survival *in vivo*. Reduced lung metastatic burden was observed even after accounting for the difference in the growth rate of primary tumors. Mechanistically, MLL1-Menin interaction controls actin filament assembly via the IL-6/pSTAT3/Arp3 axis and acto-myosin contractility via the TGF-β1/Gli2/ROCK1/2/pMLC2 axis, which together regulate dynamic protrusion generation and 3D cell migration. MLL1-Menin inhibition also decreases cell proliferation by inhibiting mitosis and cell cycle-related pathways. MLL1 depletion decreases primary tumor growth, metastatic spread, and metastatic outgrowth in mouse models of triple-negative breast cancer (TNBC), thus improving survival. When comparing metastatic burden at a threshold tumor size, rather than at a timepoint, MLL1 depletion still lowered metastatic burden. Combining an MLL1-Menin inhibitor with Paclitaxel, a standard TNBC chemotherapeutic, abrogated tumor growth and metastasis in a syngeneic TNBC mouse model. Overall, our studies show that MLL1 is an epigenetic regulator of 3D cancer cell migration, which exerts its effects by controlling the production of the key cytokines IL-6 and TGF-β1. Our *in vivo* studies demonstrate the potential of targeting the MLL1-Menin interaction in metastasis prevention and its potential to be combined with currently administered chemotherapeutics.

Interaction of interleukin-6/8/18 with prostate cancer cell secreted growth factors are crucial for osteoblast proliferation and differentiation

Aaron Jeshua Todman, Wishrawana S. Ratnayake, Luke Lajmi, Sloan Breedy, Kirpal Bisht, Mildred Acevedo-Duncan. *University of South Florida, Tampa, FL*

There is currently no effective therapy for bone metastatic prostate cancer, which is the main cause of mortality in people with prostate cancer. Poor prognosis of bone metastasis has limitations in current therapeutics mainly due to the complexity of microenvironment. Our focus was on the interactions between prostate cancer cells and the bone microenvironment, including osteoclasts and osteoblasts in regard to growth factors and cytokines, as the bone microenvironment plays a significant role in this process. The present study shows the downstream effects of Stavudine (KB-S); a known antiviral compound along with 5-fluoro-1-((1R,4R)-4-((tetrahydro-2H-pyran-2-yl)oxy)cyclopent-2-en-1-yl)pyrimidine-2,4(1H,3H)-dione (KB-G) and 1-((1R,4R)-4-hydroxycyclopent-2-en-1-yl)-5-methylpyrimidine-2,4(1H,3H)-dione (KB-H) on bone metastatic prostate cancer. Effects of KB-G/H and S on HEK-293 control cells were determined as moderate under tested conditions. A series of KB-G/H and S (10, 25, 50, 75 and 100 μM) was given for a 4-day period (with 24 h intervals) and the prostate cancer cell population was determined at the end of the 4-day treatment period. Preliminary results indicated that all 3 compounds significantly decreased DU-145 and PC-3 cell population compared to the effects on HEK-293 cells. Results suggested that all 3 compounds can decrease the prostate cancer cell progression by enhancing apoptosis. Our data also suggested that all 3 compounds downregulated interleukin (IL)-18, IL-8, IL-6 and C-X-C motif ligand-1(CXCL-1) in prostate cancer cells (PC-3 and DU-145). A human osteoblast cell line (hFOB 1.19) is being used to study the effect of cytokines in relation to transforming growth factor β (TGFβ), insulin-like growth factor (IGF) and platelet-derived growth factor (PDGF) that are secreted by prostate cancer cells. *In-vitro* migration/ invasion assays, immunoprecipitation (IP), immunofluorescence microscope, cytokine profile array, real time qPCR and Western blot techniques are being used in this study to further analyze role of cytokines and growth factors on osteoblast differentiation. Our

preliminary results suggest that all 3 compounds can be used to disrupt the main steps of prostate cancer bone metastasis. Results suggested that KB-G/H and S can be targeted to develop customized, tailored therapies for bone metastatic prostate cancer which merit further research.

Prenylated PALM2 promotes the migration of esophageal squamous cancer cells through activating ezrin

Danxia Deng, Chengyu Li, Zhenyuan Zheng, Bing Wen, Liandi Liao, Enmin Li, Liyan Xu. *Shantou University Medical College, Shantou, China*

Proteins containing a CAAX motif at the C-terminus can occur prenylation modification and regulate the localization and activity of a series of key regulatory proteins, including RAS superfamily members, heterotrimeric G proteins, nuclear lamina protein, and several protein kinases and phosphatases. However, studies of prenylated proteins in esophageal cancer are limited. Here, we found that paralemmin-2 (PALM2), a potential prenylated protein, was up-regulated and associated with a poor prognosis of patients, through research on large-scale proteomic data of esophageal cancer in our laboratory. The low throughput verification also showed that the expression of PALM2 in esophageal cancer tissues was higher than that in their paired normal esophageal epithelial tissues, and it was generally expressed in the membrane and cytoplasm of esophageal squamous cancer cells (ESCC). PALM2 interacted with the two subunits of farnesyl transferase (FTase), FNTA and FNTB. The FTase inhibitor weakened the membranous location of PALM2 and mutation in the CAAX motif of PALM2 ($PALM2^{C408S}$) impaired its membranous localization, indicating PALM was prenylated by FTase. Overexpressed PALM2 promoted the migration of cancer cells, whereas $PALM2^{C408S}$ lost this ability. Mechanistically, PALM2 interacted with the N-terminal FERM domain of ezrin of Ezrin/Radixin/Moesin (ERM) family dependent on its prenylation. The mutagenesis indicated that lysine residues K253/K254/K262/K263 in ezrin's FERM domain and cysteine residue C408 in PALM2's CAAX motif were important for their interaction and ezrin activation. The knockout of ezrin prevented enhanced cancer cell migration by PALM2 overexpression. PALM2, depending on its prenylation, made ezrin get more membranous

distribution and increased the phosphorylation of ezrin Y146 site. In summary, prenylated PALM2 promoted the migration of cancer cells through activating ezrin. (This work was supported by the National Natural Science Foundation of China (82173034, 81172264), and Innovative Team Grant of Guangdong Department of Education (2021KCXTD005)).

#3611

PAUF induces migration of human pancreatic cancer cells exclusively via the TLR4/MyD88/NF-κB signaling pathway

Fen Jiang[1], So Eun Youn[1], Da Eun Hong[1], Tae Heung Kang[1], Hye Yun Won[1], Yun Yong Park[1], Sang Seok Koh[2]. *[1]Innovative Discovery Center, Prestige Biopharma Korea, Busan, Korea, Republic of,[2]Department of Biomedical Sciences, Dong-A University, Busan, Korea, Republic of*

Background**:** Pancreatic adenocarcinoma up-regulated factor (PAUF) is a cancer-secreted protein which is overexpressed on pancreatic cancer (PC) cells and promotes tumor growth in an autocrine way. However, the receptor of PAUF on PC cells has yet to be identified. Meanwhile, it is known that PAUF, as a tumor microenvironment (TME) modulator, plays a role in immune evasion and suppression through toll-like receptors notably TLR4 which are mainly expressed on immune cells. Previous studies show that TLR4 is also highly expressed in PC tumor tissues, compared to normal tissues, and activation of TLR4 signaling pathway induces the migration and invasion of PC cells.

Objective: This study aimed to investigate if TLR4 expressed on cancer cells can act as a receptor for PAUF to mediate its tumor promoting effects.

Methods and Results: We tested the TLR4 expression in six PC cell lines and one normal pancreatic cell line. And confirmed that TLR4 is expressed in all PC cell lines at variable levels, but not in the normal pancreatic cell line.Next, we found that a chemical TLR4-specific inhibitor TAK-242 significantly reduced the migration of PC cells with high TLR4 expression (BxPC-3), but it did not impact the migration of PC cells with low TLR4 expression (Panc-1). This experiment suggests that some endogenous ligands of TLR4 may have mediated PC cell migration.Using TLR4 overexpressed and knockout PC cell lines, we showed that treatment with recombinant PAUF increased the migration and invasion of TLR4 overexpressed PC cells, but not in the TLR4 knockout cells. Likewise,

treatment of anti-PAUF antibody reduced the migration and invasion of TLR4 overexpressed PC cells, but not in the TLR4 knockout cells. These results shows that PAUF's migration and invasion promoting effects of PC cells is TLR4 dependent.To further understand the molecular mechanism of PAUF-induced metastasis (migration/invasion)-promoting effects via TLR4, we conducted a series of in vitro studies including immunoprecipitation (IP), western blot analysis, flow cytometry, and luciferase reporter assay. We demonstrated that PAUF activates TLR4/MyD88 signaling pathway, but not TLR4/TRIF pathway.
Conclusions: In conclusion, for the first time this study demonstrates that TLR4 expressed on PC cell surfaces functions as a receptor of PAUF to mediate its metastasis-promoting effects, which are exclusively through the MyD88/NF-κB signaling pathway. This study also suggests TLR4 as a potential biomarker for identification of optimal patients, and a new therapeutic target to treat PC. Anti-PAUF antibody used in this study is currently evaluated by clinical trials in France, Spain, and US FDA.

KAT8/SIRT7-medicated fascin-K41 acetylation/deacetylation regulates tumor metastasis
Da-Jia Li[1], Yin-Wei Cheng[2], Li-Yan Xu[2], En-Min Li[1]. *[1]Department of Biochemistry and Molecular Biology, The Key Laboratory of Molecular Biology for High Cancer Incidence Coastal Chaoshan Area, Shantou, China,[2]Guangdong Provincial Key Laboratory of Infectious Diseases and Molecular Immunopathology, Institute of Oncologic Pathology, Cancer Research Center, Shantou University Medical College, Shantou, China*

Background: Although it is not expressed in the normal differentiated epithelial tissue of adult animals, fascin is highly expressed in a variety of cancers, including esophageal cancer, working as an important oncogenic protein. fascin promotes migration and invasion of cancer cells by binding F-actin to promote the formation of filopodia and invadopodia. However, it is not clear how exactly the function of fascin is systematically regulated in cancer cells. There are three regions on the surface of fascin protein that are significantly rich in positively charged lysine and arginine. These regions are now thought to be potential F-actin binding sites. We hypothesize that cancer cells may regulate the function of fascin by post-translational

modifications of key amino acids in these three regions, especially by acetylation. Based on this, this study aims to identify acetyltransferases that regulate the acetylation of fascin in esophageal cancer cells and reveal the effect of acetylation on the function of fascin.
Results: 1) Co-IP, pull-down, and immunofluorescence results showed that KAT8 interact with fascin and co-localize in esophageal cancer cells. 2) Mass spectrometry identification of the products of acetylation in vitro revealed that KAT8 acetylates fascin at K41 and K241. By means of Ack41-fascin specific antibodies, further analysis proved that KAT8 acetylated fascin K41. 3) Co-IP and immunofluorescence results showed that SIRT7 interact with fascin and co-localize in esophageal cancer cells, moreover, treatment of cells with SIRT7-specific inhibitor significantly increased the level of AcK41-fascin, and however, overexpressing SIRT7 reduces the level of AcK41-fascin. 4) Immunohistochemical results showed that the level of AcK41-fascin was lower in esophageal cancer tissues of patients with lymph node metastasis; Analysis of overall survival and tumor-free survival curves showed that patients with high levels of AcK41-fascin had a better prognosis. 5) Cell wound healing and transwell assay showed that fascin K41 residue mimics acetylation inhibit the movement and invasion of esophageal cancer cells. 6) Furthermore, in vitro F-actin binding assays showed that mutations mimicing acetylation of K41 inhibited the activity of fascin bunding F-actin. 7) Immunofluorescence assay showed that fascin K41 residue mimics acetylation inhibited fascin's ability to promote filopodia and invadopodia formation in esophageal cancer cells.
Conclusions: 1) KAT8 is an acetyltransferase that catalyzes fascin K41 acetylation in esophageal cancer cells, while SIRT7 decides to catalyze AcK41-fascin deacetylation. 2) SIRT7-mediated deacetylation of AcK41-fascin promotes the formation of filopodia and invadopodia, which promotes the invasion and metastasis of esophageal cancer cells. Effect of thrombomodulin and plasminogen interaction on melanoma spheroid invasion

Thi Kim Ngan Ngo, Hua-Lin Wu, Cheng-Hsiang Kuo, Ting-Yuan Tu.
National Cheng Kung University, Tainan, Taiwan

Background: Thrombomodulin (TM), a transmembrane glycoprotein that acts as a plasminogen (Plg) receptor, has been found as a potential molecular and prognostic marker that impacts the spread of various cancers, including malignant melanoma. A previous study showed that TM plays a vital function in angiogenesis activity [1] but its role in the malignant melanoma invasion is unclear. Here, we investigate the role of TM-Plg by using melanoma spheroid (MS) embedded in an extracellular matrix (ECM) modeled to understand how TM-Plg affects the progression of MS invasion.
Methods: In this work, A2058 (A2058-GFP and A2058-TMGFP) and MeWo (siC and siTM) MS with different TM expressions were formed, harvested, and embedded in type I collagen gel for invasion assay. TM and Plg expression were determined by western blot. The surface of A2058 MS was observed by SEM imaging. Human Plg, MMPs, and Plg inhibitors, tranexamic acid (TXA) and epsilon-aminocaproic acid (ε-ACA), were utilized to investigate the effect of TM on the plasmin system. Immunofluorescence of TM and F-actin were validated.
Results: When the two cell lines expressed with TM, the formed MS invaded to the surrounding matrix more distinctively than that of the TM-silencing ones, with a 2.5-fold difference in the ratio invasive area change. Upon placing the two A2058-TMGFP MS in the vicinity of each other within the ECM, they showed a strong interaction with an observed distance between the two MS from 50 μm to 280 μm. Immunofluorescence of TMGFP assessed the role of TM in MS invasion and interaction in ECM. Microvilli structures were found on the surface of A2058-TMGFP cells that may help the cell have more cellular processes such as adhesion, signal transduction, and metabolic activities. Furthermore, TXA, ε-ACA, and MMP inhibitors inhibited the invasion of A2058-TMGFP MSs in a dose-dependent manner. Human Plg stimulated invasion in TM-expressing MSs while no effect on non-TM MSs. The results suggested that the human Plg only significantly increased the MS invasion with the presence of TM.
Conclusion: We concluded that with the presence of TM, the MS invasion and interaction become stronger than MS without TM expression. Moreover, TM enhances MS invasion in the 3D model via interacting Plg. This study provides evidence for the development of TM antagonists in the

future to analyze the drug's potential as an anti-metastasis treatment.[1] P. K. Chen *et al.*, “Thrombomodulin functions as a plasminogen receptor to modulate angiogenesis,” *FASEB J.*, vol. 27, no. 11, pp. 4520-4531, 2013, doi: 10.1096/fj.13-227561.

3D model to study migration and invasion of lung cancer

Melina Hardt, Kurt Zatloukal, Helmut H. Popper. *Medical University of Graz, Graz, Austria*

Background: In 2D cell cultures, migration of tumor cells is characterized by epithelial-to-mesenchymal transition (EMT), whereby tumor cells loose epithelial and express mesenchymal markers and very often change into a spindle cell phenotype. In contrast to 2D cultures, in 3D cultures tumor cells do not lose their differentiation. Small cell lung cancer usually moves as single cells or in small clusters, squamous cell and adenocarcinomas preferentially move in large clusters of cells. In tissue specimen, all of these carcinomas migrate in a hybrid EMT, not loosing their cytokeratin and E-cadherin expression. In AC and SCC also polarity and specification do occur, as some tumor cells act as leaders, providing orientation for the followers. However, 3D culture system might better depict real migration and come closer to the *in vivo* system as 2D cell culture systems.
Material and Method: A 3D bioprinter (TissueLabs^{R}) was used to spot an alveolar-mimicking lung-specific matrix on cell culture wells. Microscopic channels out of pluronics^{R} are created within the matrix. Pluronics is removed by cooling, leaving empty channels within the protein matrix. These channels can be filled with different interleukins, such as IL23, which will direct migration of the tumor cells. Cultured cell lines from an adenocarcinoma (A549) and small cell carcinoma (NCI-H82) are layered on top of the matrix and migration into the matrix is studied using different time points.
Results and Discussion: A matrix simulating an alveolar structure was created with Matrigel^{R}. The A549 cells were seeded on the matrix and grown for 2,5, 10, and 14 days. The cells formed cell clusters on the matrix and after one week started to invade the matrix in cell complexes. By immunohistochemistry we could show, that the A549 cells retained their epithelial differentiation. The H82 cells showed a different behavior. They

did not form large clusters, but started to invade in small groups. The use of the bioprinter enabled us not only to create a 3D tumor culture system to simulate the *in vivo* conditions but also to create matrix structures for studying invasion and migration and to stimulate carcinoma cells with migration-activating substances.

Targeting tumor-brain crosstalk in invasive brain metastases

Caitlyn Mourcos[1], Sarah M. Maritan[1], Matthew G. Annis[2], Georgia Kruck[2], Alexander Nowakowski[2], Anna-Maria Lazaratos[2], Kevin Petrecca[3], Peter Siegel[2]. *[1]Division of Experimental Medicine, Goodman Cancer Institute, McGill University, Montreal, QC, Canada,[2]Faculty of Medicine and Health Sciences, Goodman Cancer Institute, McGill University, Montreal, QC, Canada,[3]Department of Neurology and Neurosurgery, McGill University, Montreal Neurological Institute and Hospital, Montreal, QC, Canada*

Background**:** An estimated 20-40% of cancer patients develop brain metastases (BrM), mostly those affected by lung cancer, breast cancer or melanoma. Unfortunately, these patients suffer from poor outcomes and diminished quality of life. Few BrM treatment options beyond local therapy exist and this is often a short-term solution as 60% of resected BrM recur within 1 year. Our group discovered that patient prognosis is linked to BrM invasiveness, with highly invasive (HI) BrM more likely to recur, compared to minimally invasive (MI) BrM. This has presented us the opportunity to investigate exploitable biological mechanisms driving HI BrM. For instance, invasive signaling can be driven by microenvironmental proteins such as growth and immunological factors (cytokines) secreted by surrounding brain or cancer cells, through inter-cellular or self-feeding autocrine loops.

Hypothesis: Considering the influence of secreted factors on cancer invasion and the brain microenvironment, I hypothesize that secretory profiling of BrM and brain parenchymal cells will be mechanistically insightful and help identify potential targetable drivers of BrM invasion.

Results: To identify BrM invasion-related tumor- and brain-derived factors, I performed human- and mouse-specific high throughput Enzyme-Linked Immunosorbent Assay (ELISA)-based screens on conditioned media from mouse brain slices harboring intracranial MI or HI BrM patient-derived

xenografts (PDX). This secretome screen reveals distinct MI and HI secretory profiles for melanoma, breast cancer and lung cancer BrMs and several HI BrM-derived factors of interest have been identified. Such factors are important to investigate as possible drivers of invasiveness in BrM through functional studies.
Conclusion: BrM patients currently face a bleak prognosis, with few treatment options and a median survival of only 8-16 months. Considering the clinical availability of targeted therapies including inhibitors for growth factor-binding tyrosine kinases, antibody-drug conjugates, and immunotherapy, this project will help elucidate the cancer-brain crosstalk which may be exploited therapeutically with existing drugs in patients with frequently recurring HI BrM. Investigating proto-oncogene PBF-induced cell migration and invasion
Merve Kocbiyik, Selvambigai Manivannan, Ling Zha, Katie Brookes, Martin L Read, Chris J McCabe, Vicki E Smith. *University of Birmingham (UK), Birmingham, United Kingdom*

The proto-oncogene pituitary tumor transforming gene binding factor (PTTG1IP/PBF) is overexpressed in multiple tumors and associated with tumor progression. PBF mediates several tumorigenic processes, including cell motility, whereby it potently induces cancer cell migration and invasion. PBF is phosphorylated by Src kinase at Y174 and mutation of this residue (Y174A) renders PBF unable to induce cell invasion, suggesting that phosphorylation mediates the stimulation of cancer cell motility by PBF. This study aimed to further elucidate the mechanism of PBF-induced cell motility. PBF-Y174 is also the key residue in a YXXΦ endocytosis motif. Both PBF phosphorylation and endocytosis were found to be essential for PBF-induced cell motility as mutants which disrupted either process were unable to stimulate thyroid and breast cancer cell migration and invasion. To elucidate molecular events downstream of PBF overexpression, phosphoproteomic and RNA-Seq analyses of normal thyroid cells (Nthy-ori 3-1) with stable PBF overexpression were performed and showed an enrichment in molecules involved in cell adhesion and cytoskeleton organisation. These findings prompted further investigation into a physiological role for PBF in cell motility. We utilised a novel Pbf

knockout ($Pbf^{-/-}$) mouse model generated through CRISPR/Cas9-mediated deletion of Pbf exon 4 in C57BL/6N mice to determine the impact of Pbf deletion on cellular mechanisms. Mouse embryonic fibroblasts (MEFs) were isolated at embryonic day 13.5 and used as primary cultures. $Pbf^{-/-}$ MEFs showed a significant reduction in migration and invasion compared with wild-type ($Pbf^{+/+}$) MEFs. Interestingly, the loss of one functional copy of Pbf in heterozygote MEFs ($Pbf^{+/-}$) resulted in an intermediate decrease in motility suggesting a gene-dosage effect. Initial immunofluorescent studies of $Pbf^{-/-}$ MEFs suggest alterations in focal adhesions (FAs). In $Pbf^{+/+}$ MEFs focal adhesion kinase (FAK) and paxillin staining highlighted FA structures that were normally elongated and aligned with actin stress fibers. In contrast, $Pbf^{-/-}$ MEFs demonstrated a significant reduction in FAK and paxillin staining with smaller, punctate and more radially distributed FAs. These studies demonstrate a physiological role for PBF in cell adhesion and migration and further elucidate the mechanism by which PBF induces cell motility in tumor progression.

Investigating a role for PIKfyve in cell migration and invasion of clear cell renal cell carcinoma

Jolène Cormier, Sandra Turcotte. *Chemistry and Biochemistry, Université de Moncton, Moncton, NB, Canada*

Introduction. Clear cell renal cell carcinoma (ccRCC) is the most frequent type of kidney cancer. These highly vascularized tumors are characterized by mutations that inactivate the von Hippel-Lindau (VHL) tumor suppressor gene. About 30 % of patients present metastasis at diagnosis and 30-40% of patients with localized tumors relapse after surgery. Unfortunately, metastatic ccRCC remains incurable and are resistant to standard therapies. Our studies demonstrated that ccRCC with a loss of VHL can be targeted using a small molecule named STF-62247. This molecule blocks the autophagic flux causing enlargement of endolysosomes leading to cell death. More recently, we identified the lipid kinase PIKfyve as a target of STF-62247. A central complex assuring the functionality of the lysosome is formed by the lipid kinase PIKfyve, the scaffold protein ArPIKfyve (Vac14), and the phosphatase **S**ac3 (Fig4). Interestingly,

PIKfyve has shown to play a role in cell migration but the mechanisms are not well understood.
Objectives. Our project aims to i) assess a role for PIKfyve in ccRCC migration/invasion, ii) evaluate the potential of PIKfyve inhibitors on angiogenesis, and iii) assess the effect of PIKfyve inhibitors or genetic knockdown of PIKfyve, Vac14 or Fig4 on tumor growth *in vivo*.
Methods and Results. PIKfyve, Vac14 and Fig4 gene expression were modified using CRISPR/Cas9 (Cr) or the SMARTvector^{TM} Inducible Lentiviral shRNA system. qRT-PCR and western blot validated our models. Results obtained in Cr.PIKfyve and Cr.Vac14 indicated that loss of Vac14 decreased survival of VHL-deficient ccRCC. Moreover, our recent results show that migration measured by wound healing assay is reduced in CRISPR cells compared to control. To investigate a role for PIKfyve in angiogenesis, tube formation assay was performed in treated cells with PIKfyve inhibitors. Our results indicated a reduction in tube formation in STF-62247 and apilimod treated cells. Furthermore, we will use the proteome profiler human angiogenesis array to identify angiogenic proteins linked to PIKfyve activity.
Conclusion. Understanding how PIKfyve is involved in the process of angiogenesis would play a major role in the knowledge for new targeted therapies inkidney cancer.

#3618
The role of endothelial ACKR1 in triple-negative breast cancer metastasis
Samuel Tanner Roach, Chinwe Ewenighi-Amankwah, J. Dufraine, L.A. Naiche, Jan K. Kitajewski. *Department of Physiology and Biophysics, University of Illinois at Chicago, Chicago, IL*

Metastasis is the most common cause of breast cancer mortality. Of the breast cancer subtypes, triple-negative breast cancer (TNBC) is the deadliest due to its increased likelihood to metastasize. Tumor cell extravasation is a critical step of metastasis and allows circulating tumor cells to exit the vasculature and seed distant tissues. Clear understanding of the major regulators of tumor cell extravasation will provide insights into the progression of TNBC metastasis. One potential regulator of TNBC cell extravasation is ACKR1. In many contexts, ACKR1 expression is required

in endothelial cells (EC) for leukocyte extravasation. Endothelial ACKR1 binds CXCL2, a promigratory chemokine, and localizes it to EC junctions to guide neutrophils through leukocyte extravasation. CXCL2 expression in TNBC cells is also necessary for tumor cell extravasation from lung microvasculature and for tumor metastasis. Our preliminary data show that ACKR1 is required in at least one stromal cell type for TNBC metastasis from the primary tumor to the lung. These data suggest that endothelial ACKR1-CXCL2 interactions may mediate tumor cell extravasation in TNBC metastasis. Therefore, we hypothesize that endothelial ACKR1 promotes metastasis via retention of CXCL2 at EC junctions, increasing tumor cell chemotaxis and extravasation. To address this hypothesis, we will examine the in vivo significance of endothelial ACKR1 expression using our validated ACKR1 endothelial cell-specific knockout mouse model. We will test the requirement for endothelial ACKR1 for metastasis of orthotopically implanted TNBC tumors to distant sites in the lung and for extravasation of circulating tumor cells into lung tissue. We will determine which steps of extravasation require ACKR1 by evaluating ACKR1-low and ACKR1-overexpressing ECs using an Ibidi flow co-culture system that recapitulates the shear stress conditions of pulmonary microvasculature. We will examine whether these steps are dependent on CXCL2 by introducing CXCL2-neutralizing antibodies to the Ibidi flow system and observing their effects on each extravasation step. Our proposed studies will establish the role of endothelial ACKR1 in TNBC metastatic progression and determine the specific steps of tumor cell extravasation in which endothelial ACKR1 and CXCL2 function. Understanding these processes may guide development of ACKR1 as a prognostic marker for metastasis and can provide mechanistic insight into candidate chemokine and chemokine receptor inhibitors under evaluation for treatment of breast cancer.

EP4 promoted cell migration via mitochondrial biogenesis in oral cancer cells

Soichiro Ishikawa[1], Masanari Umemura[2], Rina Nakakaji[2], Akane Nagasako[2], Kagemichi Nagao[2], Yuto Mizuno[1], Fumina Suzuki[1], Kohei Osawa[1], Mitomu Kioi[3], Kenji Mitsudo[3], Yoshihiro Ishikawa[2].
[1]Cardiovascular Research Institute (CVRI), Department of Oral and Maxillofacial Surgery, Yokohama City Univ. School of Medicine, Yokohama,

Japan,[2]Cardiovascular Research Institute (CVRI), Yokohama City Univ. School of Medicine, Yokohama, Japan,[3]Department of Oral and Maxillofacial Surgery, Yokohama City Univ. School of Medicine, Yokohama, Japan

Introduction: Lymph node metastasis caused by migration of oral cancer cells is an important prognostic factor. We previously reported that EP4, a prostaglandin E_2 (PGE_2) receptor, regulates the cell migration in oral cancer cells via Ca^{2+} signaling. However, how Ca^{2+} signaling regulates cell migration remains unclear. The intracellular Ca^{2+} regulates a variety of signaling pathways, either directly or by forming complexes with proteins such as calmodulin (CaM), and then phosphorylates calcium/calmodulin-dependent protein kinase kinase 2 (CaMKK2). Furthermore, Ca^{2+} signaling is directly or indirectly involved in cancer cell proliferation and migration. Therefore, we hypothesized that EP4 regulates the cell migration via CaMKK2 and its downstream signaling in oral cancer.
Materials and Methods: Human gingival fibroblasts, HGnF and Human tongue squamous cell carcinoma cell lines, HSC-3 were used. EP4 agonist (ONO-AE1-437) and CaMKK2 inhibitor (STO-609) were used. HSC-3 cells were transduced with CaMKK2 shRNA, and scramble control shRNA using lentivirus. The protein expressions were evaluated by western blotting. The intracellular calcium concentrations were measured using Fura-2, the Fluorescent Ca^{2+} Indicator. The cell migration ability was evaluated by scratch assay. Immunocytochemistry was performed to evaluate the lamellipodium. The mRNA transcriptions of the mitochondrial associated genes were evaluated by real-time qPCR. The intracellular adenosine triphosphate (ATP) production and the reactive oxygen species (ROS) production were also evaluated by luciferase activity assay and DCFH-DA staining.
Results: EP4 protein expression of HSC-3 cells was higher than that of HGnF cells (n=4, $p<0.001$). EP4 agonist rapidly increased the intracellular calcium in HSC-3 cells but not in HGnF cells (n=4, $p<0.001$). EP4 agonist also promoted the cell migration and increased the lamellipodia formation in HSC-3 cells (n=3, $p<0.001$). Furthermore, EP4 agonist promoted the phosphorylation of CaMKK2 and AMP-activated protein kinase (AMPK) (n=4, $p<0.001$). In contrast, CaMKK2 inhibitor and CaMKK2 knockdown

suppressed EP4-stimulated cell migration and AMPK phosphorylation (n=4, $p<0.001$). Furthermore, EP4 agonist increased the expression of the transcriptional coactivator PGC1-α, mtDNA and mitochondrial transcription factor A (TFAM) (n=4, $p<0.01$). Furthermore, EP4 agonist increased the intracellular ATP production and the ROS production (n=6, $p<0.01$). Taken together, EP4 regulated the mitochondrial biogenesis via CaMKK2 and AMPK, and promoted the cell migration in oral cancer. Conclusion: EP4/CaMKK2/AMPK pathway is a novel signal transduction in oral cancer and may be a new target for oral cancer therapy.

N-myristoylation inhibition reduces angiogenesis and cancer cell migration

Rony Pain[1], Erwan Beauchamp[2], Katia Carmine-Simmen[3], Jay Gamma[4], Rebecca Reif[1], Abul Azad[4], Allan Murray[4], John Lewis[3], Luc Berthiaume[1].
[1]Department of Cell Biology, University of Alberta, Edmonton, AB, Canada,[2]Pacylex Pharmaceuticals Inc., Edmonton, AB, Canada,[3]Department of Oncology, University of Alberta, Edmonton, AB, Canada,[4]Department of Medicine, University of Alberta, Edmonton, AB, Canada

Myristoylation is the modification of proteins by the 14-carbon fatty acid myristate. In humans, two N-myristoyltransferases (NMT1 and NMT2) catalyze myristate transfer onto >200 proteins to regulate membrane binding and signal transduction. The pan-NMT inhibitor PCLX-001 has been in phase I clinical trials over a year for the treatment of lymphoma and advanced solid malignancies. Lack of myristoylation promotes the degradation of numerous normally myristoylated proteins like the proto-oncogenic Src family kinases (SFKs). SFKs like Src and Lyn are essential for downstream signaling of Vascular Endothelial Growth Factor (VEGF) and Epidermal Growth Factor (EGF) receptor tyrosine kinases. Thus, SFKs are critical for angiogenesis and cell motility. Angiogenesis is essential for tumor growth and dissemination of cancer cells to distal locations. VEGF-induced angiogenesis requires Src activation, suggesting that PCLX-001 may have antiangiogenic properties. SFKs also promote cell migration/metastasis, the leading cause of cancer-associated mortality. Lyn SFK knockdown was shown to reduce breast cancer migration and

neighbouring tissue invasion, suggesting that PCLX-001 may also inhibit cell migration/metastasis. We investigated the antiangiogenic properties of PCLX-001 *in vitro* using HUVEC umbilical cord cells. PCLX-001 treatment significantly reduced HUVEC sprouting and tube-formation to levels lower than two FDA-approved angiogenesis inhibitors Sorafenib and Sunitinib. PCLX-001 also significantly reduced neo-vascularisation *in vivo* at lower concentrations than these two drugs using a chicken chorioallantoic membrane model, demonstrating the high potential of myristoylation inhibitors to reduce angiogenesis. We then validated our observations *in vivo* using a HT-1376 bladder mouse xenograft model. Tumors from mice treated for 28 days at increasing PCLX-001 concentrations showed significant reduction of Src, Lyn, and VEGF receptor protein levels as measured by immunohistochemistry, further validating PCLX-001 effect *in vivo*. We hypothesize that PCLX-001 acts downstream of VEGF/ EGF receptors by inducing degradation of un-myristoylated SFKs. We confirmed this by knocking down NMT1 or treating breast cancer cells with PCLX-001 and found that both significantly reduced SFK protein levels. In a wound-healing assay using PCLX-001, we observed significant dose-dependent cell migration inhibition. PCLX-001 also dose-dependently reduced migration and invasion in transwell migration/invasion assays, indicating that myristoylation is required for optimal migration and potentially cancer cell metastasis. Overall, by lowering SFK levels, PCLX-001 reduces angiogenesis, cell migration/invasion, and thus potentially cancer metastasis. Reducing these classical cancer hallmarks in malignant cells may benefit a wide array of cancer patients and ultimately improve cancer treatment outcomes.

Identification of podocalyxin-positive tumor buds in pancreatic ductal adenocarcinoma: Implications for solid tumor collective invasion

Erin M. Bell, Steve E. Kalloger, Pamela M. Dean, Janel L. Kopp, Kelly M. McNagny, Calvin D. Roskelley. *University of British Columbia, Vancouver, BC, Canada*

High expression of the single-pass transmembrane sialomucin, podocalyxin, has been shown to predict poor disease outcome in a number of solid tumor

types, including pancreatic ductal adenocarcinoma (PDAC) (Taniuchi et al., 2016). In addition to the classical TMN staging measures of disease progression (tumor size, lymph node involvement, and distant metastasis) local invasion at the primary tumor site is a valuable indicator of solid tumor progression. Local invasion has been observed histologically as tumor buds, defined by the presence of small cohesive clusters of tumor cells in the invasive tumor-stromal interface. To date, tumor budding has been characterized as an indicator of poor prognostic outcome in colorectal carcinoma (CRC), pancreatic ductal adenocarcinoma (PDAC), invasive ductal breast carcinoma (IDC), lung adenocarcinoma (LUA), stomach and esophageal carcinomas, oral squamous cell carcinoma, periampullary adenocarcinoma, and head and neck squamous cell carcinoma (HNSCC). Our group has previously modelled tumor budding experimentally using the MCF7 human breast cancer cell line (Graves et al., 2016). We showed that forced over-expression of podocalyxin was a driver of local collective invasion and tumor budding *in vitro* and *in vivo*. Because podocalyxin is highly expressed in PDAC we sought to determine if its expression was involved in the process of tumor budding in this tumor context as well. We assessed large format histological sections from a cohort of patient PDAC tumors and identified high podocalyxin expression in tumor buds. Further, we generated podocalyxin-null MiaPaCa2 PDAC cell lines and demonstrated that podocalyxin-expression is required for collective invasion in 3D culture conditions. We are currently evaluating *in vivo* xenograft tumor models with these podocalyxin-expressing and podocalyxin-null MiaPaCa2 cells to determine whether changes in 3D culture invasion are representative of tumor budding in this model. Expression of podocalyxin by tumor buds provides rationale to support investigation into the impact of therapeutically targeting these invasive cells.

Characterizing the metastatic potential and clonal dynamics of invasive subpopulations in TNBC cells in response to chemotherapy

Carolina De Santiago, Amy Brock. *University of Texas at Austin, Austin, TX*

Triple negative breast cancer (TNBC) is one of the deadliest forms of breast cancer and is characterized by its high rates of metastasis, significant intra-tumor heterogeneity and lack of hormonal treatments. Through utilization of a novel genetic cell tracking technology, ClonMapper, we identify and characterize the origins of invasive subpopulations.
Genetic barcodes are stably integrated into HCC1806 cells to generate starting parental populations of ~1000 unique barcoded cells. Invasive barcoded subpopulations were selected by migration through transwell assays for 24 hours and then collected for expansion. Clonal abundance sequencing across all replicates showed a >8-fold decrease in the number of unique barcodes. Similarity was quantified using the Bray-Curtis and Cosine similarity indexes. 5 out of 8 replicates shared the same lineages, where more than 50% of the replicates were composed of the same 9 unique barcodes thus indicating the pre-existence of invasive clones. Following cell subpopulation isolation, we observed that isolated subpopulations display faster growth rates than parental populations. A scratch assay verified that the 5 similar invasive subpopulations displayed elevated migration rates in this 2D migration format (invasive populations vs parental population, n= 6). Separate transwell assays also confirmed the 3-dimensional migration rates of isolated subpopulations.
Parental HCC1806 and invasive subpopulations were treated with doxorubicin, cisplatin, paclitaxel and 5-flourouracil (5-FU) at their respective LD50 for 48 hours then allowed to recover to confluency before assessment by scratch assay. We observed that paclitaxel significantly decreased the migration rate, but that both doxorubicin and 5-FU resistant cells had a significantly higher migration rate (chemoresistant populations vs parental population, n=5) indicating that these drugs select for more migratory populations. Future studies will elucidate whether invasive clones are pre-existing or de novo and determine the effect of chemotherapeutics on these populations.

#3623
MIEN1 promoter ablation provides novel evidence for colorectal cancer genome editing-based therapeutics
Payal Ranade, Rucha Trivedi, Jamboor K. Vishwanatha. *University of North Texas Health Science Ctr., Fort Worth, TX*

Colorectal cancer (CRC) is one of the leading causes of cancer associated mortalities worldwide. It starts with hyperproliferation of epithelial cells forming a polyp & is characterized by four stages, where stages 3 & 4 are associated with acquisition of metastasis. Chemotherapy majorly focuses on attenuating symptoms with no promising cure. Hence, studying the underlying mechanism of CRC progression & identifying novel therapeutic targets is critical for early diagnosis & treatment. The process of metastasis involves a complex interplay of signaling pathways, where various proteins play crucial roles. One such important protein that aids the process of migration is Migration & Invasion ENhancer 1 (MIEN1). In CRC, MIEN1 expression is predominantly upregulated in cancerous tissue in comparison to normal colorectal tissue, which is closely associated with invasive behavior. But the exact mechanism involved in the process of metastasis is yet unexplored. It is established that MIEN1 overexpression is a result of 17q12 chromosomal amplification, & such dysregulated expression is linked to the trans-regulation of its minimal promoter region. Therefore, we aim to investigate the effect of MIEN1 promoter ablation on CRC migration properties. CRISPR-Cas9 gene editing technology was used for deleting MIEN1 promoter region in the CRC cell line HT29. RNA seq & bioinformatics tools were employed to assess the transcriptomic consequences of genome-editing. Several DEGs discerned by RNA seq analysis were involved in different biological processes & molecular pathways such as cell adhesion, migration, invasion, & angiogenesis. Out of these the genes vital to CRC biogenesis were evaluated at both RNA & protein levels. Additionally, we analyzed the effect of MIEN1 knock-out on CRC metastatic potential using functional assays such as wound healing, Matrigel invasion, hanging drop cell - cell adhesion, & found that migration potential of HT29 cells was significantly reduced in absence of MIEN1 protein. We also successfully demonstrated that MIEN1 deletion disrupts the cytoskeletal rearrangement by affecting F-actin reorganization using phalloidin staining. Confocal staining of different proteins participating in actin cytoskeleton rearrangement such as paxillin, FAK, MIEN1 gave us an insight about the role of MIEN1 in mediating phosphorylation of FAK at different phosphorylation sites such as Tyr 397 & 925. Immunoblotting analysis of an array of proteins further confirmed the role of MIEN1 in actin cytoskeleton dynamics. Taken together, our results prove that MIEN1 is involved in different signaling pathways responsible for CRC migration

& its deletion leads to perturbation of several biological processes especially the actin cytoskeleton rearrangement, involved in metastasis. Hence, targeting MIEN1 would be a potentially effective therapeutic strategy for CRC patients.

Signaling Pathways That Impact the Tumor Microenvironment

#3627
Inhibition of tumor cell-autonomous p38 MAPK suppresses IL1α-mediated inflammatory tumor-stromal crosstalk in pancreatic adenocarcinoma

Samara Singh, Austin R. Dosch, Siddharth Mehra, Iago de Castro Silva, Anna Bianchi, Vanessa Tonin Garrido, Zhiqun Zhou, Haleh Amirian, Edmond W. Box, Jashodeep Datta, Nagaraj Nagathihalli, Nipun B. Merchant. *Surgery, University of Miami Miller School of Medicine, Miami, FL*

Introduction: Pancreatic ductal adenocarcinoma (PDAC) continues to face major therapeutic challenges due to its innate and acquired chemoresistance. Oncogenic, activating *KRAS* mutations facilitate extensive cytokine-mediated crosstalk between tumor cells and the fibrotic stroma, producing a pro-inflammatory and immunosuppressive tumor microenvironment (TME). We have identified interleukin-1α (IL1α), downstream of KRAS, as a critical mediator of the inflammatory response due to its pleiotropic effects on cancer-associated fibroblast (CAF) activation and immune evasion. However, the regulatory mechanisms of IL1α expression remain incompletely understood. We identified p38 stress-associated MAPK α (p38α) as a central, KRAS-driven regulatory pathway involved in IL1α production within PDAC tumor cells.
Methods: Differential gene expression analyses were performed on patient data from The Cancer Genome Atlas (TCGA) was queried for overactive pathways downstream *KRAS* in "high-*IL1A*" PDAC cases. Inhibition of p38α was achieved pharmacologically with pexmetinib and genetically with an shRNA lentiviral system in human and murine PDAC cell lines. ChIP-qPCR and co-immunoprecipitation were performed on a human PDAC cell line with and without p38α inhibition. Single-cell RNA sequencing (scRNA-seq) and flow cytometry were performed on tumors from a PDAC

murine model, *Ptf1a*$^{Cre/+}$; *LSL-Kras*$^{G12D/+}$; *Tgfbr2*$^{flox/flox}$ (PKT), treated with or without pexmetinib. PKT mice were treated daily with pexmetinib, gemcitabine and paclitaxel chemotherapy, or combination therapy for downstream analysis and survival studies.
Results: Both pharmacologic and genetic inhibition of p38α significantly reduced *IL1A* transcription and protein levels in human and murine PDAC tumor cell lines. Furthermore, p38α inhibition reduced binding of Sp1 and NF-κB to the *IL1A* promoter and prevented IL1α-mediated polarization of inflammatory CAFs *in vitro*. In PKT mice, p38α inhibition reduced tumor cell-specific *Il1a* and inflammatory CAF gene signatures by scRNA-seq, and favorably altered the infiltrating immune populations by flow cytometry. Lastly, pexmetinib with chemotherapy significantly reduced tumor burden and improved overall survival in a PDAC murine model.
Conclusions: These findings provide a new therapeutic opportunity to target the p38α MAPK pathway for suppression of IL1α-mediated stromal activation and combination with chemotherapy to overcome therapeutic resistance by modulating the stromal and immune microenvironment in PDAC.

RAC1 aberrations in head and neck cancer affect immune microenvironments
Helen Hoi Yin Chan[1], Yuchen Liu[1], Hoi Lam Ngan[1], Vivian Wai Yan Lui[2].
[1]Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong,[2]Department of Medicine, Medical College of Georgia, Georgia Cancer Center, Augusta University, GA

RAC1 is a Rho GTPase well-identified as an oncogene overexpressed in various cancer types. *RAC1* amplification or gain account for ~40% of head and neck squamous cell carcinoma (HNSCC) while mutation of *RAC1* occurs at ~3% according to TCGA-HNSCC cohort. HNSCC patients with *RAC1* aberrations, including *RAC1* mutations and amplification or gain, are associated with poor overall and disease-free survival in HNSCC. Significantly higher tumor mutational burden is observed in *RAC1*-mutated group (p=0.0336) or in *RAC1*-amplified/gain group (p=0.0109) vs. wildtype patients in TCGA-HNSCC cohort. As increases in TMB are often associated with immune cell infiltration in cancers, we hypothesized that

RAC1 aberrations impact the tumor immune microenvironment (TIME) of HNSCC, potentially contributing to disease progression.PD-L1 (CD274) is an important immunosuppressive immune checkpoint molecule expressed in tumor cells. Here, we first reported that ectopic overexpression of *RAC1* p.P29S and p.A159V mutations in a human HNSCC cell line (PECAPJ41 clone D2, ATCC, USA) could cause upregulation of PD-L1 at both mRNA (by RNA-seq) and protein levels (by Western blotting), first demonstrating a direct effect of *RAC1* mutations on potential HNSCC TIME modulation via PD-L1. Furthermore, by tumor immune estimation resources (TIMER) analysis, we found that *RAC1*-mutated tumors have significantly higher level of neutrophils immune infiltration of 38.63% (p=0.027) compared to the wildtype tumors. From the CIBERSORTx analysis, M2 Macrophages was significantly increased by 40.42% in *RAC1*-mutated tumors vs wildtype in the TCGA-HNSCC cohort (p=0.031). We also validated this finding by immunofluorescent staining of PD-L1 and M2 Macrophages in immunocompetent mouse HNSCC xenografts models expressing *RAC1* p.P29S and p.A159V mutations as compared to controls.
Our in silico, in vitro and in vivo findings first uncover an important role of *RAC1* aberrations in HNSCC TIME immunosuppression by regulating PD-L1 expression, neutrophil and M2 macrophages infiltrations. Clinical activities of PD-L1 inhibitors in *RAC1*-mutated HNSCC patients worth future investigations.

Calcium signalling and the breast cancer microenvironment

Alice H. L. Bong[1], Krystyna A. Gieniec[2], Francisco Sadras[1], Mélanie Robitaille[1], Sarah J. Roberts-Thomson[1], Felicity M. Davis[3], Gregory R. Monteith[1]. *[1]School of Pharmacy, The University of Queensland, Brisbane, Australia,[2]School of Medical Sciences, The University of New South Wales, Sydney, Australia,[3]Department of Biomedicine, Aarhus University, Aarhus, Denmark*

Calcium is a key regulator of a variety of pathways important in breast cancer progression, including those involved in cell proliferation and invasiveness. Calcium signaling is implicated in processes relevant to the breast cancer tumor microenvironment and altered calcium influx is a feature of cancer associated fibroblasts. In these studies, simultaneous use of genetically encoded calcium indicators with distinct fluorescence spectral properties (GCaMP6m or JRCaMP1b), were used to explore the cross-talk between breast cancer cells and fibroblasts via calcium signaling and changes in different cellular compartments. HMF3S human fibroblast cells co-cultured with breast cancer cells expressing GCaMP6m or JRCaMP1b were assessed in 2D and 3D co-culture using automated epi-fluorescence or confocal microscopy. Mitochondrial calcium levels were assessed using targeted GCaMP6m (2mtGCaMP6m) in HMF3S cells expressing JRCaMP1b. Results showed distinct spatial and temporal changes in free calcium levels between both fibroblasts and breast cancer cells and the mitochondria and cytosol during activation. These methodological advances provide an opportunity to better understand calcium signaling in cancer associated fibroblasts. These techniques will also help identify the calcium channels and pumps that could be targeted to manipulate the breast cancer tumor microenvironment to inhibit pathways important in breast cancer progression.

#3630

TrkA+ sensory neurons modulate macrophage phenotype in osteosarcoma

Qizhi Qin, Sowmya Ramesh Ramesh, Thomas L. Clemens, Aaron W. James. *Johns Hopkins University School of Medicine, Baltimore, MD*

Introduction: Osteosarcoma (OS) is the most common primary malignancy of the skeleton, and inordinately affects young adults. Despite improved outcomes with current multimodal care, the prognosis for patients with metastatic disease is grim. Peripheral neural regulation of cancer growth has long been suggested by clinical observations in pancreatic and prostate cancers. Prior reports suggest peripheral nerve sprouting in osteosarcoma, but the functional roles of sensory nerves in osteosarcoma are unknown. Here, the role of $TrkA^{+}$ sensory nerves in OS disease progression was assayed.

Methods: All experiments were conducted under IACUC approval at Johns Hopkins University. $TrkA^{F592A}$ mice which are homozygous for a phenylalanine-to-alanine point mutation in exon 12 of *Ntrk1* gene were crossbred with NOD scid mice ($TrkA^{F592A}$/Scid). TrkA inhibition was performed by 1NMPP1 treatment. *In vivo* tumor growth was examined using a periosteal xenograft model. 1 million human 143B-luc OS cells were injected. Analysis was performed using serial measurements of tumor size and IVIS imaging. Nerve distribution and macrophage polarization within the tumor microenvironment was documented using immunostaining for Beta III Tubulin (TUBB3), CD86, CD206 and F4/80.
Results: Inhibition of TrkA led to a significant reduction in $Tubb3^{+}$ nerves (88.4%) within and around the OS xenografts. In addition, tumors within $TrkA^{F592A}$/Scid animals demonstrated slower growth, including a 51.5% reduction in tumor size and 60.0% reduction in IVIS luciferase activity at 4 wks. Histologic examination showed a reduction in macrophage infiltration and reprogramming of macrophages from an M2-like to M1-like phenotype in tumors with chemical denervation. Remarkably, this was associated with a reduction in Ki67 proliferative index (80.1%) and CD31 immunofluorescent staining (60.8%) within the tumors. Overall survival of mice with TrkA inhibition was significantly prolonged (p=0.0003). Retrograde tracing identified the sensory nerve fibers innervating the periosteum originated from L3-L5 lumbar DRGs and RNA seq identified OS-derived neurotrophins and axon guidance molecules.
Discussion: Disruption of $TrkA^{+}$ nerves significantly mitigates OS disease progression in a mouse xenograft model, including a significant improved overall survival. These findings are associated with a reduction of macrophage infiltration and macrophage re-polarization. Ongoing studies are examining the molecular mechanisms that mediate nerve-to-macrophage interaction in peripheral nerves and DRG neurons using a combination of sequencing approaches.
Significance/Clinical Relevance: Sensory neurons positively regulate osteosarcoma growth and disease progression. Use of chemical or microsurgical approaches to denervate tumors may represent a future adjunctive therapy to both improve pain and prognosis in high grade bone sarcomas.

#3631

Infiltrating Bruton's tyrosine kinase expressed B cells effects on prostate cancer metastasis

Crystal Byrd, Geou- Yarh Liou. *Clark Atlanta University, Atlanta, GA*

Prostate cancer is the most common type of cancer found in senior males and is the 2nd leading cause of cancer death in American males. Although prostate cancer grows slowly within the prostate glands, because of a lack of efficient treatments at the appropriate timing, cancer cells eventually become aggressive and metastatic. The progression of cancer is supported by many factors, such as signals received from surrounding cells, like B cells and other effector cells. B cells play a role as a part of the adaptive immune system to produce antibodies. To become mature B cells, they rely on activation of a non-receptor kinase, Bruton's Tyrosine Kinase (BTK). Preliminary data from our lab showed that in the prostate cancer tissues, more infiltrated B cells expressing BTK were present nearby the prostate cancer cells. Upon this finding, we hypothesize that BTK expressed B cells will support the survival of prostate cancer cells through BTK signaling. In this study, we will overexpress BTK in B cells to study the proliferation and migration of prostate cancer cells through a co-culture system. Our findings will show an increase in migration of prostate cancer cells when cultured with BTK expressed B cells. In the future, we will validate the importance of BTK in regulating prostate cancer migration and invasion; and identify their mechanisms. Our overall findings from this project would reveal key elements of the signaling pathways of BTK expressed B cells to promote prostate cancer migration.

#3633

Exploring a novel crosstalk between hyluronan/CD44 and ErbB-2 pathways in resistance to ErbB-2-targeted therapies in breast cancer.

Santiago Madera, Valentina C. Bulian, Sharon S. Merin, María F. Mercogliano, Roxana Schillaci, Rosalia I. Cordo Russo. *Instituto de Biología y Medicina Experimental (IBYME), CONICET, Buenos Aires, Argentina*

The tumor microenvironment component hyaluronan (HA) induces tumor progression through the interaction with its cell surface receptor CD44. Accumulation of HA is associated with poor prognosis and resistance to the

anti-ErbB-2 agent trastuzumab (TZ) in breast cancer (BC). ErbB-2 receptor is overexpressed in 15-20% of BC patients (ErbB-2+) and constitutes an important therapeutic target. Despite the clinical efficiency of therapies targeting ErbB-2, resistance to these drugs remains a major issue. In addition to its membrane function, ErbB-2 migrates to the nucleus (NErbB-2) where it acts as a transcription factor (TF) or as a coactivator of TF, modulating proliferation, metastasis, and resistance to anti-ErbB-2 therapies in BC. CD44 has also been found in the nucleus (NCD44). Although crosstalk between HA/CD44 and ErbB-2 pathways has been reported, how their molecular interactions mediate TZ resistance remains poorly known. Our *in silico* studies showed that TZ-resistant cells express higher CD44 levels than TZ-sensitive ones. We previously reported that stimulation with the ErbBs ligand heregulin (HRG) induces NErbB-2 translocation, acquired-TZ resistance and proliferation in the TZ-sensitive SK-BR-3 cell line. Here, we found that HRG also increased CD44 mRNA expression in SK-BR-3 cells. Then, we explored the role of HA in modulating CD44 and ErbB-2 nuclear localization in BC cells. Immunofluorescence and confocal microscopy studies showed that stimulation with exogenous HA induced nuclear translocation of ErbB-2 in T47D cells. Interestingly, we found constitutive presence of CD44 and ErbB-2 protein in nuclear lysates of JIMT-1 cells, a *de novo* TZ-resistant BC model. HA stimuli further enhanced this nuclear localization. Contrarily, treatment with the chemical inhibitor of HA synthesis 4-methylumbelliferone (4MU) decreased not only HA levels but also NErbB-2 in JIMT-1 cells. Furthermore, 4MU inhibited the proliferation of two TZ-resistant cell lines, JIMT-1 and MDA-MB-453, in a dose-dependent manner. 4MU also inhibited HRG-induced proliferation in SK-BR-3 cells. Even more, wound-healing assays showed that 4MU inhibited migration of JIMT-1 cells. This inhibition was similar to the one observed when ErbB-2 was excluded from the nucleus via transfection with the hErbB-2ΔNLS mutant. In summary, we reveal that HA induces CD44 and ErbB-2 nuclear localization in BC cells, suggesting a novel crosstalk between HA/CD44 and ErbB-2 pathways. These findings also highlight the blockade of HA synthesis with 4MU as a novel therapeutic strategy in TZ-resistant BC.

Overexpression of PLK1 activates IL4/JAK/STAT6 signaling in prostatic tumor-microenvironment

Ruixin Wang, Xiaoqi Liu. *University of Kentucky, Lexington, KY*

The correlation between PLK1 expressions with prostate cancer (PCa) stages was identified by analyzing the transcriptome profile of PLK1 in patients from the Cancer Genome Atlas (TCGA) database, and scoring the protein expression in a clinical tissue microarray (TMA) cohort. Integrating our prostate-specific PLK1 knock-in mouse model, we established an oncogenic role for PLK1 in PCa progression. To elucidate the underlying mechanism, we investigated the impact of PLK1 overexpression on prostatic tumor microenvironment (TME) *in vivo*. In addition, *in vitro* co-culture systems with both epithelial cells and macrophages were designed to uncover the regulatory function of PLK1 in macrophage polarization. We found that PLK1 induces phosphorylation of JAK3, activates the JAK/STAT6 pathway in cancer cells, and increases the secretion of IL4, which enables macrophage polarization towards the M2 phenotype in TME —ultimately accelerating PCa development. Finally, pharmaceutical inhibition of STAT6 signaling significantly reverses the PLK1-mediated M2 polarization and, subsequently, inhibits the progression of PCa. Our findings provide clinical and pre-clinical evidence to characterize the role of PLK1 in promoting PCa and novel insights into the regulatory mechanism of PLK1 in the TME. We also provide strong support for the clinical potential of targeting STAT6 for advanced PCa therapy.

TBK1 inhibition potentiates the efficacy of AXL-targeted therapy by modulating tumor microenvironment in aggressive breast cancers

Lan Phi[1], Takashi Semba[1], Ngu V. Trinh[1], Fang Zou[1], Jason M. Foulks[2], Steven L. Warner[2], Savitri Krishnamurthy[3], James P. Long[4], James M. Reuben[5], Jennifer M. Rosenbluth[6], Debu Tripathy[1], Naoto T. Ueno[1], Xiaoping Wang[1]. *[1]Breast Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Sumitomo Pharma Oncology, Inc., Lehi, UT,[3]Pathology, UT MD Anderson Cancer Center, Houston, TX,[4]Biostatistics, UT MD Anderson Cancer Center, Houston, TX,[5]Hematopathology, UT MD Anderson Cancer Center, Houston,*

TX,[6]Department of Medicine, University of California San Francisco, San Francisco, CA

Introduction: Triple-negative and inflammatory breast cancer (TNBC and IBC) are the most aggressive breast cancer subtypes. Novel actionable targets and complementary therapies are critically needed. AXL, a receptor tyrosine kinase, drives pleiotropic phenotypes of TNBC and IBC aggressiveness. Targeting AXL reduces IBC tumor growth *in vivo* and inhibits polarization of M2 macrophages. To identify novel tumor microenvironment (TME) targets to enhance the efficacy of AXL-targeted therapy, we conducted a synthetic lethal kinome siRNA screening. We identified TBK1 as a candidate to synergize with AXL growth inhibition. TBK1 is a serine/threonine protein kinase that regulates innate, adaptive responses and antitumor immune responses. We hypothesized that inhibition of TBK1 enhances the antitumor effect of AXL-targeted therapy in aggressive breast cancers.
Methods: We used knockdown, knockout (KO) and inhibitors to suppress AXL and TBK1 pathways and tested the synergistic effect of targeting AXL and TBK1 on the growth of human SUM149 and BCX010 IBC cells, and HS578T TNBC cells *in vitro*. To determine the synergistic effect of targeting both pathways *in vivo*, we inoculated control or TBK1 KO murine TNBC 4T1.2 cells into BALB/c mice. We assessed the activity of AXL inhibitor TP-0903 in reducing tumor growth. Using multicolor flow cytometry, we studied the effects of targeting AXL and TBK1 on the TME. We tested the activity of TP-0903 combined with a TBK1 inhibitor in another TNBC mouse model, E0771. We used RNA-sequencing and real-time PCR/Western blot to determine the molecular mechanisms of how TBK1 inhibition synergizes AXL-targeted therapy in these cancers.
Results: Compared with AXL or TBK1 suppression alone, genomic or pharmacologic suppression of AXL and TBK1 significantly reduced the growth of SUM149, BCX010, and HST578T cells *in vitro*. In both 4T1.2 and E0771 syngeneic mouse models, TP-0903 was more active in reducing tumor growth in TBK1-inhibited tumors than in control tumors. Tumors with TBK1 inhibition and treated with TP-0903 had a significantly higher population of cytotoxic T cells than control tumors. Depletion of CD8+ T cells blocked the synergistic effect of targeting AXL and TBK1 pathways on reducing tumor growth, suggesting that cytotoxic T cells contributed to

the anti-tumor synergy of targeting AXL and TBK1. Mechanistically, TBK1 induced M2 macrophage migration via IRF3-regulated CCL5 secretion in SUM149 and HS578T cells, and AXL KO attenuated the polarization and migration of M2 macrophages by inhibiting the CCR5/CCL5 axis. Conclusions: Targeting TBK1 enhances the efficacy of AXL-targeted therapy in aggressive breast cancer by suppressing the paracrine effect of CCR5/CCL5 axis. This combination represents a novel and effective therapy modulating the TME of aggressive breast cancer, which warrants further investigation in the clinical setting.

Liver endothelium secreted LRG1 promotes metastatic colorectal cancer growth through the HER3/RSK/EIF4B AXIS

Moeez Ghani Rathore[1], Michelle Wright[1], Wei Huang[2], Derek Taylor[3], Yamu Li[1], Jordan Winter[1], Zhenghe Wang[1], John Greenwood[4], Stephen Moss[4], Rui Wang[1]. *[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]Pharmacology, Case Western Reserve University School of Medicine, Cleveland, OH,[3]Department of Biochemistry, Case Western Reserve University School of Medicine, Cleveland, OH,[4]University College London, London, United Kingdom*

Background: 25% of patients diagnosed with colorectal cancer (CRC) have liver metastasis at presentation, and ~80% of all metastatic CRC are developed in the liver. We previously reported that liver endothelial cells (ECs), a key component of the liver microenvironment, secrete LRG1 to promote CRC growth via activating human epidermal growth factor receptor (ERbB3, also known as HER3). However, we found that LRG1-induced HER3 activation is distinct from the canonical neuregulin 1 (NRG1)-induced HER3 pathway. The present study further validated LRG1 as a new HER3 ligand for promoting mCRC growth and elucidated the novel downstream signaling pathway induced by LRG1-HER3.
Methods: We first measured the binding affinity between HER3 and LRG1 by Biolayer interferometry (BLI). We then used *in vitro* and *in vivo* xenograft approaches to determine the effect of LRG1 monoclonal antibody (15C4) on HER3 activation and CRC growth. To further determine the role of LRG1 in promoting CRC growth in the liver, we used murine CRC cells in a syngeneic orthotropic liver injection model to establish CRC allografts

in the liver of $LRG1^{-/-}$ mice with systemic LRG1 knockout and wild-type siblings ($LRG1^{+/+}$). We also performed unbiased phospho-MS analysis and subsequent validations to determine the downstream signaling pathway activated by LRG1-HER3.
Results: We identified that LRG1 binds to HER3 with the affinity at ~100nM. The LRG1 antibody 15C4 completely attenuated LRG1-induced HER3 activation and *in vitro* and xenograft growth *in vivo*. Moreover, $LRG1^{-/-}$ mice with CRC allografts in the liver had 2 times longer overall survival than tumor-bearing $LRG1^{+/+}$ mice. Lastly, unbiased -omics analysis identified eIF4-protein synthesis is significantly activated by LRG1. With target-specific inhibitors, we further determined that LRG1-HER3 activates the PI3K-PDK1-RSK1/3-eIF4 axis independent of AKT.
Conclusions: We identified LRG1 as a novel HER3 ligand and demonstrated that the liver microenvironment-derived LRG1 plays a key oncogenic role in mCRC, by activating a novel RSK-eIF4 survival pathway. Our findings highlighted the potential of blocking LRG1-HER3 and involved downstream pathways for treating patients with mCRC.

Extracellular matrix drives high-grade breast cancer immune suppression down-modulating PD-1 on Treg cells via the IL-23/SATB1 axis

Giovanna Talarico[1], Mara Lecchi[2], Massimo Costanza[3], Claudia Chiodoni[2], Vera Cappelletti[2], Paolo Verderio[2], Massimo Di Nicola[2], Francesco Bertolini[1], Mario Paolo Colombo[2], Sabina Sangaletti[2]. *[1]European Institute of Oncology, Milan, Italy,[2]IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[3]Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy*

The pathological grade defines tumor aggressiveness and, indeed, high-grade breast cancer (HGBC), regardless of molecular findings, is characterized by a very aggressive clinical course and a poor prognosis in spite of the availability of chemotherapy regimens and specific-targeted agents. Both the cellular and the extracellular compartments of the tumor microenvironment (TME) can contribute to the evolution of BC by immune escape and immune suppression processes. In this context, structural and extracellular components of the TME, namely the extracellular matrix

(ECM), has been shown to contribute to many aspects of tumor progression, exerting important regulatory functions on tumor cells. The relevance of the ECM in cancer progression is strengthened by study showing that the ECM composition is a prognostic factor able to identify patients subgroups endowed with a different clinical outcome according to the distinct enrichment in ECM genes leading to four specific ECM signatures (ECM 1-4). Among the different ECM-related signatures, only the ECM3 signature - characterizing about 35 % of HGBC - identifies the most aggressive tumors with epithelial mesenchymal transition (EMT) features, poor prognosis, T-cell exclusion and an increased infiltration of myeloid-derived suppressor cells (MDSCs). To evaluate whether local immune suppressive features of ECM3+ tumors can be intercepted in the peripheral blood (PB), to represent a potential biomarker for this subset of tumors, we collected consecutive HGBC patients that included 22 ECM3+ and 30 ECM3- and performed a multiparametric flow cytometry analysis. We found PD-1^{neg} Treg being correlated to ECM3 patients and through ad hoc mouse BC models, we provided the mechanisms through which SPARC, a key functional gene of the ECM3 signature, was responsible for the down-modulation of PD-1 on Treg, positively affecting their suppressive activity. By sustaining the release of IL-23, SPARC promotes SATB1 expression that repress PD-1. Notably, fluvastatin treatment in vivo decreased the expression of SATB1 in treated Treg cells, a result paralleled by an increased expression of PD-1 on Treg cells. Our data extend the regulatory activity of the extracellular matrix and SPARC, which are large characterized for myeloid cells, to regulatory T-cells also offering new possible targets for the treatment of high-grade breast tumors.

Integrated single-cell and spatial analysis reveal the mechanism of KRAS^{G12C} inhibitor AMG510 in HSC-humanized NOG-EXL model

Panpan Wang, Huacheng He, Jingjing Wang, Ting Ni, Dan Lu, Qiangqiang Fan, Wenting Shi, Qingyang Gu, Qiyao Zhang. *Oncology & Immunology Unit, WuXi Biology, WuXi AppTec, Shanghai, China*

Background: Intra-tumor heterogeneity is one of the biggest challenges in cancer treatment today. Current single-cell RNA sequencing technologies itself could enable the exploration of gene expression heterogeneity at the

single cell level, but they cannot require the morphological information within the tumor, nor the protein profiles of individual cells. Spatial transcriptomics (ST) is an in situ RNA capturing technique which preserved the spatial information of histological tissue section, and CITE-Seq is a method to preform scRNA sequencing along with acquiring protein information on a single cell level. Combining CITE-Seq and ST together can enable us to understand the roles of specific cell subpopulations and their interactions in tumor microenvironment at RNA, protein and spatial level at the same time. KRAS is the most frequently mutated oncogene in human cancer, and AMG510 is a small covalent specific $KRAS^{G12C}$ inhibitors by blocking KRAS in its GDP-bound state, which leads to the regression of tumors and improved the anti-tumor efficacy. But the intrinsic mechanism of AMG510 in $KRAS^{G12C}$ mutant non-small cell lung cancer (NSCLC) is not fully understood. Therefore, we develop a multi-omics method to find the mechanism of $KRAS^{G12C}$ inhibitor AMG510 in NSCLC.
Material and Method: We established a NSCLC HSC-humanized NOG-EXL model, treated it with vehicle and AMG510, and collected 3 tumor tissues from each group. Samples were processed and cDNA library of CITE-seq were constructed based on the protocol of TotalSeq-B Human Universal Cocktail (BioLegend) and Single Cell 3' Reagent Kits v3.1 (10x Genomics). Spatial sample preparation and cDNA library generation was carried out following the user guide of Visium FFPE Spatial Gene Expression Reagent Kits (10X Genomics). All the final libraries were sequenced by NovaSeq platform. After obtained feature-cell/spot matrix, data preprocessing and analysis were performed in R environment. Cell components in the tumor microenvironment were annotated by a cross-validated multi-approaches using CITE-seq data. And ST data were further analyzed by integrating CITE-seq data.
Results: Using a multi-omics analysis system, firstly, we constructed a single-cell transcriptomic atlas of NSCLC tumor microenvironment; and then explored the characterization of cell-type infiltration. Furthermore, CITE-seq and ST datasets were integrated to assess the spatial organization of infiltrated immune cells and tumor cells. We found how AMG510 affected tumor microenvironment and enhanced the checkpoint pathways. The results in return proved the reliability of the multi-omics system, which enables us to explore how drugs treat cancer by affecting its microenvironment in multiple levels.

Summary: We established a multi-omics analysis system and explored the mechanism of the $KRAS^{G12C}$ inhibitor AMG510 against the NSCLC.

Impact of KRAS oncogenic signaling in tumorigenesis and immune evasion driven by extracellular vesicles (EVs)

Zulaida M. Soto Vargas, David C. Arteaga, Ikjot S. Sohal, Humna Hasan, Andrea L. Kasinski. *Biology, Purdue University, West Lafayette, IN*

Mutations in Kristen rat sarcoma homolog (KRAS) occur in about 25% of cancers, making this protein one of the most frequently altered genes in cancer. KRAS mutations are not only associated with poor patient survival, but also with increased tumor aggressiveness and metastasis. Tumor development and metastasis are impacted by intercellular communication. Key mediators of cell-to-cell communication include vesicles secreted by cells, also known as extracellular vesicles (EVs). EVs released by cancer cells can mediate malignant transformation of non-cancerous cells as well as influence pre-metastatic niche formation. Conversely, inhibiting the secretion and release of EVs by cancer cells decreases tumor growth and metastasis. However, the mechanisms through which EVs drive tumorigenesis in KRAS mutant tumors are still understudied. Our lab recently reported that EVs from lung cancer cells drive invasion of non-tumorigenic lung epithelial cells. Here, we found that KRAS oncogenic signaling in the donor cells contributes to the EV-driven migration and invasion of non-tumorigenic lung epithelial cells. Previous studies have demonstrated that KRAS signaling drives immune evasion and promotes an "immune cold" tumor microenvironment. Our preliminary studies showed that EVs derived from $Kras^{G12C}$ lung cancer cells (H358) inhibit T cell proliferation and that blocking $KRAS^{G12C}$ signaling, using ARS-1620 ($Kras^{G12C}$ inhibitor), impairs EV-driven T cell immunosuppression. We performed a comprehensive proteomic comparison between EVs isolated from H358 treated with ARS-1620 and those isolated from cells treated with DMSO (vehicle) and identified proteins involved in migration and invasion, such as LAMB-3, to be downregulated in EVs isolated from ARS-1620 treated cells. Ongoing studies aim to pinpoint the detailed mechanisms by which cancer cells utilize mutant KRAS signaling to promote loading of

oncogenic cargo into EVs, and the resulting contributions to tumorigenesis and immune evasion.

Loss of Smad4 induces SPP1 secretion and immunosuppressive myeloid cell formation in pancreatic ductal adenocarcinoma

Gilbert Z. Murimwa[1], Francesca Rossi[2], Henry K. Fleming[2], Zeynep Yazgan[2], Dina Alzhanova[2], Huocong Huang[3], Rolf A. Brekken[3]. *[1]Surgery, UT Southwestern Medical Center, Dallas, TX,[2]Hamon Center for Therapeutic Oncology Research, UT Southwestern Medical Center, Dallas, TX,[3]Surgery, Hamon Center for Therapeutic Oncology Research, UT Southwestern Medical Center, Dallas, TX*

Up to 50% of pancreatic ductal adenocarcinomas (PDA) harbor mutations in canonical TGFß pathway genes such as *SMAD4* and *TGFBR2*. *SMAD4* mutations have been shown to drive resistance to chemotherapy, metastasis, and margin positivity following surgical resection. To characterize the unique tumor microenvironment of *SMAD4* mutant PDA, we developed isogenic, orthotopic mouse models using CRISPR mediated knockout of *Smad4* in a cell line derived from *KPfC* ($Kras^{LSL\text{-}G12D}$;$Trp53^{fl/fl}$;$Pdx1^{Cre}$) mice, a genetically engineered mouse model of pancreatic cancer. To characterize the alteration of the secretome caused by the loss of *Smad4*, we performed proteomic analysis with conditioned media collected from *Smad4* wildtype and mutant cancer cell clones. Interestingly, the loss of *Smad4* resulted in the production of neuroendocrine related factors. In addition, gene ontology analysis with the secretome suggested that these factors were associated with neuronal processes. These data indicate that loss of *Smad4* in PDA cancer cells may lead to a neuroendocrine signature change. In particular, we found one of the most up-regulated secreted factors in the mutant cells was SPP1, which has been shown to promote tumor progression by affecting cancer cell stemness and macrophage polarization. To validate the proteomic results, we established orthotopic models with *Smad4* wildtype and mutant clones. We found that loss of *Smad4* resulted in larger tumor growth. Moreover, immunohistochemistry showed a significant up-regulation of SPP1 in the cancer cells of *Smad4* mutant tumors. To further profile the alteration of immune landscape, we stained for markers of myeloid cells and lymphocytes. We found that

Smad4 mutant tumors had an immunosuppressive microenvironment characterized by increased M2 macrophage, neutrophil and MDSC infiltration. Altogether, our study suggests that loss of SMAD4 in PDA may induce a neuroendocrine signature with increased SPP1 secretion in cancer cells. The production of this unique cancer cell secretome may result in a microenvironment marked by immunosuppressive myeloid cells.

#3642

SPHK1 mediated regulation of antitumor immunity in ovarian cancer

Prachi Gupta, Sudhir Kumar, Ishaque Pulikkal Kadamberi, Sonam Mittal, Jasmine George, Anjali Geethadevi, Pradeep Chaluvally-Raghavan, Sunila Pradeep. *Medical College of Wisconsin, Wauwatosa, WI*

Introduction: Sphingosine kinase 1 (SPHK1) is an enzyme that helps to synthesize biolipid sphingosine-1-phosphate (S1P). We showed extracellular vesicles facilitate an increased accumulation of S1P in the ovarian tumor microenvironment (TME). S1P enhances the exhaustion of CD8 T cells, thus downregulating anti-tumor immunity. Furthermore, we also found less ovarian tumor burden in SPHK1$^{-/-}$ mice compared to WT mice. Based on our preliminary data, we hypothesized that the SPHK1 depleted tumor microenvironment increases the infiltration of the immune cells and its activity downregulates the tumor progression.
Methods: SPHK1 global knockout mice and WT C57BL/6 mice were used in the study. Tumor cells (ID8 P53$^{-/-}$ BRCA$^{-/-}$) were injected, and tumor progression was studied. Immunophenotyping was performed by flow cytometry on ascites and tumor samples. Activation of CD8 T cells, B cells, and dentritic cells were studied by flow cytometry. Bulk RNA sequencing was performed on SPHK1$^{-/-}$ and WT tumors.
Results: SPHK1$^{-/-}$ mice showed regression in tumor growth in multiple tumor models. Tumor tissues from SPHK1$^{-/-}$ mice enhanced infiltration of CD4 and CD8 T cells, B cells, and dentritic cells compared to WT mice. Furthermore, infiltrated immune cells were active in SPHK1$^{-/-}$ mice. Bulk RNA sequencing also showed enhanced immune response in SPHK1$^{-/-}$ tumors compared to WT tumors.
Conclusion: SPHK1$^{-/-}$ environment decreased the tumor growth by enhancing the infiltration and activation of immune cells. We are currently

focusing on identifying the immune cells which are critical players in this process. We will further implement these findings in human immune cells for clinical benefits for ovarian cancer patients.

PTEN/STAT3 pathway in cancer-associated fibroblasts in pancreatic cancer

Samaneh Saberi, Sudarshana Sharma, Cameron Bumbleburg, Julia E. Lefler, Michael C. Ostrowski. *Department of Biochemistry & Molecular Biology, Medical University of South Carolina (MUSC), Hollings Cancer Center, Charleston, SC*

This study aims to test the hypothesis that direct interactions and auto-regulatory loop between PTEN and STAT3 in cancer-associated fibroblasts (CAFs) contribute to an immunosuppressive tumor microenvironment in pancreatic ductal carcinoma (PDAC). Pancreatic cancer accounts for almost as many deaths as cases because of its poor prognosis. Many studies have led to the paradigm that stromal elements contribute to pancreatic tumor growth. Cancer-associated fibroblasts (CAFs) are a primary cell type in the desmoplastic stroma in PDAC, and targeting them to improve PDAC treatment is thought to be a promising strategy, however; studies have shown both tumor-promoting and tumor-limiting activities associated with PDAC CAFs. Phosphatase and tensin homolog deleted on chromosome 10 (PTEN) is one of the most well-described tumor suppressor genes and can regulate essential transcription factors in stromal fibroblasts. On the other hand, STAT3 signaling in pancreatic CAFs contributes to the immunosuppressive and fibrotic stroma observed with disease progression. In this study, we used novel, dual recombinase mouse models of PDAC, with Kras and p53 mutations engineered in the pancreatic epithelium (Flp-based) and Stat3 deleted in a subpopulation of CAFS (Cre). CAFs isolated from these mice were used to probe PTEN-STAT3 interaction in vitro using the Proximity Ligation Assay (PLA) and by ChIP-seq using an RNA seq. Mouse and Human pancreatic tumor samples were analyzed and quantified using multiplex-immunofluorescence and multispectral imaging. In the mouse genetic model, we found PTEN downregulated in ~80% of CAFs, consistent with previous work from our group that demonstrated PTEN loss in 25% of PDAC patient samples. At the same time, pY705-STAT3 was

activated in CAFs, and deletion of STAT3 in CAFs correlated with increased survival, decreased M2-like macrophages, and increased T-cell infiltration. STAT3 ablation in CAFS resulted in the re-expression of PTEN in CAFS, implying an autoregulatory loop. PLA on CAFs isolated revealed that IL6 treatment resulted in the transfer of a STAT3-PTEN protein complex into the nucleus ChIP-seq on CAFs with PTEN STAT3 antibodies revealed a significant overlap in PTEN and STAT3 occupation of gene promoters. This result is consistent with *in silico* analysis on the PTEN and STAT3 ChIP-Seq data in human cell lines. ChIP-Seq data is being interacted with RNA data to identify essential target genes. Human PDAC tissue microarrays are stained with pSTAT3, PTEN, CD3, and CD8.Our study suggests an autoregulatory look between PTEN and STAT3 in PDAC CAFs. PTEN may suppress specific STAT3 target genes through direct interactions with chromatin. Alternatively, PTEN/STAT3 complexes may target CAF genes that suppress tumor growth or activate anti-tumor immune responses. These investigations could identify potential targets in CAFs for restoring the anti-tumor immune responses in PDAC.

Targeting the CD51/TGF-beta pathway: a potential innovative cancer immunotherapy in T-cell lymphomas

Jérôme Giustiniani[1], Anne Marie-Cardine[2], Sadjia Belkhelouat[1], Martine Bagot[2], Armand Bensussan[2], Nicolas Ortonne[1], Adèle De Masson[2]. *[1]TEAM "NEUROFIBROMATOSIS AND LYMPHOMA ONCOGENESIS ", INSERM U955 (IMRB)-Hôpital Henri Mondor, Créteil, France,[2]Oncodermatology and therapies, INSERM U976 HIPI- Hôpital Saint Louis, Paris, France*

T-cell lymphomas are a heterogeneous group of malignancies involving T lymphocytes and generally characterized by a poor prognosis. Among them, cutaneous T-cell lymphomas (CTCL) involve primarily the skin. The most frequent CTCL are mycosis fungoides and Sézary syndrome (SS) (1). There is no cure for advanced-stage CTCL, the remissions are generally rare and short, and the overall survival is around 5 years with an impaired quality of life. Thus, the development of new treatments inducing longstanding responses in CTCL is a major unmet need (2).
Because Sézary cells express several Treg markers as PD-1, ICOS, CD39 or CCR8 (3), we analyzed the expression of CD51, the αV integrin, which is

expressed with the β8 integrin on Treg cells (4). CD51 is involved in the production of active form of TGF-β, a cytokine with immunosuppressive properties that promotes tumor escape. Thus, targeting the αVβ8 integrin with a specific antibody has been shown to inhibit TGF-β activation while not inhibiting cell adhesion (5)**.**

Our results revealed that CD51 is significantly overexpressed in circulating lymphocytes from SS patients as compared to healthy individuals. Interestingly, CD51 is not associated with the β8 integrin but with CD29 (β1 integrin), and CD61 (β3 integrin) in some patients.CD51/CD29 and/or CD51/CD61 heterodimers appear as potential therapeutic targets in T-cell lymphoma, which may be associated with the production of active TGF-β. Targeting these heterodimers with specific antibodies to prevent the release of active TGF-β could improve patient's antitumor immune response. They could also represent depleting targets through NK or CAR-T cells activities as shown in diffuse intrinsic pontine glioma and glioblastoma for CD51/CD61 heterodimer (6).

OSM-induced LOXL2 expression hinges on upregulation of c-Myc and promotes tumor growth and metastasis, IL-1beta plays synergistic role in LOXL2 expression

Simion Dinca, Cody Wolf, Laura Bond, Cheryl Jorcyk. *Biomolecular Sciences, Boise State University, Boise, ID*

Ductal carcinoma is the most commonly diagnosed breast cancer in women, the presence of metastases drops patient five-year survival from 95% to an abysmal 27%. This makes studying the mechanisms that promote metastasis of critical importance. Research shows that the extracellular matrix (ECM) of the tumor microenvironment (TME) plays an important role in invasive ductal carcinoma (IDC) progression and metastasis. Specifically; the density, stiffness, and orientation of collagen I fibers in the stroma all impact IDC motility, invasion, and metastasis. Lysyl oxidase-like 2 (LOXL2) is a secreted enzymatic protein that is implicit in ECM remodeling. By catalyzing an oxidative reaction in peptidyl lysine/ hydroxylysine present on collagen I fibers, LOXL2 initiates crosslinking of the fibers. Our previous publication demonstrates that interleukin-6-related pro-inflammatory cytokine signaling, specifically oncostatin M (OSM), led to the overexpression and secretion of the LOXL2 enzyme. This increased the metastatic potential of IDC cells by promoting the crosslinking and alignment of collagen I fibers, which in turn led to increased invasion in 3D collagen I matrices. Thus, we hypothesize that OSM-induced LOXL2 expression, secretion, and subsequent collagen I fiber crosslinking and alignment, leads to an increase in IDC metastasis. *In vivo* studies utilizing nude athymic mice injected with either MCF7-Luc-EV control or MCF7-Luc-OSM overexpressing cells were performed in conjunction with LOXL2 inhibition using specially designed chow containing either LOXL2 SMI or control. Further analysis of OSM signaling pathways was performed in MCF7 and MDA-MB-468 IDC cells to determine mechanism for OSM induction of LOXL2. Our studies demonstrate that canonical OSM signaling pathways (pERK, pSTAT3, and pAKT) all contribute to LOXL2 expression in MCF7 cells suggesting a possible mediator protein we identified as c-Myc. Furthermore, OSM-induced LOXL2 played a significant role in OSM promoted tumor growth and metastasis as LOXL2 inhibition led to decreased tumor size and far less metastatic lesions. We also analyzed and confirmed a synergistic interaction between OSM and interleukin-1beta (IL-1β) in LOXL2 expression. These results confirm the significance of LOXL2 expression in OSM promoted metastasis and suggests LOXL2 would be an important target for future breast cancer therapies, specifically in patients with elevated levels of OSM. Furthermore, the synergistic interaction between OSM and IL-1β in LOXL2

expression suggests that patients with high levels of both cytokines are at even greater risk of metastasis, making these great markers for determining at risk IDC patients.

#3646

New functional role of tamoxifen in breast cancer immunomodulation: role of RACK7 in activation of type I interferon signaling and CEACAM1/TIM-3-dependent immunosuppression

Marvin A. E. Aberin[1], Yu-Ling (Pony) Lee[2], Xin-Guo Hsu[3], Chen-Yang Shen[4], Yao-Ming Chang[4], Kun-Yuan Lin[2], Chandan Guha[5], Shu-Ping Wang[4]. *[1]Taiwan International Graduate Program in Molecular Medicine, Academia Sinica and National Yang Ming Chiao Tung University, Taipei City, Taiwan,[2]Pharmacology Discovery Services Ltd., New Taipei City, Taiwan,[3]Graduate Institute of Life Sciences, National Defense Medical Center, Taipei City, Taiwan,[4]Institute of Biomedical Sciences, Academia Sinica, Taipei City, Taiwan,[5]Department of Radiation Oncology, Albert Einstein College of Medicine, Bronx, NY*

Despite advancements of immunotherapy against various cancers, breast cancer still retains poor response to immune checkpoint blockade (ICB) therapy. Therefore, the identification of promising target or new strategy to enhance ICB therapy in breast cancer is crucial. Here, we uncover that the DNA-damaging potential of tamoxifen (TAM) can shape the unfavorable but ready-to-fire tumor immune microenvironment in breast cancer. We discover that a long-term TAM administration unexpectedly induces JAK/STAT signaling and Type I interferon (IFN)-stimulated gene expression to promote T-cell infiltration. Furthermore, TAM also induces the expression of CEACAM1, which acts as an alternative T-cell inhibitory ligand *via* binding to TIM-3, a "checkpoint" receptor expressed on $CD4^+$ and $CD8^+$ T cells. The chromatin ''reader'' RACK7/ZMYND8, which functions as a transcriptional repressor of IFN-stimulated gene (ISG) and a critical factor in DNA repair, is found to be downregulated upon tamoxifen exposure and involved in the tamoxifen-mediated cellular modulation. We demonstrate that TAM in conjunction with RACK7-knockdown (KD) triggers robust upregulation of ISGs and CEACAM1 in both estrogen receptor-positive (ER+) and triple negative breast cancer (TNBC) cells.

This immunomodulatory effect lead by loss of RACK7 is specific to TAM treatment, and is not observed when combined with other endocrine therapeutics. TAM combined with RACK7-KD promotes mitochondrial DNA damage, which leads to accumulation of cytosolic DNA and subsequent activation of the cGAS/STING pathway. The murine breast orthotopic models with TS/A, EO771 and 4T1 cells further demonstrate that TAM-mediated immunomodulatory in conjunction with RACK7-KD evokes cytokine/chemokine secretion and further induces T-cell infiltration into tumor microenvironment. However, the tumor killing effect is limited due to promotion of T-cell exhaustion from CEACAM1-TIM-3 interaction between tumor and T cells. Thus, our study indicates that targeting CEACAM1-TIM-3 interaction is crucial for TAM-mediated tumor immune response. This brings promising therapeutic approach with TAM by combining RACK7-KD with blockage to CEACAM1-TIM-3 interaction in breast cancer. The resistance of tamoxifen treatment may be overcome, and RACK7 may serve as both a therapeutic target and a biomarker to enable ICB therapy.

Anti-tumor actions of neutrophils are mediated via STAT5 inhibition

Sanjana Rajgopal[1], Massar Alsamraae[2], Diane Costanzo-Garvey[2], Leah Cook[2]. *[1]Genetics, Cell Biology & Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Pathology & Microbiology, University of Nebraska Medical Center, Omaha, NE*

The overall patient survival rate drops dramatically when localized prostate cancer (PCa) progresses to bone metastatic prostate cancer (BM-PCa). The treatment for BM-PCa is limited to palliative therapy, and it is currently incurable. Neutrophils are the most prevalent immune cell in the bone, and we have found that PCa enhances their recruitment and infiltration into the prostate tumor-bone microenvironment of patients with BM-PCa. Additionally, we observed that bone marrow neutrophils directly induce apoptosis of PCa cells both in vitro and in vivo and that this is mediated by the inhibition of STAT5, a transcription factor that promotes PCa progression. Moreover, STAT5 has also been found to contribute to the development of resistance to standard care androgen deprivation therapy. Neutrophils specifically target and kill only cells that express STAT5, as

stable knockdown of STAT5 in BM-PCa cells makes them resistant to neutrophil-mediated cytotoxicity, while the overexpression of STAT5 in STAT5-negative PCa cells, which are generally resistant to killing by neutrophils, sensitizes them to neutrophil-mediated killing. Furthermore, transcriptomic analyses derived from the STAT5 knockdown and STAT5 overexpressing cells suggest that STAT5 expression in PCa induces pro-inflammatory signaling and that neutrophil-mediated cytotoxicity may be exerted via STAT5-induced IL-1 and/or IL-6. Preliminary data in our laboratory show that STAT5-induced production of IL-1 by PCa cells leads to their death by neutrophils, as knocking out the IL-1 receptor on neutrophils reduces their cytotoxic potential against STAT5-positive PCa cells. Interestingly, in addition to killing BM-PCa cells, we have demonstrated that bone marrow-derived neutrophils are also capable of killing pancreatic cancer cells. Further delineation of the role of neutrophils in STAT5 signaling in BM-PCa growth holds promise for enhancing neutrophil cytotoxicity in the bone which could lead to novel therapeutic options for bone metastatic prostate cancer.

#3648

MSU-42011, alone and in combination with selumetinib, reduces pERK levels in NF1 cancer cells and decreases *CCL2* expression in THP-1 macrophages

Pei-Yu Hung, Lizbeth Lockwood, Karen T. Liby. *Michigan State University, East Lansing, MI*

Neurofibromatosis type 1 (NF1) is a common genetic disease that predisposes approximately 50% of affected individuals to develop plexiform neurofibromas (PNFs), which can progress to highly aggressive malignant peripheral nerve sheath tumors (MPNSTs) in approximately 10% of patients. NF1 is caused by mutations in the tumor suppressor gene *NF1,* which encodes for neurofibromin, a negative regulator of RAS activity. Selumetinib, a specific inhibitor of MEK1/2, is the only FDA-approved drug for NF1-associated PNFs. However, the anti-tumor effects of selumetinib are limited in MPNSTs and have dose-limiting side effects. Deficiency of the *NF1* gene not only promotes tumorigenesis but also has broad effects on the immune cells and cytokine signaling driven by hyperactive RAS signaling. Because macrophages account for almost half

of cells in NF1 lesions and their infiltration highly correlates with disease progression, we hypothesized that targeting tumor-promoting immune cells could be an alternative approach for NF1 treatment. The novel retinoid X receptor (RXR) agonist MSU-42011 reduces tumor growth in experimental Kras-driven cancers by decreasing pERK expression, reducing tumor-promoting immune cells like $CD206^{+}$ macrophages and regulatory T cells, and increasing activated cytotoxic T cells. Here, we tested MSU-42011 and selumetinib, either alone or in combination, to evaluate their efficacy against NF1 cancer cells and macrophages using monoculture and conditioned media (CM) treatments. Treatment with 200 nM MSU-40211, 50 nM selumetinib, and the combination for 3 hours reduced pERK protein levels by approximately 40%, 70% and 90%, respectively vs. untreated controls. Treatment for 72 hours with selumetinib and the combination reduced the viability of PNF cells in a dose-dependent manner. Moreover, CM from human PNF cells increased monocyte chemoattractant *CCL2 (*C-C motif chemokine ligand 2) mRNA expression in human THP1 monocytes and THP1 macrophages differentiated by PMA. Notably, MSU-42011 and selumetinib alone similarly inhibited *CCL2* mRNA expression by 25% in THP1 macrophages stimulated with CM from PNF cells, and the inhibition of *CCL2* mRNA expression was enhanced to 50% with combination treatment. Taken together, our data suggest that MSU-42011 should be tested in relevant preclinical models of NF1.

#3649

Elucidating the role of CXCR4-CXCL12 in the tumor microenvironment of ER+ breast cancer samples using the Akoya PhenoCycler-Fusion System

Julien Tessier[1], Amir Bayegan[1], Dinesh Bangari[2], Joon Sang Lee[1], Lily Pao[3], Robert Rowlands[4], Donald Jackson[1], Angela Hadjipanayis[1].
[1]Precision Oncology, Sanofi, Cambridge, MA,[2]Global Discovery Pathology, Sanofi, Cambridge, MA,[3]Oncology Research, Sanofi, Cambridge, MA,[4]Kymab, Large Molecules Research Platform, Sanofi, Cambridge, MA

The aim of this work is to elucidate the role of the CXCR4-CXCL12 axis in ER+ breast cancer with spatial proteomics profiling. The CXCR4-CXCL12 signaling pathway has emerged as an axis of interest in cancer

tumorigenesis [1,2,3]. Current clinical trials aim to increase immune cell inflammation in solid tumors by blocking this pathway. Our analysis of bulk-RNAseq revealed ER+ breast cancer has high gene expression levels of CXCL12 transcripts, making it a potential tumor indication to investigate. We spatially characterized 20 ER+ breast cancer FFPE samples by developing a 13-plex antibody panel for the Akoya PhenoCycler®-Fusion system. This panel was designed to identify immune cells (CD45, CD3e, CD4, CD8, FoxP3, CD68), stromal cells (FAP, SMA, Podoplanin, S100A4), tumor and epithelial cells (PanCK) as well as the signaling duo (CXCR4, CXCL12). We performed cell segmentation on the multiplex immunofluorescence images, and quantified marker intensity in each cell. Phenotypes were manually identified after normalization, integration, and clustering of over 10+ million cells across 20 samples. Overall, the composition of tumor and immune cells varies significantly between patients showing the heterogeneity of their microenvironments. We observed CD8 T-cell exclusion in tumors associated with infiltration of fibroblasts (FAP+, SMA+, PDPN+) that do not express CXCL12. Instead, the CXCL12 signal is highly correlated with PanCK in all samples suggesting that either tumor cells are producing the chemokine or are being "coated" with the CXCL12 produced by fibroblasts. We also identify at least three known CXCR4+ immunosuppressive populations (fibroblasts, macrophages and Tregs) in the tumors which are known to be recruited via CXCR4-CXCL12 signaling[4,5]. This immunosuppressive tumor micro-environment (TME) results in the CD8 T-cell exclusion we observe in our samples as well as mentioned in multiple studies[1,6]. In summary, these results show the exclusion of cytotoxic T cells in the TME and the intricate relationship between tumor cells and immunosuppressive cells through the CXCR4-CXCL12 axis. This study shows the benefits of the Akoya platform compared to conventional IHC as well as the power of spatial phenotyping to study the TME immune biology for development of therapeutic strategies.

STAT1 suppresses KRAS-driven lung adenocarcinoma depending on the tumor microenvironment

Christoph Trenk[1], Rebecca Sagmeister[1], Jaqueline Horvath[1], Monika Homolya[1], Andreea Corina Luca[1], Robert Eferl[2], Herwig Moll[1], Emilio Casanova[1]. *[1]Center for Physiology and Pharmacology, Medical University of Vienna, Wien, Austria,[2]Center for Cancer Research, Medical University of Vienna, Wien, Austria*

Lung cancer is responsible for the majority of cancer-related deaths worldwide. Within this severe disease lung adenocarcinoma (LUAD) belongs to the most common form of lung cancer. LUAD is highly correlated with KRAS mutations. Although, the first KRAS inhibitors entered into clinics recently, therapy resistance arises. Since KRAS-mutant LUAD is an inflammation driven disease, we focus on the JAK-STAT pathway as an alternative target. Preliminary data suggests that human KRAS-mutant LUAD is correlated to enriched JAK-STAT signaling, as well as STAT1 upregulation. Accordingly, we aimed to explore the tumorigenic functions of STAT1 in this form of lung cancer. Genetically engineered C57BL6/N mice which develop autochthonous KRAS-driven and P53-deficient LUAD proficient (KP) and deficient for STAT1 (KPS) were used. In a second mouse model expression of ovalbumin was induced in tumor cells, mimicking a neoantigen to increase immune infiltration in the presence (KPO) or absence of STAT1 (KPOS). Kaplan-Meyer analysis was performed to assess the overall survival. Tumor burden, as well as immune infiltration was analyzed in lungs 6 and 10 weeks after tumor induction via H&E, IHC and IF staining. Furthermore, the lung fluid was collected by bronchoalveolar lavage and used to profile inflammatory cytokines. Deletion of STAT1 reduced the survival in KRAS-driven LUAD mice only when ovalbumin was expressed. Tumor burden and tumor grades were increased in tumors lacking STAT1 at 6 and 10 weeks after tumor initiation. Surprisingly, although tumors of KPOS mice showed a decreased infiltration by T cells and CD4 T cells, CD8 T cell infiltration did not change, suggesting a tumor suppressive function of STAT1 via T cell

exhaustion. Moreover, the macrophage attracting cytokine CCL9 secretion was upregulated and the number of tumor infiltrating, immunosuppressive macrophages was increased in KPOS mice. This data implicates a tumor suppressive function of STAT1 by secretion of cytokines that can recruit suppressive myeloid immune cells to the TME leading to CD4 T cell exclusion and CD8 T cell exhaustion. Further studies are needed on the changes in the immune infiltrating cells to explain the mechanism behind these intriguing findings.

The role of caspase-1 in basal-like breast cancer and the tumor microenvironment

Wanda Marini[1], Weiyue Zheng[1], Kiichi Murakami[1], Pamela S. Ohashi[2], Michael Reedijk[3]. *[1]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[2]Department of Immunology, University of Toronto, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[3]Department of Surgical Oncology, University of Toronto, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Introduction: Breast cancer is the most common malignancy in women world-wide. Basal-like breast cancer (BLBC) is an aggressive subtype with poor prognosis for which there are no known targeted therapies. Understanding what drives complex cell-cell interactions within the tumor microenvironment (TME) is critical to developing new strategies. BLBC has previously been shown to have high expression of the inflammatory cytokine IL1β, which then promotes the recruitment of pro-tumoral tumor-associated macrophages (TAMs) to the TME. Here we report that BLBC is uniquely capable of IL1β secretion due to elevated expression of caspase-1, a key component of the inflammasome required for IL1β maturation.
Methods: Using publicly available gene expression data sets, the association between caspase-1, breast cancer subtype and estrogen receptor (ER) co-expression was examined. These associations were further assessed *in vitro* by exposing luminal (T47D/MCF7) or BLBC (MDA-MB231) cell lines to siER knockdown or ER overexpression. Using both a CRISPR/Cas9 generated caspase-1 knockout (KO) BLBC mouse line as well as pharmacological inhibition with the caspase-1 inhibitor VX-765, the effect

of caspase-1 on tumor growth was studied in syngeneic immunocompetent mice. Immune infiltrates were assessed via flow cytometry of the excised murine tumors as well as immunohistochemistry. To prove these results were IL1β specific, caspase-1 KO tumor allografts containing self-cleaving IL1β were used for comparison. Finally, to determine potential synergy between caspase-1 and immune checkpoint inhibition, wild type and caspase-1 KO allografts were simultaneously treated with anti-PD1 immunotherapy. Tumor growth and immune infiltrates were analyzed between the treatment groups as stated above.
Results: Caspase-1 was found to be associated with the basal-like subtype and have an inverse relationship with ER expression. *In vitro*, inhibition of ER increased caspase-1 expression, whereas ER overexpression decreased caspase-1. Caspase-1 KO or pharmacological inhibition resulted in a significant decrease in tumor growth and TAM infiltration, and these findings were rescued back to wild type levels with the addition of a self-cleaving IL1β. Finally, caspase-1 inhibition reversed resistance to anti-PD1 immunotherapy in murine allografts, resulting in significant deceleration of tumor growth when used in combination.
Summary: The lack of ER in BLBC promotes caspase-1 expression, allowing IL1β maturation, macrophage recruitment and tumor progression. Genetic or pharmacologic inhibition of caspase-1 inhibits TAM recruitment and reverses resistance to immune checkpoint inhibition in BLBC.
Conclusions: Our data provides new insights into the biology of BLBC and identifies the combination of caspase-1/IL1β inhibition and immunotherapy as a novel therapeutic strategy to combat this disease.

Circular RNAs repress interferon responses in the sarcoma cells and promote sarcoma growth by forging a pro-tumorigenic immune microenvironment
Jlenia Guarnerio. *Cedars-Sinai Medical Center, Los Angeles, CA*

Circular RNAs (CircRNA) arise from events of non-conventional splicing in which the 3'-tail of an exon back-splices and joins the 5'-head of the upstream exon. Because of their structural conformation, these RNAs are incredibly stable in the cellular space, where they can regulate tumor-associated and anti-immunogenic pathways. Although circRNAs have been

profiled in many tumors, their functional contribution to cancer progression is still poorly understood. In the current study, we profiled the most abundant circRNAs expressed in Soft-tissue sarcomas (STS) and characterized them functionally and mechanistically. Surgery and chemotherapy are the standard treatments for STS, but the 5-year survival rate is still below 20% for the advanced cases. Response to immunotherapies, such as immune checkpoint inhibitors, is also marginal for STS, likely because sarcoma cells are not sufficiently immunogenic to recruit a high volume of cytotoxic T cells. To implement discoveries on STS, we recently generated novel immunocompetent STS mouse models and characterized the sarcoma-elicited mechanisms to block immune-recruitment. Interestingly, we observed that two circRNAs, circCsnk1g3, and circAnkib1, promote sarcoma growth by shaping a pro-tumorigenic microenvironment, possibly due to their capabilities to regulate tumor-promoting elements extrinsic to the sarcoma cells. More specifically, we observed that circCsnk1g3 and circAnkib1 control the expression of interferon-related genes and pro-inflammatory factors in the sarcoma cells, thus directing immune cell recruitment into the tumor mass and hence their activation. Mechanistically, we observed that circRNAs might repress pro-inflammatory elements by buffering activation of the pathways mediated by RIG-I, the cytosolic viral RNA sensor. The current findings suggest that targeting
specific circRNAs could augment the efficacy of sarcoma immune response to mainstay therapies.

Oncostatin m receptor signaling reprograms tumor microenvironment for chemoresistance

Anjali Geethadevi[1], Shirng-Wern Tsaih[2], Ajay Nair[3], Zhiqiang Ku[4], Ishaque Pulikkal Kadamberi[2], Deepak Parashar[2], Prachi Gupta[2], Sudhir Kumar[2], Jasmine George[2], Sonam Mittal[1], William Bradley[1], Robert F. Schwabe[3], Zhiqiang An[4], Ningyan Zhang[4], Sunila Pradeep[2], Pradeep Chaluvally Raghavan[2]. *[1]Obstetrics and Gynecology, Medical College of Wisconsin, Milwaukee, WI,[2]Department of Obstetrics and Gynecology, MCW Cancer Center, Medical College of Wisconsin, Milwaukee, WI,[3]Department of Medicine, Institute of Human Nutrition, Columbia University, New York,*

NY,[4]Texas Therapeutics Institute, Brown Foundation Institute of Molecular Medicine, The University of Texas Health Science Center, Houston, TX

Introducti**on:** High-grade serous ovarian carcinoma (HGSOC) is the most lethal gynecological malignancy and accounts for ~70% of tumor recurrences after standard chemotherapy and immunotherapy. Ovarian tumor microenvironment (TME) is undeniably complex which presents considerable challenge in understanding the immunotherapy treatment responses. Our previous study has revealed that Oncostatin M receptor (OSMR) is highly expressed in ovarian cancer cells and cancer associated fibroblasts (CAFs), whereas its ligand OSM is predominantly expressed in tumor associated macrophages (TAMs). This study aims to investigate how the OSM-OSMR paracrine signaling between tumor cells, CAFs and TAMs reprograms the TME to influence therapeutic responses in ovarian cancer.
Methods: We employed a 3D-3-cell co-culture method *in vitro* to understand how OSM/OSMR signaling modulates the interactions between ovarian cancer cells, CAFs and TAMs, that can impact therapy response of cisplatin resistant cancer cells in the ovarian TME. We performed RNA sequencing to study the differential gene signatures of each cell component in a 3-cell co-culture with their monolayer counterparts. This system was also challenged with chemotherapy-cisplatin and immunotherapy such as our newly developed anti-OSMR monoclonal antibodies to assess the therapy response of each cell component.
Results: Using single-cell and single-nuclear RNA seq dataset analyses of 17 human HGSOC patient ascites, we found that CAFs and TAMs are the predominant stromal or immune cell population enriched in ovarian cancer tissues. Using immunofluorescence, we identified that enrichment of CAFs along with extracellular matrix proteins surrounding tumor cells as an indication of heavily desmoplastic tumors. Using tumor-infiltrating immune cells dataset-TIMER, we found that high OSMR in cancer cells or CAFs along with high OSM in TAMs are associated with poor survival in ovarian cancer patients. Further, RNA sequencing data of 3-cell coculture models revealed an invasive, desmoplastic and immune-suppressive gene signature compared to independent culture conditions. Notably, CAFs and ovarian cancer cells co-cultured with TAMs exhibited an improved activation of JAK/STAT3 and PI3K-AKT oncogenic pathways for chemoresistance in ovarian cancer cells.

Conclusions: Our preliminary findings uncovered a potential mechanism of action of OSM-OSMR signaling in reprogramming ovarian cancer cells and stromal fibroblasts in ovarian cancer TME. Importantly, we highlight the importance of crosstalk between CAFs, ovarian cancer cells and TAMs for harnessing OSM/OSMR signaling for chemoresistance in cancer cells. Our findings also demonstrated the potential of anti-OSMR antibody therapy to target cancer cells and CAFs in the tumor microenvironment for abrogating desmoplasia; thus, improving chemosensitivity.

Olaparib combined with entinostat exerts differential effects on tumor-associated macrophages in tumors compared to ascites in syngeneic HR-proficient murine models of ovarian cancer

Vijayalaxmi G. Gupta[1], Tyler Woodard[1], Simona Miceska[1], Bisiyao Fashemi[1], Sangappa Chadchan[1], Wendy Zhang[1], Katherine Roby[2], Andrew Wilson[3], Fiona Yull[4], Marta Crispens[3], Sumanta Naik[1], Asya Smimov[1], Christina Stallings[1], Dineo Khabele[1]. *[1]University of Washington, School of Medicine, St. Louis, MO,[2]University of Kansas Medical Center, Kansas City, KS,[3]Vanderbilt University Medical Center, Nashville, TN,[4]Vanderbilt University, Nashville, TN*

Poly ADP ribose inhibitors (PARPi) are most effective in ovarian cancer tumors with homologous recombination (HR) deficiency. Our group has shown that histone deacetylase inhibitors (HDACi) sensitize HR proficient ovarian cancer cells to PARPi. Our current efforts are directed towards understanding how this therapeutic regimen alters tumor-associated macrophages (TAMs) in murine models of high grade serous ovarian cancer. To investigate the effects of Ola combined with Ent, we used HR-proficient ID8 P53 wild-type and ID8 $P53^{-/-}$ syngeneic murine models. Mice were randomized into 4 groups: control, Ola, Ent and Ola+Ent. Mice (Ent and Ola+Ent) were pre-treated with 15 mg/kg entinostat or vehicle (Ola and Ola+Ent) for one week via oral gavage and then treated with vehicle/Ent/Ola (100 mg/kg)/ Ola+Ent for two weeks. Mice were sacrificed 24 h after the last dose to harvest tumors and ascites. Tumors were processed for histology to determine cell proliferation (Ki67) and immune cell markers (CCL2, M1 and M2-like macrophages). Ascites fluid was

processed for flow cytometric analysis of immune cells. Tumors from parental ID8 P53 wild type mice showed significantly lower cell proliferation marker Ki67 ($P \leq 0.05$), higher anti-tumorigenic M1-like CCL2 ($P \leq 0.05$), and lower pro-tumorigenic M2-like mannose receptor ($P \leq 0.05$) in Ent and Ola+Ent groups compared to vehicle and Ola. Ascites showed no significant change in anti-tumorigenic M1-like macrophages, but significantly increased pro-tumorigenic M2-like macrophages ($P \leq 0.005$). ID8 $P53^{-/-}$ mice tumors showed significantly lower Ki-67 ($P \leq 0.05$) in Ola+Ent group compared to vehicle and mono-treatments. Ascites showed no significant change in total macrophage or pro-tumorigenic M2-like macrophages, but a significant decrease in anti-tumorigenic M1-like macrophages in Ent and Ola+Ent groups compared to vehicle. To summarize, in HR proficient ID8 P53 wildtype and ID8 $P53^{-/-}$ syngeneic mouse models, Ola and Ent treatment exerted anti-tumorigenic effects in tumors but potentially pro-tumorigenic effects in ascites. In conclusion, concomitant targeting of tumor TAMs and ascites TAMs may be a therapeutic regimen to investigate in the future.

Exploring the role of FasL in the ovarian cancer tumor microenvironment

Grace Keegan[1], Hilary Kenny[2], Agnes Bilecz[3], Ricardo Lastra[4], Ernst Lengyel[2]. *[1]University of Chicago, Chicago, IL,[2]Department of Ob/Gyn, University of Chicago, Chicago, IL,[3]Department of Pathology, University of Chicago, Chicago, IL,[4]Pathology, University of Chicago, Chicago, IL*

Introduction: High-grade serous ovarian cancer (OvCa) remains the deadliest gynecologic cancer in the United States because it often presents at an advanced stage when the disease is incurable. Despite the impressive clinical success of cancer immunotherapy in patients with lung cancer and melanoma, it is largely ineffective in OvCa patients. Resistance to cancer immunotherapy is mediated by the apoptosis of T-cells, which can be prevented by blocking Fas ligand (FasL), a death gene. However, little is known about the expression and function of FasL in OvCa. Therefore, the aims of this study were to identify the cells in the OvCa tumor microenvironment that produce and secrete FasL, and to delineate the

functional role of FasL in T-cell apoptosis within the OvCa tumor microenvironment.
Methods: FasL protein localization and levels were evaluated in OvCa tumors by immunohistochemistry (IHC) using a FasL antibody on tissue microarrays (TMAs) containing primary and matching metastases from 72 OvCa patients. In-situ hybridization (ISH) using a FasL specific probe was performed on omental OvCa tumors from pre- (n=12) and post-chemotherapy (n=12) patients to localize FasL mRNA. To define the role of OvCa and endothelial cell derived FasL on T cell apoptosis, co-culture experiments were completed. First, FasL was knocked down with a FasL siRNA or neutralized with a FasL antibody in OvCa (OVCAR8 and OVCAR5) cells or endothelial (HUVEC) cells. Next, the OvCa or endothelial cells were co-cultured with primary human blood mononuclear cell-derived T cells. Subsequently, the level of FasL secreted was measured using a FasL specific enzyme-linked immunoassay, and early (4h; cleaved-caspase 3) and late (24h; TUNEL assay) T cell apoptosis were analyzed by flow cytometry.
Results: FasL protein and mRNA are present in OvCa and endothelial cells in the tumor microenvironment of OvCa patients. Higher levels of FasL are detected in the endothelial cells when compared to the OvCa cells in these OvCa tumors. These results were confirmed in vitro as primary human endothelial cells secrete higher levels of FasL when compared to the OVCAR8 and OVCAR5 ovarian cancer cell lines. Functionally, both OvCa and endothelial cells stimulate early and late apoptosis in primary human blood mononuclear cell-derived T cells after a four hour co-culture. Knockdown or neutralization of FasL significantly inhibits the ability of OvCa or endothelial cells to induce early and late T cell apoptosis. In summary, FasL is localized to OvCa and endothelial cells in the OvCa tumor microenvironment, and both OvCa and endothelial cell derived FasL induce T cell apoptosis.
Discussion: These findings indicate that blocking FasL may be an effective approach for reducing T-cell apoptosis and improving cancer immunotherapy response in OvCa patients.

A multi-scale approach to quantitatively evaluate the SMAD signaling pathway

Ernest Heimsath[1], Lisa Arvidson[2], Reginaldo Prioli[2], Antony Wood[2].
[1]Agilent Technologies, Inc., Santa Clara, CA,[2]Cell Signaling Technology, Inc., Danvers, MA

Angiogenesis and cell proliferation are fundamental biological processes whose pathologic states represent two hallmarks of cancer. Central to controlling both processes is the TGF-β/BMP signaling pathway, for which the SMAD proteins serve as major downstream effector molecules. Upon ligand-binding, TGF-β or BMP type I/II receptor heterotetramers phosphorylate receptor-regulated SMADs (R-SMADs). TGF-β-receptor binding leads to SMAD2/3 phosphorylation, whereas BMP-receptor binding induces phosphorylation of SMADs 1/5/8. Phosphorylated SMADs (pSMADs) then form a complex with the co-SMAD SMAD4 at which point they undergo nuclear translocation, where they function as transcriptional modulators of target genes. The magnitude of SMAD phosphorylation and functional output (e.g., stimulated angiogenesis or attenuated cell proliferation) depends on both the ligand concentration, as well as the duration of exposure. In this study, we quantitatively evaluate the phosphorylation states of R-SMADs, as well as their downstream biological effects at three different biological scales: 1) biochemical, 2) cellular, and 3) tissue/3D models. At the biochemical level, the temporal and dose-dependent phosphorylation of R-SMADs in response to growth factor stimulation can be quantified using a quantitative ELISA approach. Growth factor stimulation can be quantified at the cellular level by high content imaging of SMAD phosphorylation and nuclear translocation, while simultaneously monitoring cell proliferation rates. Lastly, high-resolution confocal imaging can be employed to observe developmental consequences of phospho-SMAD signaling using a HUVEC-based 3D angiogenesis model system.
For Research Use Only. Not for use in diagnostic procedures.

Single Cell and Spatial Considerations of the Tumor Microenvironment

Comprehensive analysis of natural killer cell-associated markers using MultiOmyx™ immunofluorescence assay

Erinn A. Parnell, Jiong Fei, Harry Nunns, Eric Leones, Elaine Yeung, Blair Russell, Flora Sahafi, Qingyan Au. *NeoGenomics, Aliso Veijo, CA*

As a promising alternative platform for cellular immunotherapy, natural killer cells (NK) have recently gained attention as an important type of innate immune regulatory cell. NK cell immunotherapy approaches have been translated into clinical applications, and clinical trials of NK cell infusion in patients with hematological malignancies (HM) and solid tumors have thus far yielded many encouraging clinical results. Understanding the pattern of NK expression and the relationship to different states of NK cells may have direct relevance for immune responses in cancer. Approaches capable of simultaneously detecting NK cells with detailed information on NK differentiation state, however, remain limited. In this study, we used MultiOmyx hyperplexed immunofluorescence (IF) assay to classify and characterize the spatial arrangement of NK cell markers in a pan-cancer cohort including 9 tissue microarrays (TMAs) from breast, head and neck, prostrate, colon, bladder, lung, kidney, ovarian and melanoma indications. The panel includes CD3, CD4, CD8, CD16, CD45, CD56, CD57, CD137, FoxP3, Granzyme B, HLA-E, NKG2A, NKP46 and tumor segmentation marker. The panel enables the detection of NK cells expressing CD56 and/or NKP46 in the 9 different tumor indications. We also studied the expression of activating and inhibiting receptors, such as CD16 and NKG2A, in NK cell population. The active cytotoxic subsets of mature NK cells were evaluated using co-expression of NK cell surface markers with CD57 and the cytotoxic molecule expression in NK cells was assessed using co-expression with Granzyme B. Using proprietary deep-learning-based image analysis, we were able to quantify the densities of these different NK cell population and study the prevalence of these NK cells in different cancer indications included in this study. Many strategies have been developed for exploiting NK-mediated anti-tumor activities. CAR-NK cell therapy and antibodies that directly target NK cell inhibitory receptors such as NKG2A and TIGIT, are currently being evaluated in the clinical trials. The MultiOmyx NK cell panel reported in this study enables the comprehensive profiling of the NK population and can provide greater understanding of NK cell biology during cancer progression. The panel can be further used to explore the efficacy of the NK cell-based immune therapy.

Spatially resolved transcriptomics deconvolutes histological prognostic subgroups in patients with colorectal cancer and synchronous liver metastases

Colin S. Wood, Kathryn A. F. Pennel, Holly Leslie, Assya Legrini, Andrew J. Cameron, Paul Horgan, Joanne Edwards, Colin W. Steele, Nigel B. Jamieson. *Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom*

Patients demonstrating strong immune responses to primary colorectal cancer (CRC) have a survival benefit following surgery, while those with predominantly stromal microenvironments do poorly. Biomarkers to identify patients with colorectal cancer liver metastases (CRLM) who have good prognosis following surgery for oligometastatic disease remain elusive. The aim of this study was to determine the practical application of a simple histological assessment of immune cell infiltration and stromal content in predicting outcome following synchronous resection of primary CRC and CRLM, and to interrogate the underlying functional biology that drives disease progression. Patients undergoing synchronous resection of primary CRC and CRLM underwent detailed histological assessment, panel genomic and bulk transcriptomic assessment, immunohistochemistry (IHC) and GeoMx Spatial Transcriptomics (ST) analysis. Integration with genomic features, pathway enrichment analysis and immune deconvolution were performed. High-immune metastases were associated with improved cancer specific survival (HR, 0.36, P=0.01). Bulk transcriptomic analysis was confounded by stromal content but ST demonstrated that the invasive edge of the metastases of long-term survivors was characterized by adaptive immune cell populations enriched for Type II Interferon signaling (NES=-2.05 P.Adj<0.005) and MHC-Class II Antigen Presentation (NES=-2.09 P.Adj<0.005). In contrast, patients with poor prognosis demonstrated increased abundance of regulatory T-cells and neutrophils with enrichment of Notch (NES=2.2 P.Adj=0.022) and TGF-β (NES=2.2 P.Adj=0.02) signaling pathways at the metastatic tumor center. In summary, histological assessment can stratify outcome in patients undergoing synchronous resection of CRLM and ST analysis has revealed significant

intra-tumoral and inter-lesional heterogeneity with underlying transcriptomic programs identified in driving each phenotype.

#4692

Comparison of interassay similarity and cellular deconvolution in spatial transcriptomics data using Visum CytAssist

Mario G. Rosasco[1], Chi-Sing Ho[1], Tianyou Luo[2], Michelle M. Stein[1], Luca Lonini[1], Martin C. Stumpe[1], Jagadish Venkataraman[1], Sonal Khare[1], Ameen A. Salahudeen[1]. *[1]Tempus, Chicago, IL,[2]UNC Chapel Hill, Chapel Hill, NC*

Next-generation sequencing (NGS) of bulk cell populations is a useful and ubiquitous tool for the molecular characterization of clinical tumor samples. Bulk NGS reveals transcript abundance within a tumor sample and can further infer cell populations via deconvolution algorithms (PMID:31570899). However, it can't ascribe the cellular context for a given gene's expression or elucidate the spatial organization of tumor microenvironments. These additional features are critical to our understanding of tumor biology and are key to the development of immuno-oncology therapeutics. Spatial Transcriptomics (ST) is an emerging technology that characterizes gene expression within the spatial context of tissue. ST data can be generated directly from archival formalin fixed paraffin embedded samples, enabling the study of spatial gene expression in real-world clinical settings.

We have studied a dataset comprising 6 samples from non-small cell lung cancer (NSCLC) patients and 1 core needle biopsy from a tumor of unknown origin. We used the 10X Visium CytAssist platform to generate ST data and additionally generated paired bulk RNAseq data. To test the interassay reliability of CytAssist on archival FFPE tissue sections, we compared ST results across 3 sample preparation conditions. We further studied the state of the tumor microenvironment by applying state-of-the-art computational approaches to deconvolve immune cell populations and produce super-resolution ST maps, validated using multiplex immunofluorescence (IF) via CODEX (PMID:30078711).

We find key quality control metrics and spatial biomarkers are consistent across all 3 sample preparation conditions. When comparing deconvolution results between bulk and spatially-resolved methods we observe modest

correlations for many cell types despite differences in sample preparation, supporting the idea that bulk and spatial samples contain complementary transcriptomic information. However, within samples, we find many of the correlations observed in bulk do not show strong spatial correlation. These comparisons indicate the importance of considering spatial context when studying the tumor immune microenvironment. Finally, we find an agreement between super-resolution ST and multiplex IF across key spatial biomarkers.
These results demonstrate clinical archival FFPE samples yield high interassay reliability via the CytAssist platform. Results were consistent through 3 different H&E staining protocols and findings were consistent when superresolution deconvolution was utilized which further strongly correlated with high-resolution multiplex IF. Our findings demonstrate the feasibility and translational utility of ST to discover spatial signatures and the cellular context in retrospective clinical cohorts to empower discovery and translational efforts in precision oncology and therapeutic development.

#4694

Single-cell analysis of glioblastoma immune contexture identifies a subset of activated and memory tumor-reactive CD8+ TILs and a Treg signature contributing to TIL irreversible dysfunction

Irene Sambruni, Silvia Musio, Natalia Di Ianni, Martina Maffezzini, Monica Patanè, Marica Eoli, Antonio Silvani, Bianca Pollo, Francesco DiMeco, Serena Pellegatta. *IRCCS Istituto Neurologico Carlo Besta, Milan, Italy*

Despite the first classification of glioblastoma (GBM) as an immunologically “cold” tumor, evidence suggests that this cancer type is susceptible to T-cell infiltration, providing a glimmer of hope for developing effective immunotherapy approaches. However, whether the “exhausted” phenotype of tumor-infiltrating lymphocytes (TILs) and the immunosuppressive signaling in the GBM microenvironment (ME) can be therapeutically reprogrammed to unlock the anticancer potential of the immune system remains to be elucidated. We performed a histological analysis of GBM specimens collected pre-therapy from 24 newly-diagnosed GBM patients treated with dendritic cell (DC)-immunotherapy as part of the DENDR1 clinical trial (NCT04801147). Our preliminary results suggest

an association between the distribution and density of CD8+ TIL subsets and patients' responses to immunotherapy. TIL spatial patterns revealed either an immune-excluded or an immune-infiltrated scenario with either scattered or widespread TILs. A widespread CD8+ TIL pattern was significantly correlated with a better response to immunotherapy. It was also observed that the frequency of CD8+ TILs was significantly increased at recurrence compared to their primary tumors, suggesting that these patients are more likely to benefit from CD8+ T cell antitumor immunity. In light of these observations, we have hypothesized that tumor-reactive (TR) TILs isolated from GBM can be used as direct personalized treatment mediators exerting an effective antitumor activity with low side effects per se. TR-TILs were isolated from GBM surgical material using CD137 as a key marker, and successfully expanded from 50% of patients' GBM showing specific reactivity against autologous tumor cells. For the remaining cases, TR-TILs failed to expand, suggesting terminal dysfunction. Single-cell sequencing of the transcriptome was performed on the immune contexture after CD137+ TILs enrichment revealing the presence of a specific signature related to exhausted, cytotoxic, and memory state. A gene signature highly upregulated in regulatory T cells (Treg) was related to a more immune-suppressive ME. Flow cytometry analysis on immune contexture confirmed the presence of FoxP3+ CD4+ T cells, expressing CD137 can be enriched and persist, dysregulating the expansion of TR-TILs during the early stage in culture. Our preliminary findings indicate that a high frequency of Treg can be investigated as a negative predictive indicator of ex-vivo expansion of TR-TILs, which should be taken into consideration when planning a personalized TIL therapy.

#4695

Expansion of the extracellular proximity labeling (ePL) technique to novel matrisome targets

Joshua Rich, Sadeechya Gurung, Sukhbir Kaur, David Roberts, William Stetler-Stevenson, David Peeney. *National Cancer Institute, Bethesda, MD*

The extracellular matrix (ECM) is a complex and dynamic meshwork of extracellular macromolecules that plays a key role in cancer progression and metastasis. The matrisome encompasses the genes encoding ECM and

ECM-associated secretory proteins, and elucidating the protein-protein interactions (PPIs) of the matrisome is a promising area of study in the quest for a better understanding of cancer pathology and therapeutics. Proximity labeling, a powerful technique for investigating protein interactomes based on enzyme-fusion constructs and affinity chromatography, has considerable potential in detailing the protein-protein interactions of the matrisome. We have recently had success in developing a proximity labeling approach based on fusion constructs containing the biotinylating enzymes BioID2 and TurboID. We apply this approach to gain new insights into the interactome of the matrisome protein tissue inhibitor of metalloproteinase 2 (TIMP2), a protein found to have antitumorigenic potential. At present, we seek to expand this approach to other ECM protein targets, including tissue inhibitor of metalloproteinase 3 (TIMP3) and thrombospondin-1 (THBS-1). TIMP3 has been shown to possess anti-tumor properties, with loss of TIMP3 function associated with poor prognosis in multiple cancers. THBS-1 is a large (129 kDa) ECM protein that is relatively promiscuous with diverse functions in the tumor microenvironment. Expression of THBS-1 is frequently lost during oncogenesis, and such loss is associated with poor prognosis in some cancers. We describe how ePL can be expanded to these matrisome targets in different cellular systems (adherent vs. suspension) and show that ePL assays can be performed with stable and transient transgene expression. We show that ePL is a suitable method for studying PPIs in novel matrisome targets and expect to apply the technique to further targets in the near future.

Characterizing CD39 and CD73 cell subtypes in the tumor microenvironment using MultiOmyx

Courtney Todorov, Kevin Gallagher, Juliana Wortman, Harry Nunns, Erinn Parnell, Eric Leones, Elaine Yeung, Blair Russell, Flora Sahafi, Qingyan Au. *NeoGenomics, Aliso Viejo, CA*

CD39 and CD73 are membrane bound enzymes that function together to convert extracellular adenosine 5’-triphospate (ATP)/adenosine diphosphate (ADP) into adenosine. CD39 first catalyzes ATP/ADP into adenosine monophosphate (AMP), which is then converted by CD73 into adenosine.

Accumulation of extracellular adenosine creates an immunosuppressive tumor environment and facilitates tumor growth and metastasis. Conversely, the presence of ATP promotes a pro-inflammatory, tumor-suppressive environment. Suppression of CD73/CD39 activity and reduction of extracellular adenosine has been shown to support an antitumor immune response. Therefore, the targeting of CD73 and CD39, both individually as well as in combination with immune checkpoint inhibitors for biomarkers such as PD-1 and CTLA-4, is an emerging strategy for cancer therapeutics. CD73/CD39 have been described in multiple cell types, including tumor cells, fibroblasts, endothelial cells, tumor infiltrating lymphocytes (TILs), myeloid cells, and natural killer (NK) cells. While known to be expressed on multiple cell types, the spatial characterization of CD39 and CD73 in the tumor microenvironment (TME) is still poorly understood. Characterizing the diversity of active CD73 and CD39 populations in the tumor environment will help improve development of targeted therapies for cancer treatment. The multiplex immunofluorescence (mIF) platform MultiOmyx will be used to define the distinct populations of cells expressing CD73 and/or CD39 in the TME. MuliOmyx is a proprietary mIF platform for the visualization and characterization of up to 60 protein biomarkers in a single FFPE section. Herein we report the design and use of a novel panel of commercially-available antibodies broad enough to characterize CD39 and CD73 subpopulations in the TME of a variety of tumor indications including lung, prostate, and colon cancer. Using this panel in combination with proprietary deep-learning based image analysis, CD39 and CD73 positive cells can be characterized into different immune and TME subtypes. Understanding of the variety and phenotype of CD39 and CD73 expressing cells in the TME is crucial to define the populations being targeted by therapies for cancer treatment.

Reproducibility in spatial biology: reducing variables to improve the reliability of insight generation

Lisa Arvidson[1], Reginaldo Prioli[1], Samuel Jensen[1], James B. Hoying[2], Michael W. Golway[2], Michael J. Smith[3], Katie O. White[3], Richard A. Heil-Chapdelaine[3], Chi-Chou Huang[3], Tuan H. Phan[3], Hideki Sasaki[3], Melinda Angus-Hill[3]. *[1]Cell Signaling Technology, Danvers, MA,[2]Advanced*

Solutions Life Sciences, Manchester, NH,[3]Leica Microsystems, Bellevue, WA

There is an ongoing crisis in reproducibility in scientific studies, and studies in spatial biology are no exception. Cell DIVETM Multiplex imaging solution (Leica Microsystems) provides reliable workflow solutions to minimize variability from study to study. Cell DIVE allows probing and imaging of dozens of biomarkers on a whole tissue section with an iterative staining and dye inactivation workflow. At its core, Cell DIVE is designed to provide methods reproducibility, from tissue preparation, antigen retrieval, and sample imaging and slide storage. Cell DIVE is designed to work with directly conjugated primary antibodies, another source of variability. However, conjugated antibodies from Cell Signaling Technology (CST) are rigorously validated using stringent acceptance criteria to reduce variability. In addition, the use of recombinant antibodies, the consistent conjugate brightness and antibody degree-of-labeling reduce lot to lot variability, ensuring reliable conjugated antibodies for spatial biology studies. High resolution imaging results are obtained by consistent round to round imaging, consistent calibration and corrections, and reduction of human error using the BAB 200 liquid handling solution (Advanced Solutions Life Sciences). We present here, an iterative biomarker study using adjacent tissue sections probed with distinct lots of CST antibody panels, imaged in temporally separated batches using a Cell DIVE imager fitted with a BAB200 liquid handler. Following robust analysis (segmentation, phenotyping and statistical analysis), we report the reproducibility findings across parameters. Methods and results reproducibility in spatial biology is essential for reliable insight generation, giving confidence in the quality of future studies aimed at improving patient outcomes.

Pan-cancer single-cell analysis reveals the interactions of *SPP1+MMP12+* macrophages with metastasis-initiating cells that drives metastasis

Baifeng Zhang, Dora Lai-wan Kwong, Xin-Yuan Guan. *Department of Clinical Oncology, The University of Hong Kong, Hong Kong, Hong Kong*

Advanced understanding of cancer immunology has contributed to a significant decline in cancer deaths in the past few decades. However, there are still vast majority of patients with no effective response for current immunotherapy drugs because of some innate immune cells, particularly macrophages and neutrophils, promoting all steps of malignant progression to metastasis. Therefore, the development of new strategies against these pro-metastatic non-tumor components in the tumor microenvironment is in need. Tumor-associated macrophage (TAMs), as the critical component of tumor microenvironment (TME), display diverse and even opposing function phenotypes, but without systematic investigation on their ubiquitous characteristics across different cancer types. Here, we perform pan-cancer analysis on 92 samples across 6 solid cancer types to profile the TME of normal, primary tumor, metastatic lymph node and distant metastasis at single-cell resolution, illustrating the commonalities/plasticity of heterogenous TAMs. We uncover 21 distinct subtypes of TAMs with varying abundance and biological function in different tissue microenvironment, providing evidence for the plasticity of TAMs. In particular, the enrichment of *SPP1+MMP12+* macrophages in the TME of lymph node metastasis, likely interacting with metastasis-initiating cells (MICs), is associated with promoting malignant progression to metastasis and survival stratifications. Multi-color immunofluorescence (mIF) staining for relevant markers is being performed in mouse models and clinical samples for comprehensive validation. Our study comprehensively describes the characteristics and dynamics of TAMs and highlights their heterogeneity and plasticity depending on their surrounding microenvironment.

#4700

Spatial analysis of the immune microenvironment and tumor cell transition in sarcomatoid renal cell carcinoma

Allison May[1], Claire Williams[2], Stephanie The[1], Sean Kim[2], Nathan Schurman[2], Greg Shelley[1], Tyler Robinson[1], Simpa Salami[1], Rohit Mehra[1], Aaron Udager[1], Evan Keller[1]. *[1]University of Michigan, Ann Arbor, MI,[2]NanoString, Seattle, WA*

Background: Sarcomatoid renal cell carcinoma (sRCC) is thought to arise by epithelial to mesenchymal transition (EMT) of the parental tumor in

diverse RCC including clear cell RCC (ccRCC). sRCC is also known to be highly immunogenic and also express high levels of inflammatory pathway genes. Cells undergoing EMT and immune cells can have reciprocal feedback on each other; however, the role of such crosstalk in sRCC is unknown. Here, we use single cell spatial transcriptomics to evaluate the heterogeneity of EMT within sRCC in correlation with the immune microenvironment and in-vitro studies to explore mechanisms of crosstalk.
Methods: A sRCC nephrectomy specimen was subjected to single cell spatial transcriptomics of 1000 mRNA targets (NanoString CosMX). Semi-supervised clustering was performed and cell types were assigned by reference to single cell RNAseq data and then mapped spatially. Differential gene expression and cell to cell distance analysis was performed. In-vitro assays included treatment of 786-O and Caki-1 ccRCC lines with recombinant SPP1 and protein and mRNA analysis.
Results: Histopathologic evaluation revealed a ccRCC zone, a transition zone (tz) between the ccRCC and sRCC in which the ccRCC cells gained an increased mesenchymal morphology, and a well-developed sRCC zone. Transcriptomic data revealed four distinct tumor cell populations: a ccRCC, a tzRCC, and two sRCC populations. Importantly, a subset of the histologically-categorized ccRCC had a tzRCC transcriptional signature, demonstrating this signature is identifiable prior to development of morphologic features of sRCC. FZD4, a factor that may function in preventing EMT, was uniquely expressed on ccRCC and lost in tzRCC and sRCC cells. CCL20, a promoter of macrophage recruitment, was highly expressed in tzRCC. Distance analysis showed macrophages were highly spatially correlated with tzRCC and sRCC cells. Macrophages near tzRCC differentially expressed SPP1. In-vitro treatment of ccRCC cells with recombinant SPP1 led to induction of EMT and further upregulation of CCL20 expression.
Conclusion: We report a unique tumor cell population characterized by ccRCC morphology but harboring a transcriptome suggestive of progression towards sRCC. This provides rationale for the development of a novel molecular signature to subclassify ccRCC. We identified FZD4, CCL20 and SPP1 as key genes in the transition of ccRCC to sRCC which may mediate crosstalk between RCC cells and macrophages, with potential for therapeutic targets.

Spatial resolution of tumor and immune cell lineages in the hypoxic microenvironment of pancreatic ductal adenocarcinoma (PDAC)

Lisa Arvidson[1], Reginaldo Prioli[1], Samuel Jensen[1], Michael J. Smith[2], Katie O. White[2], Richard A. Heil-Chapdelaine[2], Chi-Chou Huang[2], Tuan H. Phan[2], Hideki Sasaki[2], Melinda L. Angus-Hill[2]. *[1]Cell Signaling Technology, Danvers, MA,[2]Leica Microsystems, Bellevue, WA*

Understanding how the tumor microenvironment (TME) evolves during tumorigenesis and therapeutic response is crucial to developing personalized treatments with the goal of improving cancer therapy. With robust and comprehensive multiplexed imaging technologies, immune biomarker antibodies can be used to interrogate immune cell lineages and structures. When combined with specific oncology biomarker antibodies, this approach can capture the immune response within the TME in a variety of neoplasms. The Cell DIVE^{TM} Multiplex Imaging Solution allows probing and imaging of dozens of biomarkers on a whole single tissue section using an iterative staining and dye inactivation workflow. The broad portfolio of robust IHC-validated antibodies from Cell Signaling Technology (CST) enables the detection of key proteins in the TME, allowing immune cell detection and phenotyping in tissue. Here, we demonstrate multiplexed Cell DIVE imaging using a novel CST panel to probe pancreatic ductal adenocarcinoma (PDAC). These biomarker antibodies define the immune cell landscape in the hypoxic tumor. Development of the antibody panel required minimal optimization, enabled the identification of complex cell types and revealed their cell-to-cell interactions within the tumor microenvironment. The availability of cell type specific biomarkers, combined with the ability to interrogate using multiplexed tissue imaging, provides unprecedented and novel insights and spatial resolution of immune cell populations with many cell types in the TME.

#4703

Applying spatial omics and computational integrative analyses to study drug responses and cancer immune cell interactions

Xiao Tan[1], Andrew Causer[1], Tuan Quang Anh Vo[1], Ning Ma[2], Bassem Ben Cheikh[2], Laura Genovesi[1], Jazmina Gonzalez-Cruz[1], Quan Nguyen[1], Oliver Braubach[2]. *[1]University of Queensland, Brisbane, Australia,[2]Akoya Biosciences, Marlborough, MA*

Cancer responses to drug treatment are highly heterogeneous. We postulate that spatial determinants in the tumour play a critical role in cancer therapy outcomes. Here, we will present two spatial transcriptomics studies on spatial responses to immunotherapy and chemotherapy.

Immune checkpoint inhibitors (ICI) are used to treat recurrent metastatic oropharyngeal squamous cell carcinomas (OPSCC). Unfortunately, less than 30% of patients benefit from this therapy. Thus, we performed spatial transcriptomics (ST) and *in-situ* multiprotein detection (PhenoCycler-Fusion) on tissue isolated from a patient diagnosed with metastatic OPSCC. The patient's primary oral tumour responded to chemo-radio therapy, followed by nivolumab ICI. However, new soft pallet OPSCCs resurged. Subsequent pembrolizumab combined with lenvatinib (VEGFR inhibitor) treatment had an initial effect, butnew recurrent oral tumours re-emerged suggesting drug resistance. Using ST, we observed high expression of drug resistance genes such as *SNAI2*, *SOX4* and *NDRG1* consistent with the disease aggressive behaviour. Although, *PD-1/PD-L1* expression was not observed, we identified 13 over-expressed druggable targets (*i.e.*, *EGFR, TF, VEGF*) and >10 experimental targets. To rank each drug's potential success, we measured the co-expression of each target ligand-receptor pair (L/R), reducing the candidates to 4 pathways (TF/TFRC> VEGFA/NRP1> PGF/NRP1> TGFB1/VASN>VEGFA/GPC1). Furthermore, TF/TFRC and VEGFA/NRP1 expected downstream genes were differentially over-expressed where positive LR signal was detected.

Similarly, we used ST to define the cellular diversity within a sonic hedgehog (SHH) patient-derived model of Medulloblastoma (MB) and identified how cells specific to a transcriptional state or spatial location are pivotal in responses to treatment with the CDK4/6 inhibitor, Palbociclib. We distinguished neoplastic and non-neoplastic cells within tumours and from the surrounding cerebellar tissue, further refining pathological annotation. We identified a regional response to Palbociclib, with reduced proliferation and induced neuronal differentiation in both treated tumours. Additionally, we resolved at cellular resolution a distinct tumour "interface"

where the tumour cells contacted neighbouring mouse brain tissue, consisting of abundant astrocytes and microglia, and continued to proliferate despite Palbociclib treatment.
Our data highlight the power of a spatial multi-omics approach to characterise the response of a tumour to targeted therapy and provide further insights into the molecular and cellular basis underlying the response and resistance to cancer therapies.

#4704

Characterizing and developing the clinical grade next generation sequencing based gut microbiome assay with the bioinformatics solution

Danyi Wang[1], Brajendra Kumar[2], Aaron Tenney[3], Ravi Kiron[4], Yang Liu[3], Fei Zhong[3], Juergen Scheuenpflug[5], Zheng Feng[1]. *[1]EMD Serono, Billerica, MA,[2]Sigma-Aldrich Chemicals Pvt. Ltd, Bangalore, India,[3]MilliporeSigma, St. Louis, MO,[4]EMD Serono, San Jose, CA,[5]Merck KGaA, Darmstadt, Germany*

Background: It has been recognized that gut microbiome has impact on the cancer immunotherapy efficacy and Cancer Microbiome-Immune Axis is reported. Also, it is important to discover and identify clinically translatable predictive biomarker in gut microbiome to inform the treatment selections. Multiple pre-analytical and analytical steps & factors including the sample collection, DNA extraction, library preparation, sequencing and bioinformatics analysis are associated with the microbiome data interpretation as well as its potential clinical application. 16S amplicon-sequencing coupled with bioinformatics approach for advance analysis provides end-to-end solution. It is therefore essential to develop a clinical-grade assay for targeting & characterization of taxa at genus and species level microbes in stool samples, which is designed as two-phase approach: firstly, identification the optimal sample preparation reagents using pre-mixed bacteria and healthy donor stool samples coupled with proprietary bioinformatics solution; secondly, exploratory analysis of patient samples.
Methods: Healthy stool samples (n = 30, gender ratio 1:1, 10 from US west coast, 10 from US mid-west, 10 from US east coast) were extracted across extraction kits (kit A, B and C). Following isolation, bacterial 16S rRNA amplicons were generated and sequenced using a 2x300 bp paired-end

configuration on the Illumina MiSeq. FASTQ files were analyzed using the Sigma-Aldrich® M-CAMP™ web platform[1].
Results: We previously compared 5 kits using ATCC® microbiome standards (MSA 2002 and MSA 2003). Kit A, B & C were identified as high yield DNA with the similar relative abundance of microbial family. In current study, we performed the taxonomical classification, diversity analysis and comparative analysis of 16S amplicon-seq using 30 healthy stool samples. The beta diversity showed all 3 kits clustered closely together which indicated the relative abundance of microbial families were similar across the extraction kits. The Weighted Unifrac showed significant difference among the kits (P = 0.046). Kit C species abundance is significantly difference than that of Kit A & Kit B (Pairwise Permanova P = 0.027 (Kit A vs C); P = 0.017 (Kit B vs C); P = 0.991 (Kit A vs B)). Relative frequency-based group-sample level composition at phylum and species level show high level similarity.
Conclusion: The comprehensive qualification approaches including the analytically optimized extraction condition and post-analytically implement the bioinformatics solution assures the characterization of microbiota for enabling biomarker driven precision oncology. Analytical performance assessment using colorectal cancer patients' samples is ongoing for further exploring its potential clinical utilities.

Profiling of immune cell components and soluble factors in ovarian cancer ascites highlights impaired immune environment

Assia Chaibi[1], Coriolan Lebreton[2], Dominique Bodet[3], Jean-Philippe Guegan[1], Guillaume Babin[2], Antoine Italiano[2], Alban Bessede[1], Imane Nafia[1]. *[1]Explicyte Immuno-Oncology, Bordeaux, France,[2]Medical Oncology, Institut Bergonie, Bordeaux, France,[3]ImmuSmol, Bordeaux, France*

Background: It's now increasingly recognized that ovarian cancer (OC) ascites play a significant role in OC progression - behavior of tumor cells is influenced by the nature of their surrounding microenvironment. Thus, characterization of ascites composition is essential to understand how this milieu affects tumor progression and particularly the immunosuppressive

pathways that would underlie immune response dysfunctions and, in turn, how biological ascites effects can be influenced by that composition.
Methods: Ascites samples were collected from advanced OC patients. Through respective multiplexed approaches of flow cytometry-based marker expression analysis and quantitation of mediators, immune context was profiled by investigating immune cell composition and levels of a plethora of soluble factors, including cytokines/chemokines, and metabolic pathways of some amino acids known to be involved in immunosuppression. Furthermore, ascites fluids were functionally screened for their biological effects on healthy monocytes, either undifferentiated or undergoing M1 polarization.
Results: Unlike healthy PBMCs, OC ascites were mostly "enriched" in regulatory/immunosuppressive immune cell subsets including T and myeloid populations. Also, T cells were shown to highly express immune checkpoints such as PD1 in T cells and TIGIT in Tregs. Intriguingly, a high CD4/CD8 ratio was seen. Also, CD163+ tumor-associated macrophages were shown to express CSF1R, CCR8 and CCR2, and to even display a mixed phenotype since also expressing Arg1, CD80, and iNOS. On acellular fractions, most ascites demonstrated elevated CCL18, IL6, LIF, VEGF, and CCL2 levels, and low IL2, IL4, and IL17 levels. Interestingly, unlike healthy plasmas, these ascites appeared to harbor a metabolically-immunosuppressive profile characterized by high glutaminolysis and tryptophan (Trp) degradation in kynurenine (Kyn). Functionally, we demonstrated that not only ascites basically polarized monocytes into M2 macrophages, but even antagonized with their M1 polarization to ultimately tilt to M2 status.
Conclusions: Taken together, our data show that ascites fluids most favorable to the M2 phenotype were associated with high LIF, VEGF, IL6, CCL2, and CCL18 levels, and with elevated Kyn to Trp ratios - Kyn levels being strongly higher than in healthy plasmas. Our results thus highlight a peculiar altered environment of OC ascites where a mixture of suppressive cells and signaling factors mediate extracellular cues leading to immune cell activity dysfunction. Altogether, these translational findings highlight OC ascites as a valuable tool to understand the mechanisms of suppression and develop predictive profiles, and to provide new insights for the identification of new targets and development of targeted-therapies.

#4706

Multispectral immunofluorescence analysis of the olfactory neuroblastoma tumor immune microenvironment reveals macrophage and polymorphonuclear leukocyte stroma localization and tumor parenchyma exclusion

Riley Larkin[1], Diana Lopez[1], Yvette Robbins[2], Wiem Lassoued[3], Gary Gallia[4], Clint T. Allen[2], Nyall R. London[1]. *[1]Sinonasal and Skull Base Tumor Section, NIH/NCI, Bethesda, MD,[2]Section on Translational Tumor Immunology, NIH/NCI, Bethesda, MD,[3]Tumor Immune Microenvironment Laboratory, Genitourinary Malignancy Branch, NIH/NCI, Bethesda, MD,[4]Neurosurgery, Johns Hopkins, Baltimore, MD*

Background**:** Olfactory neuroblastoma (ONB), also known as esthesioneuroblastoma, is a rare malignancy of the nasal cavity and anterior skull base. Multispectral immunofluorescence (mxIF), allows for comprehensive evaluation of tumor immune cell spatial relationships and thorough characterization of the tumor immune microenvironment (TIME). The objective of this study was to comprehensively define the ONB myeloid cell TIME with mxIF.

Methods: A tissue microarray including 47 clinically annotated human ONB samples was obtained, in addition to IRB approval, from our tertiary care hospital. A myeloid specific panel was validated in ONB tissue as well as controls. The panel stained for CD15, CD68, CD11b, CD14, HLA-DR, synaptophysin, and DAPI. Phenotypes of interest included $CD11b^{+}/CD15^{+}/CD14^{-}/HLA\text{-}DR^{low/-}$ polymorphonuclear leukocytes (PMNs), $CD11b^{+}/CD14^{+}/CD15^{-}/HLA\text{-}DR^{low/-}$ monocytes, and $CD68^{+}$ Pan Macrophages. HALO image analysis v3.4 was used to objectively quantify immune cell spatial relationships. A retrospective chart review was performed from these clinically annotated specimens with collection of patient demographics, stage, Hyams grade, dural infiltration status, and outcomes.

Results: Three samples were excluded based on too little available tissue for meaningful analysis. Of the remaining 44, 38 were primary and 6 were recurrent tumors. PMNs, monocytes, and macrophages are present in the TIME of ONB at 22 cells per mm^2, 2.0 cells per mm^2, and 34 cells per mm^2 respectively. Increased PMN and macrophage cell densities were noted in

the stroma when compared to the tumor parenchyma (28 cells per mm^2 vs 14 cells per mm^2, $p<0.0001$ and 46 cells per mm^2 vs 21 cells per mm^2, $p<0.0001$). A similar trend was seen in monocytes (3.5 cells per mm^2 vs 0.80 cells per mm^2, $p=0.0588$) but it did not reach statistical significance. When we compared by Kadish Stage, higher stage (C/D) had more tumor infiltrating PMNs than low stage (A/B) (median of 1.3 cells per mm^2 vs median 0 cells per mm^2, $p=0.0011$). No further differences in cell distributions were noted when comparing for Hyams grade, stage, dural infiltration, recurrent disease, or other clinical factors. Nearest neighbor analysis demonstrates that macrophages are closer to tumor cells than PMNs or monocytes (19.68 μm vs 27.78 μm, $p<0.0001$, and 25.77 μm, $p=0.0026$, respectively).
Conclusion: This study is the first to comprehensively define the ONB myeloid TIME using mxIF. Our study demonstrates the ONB TIME contains abundant myeloid populations. As these cells have been shown to be immunosuppressive, thereby fostering tumor cell escape and host evasion, in other human malignancies we posit they play a similar role in ONB. The functional study of myeloid populations in ONB, and whether they represent targets for therapeutic intervention, is warranted.

#4707
LED photobleaching-based multiplex 3D microscopy of the tumor microenvironment
Jingtian Zheng[1], Evan Phillips[1], Yi-Chien Wu[1], Steve Seung-Young Lee[1], Vytautas Bindokas[2]. *[1]University of Illinois at Chicago, Chicago, IL,[2]The University of Chicago, Chicago, IL*

Multiplexing in immunofluorescence imaging is important for the spatial profiling of cells and molecules in tumor tissue samples. Cyclic immunofluorescence (IF) methods using oxidants (e.g. hydrogen peroxide) and enzymes (e.g. DNase) localize a great number of cellular makers and proteins in a tissue section while repeating a process of IF staining, imaging, and fluorescence deactivation. However, the repeated use of chemicals and enzymes might cause artifacts in tissue and cell morphologies. Furthermore, these methods are restricted to thin tissue sections (~5 μm thick) which are inappropriate to provide comprehensive

structural information on tissue samples. Although reconstruction of two-dimensional (2D) images from serial tissue sections can provide a certain volumetric tissue image, it takes a huge amount of time and effort. Here we introduce a three-dimensional (3D) multiplex IF imaging method using LED photobleaching. We built high-power LED illuminators with 100W warm (emission wavelength: 480-700 nm), green (430-520 nm), and red (600- 680 nm) LED chips, which can efficiently bleach a broad or selected wavelength of fluorescence signals in tissue samples. We integrated this LED photobleaching with the Transparent Tissue Tomography (T3) protocol and created a 3D cyclic IF method involving tissue macrosectioning (400 μm), three-color IF staining, D-fructose-based tissue clearing, 3D confocal fluorescence microscopy, LED photobleaching, tissue washing, and three-color IF staining for other biomarkers, and repeating the process. By applying this method to mouse mammary tumor tissues, we could perform 8-plex fluorescence microscopy for visualizing cell nuclei (DAPI), vascular (CD31, SMA) and structural (ER-TR7) cells, immune cells (CD3, CD8, CD45), and cancer cells (CK8) in the tumor macrosections in 3D at tissue and cellular resolution. To validate the method as an evaluation tool for immunotherapy, we treated the mouse mammary tumor with a STING agonist (DMAXX) intratumorally and collected the tumor tissue 1 day after the treatment, and processed it for the 3D cyclic IF protocol. The quantitative multiplex image data showed immune-driven-cancer eradication and high tumor infiltration of a large number of CD3+CD8+CD45+ cytotoxic T cells. We also examined that Red and Green LED illumination can selectively bleach fluorophores in tissues, which would be useful for patterning fluorescence in tissue as well as studying fluorescent drug-cell interaction in a tissue. In summary, this chemical and enzyme-free 3D cyclic IF imaging method will be a powerful tissue assay tool to provide comprehensive spatial information of tissue (tumor) samples including cell types, cellular and molecular location, and their 3D organization in a tissue sample.

Application of spatially resolved transcriptomics to screen multiple tumor biospecimens using tissue microarrays

Syrus Mohabbat[1], Hardeep Singh[1], Stephen R. Williams[2], Lauren M M. Gutgesell[3], David J. Sukovich[3], Govinda M. Kamath[2], Hanyoup Kim[4],

Amanda Janesick[5], Robert Shelansky[2], Ghezal Beliakoff[5], Augusto M. Tentori[4], Albert Kim[1], Cedric R. Uytingco[1], Sarah Taylor[5]. *[1]Cell Biology, 10X Genomics, Pleasanton, CA,[2]Computational Biology, 10X Genomics, Pleasanton, CA,[3]Molecular Biology, 10X Genomics, Pleasanton, CA,[4]Microfluidics, 10X Genomics, Pleasanton, CA,[5]Applications, 10X Genomics, Pleasanton, CA*

The tumor microenvironment is composed of highly heterogeneous structures and cell types that dynamically influence and communicate with each other. Although examination of singular biospecimens is sufficient for diagnostic purposes, it is inadequate and cost prohibitive when scaling for complex and overarching studies. Thus, high density multi-tumor tissue microarrays (TMAs) have been a practical and effective solution for high-throughput molecular analysis of tissues. Introduced more than a decade ago, TMAs have been instrumental in the recent study of tumor biology, the development of diagnostic tests, the establishment of quality control, and the investigation and identification of oncological biomarkers. Here, we demonstrate the pairing of the 10x Genomics Visium Cytassist Spatial Gene Expression Solution and Xenium In-Situ Platform on multi-tumor TMAs to screen for common biomarkers among a cohort of samples. Spatial transcriptomics technology has proven valuable in mapping the whole transcriptome with spatial context (Visium), whereas In Situ (Xenium) enables high-throughput cellular characterization at single-cell resolution. With the addition of our CytAssist platform, we expand on the pre-existing standard Visium solution by facilitating the retrieval of RNA transcriptomic information from tissues placed on standard or archival slides. On the other hand, the novel Xenium platform compliments whole transcriptome Visium data by unlocking the potential to assign transcripts to a particular cell with spatial context and subcellular resolution. The combination of spatial transcriptomics and targeted in situ data with FFPE TMAs promotes a high-throughput method to accelerate the uncovering of molecular signatures suitable to understanding the tumor microenvironment. We showcase the ability to spatially and comprehensively resolve individual oncogene and tumor suppressor genes associated with multiple tumors from a cohort of cancer patients and from multiple different tumor samples. In addition, these markers are mapped back to distinct morphological features within each tissue core, and use differential gene expression data to identify

distinct cell types throughout the different patient tissues. By combining the throughput of TMA samples and depth of the Visium and Xenium platforms, the strategy enables greater insights into cell-type specifics while also expanding the spectrum of biospecimen types that can be analyzed.

Spatial whole transcriptome profiling of human normal liver and HCC uncovers unique insights into metabolic zonation

Yan Liang[1], Nan Wang[2], Xia Li[2], Liang Zhang[1], Megan Vandenberg[1], Andy Nam[1], Charlie Glaser[1], Kathy Ton[1], Zhiyong Ding[2], Joseph Beechem[1].
[1]NanoString Technologies, Inc., Seattle, WA,[2]Fynn Biotechnologies, Jinan, China

Understanding the physiology and functions of the liver and cancer requires knowing transcriptional patterns driving biological activities within the functional structures of the tissue, especially the zonated features of the liver metabolic networks. Using the powerful and unique capabilities of GeoMx® Digital Spatial Profiler (DSP) with the Whole Transcriptome Atlas (WTA) panel to resolve functional units within FFPE tissues *in situ*, here we report the spatial analysis of whole transcriptomes across three micro-dissected zones (pericentral zone 3, intermediate zone 2 and periportal zone 1) of human normal liver and HCC. We also report the whole transcriptome expression data from Kupffer cells, portal traits and interlobular bile ducts from four normal liver samples and HCC. 500 - 3000 genes were detected from functional groups within each histological structure. In the liver functional units, 1000 - 2500 genes were detected in zone 1, 2 and 3 separately. By comparing the whole transcriptome profiles of zone 1 and zone 3, we have found 32 differentially expressed targets (fold change > 1.5, p value < 0.05) which showed a gradient expression pattern along the porto-central axis. The expression patterns of *CYP1A2, CYP2E1*, *CYP3A4 and ALDOB* matched well with their respective patterns of protein expression (Human Protein Atlas), recapitulating the well-studied distribution of functional activities along the porto-central axis. Moreover, by combining with Gene Set Enrichment Analysis (GSEA), we have found important pathways involved in metabolisms in either the pericentral area or the periportal area. Pathways including biological oxidations (*CYP1A2, CYP2E1*, *CYP3A4, ADH1A,* and *ADH1B*) and lipids metabolism (*AKR1C1*,

AKR1C2, and *SLCO1B3*) showed high enrichment in zone 3 and decreased towards zone 1. In contrast, pathways including platelet degranulation (*FGA*, *FGB*, *FGG*), glucose metabolism (*ALDOB* and *PCK1*) and amino acids metabolism (*HAL*, *SDS*, *NNMT*, and *GLS2*) showed high enrichment in zone 1 and decreased towards zone 3. In conclusion, our WTA data has revealed clear metabolic zonation in the liver along the porto-central axis. GeoMx technology with WTA is a powerful tool to investigate the underlying mechanisms of liver metabolism, regeneration, and tissue structure. It can be further utilized to study the whole transcriptomic differences in normal and diseased tissue.
FOR RESEARCH USE ONLY. Not for use in diagnostic procedures.

Novel 3D cytotoxicity assay to assess the impact of chimeric antigen receptor (CAR) domain design on the tumor infiltration and cytotoxicity efficacy of CAR T-cell therapies for solid tumors

Adrian Johnston[1], Zeqi Wan[1], Tina Chen[1], Yeongseo Lim[1], Cameron Lee[1], Wenxuan Du[1], Jude Philip[2], Denis Wirtz[1]. *[1]Institute for NanoBiotechnology, Johns Hopkins University, Baltimore, MD,[2]Biomedical Engineering, Johns Hopkins University, Baltimore, MD*

CAR T-cell therapy is a popular topic of discussion in and out of the scientific community. Already with multiple therapies FDA-approved for certain blood cancers, focus has rightly shifted toward FDA approval for solid tumor indications. Yet, advancing past clinical trials to FDA approval has yet to occur and has proved challenging. Of course, multiple factors are at play as to why, but we aim to use-in house expertise to elucidate one, namely CAR T-cell tumor infiltration and tissue migration and surveillance efficacy. Migration is a central parameter ignored in traditional 2D cytotoxicity assays, but there is no tumor cell killing by T cells if there is no T cell migration. We developed a novel first-of-its-kind organoid-based 3D cytotoxicity assay using multicompartment organoids and the most abundant extracellular matrix protein in human organs, collagen. We suspend solid tumor organoids in the center of CAR T-cell/collagen gel mixtures that are solidified then imaged in intervals in the span of two weeks by live-cell time-lapse reflection/fluorescence confocal microscopy, after which standard luciferase-based readouts of quantitative specific lysis

is determined. Our assay allows high-resolution tracking of CAR T-cell 3D movements through collagen fibers surrounding solid tumor organoids to determine their random and directional migration as well as their surveillance and infiltration of solid tumor organoids. We will describe the differences between currently in clinical trial mesothelin-specific CAR T-cell therapies that differ in their scFv, hinge, transmembrane, and costimulatory domains; and comparing alongside the traditional 2D luciferase-based cytotoxicity assay, we will underline how 3D migration and infiltration around and into mesothelin-expressing ovarian cancer cell organoids allow the determination of CAR T-cell therapy efficacy of different CAR T clones in a lab's arsenal for a given solid tumor through migration, infiltration, and subsequent cytotoxic capacity that is absent in traditional 2D cytotoxicity assays. CAR T-cell therapy vector design and cloning can thus be tuned for optimal migration and infiltration using our novel 3D cytotoxicity assay.

Spatial biology of tumor-stroma assembloids reveals that nothing is lost, nothing is created, everything is reorganized

Gina Bouchard[1], Irene Li[2], Weiruo Zhang[2], Sylvia Plevritis[2]. *[1]Stanford University School of Medicine, Stanford, CA,[2]Biomedical Data Science, Stanford University School of Medicine, Stanford, CA*

A close association between active fibroblastic foci (desmoplasia) and distant metastasis in the lung adenocarcinoma (LUAD) has been established decades ago and yet, the pro- and anti-tumor properties of cancer-associated fibroblasts (CAFs) are still being resolved in the hope of preventing LUAD progression. To better understand the role of stromal cells in progression, there is a growing interest in 3D patient-derived models for their translational and throughput advantages. In parallel, the emergence of multiplexed spatial biology platforms is advancing translational oncology forward by providing a more global understanding of the tumor microenvironment (TME). Despite the enthusiasm for these new technologies, there are no study showing the applicability and significance of using multiplexed spatial biology to characterized 3D patient-derived models. Here, we modeled spatial heterogeneity by assembling EGFR mutated patient-derived organoids (PDOs) with fibroblasts harvested from

the tumor edge (tumor-adjacent fibroblasts; TAFs) or tumor core (tumor core fibroblasts; TCFs) referred here as tumor-stroma *assembloids*. Using these assembloids, we generated an extensive dataset with CODEX imaging technology and used a quantitative approach to dissect tumor-stroma crosstalk. Our results show that TAFs expressing the myofibroblast marker aSMA were strictly found at the periphery of the hydrogel dome containing the assembloid, while aSMA- fibroblasts were found strictly in the center. In contrast, we did not observe a similar spatial organization in TCF assembloids. Next, we used CELESTA, an unsupervised machine learning algorithm that uses prior knowledge of the cell expression and spatial information to dissect cell heterogeneity, then performed co-localization analyses. We also leveraged the EGFR mutation status of the PDOs and observed the protective effect of the fibroblasts from erlotinib. Both assembloid conditions showed drastically different tumor-stroma spatial changes including gains and losses of colocalizations even though erlotinib did not significantly change the subpopulation fractions, cell heterogeneity, nor cell density. The top tumor-stroma colocalization pairs that persisted after erlotinib involved either myofibroblasts and PanCK-Vim+MUC1+ cancer cells or were found in the center of the assembloids, shielded by a stromal barrier of myofibroblasts. Taken together, our results show that the assembloids undergo drastic spatial reorganization following erlotinib treatment even though subpopulation fractions and cell heterogeneity remain unchanged. This study provided new insights on tumor-stroma crosstalk in the LUAD and motivates the use 3D patient-derived models coupled with multiplex imaging to answer complex spatial biology questions.

Spatial Considerations of the 3D Tumor Microenvironment

The dynamic immune behavior of primary and metastatic tumors of ovarian cancer

Elaine Stur[1], Fuduan Peng[1], Pang-ning Teng[2], Emine Bayraktar[1], Min Hu[1], Sara Corvigno[1], David J. Brown[3], Sanghoon Lee[1], Kathleen N. Moore[3], Nicholas W. Bateman[2], Kathleen M. Darcy[2], George L. Maxwell[2], Thomas Conrads[2], Nicole Fleming[1], Nicholas Navin[1], Linghua Wang[1], Anil K.

Sood[1]. *[1]The University of Texas, MD Anderson Cancer Center, Houston, TX,[2]Uniformed Services University of the Health Sciences, Bethesda, MD,[3]Stephenson Cancer Center at the University of Oklahoma Health Sciences Center/Sarah Cannon Research Institute, Oklahoma City, OK*

Background: Despite advances in cancer diagnosis and therapy, high-grade serous ovarian cancer (HGSC) is often diagnosed when spread to multiple intraperitoneal areas; it is prone to metastasize to adipose-rich tissues such as the omentum. To gain a deeper understanding of the molecular determinants of the HGSC milieu, we carried out a single-cell analysis of primary and metastatic tumors of HGSC. Thus, our aim is to identify molecular mechanisms that lead to immunosuppressive mechanisms of HGSC in primary and metastatic tumors of HGSC.
Methods: Fresh HGSC surgical samples from 19 patients were collected right after surgery, dissociated, and then frozen. For single-cells analysis, cells were sorted by a viability dye and CD45+/- populations followed by Single cell 10X 3'v3 protocol (10X Genomics) and sequenced using the NovaSeq6000 S2 sequencer. Cell Ranger toolkit v3.1.0 (10x Genomics) was applied for data processing, followed by further downstream analysis using multiple packages from R Package Seurat.
Results: To elucidate the cellular heterogeneity of HGSC, we analyzed 100,480 cells, including epithelial, lymphoid, and myeloid populations; these were identified and represented across all patients. We explored the epithelial compartment further, including a total of 21,144 cells. Given the importance of metastatic lesions for the treatment and outcome of patients with HGSC, we examined expression programs among primary and omentum tumors as well treated and untreated tumors. The major differences between primary and omental metastatic tumors included enrichment of EMT pathways and angiogenesis, as well as a decrease in the IFNα and IFNγ response in the omentum. IFNα and IFNγ response pathways were also upregulated in primary treated (P-NACT) tumors, when compared with primary untreated (P-UT) tumors. To explore the immune compartment, we clustered the immune cells across patients in 28 sub-clusters, including 19 sub-clusters of T-cells and Natural Killer cells. Altogether, the immune infiltration on P-UT indicated an immune infiltrate environment and the composition of P-UT was highly enriched in lymphoid cells with a late stage of differentiation. This finding was also demonstrated

by the analysis of T cell trajectories, with a clear definition that CD8 and CD4 cells from P-UT tumors are in a late/ final and exhausted stage of differentiation, while post-NACT tumors (independent of tissue type) are in early stages (naïve/ central memory). The measurement of a dysfunctional score showed that P-UT tumors have the highest scores, indicating a potential increase in tumor reactivity in P-UT tumors.
Conclusions: Collectively, these data indicate that HGSC primary and omentum tumors are very distinct niches for immune cells, with primary being much more dysfunctional than omentum tissue, which could indicate that the application of immunotherapies would have different impacts in variable niches of HGSC.

Integration of AI-powered digital pathology and imaging mass cytometry to identify relevant features of the tumor microenvironment

Alessandra Rigamonti[1], Marika Viatore[2], Rebecca Polidori[1], Marco Erreni[3], Maria Fumagalli[3], Daoud Rahal[4], Massimo Locati[1], Alberto Mantovani[3], Federica Marchesi[1]. *[1]University of Milan-Humanitas Research Hospital, Milan, Italy,[2]Humanitas Research Hospital, Milan, Italy,[3]Humanitas Research Hospital, Pieve Emanuele, Italy,[4]Humanitas Research Hospital, Rozzano, Italy*

Digital pathology coupled to artificial intelligence (AI)-powered approaches are receiving great attention in the oncoimmunology field, as their adoption holds promise to improve current diagnostic workflows and potentiate the analytic outputs. In this work, we aimed at combining different histopathological approaches and AI-aided analytic tools to analyze the ecosystem of tumor tissues. By deploying AI-powered standard H&E and high-dimensional imaging-mass cytometry (IMC) to FFPE tissue samples, we could extract quantitative and standardized features that couldn’t have been easily identified and integrated by eye. One tissue microarray (TMA) slide containing 108 spots of NSCLC specimens (both adenocarcinoma and squamous carcinoma) was stained with H&E and scanned through the Axio Scan.Z1 (ZEISS) to generate high-quality virtual images. A deep learning algorithm was trained and applied to H&E images to identify tumor cells. The consecutive tissue section was stained with metal-labeled antibodies and processed through the Hyperion workflow (StandardBiotools), allowing

quantitative detection of a panel of 23 markers related to tumor cells (Pan-cytokeratin), tissue architecture (aSMA, Vimentin, CD31, Collagen I, nuclei), CD45+ immune cells, comprehensive of myeloid cells (CD68, CD14, CD16, CD163, CD63, CCR4), lymphoid cells (CD3, CD4, CD8, FOXP3, CD20) and immune activation (S100A8, HLA-DR, Granzyme-B, KI67, Arginase-1). Data were exported as MCD files, visualized using the MCD viewer and further analyzed with the Qupath software. Cell segmentation was performed by the CellProfiler and Ilastik softwares and main cell populations were identified by a supervised approach through Cytomap. On H&E images, we generated a classifier of tumor heterogeneity, by exploring the spatial localization of tumor cells with the K-function summary statistic, which analyzes the distribution of tumor cells as a function of their distance. The resulting K-score value was then used to classify each tumor spot as diffuse, poorly clustered or highly clustered. Multiparametric computational analysis of the IMC images allowed to grasp immune and stromal classifiers, including frequency of immune cell populations in the tumor nests versus fibrotic stroma and immune cell interactions. In conclusion, AI-powered analysis of H&E slides is a robust approach that can improve manual scoring and unlock tissue relevant features opening to new diagnostic possibilities. Meanwhile, the analysis of the immune ecosystem by multiparametric imaging mass cytometry allows investigating spatial patterns and cell interactions at single-cell level. Integration of these approaches is feasible and allows the identification of tumor patient profiles with clinical relevance.

Spatial clustering reveals immune hub interaction with reservoir of stem-like CD8 T cells and predicts immunotherapy response in lung cancer patients

Jonathan Chen[1], Linda Nieman[2], Maxwell Spurrell[2], Justin Gainor[2], Nir Hacohen[1]. *[1]Broad Institute, Cambridge, MA,[2]Massachusetts General Hospital, Boston, MA*

Background**:** Immunologic tumor control involves coordination of multiple cell types, but the organization of these interactions in human tumors is poorly understood. We recently reported that immunogenic tumors contain spatially-localized multicellular immunity hubs characterized by expression

of interferon-stimulated genes, including *CXCL10/CXCL11* (T cell attracting chemokines), and the presence of *IFNG*+ T cells. This suggested a positive feedback loop where T cell-derived IFNγ stimulates production of CXCR3 ligands, thereby attracting more T cells. However, we did not know (1) whether these hubs predict response to immunotherapy and (2) how hubs intersect with the various CD8 T cell states which play central roles in anti-tumor immunity.

Methods: To understand the composition of this immunity hub and its potential association with immunotherapy response, we performed multiplex RNA FISH to visualize hub components in NSCLC tissue from 68 patients prior to PD1-blockade. Cells were segmented and phenotyped automatically. We additionally imaged serial sections with a second panel for markers of CD8 T cell state. We then computationally registered sequential images, integrating our panels. To identify hubs in an unbiased manner, we employed kmeans clustering.

Results: We found that the presence of the immunity hub is predictive of subsequent response to PD1-blockade. Image registration revealed that hubs are enriched for CD8 T cells in multiple states, confirming their role as key sites of anti-tumor T cell activity. Furthermore, immunity hubs in responders contained more activated CD8 T cells and *IFNG*+ cells than those in nonresponders. To determine how hub heterogeneity may influence hub functions, we subclustered hubs by phenotypic composition. This analysis uncovered a ‘hybrid hub’ subclass that spatially overlaps with structures containing stem-like TCF7+ CD8 T cells, resembling the interfollicular zone of lymph nodes. The presence of a single hybrid hub was strongly associated with RECIST response ($p = 0.0005$), found in 85% of responders and only 24% of non-responders. Hybrid hubs also showed a striking association with patient PFS ($p = 0.0014$). Using ultra-highplex RNA ISH technologies, we further explored the hybrid hubs and found they are enriched in macrophages that express CXCR3 ligands.

Conclusions: Our study provides insight into the multicellular networks that underlie anti-tumor immunity. Immunity hubs are predictive of response to immunotherapy in human lung cancer and organize intratumoral CD8 T cell activity. Moreover, hybrid hubs may represent an active intratumoral niche for tumor-specific stem-like T cells that sustain anti-tumor immunity. These multicellular networks are excellent candidates for biomarker development and targets for immunotherapy.

A pan-cancer single-cell tumor micro-environment atlas predictive of immunotherapy response

Francesca Lodi[1], Sam Vanmassenhove[1], Elena Donders[2], Pierre Van Mol[2], Amelie Franken[1], Sarah Cappuyns[3], Ayse Bassez[1], Siel Olbrecht[4], Liselore Loverix[4], Michel Bila[5], Hanne Vos[6], Joanna Pozniak[7], Kevin Punie[8], Diether Lambrechts[1]. *[1]Laboratory for Translational Genetics, Department of Human Genetics, KU Leuven, Leuven, Belgium, VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium,[2]Department of Pneumology, University Hospitals Leuven, Leuven, Belgium, VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium,[3]Digestive Oncology, Department of Gastroenterology, University Hospitals Leuven, Leuven, Belgium, VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium,[4]Department of Oncology, Laboratory of Gynaecologic Oncology, KU Leuven, Leuven, Belgium, VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium,[5]Department of Oncology, UZ Leuven - KU Leuven Laboratory of Experimental Oncology, Leuven, Belgium, VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium,[6]Department of Surgical Oncology, University Hospitals Leuven, KU Leuven, Leuven, Belgium, Leuven, Belgium,[7]Laboratory for Molecular Cancer Biology, Department of Oncology, KU Leuven, Leuven, Belgium, VIB-KU Leuven Center for Cancer Biology, Leuven, Belgium,[8]Department of General Medical Oncology, University Hospitals Leuven, KU Leuven, Leuven, Belgium, Leuven, Belgium*

The tumor microenvironment (TME) shapes response to immune checkpoint blockade (ICB). Several pan-cancer single-cell RNA-sequencing (scRNA-seq) analyses have reported how TME heterogeneity profoundly differs between cancer types. These studies mainly focused on one cell type (e.g., T-cells) and combined different technologies and bioinformatics pipelines with data being collected from both published and newly generated datasets. A comprehensive pan-cancer scRNA-seq map of the TME involving all cell types is therefore still lacking.
We obtained scRNA-seq (10x Genomics) on 234 fresh tissue samples from 161 treatment-naïve patients. Samples were collected from 9 cancer types

and subjected to a uniform in-house optimized protocol of tissue dissociation, sequencing and bioinformatics analysis. Abundancies of cell types and subtypes were correlated with each other and a tumor-reactive T-cell signature.
From 683,184 high-quality single cells, we identified 9 cell types and 71 subtypes of T-cells, B-cells, dendritic cells (DCs), monocytes/macrophages and endothelial-cells (ECs), shared between cancer types. *PDCD1* (PD1) was expressed by differentiated T-cells subtypes (e.g., $CD8^+$ exhausted and $CD4^+$ T-helper-1 subclusters), while *CD274* and *PDCD1LG* (PDL-1/PDL-2) were mainly expressed by regulatory B-cells, immune-regulatory DCs, $CXCL10^+$ and $CCL2^+$ monocyte-derived macrophages as well as inflammatory ECs. Pairwise analyses showed positive correlations between PD1-expressing T-cell subclusters, $CD4^+$ T-regulatory cells, plasma B-cells (plasmablasts, IgA and IgG plasma cells), immune-regulatory DCs, $CXCL10^+$ and $CCL2^+$ macrophages and lymphatic ECs. On the other hand, negative correlations were observed with naïve T- and B-cells, conventional DC2 (cDC2), monocytes, $CX3CR1^+$ macrophages, as well as arterial and capillary ECs. When ranking individual tumors based on a tumor-reactive T-cell signature, we found reactive tumors to correlate with positively interacting subtypes, while they anti-correlated with subclusters negatively interacting with PD1-expressing differentiated T-cells. Upon deconvolution of bulk RNA-seq data using gene signatures derived from each subcluster, these correlations were replicated in TCGA datasets across cancers. These signature scores correlated with tumor mutation burden (TMB) and other immunological features, while they were also predictive of response in clinical trials involving ICB.
We provide insights into the TME complexity at unprecedented level, identifying numerous subclusters enriched in immune-reactive (hot) or -suppressive (cold) tumors across cancer types. We validate these observations in TCGA by deconvolution of bulk RNA-seq data, and show that already pre-treatment several TME subclusters predict response to ICB.

Spatial relationships in the tumor microenvironment predict response to immune checkpoint inhibitors in urothelial and head and neck cancer

Alberto Gil-Jimenez[1], Nick van Dijk[1], Yoni Lubeck[2], Maurits L. van Montfoort[1], Dennis Peters[2], Erik Hooijberg[2], Annegien Broeks[3], Joris L. Vos[4], Charlotte L. Zuur[4], Bas van Rhijn[5], Daniel J. Vis[1], Michiel S. van der Heijden[6], Lodewyk F. A. Wessels[1]. *[1]Department of Molecular Carcinogenesis, The Netherlands Cancer Institute, Amsterdam, Netherlands,[2]Department of Pathology, The Netherlands Cancer Institute, Amsterdam, Netherlands,[3]Core Facility Molecular Pathology & Biobanking, The Netherlands Cancer Institute, Amsterdam, Netherlands,[4]Department of Head and Neck Surgery and Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands,[5]Department of Urology, The Netherlands Cancer Institute, Amsterdam, Netherlands,[6]Department of Molecular Carcinogenesis, Department of Medical Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Immune checkpoint inhibitors (ICI) can achieve remarkable clinical responses in urothelial cancer (UC). However, it remains unclear which aspects of the tumor microenvironment (TME) determine a patient's response. The TME is usually characterized by immune cell density, which ignores cells' spatial relationships relative to each other.
Methods: Using multiplex immunofluorescence data (PanCK, CD20, CD68, CD3, CD8, and FoxP3 antibody panel) of 24 pre-ICI UC transurethral resections retrieved from the NABUCCO trial (NCT03387761), we spatially profiled cancer cells, macrophages, B-cells, and distinct T-cell populations. We first quantified the TME immune cell densities at the tumor and stroma tissue compartments. We then quantified the TME spatial relationships with a novel approach based on fitting a Weibull function to the first nearest neighbor (1-NN) distance distribution, allowing us to uniquely summarize spatial relationships with two parameters (Weibull approach). We compared this approach to conventional techniques (G-functions) that rely upon a predefined distance threshold. We performed a simulation study to identify sources of variation in the spatial relationship parameters. Lastly, we associated the TME parameters with ICI (ipilimumab + nivolumab) response.
Results: Unlike the Weibull approach, the G-function quantifications manifested a variable effect size and statistical power in association studies

because of its distance threshold dependence. We found that variation in density affected the spatial relationship metrics of rare cell types (i.e., B-cells) but not of abundant cell types (i.e., cancer cells). The spatial relationship metrics from the Weibull approach outperformed immune cell density in ICI response prediction. Specifically, immune cell density did not discriminate between ICI response groups (FDR>10%). In contrast, the spatial relationship between either $CD8^+$ T-cells or macrophages to their closest cancer cell did associate with response to ICI (FDR=1%). Furthermore, non-responding tumors were characterized by $CD8^+$ T-cells close to B-cells (FDR=9%). Importantly, we validated the association between proximity and response from $CD8^+$ T-cells to cancer cells (FDR=1%) and from macrophages to cancer cells (FDR=1%) using data from 25 pre-ICI head and neck squamous cell carcinoma tumors from the IMCISION trial (NCT03003637, arm B, ipilimumab + nivolumab). Conclusion: We created a framework to quantify, study, interpret and analyze spatial relationships in the TME and illustrated its superior clinical relevance compared to density metrics for predicting ICI treatment response. Our findings emphasize the importance of spatial relationships in the TME for response and suggest that proximity between either macrophages or $CD8^+$ T-cells to cancer cells are candidate biomarkers for ICI response.

#5787

Modelling the spatial heterogeneity of CD45-positive tumor infiltrating lymphocytes in early-stage, estrogen receptor-positive breast cancer

Zak Kinsella[1], Anna Blümel[1], Mairi Lucas[1], Andreas Lindner[1], Claudia A. Gonzalez[2], Arman Rahman[2], Joanna Fay[3], Tony O'Grady[3], Verena Murphy[4], John Crown[5], Cathy Kelly[6], William Gallagher[7], Darran O'Connor[1]. *[1]Royal College of Surgeons in Ireland, Dublin, Ireland,[2]Cancer Biology Therapeutics, University College Dublin, Dublin, Ireland,[3]Beaumont Hospital, Dublin, Ireland,[4]Cancer Trials Ireland, Dublin, Ireland,[5]St Vincent's Hospital, Dublin, Ireland,[6]St James' Hospital, Dublin, Ireland,[7]University College Dublin, Dublin, Ireland*

The frequency of lymphocytes infiltrating tumors is a known prognostic in estrogen receptor (ER) negative cancers. ER+ disease is putatively believed

to be immune cold, however, there exists a subset of ER+ tumors with high immune infiltrate and with a significant spatial heterogeneity. The clinic impact of such infiltrate - especially between the Oncotype Dx Recurrence Score risk categories - remains unclear. Moreover, the distribution of tumor and stromal tissues, while noted as significantly heterogenous, is still ill-defined and not yet clinically used prognostically, despite evidence to support its utility. Using a cohort (n=450) of serial sections taken from early-stage, ER+/HER2- breast tumors of the Irish arm of the TAILORx clinical trial, we aimed to investigate the tumor architecture and spatial distribution of tumor immune infiltrate and proliferating tumor cells using digital image analysis. Antibodies against Ki67 (proliferation marker) and CD45 (leukocyte common antigen), and a routine Haematoxylin and Eosin stain were applied to serial sections of 450 full-face tumors via chromogenic immunohistochemistry, as outlined previously [1]. Digital image analysis was performed using open-source software, QuPath [2]. Pixel classifiers were trained and validated against an expert pathologist in order to define observed lymphocytes as tumor or stromal-infiltrating, and to establish a classifier to quantify the tumor-stroma ratio (TSR) and infiltrating tumor area. Distances of CD45-positive cells from tumor were computed, along with autocorrelation statistics [3,4] of CD45 and Ki67 hotspots; firstly in order to quantify spatial heterogeneity, and secondly to examine whether Ki67 as a component gene in the Oncotype Dx assay has a foundation in tumor biology or is being confounded by potentially Ki67-positive lymphocytes. Subdividing by Oncotype Dx risk categories, no significant difference in TSR was observed ($p=0.09799$), neither for intermediary risk patients receiving hormone therapy alone or in combination with chemotherapy ($p=0.3873$). While there was an observed trend overall ($p=0.092$), no significance was found for recurrence between intermediary risk subcategories (HT alone: $p=0.393$, HT+CT: $p=0.288$). However, in the cohort as a whole, median TSR was 0.3215 (range 0 - 5.023), with statistically significant differences in recurrence risk observed (cohort high v low by median TSR. HR: 6.356, 95CI: 2.263-17.84, $p<0.0001$).

Thompson[1], Betty YS Kim[1], Dima Suki[1], Melike Mut[5], Figen Soylemezoglu[3], Giannicola Genovese[1], Kadir C. Akdemir[1], Hussain A. Tawbi[1], Nizar M. Tannir[1], Florencia McAllister[1], Michael A. Davies[1], Padmanee Sharma[1], Jason Huse[1], Frederick Lang[1], Nicholas Navin[1], Eric Jonasch[1]. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]School of Biomedical Sciences, The University of Hong Kong, Hong Kong,[3]Hacettepe University Faculty of Medicine, Ankara, Turkey,[4]Emory University School of Medicine, Atlanta, GA,[5]University of Virginia, Charlottesville, VA*

Introduction: The discovery of immune checkpoint inhibitors has revolutionized metastatic renal cell carcinoma (RCC) treatment. However, in patients with RCC brain metastases, response rates are low and survival outcomes poor. To understand the tumor microenvironmental differences between primary kidney tumors, extracranial metastases, and brain metastases, we developed a detailed single-cell atlas of RCC brain metastases along with their matched extracranial and primary tumors.
Methods: We performed single-nucleus RNA-seq on 27 samples (nearly 200,000 cells) from RCC patients; samples included 14 brain metastases, 8 matched primary kidney tumors, and 5 matched extracranial metastases. We performed multiplex IHC to validate selected transcriptomic findings. We used Nanostring CosMx 960-plex RNA spatial molecular imaging technique on selected samples to validate cellular interactions in a spatial context.
Results: We established a multi-tissue single-cell atlas of RCC brain metastases by identifying 9 major and 37 minor malignant, immune, and stromal cell clusters. Brain metastases had higher neuronal and glial cells interacting with immune and tumor cells. Brain metastasis tumor cells were also transcriptomically reprogrammed to adapt to the brain microenvironment through enrichment of MYC targets, MTORC1

signaling, epithelial-mesenchymal transition, fatty-acid metabolism, oxidative phosphorylation, and reactive oxygen species pathways. Moreover, cell-to-cell communication and downstream target gene expression analyses showed that brain metastasis tumor cells expressed ligands and receptors that induce tumor cell proliferation in both autocrine and paracrine fashions. Among T-cell populations, we found fewer proliferating cytotoxic T lymphocytes in the brain than in other sites. Moreover, T cells in brain metastases expressed higher levels of several targetable inhibitory checkpoints than did extracranial metastases. In addition, we found that naïve/memory T cells in brain metastases were a favorable prognostic marker for overall survival after craniotomy. Our characterization of myeloid cell populations across the 3 disease sites found fewer dendritic cells and monocytes in the brain compared to other sites. Macrophages in brain metastases more highly expressed an M2 immunosuppressive gene signature than did those in primary RCC tumors. Conclusion: Our findings from the largest single-cell atlas of RCC brain metastases with matched primary and extracranial metastases suggest several unique targetable, immunosuppressive biological mechanisms in the brain microenvironment. These results provide a foundation for a deeper understanding of RCC brain metastasis biology and can serve as a resource for the scientific community to further explore therapeutically targetable tumor and immune-related mechanisms.

Stem Cells and the Microenvironment

#3659
RAS drivesmalignancy through stem cell crosstalk with the microenvironment

Shaopeng Yuan. *The Rockefeller University, New York, NY*

Squamous cell carcinomas (SCCs) are triggered by marked elevation of RAS/MAPK signaling and progression from benign papilloma to invasive malignancy. At tumor-stromal interfaces, a subset of tumor-initiating progenitors, the cancer stem cells (CSCs), obtain increased resistance to chemo and immunotherapy along this path. The distribution and changes in CSCs during progression from a benign state to invasive SCC remain elusive. Here, we show that following $HRAS^{G12V}$ activation, CSCs rewire

their gene expression program and trigger a self-propelling, aberrant signaling crosstalk with their tissue microenvironment that drives their malignant progression. Surprisingly, the non-genetic, dynamic cascade of intercellular exchanges involves downstream pathways often mutated in advanced metastatic SCCs with high mutational burden. Coupling our clonal skin $HRAS^{G12V}$ model with single-cell transcriptomics, chromatin-landscaping, lentiviral reporters and lineage-tracing, we show that aberrant crosstalk between CSCs and their microenvironment triggers angiogenesis and TGFβ-signaling, creating conditions ripe for hijacking leptin and leptin receptor (LEPR)-signaling, which in turn launches downstream PI3K-AKT-mTOR signaling at the benign-malignant transition. By functionally interrogating each step in this pathway, we unravel how dynamic temporal crosstalk with the microenvironment and orchestrated by the stem cells (SCs) profoundly fuels this path to malignancy. These new insights suggest broad implications for cancer therapeutics.

Bone mechanics influence cancer stem cell formation in osteosarcoma

Zunaira Shoaib[1], Aleczandria S. Tiffany[2], Brendan Harley[2], Joseph Irudayaraj[3], Timothy M. Fan[1]. *[1]Pathobiology, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL,[2]Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL,[3]Bioengineering, University of Illinois at Urbana-Champaign, Urbana-Champaign, IL*

Osteosarcoma (OS) is the most common primary tumor of bone and is characterized by rapid bone remodeling accompanied by structural and mechanical heterogeneity across the tumor. Chemoresistance and recurrence of OS can be attributed to a subpopulation of OS cells known as cancer stem-like cells (OS-CSCs). It can be hypothesized that tumor niches possessing distinct structural and mechanical properties could be harboring different OS cell populations, and certain niches might be more conducive for OS-CSCs formation and maintenance.
To evaluate the presence of OS-CSCs, mineralized collagen scaffolds mimicking heterogenous bone niches with distinct structural and mechanical properties were fabricated by changing collagen content and pore alignment and were cultured with the highly metastatic human OS cell

line 143B. Scaffolds with 47% collagen by weight but different pore alignment were chosen for further analysis because they possessed different stiffness and topographical properties. Cytoskeletal changes, epigenetic changes, chemoresistance and chemoresistance-related pathways, and the levels of stemness genes were assessed in the 3D scaffold cultures.
A consistent trend of OS-CSC phenotype was observed in the cell population grown in the softer bone niches (12 kPa) with aligned pores as compared to stiffer niche (31 kPa) with non-aligned pores. The cell population growing in softer, aligned scaffolds had a significantly higher expression of stemness genes (OCT4, NANOG, SOX2, ALDH1A1) and drug efflux gene ABCB1 and increased chemoresistance to doxorubicin and cisplatin. Epigenetic changes associated with cisplatin resistance in OS such as a decrease in methyl transferase EZH2 accompanied by the upregulation of LIF/Notch and PRKCA pathways was observed in cells grown in softer, aligned niches. Fluorescent imaging of actin organization showed rounder cells in the aligned niche indicative of the CSC phenotype, and stretched, elongated cells in the non-aligned niche indicative of a differentiated phenotype.
Our study showed that the mechanical and structural properties of bone niches influence the formation of distinct OS cell populations. A softer niche with an aligned structure is more conducive for maintaining OS-CSCs.

#3661

Extracellular vesicle derived from neural stem cells as potential vehicles of genetic information to modulate glioblastoma biology

João Pedro Alves de Araújo[1], Lilian Cruz[2], Maria Clara da Silva Souza[1], Mariana Brandão Prado[1], Rodrigo Nunes Alves[1], Bárbara Paranhos Coelho[1], Samuel Ribeiro Soares[1], Camila Félix de Lima Fernandes[3], Marilene Hohmuth Lopes[1]. *[1]Department of Cell and Developmental Biology, Institute of Biomedical Sciences (ICB), University of São Paulo, São Paulo - SP, Brazil,[2]Vertex Pharmaceuticals, Cambridge, Massachusetts, United States of America (USA), Cambridge, MA,[3]University of Cologne (UoC), Cologne, Germany*

Glioblastoma (GBM) is a deadly brain tumor and its high aggressiveness is partly due to a subpopulation of tumor stem cells known as glioblastoma

stem-like cells (GSCs). GBM establishes crosstalk with non-tumoral cells, mediated mainly by extracellular vesicles (EVs) and the interaction between GSCs and neural stem cells (NSCs) from the subventricular zone may influence GBM biology. Literature data suggests that cellular communication is an important process for GSCs stemness maintenance, and some authors consider NSCs as a possible cell of origin for GSCs. However, the specific effects that neural stem cells-derived extracellular vesicles (NSCs-EVs) promote in GSCs are still uncertain. Previous data from our group demonstrated specific groups of microRNAs (hsa-miR -137, -216a-5p, -216b-5p, 217), enriched in NSCs-EVs in contrast to intracellular compartments, suggesting these molecules are being produced for secretion. Our study aims to evaluate the role of the miRs contained in NSCs-EVs in GSCs biology. Human induced pluripotent stem cells (hiPSC) were differentiated into NSCs. NSCs were characterized by western blotting and immunofluorescence by the expression of neural commitment markers, such as nestin and β-III-tubulin. NSCs-EVs were isolated from NSCs' culture media with a commercial kit and analyzed by NTA (nanosight) for EVs size profiling and western blotting to detect specific markers, such as Alix, CD63, and HSP90. In a first approach, we analyzed the effects played by those miRs through predictive online tools. We identified target genes related to stemness (NANOG, SOX2, KLF4), oncogenesis (KRAS, CDC42, CDK6) and metabolism (CAMK2A), besides the Wnt and Notch signaling pathways. The online predictions also identified transcriptional factors related to vasculogenesis and self-renewal, key processes for GSCs activity. We will expose GSCs to NSCs-EVs and evaluate the expression of neural and stemness markers. In a future step, the GSCs previously exposed to NSCs-EVs will be treated with temozolomide, and viability assays will be performed. Additionally, we intend to modulate the four miRs identified and evaluate if they act as effector molecules of NSCs-EVs. Our data corroborate with our initial hypothesis that NSCs-EVs may act as important signalling modes in GSCs activity and consequently in GBM biology. Supported by FAPESP:22/08106-1.

Mechanism for bone marrow failure differs between acute myeloid and lymphoid leukemia

Ryan Matthew Bertoli[1], Peter D. Aplan[2], Yang Jo Chung[2]. *[1]NIH-NCI, Bethesda, MD,[2]Center for Cancer Research, NIH-NCI, Bethesda, MD*

Acute lymphoid leukemia (ALL) and acute myeloid leukemia (AML) are aggressive forms of blood cancer that impair normal hematopoiesis and are typically associated with bone marrow (BM) failure, reflected by peripheral blood pancytopenia. While BM failure is thought to be mediated by the loss of hematopoietic stem and progenitor cells (HSPCs) due to leukemic expansion, with leukemic cells "crowding out" normal HSPCs, the mechanisms underlying this process remain unclear. To elucidate these mechanisms, we examined the effects of AML or ALL on residual normal or wild type (WT) hematopoiesis. The 961C cell line is an AML cell line derived from a NUP98-PH23 (NP23) transgenic mouse, and the T259 cell line is a B cell precursor ALL (BCP ALL) cell line also derived from an NP23 mouse. AML and BCP ALL were generated by transplantation of 961C or T259 cell lines into congenic recipients without cytotoxic conditioning. The use of congenic mice allowed engraftment of immunocompetent mice, and the lack of cytotoxic conditioning prevented damage to the BM microenvironment. Mice with AML demonstrated severe anemia, thrombocytopenia, and depletion of HSPCs, along with a marked reduction of total BM cellularity (WT + AML cells), suggesting that BM suppression was not due to a physical "crowding" mechanism. Instead, BM suppression in the absence of BM replacement with myeloblasts suggested that hematopoiesis may be inhibited by a factor secreted by the AML blasts. The inflammatory cytokines TNF-A and IL-6 were markedly increased in the peripheral blood of mice with AML, suggesting these were candidates for a factor responsible for decreased cellularity and pancytopenia. In contrast, mice with BCP ALL demonstrated normal hemoglobin and leukocyte counts, even with significant ALL engraftment. The loss of WT hematopoietic cells in the BM was equivalent to the gain of leukemic cells in the BM, and the total number of leukemic cells in mice with BCP ALL was 14-fold higher than the number of leukemic cells in mice with AML. Of note, the spleen of mice with BCP ALL displayed a 100x increase in WT HSPCs compared to non-transplanted mice with healthy BM. These findings suggest that BCP ALL depletes WT HSPCs in the BM through a physical expansion mechanism. WT splenic HSPCs from mice with AML were shown to have normal

numbers of functional hematopoietic stem cells via a limiting dilution assay. In addition, WT HSPCs harvested from mice with BCP ALL generated similar numbers and types of colonies in vitro compared to WT HSPC harvested from non-leukemic mice. Both experiments suggest that neither BCP ALL nor AML induced a permanent change in the functionality of WT HSPCs. In conclusion, our results suggest that AML induces BM failure independent of leukemic burden, possibly via a secreted cytokine, whereas BCP ALL induces BM failure through physical expansion that replaces WT HSPCS with leukemic cells.

Umbilical cord blood endothelial progenitor cell-derived extracellular vesicles control important endothelial cell functions

Sawssen Ben Fraj[1], Sina Naserian[2], Bileyle Lorenzini[2], Sylvie Goulinet[2], Philippe Mauduit[2], Georges Uzan[2], Houda Haouas[1]. *[1]of Biological and Chemical engineering, National Institute of Applied Sciences and Technology (INSAT) Carthage University, LR18ES40, Inflammation, environment and signalization pathologies, Tunis, Tunisia,[2]INSERM UMR-S-MD 1197, Hopital Paul Brousse, Villejuif, France*

Background: Circulating endothelial progenitor cells (EPCs) play a pivotal role in vascular regeneration and the repair of diseases in which angiogenesis is required, including ischemia and tissue transplantation. Although they are a potentially valuable cell therapy tool, their clinical use remains limited due to suboptimal storage conditions and especially, immune rejection. Even if these cells have been shown to be tolerated by the immune system, their *in vivo* long-term effects still remain to be elucidated. EPC-derived extracellular vesicles (EPC-EVs) may be an attractive alternative to EPCs given their key role in cell-cell communication and expression of the same parental markers. In this study, we investigated the regenerative effects of umbilical cord blood EPC-EVs on EPCs *in vitro.*

Methods: EPCs were obtained from human umbilical cord blood (CB) and characterized by flow cytometry. After amplification, EPCs were cultured in a medium containing an EVs-depleted serum (EV-free medium). Then the conditioned medium was used to isolate the EVs with Tangential Flow Filtration (TFF). The EVs were characterized by a series of tests defining

their size, number, and protein content. The regenerative effects of EPC-EVs on endothelial cells were investigated by analyzing cell migration, wound healing, and tube formation. We also analyzed the effect of EPC-EVs on endothelial cell inflammation and NO production.
Results: We showed that adding different doses of EPC-EVs on EPCs does not alter the basal expression of the endothelial cell markers CD31, CD144, and KDR, nor change their proliferative potential and NO production level. Furthermore, we demonstrated that
EPC-EVs, when used at a higher than physiologic dose, create a mild inflammatory condition that activates EPCs and boosts their regenerative features like migration and tube formation functions.
Conclusions: Our results reveal for the first time that EPC-EVs, when used at a high dose, could enhance EPC regenerative functions without altering their endothelial identity.

A human skeletal muscle stem/myotube model reveals multiple signaling targets of cancer secretome in skeletal muscle

Ruizhong Wang[1], Brijesh Kumar[1], Poornima Bhat-Nakshatri[1], Aditi Sanjay Khatpe[1], Michael P. Murphy[2], Kristen E. Wanczyk[2], Emma H. Doud[3], Amber L. Mosley[1], Yunlong Liu[1], Duojiao Chen[1], Ed Simpson[1], Hongyu Gao[1], Harikrishna Nakshatri[2]. *[1]Surgery, Indiana University School of Medicine, Indianapolis, IN,[2]Surgery, Indiana University School of Medicine, VA Roudebush Medical Center, Indianapolis, IN,[3]Indiana University School of Medicine, Indianapolis, IN*

Skeletal muscle dysfunction due to the effects of cancer secretome is observed in multiple cancer types and extreme dysfunction is manifested as cachexia. Major preclinical studies on cancer-associated muscle defects utilized mouse models or mouse C2C12 mouse myoblast cell line for *in vitro* studies. Because of species specificity of certain cytokines/chemokines in the secretome, a human model system is required to fully comprehend the effects of cancer secretome on skeletal muscle. Here, we report a simple method to establish skeletal muscle stem cell line (hMuSC), which can be differentiated into myotubes. Using single nuclei ATAC-seq (snATAC-seq) and RNA-seq (snRNA-seq), we document chromatin accessibility and transcriptomic changes associated with

hMuSCs to myotube transition. Cancer cell line derived factors accelerated stem to myotube differentiation with accompanying changes including an increase in PAX7+/MyoD+ myogenic progenitor cells. Among the pathways activated by cancer-derived factors include inflammatory pathway involving CXCL8 (also called IL-8), glucocorticoid receptor (GR) pathway, and wound healing pathway. Furthermore, cancer-derived factors significantly altered splicing machinery in hMuSCs. Additionally, AKT and p53 pathways that function in metabolic/survival pathways of the skeletal muscle were adversely affected when hMuSCs were exposed to cancer cell-derived factors. Cancer-derived factors increased the expression levels of previously known cachexia-associated genes such as MT-2, ZIP14, and PDK4. Thus, the model system not only recapitulates results of previous mouse studies but also provides much needed human model system that can easily be adapted for large scale studies to explore the epigenomic changes during hMuSC differentiation and to screen for drugs that restore skeletal muscle function in various diseases.

Identification of coding and non-coding genes associated with survival outcomes in uterine cancer

Enrique I. Ramos[1], Axel M. Hidalgo[1], Ken Y. Lin[2], Shrikanth S. Gadad[1].
[1]Molecular and Translational Medicine, Texas Tech Univ. Health Sciences Ctr. El Paso, El Paso, TX,[2]Department of Obstetrics & Gynecology and Women's Health, Albert Einstein College of Medicine Montefiore Medical Center, Bronx, NY

Endometrial (or uterine) cancer is the most commonly diagnosed cancer in the female reproductive system and it disproportionately affects Black women, who are twice as likely to die from the disease than White women. In this study, we focused on the molecular characterization of copy-number high (CN-high) molecular subclassification of uterine cancer tumors, which includes most serous and serous-like endometroid tumors. These poorly characterized subcategories account for less than 10% of all uterine cancers but are responsible for over 80% of the mortality in uterine cancers and occur more commonly in Black women.We leveraged publicly available Pan-Cancer Atlas data to perform differential gene expression analyses between control and cancer samples in the Black and White CN-high groups with the aim of identifying relevant genes that could play a role in the aggressiveness of this cancer. We then performed survival analysis using the genes of interest using Kaplan-Meier estimators to ascertain the gene-specific survival outcomes.In the significantly upregulated subset of genes, we found that the high expression of the candidate gene was associated with higher survival in both White patients (p=0.046), and Black patients (p=0.021). Additionally, the expression levels of one of the noncoding genes were associated with differential survival between the groups, with low expression being associated with higher survival in White patients (p=0.0045), and high expression associated with higher survival in Black patients (p=0.018). This differential association of survival was also observed in one of the most downregulated genes in both groups, with low expression predicting higher survival in white patients (p=0.004), and Black patient survival is associated

with high expression (p=0.0082). We also identified novel non-coding genes that predicted different survival outcomes in both groups, with high expression predicting better survival in Black patients and low expression predicting better survival in White patients (p=0.048 and p=0.039, respectively). These results showcase the identification of both coding and noncoding potential genomic targets that are associated with clinical outcomes in the aggressive CN-high molecular subtype of uterine cancer. These targets merit further characterization and experimental validation to elucidate their molecular roles in the progression of endometrial cancer.

Single cell transcriptomics uncovers cellular and molecular differences in PBMCs of responders and non-responders to the MUC1 cancer vaccine given in the preventative setting

Daniel Y. Yuan[1], Michelle L. McKeague[2], Matthew T. Dracz[2], Olivera J. Finn[2], Panayiotis V. Benos[3]. *[1]Computational and Systems Biology, University of Pittsburgh, Pittsburgh, PA,[2]Immunology, University of Pittsburgh, Pittsburgh, PA,[3]Epidemiology, University of Florida, Gainesville, FL*

Introduction: A single arm trial (NCT007773097) and a double-blind, placebo controlled randomized trial (NCT02134925) were conducted in patients with newly diagnosed advanced colonic adenomas to test the safety and immunogenicity of the MUC1 antigen vaccine and its potential to prevent new adenoma formation. These are the first trials of a non-viral cancer vaccine administered in the absence of cancer. In both trials, the vaccine was safe and strongly immunogenic in 43% and 25% of participants (Responders), respectively. The lack of robust response in a significant number of participants suggested, for the first time, that even in a premalignant setting, the immune system may have already been exposed to regulatory influences that, in the case of the vaccine, determine who does and who does not respond. We hypothesized that there could be molecular and cellular differences in the immune competence between vaccine responders and non-responders, and that they could be identified by studying their pre-vaccination peripheral blood mononuclear cells (PBMCs).

Methods: The two MUC1 vaccine trials are described in https://doi.org/10.1101/2022.10.05.22280474 and https://doi.org/10.1158%2F1940-6207.CAPR-12-0275. We performed single cell RNA-sequencing (scRNAseq) on banked pre-vaccination PBMCs from 16 Responders and 16 Non-Responders, determined by anti-MUC1 IgG response. Using differential gene expression (DGE), pathway enrichment, and network estimation analyses, we identified specific cell types, genes, and pathways that differ between responders and non-responders.
Results: Pre-vaccination PBMCs from Responders contained a significantly higher percentage of CD4+ naive T cells, while Non-Responders showed significantly higher percentage of CD8+ T effector memory (TEM) cells and a higher percentage of CD16+ monocytes. DGE and gene interaction network analysis showed a higher level of expression of T cell activation genes, such as Fos and Jun, in the CD4+ naive T cells in Responders. Further network analysis showed that these genes were directly connected to response. We also found pre-vaccination specific gene ontology (GO) pathways for translational and transcriptional activity enriched in all cell types in Responders compared to Non-Responders.
Conclusion: Our analyses identified candidate biomarkers that are predictive of a preventative cancer vaccine response. Thus, our results can be used for patient selection for vaccine administration. Furthermore, we identified cell type differences and transcriptional pathways that provide information of possible mechanisms of vaccine response.

Development and refinement of functional gene expression signatures as a computational tool for comprehensive characterization of transcriptomic data

Elena Ocheredko, Nadezhda Lukashevich, Maria Savchenko, Sofia Kust, Syune Ambaryan, Dmitry Tabakov, Maria Sorokina, Linda Balabanian, Kushal Suryamohan, Anastasiya Zotova, Nathan Fowler, Aleksander Bagaev.
BostonGene, Corp., Waltham, MA

Functional gene expression signatures (FGES) are widely used as biomarkers in cancer diagnostics as descriptive and predictive models for treatment selection. Since FGES scores are based solely on gene expression profiles, they can be applied to data from bulk and single-cell RNA-seq or gene expression microarrays. However, FGES development and implementation has several challenges including technical limitations of calculating FGES scores based on

ranked gene expressions such as background noise and gene cross-correlations and difficulty in assessing the biological relevance of FGES. Here, we developed an FGES validation pipeline that addressed these limitations by examining publicly available and internally-developed FGES.
The pipeline was developed by applying a modified single-sample gene set enrichment analysis (ssGSEA) to a manually curated database of more than 50,000 RNA-Seq samples, including sorted cells, cell lines, and tumor and normal tissue biopsies. We defined technical and biological criteria to validate signature quality: 1) single gene expression noise distribution minimum is greater than zero; 2) cross-correlation of genes comprising a signature is positive; 3) specificity, whereby a FGES differentiates a group of interest and has a minimal overlap with other unrelated signatures and molecular pathways; 4) generalizability, requiring FGES score to differentiate a group of interest across datasets of different origin, cell type, or diagnosis.
We tested these criteria on FGES that describe cellular processes such as epithelial-mesenchymal transition (EMT) and senescence as well as FGES that can delineate cell types such as macrophages. We were able to better distinguish 12 different cell types using the corresponding cell type-specific FGES with significantly higher ssGSEA scores (p-adj ≤ 0.00004 in 99.9% cases) than 911 analogous MSigDB gene signatures. Our EMT FGES, tuned specifically for melanoma, exhibited higher precision than the MSigDB Hallmark EMT gene set ($p < 0.001$) for predicting histological pigment scores. The senescence FGES also accurately distinguished senescent from non-senescent cells in datasets of differing cell origin and data acquisition methods, demonstrating signature generalizability. Finally, using macrophage-describing FGES, we showed that specificity of a publicly available gene set can be significantly improved (p-adj = 0.00001) by tuning it according to the aforementioned criteria.
Taken together, our proposed workflow enables better assessment of the technical quality and biological adequacy of FGES for their further use in transcriptomic analyses and computational models of complex biological processes and tumorigenesis.

Application of optical genome mapping to identify samples with homologous recombination deficiency

Andy Wing Chun Pang[1], Kelsea Chang[1], Nikhil Sahajpal[2], Daniel Saul[1], Ravindra Kolhe[3], Alka Chaubey[1], Alex Hastie[1]. *[1]Bionano Genomics, San Diego, CA,[2]Greenwood Genetics Center, Greenwood, SC,[3]Augusta University, Augusta, GA*

Certain cancer treatments, such as the poly (ADP-ribos) polymerase (PARP) inhibitors, have been shown to be effective in killing cancer cells exhibiting genome instability signatures indicative of homologous recombination deficiency (HRD). Hence, these signatures are used as biomarkers to inform treatment decisions and prognosis. There are three measurements of HRD signatures commonly employed: loss of heterozygosity (HRD-LOH), telomeric allelic imbalance (TAI) and large-scale state transition (LST). It has been shown that combining all three scores can better determine the HRD phenotype, leading to a higher clinical impact. Yet current HRD signature tests, used to estimate HRD, have low negative predictive value, and one possible reason is that current genomic technologies lack sensitivity to capture the full extent of somatic genomic rearrangements. Here, optical genome mapping (OGM) was used to detect large structural variants (SVs) and calculate a HRD score. OGM captures high molecular weight DNA to call SVs by aligning these molecules to the public reference genome. OGM can comprehensively detect insertions and deletions >5kbp, inversions, interchromosomal translocations, plus large interstitial copy number variation (CNV) and aneusomies. Subsequently, an automated script was developed to compute the HRD score, which is the summation of the three HRD signatures: HRD-LOH, the number of regions with a loss >15 Mbp but shorter than the whole chromosome; TAI, the number of regions of gain and loss >10Mbp that extend to a subtelomere but do not cross the centromere; and LST, the number of chromosomal breakpoints whose SV size >10Mb but not the whole chromosome. We applied this script on 20 samples of solid tumors and myeloid neoplasms, and the automated scores are concordant with expertly curated scores, confirming the validity of the calculation. We believe that OGM data combined with this automated analysis of HRD signatures is much more sensitive and accurate for detection of HRD signatures and that this will enable more precise prediction of drug response for multiple tumor types.

Multiscale protein networks: de novo aberrant protein interactions and oncogenic regulators in seven cancer types

Won Min Song, Abdulkadir Elmas, Richard Farias, Peng Xu, Xianxiao Zhou, Benjamin Hopkins, Kuan-lin Huang, Bin Zhang. *Icahn School of Medicine at Mount Sinai, New York, NY*

We conducted integrative proteomic network analyses of 687 cases across 7 cancer types including breast cancer (115 tumor samples), clear cell renal carcinoma (100 tumor samples), colorectal cancer (91 tumor samples), hepatocellular carcinoma (101 tumor samples), lung adenocarcinoma (104 tumor samples), stomach adenocarcinoma (80 tumor samples), and uterine corpus endometrial carcinoma (96 tumor samples). Using Multi-scale embedded gene co-expression network analysis (MEGENA), we constructed co-expression protein network for each cancer type, and interrogated the network topology and co-expressed protein modules. For each cancer type, we identified disease-associated pathways as co-expressed protein modules enriched for differentially expressed proteins in tumor. Comparing with respective cancer transcriptome network models, this systematically revealed proteome-specific cancer subnetworks associated with heme metabolism, DNA repair, spliceosome, oxidative phosphorylation and KRAS oncogenic signaling pahways in several cancer types. Cross-cancer comparison identified highly preserved protein modules showing robust pan-cancer interactions and identified endoplasmic reticulum-associated degradation (ERAD) and N-acetyltransferase activity as the central functional axes. Then, we utilized these network models to predict pan-cancer protein network regulators in the up-stream of disease-associated pathways. The predicted pan-cancer regulators were experimentally validated by loss-of-function to confer anti-tumor effects in diverse cancer types: lung (H847), colon (HCT116), fetal kidney (HEK293T) and breast (MDA-MB-231) cancer cells. Overall, the study was designed to provide tractable network models of cancer proteome, and unlock the further potentials to understand oncogenic regulators and mechanisms in different cancer types.

Geometry of gene expression network reveals potential novel indicator in Ewing sarcoma

Rena Elkin[1], Jung Hun Oh[1], Filemon Dela Cruz[1], Larry Norton[1], Joseph O. Deasy[1], Andrew L. Kung[1], Allen R. Tannenbaum[2]. *[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Stony Brook University, Stony Brook, NY*

Oncogenic driver mutations in different pediatric sarcoma subtypes have been identified but may not be druggable. In general, identifying novel therapeutic targets and biomarkers for response remains a major challenge. We hypothesize that considering the structure of the interaction network in which the genes operate as a system is crucial for understanding a gene's role. We propose to use the protein interaction network geometry to characterize the shape of network

architecture and identify key aspects of direct and indirect cooperation pertaining to the cancer network and prognosis using geometrical methods.
We model gene networks as weighted graphs where edges indicate protein-level interactions and edge weights estimate the strength of the interaction. The Human Protein Reference Database was used to define the gene network topology. RNA-Seq data from pediatric sarcoma tissues extracted from patients treated at MSK (n=12 Ewing sarcoma; n=29 osteosarcoma; n=20 desmoplastic small round cell tumor) was employed to prescribe correlation-based weights to create pediatric sarcoma subtype-specific weighted graphs. The geometry of the weighted gene networks was computed via a discrete notion of Ricci curvature. Intuitively, the curvature provides a measure of feedback (triangles) in the network. Positive curvature reflects robust communication and ease of information transfer, while negative curvature reflects bridge-like architecture or bottlenecks of information flow. We utilized a dynamic (multi-scale) notion of curvature to quantify the functional associations between genes, computed as a function of scale between diffusion processes initially localized on each node (i.e., gene). The curvature becomes more positive on edges between communal genes and more negative on bridge-like edges between communities, until reaching the critical scale. Curvature therefore, as we demonstrate, partitions the cancer networks into functionally associated communities.
Community detection by removing bridge-edges, determined as edges with negative curvature at the critical scale, revealed sarcoma subtype-specific preferential gene associations. In particular, we agnostically found the *EWSR1-FLI1* association in a cluster that was unique to the Ewing sarcoma network. Interestingly, we found *ETV6* in the same community as the characteristic Ewing sarcoma *EWSR1-FLI1* feature, suggesting a novel implication of *ETV6* in Ewing sarcoma. These results suggest that persisting communities found by leveraging the cancer network geometry may identify potential mechanisms of drug resistance and actionable therapeutic targets.

Detection of androgen receptor splice variants from clinical sequencing
Suhyun Hwangbo, Sungyoung Lee, Sheehyun Kim, Hongseok Yun. *Seoul National University Hospital, Seoul, Korea, Republic of*

Androgen receptor (*AR*) splice variants (*AR*-Vs) have been widely studied on its important role in prostate cancer (PC) progression. In particular, *AR*-Vs lacking ligand binding domains, such as *AR* splice variant 7 (*AR*-v7) that links exon 3 and cryptic exon 3 or *AR* variant that losses exons 5 to 7 (AR^{v567es}), have been

demonstrated as one of the resistant mechanisms to androgen deprivation therapy in PC. Despite its clinical importance, the current algorithms to detect fusions such as TopHat-Fusion have limitation to detect intra-chromosomal rearrangements including *AR*-Vs. In this respect, we propose a novel approach to identify *AR*-Vs from targeted RNA sequencing (RNA-seq) dataset. In short, our two-step approach first gathers soft-clipped or divided reads that are adjacent to the splicing sites of *AR*-Vs and then yields the number of splitting reads that support the existence of *AR*-Vs. Next, the algorithm selects the paired-end reads whose one side and the other side are mapped to the preceding and following exons, respectively. The final number of spanning reads are calculated following to the removal of low-quality reads. We validated the proposed approach using two large-scale, independent RNA-seq datasets of PC samples: 34 samples from Seoul National University Hospital (SNUH) and 558 samples from The Cancer Genome Atlas (TCGA) dataset. Overall, our approach successfully identified samples with putative *AR*-Vs, including *AR*-v7 and AR^{v567es}. In addition, our approach successfully detected *AR*-v7 with reliable number of supporting reads, from the RNA-seq dataset of *AR*-v7-expressing cell line. Finally, statistical analyses of 34 SNUH PC patients suggested potential detection threshold in clinical sequencing settings (at least 10 split reads and 1% proportion). In the SNUH dataset, The *AR*-v7 positive group, which included 6 patients (17.1%) with values above the threshold, had higher *AR*-v7 expression levels than the negative group (p=4.8E-04). The similar pattern was also found in the analysis of TCGA dataset. Owing to its flexibility, we also confirmed that the developed approach can be used to detection of other *AR*-Vs, including *AR*-v3 and AR^{v567es}. We expect that the further in-depth analyses including larger samples and clinical outcomes can discover clinical applicability of *AR*-Vs.

Comparative analysis of immune landscape according to EGFR mutation and tumor PD-L1 proportion scores in non-small cell lung cancer at single cell resolution

YoungJoon Park, Su-Jin Choi, Jii Bum Lee, Dong Kwon Kim, Sun Min Lim, Seong Gu Heo, Ke Jia Qi, Byoung Chul Cho, Kyoung-Ho Pyo. *Yonsei University College of Medicine, Seoul, Korea, Republic of*

Introduction: In EGFR-mutant non-small cell lung cancer (NSCLC), the efficacy of immune checkpoint blockade (ICB) is limited with higher incidence of toxicity profiles. EGFR-mutant NSCLC is associated with immune suppressive microenvironment, including lower programmed death-ligand 1

(PD-L1), tumor mutational burden (TMB), and tumor-infiltrating $CD8^+$ T lymphocytes. However, tumors expressing high levels of PD-L1 show improved and durable clinical benefit in immunotherapy. In addition, Understanding the dynamics of tumor microenvironment may elucidate immune response in terms of immune composition, and help overcome resistance to immune checkpoint inhibitors. Here, we demonstrate that conventional type 1 dendritic cells (cDC1s) is one of the key tumor microenvironment, resulting in priming of $CD8^+$ T cells and production of chemokines, such as CXCL9/CXCL10 and cytokines that augment anti-tumor immunity.

Methods: A total of 31 surgical samples of NSCLC, including EGFR wild and mutant NSCLC of stages I-III, and 16 normal lung tissue samples were collected. PD-L1 expression in EGFR wild type was categorized into tumor proportion score (TPS) of < 50% and ≥ 50% using immunohistochemistry (IHC). Single cell RNA sequencing was performed with the Scanpy toolkit on the retrospective cohorts of normal (n=16), EGFR mutant (n=14, L858R=6, E19Del=8), EGFR wild TPS ≥ 50% (n=10), and TPS < 50% (n=7).

Results: We observed that an overall tumor specific immune response occurred in EGFR wild-type TPS ≥ 50% compared with others. *XCL1*$^+$ innate-like T cells, which act as an orchestra of tumor specific immune response, were found. These cells had high expression of *FCER1G* and *IL2RB*, a receptor for IL-15, However, expression of *CD8A/B*, *CD4* and *FCGR3A* was low. Interestingly, in these innate-like T cells, the expression of *ITGAE*, which interacts with E-cadherin in cancer cells, and *CD81*, which interacts with CD3 and enhances immunological synapse, was observed in EGFR wild TPS ≥ 50%. According to these results, *XCR1*$^+$ cDC1s were enriched in EGFR wild-type TPS ≥ 50%. *CXCL9*/*CXCL10*, which recruits $CXCR3^+$ effector T cells which are primed at the lymph node, was highly expressed in activated DCs at EGFR wild TPS ≥ 50%. $CD8^+$ T cells were significantly enriched in EGFR wild-type TPS ≥ 50%. These cells also expressed *IFNG* and *FLT3LG*, which maintain the function of intra-tumoral dendritic cells (DCs), and were also up-regulated in EGFR wild-type TPS ≥ 50%. Among them, exhausted $CD8^+$ T cells expressing *PDCD1* were observed in EGFR wild TPS ≥ 50%, and these cells also expressed *ITGAE* and *CD81*. In addition, these cells also showed high expression of *CXCR3*, a receptor for CXCL9/CXCL10 which were expressed in the activated DCs.

Conclusion: cDC1s-mediated tumor specific immune response occurred in patients with EGFR wild TPS ≥ 50%, which could be an important mechanism to predict anti-PD-1 response.

#6544

Identification of epigenetic regulatory networks associated with the basal-like breast cancer subtype

Larissa Miyuki Okano[1], Alexandre Luiz Korte de Azevedo[2], Tamyres Mingorance Carvalho[2], Fernanda Brandão Berti[1], Luciane Regina Cavalli[1].
[1]Instituto de Pesquisa Pele Pequeno Principe, Curitiba, Brazil,[2]Genetics Department, Universidade Federal do Paraná, Curitiba, Brazil

Purpose: Basal-like breast cancer (BLBC) is a biologically aggressive and molecular heterogeneous breast cancer subtype that confers to the patient´s poor prognosis. The crosstalk of epigenetic regulators, such as methylation events and microRNA (miRNA) deregulation, drives breast cancer progression and modulates aggressive tumor phenotypes. However, few studies have specifically characterized the epigenetic regulatory networks of genome-wide DNA methylation-based modifications, miRNAs and transcription factors (TF) expression in BLBC. Therefore, the main objective of this study was to identify and correlate the DNA methylation profiles and the transcriptional expression of miRNAs and TFs of the BLBC subtype.
Methods: To achieve our goal, a comprehensive computational pipeline using the R language was used. First, the transcriptional expression profiles and DNA methylation data of BLBC and non-tumor samples were downloaded from The Cancer Genome Atlas (TCGA). Then, the ELMER package was used to determine the differentially methylated distal probes between these two groups, identifying gene-probes pairs that can be regulated by un/methylated regions that affect the function of TFs. The different expressed (DE) miRNAs were identified using the DESeq2 package. To determine the regulatory pairs (gene, miRNA and TF interactions) the multiMiR, miRWalk, ENCODE, and hTFtarget were used and the regulatory networks were identified by the FANMOD algorithm. Finally, pathway enrichment analysis (PEA) was conducted using the Reactome database and microT-CDS (Diana Tools mirPath v.3).
Results: A total of 147 and 199 pairs of gene-probes were identified in hypermethylation and hypomethylation analyses, respectively. Fifty genes and 59 regulatory TFs whose expression was associated with DNA methylation were selected, including members of the E2F (E2Fs) and Krüppel-like factor (KLFs) family. Eleven DE miRNAs, out of the 51 identified, were selected based on their interaction with genes and TFs. These pairs of miRNAs, TF, and genes generated three types of feed-forward loops (FFLs): coherent FFLs, mediated by miRNAs; incoherent FFLs, mediated by TFs; and compost FFLs, mediated by TF and miRNAs. Finally, the PEA analysis showed 51 pathways in which miRNAs, genes, or TFs may interact, including pathways related to DNA repair,

cell cycle, pathways in cancer, as well as the defective binding of RB1 mutants to E2F1, and the ErbB signaling pathway.
Conclusion: Our findings demonstrated the epigenetic regulation of methylation patterns and miRNA expression and their impact on the expression of TFs that may exert critical roles in the BLBC. The functional analysis of these regulatory networks in well-established BLBC models, targeting the signaling pathways identified, can determine whether they modulate the BLBC phenotype and can be used as potential clinical targets.

Investigating secondary findings in a pediatric cancer cohort: preliminary findings

Safa Majeed[1], Stephenie Prokopec[2], Brianne Laverty[1], Vallijah Subasri[1], Michael Taylor[3], Yvonne Bombard[4], Trevor Pugh[2], Adam Shlien[1], Anita Villani[3], David Malkin[3]. *[1]Genetics and Genome Biology, Hospital for Sick Children, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[3]Hospital for Sick Children, Toronto, ON, Canada,[4]Genomics Health Services Research Program, Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada*

Purpose: An expected outcome following germline genome sequencing in oncology is the discovery of 'secondary findings' (SFs). SFs comprise pathogenic(P)/likely P (LP) germline variants in cancer genes not typically associated with the presenting cancer, in addition to germline variants of uncertain significance (VUS) to the patient's cancer. Due to the rarity of childhood cancers and a dearth of studies analyzing SFs, many pediatric SFs are categorized as VUS without clinical interpretation. Interpreting SFs poses significant challenges: VUSs and other SFs are frequently not included in clinical molecular reports, and even when reported (often through research), their clinical utility and long-term impact on patient health are unclear. However, we know VUSs can have clinical importance because some VUSs, when investigated thoroughly, have been reclassified as pathogenic predictors of significant health conditions in children. We hypothesize that an in-depth characterization of the landscape of germline SFs/VUSs across a diverse pediatric cancer cohort will reveal new roles of these genes and mutations in pediatric cancers.
Methods: To explore germline SFs in pediatric cancer patients, we analyzed germline whole-genome sequencing (WGS) data for patients with rare, relapsed, refractory, and metastatic childhood cancers enrolled in the SickKids Cancer

Sequencing Program (KiCS). We developed a custom analysis pipeline to identify germline single-nucleotide variants and indels deemed SFs, auto-classify their pathogenicity (ex. P, LP, or VUS) using CharGer, filter for PanCanAtlas-indicated cancer predisposition genes, and sort the remaining variants by cancer and non-cancer associations.
Results: The KiCS cohort (n = 511) encompassed over 133 different tumor types; the median age of participants was 14 years (SD = 10.27) and 55% of patients were male. Ongoing work in our lab will catalogue the frequency and distribution of SFs in KiCS and analyze germline variants by subgroup (gene, tumor subtype, stage, demographics, gene function). We will also compare SF prevalence in KiCS to the general population using the gnomAD dataset. Results from preliminary analyses of this cohort will be presented.
Significance: SFs/VUSs are under-utilized in cancer management. This work advances the holistic understanding of germline genomics in pediatric oncology and the roles of SFs in disease. Future studies will evaluate SFs by patient ancestry and validate cancer associations through the evaluation of allelic imbalance/loss of heterozygosity in matched tumor genomes.

Peritoneal microenvironment promotes appendiceal adenocarcinoma tumor formation in PDX models

Vinay K. Pattalachinti[1], Ichiaki Ito[1], Saikat Chowdhury[1], Abdelrahman Yousef[1], Yue Gu[1], Keith F. Fournier[2], John P. Shen[1]. *[1]Gastrointestinal Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX*

Background: Few preclinical models of appendiceal adenocarcinomas (AAs) exist. Orthotopic patient-derived xenografts (PDXs) better recapitulate the original tumor microenvironment. Therefore, we hypothesized that AA patient tumors should grow more successfully in orthotopic PDXs compared to standard flank implanted PDXs.
Methods: After obtaining informed consent, tumor samples were obtained from 16 patients with AA undergoing surgical resection at MD Anderson Cancer Center. Tumors were implanted in both the flank and peritoneum of NSG mice; from each patient, at least 6 mice (n≥3 IP, n≥3 flank) were implanted with an approximately 0.5 cm^3 tumor. Mice were assessed after 6 months for tumor formation.
Whole transcriptomic RNAseq was performed on tumor samples taken from either the flank (n=3) or peritoneum (n=3) of two poorly differentiated (grade 3)

patient tumors. The R package DESeq2 was used to conduct differential gene expression analysis comparing IP to Flank PDXs, controlling for the specific patient tumor. Finally, Gene Set Enrichment Analysis (GSEA) with the hallmark gene sets from MSigDB was implemented to study the relative up/down-regulation patterns of gene sets in each PDX cohort.
Results: Tumor formation rate, regardless of grade, was greater in IP vs. flank implantation (31.4% vs 11.7%). Higher grade was associated with higher average tumor formation rates (IP—G1: 13.3%, G2: 33.8%, G3: 44.5%; Flank—G1: 0%, G2: 0%, G3: 31.2%).
GSEA identified that cell proliferation and energy metabolism gene sets were significantly enriched in IP tumors relative to flank: E2F Targets, G2M Checkpoint, Oxidative Phosphorylation, MYC Targets V1, MYC Targets V2, and DNA Repair (NES = 2.91, 2.62, 2.60, 2.31, 1.61, 1.82, respectively; FDR q-val $\leq$ 0.01 for all). Meanwhile, gene sets associated with tumor environmental stress were enriched in flank tumors: Angiogenesis, Hypoxia, and TGF-β Signaling (NES = -2.00, -1.73, -1.62, respectively; FDR q-val $\leq$ 0.01 for all). Epithelial Mesenchymal Transition and TNF-α signaling via NF-κB were also enriched in flank tumors (NES = -2.28, -2.20; FDR q-val < 0.01).
Conclusions: The peritoneal microenvironment promotes growth of appendiceal tumors in PDXs, with higher-grade being associated with greater tumor formation rate. GSEA also suggests that AAs preferentially grow in the peritoneal microenvironment in association with greater activation of cellular proliferation and energy metabolism pathways and lower activation of tumor environmental stress pathways.

#6547
Features of the TCR repertoire associate with patient's clinical and molecular characteristics in acute myeloid leukemia
Mateusz Pospiech, Mukund Tamizharasan, Yu-Chun Wei, Advaith M. S. Kumar, Mimi Lou, Joshua Milstein, Houda Alachkar. *USC - University of Southern California, Los Angeles, CA*

Allogeneic hematopoietic stem cell transplant (allo-HSCT) remains the most effective strategy for high risk patients with acute myeloid leukemia (AML). Leukemia specific neoantigens when presented by the major histocompatibility complexes (MHCs) are recognized by the T cell receptors (TCR) triggering the graft versus leukemia effect. Unique TCR signature is generated by a complex rearrangement process of an array of variable (V), diversity (D), and joining (J) exons to form a functional receptor with complementary determining regions 3

responsible for the interaction between the TCR and the peptide-MHC. The generated TCR repertoire undergoes dynamic changes with the onset and progression of leukemia and with the course of treatment.
To better understand how the TCR repertoire impacts disease progression and patient's clinical outcome, we leveraged RNA-seq data from The Cancer Genome Atlas (TCGA) to extract the TCR sequences using TRUST4 and MIXCR and examined the association between features of the TCR repertoire in patients with AML and their clinical and molecular characteristics. Data were analyzed by normalizing the number of unique clones to the number of total RNA-seq reads specific for each sample and one minus peripheral blood blast percentage.
Both TRUST4 and MIXCR data showed a strong correlation between the number of unique clones for TCRA and TCRB per patient ($r=0.944$, $p<0.001$ for TRUST4, $r=0.941$, $p<0.001$ for MIXCR). Only 1389 TCRA clones (28.9%; TRUST4: 3450, MIXCR: 2747) and 1327 TCRB (31.3%; TRUST4: 3986, MIXCR: 1584) unique clonotypes were shared by the two computational tools. Nevertheless, we were able to identify the majority of the known TRAV and TRBV segments. Our analysis shows that the normalized number of unique TCRA and TCRB clones were lower in patients carrying FLT3 mutations (TRUST4: TCRA: $p=0.013$; TCRB: $p=0.058$; MIXCR: TCRA: $p=0.043$; TCRB: $p=0.030$), and higher in patients carrying IDH1 mutations (TRUST4: TCRA: $p=0.037$; TCRB: $p=0.038$; MIXCR: TCRA: $p=0.037$; TCRB: $p=0.002$) compared with patients carrying the wild type gene. No significant difference was observed for DNMT3A, NPM1, TET2, RUNX1, CEBPA IDH2, NRAS, WT1 and TP53 compared with wild type. Although the normalized number of unique TCR clones was not significantly associated with patient's overall survival, we found that patients that shared TCRB clones with any other patients had a trend toward an improved overall survival compared with patients that did not share any TCRB clones with other patients (median OS: 32.3 vs 16 months, $p=0.068$).
Despite the limitations of low TCR gene coverage associated with RNAseq data and the small sample size, we were able to find associations between TCR repertoire and clinical and molecular features in patients with AML using two different computational tools. This study further supports the need for TCR-Seq analyses to provide the depth needed to characterize the TCR repertoire in patients with AML.

Bioinformatic characterization of dendritic and T cell subpopulations in the tumor microenvironment across different cancer types by single-cell RNA-Seq analysis

Yamil D. Mahmoud[1], Natalia Rego[2], Marcela Vilarino[3], Florencia Veigas[1], Maria R. Girotti[1], Juan M. Perez Saez[1], Gabriel A. Rabinovich[1], Marcelo Hill[3].
[1]Laboratorio de Glicomedicina, IBYME, Buenos Aires, Argentina,[2]Bioinformatics Unit, Institut Pasteur de Montevideo, Montevideo, Uruguay,[3]Laboratory of Immunoregulation and Inflammation, Institut Pasteur de Montevideo, Montevideo, Uruguay

Although the development of single-cell RNAseq (scRNAseq) has improved the knowledge of the tumor microenvironment (TME), there is not a clear understanding of specific cell subtypes, markers that define these cell populations, nor the interaction between them. Previously, we showed that inflammasome activation is correlated with antitumor responses triggered by immune checkpoint blockade (ICB). This highlights a central role for TMEM176B, mostly expressed in myeloid cells, that impairs the recruitment of cytotoxic immune cells in the TME by inhibiting NLRP3 inflammasome activation. Still, the roles of the different subsets of myeloid and T cells in the TME and to what extent they are connected remain controversial. Here, we used scRNAseq data from human tumors to identify and characterize cDC2, Th17 and exhausted $CD8^+$ T cell subpopulations in cancer. Five scRNAseq data sets of melanoma, basal cell carcinoma, breast, lung, colorectal, and ovary cancer patients were integrated, accounting for 382,019 immune cells in total. We applied and compared different bioinformatic tools for scRNASeq data normalization and data sets integration to find conserved immune cell populations across samples, data sets, and cancer types. Then, we evaluated different parameters using well-established methods for clustering and cell type classification to identify subtypes of DCs and T cells in the integrated data. We combined automatic methods with manual analysis of cluster markers to improve robustness and confidence in the cell populations identified. Three clusters of cDC2 were defined and characterized using different scRNAseq analysis tools for pathway enrichment analysis and transcription factors (TF) activation prediction. We found a subset of inflammatory cDC2 with high gene expression of *IL1B* and *NLRP3*, in contrast with another cluster characterized by high expression of *TMEM176B* and *CD14*. A third cluster showed an intermediate transcriptomic profile. The $TMEM176B^+$ $CD14^+$ cluster was characterized by the activation of JAK-STAT and hypoxia pathways, and the TF FOXL2, ETS2, and ESR2. The $NLRP3^+$ $IL1B^+$ cluster showed more activation

of MAPK, Trail, and PI3K pathways, and the TF CEBPE. Moreover, the activation of TNFα and NFkB signaling pathways was found in both clusters. In addition, a conserved population of Th17 cells in the integrated data was observed. Th17 cells were heterogeneous, making the subpopulations and transcriptome signature difficult to define. Further analysis is being performed to identify Th17 subsets and their potential interactions with the cDC2 subclusters. A robust identification and characterization of these immune cell subsets will build towards our understanding of the interactions between these subpopulations triggered by inflammasome activation within the TME and the mechanisms behind ICB response.

Investigating the effects of density and frequency-dependent selection on subpopulations of cancer cells defined by copy number

Thomas A. Veith[1], Andrew Schultz[1], Noemi Andor[1], Saeed Alahmari[2]. *[1]Moffitt Cancer Center, Tampa, FL,[2]Najran University, Najran, Saudi Arabia*

Intratumoral heterogeneity is a major obstacle for many cancer therapies. Treatment modalities which target a particular phenotype select for cells with different phenotypes. For example, chemotherapy which targets fast-dividing cells may select for a tumor composed of slower-dividing cells which cannot be effectively targeted by the drug. We hypothesize that subpopulations (SPs) of cells defined by somatic copy number alterations (sCNAs) differ in how quickly they divide and how well they can compete at high population densities. Additionally, we expect that sCNA-defined SPs affect the fitness of one another through cooperative (e.g., exchange of growth factors) and competitive (resource depletion) interactions. To test these hypotheses and compare the relative effects of (i) density and (ii) frequency-dependent selection on tumor evolution, we have developed two mathematical models integrated with experimental and computational techniques. In both models, we evaluate the growth dynamics of cancer cell SPs defined by sCNAs detected in single cell RNA/DNA-sequencing data from 4 gastric cancer cell lines (HGC-27, KATOIII, NUGC-4, SNU-16). To investigate the effects of density dependent selection (i), we start by growing the cell lines in our lab in order to infer growth rate (r) and carrying capacity (K). Next, linear models are built correlating pathway expression levels with r/K values. We tested 50 KEGG pathways previously identified as differentially expressed between r and K-selected cells as transcriptomic biomarkers of growth parameters. The best fitting models are then used to infer SP-specific r/K values. For growth, we found r as a function of the KEGG pathway ‘RNA Polymerase’

(R^2 = 0.9636, p-val=0.0019). For carrying capacity, we used 'Pathways in Cancer' (R^2 = 0.7898, p-val=0.0629). In each cell line, an r/K tradeoff existed between at least one pair of SPs, suggesting sCNAs indeed have effect on r/K parameters. For frequency-dependent selection (ii), we use an inverse game theory algorithm which takes SP frequencies over time as input and outputs a parameterization for the replicator equation to recapitulate detected frequencies and predict future growth. The algorithm uses a penalized least squares method that takes the error to be the difference between replicator equation output and SP frequency input. SP growth over time can then be modeled with the replicator equation to characterize conditions for co-existence or dominance. These approaches reveal the dynamics of heterogeneous tumor growth, and make it possible to compare the relative influence of different selective pressures. We can examine how the growth of a tumor would change with the elimination of a given SP. This greater understanding can contribute to a better design of evolution-based therapies that avoid, or at least delay, the evolution of resistance to treatment.

HiTAIC: Hierarchical tumor artificial intelligence classifier traces tissue of origin and tumor type in primary and metastasized tumors using DNA methylation data

Ze Zhang[1], Brock Christensen[2], Lucas Salas[2]. *[1]Dartmouth Geisel School of Medicine, Hanover, NH,[2]Dartmouth Geisel School of Medicine, Lebanon, NH*

Background: Human cancers are heterogenous by their cell composition and origination site. Cancer metastasis generates the conundrum of the unknown origin of migrated tumor cells. Tracing tissue of origin and tumor type in primary and metastasized cancer is vital for clinical significance. Researchers have demonstrated the high performance of DNA methylation-based machine learning models tracing the tissue origin of tumor cells. However, previous models were devised based on tissue site instead of tumor type, generating potential problems of indistinguishable tumor subtypes from the same site, e.g., esophageal squamous cell carcinoma versus esophageal adenocarcinoma. Methods: we employed a novel tumor-type-specific hierarchical model using DNA methylation data to develop a multilayer perceptron model (MLP) to trace tumor tissue of origin and subtype. DNA methylation data on 7735 tumor samples from 27 cancer types were downloaded from GEO and TCGA to develop tumor-type-specific libraries. The discovery data set was split into 80% training and 20 % testing. The tumor classifier hierarchy was established with

two layers for 27 cancer types. In each layer of the hierarchy, the MLP model was trained using the selected cancer-type discriminatory CpGs. HiTAIC was established based on the four hierarchical MLP models. To validate HiTAIC, we applied the model to the external validation data sets computing stratified and overall precision, recall, and f1-score to evaluate the performance. Next, we applied the model to the application data sets and used stratified and overall precision, recall, and f1-score to evaluate model performance in metastasized cancers.
Results: We observed high accuracy of HiTAIC's performance in primary cancer tracing with 99% accuracy and 99% weighted average F1-score in the testing dataset. We observed 93% accuracy and 93% weighted average F1-score for external validation across 25 cancer types. In metastasized cancer, HiTAIC demonstrated 96% accuracy and 98% weighted average F1-score across five cancer types with six different metastatic locations. HiTAIC traces tumor tissue of origin and cancer subtype with high accuracy in primary and metastasized cancer.
Conclusion: We developed HiTAIC, a DNA methylation-based classifier, to trace tissue of origin and tumor type in primary and metastasized tumors. The model's capability to trace the tumor origin and subtype with high resolution and accuracy promises potential clinical use in identifying cancer of unknown origin. HiTAIC can be easily deployed in a web-based application, transforming computational sophistication into a user-friendly public tool.

#6552

ZEB1-AS1 lncRNA prevents ZEB1 suppression and leads to tumor progression in undifferentiated AML subtype

Stefano Percio[1], Daniela Magliulo[2], Silvia Martini[1], Sandro Pasquali[1], Rosa Bernardi[2]. *[1]DRAST, Fondazione IRCCS - Istituto Nazionale dei Tumori di Milano, Milano, Italy,[2]DRAST, San Raffaele Scientific Institute, Milano, Italy*

The zinc finger E-box binding homeobox 1 (ZEB1) transcription factor is a master regulator of the epithelial to mesenchymal transition (EMT). In solid tumors, its overexpression induces EMT, which activates cellular motility and is also associated with the maintenance of stem cell properties, driving tumor progression and metastasis. A double-negative feed-forward loop circuit has been described where, to promote EMT, ZEB1 suppresses the expression of *miR-200* family members, which in turn inhibits its activity. Albeit recent evidence highlighted the existence of EMT processes also in hematological malignancies, the role of ZEB1 is not completely defined yet. Hence, this study aims to

characterize ZEB1 behavior in acute myeloid leukemia (AML). To this purpose, we retrieved and analyzed RNA-Seq data from public repositories to evaluate the expression levels of the main EMT master regulator genes in normal and malignant hematopoietic cells. We observed a heterogeneous expression of these genes among AML morphological subtypes (from M0 to M5) defined by the French-American-British (FAB) classification system. Specifically, *TWIST1* has the highest expression value in M3 and *ZEB2* in M5, as already observed in published studies, while *ZEB1* has the highest expression in M0, which significantly decreases until M5. To evaluate the ZEB1 transcriptional program, we performed a gene set enrichment analysis of hallmark signatures based on gene-wise correlation with *ZEB1* among FABs that revealed the up-regulation of EMT in the M0 subtype. Moreover, the highest value of correlation was found between *ZEB1* and its antisense lncRNA (*ZEB1-AS1*). This trait emerged as peculiar to AML both with respect to other cancer types and normal hematopoietic cells. Since ZEB1 orchestrates its transcriptional program by inhibiting the activity of specific miRNAs, we selected putative candidates that may take part in this circuit in AML by calculating their bimodality distribution, which reflects the toggle switch behavior typical of the double-negative feed-forward loop. We identified *miR-425-5p*, which was coherently down-regulated in M0 with respect to other FABs, and *miR-151-3p* which was surprisingly up-regulated. Specifically, the simultaneous up-regulation in the M0 subtype of *miR-151-3p* and its target *ZEB1* is inconsistent with the toggle switch behavior of the circuit. Thus, we hypothesized that *miR-151-3p* is not able to inhibit *ZEB1* expression in M0 due to the presence of *ZEB1-AS1*, which is supposed to disrupt the circuit mechanism protecting *ZEB1* from miRNA-mediated inhibition. This hypothesis is also supported by the fact that all target genes of *miR-151-3p* were significantly up-regulated. A better comprehension of this regulatory circuit could allow identifying aberrant epigenetic mechanisms during leukemic development and discriminating of the different AML subtypes.

#6553

The development of homologous recombination repair deficiency (HRD) score methodology using WES data and its application in patient-derived xenograft models

Jixin Wang[1], Krista Kinneer[2], Wenyan Zhong[1], Zhongwu Lai[1]. *[1]Oncology Data Science, AstraZeneca in Cambridge, Gaithersburg, MD,[2]Translational Medicine, AstraZeneca in Cambridge, Gaithersburg, MD*

Homologous recombination repair deficiency (HRD) and mutations in genes involved with homologous recombination repair (HRR) are associated with sensitivity to platinum-based chemotherapy, topoisomerase 1 inhibitors and inhibitors targeting DNA repair pathway. Use of the Myriad HRD test for HRD determination in preclinical models is not feasible globally. To address this challenge, we developed an approach to generate HRD scores from whole exome sequencing (WES) data and applied it to assess HRD status in patient-derived xenograft (PDX) models.

We used python package CNVkit for segmentation and gene-level/allele-specific copy number calling with customized settings according to CNVkit documentation. The reference was constructed using the WES BED file and hg38 reference genome when there are no paired control samples available. Next R package scarHRD was used to determine the HRD score that is the sum of loss of heterozygosity (LOH), telomere allele imbalances (TAI), and large fragment migrations (LST). The method was applied to the WES of 25 Xentech triple negative breast cancer (TNBC) PDX models to derive HRD scores. The samples were also separately profiled using Myriad's MyChoice CDx assay. The two scores showed moderate correlation with Pearson r = 0.56. However, when n = 6 PDX models with low coverages (average depth <100x) were excluded, the Pearson r improved to r = 0.76. We also found that the absolute value of HRD score calculated by CNVkit/scarHRD is lower than that of Myriad HRD score. Furthermore, we evaluated the genomic landscape in this cohort of TNBC PDX models for the selected genes of HRR pathway (BRCA1, BRCA2, ATM, BRIP1, PALB2, RAD51C, BARD1, CDK12, CHEK1/2, FANCL, RAD51B, RAD51D, RAD54L). Sixteen models found to carry HRR mutations, with ATM and BRCA1 mutations being the most common ones, being found in 9 and 5 of 25 models, respectively. Although HRRm positive (HRRm+) models have higher HRD score for both Myriad HRD score and HRD score generated with CNVkit/scarHRD approach, the association between HRR (HRRm+/HRRm-) and Myriad HRD (HRD+/HRD- defined by HRD threshold of 42) is not statistically significant (Fisher's exact test p value = 0.1998, odds ratio=3.5), likely due to small cohort sizes.

These results suggest that combination of CNVkit and scarHRD for HRD score calculation may be an alternative approach for HRD identification in preclinical PDX models.

Prediction of MET amplification from H&E images in non small cell lung cancer using self-supervised deep learning and its role in clinical trial

enrollment

Chaitanya Parmar[1], Oscar M. Carrasco-Zevallos[2], Joshua C. Curtin[2], Darshana Govind[3], Bing Xia[4], S. Martin Shreeve[1], Songbai Wang[2], Timothy Jatkoe[2], Patricia Raciti[1], Levon Demirdjian[1], Joel Greshock[2], Kristopher Standish[1], Stephen S.F. Yip[5]. *[1]Janssen R&D, US, San Diego, CA,[2]Janssen R&D, US, New Jersey, NJ,[3]Janssen R&D, US, San Francisco, CA,[4]Janssen R&D, US, New jersey, NJ,[5]Janssen R&D, US, Boston, MA*

Objective: DNA amplifications of the cMET locus (METamp) are rare (1-6%) in non-small cell lung cancer (NSCLC). The ability to efficiently identify patients with METamp could accelerate development of cMET-targeting therapies by identifying patients for enrollment efficiently. We developed a self-supervised deep learning algorithm (SSDL) to predict METamp status using H&E stained whole slide images (WSI).

Methods:Three datasets (CD_{train}, CD_{NGS}, CD_{FISH}) consisting of data from 1,436 advanced NSCLC patients (1 slide/pt) were used to develop an SSDL algorithm to predict METamp status. The METamp+ status across datasets was standardized for CD_{train} (n=788, METamp+ Prevalence=15%), CD_{NGS} (n=186, 19 positive, 167 negative, Prev=10%) as harboring ≥5 copies of the gene using NGS(Next Generation Sequencing) and for CD_{FISH} (n=462, 36 positive, 426 negative, Prev=8%) as MET CN gain to centromere 7 ratio (CEN) ≥2.5. The datasets were divided into a discovery set (CD_{train}) for training and held-out test sets (CD_{NGS}, CD_{FISH}) for validation. To improve robustness of SSDL, we first pre-trained ResNet34 with Simple Contrastive Learning, using >25k WSIs from diverse sources. During the training phase, 4-fold cross validation was applied on CD_{train}. The first 3-layers of ResNet34 were frozen while the final layer and an attention-based aggregation system were trained for METamp prediction. The performance was assessed using sensitivity, specificity, AUC, positive predictive value (PPV), and negative predictive value (NPV) on the test sets. Predictions from the model were binarized using two separate thresholds selected from CD_{train}, resulting in a High-Sensitivity model ($SSDL_{Sens}$ = 90% Sensitivity) and High-Specificity model ($SSDL_{Spec}$ = 90% Specificity). Each model's potential impact on patient enrollment is presented below.

Results: The trained SSDL models achieved an average cross-validation AUC of 0.77±0.04 across folds. The final trained model with the highest cross-validated AUC was chosen for METamp status prediction on the test sets. The selected model maintained predictive performance on CD_{NGS} (AUC=0.82) and CD_{FISH}

(AUC=0.75) test sets. The $SSDL_{Spec}$ model had a PPV more than twice the baseline prevalence in both CD_{NGS} (PPV=27%), and CD_{FISH} (PPV=29%), providing a significant enrichment in METamp+ patients. The $SSDL_{Sens}$ model correctly classified ~55% of METamp– in CD_{NGS} and CD_{FISH} with NPV of ≥97%. These results suggest a potential reduction in genetic screening by 50% while maintaining high sensitivity.
Conclusions: The SSDL model robustly predicted METamp status in independent patient cohorts, regardless of METamp definitions (i.e., by NGS or FISH). We demonstrate the ability to classify patients with high sensitivity or specificity, which can help reduce genetic testing or surface potentially eligible patients for trials, respectively.

Integrated bioinformatics analysis identified ASNS and DDIT3 as the therapeutic target in castration resistance prostate cancer
Ae Ryang Jung, Sun Shin, U-Syn Ha, Mee Young Kim, Sung-Hoo Hong, Ji Youl Lee, Sae Woong Kim, Yeun-Jun Chung, Yong Hyun Park. *Catholic University of Korea, Seoul, Korea, Republic of*

Background: Many studies have demonstrated the mechanisms of progression to castration-resistant prostate cancer (CRPC) and novel strategies for the treatment of CRPC. Despite these advances, the molecular mechanism underlying the progression to CRPC remain unclear, and no effective treatments for CRPC are currently available. Here, we characterized the pathways and key genes involved in the progression to CRPC to gain insight into the mechanisms and potential therapeutic targets of CRPC.
Methods: Bicalutamide-resistant prostate cancer cells derived from LNCaP was generated and named Bical R. RNA sequencing was used to identify differentially expressed genes (DEGs) between LNCaP and Bical R. DAVID and Clue GO were used to perform functional enrichment analysis, and the Cytohubba plug-in Cytoscape was used to identify hub genes associated with progression to CRPC. To validate the expression of hub genes, we performed qRT-PCR and western blot analyses. Further validation was performed using GEO microarray (GSE 32269 and GSE28403). To elucidate the clinical usefulness of these genes, we assessed the disease-free survival of patients with prostate cancer from The Cancer Genome Atlas (TCGA) database.
Results: In total, 631 DEGs (302 upregulated genes and 329 downregulated genes) were identified, and Kyoto Encyclopedia of Genes and Genomes pathways were analyzed based on DAVID and Clue GO. We found that the

PI3K-Akt and MAPK signaling pathways are of great significance for investigating the mechanism of CRPC progression. Hub genes from protein-protein interaction network of upregulated DEGs (AGT, ASNS, ATF3, ATF4, DDIT3, EFNA5, and VEGFA) were identified. Among the hub genes, ASNS and DDIT3 were markedly up-regulated in CRPC cell lines and CRPC tissues, respectively. Additionally, patients with high expression of ASNS and DDIT3 showed worse disease-free survival in TCGA database.
Conclusion: Our study revealed that the PI3K-Akt and MAPK signaling pathways may be important in the mechanism of CRPC progression, and ASNS and DDIT3 may be associated with progression to CRPC. These results may contribute to the development of potential therapeutic targets and mechanisms underlying the progression to CRPC to improve clinical efficacy for CRPC treatment.
Acknowledgements: This work was supported by the National Research Foundation of Korea(NRF) grant funded by the Korea government(MSIT) (No. 2022R1A2C2003513).

A gene signature of DNA damage response pathway is predictive of patient clinical outcomes and is associated with tumor immune microenvironment of lung adenocarcinoma
Xiaoli Zhang, Junran Zhang. *The Ohio State University, Columbus, OH*

DNA damage response (DDR) is crucial to prevent the accumulation of DNA lesions that can lead to genomic instability and promote tumorigenesis. Dysregulation of DDR pathways also provides therapeutic opportunities for new cancer therapy. Given that lung cancer displays a high level of genetic mutation and genomic instability, a comprehensive understanding of the dysregulation of DDR genes in lung cancer, especially non-small cell lung cancer (NSCLC) which accounts for 85% of all lung cancer cases, will be critical for identifying new genes contributing to tumorigenesis and novel targets for lung cancer therapy.
The goal of this study is to identify novel targets for lung cancer treatment through a comprehensive analysis of DDR genes and its association with patient survival, genomic mutation/instability, tumor immune microenvironment (TIME), and tumor proliferation ability. To this end, we have comprehensively characterized the expression of 276 DDR genes using the Cancer Genome Atlas (TCGA) and other publicly available data of lung adenocarcinoma (LUAD), the most common NSCLC. We found that 36 out of 276 DDR genes are

dysregulated with majority being upregulated in tumors and are associated with patient overall survival (OS) and progression free survival (PFS) based on the TCGA LUAD cohort. A gene expression signature, i.e., DDR gene expression dysregulation score (DDRDS), was constructed based on the geometric mean of the differentially expressed genes that were also associated with patient OS. Patients with a higher DDRDS showed significantly worse OS and PFS, more advanced tumor stage, a higher tumor mutational burden (TMB), neoantigen load, and homologous recombination deficiency (HRD) score. In addition, tumors with higher DDRDS displayed an increase in CD4+ activated memory T-cells, CD8+ T- cells, M0 and M1 macrophage, and NK cells, but a decrease in B cells, CD4+ resting memory T-cells, monocytes, and dendritic cells in TIME. Further, these tumors also showed a higher expression of immune check point molecules PD1 and PD-L1. Lastly, gene set enrichment analysis demonstrated that these tumors had significantly increased nuclear division, DNA replication, chromosome segregation, and cell cycles, reflecting the aggressiveness of the disease. Hence, despite the previous studies demonstrating that mutation and deletion defects in DDR genes are frequent in tumors, we found that the dysregulated DDR genes are mainly upregulated, and DDRDS based on the dysregulated expression of DDR genes is associated with the alteration in TMB/HRD/TIME, tumor aggressiveness, and ultimately patient outcomes. These results suggested that patients with a higher tumor DDRDS are associated with poor prognosis but might benefit from immune checkpoint blockade-associated immunotherapy.

A 6-microbial signature risk score for overall survival prediction in hepatocellular carcinoma: a machine learning approach

Nour N. Al-Bzour[1], Ayah N. Al-Bzour[2]. *[1]Jordan University of Science & Technology, Irbid, Jordan,[2]Faculty of Medicine, Jordan University of Science & Technology, Irbid, Jordan*

Introduction: Hepatocellular carcinoma (HCC) is a severe type of cancer associated with high malignancy and poor prognosis. To reach a better prognosis, several factors affecting HCC patients must be considered. In this study, we aim to investigate the relationship between gut microbiota with the survival of HCC patients, and to build a machine learning (ML) prognostic model based on microbiome signatures.
Methods: Microbial and survival data for HCC patients from The Cancer Genome Atlas Program (TCGA) were obtained using the cBioportal database.

The microbiome signatures were screened for prognostic effect using the univariate cox regression. The significant microbial signatures were fitted into the Least Absolute Selection and Shrinkage Operator - Cox (LASSO-Cox) model to reduce multicollinearity. Signatures with non-zero LASSO coefficients were screened for independent effect in the multivariate cox regression analysis. Results: A total of 1407 microbial signatures were downloaded from TCGA dataset. 63 prognostic microbial signatures were identified using the univariate cox. A total of 30 prognostic microbial signatures were screened out using LASSO and further evaluated using independent effect to obtain microbiome risk score. Six microbial signatures were identified as independent prognostic markers including: Marichromatium (HR: 1.26; 95%CI: [0.01-1.56]), p=0.038), Paraclostridium (HR: 1.45; 95%CI:[1.15-1.82], p=0.002), Pseudorhodoferax (HR: 1.20; 95%CI:[1.01-1.43], p=0.037), Chitinimonas (HR: 1.47 95%CI: [1.10-1.97], p=0.009), Marinobacter (HR: 0.79; 95%CI: [0.65-0.97], p=0.022), Desulfovermiculus (HR: 1.44; 95%CI: [1.16-1.78, p=0.001]). Kaplan-Meier survival plot showed better overall survival (OS) in the low-risk group compared to the high-risk group (median OS: 83.6 vs. 41.8; log-rank p-value <0.0001). Conclusion: Our results show that the gut microbiota is significantly associated with HCC prognosis, in which 5 of them were associated with poorer prognosis and one was associated with better survival. These microbial signatures provide a potential prognostic marker for HCC survival.

Defining differentiation States in well-differentiated and de-differentiated liposarcoma

Danh Truong, Hannah C. Beird, Chia-Chin Wu, Sandhya Krishnan, Davis Ingram, Alexander Lazar, Emily Keung, Christina Roland, Wantong Yao, Robert Benjamin, Neeta Somaiah, Barry W. Feig, Joseph A. Ludwig. *UT MD Anderson Cancer Center, Houston, TX*

Among the many sarcoma subtypes, high-grade tumors that have failed to differentiate or undergone dedifferentiation strongly correlate with metastatic potential and poor clinical outcomes. To examine the factors that regulate cell fate, lineage plasticity, and tumor grade, we focused on two common liposarcoma variants, dedifferentiated liposarcoma (DDLS) and well-differentiated liposarcomas (WDLS), that exist at both ends of the differentiation spectrum. Since tumor grading using histology is highly subjective due to widespread tumor heterogeneity, we hypothesized that an sc/snRNA-seq-based approach would be more accurate. To determine if candidate therapies modulate

differentiation, we developed a quantitative metric of differentiation using scRNA-seq. The resulting mesenchymal tissue landscape (MTL) is akin to a Waddington landscape but optimized to distinguish DDLS from WDLS. After prospectively obtaining tumors from seven chemo-naïve patients, we performed scRNA-seq on three DDLS and five WDLS specimens, totaling 59,917 cells. Classical markers were used to identify cell types. Since no pre-existing liposarcoma training sets existed, malignant cells were identified by copy number variation (CNV) inferred from the scRNA-seq data. Overexpression of MDM2, CDK4, and HMGA2, known markers of LS, were positive in clusters classified by SingleR as fibroblasts, adipocytes, and myocyte - the mesenchymal subpopulation. We also inferred CNVs and found expected amplifications in 12q13-15 in the mesenchymal subpopulation. Next, we measured cell differentiation by CytoTRACE. A subcluster of malignant fibroblast-like cells positive for MDM2 and CDK4 was the most de-differentiated. Conversely, cells labeled as adipocytes and endothelial cells were the most differentiated cells. Mapping WDLS and DDLS onto the MTL demonstrated that WDLS had more mature cells than DDLS. Surprisingly, while the pathology-assigned diagnosis falls into just two categories, our approach identified a wide range of liposarcoma cells spanning the full spectrum of possible differentiation states. Though follow-on studies are needed, our data suggest that quantitative differentiation metrics can identify malignant cells in transit from a DDLS-to-WDLS state, or possibly the reverse, whereby cells undergo dedifferentiation. Both phenomena are suspected clinically, given the frequent co-existence of WDLS and DDLS in the same tumors, and the noted emergence of DDLS from WDLS diagnosed years earlier. Summarizing our key findings, we measured the degree of differentiation in liposarcoma cells as a precursor to ongoing studies aimed at understanding the molecular mechanisms that underpin LS plasticity and differentiation. Ultimately, we aim to identify the genes and pathways linked to cell fate and discover novel biologically targeted therapies capable of pushing DDLS toward a less aggressive, slower-growing state.

Model constructed by ferroptosis-related genes and m6A genes predicts the sensitivity to different drug treatments

Tao Han[1], Mengyuan Liu[2]. *[1]The First Hospital of China Medical University, Beijing, China,[2]ChosenMed Technology Co. Ltd, Beijing, China*

Background: Immune checkpoint blockade (ICB) therapies exhibit distinct response in hepatocellular carcinoma (HCC) patients, therefore biomarkers to

screen beneficial patients remains an urgent need in clinical practice. Ferroptosis, an unique form of programmed cell death (PCD), has been implicated in the carcinogenesis and considered as one of the underlying mechanism of targeted and chemotherapeutic therapies in HCC. N6-methyladenosine (m6A), the most dominant form of RNA post-transcriptional modification, has been reported to regulat cancer-associated genes, including ferroptosis-related genes.
Methods: Differentially expressed genes (DEGs) between tumor and normal tissues were screened from TCGA-LIHC dataset. The overlap of DEGs and ferroptosis-related genes (FRGs) resulted in a set of 51 genes. These genes together with 22 m6A-related genes were next subjected to univariate Cox regression for their association with survival. In total, 35 genes showed significant association with survival in this analysis, and they were then used to construct the regression model by Lasso-Cox regression analysis. We then validated the performance of the signature derived from the model in TCGA-LIHC and an external dataset (GSE14520). The signature was also examined for their association with immune-related characters, and their performance in predicting drug response using datasets of immunotherapy cohort studies and cellular experimental studies.
Results: We constructed this prognosis model by expression level of four genes (G6PD, YTHDF1, STMN1, and SLC7A11). Patients with a high-risk score of the signature have a shortened survival time, and the signature is an independent predictor of the prognosis. We also found that the difference between the risk score before and after ICB treatment was significantly associated with sensitivity to the treatment: an increase in the risk score after the treatment correlated with an adverse response. Using the in vitro cellular experimental dataset, we detected a positive association between the risk score and the sensitivity to 5-fluorouracil and sorafenib.
Conclusion: The prognosis signature constructed by four ferroptosis- and m6A-related genes exhibited promising predictive value for OS of HCC patients. The signature could also indicate the sensitivity for different kinds of clinical treatment. A higher risk score indicated a higher resistance for immunotherapy but a higher sensitivity for chemotherapy and RTKs inhibitor. The results of this study not only help to improve the clinical practice of HCC, but also provide new insights into unveiling the underlying mechanisms of tumorigenesis and progression.

Identification of distinct patterns in diffuse large B-cell lymphoma through alternative splicing analysis

Sanyeowool An[1], Youngil Koh[2], Sung-Soo Yoon[2]. *[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of*

Background Aberrant splicing in cancer cells contributes to cellular proliferation, escape from cell death, growth inhibition, invasion and metastasis, and immune escape. Diffuse large B-cell lymphoma (DLBCL) is the most common type of non-Hodgkin lymphoma, but the effect of AS on its pathogenesis has not been fully elucidated, so it is essential to find out DLBCL-specific splicing patterns and their potential as treatment targets.
Material and Method RNA-Seq dataset from DLBCL patients was retrieved from The Cancer Genome Atlas (TCGA) DLBCL (N=48) and Pan-cancer Analysis of Whole Genomes (PCAWG) DLBC (N=7) were used as the cancer group. In order to identify spliced genes that are significantly different from normal tissue, RNA-Seq data of normal lymphoid tissue produced in two studies of E-MTAB-513 (N=1) and E-MTAB-1733 (N=13) from the BioStudies were downloaded. Sequence reads were aligned to the GRCh38 reference genome using STAR aligner.
Results 5,470 genes identified as differentially spliced compared to normal in both rMATS and MAJIQ tools were studied. After sorting the AS events of these genes in order of highest average PSI value, events with an average PSI value of 0.7 or more in the top 2/3 samples and events with an average PSI value of 0.3 or less in the bottom 2/3 samples are selected. 8 exons of 7 genes were involved in Exon skipping (ES) events, 6 exons of 5 genes were involved in mutually exclusive exon (MXE) events, and an exon of a gene was involved in alternative 5' splice site (A5SS) Among these genes, exons 6 and 7 in *CD53* showed high PSI values between exons 4 and 9. The average PSI values for exons 6 and 7 of *CD53* in DLBCL were 0.923855 and 0.89096, respectively, which were significantly higher than the Normal group ($p<0.05$). *CD53* mediates *IL-7R* signaling and plays a role in the regulation of normal B-cell development. As a gene coding for cell surface protein, it is involved in various immune systems in T-cell and B-cell surfaces. In healthy tissue, transcripts that skip exon 5 and have a junction between exon 4 and exon 6 or 7 are not yet known and should be further studied. In addition, *SLAMF8*, which has an exon with a PSI value specific to DLBCL, is also involved lymphocyte activation and regulates B-cell receptor signaling.
Conclusion These DLBCL-specific patterns of selective exon usage are expected to be potential targets for cancer immunotherapy.

Specific binding mode of RNA binding protetin FAM120A to lncRNA

Kenichiro Kawai. *Nagoya University, Nagoya, Japan*

Long noncoding RNAs (lncRNAs) are defined as transcripts >200 nucleotides in length with no protein-coding potential. LncRNAs play diverse roles in regulating gene transcription, post-transcription, translation, and epigenetic modification through interaction with RNA binding proteins (RBPs). Here, we analyzed binding motif of a RBP, family with sequence similarity 120A (FAM120A), which is highly expressed in multiple cancer types and associated with poor prognosis. To investigate FAM120A interacting RNAs genome-wide, we conducted cross-linking immunoprecipitation combined with deep sequencing (CLIP-seq) using an anti-FAM120A antibody in osteosarcoma cell line, U2OS. We identified 37,151 FAM120A-binding clusters by a peak detection algorithm. Up to 92% of these clusters were found within about 5,700 mRNAs, with the highest enrichment at 3'-UTRs. Interestingly, other clusters located within 959 lncRNAs, with peaks at 5’ and 3’ end. Fold enrichment analysis of CLIP reads in comparison with input reads revealed that FAM120A binds more preferentially to lncRNA than mRNA (median fold enrichments, 4.81 (lncRNA) versus 4.41 (mRNA), $P<0.001$, Mann-Whitney *U* test). Motif analysis using the HOMER algorithm showed that FAM120A enriched sequence motifs in 3’ of mRNAs, 5’ and 3’ of lncRNAs were completely distinct. These results suggest that FAM120A may exhibit a motif-dependent selective binding to lncRNA in cancer cells. Given that RBPs bind to RNA molecules immediately after their transcription on chromatin, FAM120A may also selectively recognize RNA species and classify lncRNA and mRNA at the transcriptional stage. Since lncRNAs play pivotal roles in cancers FAM120A may exert oncogenic effects by the post-transcriptional regulation of a certain set of lncRNAs.

Comparative analysis of blood-based tumor fraction estimation in 300 cancer patients

Chao Dai, Tiantian Zheng, Xiaoxi Dong, Wei Mo, Xiaohong Wang, Shujun Luo, Kemin Zhou, Shidong Jia, Pan Du. *Predicine Inc, Hayward, CA*

Introduction Tumor fraction (TF) in cell-free DNA is an important known biomarker for monitoring treatment response and disease progression. cfDNA TF is usually estimated by variant allele frequency (VAF) of somatic mutations or copy number variation (CNV). cfDNA assays provide high VAF detection

sensitivity by using deep sequencing depth based on target panels, which often makes TF underestimated due to limited panel gene coverage. Also because the interference of copy number changes and lack of matched normal, the VAF estimation is often inaccurate. On the other hand, although CNV based TF estimation does not require matched normal samples, it has lower detection sensitivity and underestimates cfDNA TF for patients without copy number changes. Importantly, tumor heterogeneity exists in many clinical cancer patient samples, where tumor DNA has complex subclone structures, which makes accurate TF estimation even more challenging.
Methods Here we performed comprehensive concordance study of cfDNA TF estimation, by applying both PredicineWES+ (20,000x sequencing depth in boosted cancer-related genes and 2,500x depth in rest exome regions) and PredicineCNB (LP-WGS with 3× sequencing depth) on more than 300 plasma samples from cancer patients. Using a proprietary algorithm, we calculated TF by integrating PredicineWES+ derived VAFs and PredicineCNB derived CNVs for each sample, where tumor subcloning was taken into the consideration. We implemented proprietary EM algorithm to infer subclone populations, where CNV has high concordance with TF in each subclone.
Results Our study showed that CNV-based TF estimation is highly concordance with VAF-based TF from PredicineWES+ (correlation coefficient > 0.8) when TF is >5%. For clinical samples with < 5% TF inferred from PredicineCNB, we used VAF-based TF. We developed an integrated TF estimation methodology by leveraging molecular insights derived from PredicineWES+ and PredicineCNB, and further performed clinical evaluation study using 50 longitudinal plasma samples from prostate cancer patients that are under different cancer stages or therapies. Our results demonstrated that the integrated TF estimation shows a positive correlation with therapy response and disease stage revealed by CT scan. Finally, serial analysis of plasma cfDNA demonstrated an increase in ctDNA TF and cancer variants, preceding evidence of radiographic and clinical disease progression in many patients.
Conclusion We conducted a comprehensive concordance study to infer cfDNA TF using PredicineWES+ and PredicineCNB in more than 300 patient samples. Our study demonstrated its clinical utility where the integrated TF analysis may provide a more robust and accurate estimation of disease burden in cancer patients.

Glioma stem cell index recapitulates grade, IDH mutation status and correlates with survival of glioma patients

Renan L. S. Simões, Maycon Marção, Tathiane M. Malta. *School of Pharmaceutical Sciences, University of São Paulo, Ribeirão Preto, Brazil*

Adult diffuse gliomas are heterogeneous and the most common primary brain tumors. Gliomas have high tissue invasion, proliferation and therapeutic resistance potential. Although much knowledge has been recently gained regarding glioma biology and evolution, many questions are still open, such as which is the cell of origin, what are its characteristics and how the tumor propagation occurs. The cancer stem cell (CSC) model proposes a population of cells with high self-renew capacity and capable of propagating the tumor with more differentiated cells, generating intratumoral heterogeneity. Based on the CSC model, our work aims to integrate the most advanced techniques available such as scRNAseq and machine learning models to estimate the enrichment of glioma stem cells (GSCs) in tumors, by defining a GSC-Stemness Index (GSCsi). To build the prediction model, we used public scRNA-seq data from glioblastoma (GBM)-enriched GSCs. We used the standard Seurat pipeline for quality control, normalization and downstream analysis. The GSC single cell data was used to train a prediction model using the One Class Logistic Regression (OCLR) algorithm. Several models were tested, including overdispersed genes, differentially expressed genes between GSCs and the whole tumor, GSCs from each patient individually and a model with all GSCs. The prediction models were applied to gene expression data from TCGA, GLASS, and publicly available scRNA-seq data from different glioma subtypes. The model built with all the GSCs and all genes showed the best performance, being able to identify with higher indices grade 4 gliomas and IDHwt in the TCGA and GLASS data. Survival analysis resulted in a hazard ratio greater than 20, indicating a high correlation between increased GSCsi and poor prognosis. By applying the model to scRNA-seq data from gliomas, clusters of high GSCsi were identified. We can partially conclude that the GSCsi obtained with the model is capable of identifying grade 4 gliomas and IDHwt and we are performing analyzes with the genes with the highest correlation (positive and negative) with the GSCsi in the TCGA and GLASS data. The analysis of these genes together with genes differentially expressed in the high GSCsi clusters in scRNA-seq data can elucidate pathways responsible for the therapeutic resistance and propagation of gliomas, in addition to proposing theories about the cell of origin and potential therapeutic targets to improve the diagnosis and treatment of these patients.

Biomarker discovery in triple negative breast cancer using RNA-sequencing analysis

Jenna B. Poulsen, Mauri E. Dobbs, Naomi Rapier-Sharman, Brett E. Pickett.
Brigham Young University, Provo, UT

Breast cancer is the most common form of cancer, and afflicted over 2.2 million people in 2020. The sheer volume of patients who suffer from breast cancer warrants continued research and discovery efforts to improve treatment options. Triple negative breast cancer (TNBC) affects 10-15% of breast cancer patients. Unlike other forms of breast cancer, TNBC does not have estrogen or progesterone receptors and makes little to none of the HER2 protein. Due to the lack of these biomarkers that are typical treatment targets for other kinds of breast cancers, the hormone therapies and drugs that target other breast cancers are often ineffective against TNBC. This leaves chemotherapy and radiation therapy as the main treatment options. Although chemotherapy and radiation have treatment benefits, the recurrence rate after treatment is around 40%. Furthermore, these treatment options are very detrimental to the body, resulting in a weaker patient and a necessary recovery time between treatments. In this study, we analyzed publicly available RNA-sequencing (RNA-seq) data to identify the upregulated and downregulated transcriptional mechanism(s) that play a role in TNBC compared to healthy breast tissue. The analysis of the RNA-seq data was completed with the Automated Reproducible Modular Workflow for Preprocessing and Differential Analysis of RNA-seq Data (ARMOR), which trims, maps, and quantifies the mRNA sequencing reads to the human transcriptome for each read. The ARMOR program identified more than 12,000 differentially expressed genes between TNBC and healthy breast tissue samples. We then applied an artificial intelligence-based classification method, a random forest algorithm, to identify new biomarkers that best differentiate TNBC cells from healthy cells. These specific transcriptional biomarkers for TNBC could potentially be used as diagnostic biomarkers or as therapeutic targets. We anticipate that this data may expand the treatment options for TNBC.

Extended support for model organisms: The next frontier for the molecular signatures database

Anthony S. Castanza[1], Jill M. Recla[2], David Eby[1], Alexander T. Wenzel[1], Helga Thorvaldsdottir[3], Carol J. Bult[2], Jill P. Mesirov[1]. [1]*Department of Medicine,*

University of California, San Diego, La Jolla, CA,[2]The Jackson Laboratory for Mammalian Genomics, Bar Harbor, ME,[3]Broad Institute of MIT and Harvard, Cambridge, MA

In 2005, we introduced the Gene Set Enrichment Analysis (GSEA) method to enable the identification and estimation of significance of activated biological pathways and processes in molecular data. Serving a community of over 300,000 registered users, and contributing scientific analysis to more than 30,000 publications, GSEA has become ubiquitous in gene expression analysis and particularly in cancer research. The power of GSEA relies, in a large part, on the Molecular Signatures Database (MSigDB) that provides tens of thousands of expertly curated and annotated gene sets representing cellular processes, canonical pathways, response signatures, etc., derived from prior studies, public data, and curated pathway databases. Here we describe an important recent addition to the GSEA/MSigDB resource.

Historically, the GSEA-MSigDB resource has focused specifically on human data, offering guidance and support for analysis of model organism data through limited provision of orthology mapping files. In recognition of the importance of the mouse as a model organism for cancer research, we recently significantly expanded our support for mouse data in two ways.

(1) We introduced Mouse MSigDB with a total of about 15,000 sets that are provided in the native mouse gene symbol space and are derived from published mouse datasets and mouse-focused resources. This allows GSEA analysis of mouse datasets without the need for orthology conversion.

(2) For investigators who wish to use MSigDB's human gene sets to analyze mouse data, or vice versa, we also implemented a new procedure for orthology mapping gene identifiers in an input dataset to match the identifiers of the gene sets. The new mapping considers the particular requirements of gene set enrichment analysis, and incorporates high confidence gene ortholog data from the Alliance of Genome Resources and ortholog-match refinement utilizing Ensembl's ortholog datasets.

Together, these new additions offer a substantial step forward for making mouse a first-class citizen of the GSEA-MSigDB ecosystem. The new Mouse MSigDB, and the full GSEA-MSigDB resource, is available at gsea-msigdb.org.

ClinGen Somatic and CIViC collaborate to comprehensively evaluate somatic variants in cancer

Jason Saliba[1], Arpad Danos[1], Kilannin Krysiak[1], Adam Coffman[1], Susanna Kiwala[1], Joshua McMichael[1], Cameron J. Grisdale[2], Ian King[3], Shamini Selvarajah[3], Xinjie Xu[4], Rashmi Kanagal-Shamanna[5], Laveniya Satgunaseelan[6], David Meredith[7], Mark Evans[8], Charles G. Mullighan[9], Yassmine Akkari[10], Gordana Raca[11], Angshumoy Roy[12], Alex H. Wagner[10], Ramaswamy Govindan[1], Obi L. Griffith[1], Malachi Griffith[1], on behalf of the ClinGen Somatic Clinical Domain Working Group. *[1]Washington University School of Medicine, St. Louis, MO,[2]BC Cancer, Vancouver, BC, Canada,[3]University Health Network and University of Toronto, Toronto, ON, Canada,[4]Mayo Clinic, Rochester, MN,[5]The University of Texas MD Anderson Cancer Center, St. Louis, MO,[6]Royal Prince Alfred Hospital, Sydney, Australia,[7]Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA,[8]Caris Life Sciences, Phoenix, AZ,[9]St. Jude Children's Research Hospital, Memphis, TN,[10]Nationwide Children's Hospital, Columbus, OH,[11]Children's Hospital Los Angeles, Los Angeles, CA,[12]Baylor College of Medicine, Houston, TX*

The comprehensive evaluation of somatic variants in cancer requires consensus interpretation of their potential clinical significance (diagnosis, prognosis, and treatment response) and oncogenicity. To aid precision medicine through public interpretations, a multifaceted collaborative effort is required to bring together a community, structured guidance, and a public platform. The over 200 multi-disciplinary experts in the Clinical Genome Resource (ClinGen) Somatic Cancer Clinical Domain Working Group (CDWG) provide a community that develops data curation guidelines and standards and curates evidence to determine the clinical significance and oncogenicity of somatic alterations in cancer. The Somatic CDWG established the Pediatric Cancer, Hematological Cancer, and Solid Tumor Taskforces to facilitate membership growth and targeted curation projects. Within these Taskforces, Somatic Cancer Variant Curation Expert Panels (SC-VCEPs) are developed through a 4-step approval process adapted from ClinGen germline VCEP procedures. Five SC-VCEPs (NTRK-fusions, FGFR variants, FLT3 variants, Histone H3 variants, and BCR::ABL1-like B-ALL alterations) are working through the approval process and one (Established Significance) is in the planning stage. SC-VCEPs tailor AMP/ASCO/CAP [PMID:27993330] and ClinGen/CGC/VICC Oncogenicity [PMID:35101336] guidelines, or create new classification guidance to aid granular assessment of their genomic alterations of interest.
The Clinical Interpretations of Variants in Cancer (CIViC) knowledgebase provides the public platform for the Taskforces and SC-VCEPs to display their

high-quality somatic cancer variant interpretations. These groups curate evidence from published literature and create Assertions summarizing evidence collected. These Assertions are further disseminated through other resources like ClinVar and the Variant Interpretation for Cancer Consortium (VICC) MetaKB. CIViC supports the application of AMP/ASCO/CAP tiering and levels for clinical significance Assertions. CIViC recently created Oncogenic Assertions, which supports the application of ClinGen/CGC/VICC codes. Three SC-VCEPs (FGFR, FLT3, and Histone H3) are tailoring the ClinGen/CGC/VICC Oncogenicity guidelines to their specific genes and CIViC will enable their ClinGen-approved, modified codes to be applied directly to their Oncogenic Assertions. Also, two SC-VCEPs (NTRK and BCR::ABL1-like) are developing fusion specific oncogenicity classification guidelines, which will be applied to their fusion specific CIViC Oncogenic Assertions. ClinGen Somatic groups have generated 695 CIViC Evidence Items and 33 Assertions from over 400 published papers. These numbers will continue to grow along with the development of more SC-VCEPs. ClinGen Somatic and CIViC foster collaboration, innovation, and most importantly the advancement of precision medicine.

Integrative pan-cancer genomic and transcriptomic analyses of refractory metastatic cancer

Yoann Pradat[1], Julien Viot[2], Konstantin Gunbin[2], Andrey Yurchenko[2], Luigi Cerbone[2], Marc Deloger[2], Guillaume Grisay[2], Loic Verlingue[2], Véronique Scott[2], Ismael Padioleau[2], Leonardo Panunzi[2], Stefan Michiels[2], Antoine Hollebecque[2], Gerome Jules-Clément[2], Laura Mezquita[2], Antoine Lainé[1], Yohann Loriot[2], Benjamin Besse[2], Luc Friboulet[2], Fabrice André[2], Paul-Henry Cournède[1], Daniel Gautheret[1], Sergey Nikolaev[2]. *[1]Université Paris-Saclay, Gif-Sur-Yvette, France,[2]Gustave Roussy, Villejuif, France*

Metastatic relapse after treatment is the primary cause of cancer morbidity and mortality. While genetic mechanisms of primary tumors and, to a lesser extent, metastatic cancers have been studied in large cohorts, refractory metastatic tumors are not yet sufficiently characterized. Markers of aggressiveness and resistance that molecular profiling can extract from these tumors have yet to be identified and incorporated into clinical care. In this study, we present a pan-cancer cohort of 1,031 metastatic tumors (which we refer to as META-PRISM) that are resistant to at least one systemic therapy or with no approved treatment options. We retrieved the complete clinical history of patients and performed whole-exome (n=571) and transcriptome sequencing (n=947) for this cohort.

The prevalence of detected cancer biomarkers was assessed and compared to an external cohort of primary tumors. In the META-PRISM cohort, we observed an increase in (i) whole-genome duplication frequency, (ii) tumor mutational burden, (iii) germline cancer-predisposing variants, and (iv) somatic alterations in cancer genes, including KRAS, EGFR, CCND1, MYC, and TP53, as compared to the tumor type-matched primary tumors. The most extensive increase in genomic variation at metastatic stage was observed in prostate bladder, and pancreatic cancer types. We also identified enrichment of standard-of-care resistance biomarkers in most cancer types. However, only 9.3% of tumors harbored at least one such biomarker, indicating that the current understanding of resistance mechanisms remains insufficient. Our cohort demonstrated a significantly improved 6-month survival prediction from models incorporating molecular markers over models with only clinical markers for breast cancer patients and to a lesser extent for other studied tumor types. Overall, our data establish a unique resource for investigating treatment resistance mechanisms and performing predictive analyses in cancer.

#6571

Mammonc-DB: A web based user-friendly tool for comprehensive multi-omics data analysis in breast cancer

Santhosh Kumar Karthikeyan[1], Darshan S. Chandrashekar[1], Upender Manne[2], Chad Creighton[3], Zhaohui S. Qin[4], Sidharth Kumar[5], Sooryanaraya Varambally[2].
[1]University of Alabama at Birmingham, Birmingham, AL,[2]Department of Pathology, University of Alabama at Birmingham, Birmingham, AL,[3]Bioinformatics, Baylor College of Medicine, Ann Arbor, MI,[4]Biostatistics and Bioinformatics, Emory University, Atlanta, GA,[5]Department of Computer Science, University of Alabama at Birmingham, Birmingham, AL

Breast cancer (BC) accounted for 15% cancer related death among women, in the United States last year. It is a highly heterogeneous and complex diseases with multiple molecular events occurring during cancer initiation and progression. It is important to unravel the heterogeneity of breast cancer and the molecular events to develop diagnostic biomarkers and targeted therapies. There is need for comprehensive and user-friendly tool for the utilization of available breast cancer data including metastatic and treatment response data. We have earlier created a highly used pan-cancer proteogenomic portal called UALCAN (ualcan.path.uab.edu). Based on the current unmet need for comprehensive BC data analysis and visualization resource, we developed an integrated proteo-genomicbreast cancer data analysis portal, called Mammonc-DB

(http://resource.path.uab.edu/MammOnc-ge.html)**.** For Mammonc-DB, we collected data from public repositories like NCBI Gene Expression Omnibus (GEO), The Cancer Genome Atlas (TCGA) for collecting and analysis of genomics and epigenetics data, and, PRIDE, and, ProteomeXchange for proteomics data. We procured and processed multi-omics studies related to normal, primary, and metastatic human breast cancer data with other clinical information available, for different clinical models. We also collected and analyzed different therapy, and treatment studies that are currently employed in treating BC patients. Mammonc-DB has user friendly interface that aid breast cancer researchers and clinicians in, a) allows users to identify potential biomarkers in breast cancer, b) accessing publicly available breast cancer multi-omics data, c) Visualizing the expression pattern of gene or protein of interest with clinical feature stratification in each dataset among others This resource serves as a one-stop resource to study gene expression (protein-coding and non-coding) analysis along with epigenetic regulation, and protein expression patterns in BC. With this platform, we tend to create global user base that will accelerate discovery of biomarkers in BC that might be involved in diagnosis, therapeutic target identification and treatments of breast cancer.

A lung cancer cell line explorer

Ling Cai, Luc Girard, Ralph DeBerardinis, Guanghua Xiao, John Minna, Yang Xie. *UT Southwestern Medical Center, Dallas, TX*

Over 300 lung cancer cell lines have been established in the past few decades with clinical annotations. Efforts from multiple institutions comprehensively profiled these cell lines for their genetic and epigenetic variations, gene and protein expression, metabolism, and functional liabilities. These data provide an unprecedented opportunity to accelerate lung cancer research. We developed a lung cancer cell line explorer at https://lccl.shinyapps.io/LCCL/ integrating over 35 datasets. We also incorporated engineered features such as pathway enrichment scores from copy number-denoised transcriptomic data and neuroendocrine scores. Our web application allows users to 1) query and download the processed datasets, 2) assess data reproducibility across studies, 3) review genomic abnormalities, 4) perform ad hoc bivariate analyses with the option to add filtering or coloring by a third feature, 5) generate heatmaps and correlation maps, 6) perform global association test to screen for significant association between a feature of interest and all features from a dataset of interest, and 7) upload their own datasets to be analyzed in conjunction with our

in-house datasets. In summary, this online tool will greatly facilitate the utilization of high-dimensional datasets that characterize lung cancer cell lines.

#6573

Drug Combo: A unique resource for efficient phase 1 trial design with manually curated MTD and DLT

Lei Wang, Shijun Zhang, Lai Wei, Yuxi Zhu, Dwight Owen, Lang Li. *The Ohio State University College of Medicine, Columbus, OH*

Background: With prior preclinical and clinical knowledge, an effective and efficient cancer drug combinatory trial design could be expected, which will significantly accelerate the translation. However, our internal survey results suggested that some knowledge and data sources were underused or underestimated by researchers. One primary reason is that knowledge of drug combinations is scattered in many distinct databases. Moreover, some essential information, such as MTD and DLT was missed in current databases. Drug Combo (https://drugcombo.shinyapps.io/DrugCombo/) is the first knowledge base that integrates drug toxicity and PK data that may help design an efficient Phase I trial. It is a unique informatics resource that manually curated MTD and DLT are well organized in the knowledgebase.
Methods: Drug Combo integrates various publicly available PK and toxicity knowledge for individual drugs and drug combinations (Table 1). More importantly, it is the unique knowledgebase with MTD and DLT. An expert team manually curated MTD and DLT data from publicly available publications. Some standard healthcare terminologies, e.g., Rx-Norm and MedDRA were applied for concept normalization at the back end. We implemented a User-Centered Design process in the user interface (UI).The UI layout will be simple, consistent, purposeful, comprehensive, easy to navigate and informative with readable or scannable typography. A summary view was provided to inform users of some essential information, e.g., MTD, and Overlapping toxicities. The user can find the details in the “Detail Tab”.
Results: Currently, Drug Combo integrates pharmacological, pharmacokinetics, and toxicity data. Especially, MTD and DLT data from more than 1,600 published Phase I trials results are exclusive in Drug Combo.
Conclusions: Drug Combo is the first knowledge base that provides expert-curated MTD and DLT information. It could help design an effective and efficient drug combination phase 1 trial.

Current knowledge type in Drug Combo	
Type	Source

Drug Names	DrugBank, RxNorm
Target	DrugBank, Manual curation
Associated Condition	RxNorm, Drug Labels
PK profiles	DrugBank
Adverse Drug Event	Drug Label, FAERS
MTD	Manual curation
DLT	Manual curation
DDI	DrugBank, Manual curation

#6574

Systematic analysis of the predictive gene expression signatures of immunotherapies across multiple cancer types using IOSig

Samuel Coleman[1], Caroline Wheeler[2], Rebecca Hoyd[2], Louis Denko[2], Ching-Nung Lin[1], Muhammad Z. H. Fadlullah[1], Siwen Hu-Lieskovan[1], Christine Chung[3], Ahmad A. Tarhini[3], Daniel Spakowicz[2], Aik Choon Tan[1]. *[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[2]Ohio State University Wexner Medical Center, Columbus, OH,[3]Moffitt Cancer Center, Tampa, FL*

Immune checkpoint inhibitors (ICI) have provided durable responses in a subset of patients in multiple solid tumor types. However, developing robust and reproducible predictive gene signatures for ICIs remains a challenge partly due to the lack of systematic comparisons across a large pan-cancer transcriptomics compendia. We recently developed Immuno-Oncology Signatures Explorer (IOSig), a user-friendly web tool, to allow users to query and explore predictive biomarkers from a large collection of pan-cancer patient samples treated with ICIs (> 2500 patient samples from 40 studies). Here, we investigated six solid tumors: kidney, melanoma, bladder, head and neck squamous cell, gastrointestinal, and non-small cell lung cancers tissue-based RNA-seq datasets in IOSig. The 2175 samples, from 45 cohorts, were Z-normalized with the genes from each signature being averaged to assign a sample a single score per signature. Area Under the Receiver Operating Characteristic (AUROC) curve was used to summarize the gene signatures' ability to predict response to ICIs. We focus on the top 10 predictive gene signatures for each cancer type. There were 22 unique gene signatures from the top 10 of the six cancer types. Overall, 17 signatures were predictive in GI, NSCLC, melanoma and HNSCC. Many of these signatures were enriched in immune activation and inflammatory signatures. Conversely, the MYC, DNA damage repair, and proliferation

signatures are only predictive in bladder cancer. No predictive signatures were associated with kidney cancer. Interestingly, the immune activation signatures were highly predictive in the GI cancer cohorts in our study, as the cohorts were enriched with patients having high tumor mutational burdens and microsatellite instability. In summary, we used IOSig to analyze the predictive ability of previously published gene signatures across 6 cancer types. Some of these signatures warrant further investigation in a cancer-specific manner.

A table showing the AUROC value of the 22 selected gene signatures in each cancer type.

LinkedOmicsKB: A web portal to explore pan-cancer molecular and phenotype associations

Sara R. Savage, Yuxing Liao, Yongchao Dou, Zhiao Shi, Xinpei Yi, Wen Jiang, Jonathan T. Lei, Bing Zhang. *Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX*

Pan-cancer multi-omics data produced from integrated genomic, epigenomic, transcriptomic, proteomic, and post-translational modification (PTM) profiling of a wide variety of cancer types holds great potential for understanding cancer biology and generating therapeutic hypotheses. To realize this potential and make analysis and visualization of these complex and interconnected data easily accessible to cancer biologists and clinicians, we have developed a web portal, LinkedOmicsKB. The web portal provides access to a harmonized proteogenomic dataset of over 1000 patient samples covering 10 cancer cohorts from the Clinical Proteomic Tumor Analysis Consortium (CPTAC). We calculated associations between methylation, copy number variation (CNV), RNA, protein, and phosphosite data for each gene and further correlated the proteogenomics data with clinical and computed molecular phenotypes. All results are stored in a MongoDB database and visualizations are provided for exploring pan-cancer multi-omics relationships as well as individual statistics. We demonstrate the utility of LinkedOmicsKB to provide insights into clinical phenotypes, somatic mutations, and understudied genes. In the pan-cancer CPTAC data, overall survival was correlated with proteins involved in protein hydroxylation, including PLOD1 and PLOD2. Additionally, two phosphorylation sites on the tumor suppressor MIG-6 were associated with worse survival. These sites were also associated with hypoxia, MAPK, and EGFR pathway activity scores, suggesting a relationship between the signaling in these pathways and cancer prognosis. STK17B is an understudied kinase that regulates apoptosis. We found STK17B was

upregulated in 6 cancer types at the protein level but only two at the RNA level. The protein abundance of STK17B was highly associated with immune scores and JAK/STAT signaling, supporting a role for STK17B in the immune response. We identified 3 phosphorylation sites on STK17B, which were associated with EGF pathway activity scores and immune-related scores. LinkedOmicsKB is a valuable tool that can be used to generate biological and clinical insights into any gene, phosphosite, mutation, or phenotype.

Gabriella Miller Kids First Data Resource Center (KFDRC): Empowering discovery across germline and somatic variation in pediatric cancer

David Higgins[1], Jean-Philippe Thibert[2], Michele Mattioni[3], Jack DiGiovanna[3], Robert L. Grossman[4], Bailey K. Farrow[1], Eric Wenger[1], Samuel Volchenboum[4], Robert J. Carroll[5], Melissa A. Haendel[6], Deanne M. Taylor[1], Yuankun Zhu[1], Vincent Ferretti[2], Adam C. Resnick[1], Allison P. Heath[1]. *[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]CHU Sainte-Justine, Montreal, QC, Canada,[3]Seven Bridges Genomics, Boston, MA,[4]University of Chicago, Chicago, IL,[5]Vanderbilt University Medical Center, Nashville, TN,[6]University of Colorado Anschutz Medical Campus, Denver, CO*

The Gabriella Miller Kids First Pediatric Research Program (Kids First) has enabled genomic and transcriptomic characterization across a multitude of pediatric diseases at an unprecedented scale. This includes both pediatric cancer cohorts and structure birth defect cohorts, as co-occurrences of these suggest a shared context of developmental biology alterations. Making this quantity of data findable, accessible, interoperable and reusable (FAIR) to researchers around the world has been enabled via the Gabriella Miller Kids First Data Resource Center (KFDRC). Twenty-six Kids First studies are released on the Kids First Data Resource Portal, representing more than 21,000 participants and more than 1.25 PB of data, with additional datasets being released yearly. Additionally, via a partnership between NCI Childhood Cancer Data Initiative and Kids First, large studies currently

undergoing sequencing on childhood sarcomas and brain tumors will also be made available via the KFDRC.
The KFDRC Portal (https://portal.kidsfirstdrc.org/) provides an interactive cohort building interface as well as powerful search capabilities across 61 billion germline variants in real-time. The somatic variants are made available on the open-access PedcBioPortal (https://pedcbioportal.kidsfirstdrc.org/). Search features include leveraging ontologies to enable different granularity across studies to be cross-querable. The use of these ontologies enable semantic interoperability, while also leveraging FHIR as an interoperable standard for exchange of clinical and other relevant metadata. GA4GH DRS and Passport services via Gen3 and NIH's Researcher Authentication Service (RAS) enable streamlined access to controlled access data within researchers' cloud platform of choice, including CAVATICA (https://cavatica.org) which is directly integrated with the KFDRC Portal.
The KFDRC is part of the NIH Cloud-Based Platform Interoperability efforts, which includes the NCI Cancer Research Data Commons. This enables discovery and analysis across combined cancer datasets and data modalities and further potential for the cross analysis between cancers and structural birth defects to accelerate the discovery process to ultimately lead to improved knowledge and outcomes for childhood cancer and more generally pediatric disease from genetic causes.

#6577

CARMEN: A pan-HLA and pan-cancer proteogenomic database on antigen presentation to support cancer immunotherapy

Ashwin Adrian Kallor[1], Michał Waleron[1], Georges Bedran[1], Patrícia Eugénio[2], Catia Pesquita[2], Daniel Faria[2], Fabio Massimo Zanzotto[3], Christophe Battail[4], Ajitha Rajan[5], Javier Alfaro[1]. *[1]Intercollegiate Faculty of Biotechnology & Medicine (IFB), International Center for Cancer Vaccine Science, University of Gdansk, Gdansk, Poland,[2]LASIGE, Faculdade de Ciências, Universidade de Lisboa, Lisboa, Portugal,[3]Dipartimento di Ingegneria dell'Impresa (DII), University of Rome Tor Vergata, Rome, Italy,[4]French Alternative Energies and Atomic Energy Commission (CEA), Grenoble, France,[5]School of Informatics, University of Edinburgh, Edinburgh, United Kingdom*

Cancer immunotherapy has greatly improved the quality of life of cancer patients and it hinges on the discovery of novel cancer antigens that could be targeted to improve disease outcomes. The creation of databases such as IEDB, SysteMHC, TANTIGEN, caAtlas, HLA Ligand Atlas, Cancer Antigenic Peptide Database, SPENCER and IEAtlas support the immunopeptidomics community in understanding the landscape of antigen presentation. We have developed a pan-cancer, pan-HLA, and pan-tissue database containing immunopeptidomics data mapped to transcriptomic, genomic, immunological and biochemical data. The database was generated from 80 different publicly available immunopeptidomics mass spectrometry datasets collected between 2015-2022 (76 cancer and 4 normal datasets), covering 15 different types of cancers and 152 different HLA-I alleles. The peptides contained in our database were obtained by a combination of closed, open and de novo searches using an in-house developed computational pipeline. Following rigorous false discovery rate estimation at 1% and a second-round search to eliminate any false signals that may not have been detected in the previous round of FDR estimation, we obtained a list of 11.2 million peptide-HLA combinations comprising both coding and non-coding regions of the genome as well as bacterial peptides. These peptides have been mapped to chromosomal coordinates to facilitate adoption by the genomics community of this useful resource on antigen presentation. Pathway/biochemical analysis of each peptide was performed using the rWikiPathways package. Finally, mutations associated with each peptide were annotated using COSMIC and dbSNP resources. Our database includes a FAIR knowledge graph which contextualizes and enriches the data to enable clinicians to take effective therapeutic decisions on the appropriate form of treatment for cancer immunotherapy with the case study of clear cell renal cell carcinoma (ccRCC). We will continue to expand our database with new data over the next two years and expand the scope of its applications to facilitate uptake by the larger scientific community.

#6578

reVUE: repository for variants with unexpected effects

Ino de Bruijn[1], Aditi Gopalan[2], Xiang Li[1], Hongxin Zhang[1], Onur Sumer[1], Thomas Y. Cong[3], Tona Gonzalez[4], Madelaine Rangel[5], Nikolaus Schultz[1],

Debyani Chakravarty[1]. *[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Graduate School of Medical Sciences, Weill Cornell Medicine, New York, NY,[3]Ossining High School, New York, NY,[4]Harvey Mudd College, Claremont, CA,[5]Cornell University, Ithaca, NY*

Clinical sequencing of tumor samples is now a component of routine cancer care used to identify predictive biomarkers of drug response, refine patient cancer diagnoses, assess heritable cancer risk, or inform patient prognosis. Most genomic alterations are accurately annotated with tools such as the Variant Effect Predictor (VEP) that infer the effects of these alterations on the mRNA and protein by following basic rules of transcription, mRNA post-transcriptional processing, and translation. However, some genomic variants are not as easily captured by these rules, which can cause inappropriate or unclear annotation of the protein effect. For example, a variant that alters an existing splice site or creates a new one can activate or inactivate the protein. Similarly, specific mutations in the non-coding promoter region of a gene may de-regulate gene expression (e.g., TERT promoter mutations). In some instances, these so-called variants with unexpected effects (VUE) may have therapeutic implications. For example, while ~2-3% of GIST tumors harbor KIT exon 11 deletions that extend into the non-coding intron between exons 10 and 11 and are shown to cause in-frame deletions, they are typically misclassified as inactivating splice site mutations, precluding patients with tumors harboring these mutations from receiving standard care imatinib.

Thus, while many VUEs are functionally characterized and documented in the literature, there are no resources to systematically identify, curate and store these events such that they can be correctly annotated in routine clinical sequencing leading to suboptimal treatment decisions.

To address this unmet clinical need, we built a novel bioinformatic resource, the Repository for Variants with Unexpected Effects (reVUE - cancerrevue.org). The reVUE resource consists of (1) an intuitive website listing curated VUEs with their observed effects as demonstrated by functional characterization in peer-reviewed literature and (2) an application programming interface (API) for programmatic annotation of variants. We built reVUE as a crowd-sourced resource to enable contributions of VUEs to the repository from the clinical and scientific communities. Both the software and data are openly available. Our goal is to enable clinical

bioinformatic pipelines to accurately annotate all DNA mutations, including those with unanticipated protein coding effects, some of which can have therapeutic implications.

#6579

Accelerating de-identification of images with cloud services to support data sharing in cancer research

Benjamin P. Kopchick[1], Laura K. Opsahl-Ong[1], Qinyan Pan[2], Michael W. Rutherford[3], Ulrike Wagner[4], Bhavani S. Singh[1], Scott Gustafson[2], Fred W. Prior[3], David A. Clunie[5], Juergen A. Klenk[6], Keyvan Farahani[7].
[1]Biomedical Data Science, Deloitte Consulting LLP, Arlington, VA,[2]Ellumen, Inc., Silver Spring, MD,[3]Biomedical Informatics, University of Arkansas for Medical Sciences, Little Rock, AR,[4]Bioinformatics and Computational Sciences, Frederick National Laboratory for Cancer Research, Frederick, MD,[5]PixelMed Publishing, Bangor, PA,[6]Health Data & AI, Deloitte Consulting LLP, Arlington, VA,[7]Center for Biomedical Informatics and Information Technology, National Cancer Institute, Bethesda, MD

Purpose: De-identification of cancer imaging data is vitally important for data sharing and the advancement of research, however it is a time consuming and complex process that limits access to new cancer data sets such as those shared through NCI's Imaging Data Commons (IDC), built on the Google Cloud Platform (GCP). Our research demonstrates how this process can be automated using GCP-native services.
Methods: We configured the Medical Image De-Identification (MIDI) pipeline to automate de-identification of cancer imaging data. De-identification is performed using an alpha release of GCP's Healthcare API which was configured to scrub all Protected Health Information (PHI) from both Digital Imaging and Communications in Medicine (DICOM) headers and burnt-in text in pixel data. A dataset containing 216 patients and 23,921 images was prepared to test the de-identification algorithm by placing synthetic PHI in both DICOM headers and pixel data. The synthetic data matched real data seen during curation at The Cancer Imaging Archive (TCIA) and included data difficult for an algorithm to detect. Accuracy of the MIDI pipeline was measured against TCIA's standard tools and

procedures for de-identification. Measures included correct detection of all PHI data and correct action taken (e.g., remove, encrypt, or otherwise obscure). Throughput was also measured.
Results: Throughput was measured at 22.0 images per second over 10 runs. The MIDI pipeline's accuracy for DICOM headers was 98.7%, accurately detecting dates, addresses, phone numbers, unique identifiers, names, and other common PHI. The most common PHI failed to remove were special cases that included uncommon names or names with symbols, dates in string data types that were mistaken for other IDs, patient IDs, and abbreviated institution names. Private Creator data elements were consistently failed to be retained. These errors were due to options not currently available, and algorithms not trained on specific PHI, such as abbreviated institution names. UIDs were correctly replaced. PHI burnt-in the pixel data was successfully detected and removed, with one false positive.
Conclusion: We demonstrate the current capability and performance of automated cancer image de-identification. Our results show that while full automation is within grasp, a semi-automated pipeline is now feasible. A human expert in the loop can be used for final verification. This will lead to a much-needed acceleration of image de-identification, to handle the rapidly growing volume of data and provide rapid timely access in support of cancer research. Future work will focus on including pre- and post-processing tools to aid the human expert in the loop, such as identifying and flagging questionable images for manual review. These tools will also be used to catch the errors mentioned in results.

#6580

A machine learning-based pipeline and web server ImmuneMirror for neoantigen prediction

Wei Dai[1], Gulam Sarwar Chuwdhury[1], Yunshan Guo[1], Zhonghua Liu[2].
[1]The University of Hong Kong, Hong Kong, Hong Kong,[2]Columbia University, New York, NY

Background: Gastrointestinal tract (GIT) cancer is a group of cancers that affect the digestive system. It has become a leading cause of cancer mortality worldwide. However, the clinical outcome for advanced-stage patients with cancer metastasis after conventional treatment remains poor.

Although cancer immunotherapy has attracted much attention for the treatment of these deadly cancers as a single agent or in combination with chemotherapy, the objective response rate to this treatment remains low and most of the responsive patients only have a partial response. Accumulating evidence suggests that multiple mechanisms are involved in the resistance to cancer immunotherapy.

Methods: To facilitate the identification of the cancer patients who most likely respond to immunotherapy, we developed a stand-alone open-source ImmuneMirror pipeline with graphical analysis results for evaluating the selected features including tumor mutation burden, microsatellite instability (MSI) status, HLA typing, predicted neoantigen load and the top-ranked neoantigens with T cell immunogenicity as well as the expression of innate anti-PD1 resistance (IPRES) gene signature. We incorporated a machine-learning model for neoantigen prediction and prioritization in ImmuneMirror and established a web server. The model was trained and tested using the known neopeptides with T cell immunogenicity collected from 19 published studies, and combined neoantigen-relevant features: agretopicity, foreignness, hydrophobicity, binding stability, peptide processing, and transportation scores.

Results: The accuracy of neoantigen prediction accuracy of ImmuneMirror model is 0.87. We utilized ImmuneMirror to analyze 805 normal-tumor paired samples in GIT cancers including esophageal squamous cell carcinoma (ESCC), colorectal cancer (CRC) and hepatocellular carcinoma (HCC). Elevated neoantigen load was correlated with good clinical outcomes in ESCC. Interestingly, we identified a subgroup of MSI-H CRC with relatively low neoantigen loads for MHC Class I and Class II, respectively, though the tumor mutation burdens of this subset of patients were comparable with other MSI-H CRC. Our result suggests this subset of patients may not respond well to immunotherapy. In addition, the neopeptide YMCNSSCMG<u>V</u> derived from the TP53 hotpot mutation G245V mutation restricted by HLA-A02 was identified as the actional target in the ESCC patient by ImmuneMirror and confirmed by the experimental validation.

Conclusions: These results showed the reliability and effectiveness of ImmuneMirror for evaluating the relevant features and predicting putative neoantigens.

Acknowledgments: We acknowledge the support from Health Medical Research Fund (Grant No. 07182016) from the Research Fund Secretariat of Health Bureau in Hong Kong.

#6581

SLKB: Synthetic lethality knowledge base for gene combination double knockout experiments

Birkan Gökbağ[1], Shan Tang[2], Kunjie Fan[1], Lijun Cheng[1], Lang Li[1].
[1]Department of Biomedical Informatics, The Ohio State University College of Medicine, Columbus, OH,[2]The Ohio State University College of Pharmacy, Columbus, OH

Introduction: Synthetic lethality (SL) of two genes is defined that a cell loses its viability if both genes lost their functions, but it remains viable if losing only one gene. Because of the emerging CRISPR-cas9 technology, a number of cancer cells were screened in gene combination double knockout (CDKO) experiments. These CDKO experiments have been effective in identifying SL gene pairs as potential combination targets in treating cancer. The existing SL database, SynLethDB v2.0, attempted to integrate SL experiments and data, but has several knowledge gaps: (1) missing all non-SL gene pairs; (2) inaccurate cell line annotations; (3) incomprehensive coverage of CDKO experiments; (4) deviation from originally reported SL scores, and most importantly (5) ignoring the difference among various SL calculation methods, including sequence mapping, sequence count processing, sample normalization, background control normalization, and SL score calculation.
Methods: SL knowledge base (SLKB) is developed. It includes SL data from 11 published CDKO experiments in 22 cell lines. Between SLKB and SynLethDB, their cell line data and positive/negative SL gene pair data collected from CDKO experiments were compared. Five SL calculation methods are compared: median SL score with and without background control normalization (Median-B/NB), similarly sgRNA-Derived B/NB, Horlbeck-Score, GEMINI, and MAGeCK-based SL score (MAGeCK-Score). We compared their overall overlapping and pairwise overlapping among top 10% SL gene pairs.
Results:

- For human SL, SynLethDB only included two CDKO experiments, 189 SL gene pairs, and 0 non-SL gene pairs. Our SLKB has 11 CDKO experiments, 22 cell lines, 16,044 SL gene pairs, and 264,444 non-SL gene pairs..
- Among top 10% SL gene pairs from five SL calculation methods, only 0.05% are overlapping.
- In pairwise overlapping analysis, Median-B/NB Score has the highest averaging pairwise overlapping with the other four methods, 26.82%. GEMINI has the lowest average pairwise overlapping with the other methods, 5.11%. The averaging overlapping rates for MAGeCK-Score, sgRNA-Derived B/NB Score, and Horlbeck-Score are 24.52%, 18.50%, and 9.89% respectively.

Conclusion: SLKB is a much more comprehensive SL database than SynLethDB in CDKO experiment data integration and includes original scorings. There is a significant amount of difference between five SL calculation methods and their SL scores. All five SL scores can be queried and ranked in SLKB. SLKB also documents sufficient technical details of these five methods, allowing users to review and choose proper methods for their data analysis and presentation.

A path to sustainability for the National Cancer Institute's Cancer Research Data Commons

Juergen A. Klenk[1], Angela Maggio[1], Bhavani S. Singh[1], Erin N. Byrne[1], Erika Kim[2], Tanja M. Davidsen[2]. *[1]Deloitte Consulting LLC, Arlington, VA,[2]Center for Biomedical Informatics and Information Technology, National Cancer Institute, Rockville, MD*

Purpose: The volume of data produced by the biomedical research community continues to grow rapidly. Efficient collection, curation, and sharing of these data are expected to enable researchers to synthesize larger datasets and apply novel methods to discover new patterns for diagnosis, treatment, and care of disease. Consequently, data platforms that support these functionalities have become an important instrument for the biomedical research community. The National Cancer Institute’s (NCI’s) Cancer Research Data Commons (CRDC) is a data platform for the cancer research community that provides cloud-based, secure storage and analytic

tools for cancer data, including genomics, proteomics, imaging, and clinical trial data. CRDC has been funded by multiple sources, including the Beau Biden Cancer Moonshot program. Achieving long-term sustainability of the CRDC program is the focus of our study.
Methods: We applied a Financial Operations (FinOps) framework to map all costs to functionalities provided by the CRDC, including processes such as data intake, storage, compute, user support, and project management. We established a comprehensive financial baseline for the operations of the CRDC, identified opportunities for optimization across multiple dimensions (people, processes, technology), projected future costs based on trends for cancer data, and evaluated sustainability under defined funding scenarios.
Results: We identified 15 recommendations for optimization of the CRDC, including automation and centralization of core services (e.g., intake, curation, indexing), optimization of storage (e.g., compression, archiving), and harmonization of common services across the CRDC components (e.g., common architecture, governance). If implemented, we could demonstrate that these recommendations offer a path to long-term sustainability of the CRDC program under a variety of funding scenarios.
Conclusion: Data platforms such as the CRDC will see rapid increases in operational costs due to the growing data volumes and demand from researchers. Optimizing governance and operational frameworks will result in efficiency gains that can ensure long-term sustainability. Taking these steps will be critical to provide the necessary infrastructure to advance the field of data-driven biomedical research.

Potential carcinogenic effects of electronic nicotine delivery systems through epigenetic reprogramming in oral, brain, and lung stem cells

Akilah Shepard[1], Oneilia Yearde[1], Juan Sanchez[2], Ryan Amador[2], Gabriel Xirinachs[2], Erika Hernandez[2], Elizabeth Corrales[2], Swarnava Das[3], Marco Ruiz[4], Madhumita Das[2], Rose M. Stiffin[1], Marilyn Sherman[1], Alessandra Manzon[1], Ayivi Huisso[1], Jayanta K. Das[1]. *[1]Florida Memorial University, Miami, FL,[2]Miami Dade College, Miami, FL,[3]Miami Coral Park Senior High School, Miami, FL,[4]Baptist Health Medical Group, Miami, FL*

Recent scientific studies exhibited that the electronic nicotine delivery systems (ENDS) aerosols comprise numerous carcinogens namely

propylene glycol, diacetyl, formaldehyde, acetaldehyde, crotonaldehyde (2-butenal), acetone, acetyl propionyl (2,3-pentanedione), acrolein, nicotine, arsenic, cadmium and radioisotopes, such as Polonium-210 and lead-210. However, there was no such investigation for clarifying the mechanism of carcinogenic effects and epigenetic reprogramming of human oral, brain, and lung stem cells. In this study, we investigated the carcinogenic effects of ENDS aerosols, and the mechanism of epigenetic reprogramming using the Comparative Toxico-genomics Database (CTD), NIH Toxicology Data Network (TOXNET), the database of the National Institute of Environmental Health Sciences (NIEHS), AACR Genomics Evidence Neoplasia Information Exchange (GENIE) database, and other bioinformatics databases. We found from CTD analysis that the chemical gene interactions showed approximately 3% of genes highly expressed by propylene glycol and diacetyl from a total of 98 genes. The AACR GENIE database analysis showed EGFR, is associated with gliomas (191 clinical data, DFCI glioma cohort), found among 98 genes regulated by propylene glycol and diacetyl. The CTD analysis also exhibited the chemical gene interactions of highly expressed 9 common genes (with miR140 by propylene glycol, and formaldehyde from a total of 3983 genes; 5 common genes by propylene glycol, acetaldehyde, from a total of 275 genes; 1 common gene by propylene glycol, crotonaldehyde (2-butenal), from a total of 227 genes; 7 common genes by propylene glycol, acrolein from total 2185 genes; 18 common genes by propylene glycol, and nicotine from total 1244 genes; 11 common genes by propylene glycol, and arsenic from total 4983 genes; 9 common genes with HDAC4, CD86, miR21 by propylene glycol, and cadmium from total 5242 genes. The ENDs aerosols contain Polonium-210 and lead-210 (concentration; 13 ± 2 Bq/kg), which have been reported as Group 1 human carcinogens and emit alpha particles. We found that alpha particles caused DNA lesions, and gene mutations in human oral, brain, and lung stem cells and resulted in long-term chromosomal instability in primary human T lymphocytes by analyzing recent works of literature. The epigenetic mechanisms of histone modifications and these potential carcinogens have been revealed by the database of NIH Roadmap Epigenomics Mapping Consortium and our analysis discovered that Mitogen-activated protein kinase 1(MAPK1) is epigenetically reprogrammed with close interaction of teen genes. Therefore, it is important to find the actual epigenetic mechanism of transcriptional

regulation by these potential carcinogens on oral, lung, and brain stem cells, and our current study revealed this important relationship.

OncoKB, MSK's precision oncology knowledge base

Sarah P. Suehnholz, Moriah Nissan, Hongxin Zhang, Ritika Kundra, Calvin Lu, Amanda Dhaneshwar, Nicole Fernandez, Stephanie Carrero, Maria E. Arcila, Marc Ladanyi, Michael F. Berger, Aijazuddin Syed, Rose Brannon, Ross Levine, Ahmet Dogan, Ezra Rosen, Alexander Drilon, David B. Solit, Nikolaus Schultz, Debyani Chakravarty. *Memorial Sloan Kettering Cancer Center, New York, NY*

OncoKB, Memorial Sloan Kettering Cancer Center's (MSK) precision oncology knowledge base (www.oncokb.org), is an FDA-recognized* somatic variant database that contains information about the oncogenic effect and clinical implications of genomic alterations in cancer. Since its 2016 public release, OncoKB has grown to include annotation for >5,770 alterations in ~700 cancer-associated genes. OncoKB data is integrated into the cBioPortal for Cancer Genomics and used to annotate >12,000 MSK patient sequencing reports annually, encompassing both solid tumor and hematological malignancies. Users in academic, commercial and hospital settings outside MSK can programmatically access OncoKB data via its web API with an OncoKB license, which is free for academic research. To date, users from ~ 1400 institutions across >70 countries have licensed access to OncoKB annotations. The OncoKB Therapeutic (Tx) Levels of Evidence assign tumor-type specific clinical actionability to individual mutational events based on data supporting whether an alteration is predictive of response to matched targeted therapies. To date, OncoKB includes 44 Level 1 genes (included in the FDA drug label), 23 Level 2 genes (included in professional guidelines), 33 Level 3A genes (predictive of drug response in well-powered clinical studies), 27 Level 4 genes (predictive of drug response based on compelling biological evidence), and 11 R1/R2 resistance genes. In 2022, several major content additions were made to OncoKB based on key shifts in the precision oncology landscape. For example, OncoKB included 2 new tumor-agnostic FDA drug approvals, dabrafenib + trametinib and selpercatinib for BRAF V600E and RET fusion-positive solid tumors respectively (Level 1), capturing 5 tumor-

agnostic FDA drug approvals to date. OncoKB promoted ERBB2 oncogenic mutations and FGFR1 fusions to Level 1 following their inclusion as patient eligibility criteria in FDA drug labels for trastuzumab deruxtecan (NSCLC) and pemigatinib (myeloid/lymphoid neoplasms) respectively. NCCN guidelines for uterine sarcoma and pancreatic cancer listed PARP-inhibition for BRCA-mutant disease, making them Level 2 in these indications. Lastly, previously considered undruggable targets, TP53 Y220C and KRAS G12D, were included in OncoKB based on compelling evidence demonstrating response to allele-targeting drugs, PC14586 and RMC-6263, respectively. In sum, 7 novel clinically actionable biomarkers (Levels 1-4) and 11 follow-on precision oncology therapies for existing leveled biomarkers were added to OncoKB in 2022. Current OncoKB efforts are focused on prioritized high-volume cancer gene curation for annotation of whole exome/genome data, annotation of germline alterations and development of a clinical trials matching system. *FDA recognition of OncoKB is partial and limited to the information clearly marked on www.oncokb.org.

Updates to UALCAN, a comprehensive cancer proteogenomic data analysis platform for discovery research

Darshan Shimoga Chandrashekar[1], Sooryanarayana Varambally[2], Santhosh Kumar Karthikeyan[2], Praveen Kumar Korla[2], Henalben Patel[2], Mohammad Athar[3], Upender Manne[2], George J. Netto[2], Ahmedur Rahman Shovon[4], Sidharth Kumar[5], Zhaohui S. Qin[6], Chad J. Crieghton[7]. *[1]University of Alabama at Birmingham, Birmingham, AL,[2]Pathology, University of Alabama at Birmingham, Birmingham, AL,[3]Dermatology, University of Alabama at Birmingham, Birmingham, AL,[4]Computer Science, University of Alabama at Birmingham, Birmingham, AL,[5]Computer science, University of Alabama at Birmingham, Birmingham, AL,[6]Department of Biostatistics and Bioinformatics, Emory University, Atlanta, GA,[7]Baylor College of Medicine, Houston, TX*

Background: Recent advances in high throughput technologies and initiation of multiple consortium driven projects have led to generation of high volume of molecular data related to thousands of cancer patients.

These high throughput data are extremely useful for novel biomarker identification, therapeutic target identification in tumor subclasses and allows numerous hypothesis driven cancer research projects. However, the sheer volume of data and diverse data formats presents tremendous challenge for researchers with no programming experience to access and analyze comprehensively. These factors prompted us to develop **UALCAN** (University of ALabama CANcer portal, Yes! You All Can) for comprehensive cancer data analysis in a user-friendly manner. UALCAN enables cancer researchers/clinicians in tumor subgroup based gene expression, protein expression and survival analyses. UALCAN is extremely popular among cancer researchers round the world with well over a "MILLION" site visits and cited over 3400 times in research articles. UALCAN integrates The Cancer Genome Atlas (TCGA) and Clinical Proteomic Tumor Analysis Consortium (CPTAC), as well as gene expression data from Children Brain Tumor Tissue Consortium (CBTTC). Users can also analyze non-coding RNA (miRNA and lncRNA) expression data from The Cancer Genome Atlas (TCGA) and the epigenetic data though the promoter DNA methylation analysis form the TCGA data. **Results:** UALCAN now enables user to study expression profile of ~10000 proteins in 14 CPTAC cancers and expression pattern and survival impact of 20,500 protein-coding, ~17,000 lncRNA and 1800 miRNA in 33 TCGA cancers. It also facilitates analysis of gene expression pattern in pediatric brain cancer. User-friendly graphical user interface of UALCAN facilitates a) analyzing protein/non-coding RNA expression in tumor subgroups based on race, stage, age and molecular types; b) identifying top differentially expressed lncRNA/miRNA in specific cancer subtype; c) listing potential gene targets of non-coding RNA; d) performing pan-cancer analysis and e) determining impact of gene expression on patient's overall survival. **Conclusions:** UALCAN is freely available at http://ualcan.path.uab.edu (Google: UALCAN) This dynamic data portal provides constant updates that empower cancer researchers in studying gene and protein level expression and identifying tumor subgroup specific non-coding RNA biomarkers. UALCAN serves a one-stop platform for access, study, analyze and leverage large cancer datasets.

Method to increase performance of genome-wide association study using imputation for Asian ancestry

GangPyo Ryu[1], Youngil Koh[2], Sung-soo Yoon[2]. *[1]Seoul National University, Seoul, Korea, Republic of,[2]Department of Internal Medicine, Division of Hematology and Medical Oncology, Seoul National University Hospital, Seoul, Korea, Republic of*

The emergence of the large-scale public genomic database facilitates genome-wide association study. An unprecedented number of samples emerged, which enable elucidate valid genetic inferences and contribute to finding novel associations for various phenotypes including cancer. However, most of the genome data is from European-based ancestry, which leads to the disparity in study for relatively minor ethnic groups including Asian. Meanwhile, among public genomic database, TOPMed consortium consists of ~180k participants, over 60% of the 180k samples are of predominantly non-European ancestry, and Asian ancestry consisted of 8 % in total. In addition, 1000 Genomes Project(1KG) contains 2,504 individuals from 26 populations and has sequenced 698 samples in addition. These projects serve as a reference to impute missing variants to improve association power for Genome-Wide Association Study (GWAS) subsequently. We compared the imputation results using those reference panels.Korean Genome Project (Korea1K), including 1094 whole genomes are public datasets consisting of only Korean (East Asian) origin. On GRCh38, Korea1K variants consisting of 59,463,566 variants in total, 99.6% with MAF <1% rare variant, only 35.7% of those rare variants passed from GATK Best Practice VQSR filter. With Korea1K data, we have downsampled the result into the exonic level, imputed with reference panels, and seen the consequences for which reference panel shows the best performances. Using 1KG as a reference, we could identify novel rare variants only in 0.1 to 0.38 fold of filtered rare variant in 1KG phase3 and 1KG phase3 30X respectively. On the other hand, TOPMed imputation resulted in rare variants over 1.65 fold increase. With well-imputed variants R^2 over 0.8, all three reference database showed poor conservation which only 0.009 % of rare variant are rescued. The reference panel we commonly use are large but required to have more diversity in a Asian rare variant perspective. Despite increase of the Asian fraction in the public genomic database, our result suggests that the number of reference Asian samples are

still low to perform association study. In conclusion, our finding highlights both the utility and limitation of the imputation reference panel for Asian ancestry. Novel variants filled by imputation are promising for adding power to various association studies.

Systems biology-based drug repositioning and biomarker discovery for Thai liver fluke-associated cholangiocarcinoma

Supawan Jamnongsong[1], Patipark Kueanjinda[2], Piyathida Tawornparcha[1], Kulthida Vaeteewoottacharn[3], Seiji Okada[4], Siwanon Jirawatnotai[1], Ananya Pongpaibul[5], Krittiya Korphaisarn[6], Somponnat Sampattavanich[1].
[1]Department of Pharmacology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand,[2]Department of Microbiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand,[3]Department of Biochemistry, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand,[4]Division of Hematopoiesis, Joint Research Center for Human Retrovirus Infection, Kumamoto University, Kumamoto, Japan,[5]Department of Pathology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand,[6]Division of Medical Oncology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Our group has recently reported the successful use of comprehensive drug response and pan-omic profiling for identifying repurposable drug shortlists in Asian cholangiocarcinoma. We also developed the CCA45 gene-expression signature that could accurately predict the prognosis of CCA patients, especially those with Asian ethnic backgrounds. To further explore therapeutic candidates and potential resistance mechanisms, we have established CCA1 cell lines resistant to their subgroup-specific drug candidates: MEK and SRC inhibitors. Reverse-phase protein arrays (RPPA)-based proteomic profiling revealed upregulation of cell cycle, apoptosis, MAPK, and mTOR-related proteins in both MEKi- and SRCi-resistant cells. Src pathway activity was found to be more significantly reduced in SRCi-resistant cells. We identified CDK4/6 inhibitors as the second-line therapeutic candidates for MEK inhibitor-resistant cells by systematic drug screening. SRCi-resistant cells unexpectedly developed

cross-resistance to MEK inhibitors and showed sensitivity to only a few CDK4/6 inhibitors. These data are beneficial for the clinical translation of our proposed drug candidates for Asian CCA, preparing the alternate regimens after drug resistance. We also adopted the DSP-based spatial transcriptomic platform to compare the tumor microenvironment between chemotherapy-sensitive and chemotherapy-resistant CCA patients. While the CTA panel showed consistent patterns of normalized gene expression to those of the WTA panel, the CTA panel can only measure 17 of the 45 genes required for our CCA45 signature. Out of these 17 genes, *ITGB4*, *FGFR3*, *VEGFC*, *NOTCH1*, and *RRAD* showed significant gene expression changes with reducing tumor percentage. The microenvironment of gemcitabine/cisplatin responder (R) non-responder (NR) exhibited negative regulation of ERK1/2 and MAPK, high WNT pathway activity, and high tumor-infiltrating lymphocyte (TIL). In contrast, the microenvironment of the non-responder (NR) subgroup showed high neutrophil-related activity, high NFκB, high Treg, and the exhausted immune phenotype. Overall, our study contributes toward realizing the precision medicine concept for CCA patients.

Undergraduate e-mentoring in cancer research: The ACE scholars program

Cristina Baciu, Compton Zachary, Carlo Maley. *Arizona State Univ. Biodesign Institute, Tempe, AZ*

Only 1 in 4 undergraduate college students report having had access to mentoring while in college. To create community and training opportunities for a diverse body of undergraduate students (incl. online students) interested in cancer research, we developed a well-rounded e-mentoring program that incorporates alternated sessions of scientific mentoring (i.e., design a study, create a poster) and professional development (i.e., graduate school strategy and applications, networking). The theoretical background of our program derives from project and team-based learning, which state that students tend to learn better and be more engaged when working hands-on on a given project, in teams. Our teams are led by experienced undergraduate researchers, which enables them to gain leadership experience before applying to graduate school.

We implemented this e-mentoring program in a research center at a large southwestern public university, where 43 undergraduate research assistants were mentored via Zoom during the Spring of 2022. At the end of the semester, we administered a survey to assess program effectiveness and collect student feedback. 31 students took the survey, which revealed that during Spring 2022, 25% of students were responsible for the care of children or other family member(s), 47% worked part-time and 22% worked full-time, and 56% of students encountered personal and/or professional challenges. Furthermore, we measured program effectiveness using the College Student Mentoring Scale, a comprehensive tool that measures students' perceived psychological and emotional support, degree and career support, academic knowledge support, and role modeling they received during their time in the program. Findings indicate that 82% of students felt they received psychological and emotional support and degree and career support while in the program. Moreover, 96.3% of students indicated that they felt they received academic knowledge support and benefited from role modeling while in the ACE Scholars Program. Additionally, 85% of students agreed or strongly agreed that the ACE Scholars Program, with its research experience and career and professional development components, has helped them be prepared for their future endeavors. Overall, 86% of the students indicated that they were extremely satisfied with the ACE Scholars Program. We will discuss the implications of this program and its findings for the practice of e-mentoring undergraduate students who are interested in cancer research.

A universal atlas of cellular and oncogenic phenotypes

Corey Weistuch[1], Kevin Murgas[2], Ken Dill[2], Larry Norton[1], Joseph Deasy[1], Allen Tannenbaum[2]. *[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Stony Brook University, Stony Brook, NY*

Tumors and healthy tissues exhibit gene expression variability in many of the same pathways. We propose that these commonalities result from a performance trade-off between universal cellular phenotypes; each phenotype is defined by an orthogonal gene expression profile identified using unsupervised dimensionality reduction. Using two publicly available RNA-seq datasets (n=54 normal tissues; n=1504 cancer cell lines), we show

that both healthy and cancerous cells occupy a trade-off between five canonical phenotypes: OxPhos, Warburg, Fibroblastic, Immune, and Growth. Each cell is assigned a phenotype score that, as we demonstrate, predicts differential drug sensitivities and mutational signatures, even among cancers of the same tissue type. Since these phenotype scores are defined using only healthy tissues, they can be generally applied to other diseases as well.

An AI platform for vascular and fibrosis analysis of pathology images

Yawen Zheng, Likun Zhang, Dawei Wang, Sheng Gao. *Crown Bioscience Inc, Suzhou, China*

Introduction: Changes in the number of blood vessels and the proportion of fibrosis regions in xenograft tumors are key indicators for efficacy of oncology drugs, which currently are assessed mainly by human visual examination that is time-consuming, inaccurate and biased because only part of a pathology image is checked. We developed an online AI platform that integrates machine learning algorithms in Computer Vision to quickly and automatically obtain accurate and comprehensive information on blood vessels and fibrosis regions from a whole pathology image.
Methods: In a stained pathology image, blood vessels are stained with a different color than other components (e. g. connective tissues, tumor cells, background), so we can directly locate pixels representing them. They also have different topological structures, so we can outline and count the contours of vessels. To count the number of vessels more precisely and reduce the interference of noise, we keep a contour only if it intersects with some located pixels and the number of pixels in the intersection exceeds an adjustable threshold. The fibrosis regions are identified by color contrast since they are stained with a distinct and easily recognizable color. The algorithms were implemented using the OpenCV package.
Results: Our AI platform automatically annotates blood vessels and fibrosis regions in pathology images, and generates reports in excel format to report the number and total area of blood vessels, the area and ratio of fibrosis regions, and execution time. It demonstrates superior performance to standard pathology software.

Integrative Spatial and Temporal Multi-omics of Cancer

Genomic and proteome analysis using preoperative cell free DNA and extracellular vesicles of lung cancer patients

Hayato Koba, Hideharu Kimura, Seiji Yano. *Kanazawa Univ. Hospital, Kanazawa, Japan*

Background: The detection of circulating cell free DNA (cfDNA) has been examined as a predictor of postoperative recurrence and survival in lung cancer patients. Extracellular vesicles (EVs) have potent for searching a new target to cancers.
Objective: To analyze the association between cfDNA/EVs and prognosis after lung cancer surgery.
Methods: We retrospectively examined patient background, disease-free survival, overall survival, and preoperative cfDNA in lung cancer patients who underwent surgery at Kanazawa University Hospital between January 2017 and May 2020, in whom preoperative chemotherapy was not administered. We extracted cfDNA from 4 ml plasma within 7 days before surgery and measured its concentration. EVs were extracted from 500 μl serum via Tim4 protein. Proteins included in EVs were analyzed by mass spectrometry.
Results: 285 patients were included, 179 males and 106 females, median age 71(36-88) years, and 8 patients had SCLC. EGFRm- positive lung cancer was included in 93 cases (32.6%). The pStage0/l/ll/lll/lV of NSCLC was 7/187/42/36/6 respectively, and the pStagel/ll/lll of SCLC was 4/1/3 respectively. The mDFS of NSCLC was 14.6 (7.8-29.7)/21.5 (8.5-NA) months in pStage lll/lV, respectively. mOS was 53.3 (28.7-NA) months in pStage lll and was not achieved in other stages. The mDFS of SCLC was 19.8 (1.9-NA)/NA/5.7 (1.9-NA) months in pStage l/ll/lll, respectively. mOS was NA/NA/9.3 (9.3-NA) months, respectively. cfDNA was detected in 283 (99.2%) patients, with a concentration of 4.7 (0-60.0) ng/μl. The correlation coefficient between cfDNA concentration and DFS/OS in NSCLC was -0.023 (P=0.70)/-0.014 (P=0.81). The correlation coefficient between cfDNA concentration and DFS/OS for SCLC was -0.86 (P=0.024)/-0.89 (P=0.012). No recurrence was observed in patients in whom cfDNA was not detected.EVs were detectable from pre-operative serum samples, and

the proteins included in these were different, whether disease was recurrent or not.
Conclusion: The cfDNA concentration did not correlate with DFS/OS in post-operative NSCLC, whereas it correlated negatively with DFS/OS in SCLC. In the presentation, we will further discuss about the concrete genetic alterations and protein expression, based on the cfDNA sequencing and proteomics analysis.

#6597

A multi-omics classifier achieves high sensitivity and specificity for pancreatic ductal adenocarcinoma in a case-control study of 146 subjects

John Blume, Ghristine Bundalian, Jessica Chan, Connie Chao-Shern, Jinlyung Choi, Rea Cuaresma, Kevin Dai, Sara N. Golmaei, Jun Heok Jang, Manoj Khadka, Ehdieh Khaledian, Thidar Khin, Yuya Kodama, Ajinkya Kokate, Joon-Yong Lee, Manway Liu, Hoda Malekpour, Megan Mora, Nithya Mudaliar, Preethi Prasad, Madhuvanthi Ramaiah, Saividya Ramaswamy, Peter Spiro, Kavya Swaminathan, Dijana Vitko, James Yee, Brian Young, Susan Zhang, Chinmay Belthangady, Bruce Wilcox, Brian Koh, Philip Ma. *Prognomiq Inc, San Mateo, CA*

Pancreatic ductal adenocarcinoma (PDAC) is currently the 3rd leading cause of cancer-related deaths in the US. Although the all-stage 5-year survival rate is ~10%, early-stage 5-year survival is markedly superior and in excess of 40%. Hence, early detection of PDAC via blood-based liquid biopsies holds promise to reduce morbidity and mortality. PrognomiQ's multi-omics platform performs deep and unbiased molecular profiling of blood samples to detect proteins, metabolites, lipids, mRNA, miRNA, cfDNA fragmentation and copy-number, and CpG methylation. Here we report results from training and validation of a classifier on a subset of that multi-omic data with the potential to enable the development of high sensitivity and specificity tests for early detection of PDAC.We conducted a case-control study comprising 146 subjects across 16 clinical sites, including 63 pathology-confirmed, untreated PDAC cases (12 stage I, 8 stage II, 4 stage III, 36 stage IV, and 3 stage unknown) and 83 age- and gender- matched controls without any known cancer. For each subject, venous blood samples including plasma were collected. Unbiased LCMS was used to detect and

quantify proteins, and targeted, multiplexed MRM-LCMS assays were used for both metabolites and lipids. After data processing, we detected 54,114 proteomic features, 898 lipids, and 373 metabolites. 445 proteomic features, 170 lipids, and 37 metabolites were found to be significantly different as determined by Bonferroni-corrected Wilcoxon tests with FWER $\leq$ 0.05. For classification, the dataset was split into training (37 cases and 37 controls) and validation (26 cases and 46 controls) sets, with control for collection site and date, age, and gender. XGBoost models were constructed for each analyte class using ten repeats of 10-fold cross-validation. To improve specificity to PDAC, all proteomic features which mapped to GOBP terms associated with acute-phase response, inflammation, and immune response were excluded prior to training. The best-performing hyperparameters were used for a final model built on the full training set and then used for inference on the validation set. At 99% specificity, the proteomic classifier had sensitivities of 77%, 57%, and 88% for Stages 1-4, Stages 1-2, and Stages 3-4, respectively, estimated by bootstrap re-sampling of the validation results. Metabolomics had sensitivities of 81%, 71%, and 88%. Lipidomics had sensitivities of 65%, 71%, and 65%. A joint, multi-omic model was constructed by averaging the scaled probabilities of all models. This joint model improved performance at 99% specificity with sensitivities of 92%, 86%, and 94%, highlighting the synergy of multi-omics data, particularly phenotypically related omics such as those described here. Multi-omic classifiers such as these can serve as the foundation for blood-based liquid biopsies for the early detection of PDAC.

The development of a tumor-agnostic liquid biopsy assay for minimal residual disease detection and monitoring in cancers

Giancarlo Bonora, Hang Dong, Chao Dai, Binggang Xiang, Billie Gould, Tiantian Zhen, Wei Mo, Xiaohong Wang, Kemin Zhou, Shidong Jia, Shujun Luo, Pan Du. *Predicine, Inc., Hayward, CA*

Purpose

Non-invasive liquid biopsy (LBx) based assays hold great promise for early cancer diagnosis and disease progression monitoring. Personalized baseline tissue-informed minimal residual disease (MRD) monitoring exhibits a particularly high detection sensitivity in many studies, however, baseline

samples (especially tissue biopsies) are often difficult to acquire in a clinical setting, and the personalized panel design and tracking creates operation complexities.

Methods

We developed PredicineALERT^{TM}, a baseline-agnostic MRD LBx assay that measures methylation and mutational variants associated with cancers. At its core lies the PredicineEPIC^{TM} DNA methylation assay with the advantage of low DNA damage and low input amount. Tumor burden is assessed by detecting abnormally methylated DNA fragments with high sensitivity using the Predicine DeepSea bioinformatics analysis pipeline. PredicineALERT^{TM} provides integrated methylation and mutational profiling, as well as copy number variation (CNV) profiling.

Results

The PredicineALERT^{TM} assay was tested using longitudinal LBx samples (blood, urine, CSF) from patients with mCRPC, CRC, NSCLC, breast, liver, kidney, prostate, and bladder cancers. The PredicineALERT^{TM} assay demonstrates highly-sensitive MRD detection and quatification capability (LOD < 0.01%) using 2.5 - 15ng input cfDNA. It has the ability to identify unique cancer biomarker signatures, and robustly detect MRD ctDNA dynamics during treatment. By leveraging genome-wide fragment-level DNA methylation, PredicineALERT^{TM} measures molecular response and MRD in targeted therapy, immunotherapy and chemotherapy. A strong concordance was observed in the pattern of tumor burden as ascertained by CNV and methylation analyses, respectively.

Conclusion

We developed PredicinceALERT^{TM}, a baseline agnostic, multidimensional MRD LBx assay without the need for baseline samples and personalized panel design. It integrates DNA methylation, mutation, and copy number changes for detecting MRD from genome-scale data without relying on target selection before library generation.

Neomer and fragmentation profiles of cell-free DNA with low-pass whole genome sequencing to predict prostate cancer biopsy outcomes

Fei Liu[1], Kaoqing Peng[2], Rui Chen[3], Mingzhao Li[2], Tao Zeng[4], Yan Zhao[4], Ming Wang[2], Hongxing Liu[2], Jianhao Wu[2], Min Wu[5], Haimeng Tang[5], Hua

Bao[5], Xue Wu[5], Yang Shao[5], Di Gu[2], Shancheng Ren[6]. *[1]Department of Urology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China,[2]Department of Urology; Guangdong Key Laboratory of Urology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China,[3]Department of Urology, Shanghai Changhai Hospital, Shanghai, China,[4]Department of Urology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China,[5]Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China,[6]Department of Urology, Shanghai Changzheng Hospital, Shanghai, China*

Prostate cancer is one of the most common types of cancer in men. Current prostate-specific antigen (PSA)-based diagnostic strategy for prostate cancer may frequently cause overdiagnosis. In this study, we prospectively recruited 380 individuals, including 167 with pathologically confirmed prostate cancer, 127 with negative prostate biopsy results, and 86 assessed healthy cohort with no need for biopsy. We collected a plasma sample from each participant, performed whole-genome sequencing, and profiled cell-free DNA (cfDNA) neomer and fragmentation characteristics. We then developed a machine learning model using these cfDNA profiles to predict prostate cancer biopsy outcomes. Our results showed that this assay could achieve high accuracy (Accuracy: 85.3%, AUROC: 0.919, 95% CI: 0.892 - 0.946) in repeated 5-fold cross validations. Patients with negative biopsy results had higher prediction scores than healthy individuals ($P < 2.2X10^{-16}$), making them less distinguishable from prostate cancer patients (AUROC: 0.878, 95% CI: 0.837 - 0.918 vs. AUROC: 0.980, 95% CI: 0.963 - 0.997). We further combined this cfDNA-based assay with the PSA testing and constructed an ensemble model. The classification performance was further improved in the ensemble model, showing AUROC metrics of 0.951 (95% CI: 0.932 - 0.969) between cancer and non-cancer, 0.919 (95% CI: 0.889 - 0.949) between cancer and negative biopsy, and 0.998 (95% CI: 0.994 - 1.000) between cancer and healthy individuals. At a sensitivity of 90.4%, the ensemble assay accurately identified 85.4% of non-cancerous conditions, including 76.4% of negative biopsy patients and 98.8% of healthy individuals. We concluded that our cfDNA fragmentation and

neomer-based assay could be incorporated into the PSA-based predicting system for prostate cancer to increase the accuracy and reduce the overdiagnosis.

#6600

The nRichDX ® revolution sample prep system enables recovery of more amplifiable copies and more cancer fraction detection from cfDNA as evaluated on the MassARRAY ® System

Nafiseh Jafari[1], Mayer Saidian[1], Darryl Irwin[2]. *[1]nRichDX, Irvine, CA,[2]Agena Bioscience, San Diego, CA*

Introduction Liquid biopsies utilize cell-free DNA (cfDNA) in blood plasma or urine across various applications, including cancer detection, treatment selection, and treatment/minimal residual disease monitoring. Higher amplifiable copies recovered from liquid biopsies can lead to better cancer detection and monitoring. In this study, we evaluated the recovery of cfDNA amplifiable copies and circulating tumor DNA (ctDNA) dynamics using the nRichDX extraction method, which can extract cfDNA from a broad range of biological fluids (1mL - 20mL). cfDNA quality and ctDNA dynamics were assessed using Liquid IQ and UltraSEEK on the MassARRAY System.

Methods Whole blood from healthy donors was collected in K2EDTA tubes, and plasma was isolated and then pooled in preparation for cfDNA extraction. Plasma aliquots at 5mL (6) and 20mL (6) were extracted using the Revolution Max20 cfDNA Extraction Kit. (12) replicate samples were extracted using QiAmp Circulating Nucleic Acid Kit. Half of the samples were spiked with a cfDNA standard containing a KRAS p.G12V mutation. The quantity and quality of extracted cfDNA were determined using the Liquid IQ panel on the MassARRAY system, which measures amplifiable cfDNA copies, high/low molecular weight dynamics, white blood cell (WBC) contamination along with a molecular barcode for sample matching. Recovery and frequency of the spiked ctDNA standard were performed with the UltraSEEK Lung V2 Panel, capable of detecting variants as low as 0.1% allele frequency.

Results This study compared the amplifiable copies recovered from cfDNA extracted using the nRichDX and Qiagen kit. The amplifiable copies for the nRichDX and Qiagen methods, respectively, were: 5mL non-spiked

517+/-36 Vs. 398+/-17, 5mL spiked 946+/-99 Vs. 732+/-73; 20mL non-spiked 1526+/-26 Vs. 1071+/-55 and 20mL spiked 3004+/-278 Vs. 1777+/-207. All results were statistically different by conventional criteria, evaluated by a two-tailed t-test. Other cfDNA quality characteristics, such as low/high molecular weight DNA and WBC contamination, were concordant between the 2 methods. The spiked KRAS mutation was recovered consistently by both methods with a mutation frequency (5.3+/-0.3) and mutation significance z-score (296+/-19).
Conclusion The nRichDX Revolution System extracts cfDNA and ctDNA with consistently high yields. Two sample T-Test analysis shows that nRichDX, at all levels, performed significantly better than Qiagen at $p < 0.05$. The results demonstrate the capability of the nRichDX system to recover more amplifiable copies with consistent cfDNA quality and ctDNA frequency and hence offer the opportunity to increase the sensitivity of detecting lower frequency mutations in cfDNA and a wider variety of biomarkers.

#6601
Analytical validation of a robust integrated genomic and epigenomic liquid biopsy for biomarker discovery, therapy selection, and response monitoring
Tingting Jiang, Indira Wu, Yvonne Kim, Nageswara Alla, Giao Tran, Dustin Ma, Forum Shah, Jun Zhao, Sai Chen, Sante Gnerre, Melis Hazar, Hao Wang, Catalin Barbacioru, Karen Ryall, Ankit Jambusaria, Anupam Chakravarthy, Anthony Zunino, Theresa Pham, Farsheed Ghadiri, Evan Diehl, Benjamin Morck, Arancha Sanchez, Rochelle Dayan, XianXian Liu, Jeffrey Werbin, Jill Lai, Brett Kennedy, Ross Eppler, Justin Odegaard, Han-Yu Chuang, Helmy Eltoukhy. *Bioinformatics, Guardant Health, Palo Alto, CA*

Background: Despite its revolutionary impact, cancer genomics alone provides little information on tumor phenotype or functional state, which are governed by epigenetic mechanisms, notably methylation of regulatory regions. Tumor and host epigenetic methylation signatures reflect not only tumor phenotype, such as histology, prognosis, protein expression, and functional sub-type, but also that of the tumor microenvironment and the patient, including immune status, therapy-related adverse events,

comorbidities, and disease location. Epigenetic markers also provide more sensitive and precise measures of tumor burden, opening up applications for longitudinal therapy response and monitoring. Here we report the initial validation of GuardantINFINITY, a liquid biopsy assay combining genomic information from >800 genes with characterization of the blood-quiet regulatory methylome, both at single-molecule sensitivity from a single tube of peripheral blood.
Methods: Analytical performance was assessed using 594 cancer patient cfDNA, cell line, and cancer-free donor samples at 5-30ng cfDNA input.
Results: Reportable ranges established for SNVs were ≥0.04% variant allele fraction (VAF), ≥0.04% for indels, ≥0.06% for fusions, ≥2.12 copies for amplifications (CNAs), <1.7 copies for copy loss. Observed 95% limits of detection (LoD) were 0.282% for SNVs across all genes (0.2% for oncogenic hotspots), 0.397% for non-homopolymeric indels, 0.05% for fusions, 2.5 copies for CNAs, 16.3% VAF or 1.84 copies for gene deletions, 7.3 copies for viral (HPV, EBV) detection, and 0.06% for MSI-H. For promoter and sample-level methylation, LoDs were 0.06% and 0.05% tumor fraction, respectively. cfDNA cancer samples demonstrated 100% accuracy for SNVs and Indels above 0.5% VAF and 100% for CNAs and fusions across the reportable range. The analytical false positive rate per base was 6.84e-6 for SNVs, 3.42e-6 for indels, and 0 for CNAs and fusions, with positive predictive values of 97.5% for SNVs, 98% for indels, and 100% for CNAs above 2.5 copies and all tested fusions.
Conclusions: GuardantINFINITY is a patient-care-ready liquid biopsy capable of integrated genomic and epigenomic analysis of all solid tumors at single-molecule sensitivity. In addition to traditional genotyping compatible with Guardant360 for more content, the technology's demonstrated LoD showed the potential for ultra-sensitive ctDNA detection for MRD and recurrence surveillance, tumor fraction quantitation for therapy monitoring, oncogenic virus detection, immunogenotyping, epigenotyping, and tumor phenotype characterization, representing a new standard in biomarker discovery.

Refining liquid biopsy: generating more information from cell free DNA

Fabio Puddu, Casper K. Lumby, Nick Harding, David J. Morley, Jamie Scotcher, Robert Crawford, Jens Füllgrabe, Walraj S. Gosal, Shirong Yu, Daniel Brudzewsky, Jane Haywood, Andrada Tomoni, Philippa Burns, Joanna D. Holbrook, Paidi Creed. *Cambridge Epigenetix Limited - CEGX, Cambridge, United Kingdom*

Liquid biopsy for profiling of cell free DNA (cfDNA) in blood holds huge promise to transform how we experience and manage cancer by early detection and identification of residual disease and subtype. However, a standard blood draw yields an average of only 10 ng of cfDNA, of which DNA derived from the tumor is a small minority. Therefore, we are faced with a dilemma when utilizing the limited sample to obtain maximum information. Genetic sequencing provides information on actionable somatic mutations but detection of a few loci in a minority of the sample is challenging. Modified cytosine profiles of cancer are differential from non-cancer at many more loci and so provide a stronger signal. Moreover, they can be used to distinguish tissue-of-origin of the tumor. However, methods such as bisulfite sequencing, EM-seq and TAPS sacrifice genetic information (namely C->T mutations, which are the most common mutation in cancer) to measure modified cytosine. Genetic and modified cytosine data together have been shown to be more powerful for the detection of early cancer than either alone. Here we present a technology, which sequences at base resolution the complete genetic sequence integrated with modified cytosine from low nanogram amounts of cfDNA. It consists of (i) a single pre-sequencing workflow, which creates a copy of the original DNA and performs enzymatic base conversions which discriminate genetic and epigenetic states and (ii) post-sequencing data processing which resolves the resultant sequencing data to an information-rich 16-state code and derives genetic variants integrated with modified cytosine levels, within easy-to-use software. It is, in principle, compatible with any sequencing methodology and is shown here optimized for the Illumina fleet. In cfDNA we show accuracy of modC measurement is higher than that of bisulfite sequencing and EM-seq; and the accuracy of genetic sequencing is higher than that of Illumina alone. Accuracy of measurement is extremely important for liquid biopsy where tumor DNA is in the minority and observed in a small number of reads. We demonstrate the impact of varying base calling error rate on limit of detection for rare alleles in cfDNA

samples. Further we show derivation of cfDNA fragment characteristics and that this is produced in combination with genetic and modC information. This further increases the signal available from cfDNA in only one workflow. We suggest this method will help advance the field of liquid biopsy towards its promise.

BRCA1 promoter methylation in sporadic breast cancer patients detected by liquid biopsy

Jennifer Yen[1], Sai Chen[2], Colby Jenkins[1], Brooke Overstreet[1], Yu Fu[3], Jun Zhao[1], Tingting Jiang[2], Leylah Drusbosky[1], Stephen Pettitt[4], Michael Dorschner[3], Lauren Lawrence[1], Han-Yu Chuang[1], Andrew Tutt[4]. *[1]Guardant Health, Palo Alto, CA,[2]Guardant Health, San Diego, CA,[3]Guardant Health, Seattle, WA,[4]The Institute of Cancer Research, London, United Kingdom*

Background: *BRCA1* promoter methylation (PM) is an early initiating event in cancer, occurring in 3 to 65.2% of all breast tumors, and 30 to 65% of triple negative tumors. *BRCA1* PM has been associated with defective homologous recombination repair (HRR), early onset of breast and ovarian cancer, and improved clinical response to adjuvant chemotherapy. Historically, there has been no diagnostic assay that comprehensively evaluates both *BRCA1* PM and genomic alterations in cell-free circulating tumor DNA (ctDNA). Here, we describe the novel detection of *BRCA1* PM and genomic alterations in a cohort of patients with breast cancer using GuardantINFINITY, a liquid biopsy assay interrogating 800+ genes and genome-wide methylation detection.

Method: We assessed for *BRCA1* PM in ctDNA from 274 patients with late-stage breast cancer. Genomic sequencing of 800+ genes and PM profiling of 398 genes was performed by GuardantINFINITY. The positive calling threshold for PM was established by comparing cell-free DNA derived from patients with cancer and cancer-free donors. The limit of detection (LoD) was determined through *in silico* and experimental titrations of ctDNA from clinical samples and cell lines with known gene PM into the plasma of cancer-free donors.

Results: Among the 274 patients with advanced breast cancer, 8 (2.9%) had germline pathogenic mutations in *BRCA1, BRCA2, or ATM. BRCA1* PM was detected in 11/274 (4.0%) patients at the predefined threshold of >99%

specificity. *BRCA1* PM detection in this cohort was 8.9% (8/90) when excluding samples with low tumor shedding (<1% epigenomic tumor fraction in cfDNA). Among the 11 patients with *BRCA1* PM detected in ctDNA, one had a co-occurring somatic *BRCA1* nonsense variant (p.S361*); none of the remaining patients with *BRCA1* PM had another HRR-related mutation detected in cfDNA. Among patients without *BRCA1* PM detected, pathogenic somatic alterations were detected in *BRCA2, ATM,* and *CHEK2* in 25 (9.4%) patients. *In silico* simulations using clinical samples with *BRCA1* PM indicated an LoD of 0.0408%. *BRCA1* PM was not detected in 3210 individual and mixed cancer-free clinical samples, indicating a high specificity for *BRCA1* PM calls.
Conclusion: GuardantINFINITY, a plasma-based diagnostic assay, detected both *BRCA1* PM and genomic alterations in this unspecified advanced breast cancer cohort. The *BRCA1* PM
detection rates of 4.0-8.9% are consistent with values previously reported in the literature. As *BRCA1* PM has important prognostic and therapeutic implications for the management of breast (as well as ovarian) cancers, additional studies are warranted to further describe the PM patterns across breast cancer subtypes and how these patterns both influence and are influenced by disease evolution and therapeutic response. Liquid biopsy thus serves as a suitable method to noninvasively identify and monitor changes in both genomics and epigenomics.

Analytical development and validation of a personalized hybrid capture based assay for high sensitivity monitoring minimal residual disease (MRD)

Xiaoqiang Wang, Lei Ye, Chao Zhang, Wanglong Deng, Yongjie Wei, Jing Chen, Xuan Tang, Xiaoxuan Wang, Chao Song, Qing Xu, Yong Ren. *State Key Laboratory of Translational Medicine and Innovative Drug Development, Jiangsu Simcere Diagnostics Co., Ltd., Nanjing, China*

Introduction: 5-30% of patients with early-stage cancer relapse, even though most patients had undergone radical surgery. There is increasing evidence that circulating tumor DNA (ctDNA) minimal residual disease (MRD) predicts relapse following treatment for solid tumors. However, liquid biopsy analyses are challenged by the very low concentrations of

ctDNA in blood samples. Existing ctDNA methods lack the sensitivity needed for detecting minimal residual disease (MRD) following therapy. Here, we describe a tumor-informed personalized hybrid capture based method using next-generation sequencing (NGS) to highly sensitive and specific detect MRD and predict recurrence in plasma cell-free DNA. To validate the performance of the assay, we present a technical validation study on DNA from cancer cell line material, including lung cancer cell line, reference material, Onco gDNA reference standard and wild type gDNA reference standard.
Method: The performance of the assay was assessed using samples from Onco gDNA reference standard and lung cancer cell line. To estimate number of monitoring single nucleotide variants (SNVs) at input volume of 20-80ng, Onco gDNA reference standard was diluted into 8 concentrations (10, 20, 30, 40, 50, 60, 150 and 750 ppm with a variant allele frequency [VAF] range of 0.001% to 0.075%).To estimate limit of detection (LoD) of the assay at input volume of 20ng and 40ng, lung cancer cell line was diluted into 5 concentrations (10, 20, 40, 80 and 160 ppm with a variant allele frequency [VAF] range of 0.001% to 0.016%).10 samples were performed for each concentration, as well as 10 negative reference samples. Personalized panel was performed using ultradeep (100,000X) NGS with customized 55 or 60 SNVs.
Result: Validation results of Onco gDNA reference standard: using 40 variants, sensitivity of input volume of 20ng and 40ng are 95% and 98% at 40 ppm, with a specificity of 100%, respectively. Using 40 variants, sensitivity of input volume of 60ng are 95% at 20 ppm, with a specificity of 100%. Using 50 variants, sensitivity of input volume of 60ng are 70% at 10 ppm, with a specificity of 100%. Validation results of lung cancer cell line: using 40 variants, sensitivity of input volume of 20ng and 40ng are 98% and 100% at 50 ppm, with a specificity of 100%, respectively.
Conclusion: The assay was validated by sequentially diluting of lung cancer cell line and Onco gDNA reference standard. With input volume of 20ng, sensitivity of the assay is 95% at 40ppm when monitoring 40 variants, while with input volume of 60ng the LoD reached as low as 10 ppm with sensitivity of 70% when monitoring 50 variants. The assay demonstrates high sensitivity, while maintaining specificity above 99%.

Automated isolation and identification of circulating rare cells from blood samples using a label-free rare cell isolation platform - the Genesis System with Celselect Slide technology

Yoon-Tae Kang[1], Errile Pusod[1], Ally Crudgington[1], Abiodun Bodunrin[2], Nick Bosio[1], Susana Chan[1], David Coe[1], Michelle Racey[3]. *[1]Bio-Rad Laboratories, Ann Arbor, MI,[2]Bio-Rad Laboratories, Pleasanton, CA,[3]Bio-Rad Laboratories, Boulder, CO*

Introduction: Isolation and identification of circulating tumor cells (CTCs) offers a promising non-invasive diagnostic tool for cancer research, but significant technical hurdles have made practical application challenging. Recent studies have shown that CTCs undergo cellular changes, such as an epithelial-mesenchymal transition (EMT), with disease progression and metastasis, implying the heterogeneity of the tumor cell population in circulation. Systems for CTC isolation are often limited by a requirement for epithelial markers or separate systems for identification of CTCs. As such, an automated platform that successfully isolates both epithelial and mesenchymal cells and enables identification of cells is necessary for successful study of CTCs. The Genesis System from Bio-Rad™ Laboratories, Inc. isolates rare CTCs based on size and deformability. It also enables users to identify isolated cells through use of an on-slide immunofluorescence (IF) staining workflow, which minimizes sample manipulation and potential sample loss.

Methods: In order to achieve high-throughput label-free CTC isolation, the Genesis System uses Celselect Slides™. Each slide contains 56,400 individual microchambers to capture CTCs while maintaining viability. This Celselect Slide technology can be used for either enrichment or enumeration protocols. For this study, enumeration protocols were performed to capture and identify CTCs using on-slide IF staining. Enrichment protocols were utilized to capture, enrich, and retrieve CTCs for downstream applications. The performance was evaluated using a breast cancer cell line, MCF-7, spiked into whole blood from healthy donors.

Results: The slide isolated 83.95 ± 10.25% of spiked cancer cells in blood samples at a concentration of 10-250 cells/ml. During the CTC enrichment procedure, 99.92% of blood cells were eliminated. Afterwards, 70% of the isolated CTCs were successfully released from the slide and over 92% of the released cells remained viable.

Discussion and Conclusion: We present a fully automated platform to isolate and identify CTCs using on-slide immunofluorescence staining, which minimizes inevitable cell loss during the workflow. Captured cells can be retrieved for downstream applications to facilitate discovery of unknown CTC functions and their clinical relevance in cancer research. The wide range of possible downstream applications include Droplet Digital™ PCR, quantitative PCR, western blot assays, bulk/single-cell genomics, cell culture, fluorescence in situ hybridization, and RNA-Seq. Additionally, the design of the system is amenable to other biofluids which may be utilized for liquid biopsies. The Genesis System with Celselect Slide technology offers a powerful diagnostic tool to monitor disease progression and personalized treatment.

Biomarker discovery in non-small-cell lung cancer enabled by deep multi-omics profiling of proteins, metabolites, transcripts, and genes in blood

Jinlyung Choi, Ajinkya Kokate, Ehdieh Khaledian, Manway Liu, Preethi Prasad, John Blume, Jessica Chan, Rea Cuaresma, Kevin Dai, Manoj Khadka, Thidar Khin, Yuya Kodama, Joon-Yong Lee, Hoda Malekpour, Megan Mora, Nithya Mudaliar, Sara Nouri Golmaei, Madhuvanthi Ramaiah, Saividya Ramaswamy, Peter Spiro, Dijana Vitko, Kavya Swaminathan, James Yee, Brian Young, Chinmay Belthangady, Bruce Wilcox, Brian Koh, Philip Ma. *Prognomiq Inc, San Mateo, CA*

Lung cancer is the leading cause of cancer-related deaths in the United States, with estimates of 236,740 new cases and 118,830 deaths in 2022 secondary to the disease. Blood-based liquid biopsies hold promise to reduce morbidity and mortality from lung cancer by enabling early detection to downstage disease at diagnosis, theragnostic identification of patients most likely to be helped or harmed by therapy, monitoring of therapeutic efficacy, and detection of residual disease. PrognomiQ's multi-omics platform comprehensively profiles proteins, metabolites, lipids, mRNA, and cfDNA in blood samples which can be used for the development of liquid biopsy tests with high sensitivity and specificity for lung cancer. We conducted a case-control study comprising 1031 subjects: 361 subjects with untreated non-small-cell lung cancer (NSCLC) and 670

matched controls which included 340 subjects with salient pulmonary and gastrointestinal co-morbidities. Blood samples from each subject were processed to provide 7 different `omics readouts. LCMS was used to detect and quantify proteins, metabolites, and lipids. In addition, cfDNA and mRNA were assayed using next-generation sequencing. cfDNA reads were analyzed to estimate fragment-lengths, copy-number variation, and CpG site methylation. All molecular data were normalized using standard methods specific to each assay. Univariate analyses of cases vs controls were performed to identify differentially abundant features on all available samples per assay. We detected 9,868 proteins, 605 lipids, 329 metabolites, and 109,070 mRNA transcripts. Of these, 3,098 proteins, 210 lipids, 57 metabolites, and 30,236 mRNA transcripts were significantly different (FWER < 0.05) in cases versus controls. Gene set enrichment analysis on statistically significant transcripts and proteins identified multiple gene-ontology terms associated with cancer including the Wnt signaling process and IgA immunoglobulin complex, respectively. From cfDNA data, we identified 234 non-contiguous genomic regions associated with the fragment-length disorder, 4,790 with copy-number variation, and 74 differentially methylated genomic regions spanning 184 CpG sites (FWER < 0.05). With the premise that deviations from copy number neutrality are more likely to indicate a tumor contribution, we then focused our examination on those differentially expressed proteins that overlap with differentially expressed mRNA transcripts as well as CNV genomic regions. We identified 52 protein coding genes including E-cadherin (associated with EMT) and related binding proteins such as RAB11B, CAPZB, EPS15, FLNB, MYH9, STK24 and YWHAE. Ongoing machine-learning-based classifier training to distinguish between cancer and non-cancer can serve as the basis for the development of high-sensitivity liquid-biopsy tests for lung cancer.

#6607

Dried blood spot (DBS) sample analysis for drug and metabolomic profiling in oncology clinical trials: Cost-effective decentralized sampling modality for precision oncology

Kelli Goodman, Megan R. Showalter, Anne M. Evans, Matthew W. Mitchell, Rangaprasad Sarangarajan. *Metabolon, Inc., Morrisville, NC*

The COVID19 pandemic accelerated opportunities for innovation within the decentralization process of clinical trials with opportunities for implementation of patient-centric workflows for efficiency and cost-reduction. Decentralized sample collection, particularly whole blood using dried blood spots (DBS) provides the ideal mechanism for patient driven sample collection with ease of access to sample generation, drug level assessments and metabolomic prMegofiling, providing longitudinal real-time measure of drug specific pharmacodynamic readout for safety and efficacy. In this study, we report the development of a protocol for the capture and comprehensive profiling of metabolomics using dried blood spots from a cohort of 49 healthy volunteer donors. Using liquid chromatography combined with mass spectrometric (UPLC-MS/MS) methods an untargeted metabolomic approach resulted in the identification of >800 biochemicals of which a significant subset was found to be presented in corresponding matched plasma (from whole blood) samples. The biochemicals identified from the DBS samples included metabolites that were part of the lipid, amino acid, nucleotide, peptide, cofactors, carbohydrate and energy super pathways. A significant number of metabolites identified in the DBS samples were xenobiotics including those representing the biotransformation products of drugs. The overall metabolite profiles were analyzed for precision and accuracy of measure, variability in performance and dynamic range to establish benchmarks for evaluation. An additional cohort with a longitudinal sampling as part of the protocol provided the reproducibility of the analytic method for inter-day variability of metabolite performance over time. Although metabolomic profiles varied between individuals from a population perspective, there was minimal variation observed within individuals when samples were profiled longitudinally over several weeks. Thus, the protocols for DBS collection and the corresponding capture of a large set of metabolites with reproducible performance provides an opportunity for its implementation in oncological clinical trials as part of a de-centralized clinical trial solution.

#6608

High-sensitivity detection of specific ultra low-frequency somatic mutations for minimal residual disease monitoring

Tong Liu, Michael Bocek, Patrick Cherry, Shawn Gorda, Jean Challacombe, Derek Murphy, Esteban Toro. *Twist Bioscience, South San*

Francisco, CA

Minimal/Molecular residual disease (MRD) refers to the small number of tumor cells which may remain within a patient after therapeutic intervention. The detection of these remnants and monitoring of their abundance is a promising prognostic marker to identify individuals at risk of recurrence or in need of adjuvant therapy. Due to the low abundance of ctDNA present in samples obtained during remission, MRD assays need to be highly sensitive. In addition, each individual will have a different set of somatic variants, requiring personalized solutions for detection. Therefore, personalized NGS assays with high sensitivity and specificity are needed for MRD diagnostics.

To address this need and empower accurate assessments of MRD, Twist Bioscience has developed the MRD Rapid 500 Panels. This product enables customers to design, manufacture and ship fully personalized MRD panels (up to 500 targets) in as little as six days.

To demonstrate the detection sensitivity of Twist Rapid 500 MRD panels, we designed five custom MRD panels which specifically target somatic variants found in Breast, Lung, CRC, Melanoma and Renal Cell Carcinoma. Each of these MRD panels were designed to include 197 targets, with 3-5 variants per tissue origin and a selection of passenger mutations. To create the sample set, we blended synthetic variant sequences with fragmented cell line gDNA (NA12878) to form a contrived specimen which approximates the profile cell-free and circulating tumor DNA. Five frequency levels were created with average VAFs of 0% (WT), 0.01%, 0.05%, 0.1% and 2%. Libraries were prepared with UMI adapters and target enrichment was performed using the MRD panels.

With a sequencing depth of 80,000x, variant calling results revealed that an average of 20 SNV targets can be detected with confidence in the 0.01% VAF samples for each MRD panel, clearly distinguishable from the WT control samples. In addition to demonstrating the accuracy of variant calling, we showcase the utility of targeting a large number of variants for the detection of an MRD signature at very low levels (e.g. 0.01% VAF).

In summary, the performance of the Twist MRD Rapid 500 Panels showed high detection sensitivity of ultra low-frequency somatic mutations while maintaining high specificity for the purposes of MRD monitoring.

For Research Use Only. Not for use in diagnostic procedures.

Detection of rare mutations, copy number variation, and DNA methylation in the same template DNA molecules

Yuxuan Wang, Christopher Douville, Joshua Cohen, Chetan Bettegowda, Nick Papadopoulos, Ken Kinzler, Bert Vogelstein. *Johns Hopkins, Baltimore, MD*

The analysis of cell-free DNA (cfDNA) from plasma offers great promise for the earlier detection of cancer. At present, changes in DNA sequence, methylation, or copy number are the most sensitive ways to detect the presence of cancer. To increase the sensitivity of such assays, it would be useful to be able evaluate the same template molecules for all these changes. Here we report an approach, called MethylSaferSeqS, that achieves this goal, and can be applied to any standard library preparation method suitable for massively parallel sequencing. The innovative step was to copy both strands of each DNA-barcoded molecule with a primer that allows the subsequent separation of the original strands (retaining their 5-methylcytosine residues) from the copied strands (in which the 5-methylcytosine residues are replaced with unmodified cytosine residues). The original and copied strands are queried for epigenetic and genetic alterations, respectively. We applied this approach to plasma from 265 individuals, including 198 with cancers of the pancreas, ovary, lung or colon, and found the expected patterns of mutations, copy number alterations, and methylation. Furthermore, we could determine which original template DNA molecules were methylated and/or mutated. MethylSaferSeqS should be useful for addressing a variety of questions relating genetics and epigenetics in the future.

#6610

Increasing blood volumes to detect minimal residual disease in neoadjuvant-treated early breast cancer patients

Alfonso Alba-Bernal[1], Ana Godoy-Ortiz[1], María Emilia Domínguez-Recio[1], Begoña Jimenez-Rodriguez[1], María Elena Quirós-Ortega[1], Esperanza López-López[1], Guillermo Carbajosa-Antona[2], Jesús Peralta-Linero[3], Luis Vicioso[2], Estefanía Bellagarza-García[3], Guadalupe Dolores Garrido-Ruiz[4], Cynthia Robles-Podadera[1], Alicia Garrido-Aranda[1], María

Dunia Roldán-Díaz[1], Jesús Velasco-Suelto[1], Rocío Lavado-Valenzuela[1], Martina Álvarez[2], Nuria Ribelles[1], Javier Pascual[1], Emilio Alba[2], Iñaki Comino-Méndez[1]. *[1]Biomedical Research Institute of Málaga, Málaga, Spain,[2]University Of Málaga, Málaga, Spain,[3]Unidad de Gestión Clínica Intercentros de Oncología Médica, Hospitales Universitarios Regional y Virgen de la Victoria, Málaga, Spain,[4]Radiology Department, Hospital Clínico Universitario Virgen de la Victoria de Málaga, Málaga, Spain*

Breast cancer (BC) is the most frequent neoplasia affecting women worldwide normally detected at early stages. In this regard, early diagnosis drastically decreases mortality, however, around 20% of these patients will later relapse. This is mainly caused by undetectable molecular residual disease (MRD) not eliminated by standard primary treatments. Therefore, it is crucial to detect the after-treatment MRD to stratify the patients by their risk of relapse. Liquid biopsies have emerged as non-invasive method to obtain information about tumors and improve clinical cancer management. Regarding this, much has been hypothesized about utilizing high blood volumes to overcome the necessity of complex and resource-intensive next generation sequencing (NGS) methodologies to detect highly diluted blood tumor components in localized cancers. Herein, we employed a combined analysis of circulating tumor DNA (ctDNA) and circulating tumor cells (CTCs) together with high blood volumes and single-assay droplet digital PCR (ddPCR) to detect MRD with ultra-high sensitivity. We prospectively assayed 124 samples extracted at baseline, post-neoadjuvant therapy (NAT), post-surgery and a follow-up on a six-monthly basis. A median of 76.40 mL of blood to detect CTCs and 40 mL of plasma to detect ctDNA per patient from 19 BC women were used in this study. ddPCR assays were performed with a median of 14 partitions per determination to detect ctDNA and 12 partitions for CTCs. Overall, ctDNA, CTCs and ctDNA and/or CTCs were detected in 84.21%, 66.66% and 89.47% respectively in the pre-treatment blood samples. MRD (ctDNA and/or CTCs) was detected in 73.68% of the after NAT blood samples. On the other hand, it was detected in 46.66% and 70.00% of the post-surgery and follow-up samples respectively. Post-NAT MRD was detected in 57.14% (4/7) and 83.33% (10/12) of patients with and without pathological complete response pCR respectively. To note, the discordant patients achieving pCR in tissue with detectable MRD in blood were high-risk BC. Importantly, in one of the two patients without pCR and

no MRD detected, not enough sample were available to complete the analysis. The other discordant patient presented a localized disease with residual cancer burden value of 1 and no lymph nodes affected. In 1 out of 19 (5.26%) patient clinically relapsed with a positive MRD detection 6 months earlier. Applying this methodology, we observed a sensitivity of 0.004% in ctDNA detection and 0.224 CTCs per mL of blood. Overall, this novel methodology greatly improves sensitivity for ctDNA and CTCs detection in treatment-naïve early BC. In addition, MRD was successfully detected in post-treatment samples antedating clinical relapse by 6 months in one patient. This prospective study is potentially demonstrating that using high blood volumes and a single-assay ddPCR is a cost-effective strategy to monitor localized BC and predict relapses.

#6611

Harnessing the power of multiomics from a single sample to explore tumor heterogeneity and advancing immuno-oncology research

Bhagyashree S. Birla, Andrea O'Hara, Elizabeth Louie, Ben Niu, Haythem Latif, Vanessa Tumilasci, Yang Han, Yongjun Fan, David Corney, Pranay Vishwanath, Wei Wang, Alfredo Staffa, Ilaria DeVito, Laure Turner, Chris Mozdzierz, Peter Nowacki, Ginger Zhou. *Azenta, Life Sciences, South Plainfield, NJ*

The omics era has greatly expanded the repertoire of approaches available for researchers and clinicians to unravel the complexity behind cancer onset in humans: Next Generation Sequencing (NGS) approaches can characterize genomes, epigenomes, transcriptomes and proteomes of patient samples. Advanced DNA barcoding and automated microfluidics can take this to the next level, enabling multiomic characterization of single cells. Peripheral blood mononuclear cells (PBMCs) offer a window into the immune system that, when combined with these omics tools, can provide an insight into immune cells mediating anti-tumor responses in cancer patients. Here we detail a workflow using a single blood draw to rapidly produce a diverse set of multiomics results including genomics, epigenomics, transcriptomics and proteomics. This starts with automated sample handling and processing of the primary blood draw to ensure high viability and yield of PBMCs, along with simultaneous plasma separation and collection. These samples are then aliquoted and simultaneously processed for

automated and semi-automated whole exome sequencing, single-cell RNA sequencing, methylation sequencing and Olink proteomics assay. Germline and somatic mutations can be detected using whole exome or whole genome sequencing with deep coverage, whereas methylation, ATAC or ChIP sequencing can be used for epigenetic characterization of the same sample. While bulk expression offers a high-level transcriptomics profile, single-cell transcriptomics facilitates detection of gene expression changes in each individual cell type, allowing for analysis of rare cell types including circulating tumor cells. Olink proteomic assays can be utilized for both biomarker discovery and validation, with highly targeted or broad-spectrum panels. With this robust workflow and advanced robotics for sample handling and processing to minimize potential batch effects, all these datatypes can be produced within days of primary sample collection using minimal sample amounts. High throughput integrative omics workflows, as described here, are useful in gaining a multidimensional view of cancer and advance immunotherapies by characterizing immune cell modulation in tumor progression, and can be expanded for use in tumor/normal analysis, evaluation of metastases and exploration of tumor microenvironment.

Data-driven hallmarks of cancer as a new paradigm for precision medicine: multi-omics and functional profiling in acute myeloid leukemia

Tom Erkers[1], Nona Struyf[1], Tojo James[1], Francesco Marabita[1], Mattias Vesterlund[1], Nghia Vu[1], Cornelia Arnroth[1], Albin Österroos[2], Anna Bohlin[1], Sofia Bengtzén[1], Matthias Stahl[1], Rozbeh Jafari[1], Lukas Orre[1], Yudi Pawitan[1], Brinton Seashore-Ludlow[1], Janne Lehtiö[1], Sören Lehmann[2], Päivi Östling[1], Olli Kallioniemi[1]. *[1]Karolinska Institutet, Stockholm, Sweden,[2]Uppsala University, Uppsala, Sweden*

The cancer hallmark concept defines biological properties that play a key role in cancer development and progression. The hallmarks reflect generic properties across all cancer types, and are not directly quantifiable nor applicable in cancer diagnostics. Here, we applied a data-driven approach to identify quantifiable hallmarks to be used as a basis for precision cancer medicine (PCM) in Acute Myeloid Leukemia (AML).

We applied deep exome, transcriptome, DNA methylation and proteome profiling as well as ex-vivo functional testing of 525 drugs to 118 AML patient samples. Unsupervised multi-omic dimensionality reduction defined 11 independent axes of biological variability that we interpreted to reflect data-driven hallmarks (DDHM) of AML. Each DDHM integrates and ranks different data types and features, pinpointing those molecular features that were most informative for each hallmark. We calculated values for the 11 DDHM for each patient, constructing a DDHM-based precision medicine approach for AML diagnosis and therapy assignment.

Most DDHMs were driven by other data types than genomics. For several DDHMs, different cytogenetic and mutational drivers converge on the same hallmarks and specific drug vulnerabilities. We also see how DDHM predictors of poor prognosis and high-risk AML are distinct from those that dictate specific drug response vulnerabilities.

DDHM 2 reflected the cell differentiation path leading towards resistance to BH3 mimetics, ACK-inhibitors, and anthracyclines, and sensitivity to MEK inhibitors and TLR8 agonists. DDHM 2 derived a strong impact from protein expression of GATA2, MLLT11, DNMT3B and from RNA expression of WT1 and SOX4 as well as from multiple markers of different monocytic subtypes. DDHM 5 depicted cell cycle regulation and the Megakaryocytic-erythrocyte progenitor cell state that was enriched in AML patients with antecedent hematological disease. Interestingly, DDHM5 was linked to the sensitivity to purine analogs and vinca alkaloids. Moreover, DDHMs 1 and 8 captured clinical risk groups, prognosis, and responsiveness to hypomethylating agents. These DDHMs also revealed the phenotypic and functional biology that distinguished patients with high versus low FLT3-ITD mutant allele frequency.

Validation of the DDHMs is realized through profiling and analysis of prospective AML samples, AML cell lines and previously published datasets.

In summary, we present a data-driven approach for defining hallmarks in AML. The application of the DDHMs in AML provides a new paradigm for PCM and an opportunity for combinatorial therapeutic targeting. Each patient is characterized by a combination of independent and potentially druggable hallmarks, as opposed to traditional stratification in PCM, where each patient is assigned to one specific subgroup defined by genetic or other biomarkers.

Label-free multimodal multiphoton microscopy for predicting DNA damage response in patient derived non-small cell lung cancer organoids

Terrence T. Roh[1], Aneesh Alex[1], Janet E. Sorrells[2], Prasanna Chandramouleeswaran[1], Marina Marjanovic[2], Steve R. Hood[3], BanuPriya Sridharan[1], Stephen A. Boppart[2]. *[1]GSK, Collegeville, PA,[2]Bioengineering, University of Illinois Urbana-Champaign, Champaign, IL,[3]GSK, Stevenage, United Kingdom*

Background: DNA damage response (DDR) is a fundamental mechanism for evaluating efficacy of cancer therapeutics, many of which target DNA or associated processes (e.g., etoposide: inhibits DNA synthesis, cisplatin: crosslinks DNA). Current techniques to evaluate DDR rely on immunostaining for gamma H2AX foci (γH2AX), which is an indicator of DNA double-strand break formation. While γH2AX immunostaining can provide a snapshot of DDR in fixed cellular and tissue samples, this method is technically cumbersome as: 1) temporal monitoring of DDR requires timepoint replicates; 2) extensive assay development efforts for 3D samples such as organoids, and 3) protocols for γH2AX immunostaining and its evaluation are time-consuming. The goal of this project is to reduce overall burden on assay duration and development in NSCLC organoids by leveraging label-free multiphoton imaging.
Method: To predict DDR in 3D organoid samples, label-free multimodal multiphoton techniques such as simultaneous label-free autofluorescence multiharmonic (SLAM) imaging can provide intracellular information based on endogenous contrast mechanisms. SLAM makes use of a single laser to excite autofluorescence in multiple cellular components including FAD and NAD(P)H, enabling the calculation of the optical redox ratio, which estimates the equilibrium of electron donating versus accepting species in cells. Moreover, label-free, multiphoton systems enable imaging of live samples without the need to add labels or generate sacrificial samples and have improved image acquisition in 3D space over conventional confocal microscopy. Using SLAM, we propose to predict DDR in non-small cell lung cancer (NSCLC) organoids. NSCLC organoids

recapitulate histological and genetic features of their derived patient tissue, retaining tumor variability.
Results: Predictive modeling via gradient boost regressor between handcrafted SLAM image features and γH2AX immunostained images on weakly-paired images confirmed strong correlation between SLAM image features and γH2AX speckles/nuclei. Across multiple patient derived NSCLC organoid lines and multiple DNA targeting chemotherapeutics, the optical redox ratio was demonstrated to robustly predict DDR.
Conclusion: Label-free imaging via SLAM can be used to predict DDR in live 3D NSCLC organoids with minimal sample handling and without the need to add labelled reporters, enabling quicker and less technically involved DDR assaying.

#6614

Spatial transcriptomic driven mechanistic model to investigate and predict pathogenesis of oligodendroglioma

Sandhya Prabhakaran[1], Heyrim Cho[2], Maximilian Strobl[3], Russell Rockne[4], Alexander R. A. Anderson[3]. *[1]Integrated Mathematical Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[2]University of California Riverside, California, CA,[3]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[4]City of Hope, California, CA*

Rationale: Oligodendrogliomas represent the second most common glioma in adults after glioblastoma. Recent studies conjecture that oligodendrocyte progenitor cells (OPCs) are precursors for glioma. The etiology of OPC derived oligodendrogliomas, the corresponding genetic program and genetic aberrations, and the underlying mechanisms leading to the pathogenesis of oligodendroglioma is yet to be explored. We hypothesize that genetic mechanisms mediating oligodendrogenesis (the process of OPCs maturing to oligodendrocytes (OL)) are temporally and spatially coordinated. In this study, we spearhead a comprehensive computational framework that utilizes a) Machine learning (ML) to interpret spatial transcriptomic (ST) images of a normal whole mouse brain dataset obtained from Vizgen's MERFISH Mouse Brain Receptor Map and b) mathematical modeling to perturb the cellular mechanisms in the normal brain to understand the abnormalities leading to the pathogenesis of oligodendroglioma.

Methods: Using ML for clustering and trajectory inference, we create a comprehensive spatial catalog of cell types. The cell types are validated using canonical genes from the scRNAseq mouse brain data from CZI Biohub's Tabula Muris Consortium. From the cell types, we extract potential OL pseudotime differentiation (from immature to mature OLs) trajectories. These trajectories are used to develop a phenotype structured partial differentiation equation (PDE) model of oligodendrogenesis. This can be used to simulate both spatial and phenotypic interactions, differentiation status, and the pathogenesis of oligodendroglioma by mathematically perturbing the process of cellular proliferation and differentiation using genes known to cause oligodendroglioma: PDGFRA, OLIG1, MAS1.
Results: We mathematically perturb cell differentiation lineages in normal oligodendrogenesis to simulate, and predict the effects of perturbation and how this leads to abnormal (cancer aiding) cell states. Our PDE simulations reinforce that OPC proliferation and OL differentiation occur more in the white matter in the normal mouse brain, and further postulate that OPC and OL differentiation occur more in gray matter in malignant mouse brains.
Conclusions: Our study is one of the earliest attempts to integrate qualitative and scalable ML techniques with quantitative and interpretable mathematical modeling at the cellular, omics, and organ level using ST imaging and sequencing data. We develop and calibrate PDE mathematical models for robustly simulating, predicting, and studying the effects of perturbation from sparse, noisy single cell spatial measurements to forecast abnormal behavior in OLs based on spatial and (pseudo)temporal changes. In future work, we will apply our framework to jointly perturb differentiation trajectories of multiple cell types to understand their cumulative effects in tumor progression.

#6615

Novel digital pathology tools for exploring role of myeloid cells in modulating next generation immunotherapies

Richard Van Krieken[1], Lisa Adams[1], Beiru Chen[2], Emmanuel Pacia[1], Naveen Dakappagari[2], Brian Bourke-Martin[3], Jennifer Bordeaux[1]. *[1]Digital Pathology, Navigate BioPharma, Carlsbad, CA,[2]Navigate BioPharma, Carlsbad, CA,[3]Data Science, Navigate BioPharma, Carlsbad, CA*

Purpose: Deeper understanding of the immune landscape in tumor microenvironments is critical for creation of next generation immunotherapies (I-O). While significant investments were made to understand the role of T-cells, the contribution of myeloid cells in limiting the effectiveness of I-O therapies is not well understood primarily due to limitations posed by conventional immunohistochemistry (IHC) analysis that typically provides information on a single target. We developed a clinical grade multiplex fluorescence IHC (mFIHC) assay to simultaneously evaluate different subsets of myeloid cells (e.g., M1, M2 and MDSC) as well as PD-L1 receptors associated with these subsets as the latter is known to have profound positive impact on patients treated with PD-1 blockers *(Liu et al., CCR, 2019)*. In addition, we developed an algorithm to identify the microenvironment using imaging datasets from AQUA® (Automated Quantitative Analysis) and HALO to understand the spatial relationship between tumor cells and myeloid cell subsets as well as immune checkpoint (IC) expression. mFIHC combined with hypothesis driven spatial profiling algorithms (e.g., AQUA Technology) were found to provide superior predictors of I-O therapies in a systematic meta-analysis of over 8000 patients treated with PD1/L1 pathway blockers (*Lu et al., JAMA Oncol 2019)*. Furthermore, spatial profiling by AQUA has proven to robustly identify powerful biomarker predictors (PD1/PDL1) in melanoma (*Johnson et al., CCR, 2018*). Implementation of mFIHC coupled with robust image analysis may provide great insight into immune surveillance, mechanisms of resistance and patient stratification.
Study Design: We designed a novel mFIHC assay (CD68, CD163, HLA-DR, IDO-1, PD-L1, PanMel-CK) and evaluated various myeloid and tumor cell types on tissue sections (e.g., non-small cell lung cancer, gastric carcinoma, breast carcinoma, and renal cell carcinoma). Following the initial evaluation, the mFIHC assay was validated for clinical trial application using automated staining (Leica Bond RX) and imaging (PhenoImager HT). We conducted image analysis using AQUA and HALO technologies.
Results: Analysis of samples by AQUA and HALO revealed unique myeloid microenvironments in the examined tissue types. Microenvironment data from AQUA and HALO were assessed by analyzing enrichment of macrophage phenotypes in areas dense with

checkpoint markers. Our analysis revealed unique myeloid cell clusters in the assessed tumor microenvironments.
Conclusion: We anticipate this hypothesis driven clinical trial grade mFIHC assay design combined with novel analyses algorithms will aid in the better understanding of the immunomodulatory effects of myeloid cells in several cancer types and the development of next generation I-O therapies.

Development of a high-throughput image processing pipeline for multiplex immunofluorescence whole slide images at scale
Waleed Tahir, Emma Krause, Jin Li, Howard Mak, Mohammad Mirzadeh, Kevin Rose, Judy Shen, Vignesh Valaboju, Guillaume Chhor, Joseph Lee, Jun Zhang, Jacqueline Brosnan-Cashman, Michael G. Drage, Justin Lee, Carlee Hemphill, Saumya Pant, Robert Egger. *PathAI, Inc., Boston, MA*

Background. Fluorescent imaging technologies now allow for multiplex immunofluorescence (mIF) for up to 100 targets on a single slide. However, the ability to quantitatively analyze the resulting data, especially on whole-slide images (WSI), is limited by scalability and reproducibility. Currently available platforms for segmenting cancer cells and nuclei involve segmentation algorithms that are hand-tuned on individual fields of view, making these methods subjective and difficult to replicate. To this end, we sought to develop an end-to-end workflow for WSI mIF data in cancer, from raw images to cell-level features, using state-of-the-art deep learning models for tissue, cell, and nuclei segmentation.
Methods. mIF was performed using the Akoya 6-plex Lung IO panel (CD8, FoxP3, CD68, PD-1, PD-L1, and pan-cytokeratin) with a DAPI counterstain on clinical NSCLC specimens obtained from commercial sources (N=41). Slides were scanned using the Akoya PhenoImager HT. To remove bleed-through between different fluorophores, mIF WSIs were linearly unmixed based on a reference single-stain matrix, generated by selecting pure stain regions in mIF images. Convolutional neural network models previously trained on hematoxylin and eosin (H&E) images for 1) artifact detection, 2) tissue region identification, and 3) nucleus detection and segmentation were then deployed on mIF images that were converted to RGB images using a synthetic H&E transformation. Cell segmentation models were developed and implemented for each marker assessed. For

each demixed channel representing a single antibody signal, expert annotations were used to train deep learning models for cell detection and segmentation. Finally, segmentation results from separate channels were aggregated based on spatial colocalization to identify cells and cell phenotypes.
Results. We developed a pipeline for mIF image analysis at scale. After unmixing, conversion of an mIF image to a synthetic H&E image allowed for 1) removal of artifact regions, 2) detection of cancer and stroma using tissue segmentation, and 3) nuclei segmentation. Nuclear segmentation using this approach improved upon a widely used commercial segmentation platform when compared to manual expert annotations (Dice scores = 0.85 and 0.52, respectively). Finally, using state-of-the-art instance segmentation models allows a novel approach to cell phenotyping compared to currently available platforms, allowing positive identification of cells lacking a nuclear signal in the sectioned plane (e.g. large cytokeratin-positive cells).
Conclusions. We developed a robust workflow to accurately segment cells and nuclei from mIF WSIs at scale. Improving the scalability and reproducibility of complex mIF image analysis may help improve the adoption of this approach for biomarker development and incorporation into clinical trial workflows in oncology.

Gleason score 6 often coexists with Gleason score 7 adenocarcinoma within 3D z-levels of a prostate biopsy
Xavier Farré[1], Vanessa Roybal[2], Can Koyuncu[3], Sarah Chow[2], Hongyi Huang[2], Alan Aberdeen[4], Andrew Janowczyk[3], Anant Madabhushi[3], Lawrence D. True[2], Jonathan T. C. Liu[2]. *[1]Public Health Agency of Catalonia, Lleida, Spain,[2]University of Washington, Seattle, WA,[3]Emory University, Atlanta, GA,[4]Ground Truth Labs, Oxford, United Kingdom*

Background: Primary prostate cancer is diagnosed by biopsy. However, biopsies sample only a limited amount of the prostate gland. Many studies report that GS6 cancer at biopsy is often upgraded in the radical prostatectomy. Undergrading results from sampling limitations of the biopsy - both of the prostate and of tissue within the biopsy. Since pathological diagnosis is based on 4 micron thick sections of 1 mm thick biopsies, only 0.4% of the biopsy is analyzed. We hypothesize that the

evaluation of a biopsy in 3D results in variable Gleason scores or even no cancer in certain z-levels. Here, we examined 3D pathology image datasets of Gleason score 7 (GS7) biopsies using a web-based image viewing platform to determine if they underdiagnose and/or undergrade cancer when examined by conventional 2D slide-based histology.
Methods: We used a custom-developed 3D open-top light-sheet (OTLS) microscope, not yet available for clinical use, to study all z-levels of a prostate biopsy. The patient cohort used in this study came from the Canary TMA study. 105 prostate biopsies were non-destructively digitized in 3D with at least 500 z-levels per biopsy (at a spacing of ~1 micron per level). Samples were stained with fluorescence analogs of H&E. The image datasets were false colored to mímic conventional H&E histology. A pathologist reviewed the images using a web-based image platform and gave overall Gleason scores (OGS) based examing all z-levels within a biopsy. Six z-levels (1, 100, 200, 300, 400 and 500) were selected for 2D Gleason scoring.
Results: 63 images had a OGS of 3+4 and 42 a OGS 4+3. We found presence of GS6 (Gleason grade 3 glands only) in some z-levels: 32 cases (50.8%) with OGS 3+4 and 4 cases (9.5%) with OGS 4+3. When we only studied the 6 selected z-levels, we found z-levels with no cancer in 4 cases (6.3%) of OGS 3+4 and 2 cases (4.8%) in OGS 4+3. In addition, we found z-levels with limited number of glands. We reported these levels as Atypical Small Acinar Proliferation (ASAP) in 2 cases (3.2%) with OGS 3+4 and 3 cases (7.1%) with OGS 4+3. Examining all z-levels enabled unambiguous grading of biopies containing z-levels with ASAP and tangential sections.
Conclusion: We describe the frequent coexistence of GS6 z-levels within a OGS7 3D prostate biopsy. This finding supports prior observations that finding of GS6 prostate cancer in a 2D-based sections of prostate cancer does not rule out a higher Gleason grade areas in other parts of the prostate nor in other levels of each biopsy. We also show that availability of 3D levels eases the interpretation of ASAP glands and tangential sections.

Longitudinal, multimodal profiling of metastatic ER+ breast cancer on CDK4/6 inhibitor therapy

Allison L. Creason[1], Julian Egger[1], Cameron Watson[1], Shamilene Sivagnanam[1], Jia-Ren Lin[2], Koei Chin[1], Peter K. Sorger[2], Lisa M.

Coussens[1], Zahi I. Mitri[1], Joe W. Gray[1], Gordon B. Mills[1], Jeremy Goecks[1].
[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]Harvard Ludwig Cancer Center and Laboratory of Systems Pharmacology,Harvard Medical School, Boston, MA

Introduction: Use of CDK4/6 inhibitors (CDK4/6i) in combination with endocrine therapy has transformed treatment and greatly improved outcome for ER+ breast cancer (BC) patients. However, many BC patients eventually progress on therapy. To understand how ER+ metastatic BC (mBC) tumors become refractory to CDK4/6i, we have created a multimodal, longitudinal tumor atlas to investigate tumor mechanisms of therapeutic resistance, as part of the NCI Cancer Moonshot Human Tumor Atlas Network. By deeply profiling individual patients, we identified a wide variety of putative tumor intrinsic and extrinsic mechanisms of resistance to CDK4/6i.
Methods: mBC ER+ patients (n=5) enrolled in the Knight Cancer Institute SMMART Trials program underwent biopsies before treatment and on progression with combination CDK4/6i and endocrine therapy. Biopsies were profiled using: clinical imaging, bulk genomics (WES), transcriptomics (RNAseq), and proteomics (RPPA), multiplex tissue imaging (mIHC, cycIF), single-cell genomics (scDNAseq) and epigenomics (sci-ATAC-seq).
Results: Upon progression, patients displayed dysregulated tumor-intrinsic activity via upregulation of gene expression in cell cyclins and kinases as well as genomic copy loss of regulatory factors, such as Rb. On-progression biopsies exhibited increased expression and pathway activity of IL-Jak-Stat and Interferon signaling and changes in tumor microenvironment immune cell composition, including elevated immune cytotoxicity; however, a subset of CD8 T cells expressed LAG3, Tbet, and TIM3, indicating signs of immune activation trending toward exhaustion. Patients also exhibited increased M2 Macrophage and T regulatory cell infiltration, suggesting compensatory feedback to dampen immune activity. Analysis of spatial organization identified cellular neighborhoods recurring across all samples with changes after therapy observed primarily in neighborhoods associated with epithelial-stromal density and immune reactivity/suppression.
Conclusion: Findings from this mBC ER+ cohort highlight heterogenous molecular and cellular changes that occur after treatment with a CDK4/6i.

We observed multiple tumor intrinsic and extrinsic factors, including modulation of proliferation in neoplastic cells and tumor microenvironment composition, that are suggested to play a role in acquired resistance. We hypothesize a set of patients that initially respond to CDK4/6i therapy may initially display immune activation, but the sustained activation and long-term exposure to therapy may lead to chronic inflammation and immunosuppression. These observations suggest combining CDK4/6i therapy with immunotherapy may provide benefit. We also observed recurrent spatial cellular patterns that recapitulate known biological structures in these tissues; future work will explore association of spatial organization with therapeutic response.

Virtual staining enabled combined morphological and spatial transcriptomic analysis of individual malignant B cells and local tumor microenvironments

Michael E. Kallen[1], Alyssa Rosenbloom[2], Zihang Fang[3], Raymond Kozikowski[3], Yair Rivenson[3], Kevin de Haan[3], Serge Alexanian[4], Mark Conner[2], Daniel Newhouse[2], Felicia New[2], Yan Liang[2], Kyla Teplitz[2], Joachim Schmid[2], Jaemyeong Jung[2]. *[1]University of Maryland School of Medicine, Baltimore, MD,[2]Nanostring Technologies, Seattle, WA,[3]PictorLabs, Los Angeles, CA,[4]PictorLab, Los Angeles, CA*

B-cell lymphomas, commonly classified by histological presentation and B-cell lineage, are in fact heterogeneous diseases with respect to gene expression and tumor microenvironment. Certain lymphomas, such as Hodgkin and T-cell rich B-cell lymphoma, may contain fewer than 1% malignant cells in a largely inflammatory background. These rare malignant cells have unique interactions with local tumor microenvironments (TME), in some cases driving distinct gene expression patterns for individual B-cells. This presents a challenging fundamental biology landscape, which can create uncertainty in directing patient care or developing new therapies. The lack of tools allowing subtyping of malignant B-cells while simultaneously preserving the context of local TMEs and providing deep spatial transcriptomic sequencing further complicates analysis.
Here we have developed an integrated, single-slide workflow of virtual H&E staining using the inherent tissue autofluorescence (PictorLabs, Los

Angeles, CA) of formalin-fixed, paraffin embedded lymphoma tissue sections on the GeoMx® Digital Spatial Profiler (Nanostring, Seattle, WA) combined with spatial expression analysis of 1,800 genes using the Cancer Transcriptome Atlas (CTA) panel. The H&E virtual staining allows for the assessment of B-cell lymphoma subtypes, identification and phenotyping of malignant B-cells and the immediately proximal (within 30μm) TME regions by a certified pathologist. These regions of interest (ROI) are spatially profiled for transcriptional expression determined by NGS sequencing of the RNA target specific DNA oligo tags.
We benchmarked our system by analyzing four lymphoma cases: Nodular sclerosis classical Hodgkin, Nodular lymphocyte-predominant Hodgkin, T-cell/histiocyte rich large B-cell, and Diffuse large B-cell lymphomas. Using virtual H&E staining on the GeoMx Digital Spatial Profiler platform, a pathologist correctly identified the diagnosis and subtype based on the morphology. Regions of inflammatory B- and T-cells could be distinguished from lymphoma cells on virtual staining, allowing subset segregation for digital transcriptional expression profiling with the GeoMx CTA panel. Additionally, background TME more distant to B-cell lymphoma as well as regions of high T-cell infiltration were selected for profiling. Analysis of the ROIs revealed distinct transcriptional profiles of malignant B-cells (including cell-of-origin signature), the signaling contributions of local TMEs (versus non-adjacent regions) and confirmed that the expression patterns are further influenced by the presence of T-cell infiltration.

#6620

Identification of crosstalk signaling between brain-tumor niche and reactive human cytomegalovirus in brain metastases

Xin Wang, Puri Akshjot, Kun Han, Amna Irfan, Liliana Guzman, Wei Qian, Roberto Rosato, Hong Zhao, Jenny Chang, Stephen Wong. *Houston Methodist Hospital, Houston, TX*

Purpose: Human cytomegalovirus (HCMV) is a common neurotropic herpes virus although its DNA was confirmed highly prevalent in various peripheral cancers. HCMV is also a major cause of neuropathology in immune-compromised patients. Since HCMV reactivation frequently causes encephalopathy during chemotherapy or radiation therapy in brain

tumor patients, understanding the brain niche-HCMV crosstalk signaling may pinpoint effective strategies in managing brain metastases.
Methods: We collected nine pairs of primary breast and brain metastatic tumor samples from our institution and analyzed their RNA-Seq data. Pairwise differential gene expression analysis and gene set enrichment analysis (GSEA) were conducted. TCGA-BRCA (n=1,222) dataset was used for clinical and immune-infiltration correlation analysis. GSE12276 (n=204) dataset was used for brain-metastasis free survival correlation. Immunohistochemistry staining of HCMV was conducted on sixteen primary breast and brain metastatic tumor sections and an 86-core tissue microarray (TMA) of human brain metastasis tissue. CCCExplorer software was used to explore molecular crosstalk signaling between the secretome proteins from HCMV-infected cells and brain metastatic niche cells.
Results: *Reactome Human cytomegalovirus (HCMV) early and late events* was the top enriched pathway for the 371 brain metastasis up-regulated genes while *Reactome IL4 and IL5 signaling* was the top enriched pathway for the 2,153 primary breast tumor up-regulated genes. Among the 371 brain metastasis up-regulated genes, 287 genes are also up-regulated in primary breast cancer *vs.* normal breast in the TCGA 1222 cohort ($P<0.05$). High expression of 19 out of the 287 genes are significantly associated with poor brain metastasis-free survival in the GSE12276 cohort (Logrank $P<0.05$). We further identified that elevated expression of 12 out of the 19 genes are consistently associated with Th2 cell activation and NK cell deactivation in the TCGA 1,222 cohort, for which immunosuppressive Th2 cells are defined by secretion of IL4 and IL5 signature cytokines. Immunoreactive HCMV reactivation proteins were examined in the paired breast tumor and brain metastatic specimens, and most of the TMA tumors. Preventive treatment of an anti-HCMV drug, ganciclovir, by suppressing viral DNA replication inhibited tumor colonization in the mouse brains of the two HCMV-positive PDX models. Several HCMV cell-entry co-receptors are highly expressed in brain metastatic niche. Furthermore, from the secretome of HCMV-infected cells, we identified 89 paired receptors that potentially regulate niche cell behaviors.
Conclusions: Our systemic analysis revealed a causal relationship between HCMV reactivation and brain metastatic outgrowth. Targeting the key brain-tumor niche-HCMV crosstalk signaling may benefit the management of brain metastases.

Simulating the distortion of clonal fractions in ctDNA due to spatially heterogenous selection

Thomas W. Rachman, Oana Carja, Russell Schwartz. *Computational Biology, Carnegie Mellon University, Pittsburgh, PA*

Time-series circulating tumor DNA (ctDNA) sequencing has the potential to reveal emerging variants in the tissue in real time, and there is now substantial evidence that it can detect tumor growth and treatment-resistant mutations long before growth is visible. However, the reliability of ctDNA for profiling the primary tumor may be compromised by spatial heterogeneity in the tumor genetics, for example due to selective effects of differential drug penetration, immune infiltration, and oxygenation. We explore the influence of spatial factors on tumor genetics through a lattice-based branching process model of solid tumor evolution and ctDNA shedding with the goal of understanding where spatially variable selection pressure could lead to a significant difference between the clonal fractions in the blood and the tissue. The lattice model divides space into regions with different growth rates which result in different rates of driver mutation accumulation. The effects of regional differences in selection cause different apoptosis rates to correlate with the location of expanding driver clones. Using these rates to simulate ctDNA shedding, our model found that clones fit enough to invade a hostile region are temporarily amplified in the blood compared to their tissue frequency by as much as 300% for a limited window of time before the population expands further and the clonal fraction in the blood returns to close agreement with tissue. The results suggest evolutionary contexts in which liquid biopsy might provide highly biased estimates of tumor state, but also shows how this effect might be exploited to provide more sensitive detection of clonal expansion with implications for blood-based detection of recurrence and metastasis.

Developing spatial molecular correlates of response to immunotherapy in kidney cancer

Kathryn Beckermann[1], Scott Haake[1], Alex Nesta[2], Michael Caponegro[2], N R Nirmala[2], Anupama Reddy[2]. *[1]Vanderbilt University Medical Center,*

Nashville, TN,[2]Vindhya Data Science, Morrisville, NC

Immunotherapy has emerged as a promising new therapy for kidney cancer with durable clinical responses in a subset of the patients. However, discovery of biomarkers that predict patient response to immunotherapy has thus far been unsuccessful. Diverse sets of biomarkers have been proposed, (e.g., PD-L1 immunohistochemistry, tumor mutation burden, gene expression signatures), but have failed to validate in clinical studies. There is an urgent need to identify predictive biomarkers for selecting kidney cancer patients most likely to respond to immunotherapy.Spatial biology technologies provide molecular data at single cell resolution along with spatial coordinates in patient's tumor slides. We hypothesized that the presence of immune cell types and their spatial 2-D patterns in a histology image could potentially predict response to immunotherapy. For this project we are using Tissue Microarray (TMAs). We are using two cohorts of data: (Dataset-1) 70 clear cell renal cell carcinoma (CCRCC) patients treated with checkpoint inhibitors, and (Dataset-2) 180 patients, early stage papillary RCC (PRCC) cohort. Dataset-1 was assayed using CosMx (Nanostring technologies) for a RNA panel of 980 immune-related genes. Dataset-2 was assayed with PhenoCycler (Akoya Biosciences) for a 31 marker protein panel with immune-related genes. We have developed methodology and novel algorithms to process both the datasets and to identify spatial phenotypes. Our pipelines include QC, normalization, dimensionality reduction and clustering. For annotation of cell types, we used as reference single cell datasets from RCC to identify tumor-type specific cell types. These cell types were mapped back to their spatial coordinates and visualized. We verified the annotations based on visual checks of their cellular morphology and organization. Next, we identified cellular neighborhoods around each cell and identified spatial clusters. We also performed a network-based analysis to identify additional spatial patterns. We performed correlation analysis with clinical phenotypes and identified spatial clusters of immune cell subtypes located in proximity of cancer cells to be associated with response to therapy.

#6623
Spatial organization of tumor-infiltrating lymphocytes (TILs) is prognostic for survival in triple negative breast cancer (TNBC)

Sahil H. Patel[1], Germán Corredor[2], Rachel Yoder[3], Cristian Barrera[2], Miluska Castillo[4], Luis Bernabe[4], Joshua Staley[3], Shane Stecklein[3], Satish E. Viswanath[1], Carlos A. Castaneda[4], Priyanka Sharma[5], Anant Madabhushi[2]. *[1]Case Western Reserve University, Cleveland, OH,[2]Emory University, Atlanta, GA,[3]The University of Kansas Cancer Center, Westwood, KS,[4]Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru,[5]University of Kansas Medical Center, Westwood, KS*

Introduction: TILs quantification is a predictor of response to neoadjuvant chemotherapy and prognostic for long term outcomes in TNBC. TILs are typically quantified using standard hematoxylin/eosin (H&E) slides manually by trained pathologists; limitations include interobserver variability and need for cutoffs that aid in clinical decision making. Computational approaches utilizing H&E slides have potential to improve reproducibility and refine predictive/prognostic utility by evaluation of additional metrics beyond quantification.
Methods: H&E whole slide images digitized at 20x magnification from patients with stage I-III TNBC (ER/PR ≤10%, HER2 negative) treated with neo/adjuvant chemotherapy at two institutions were utilized. All cell nuclei were automatically segmented using a deep learning model (Hover-Net) and classified as TIL or non-TIL based on morphological features. Features related to TIL density, spatial distribution, and morphological features were extracted. The top 3 features determined by least absolute shrinkage and selection operator were used to train a Cox proportional hazards regression model (SpaTILs) that assigned a recurrence free survival (RFS) event risk score to each patient. First quartile risk score in the training cohort was used as a cutoff for SpaTILs high vs low risk. Model performance for prediction of RFS and overall survival (OS) was evaluated in the testing cohort by Kaplan Meier method, with SpaTILs high vs low risk groups compared by log rank test and Cox regression analysis.
Results: In the training cohort (n=26) and testing cohort (n=62), median age was 51 and 53 years, 77% and 36% were node positive, and 81% and 45% received neoadjuvant chemotherapy, respectively. Median follow up in testing and training cohorts was 2.3 and 6.8 y, respectively. In the testing cohort, 31% and 69% of patients were categorized as SpaTILs high and low risk, respectively. Baseline characteristics were not significantly different

between SpaTILs high and low risk patients. In the SpaTILs high and low risk groups, 5y RFS was 53% and 90%, respectively (HR 4.85 [95% CI: 1.62-14.52], p=0.002) and 5y OS was 78% and 98%, respectively (HR 13.91 [95% CI 1.67-115.66], p=0.001). SpaTIL high risk remained a significant predictor for RFS and OS after adjusting for T stage and nodal status: HR 7.25 (95% CI 2.14-24.39), p=0.001 for RFS; HR 4.80 (95% CI 1.31-131.06), p=0.028 for OS.
Conclusion: The computational model based on TILs density, spatial, and morphological features (SpaTILs) was independently prognostic for RFS and OS in early stage TNBC. This model is being validated in larger TNBC cohorts and warrants prospective evaluation in clinical trials.

3D assessment of the lung cancer microenvironment using multi-resolution open-top light-sheet microscopy

Alexandra Alvarsson[1], Carl Storey[1], Brandy Olin Pope[1], Caleb Stoltzfus[1], Robert Vierkant[2], Jessica Tufariello[3], Aaron Bungum[4], Julia Naso[5], Cheuk Ki Chan[5], Eric Edell[6], Christopher Hartley[5], Janani Reisenauer[7], Nicholas Reder[1]. *[1]Alpenglow Biosciences, Inc., Seattle, WA,[2]Mayo Clinic, Rochester, MN,[3]BioPharma Diagnostics, Mayo Clinic, Rochester, MN,[4]Pulmonary and Critical Care Medicine and Thoracic Surgery, Mayo Clinic, Rochester, MN,[5]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[6]Pulmonary Medicine, Mayo Clinic, Rochester, MN,[7]Pulmonary Medicine and Thoracic Surgery, Mayo Clinic, Rochester, MN*

Background: Non-small cell lung cancer (NSCLC) tissue is a valuable resource for diagnosis, treatment planning, and drug development. Current 2D histopathological techniques introduce under-sampling error (i.e., a single 5 um section represents 0.5% of a 1 mm thick biopsy), interobserver variability, and fail to capture the biology contained within the entire tissue sample. We have developed a suite of technologies to stain, chemically clarify, image, visualize, and analyze entire intact NSCLC tissue samples.
Methods: Human NSCLC tissue, stored frozen in OCT, was fixed in 4% paraformaldehyde, stained with nuclear (TOPRO-3) and general protein (Eosin) fluorescent dyes, and optically cleared using a modified iDISCO protocol with ethyl cinnamate as the refractive index matching solution.

Whole, intact tissue samples, roughly 1-5mm3 in volume, were imaged at 2 microns/pixel resolution with an open-top light-sheet microscope (3Di, Alpenglow Biosciences). Smaller regions of interest (ROIs) with key pathologic features were reimaged at higher resolution, 0.17 microns/pixel, to reveal subnuclear features and for cell typing. Visualization was performed using Aivia software.
Results: NSCLC tissue samples were successfully imaged in 3D. Low resolution images (2 microns/pixel) were obtained within 4-31 minutes, depending on the tissue volume. The 3D distribution of cancer cells, immune cells, vessels, and fibrosis varied substantially throughout the volume of the tissue. Recognizable histologic features, including nests of tumor cells surrounded by vasculature and immune cells, were readily visualized. Squamous and adenocarcinoma with its subtypes (solid, acinar, lepidic, and micropapillary) morphologies were recognizable in 2D optical sections of the 3D datasets. Imaging quality degraded in tissue deeper than 1 mm due to light scattering.
Conclusion: We assessed intact NSCLC tissue samples measuring up to 5 mm3 using our custom light-sheet microscope and tissue clearing techniques. This novel method enables us to visualize key features of NSCLC such as the tumor interfaces, tertiary lymphoid structures, vessels and fibrosis in the entire tissue sample, preventing under sampling error, and potentially enabling new biologic insights. Next steps include segmentation and quantification of key tissue structures such as tumor volume, immune cell distribution, and fibrosis / immune cell exclusion. This proof-of-concept study provides motivation for further investigation into the significance of 3D tissue features in NSCLC tissue samples.

Mathematical modeling of single-cell data reveals the key role of stochasticity - not fitness - in determining the clonal origins of relapse in childhood leukemia

Virginia Turati[1], Javier Herrero[2], Mark Robertson-Tessi[1], Tariq Enver[2], Andriy Marusyk[1], Alexander RA Anderson[1]. *[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]University College London, London, United Kingdom*

Acute lymphoblastic leukemia (cALL) is the most common pediatric cancer, and since up to 20% of children relapse after initially responding to

chemotherapy treatment, the largest cause of cancer-related childhood deaths in the western world. With the idea that dissecting the evolutionary population dynamics leading to relapse would help explain treatment failure from a mechanistic standpoint, several studies have performed comparisons of genetic heterogeneity at diagnosis and relapse. These showed that as many as 70% of relapses are dominated by a single diagnostic subclone or one of its evolutionary progeny; leading to the prevailing view that treatment selection in cALL primarily operates at the genotype level. However, a crucial caveat of these studies is their reliance, due primarily to technical and economic constraints, on very limited data timepoints. While the dynamics linking said timepoints are often interpreted based on simple intuition. To overcome this sparse data challenge and reconstruct the entire spatial and temporal evolutionary trajectories of individual cALL cells from diagnosis to relapse, we have integrated experimental data with an *in silico* model. Single-cell WGS and RNAseq data were obtained from primary and xenografted leukemic cells before and after chemotherapy. These were then used to parameterize an agent-based mathematical model allowing tracking of the genotype and evolving phenotype of individual cells over time. When short treatment courses akin to those we delivered *in vivo* were used, the *in silico* model closely recapitulated the experimental results. Since cALL treatment lasts several years, it cannot be entirely modelled in vivo. Due to the rarity of post-treatment residual cells and the lack of universal cell surface markers to isolate them, direct analysis of clinical samples is also challenging. However, based on the initial treatment data, our calibrated model provided a unique opportunity to simulate longer remission-relapse dynamics of several leukemias. Mechanistic analysis of the collected data showed that, strikingly, in most cases, clonal dominance at relapse results from stochastic sweeps rather than deterministic differences in clonal fitness. Indeed, independent treatment of the same leukemia with an identical drug regimen more frequently ended with a considerably different clonal landscape (either polyclonal disease or a different dominant clone) than with the same outcome initially observed. Rather than genotype differences, the size of residual disease and a founder effect linked to the stochastic exit, post-treatment, of individual cells from quiescence were the key determinants of the relapse genetic landscape. Altogether, our data highlight the misinterpretation risk associated with snapshot analysis and might inform promising alternative treatment schedules.

Genomic and immunophenotypic landscape of acquired resistance to PD-(L)1 blockade in non-small cell lung cancer

Biagio Ricciuti[1], Giuseppe Lamberti[1], Sreekar Puchala[2], Navin Mahadevan[3], Joao Alessi[1], Xinan Wang[4], Yvonne Li[2], Federica Pecci[1], Alessandro Di Federico[1], Malini Gandhi[1], Adriana Barrichello[1], Victor Vaz[1], Andy Pangilinan[1], Danielle Haradon[1], Elinton Lee[1], Hersh Gupta[2], Mizuki Nishino[5], Andrew Cherniack[2], Scott Rodig[6], Lynette Sholl[1], Renato Umeton[7], MArk M. Awad[1]. *[1]Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Informatics and Analytics, Dana-Farber Cancer Institute, Boston, MA,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Biostatistics, Harvard Medical School, Boston, MA,[5]Lowe Center for Thoracic Oncology, Brigham and Women's Hospital, Department of Radiology, MA,[6]Lowe Center for Thoracic Oncology, Brigham and Women's Hospital, Department of Pathology, MA,[7]Department of Informatics and Analytics, Dana-Farber Cancer Institute, Boston, MA*

Background: Despite immune checkpoint inhibition (ICI) has extended survival in patients (pts) with non-small cell lung cancer (NSCLC), acquired resistance to ICI develops after an initial clinical benefit. However, the mechanisms underlying the development of acquired resistance to ICI in NSCLC are largely unknown.
Methods: Tumor genomic profiling, immune cell subsets assessment from standard haematoxylin/eosin (H&E) stained slides using machine learning, multiplexed immunofluorescence (CD8, PD1, PD-L1, Foxp3, CK7), and HLA-I immunohistochemistry (IHC) were performed on matched pre and post ICI tumor biopsies from pts with NSCLC treated with ICI at the Dana-Farber Cancer Institute who developed acquired resistance to ICI.
Results: Among 1823 pts with advanced NSCLC who received ICI, 80 developed acquired resistance to treatment and had matched pre- and post-

ICI tissue samples for correlative analysis. Putative resistance mutations were identified in 27.3% of cases. The most common acquired loss-of-function mutations included *STK11* (9.1%), *B2M* (6.5%), *NF1/2* (5.2%), *SMARCA4* (5.2%), *APC* (3.9%), *KEAP1* (2.6%), and *JAK1* (2.6%). In addition, acquired activating mutations were found in *PI3KCA* (3.9%) and *SOS1* (1.3%). In examining copy number variations (CNVs), we identified acquired CNVs in 49.3% (38/77) of ICI-resistant samples, including heterozygous loss of *B2M* (23.4%), *STK11* (16.8%), *SMARCA4* (16.9%), *KEAP1* (15.6%), *PTEN* (10.4%), *CDKN2A*/B (9.1%) and *PD-L1*/*PD-L2* genes (9.1%), among others. Importantly, we also noted acquired homozygous deletions in *CDKN2A*/B (9.1%), *PD-L1*/*PD-L2* (1.3%) and *JAK2* (1.3%), and amplification in *MDM2* (5.2%), *KRAS* (3.9%) and *MYC* (2.6%), at the time of resistance to ICI. Among 16 cases with pre- and post-ICI H&E stained slides, digital pathology analysis showed a significant decrease in the density of intratumoral lymphocytes in ICI-resistant tumor samples compared to pre-ICI samples (88 vs 36 cells/mm^2, P=0.03). Consistently, among 6 pts with pre- and post-ICI multiplexed immunofluorescence we observed a significant decrease in CD8+ PD1+ T cells in ICI-resistant vs pre-ICI tumor samples (24 vs 10 cells/mm^2, P=0.01). Among pts with tissue available for HLA-I IHC (N=9), we found a significant decrease in HLA-I expression by H-score at the time of acquired resistance (300 vs 260, P=0.03). In control cohorts of pts with pre- and post-chemotherapy (CT) (N=32) or targeted therapies (TT) (N=89) tumor genomic profiling no acquired mutations in *STK11*, *KEAP1, B2M, JAK1, APC, SOS1* were detected. Similarly, intervening chemotherapy and targeted therapies were not associated with changes in lymphocytes density and HLA-I expression.

Conclusion: Mechanisms of acquired resistance to ICI are heterogenous, including both genomic and immunophenotypic factors. New therapeutic strategies are required to delay and overcome ICI resistance in pts with NSCLC.

#6630

Flow cytometry immunophenotyping using commercial antibodies to maximize detection of PD-1 in immuno-oncology (I-O) clinical studies with anti-PD-1 check point inhibitors

Venkat Mohanram, Ming Yang, Angelina Bisconte, Deborah Phippard.
Precision for Medicine, Frederick, MD

Precision for Medicine's translational biomarker expertise supports global clinical trials with flow cytometry. A biomarker strategy which includes flow cytometry to generate pharmacokinetic/pharmacodynamic (PK/PD) models for rational design of dose escalation and expansion of clinical studies, may need to consider concomitant drugs for checkpoint inhibition like Pembrolizumab.

Precision has optimized the use of commercial anti-PD-1 and anti-IgG4 reagents to detect both free PD-1 and/or Pembro-bound PD-1 when patients are on study with a new molecular entity as either a monotherapy or in combination with concomitant checkpoint inhibitors. For I-O studies conventional efficacy endpoints combined with flow biomarker driven surrogate endpoints enhance therapeutic decisions for determining mechanism of action and biological response when incorporated in early-phase clinical studies. Precision developed and qualified a flow immunophenotyping assay to quantify PD-1 on CD4+ and CD8+ T cells using a commercial PD-1 clone (PD1.3.1.3) and an anti-IgG4. This enabled detection of both free and drug bound PD-1 receptor. We compared detection of PD-1 in PHA stimulated healthy donors treated with saturating Pembrolizumab or no drug treatment. There was not a significant difference observed in PD-1 quantification in the presence or absence of Pembrolizumab, which demonstrated that our approach was able to accurately measure total PD-1 whether free or bound. As Pembrolizumab was titrated from the saturating concentration there was a dose-dependent decrease in detection of PD-1. We have used this assay to detect PD-1 with several new I-O therapies that combined standard anti-PD-1 checkpoint inhibitors, and in these clinical studies for advanced and rare solid tumor indications, we observed an average of 20-40% increase in PD-1 compared to no drug treatment.

Immuno-oncology clinical trials which incorporate checkpoint inhibitors like either PD-1 or PD-L1, the availability of commercial reagents are key considerations to detect these receptors when designing a sensitive, selective, and accurate biomarker assay.

#6631

Association between poliovirus receptor (PVR) expression in tumor and exclusion of immune cells expressing T cell immunoreceptor with Ig and ITIM domain (TIGIT) from tumor area

Sara A. Moore, Julie Cheung, Aram B. Cholanians, June Clements, Jessica L. Baumann, Tsu-Shuen Tsao. *Roche, Tucson, AZ*

Context: TIGIT has grown to be an increasingly important target for immunotherapy of cancer. However, it is unclear if there is an association between abundance of TIGIT expressing immune cells in tumor microenvironment and effectiveness of TIGIT-based intervention. This study utilizes an exploratory novel duplex immunohistochemical (IHC) assay to assess if the distribution patterns and/or the abundance of TIGIT-positive immune cells are related to the expression levels of TIGIT's receptor PVR in tumor.
Methods: Individual formalin-fixed, paraffin-embedded surgical resections and tissue microarray cores of 75 cervical, 84 esophageal, 79 non-small cell lung , and 81 small cell lung carcinoma specimens were stained using a duplex chromogenic IHC assay that detects PVR and TIGIT sequentially on a single slide. The slides were examined for (1) overall intensity and percentage of tumor staining positive for PVR, (2) percentage of tumor area occupied by TIGIT-expressing immune cells, and (3) distribution pattern of TIGIT-positive cells. For each specimen, overall PVR intensity was multiplied by percentage of tumor positive for PVR to generate the PVR Expression Score.
Results: PVR and TIGIT staining at any intensity was widely observed in all four tumor types ranging from 91% to 100% of specimens positive for PVR and 77% to 100% of specimens positive for TIGIT. Little to no differences in the average percentages of PVR tumor positivity or TIGIT tumor area positivity were found among the four tumor types. However, individual tumor specimens differed widely in these two parameters. Among all 319 tumor specimens evaluated, the percentages of tumor expressing PVR at any intensity ranged from 0 to 100% with approximately 1/3 of the specimens having less than 50% and 3% showing no PVR expression. Percentages of tumor area occupied by TIGIT-positive cells ranged from 0% to 30% with approximately 40% of the specimens having less than 1%. Distribution patterns of TIGIT-expressing cells in each specimen was classified as peritumoral, intratumoral, or mixed. Specimens

classified as peritumoral exhibited higher PVR Expression Scores than those classified as intratumoral. Specimens classified as having a mixed TIGIT-positive cell distribution pattern had an average PVR Expression Score that was intermediate between specimens having intratumoral and peritumoral TIGIT distribution patterns. Interestingly, no correlation was found between tumor PVR Expression Scores and abundance of TIGIT expressing cells in tumor area.
Conclusion: The correlation between high tumor PVR expression levels and peritumoral distribution patterns of TIGIT-positive cells suggests PVR/TIGIT signaling pathway activation status could be important in infiltration of T cells into tumor parenchyma.

Simultaneous comparison of response to two different anti-PD1 drugs in the same patient using a human tumor histo-culture platform

Satish Sankaran[1], Biswajit Das[1], Kowshik Jaganathan[1], Gowri Shankar K[1], Jayaprakash C[2], Ganesh MS[3], Amritha Prabha[3], Vijay Pillai[4], Syamkumar V[1], Chandan Bhowal[1], Rajashekar M[1], Oliyarasi M[1], Ritu Malhotra[1], Govindraj K[1], Nandini Pal Basak[1]. *[1]Farcast Biosciences, Bangalore, India,[2]DBR & SK Superspeciality Hospital, Tirupati, India,[3]Vydehi Multi Specialty Hospital, Bangalore, India,[4]Mazumdar Shaw Medical Centre, Bangalore, India*

Based on preclinical and clinical study data, anti-programmed cell death protein 1 (PD-1) drugs Pembrolizumab (P), and Nivolumab (N) have been considered equivalent in terms of response efficacy. Both the antibodies have IgG4 backbone but vary considerably in terms of the PD-1 epitopes they bind to.. Given that there is almost no overlap between the PD-1 binding sites there is a definite possibility of nuanced drug-dependent differences in patient response to treatment. These differences would not be possible to discern unless the same patient with the same tumor microenvironment were evaluated with both drugs simultaneously. We attempted to address this question using the near native Farcast^{TM} TruTumor histoculture platform. Fresh surgically resected Head and Neck squamous Cell Carcinoma (HNSCC) samples (n=8) along with matched blood were collected from consented patients. The tumor sample was

processed to generate explants that were distributed into arms. These arms were treated in culture with P (32.9 µg/ml) or N (132 µg/ml) for 72 hours. The response was characterized using histopathology, cytokine release and flow cytometry. T-cell re-invigoration was assessed by evaluating Interferon gamma release while a decrease in tumor content and/or increase in cleaved Caspase expression was correlated with tumor cytotoxicity Pre-treatment cytokine levels across control and both treatment arms were equivalent (z-score <1.5) across all samples. Additionally, when treated with the same drugs in duplicate arms similar tumor cytotoxic response was observed in the replicate arms (n=1). These data established arm equivalence. Post treatment with N or P, 6 out of 8 samples exhibited a T-cells reinvigoration phenotype. Of the remaining 2 samples, one exhibited tumor cytotoxicity with both treatments while the other showed tumor cytotoxicity only on N treatment. We evaluated the 6 samples that exhibited T-cell re-invigoration response further to understand the subtle differences in response to either N or P. While the response trends were similar for both drugs, the rate of response, as evaluated by significant increase in cleaved caspase-3 or decrease in tumor content, seem to be different in 3 samples. These 3 samples responded better with P compared to N.In this study, we broadly observed equivalent response to both the drugs with some patient samples responding slightly better to one over the other. Further studies are required to tease out the molecular reasons for these nuanced differences in response to these two anti-PD1 treatments. The FarcastTM TruTumor platform provides the unique opportunity to make personalized choice of the drug treatment that might provide best response in a patient.

#6633

T regulatory cell subsets in colorectal cancer: friends or foes

Eyad Elkord. *University of Nizwa, Nizwa, Oman*

T cells in the tumor microenvironment (TME) have diverse roles in anti-tumor immunity. Different T cell subsets may have opposing roles in tumor progression, especially in inflammatory cancers such as colorectal cancer (CRC). In different series of studies, we performed extensive characterization and critical analyses of T regulatory cell (Treg)-related markers and key inhibitory immune checkpoints (ICs) in $CD4^+$ and $CD8^+$ T cell subsets in the TME and periphery of CRC patients. We found a

significant increase in levels of $CD4^+FoxP3^+Helios^+$ T cells, which represent potentially highly immunosuppressive Tregs, in the TME. Additionally, tumor-infiltrating $CD4^+$ T cells upregulated PD-1, CTLA-4, TIM-3 and LAG-3 immune checkpoints. CTLA-4, TIM-3, and LAG-3 were mainly co-expressed on $FoxP3^+Helios^+$ Tregs in the TME. Additionally, we found that FoxP3 expression and ICs including PD-1, CTLA-4, TIM-3, and LAG-3 were significantly upregulated in tumor-infiltrating $CD8^+$ T cells. We then investigated associations between different tumor-infiltrating $CD4^+$ and $CD8^+$ T cell subpopulations and disease-free survival (DFS). Interestingly, a high frequency of circulating $CD4^+FoxP3^+$ Tregs was associated with poorer DFS, while higher frequency of these cells in the TME was associated with better DFS. Additionally, high frequencies of circulating $CD4^+FoxP3^+Helios^+$ Tregs and tumor-infiltrating $CD4^+FoxP3^-Helios^-$ T cells were associated with poorer DFS. Moreover, a high frequency of $CD4^+FoxP3^+Helios^-PD\text{-}1^+$ Tregs in circulation was associated with worse DFS. In contrast, high frequencies of $CD4^+TIM\text{-}3^+$ T cells, $FoxP3^+Helios^+TIM\text{-}3^+$ Tregs, and $FoxP3^-Helios^+TIM\text{-}3^+$ $CD4^+$ T cells in circulation were associated with longer DFS. Additionally, we found that high levels of certain circulating $CD8^+$ T cell subsets ($TIM\text{-}3^+$, $FoxP3^-Helios^-TIM\text{-}3^+$ and $FoxP3^-Helios^+TIM\text{-}3^+$ cells) were associated with longer DFS. In the TME, elevated levels of $CD25^+$ and $TIM\text{-}3^+$ $CD8^+$ T cells, and $FoxP3^+Helios^-TIM\text{-}3^+$ $CD8^+$ Tregs were associated with better DFS. These data show that circulating and tumor-infiltrating immune checkpoint-expressing $CD4^+$ and $CD8^+$ Treg/T cell subsets play different roles in disease prognoses, and certain subsets could serve as independent predictive biomarkers in CRC patients.

Digital and spacial characterization of PD-L1 expression and IVD assay performance in the immune landscape of head and neck squamous cell carcinoma: A multimodal approach

Clara Troccoli, Lauren Matelski, Adam Beharry, Vanessa Ly, Morgan Wambaugh, Melanie Amen, Will Paces, Geoffrey Metcalf, Roberto Gianani, Tom Turi. *Flagship Biosciences, Broomfield, CO*

The anti-PD-L1 antibody (22C3) is used as a companion diagnostic for successful checkpoint inhibitor therapy in head and neck squamous cell carcinoma. The positive predictive value of this assay, however, is less than ideal as a high PD-L1 score does not necessarily associate with a good response, and a good response may be seen with a low or negative PD-L1 score. In principle, this could be due to lack of accuracy and/or precision of the assay, as well as biological factors, such as variable expression across tumor cells and interacting immune cells. In this study, we describe a digital image analysis algorithm to address assay-related problems and improve both accuracy and precision, as well as improve identification of PD-L1 expression in differing cell populations of the tumor microenvironment. In addition, we propose a panel of assays that in aggregate might reveal inherent heterogeneity among cases with similar PD-L1 score and thus provide vital context underlying the efficacy of checkpoint inhibitors in the clinic. Here we show that applying novel machine-learning based digital image analysis to multiplex assays together with digital scoring of PD-L1 provides an accurate and precise assessment of the real-world tumor milieu that we hypothesize will help establish the immunophenotypes that inform therapeutic efficacy of checkpoint inhibitors. We have additionally interrogated whether expression of PD-L1 in these groups are consistent with known molecular patterns assayed using novel methodologies, such as high-plex digital spatial transcriptomics through the nanoString GeoMx Digital Spatial Profiler (DSP) platform and assessed the ability of the different digital platforms to provide concordant data relating to real-world expression patterns of PD-L1 and associated biomarkers. Thus, our results point to the importance of robust methodologies, used in combination, to evaluate complex tumor immune landscapes and the advantages of digital analyses to provide accurate and precise clinical contexts for better patient outcomes.

#6635

Lipid and glycolipid antigen presentation faults as a mechanism of resistance to immune checkpoint therapy in poorly immunogenic melanomas

Carlos Rogerio Figueiredo. *Faculty of Medicine / Medical Immune Oncology Research Group, University of Turku, Turku, Finland*

Introduction: Cold tumors are characterized by lacking infiltration of antitumor T cells. These tumors are universally refractory to immune checkpoint therapies (ICT). While poor T cell infiltration has been partly ascribed to low tumor mutational burden (TMB), TMB doesn't necessarily exclude immunogenic responses nor ensure a response to ICT. Mechanisms of T cell exclusion in tumors with sufficient TMB may be caused by molecular failure of the antigen processing and presentation (APP), which impacts T cell generation. It was previously described that loss of heterozygosity (LOH) of an essential component of the MHC class I molecule, the beta-2-microglobulin (B2M), is associated with low antigen presentation, tumor T cell infiltration, and ICT resistance in melanoma. Here we provide further insight into APP and ICT response in melanoma.
Methods: Transcriptomic analysis and visualization of genomic data from the GDC-TCGA skin cutaneous melanoma (SKCM) study were performed using the Xena platform. Four anti-PD1 metastatic melanoma cohorts were normalized with transcripts per million units. STRING protein-protein interaction analysis was performed in the human database with 11 nodes and 39 edges. Nanostring transcriptomic data from metastatic uveal melanoma (mUM) was revisited from our previous publications for *Spearman's* correlational and group analysis of APP signatures amongst ICT responders and non-responders.
Results: In an expanded analysis of 4 normalized anti-PD1 treated metastatic melanoma cohorts (n=272), we confirmed that transcriptomic levels of *B2M* are significantly reduced in non-responders. Moreover, STRING protein-protein interaction analysis of B2M revealed CD1D as a potential molecular partner of B2M. We, therefore, observed that *CD1D* transcriptomic expression is not only reduced in anti-PD1 poor responders but is a survival prognosticator in primary tumors from the GDC-TCGA study. Interestingly, *CD1D* expression is also significantly reduced in poorly immunogenic mUM tumors, a cancer type regarded as universally refractory to ICT.
Conclusions: These findings suggest that APP faults in ICT-resistant tumors are not restricted to faults in peptide presentation to T lymphocytes (via B2M) but may also impact the presentation of tumor-associated lipid and glycolipid antigens via CD1d, which can impact antitumor responses of natural killer T cells (NKT). Adjuvant therapies that restore MHC-I and CD1d-mediated antigen presentation may unleash the response to ICT via

NKT. Understanding CD1d expression faults locally and systemically may provide valuable prognostication information likely to impact how cancer is treated by optimally selecting patients for ICT and validating novel therapeutic targets for immunotherapy development.

Metformin suppresses tumor immune evasion through downregulation of PD-L1 expression in cancer cells and PD-1 expression in NK cells and T cells

Su Hwan Park, Jong-Ho Lee. *Dong-A University, Busan, Korea, Republic of*

Up-regulation of programmed cell death 1 (PD-1) receptor on T cells and its ligand (PD-L1) on cancer cells is reported in various tumor microenvironment, and the interaction between PD-L1 and PD-1 inhibits the cytotoxic activity of NK cells and T cells, allowing cancer cells to evade immune destruction. Extensive studies suggested that metformin, the most widely used first-line drug for treatment of type 2 diabetes, had a potential efficacy of enhancing anti-tumor immune response. However, the detail mechanisms underlying the efficacy are unknown. Here, we showed that metformin decreases AKT-mediated β-catenin S552 phosphorylation and β-catenin transactivation in an AMPK activation-dependent manner, resulting in reduced *CD274* transcription in cancer cells. In the cocultures of cancer cells with NK cells or T cells, cancer cells induced PD-1 protein stability and expression in the NK cells and T cells, these PD-1 upregulation was also observed in infiltrated NK cells and T cells *in vivo* mouse tumors. Metformin reduced the half-life and expression of PD-1 in an AMPK activation-dependent manner *in vitro* and *in vivo*. These inhibitory roles of metformin in PD-L1 expression in cancer cells and in cancer cell-induced PD-1 expression in NK cells and T cells led to ameliorated the cancer cell-reduced cytotoxic activity of NK cells and T cells and inhibited tumor growth *in vivo* models. These findings suggest that metformin may act as both PD-L1 and PD-1 blockades within tumor microenvironment, providing a mechanistic insight for the efficacy of metformin to improve immunotherapy in human cancer.

#6637

Transcriptomic biomarkers of immunotherapy response in solid tumors

Balazs Gyorffy, Szonja Anna Kovacs, János Tibor Fekete. *Research Centre for Natural Sciences, Budapest, Hungary*

Background. Immune-checkpoint inhibitors can be administered in multiple solid tumor types. Currently available biomarkers, like the expression of PD-L1 or tumor mutational burden, miss a significant proportion of patients who could benefit from the therapy. Our goal was to set up a database consisting of both gene expression and clinical response data and to uncover the most significant biomarkers of response to anti-PD-1, anti-PD-L1, and anti-CTLA-4 immunotherapies.
Methods. The GEO repository was screened to identify datasets with simultaneously available transcriptomic and clinical response data across different solid tumor types. The screening focused on studies involving the administration of nivolumab (anti-PD-1), pembrolizumab (anti-PD-1), atezolizumab (anti-PD-L1), durvalumab (anti-PD-L1), and ipilimumab (anti-CTLA-4). Mann-Whitney U-test and receiver operating characteristic analysis were performed across all genes to identify features related to therapy response. False discovery rate was computed to correct for multiple hypothesis testing.
Results. The database that we established consists of 1,439 unique tumor samples from nineteen datasets with gastric-, lung-, esophageal-, head, neck-, and urothelial cancers, and malignant melanoma. The strongest upregulated candidates linked to resistance in anti-PD-1 treated tumors were PRXL2A (AUC=0.771), ODR4 (AUC=0.734), and RBM15B (AUC=0.734). The most robust hits in the anti-PD-L1 treated cohort were NOTCH3 (AUC=0.639), NECTIN1 (AUC=0.631) and ITGAV (AUC=0.63). In the anti-CTLA-4 treatment cohort C5orf24 (AUC=0.76) was the most promising candidate. We have also established a portal for additional analysis and ranking of further biomarker candidates by extending our previously established ROC plotter. The immunotherapy-treated transcriptomic database is accessible at the website www.rocplot.com/immune.
Discussion. An integrated database and an online platform were set up to validate potential biomarkers of immunotherapy response in a sizeable cohort of cancer samples from multiple tumor types. By using the direction

of expression change as a filter, we have identified the most promising biomarker candidates.

#6638

Pulsed electric fields combined with anti-PD1 prolongs survival and triggers an adaptive immune response in an IO-non-responsive orthotopic mouse model

Ebtesam Nafie[1], Mukta Wagh[1], Chiara Pastori[1], Mo Trikha[2], Robert Neal[1]. *[1]Immuno-oncology, Galvanize Therapeutics Inc, San Carlos, CA,[2]Immunology, Apple Tree Partners, San Fransisco, CA*

Background: Although anti-PD1 therapy is standard of care in multiple tumor types, unmet need remains for those non-responsive to immunotherapy. Pulsed Electric Field (PEF) treatment may alter the tumor micro-environment, converting an immune "cold" tumor into an immune "hot" tumor, triggering an adaptive immune response and abscopal effect. We evaluated PEF in combination with anti-PD1 in a highly aggressive orthotopic triple negative breast tumor mouse model.

Methods: Murine mammary 4T1 cells ($2x10^5$) non-responsive to anti-PD1 therapy were orthotopically implanted in mammary fat of 48 female Balb/C mice. Once tumors were established (5 mm diameter), mice were randomized into six groups: Sham+IgG controls, aPD-1-only, PEF (1X), PEF (2X), aPD-1 + PEF (1X), and aPD-1 + PEF (2X). Groups 4 and 6 received two PEF treatments, five days apart. Anti-PD1 and isotype matched control IgG was administered (200 ug, intraperitoneal) weekly, starting 3 days after PEF treatment. Tumor volumes were recorded 3x/week and standard survival analyses were conducted per IACUC protocol. In the cohort of tumors collected 30 days after PEF, flow cytometry (FC) evaluated T-cell immune infiltrates and associated markers. Blood was collected at different time points to evaluate systemic immunological response. Tumor-specific cytotoxic lymphocytes (CTL) were isolated from tumor-infiltrating and circulating lymphocytes by gp70 MHC tetramer formation assay.

Results: Single PEF reduced tumor growth compared to IgG and aPD-1-only groups by 65% and 62%, respectively. Double PEF treatment reduced tumor growth by 74% and prolonged survival. FC demonstrated circulating helper T-cells and CTL frequency was increased two weeks post-PEF compared to the control group. The tetramer detected substantial increases in antigen-specific T-cell populations in both single and double PEF treatment groups. PEF groups had significant tumor and spleen infiltration of CD8 and CD4 T-cells, including increased tetramer levels. Anti-PD1-only animals showed no meaningful reductions in tumor growth, prolonged survival, or significant changes in CD8, CD4 T cells or in the tetramer assay.

Conclusions: PEF treatments prior to initiation of anti-PD1 in orthotopic 4T1 mouse model triggers a tumor-specific adaptive immune response in an immune "cold" tumor model, irrespective of anti-PD-1 therapy. PEF increases circulating and tumor-infiltrating T-cells and antigen-specific T-cells, with these effects observed after a single or two treatments with PEF. Collectively, our results demonstrate that PEF treatment prior to initiation of anti-PD1 treatment can reduce tumor growth, prolong survival, and activate an adaptive immune response in an immune "cold" tumor. These findings suggest that PEF treatment merits further evaluation in IO-non-responsive cancer patients.

Preclinical characterization and clinical biomarker studies with RP3, a novel oncolytic immunotherapy expressing a fusogenic protein, a human anti-CTLA-4 antibody, hCD40L and h4-1BBL

Praveen K. Bommareddy[1], Kevin Harrington[2], Victoria Roulstone[2], Joan Kyula[2], Aaron Clack[1], Linta Kuncheria[1], Sylwia Jones[1], Robert Coffin[1]. *[1]Replimune, Inc., Woburn, MA,[2]The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Introduction: RP3, a tumor-directed oncolytic immunotherapy (TDOI), is a selectively replication-competent HSV-1 that contains the codon-optimized sequence for the fusogenic GALV-GP-R- protein, an anti-CTLA-4 antibody-like molecule, CD40L, and 4-1BBL. The expression of GALV-GP-R- potentiates immunogenic tumor cell death through the induction of cell-to-cell fusion. CD40L enhances dendritic cell and macrophage activation and 4-1BBL promotes CD8+ T-cell activation and co-stimulation. The anti-CTLA-4 antibody-like molecule blocks the interaction of CTLA-4 with its ligands B7.1 and B7.2, further enhancing T cell activation. RP3 is currently being assessed in a Phase 1 clinical trial with or without nivolumab in patients with advanced solid tumors (NCT04735978).

Methods: CD1 nude mice with A375 melanoma xenograft tumors (Group 1) were treated with a single intratumoral injection of $1x10^7$ PFU/mL of RP3. Tumors and blood samples were collected 3 days later, and immunohistochemistry (IHC) was performed to detect CD40L, 4-1BBL and HSV-1. For anti-CTLA-4 detection, two doses of 10^7 PFU/mL of RP3 were injected intratumorally into C57BL/6 mice bearing 4434 murine

$BRAF^{V600E}$ mutant melanoma tumors (Group 2). Tumors and blood samples were collected at 3, 6, 9, 12 and 15-days post-dosing and anti-CTLA-4 ELISA was performed. For clinical biomarker studies, tumor biopsies were collected pre- and post-RP3 treatment. CD8 and PD-L1 were characterized by IHC, and gene expression analysis (GEA) was performed. TCR analysis was also performed using PBMCs.
Results: IHC analysis from Group 1 confirmed abundant and widespread expression of CD40-L and 4-1BBL, which were detected alongside with HSV-1 antigen. In the blood samples collected from Group 2, robust levels of anti-CTLA-4 antibody were detected, which stayed in detectable range up to 15 days after the 2nd RP3 injection. IHC analysis of patient tumor samples demonstrated a marked increase in CD8 T cells and PD-L1 expression. GEA of patient tumor biopsies demonstrated increased levels of genes associated with innate and adaptive immune activation and genes previously reported to be associated with responsiveness to anti-PD1 therapy. TCR sequencing of PBMCs and multiplex IHC analysis are ongoing and updated results will be presented.
Conclusion: Preclinical experiments from mice models confirmed the robust expression of CD40-L, 4-1BBL and anti-CTLA-4 in RP3-injected tumors. Biomarker studies from patients demonstrate increases in CD8-T cell infiltration and PD-L1 expression post RP3 +/- nivolumab treatment, including increases in the expression of genes associated with response to anti-PD-1 therapy. These data indicate the potential for broad utility of RP3 in a range of tumor types, including in tumors that are not sensitive to PD-1 blockade.

ATG-031, a first-in-class humanized anti-CD24 antibody, demonstrates potent *in vivo* efficacy and repolarizes tumor-associated macrophages in the TME
Peng Chen[1], Min Deng[1], Yun Liu[1], Jiamei Luo[1], Linjie Tian[2], Jay Mei[3], Bo Shan[3], Bing Hou[3]. *[1]Antengene Corporation Limited, Shanghai, China,[2]Antengene Biotech LLC, Doylestown, PA,[3]Antengene Corporation, Shaoxing, China*

Background: Tumor microenvironment (TME) is shaped by not only cancer cells but also a variety of resident and infiltrating cells, including stromal fibroblasts, endothelial cells and immune cells like tumor-associated macrophages (TAM) and lymphocytes (Roghayyeh et al., 2020). Most TAMs are considered as the M2 subtype with pro-tumor/anti-inflammation effects. CD24 is a small, highly glycosylated cell adhesion protein and was reported to be the dominant innate immune checkpoint in ovarian cancer and breast cancer, and acts as a novel "don't eat me" target . CD24 is over-expressed on tumor cells and can help them avoid being engulfed by macrophages through its interaction with Siglec-10 expressed by TAM. ATG-031 is a humanized anti-CD24 monoclonal antibody that binds to CD24 with high affinity and specificity and blocks the interaction of CD24 with Siglec-10 on macrophages, enhancing macrophage-mediated phagocytosis of tumor cells. In this study, we evaluated the *in vivo* efficacy of ATG-031 and explored its pharmacodynamic effects.
Methods: C57BL/6J mice were inoculated with wild-type (WT) MC38 cells on the left flank and MC38 cells that express human CD24 (MC38-hCD24) on the right flank. When the average tumor volume reached 120 to 140 mm^3 for MC38-hCD24, mice were treated with vehicle control (PBS) or ATG-031 at 3 mg/kg intravenously twice a week for four doses. A group of mice inoculated with only MC38 tumor cells was set as the control and treated with ATG-031 by the same way. Tumor volume was measured twice a week to evaluate the efficacy of ATG-031. Tumor samples were isolated at the endpoint of this efficacy study, and a multiplex IHC staining was performed to evaluate the change of tumor-infiltrating immune cells in response to ATG-031.
Results: ATG-031 treatment significantly inhibited the tumor growth of MC38-hCD24 on the right flank of mice with a tumor growth inhibition (TGI) of 60.52%. Interestingly, although the WT MC38 tumor on the left flank did not express the antigen, human CD24, ATG-031 still demonstrated efficacy in controlling the tumor growth with a TGI of 21.17%. Without the co-inoculation of MC38-hCD24, ATG-031 did not affect the WT MC38 tumor growth in the control group. Multiplex IHC staining revealed that the proportion of M1 macrophage increased in response to ATG-031 treatment, not only in MC38-hCD24 tumors but also in WT MC38 tumors on the left flank.
Conclusions: ATG-031, a first-in-class anti-CD24 antibody, demonstrated potent anti-tumor activity *in vivo*, re-polarizing M2-like TAM to anti-tumor M1 subtype in the TME and induced systemic anti-tumor immunity. A clinical study to investigate the safety and efficacy of ATG-031 in cancer patients is being developed.

#6642
Rapid tissue donation identifies LAG3 as a potential therapeutic target for ALK fusion positive lung cancer
Hilal Ozakinci, Gina Nazario, Karina Colossi Furlan, Dung-Tsa Chen, Trevor Rose, Matthew B. Schabath, Eric B. Haura, Bruna Pellini, Amer Beg, Theresa A. Boyle. *Moffitt Cancer Center, Tampa, FL*

Introduction: The rapid tissue donation (RTD) program provides post-therapy primary and metastatic tumor tissue samples at the time of death for the study of resistance mechanisms and the tumor microenvironment to inform therapeutic opportunities. NCCN guidelines (NCCN v5.2022) recommend against PD-1/PD-L1 inhibitor monotherapy in the second-line setting for *ALK* fusion+ non-small cell lung cancer (NSCLC) due to lack of efficacy, irrespective of tumoral PD-L1 expression. We observed high LAG3 protein expression by multiplex immunofluorescence (mIF) in postmortem *ALK* fusion-positive tumor tissue samples from 3 RTD donors who were treated with ALK inhibitors. Further studies are recommended to investigate the therapeutic potential of LAG3 inhibitors in this patient population.
Case Series: Of the 38 patients with lung cancer tissue collected by RTD, 3 patients had *ALK* fusion and were treated with ALK inhibitors. Despite the initial response, all 3 patients succumbed to the disease. Tissue samples were collected from primary and multiple metastatic sites after death. Immune checkpoint markers, including LAG3, were quantitated via multiplex immunofluorescence staining, and genomic analyses were performed.
Results: Analysis of two tissue microarrays comprised of 130 tumor cores from multiple tissue sites of the first 10 NSCLC RTD donors revealed that 66% of tumor cores had >1% LAG3 expression in CD3+ T cells. Among the three patients with *ALK* fusion-positive NSCLC, 83% (5 of 6 cores), 85% (6 of 7 cores), and 100% (18 of 18 cores) of the tissue cores had >1% LAG3 expression in T cells. The median LAG3 expression in T cells measured by mIF was 1.8% in 99 tumor cores from the *ALK* fusion-negative study cohort versus 7.3% in the 31 cores from the *ALK* fusion-positive subset (p=0.004). Postmortem genomic analyses revealed an *ALK* p.L1196M resistance mutation in the first patient and an *AGK-BRAF* fusion in the 2nd patient. No known ALK-TKI resistance mutations were detected in the 3rd patient.
Discussion: High-quality post-therapy tumor samples collected by the RTD program enable the investigation of genomic and potential immune-related resistance mechanisms. Such studies can inform potential targets for drug development and the study of new therapies to overcome treatment resistance. Our observation of high LAG3 expression in 3 RTD donors with *ALK* fusion-positive NSCLC suggests the need for further studies to explore the potential for LAG3 inhibitors in patients with NSCLC whose tumors develop resistance to ALK inhibitors.

Immune checkpoint reporter cell lines based on the protein profiling of ATCC cell lines for cancer immunotherapy drug screening
Hyeyoun Chang, Kevin Tyo, John Foulke, Luping Chen, Zhizhan Gu, Fang Tian. *ATCC, Gaithersburg, MD*

The success of immune checkpoint inhibitors in the treatment of various types of cancers and their continued growth in the market have driven burgeoning interests in developing more drugs in this category. However, the intrinsic complexity of the immunological models and the variable drug responses among different cancer types have become the most prominent challenges. To facilitate large scale research projects and drug discovery of immune checkpoint inhibitors, we conducted a comprehensive protein profiling of ATCC's vast portfolio of human tumor and immune cell lines for several established and novel immune checkpoint molecules. Based on this protein profiling data, we generated immune checkpoint reporter cancer cell lines with high expression of endogenous immune checkpoint molecule ligands (PD-L1, CD155, and B7-H3). The reporter system contains a gamma interferon activation site (GAS)-response element upstream of the luciferase gene, preventing luciferase expression when the immune checkpoint molecule ligand binds to its corresponding receptor that suppresses T cell-mediated antitumor activity. In the presence of a relevant immune checkpoint inhibitor, a luciferase expression-based bioluminescent signal is produced, which can be readily detected and quantitated to evaluate the efficacy, potency, and dynamics of the inhibitor. Our data showed that the bioluminescence in the reporter cancer cells increased approximately 100-250 folds in a dose-dependent manner in response to interferon gamma stimulation, which mimics the signaling from activated CD8+ cytotoxic T cells. The bioluminescence increased approximately 50-100 folds in response to CD8+ primary T cell-conditioned media stimulation. In particular, we observed up to 5-fold increase in luciferase signal from our PD-L1 reporter cell line in response to co-culture with CD8+ primary T cells in the presence of an anti-PD-L1 blocking antibody in a dose-dependent manner. The luciferase expression and endogenous immune checkpoint molecule ligand expression were well maintained after the cell lines had reached >30 population doubling level. These results highlight the robustness and responsiveness of the reporter system for the assessment of T cell-mediated immune responses triggered by checkpoint inhibitors. These immune checkpoint reporter cancer cell lines yield exceptional in vitro and ex vivo assay sensitivity and reproducibility, while simplify the complex immunological model by providing physiologically relevant

expression of immune checkpoint molecule ligands, in comparison to similar assays with an artificial checkpoint ligand overexpression system.

Investigating the effect of immune checkpoint inhibitors (ICI) on ovarian function in young patients with melanoma

Ashley Hickman[1], Katherine Smith[1], Zaraq Khan[2], Elizabeth Ann Enninga[3], Yulian Zhao[2], Elizabeth Cathcart-Rake[1], Haidong Dong[4], Lisa Kottschade[1], Svetomir Markovic[1], Heather Montane[1], Anastasios Dimou[1], Yiyi Yan[5]. *[1]Mayo Clinic Medical Oncology, Rochester, MN,[2]Mayo Clinic Obstetrics and Gynecology, Rochester, MN,[3]Mayo Clinic Research Services, Rochester, MN,[4]Mayo Clinic Urology, Rochester, MN,[5]Mayo Clinic Medical Oncology, Jacksonville, FL*

Immune related adverse events (irAEs) from immune checkpoint inhibitors (ICIs) are well documented for nearly every organ system, except for the reproductive system. Mouse models have demonstrated that ICIs can decrease ovarian follicular reserve and impair oocyte maturation, which may have implications for fertility (PMID: 36008687). There are no studies investigating the effect of ICIs on fertility in humans. We sought to evaluate ovarian function in women treated with ICIs compared to untreated women by evaluating non-invasive surrogate markers of ovarian reserve, anti-müllerian hormone (AMH) and antral follicle counts (AFC). We enrolled women 18 - 40 years old diagnosed with stage III or IV melanoma. Participants underwent phlebotomy for AMH levels and a pelvic ultrasound to assess AFC. The medical record was retrospectively reviewed to obtain data on patient characteristics, treatments, and outcomes. A total of 14 patients with stage IIIA - IV melanoma participated. Six patients received ICI treatment before AMH and AFC testing while 8 had no prior ICI exposure. The ICI group ages ranged from 22-40 years with a median age of 31 years. The untreated group ages ranged from 25-39 years with a median age of 32 years. The time between starting an ICI and enrolling in the study ranged from 28 - 351 days. ICI regimens included ipilimumab/nivolumab, nivolumab, pembrolizumab, and atezolizumab (on a clinical trial). Four of these six patients experienced an irAE during their course, including: dermatitis, hepatitis, colitis, thyroid dysfunction, and adrenal insufficiency. Median AMH levels were lower for patients treated with ICIs (2.9 vs 4.0 ng/mL), as was median AFC (22.5 vs 23.5 ng/mL). Only three patients' clinicians discussed fertility preservation. None of the patients underwent fertility preservation. Our study found lower AMH and AFC in women with melanoma who were treated with an ICI compared to untreated women. Although AMH and AFC are surrogate markers for ovarian reserve and fertility, and our study is a small cohort, these early results suggest that ICIs may impact ovarian function. Age is less likely to be a confounding factor as the median age of the treated group was younger than the untreated group. While these results are preliminary, when considered in conjunction with recent pre-clinical data showing changes within the ovaries after ICI treatment, fertility consultation should be considered for young women prior to ICI initiation. We are investigating associations between AMH, AFC, age, ICI exposure, and future pregnancies in an ongoing prospective study.

A systematic approach for detection of tumor genomic alterations which alter the immune microenvironment

Raven Vella, Emily L. Hoskins, Julie W. Reeser, Michele R. Wing, Eric Samorodnitsky, Anoosha Paruchuri, Amy Smith, Leah Stein, Thuy Dao, Zachary Risch, Sameek Roychowdhury. *The Ohio State University, Hilliard, OH*

Objectives: Leveraging whole exome and transcriptome data from large cancer datasets, we sought to develop a computational approach to nominate candidate genomic alterations that are associated with hot or cold tumor. We anticipate this tool will identify candidate novel drug targets and biomarkers for immunotherapy in cancer. Methods: The user selects a gene of interest (GOI) as input for the pipeline. The pipeline searches TCGA (The Cancer Genome Atlas) mutation and structural variant outputs to collect hits in the gene of interest. Each sample with an alteration in the GOI is annotated with the alteration's predicted biological function (loss-of-function or LOF vs gain-of-function or GOF) using gene set enrichment analysis and pathway analysis from RNA sequencing. After annotating by sample, the alterations themselves are scored and recorded. Next, Quantiseq and Trust4 are employed to estimate features of the immune microenvironment in both the LOF and GOF samples. These results along with cancer type distributions, genomic position maps, and oncoplots are delivered to the user for further investigation. We are creating an online application to provide these results to the public. Simultaneously, a command line tool is being developed for application to any data source.

Results: We will present findings for the pipeline using positive controls including genomic alterations in ADAR, MTAP, IDH1, and CD274 (PD-L1). Preliminarily, we identified candidate GOF mutations (n=81) in PD-L1 that have inflamed tumor immune microenvironments like those of samples with known GOF structural variations in PD-L1. These samples have an overall "hot" immune microenvironment with significantly ($p<.05$) increased M1 macrophages, increased expression of IFN-gamma, and decreased M2 macrophages.
Conclusion: Currently there are no systematic approaches to interrogate individual genomic alterations and their association with an altered immune microenvironment. Our approach is pragmatic for any gene of interest, can be applied to any database, and identifies clinically actionable targets. This approach will identify heretofore unstudied connections between genomic alterations and immune microenvironment and support personalized drug development strategies in immuno-oncology.

Inhibition of HuR/CD147/IL-6 axis enhances anti-PD1 immunotherapy response in cancer

Qi Zhang, Lauren Dandreo, Xiaoqing Wu, Liang Xu. *Molecular Biosciences, University of Kansas, Lawrence, KS*

Immune checkpoint blockade (ICB) targeting PD-1/PD-L1 has emerged as a revolutionizing treatment modality for multiple cancers. However, durable remission and objective response rates with ICB monotherapy remain low. Several immune resistance mechanisms have been revealed and used to develop combinational therapy. In consideration of the durable and impressive responses observed in 'hot' tumors, it will be valuable to make an endeavor to elucidate the tumor evasion mechanisms. Despite the well-established mechanisms in immunotherapy resistance, our study uncovered a new mechanism of tumor immune evasion through the RNA-binding protein HuR/CD147 axis. The RNA-binding protein Hu antigen R (HuR) is overexpressed in a variety of cancers and promotes tumorigenesis by interacting with a subset of oncogenic mRNAs. The tumor-associated antigen CD147, a highly glycosylated transmembrane immunoglobulin, is widely and specifically expressed in multiple malignancies. We phenotypically observed the downregulation of CD147 in HuR-deficient cells and elucidated that HuR regulates *CD147* mRNA via binding to the AU-rich elements of its 3' UTR. The direct binding of HuR to *CD147* mRNA in multiple types of cells was validated by Ribonucleoprotein immunoprecipitation (RNP-IP) and RNA pulldown assay. These data together clarify HuR is engaged in *CD147* post-transcription regulation. KH-39 is a HuR-specific small molecule inhibitor, which disrupts the HuR function by competing for the binding site with its target mRNAs. KH-39 treatment reduced CD147 level in a time-/dose-dependent manner. We also tested the anti-tumor action of HuR small molecular inhibitor KH-39 in tumor proliferation, clonogenicity, cell death, cytokine secretion, and *in vivo* tumor growth. The cytokine array assay indicated multiple immune-related cytokines changed after HuR inhibition and CD147 knockdown, including IL-6, which is proven to act as an immunomodulating agent in the tumor microenvironment. These data demonstrated the potential mechanism of overcoming immunoresistance by inhibiting the HuR/CD147/IL-6 axis. To test the combination strategy using HuR inhibitor and anti-PD-1 antibody in vivo, we established the EMT6 orthotopic mouse breast cancer model. A combination of HuR inhibitor KH-39 and anti-PD-1 antibody enhanced the anti-PD1 immunotherapy response and prolonged survival compared to the single agent group. Taken together, we preliminarily explored the HuR/CD147/IL-6 axis in tumor immune evasion, which might be a promising therapeutic target to overcome immune evasion and improve immunotherapy response in cancer. This finding may have reference significance for clinical cancer therapy.

#6647

Dostarlimab shows dose-dependent immune activation of the tumor microenvironment in a patient-derived NSCLC explant model similar to pembrolizumab

Jessica Perrin[1], Frank Wippich[1], Valeriia Sherina[2], Dmytro Dvornikov[1], Katharina Lupar[1], Murad M. Melhem[2], Patrick Hanafin[2], Jeremy Waight[2], Jong Yu[2], Sapna Yadavilli[2], Daniel Poeckel[1], Giovanna Bergamini[1]. *[1]Cellzome, GSK, Heidelberg, Germany,[2]GSK, Upper Providence, PA*

The ability to more faithfully mimic the tumor microenvironment (TME) of cancer patients offers a wide range of possibilities for non-clinical evaluation of anti-cancer therapeutics, including guidance for patient selection, dose, and combinations. We have established a patient-derived tumor explant (PDE) model to monitor immune activation within a structurally preserved TME, following *ex vivo* incubation with immune check point inhibitors (ICI). When testing anti-PD-1 agents, such as dostarlimab and pembrolizumab, in a cohort of NSCLC explants from stage I-III treatment-naïve patients, we observed that approximately half demonstrate release of inflammatory cytokines after two days incubation. Interestingly, responsive tumors presented with a high level of PD-L1

expression (high TPS), had elevated TMB, and were highly infiltrated by CD8+ T cells at baseline, in line with tumor baseline characteristics predictive of clinical response to anti-PD-1. When testing a dose-range of dostarlimab and pembrolizumab comparable potencies were observed when measuring cytokine release after treatment of the NSCLC explants. In conclusion, we describe here an *in vitro* patient-derived NSCLC model that mirrors the heterogeneity of patients' response for anti-PD-1 agents observed in clinical settings, representing a valuable tool for comparative analysis of novel ICI assets and combinations, such as the CD226 axis members. Importantly, this system is also amenable to extensive multi-omics and genetics-based analyses, providing the opportunity to better identify predictive or pharmacodynamic characteristics within patient tumors.

#6648

Prediction of anti-PD-1 efficacy based on immune marker densities and their spatial distribution in colorectal cancer

Bahar Saberzadeh-Ardestani[1], Rondell P. Graham[2], Qian Shi[3], Eze Ahanonu[4], Sara McMahon[4], Crystal Williams[4], Antony Hubbard[4], Wenjun Zhang[4], Andrea Muranyi[4], Dongyao Yan[4], Kandavel Shanmugam[4], Frank A. Sinicrope[5]. *[1]Gastrointestinal Research Unit, Mayo Clinic, Rochester, MN,[2]Pathology, Mayo Clinic, Rochester, MN,[3]Quantitative Health Science, Mayo Clinic, Rochester, MN,[4]Roche Tissue Diagnostics, Tucson, AZ,[5]Oncology and Gastrointestinal Research Unit, Mayo Clinic, Rochester, MN*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of patients with deficient DNA mismatch repair (d-MMR) metastatic colorectal cancer (CRC), yet less than half of patients receive clinical benefit. We hypothesized that immune contexture including spatial distribution of cells expressing immune molecules in the tumor microenvironment may predict immunotherapy outcome. Methods: Primary CRC tissues from consecutive patients with d-MMR metastatic CRC (N=33) were treated with anti-PD-1 antibodies at Mayo Clinic Comprehensive Cancer Center (2015-2018). Tumors were stained for PD-L1, PD-1, CD8, CD3, CD68, LAG3, TGFβR2, MHC-I, CD14, B2M, DAPI and pan-cytokeratin in 5 compartments (overall tumor, tumor epithelia, tumor stroma, peritumor inside vs outside) by multiplex immunofluorescence with digital image analysis. Features computed within each image analysis region included positive cell density, fraction of positive cell types, intensity of positive cells, and spatial distribution between distinct cell types (distances measured using image analysis software). Prior to model fitting, feature selection was performed using regularized Cox regression with LASSO. Regularization parameter was chosen based on 5-fold cross validation. A Cox proportional hazards model was fitted to predict patient progression-free survival (PFS).
Results: Among patients with d-MMR CRCs, 16/33 (48.4%) were female, 10 received first-line ICI therapy, and 23 had received $\geq$ 1 prior chemotherapy regimen. Median age was 61.6 years (IQR of 49.4, 73.7). Eight patients (24.2%) harbored $BRAF^{V600E}$, 9 (27.2%) had mutant KRAS, and median PFS was 22.2 months (95% CI: 11.8, NR) with 20 events. PD-L1 was expressed in tumor cells, $CD68^+$ macrophages, and $CD3^+$ T lymphocytes. PD-1 expression on $CD8^+$ T lymphocytes was also observed. By univariate analysis, only cell-cell distance readouts achieved statistical significance. Multivariable feature selection identified the mean number of $PD\text{-}1^+$ cells within 10 microns of a $PD\text{-}L1^+$ cell in the overall tumor as the strongest predictor of anti-PD-1 efficacy, and was significantly associated with PFS (HR=0.87, 95% CI: 0.79-0.95, $p< 0.001$). In contrast, the ratio of $PD\text{-}1^+/PD\text{-}L1^+$ cells was not predictive of treatment efficacy ($p= 0.47$), thereby underscoring the importance of spatial distribution for PFS prediction.
Conclusion: The mean number of $PD\text{-}1^+$ cells in proximity to $PD\text{-}L1^+$ cells in tumors was a predictive biomarker of anti-PD-1 efficacy. Confirmatory studies are warranted.

Prevalence and spatial interplay of mononuclear phagocyte and lymphocyte subpopulations in 49 carcinoma entities in respect to its TIM3, PD-1, PD-L1 and CTLA-4 expression using BLEACH&STAIN

Zhihao Huang, Nicolaus F. Debatin, Elena Bady, Jan H. Mueller, Tim Mandelkow, Magalie C. J. Lurati, Ronald Simon, David Dum, Guido Sauter, Franziska Büscheck, Doris Hoeflmayer, Sören Weidemann, Claudia Hube-Magg, Till Clauditz, Maximilian Lennartz, Eike Burandt, Niclas C. Blessin. *University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: A combination of different immune-checkpoint-inhibitors (ICIs) have shown remarkable success in several tumor entities. However, the likelihood of positive response to ICIs is poor in most tumor entities and recent evidence suggests that the quantity and the expression level of immune checkpoints such as TIM3, CTLA-4,

PD-1 of tumor infiltrating lymphocytes (TILs) influences the likelihood of response to immune checkpoint inhibitors.
Design: To assess the density and spatial interplay of 42 immune checkpoint expressing leukocyte subpopulations in 6031 tumor samples from 49 carcinoma (sub)entities two different types of tissue microarrays (0.6 mm and 4 mm in diameter) were stained with 21 antibodies using our BLEACH&STAIN multiplex fluorescence immunohistochemistry approach. A deep learning-based framework comprising two different convolutional neuronal networks (U-Net and DeepLabv3+) was used for image analysis.
Results: We found that the mean overall fraction of TIM3, PD-1, PD-L1 and CTLA-4 expression on M1, M2 macrophages, cD11c$^+$ dendritic cells, CD8$^+$ cytotoxic T-cells, CD4$^+$ T-helper cells, FOXP3$^+$ Tregs and CD20$^+$ B-cells, ranged from 10% (sum of the fractions of immune checkpoint expression) in small cell carcinomas of the prostate up to 123 % in squamous cell carcinoma of the lung. Tumor types approved for checkpoint inhibitor therapy, including adenocarcinomas of the lung (121 %), small cell carcinoma of the lung (74%), malignant melanoma (59 %), and clear cell renal cell cancer (49%) were all ranking among the upper half of our list of mean fractions of overall immune checkpoint expression. Spatial analysis and the shift in immune cell compositions revealed that in most carcinoma (sub)entities, the overall immune cell density and fraction of immune checkpoint expression of individual patients occasionally exceeded the average immune cell density and fraction of tumors for which checkpoint inhibitors have been approved.
Conclusion: These data support the concept that among most carcinoma entities at least some individual patients may benefit from treatment with immune checkpoint inhibitors.

#6650
Cell-based assay to support development and characterization of new drugs in immuno-oncology
Mohammad Haque, Safnas Abdul Salam, Shawn McGinley, Haiching Ma, jianghong Wu. *Reaction Biology Corporation, Malvern, PA*

The years since 2009 have seen tremendous progress in unlocking the curative potential of the immune system for the treatment of cancer. Much of that revolution in immuno-oncology has been fueled by the clinical success of immune checkpoint inhibitors, targeting cytokines, antibody dependent cell cytotoxicity and complement dependent cytotoxicity via the T cell activation. Reaction biology has established state-of-art high throughput screening procedures for measuring the ability of new Biologics or compounds to activate T cells. Antibody Dependent Cell Cytotoxicity (ADCC), T cell activation assay (NFAT), immune checkpoint inhibitor assay (PD-1/PD-L1 blockade bioassay), cytokines activation assay and Complement Dependent Cytotoxicity (CDC) are commonly used for drug discovery industry. ADCC is a desirable mechanism for killing target cells using antibody-based drugs. T cell activation assay can be used for the discovery and development of novel biologics and cell therapies aimed at inducing, strengthening and/or engineering T cell response. Blocking of immune inhibitory receptors by their respective ligands on an adjacent cell inhibits TCR mediated proliferation, transcriptional activation and cytokines production. Biologics or compounds designed for measuring the stimulatory or inhibitory function of cytokines are promising in the field of immune oncology. Reaction Biology developed biochemical assays for PD-1/PD-L1, CTLA4/CD80 and CTLA4/CD86 to screen immune checkpoint inhibitors. All of these screening procedures and experimental methods will help to identify new therapeutic biologics or compounds for drug discovery in immune-oncology field.

#6651
MoA-based potency bioassays for immunotherapy programs targeting the TIGIT/CD112R/CD96 axis
Steven Edenson, Jamison Grailer, Denise Garvin, Frank Fan, Jim Harnett, Mei Cong. *Promega, Madison, WI*

Immune checkpoint (IC) receptors play critical roles in maintaining immune homeostasis and have emerged as proven therapeutic targets for the treatment of various cancers and autoimmune disorders. Monoclonal antibodies (mAbs) designed to block immune inhibitory receptors PD-1 and CTLA-4 have shown unprecedented efficacy in cancer treatment. This led to rapid expansion of mAb discovery programs to many more IC receptors including members of the T cell immunoreceptor with Ig and ITIM domains (TIGIT) - CD112R - CD96 Axis. TIGIT binds to its ligands CD155 (PVR) and CD112 (PVRL2) while CD112R (PVRIG) binds to CD112 and CD96 (TACTILE) binds to CD155. Binding of TIGIT/CD112R to CD155/CD112 inhibits the co-stimulatory activity of the paired receptor CD226. Human CD96 can have co-stimulatory or co-inhibitory activity based on the cell type and context. Thus, therapeutic targeting of this axis can modulate T cell and NK cell activation and unleash anti-cancer immunity. One of the bottlenecks of immunotherapy mAb development is the lack of quantitative and reproducible

bioassays for functional analysis and potency determination. Existing methods rely heavily on primary immune cells, which is labor- and cost-intensive and highly variable. To address this need, we developed a panel of cell-based reporter bioassays that can quantitatively measure the potencies of mAbs targeting TIGIT/CD155, TIGIT/CD112, CD112R/CD112, and CD96/CD155. Owing to the clinical combination of TIGIT blockade with PD-1/PD-L1 blockade, we further developed a potency bioassay for bispecific antibodies simultaneously targeting TIGIT and PD-1/PD-L1. These bioassays each consist of an engineered T effector cell line that expresses T cell receptors and IC receptors of interest, and an engineered artificial antigen presenting cells (aAPC) expressing the cor
responding ligands for the IC receptors. The T effector cell lines also express a luciferase reporter driven by a promoter specifically responding to TCR activation which can be inhibited by signaling from the IC receptors. Additionally, we developed bioassays that can measure potencies of agonist or antagonist mAbs targeting CD226. These bioassays are designed to reflect the mechanisms of action for the drug candidates designed for each IC receptor and the assay signals are specific. Most are prequalified according to ICH guidelines and show the precision, accuracy and linearity required for cGMP environments. Therefore, these MoA-based bioassays can serve as valuable tools for early drug discovery, potency determination and stability studies throughout the development of mAbs targeting the TIGIT/CD112R/CD96 axis.

Overcoming immune resistance in DNA mismatch repair deficient tumors

Guillaume Mestrallet. *Icahn School of Medicine at Mount Sinai, New York, NY*

Patients with Lynch Syndrome, an inherited mismatch repair deficiency, have an increased risk for developing microsatellite unstable (MSI-H) cancers. Our team recently identified shared immunogenic frameshift peptides in patient tumors that can be targets of T cell surveillance and preventative MSI-H cancer vaccines. We hypothesize that in Lynch Syndrome some premalignant lesions are capable of evading immune surveillance from cytotoxic T lymphocytes due to immune checkpoint expression and immunosuppression from tumor, myeloid and stromal cell populations. Immune checkpoint blockade (ICB) showed promising results in the treatment of MSI-H tumors and are being evaluated in the adjuvant setting of patients with Lynch syndrome post surgical resection. However, a significant percentage of advanced MSI-H tumors resist ICB suggesting evolving mechanisms of immune resistance. We will use a MSI-H in vivo mouse model and additionally develop 3D spheroids cocultured with immune cells to characterize the underlying immune resistance mechanisms. The MSI-H mouse model will first be applied to identify shared frameshifts in MSI-H tumors by WES to develop vaccination approaches preventing tumor growth. Then, we will quantify MSI-H tumor growth and immune infiltration in the MSI-H mouse model, with or without ICB. We will analyze the presence of immunosuppressive pathways and myeloid subsets in high growth resisting tumors by immunohistochemistry, scRNAseq, spatial transcriptomics and flow cytometry. In addition, we will perform short-term in vitro spheroid-splenic cell co-cultures to better characterize the early immune resistance mechanisms. We will also perform these spheroid-immune cell co-cultures using the immune cells taken from mice after vaccination or ICB to identify the early myeloid immune resistance mechanisms. Overall, the identification of shared immune frameshifts in MSI-H tumors will allow developing peptide vaccination approaches to prevent tumor growth. Further, the identification of myeloid resistance pathways will guide therapeutic strategies against tumor resisting to ICB and/or vaccination.

Analysis of selective response of anti-PD-L1 treatment in huPBMC-NCG mice reconstituted with different donors

Tingting Gu[1], Weiwei Yu[1], Hongyan Sun[1], Fang Zhu[1], Huiyi Wang[1], Mengting Wang[1], Shuai Li[1], Jianming Xu[1], Santi Suryani Chen[2], Zhiying Li[2], Mark Wade Moore[2], Cunxiang Ju[1], Hongyu Wang[1], Jing Zhao[1], Xiang Gao[1].
[1]Gempharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA

Despite the success of programmed death ligand 1 (PD-L1) and programmed death 1 (PD-1) blockage as cancer therapies, the overall clinical response rates are still unsatisfying, with only a 25% response rate in most cancers. The underlying mechanisms of non-responsiveness towards anti-PD-L1 treatment have been extensively studied and associated with many factors, including PD1/PD-L1 expression level, tumor mutation burden, IFN signaling, loss of MHC-I, tumor microenvironment (immune infiltration, suppressive immune system), and so on. Immunodeficient mice such as the NSG and NCG are commonly used to study the efficacy of cancer immunotherapies. These mice, reconstituted with either human PBMC or HSC, act as an avatar to provide a

window of the potential agent efficacy at the preclinical level. However, due to the challenge of obtaining an HSC/PBMC donor, and often cost and time can also be a limiting factor, many studies only use 2-5 human donors. Here we present data demonstrating the significant variation observed between donor-to-donor, highlighting the importance of testing multiple donors.
We reconstituted immune system and tumor tissue humanized mouse models using peripheral blood mononuclear cells (PBMCs), and cell line-derived xenografts (CDX) in severe immunodeficiency NCG mice. Anti-tumor efficacy of anti-PD-L1 (Tecentriq) in huPBMC-NCG mice engrafted with several tumor cells including MDA-MB-231, HCC827, NUGC4, and some other CDX cell lines was tested in our system. In the cases of MDA-MB-231, HCC827, and NUGC4, different donors were enrolled in the same study, and tumor growth inhibition measured by tumor volume (TGI_{TV}) of 3% to 52.40% (MDA-MB-231), 5% to 33% (HCC827) and 4.75% to 20.74% (NUGC4) were observed. Especially, In the case of MDA-MB-231, 6 donors were enrolled in this study at the same time. About 40% of immune infiltration was first observed in tumors. High expression of PD1 on immune cells and PDL1 on tumor cells were also detected from different donors simultaneously. Although the similar immune infiltration and PD1/PDL1 expression, the TGI_{TV} of 6 donors varied between 3% and 52.40%, suggesting the donor-dependent response to anti-PD-L1 treatment, which is similar to the clinical trials.
Our data showed diverse in vivo responses when multiple human PBMC donors were used for preclinical agent evaluation. While unsurprising, it showed the critical need to include various human PBMC donors when an agent is in preclinical status because the donors' immune profile may dictate the study's outcome. This can be divided into two parts, on the one hand, donor screening for favorable efficacy response donors in advance is an alternative approach to ensure the positive efficacy of anti-PDL1 blockade relative therapy. On the other hand, the low-efficacy response donors also can be candidates for anti-PD1/PDL1 combination therapy.

Association PD-L1 overexpression with immune checkpoint inhibitor effect in triple-negative breast cancer

A Young Park[1], Ju Hee Kim[2], Sangen Lee[1], Hong Kyu Kim[2], Han-Byoel Lee[3], Wonshick Han[3]. *[1]Seoul National University Graduate School, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of,[3]Seoul National University College of Medicine, Seoul, Korea, Republic of*

Background: Recently, studies on the antitumor effects of PD-L1 inhibitors have gained importance in difficult to treat solid tumors. In particular, the expression of PD-L1 could be an important factor in evaluating the possibility of immunotherapy in triple-negative breast cancer where targeted therapy is not possible and the prognosis is poor. Accordingly, this study investigated the effect of PD-L1 overexpression on the immune checkpoint inhibitor effect in triple-negative breast cancer.
Method: The relationship between T stage and N stage according to PD-L1 mRNA expression was analyzed in the TCGA and METABRIC datasets of breast cancer. To evaluate the role of PD-L1, PD-L1-overexpressing breast cancer cell lines for *in vitro* and *in vivo* experiments were established.
Result: Using TCGA and METABRIC datasets, we found that PD-L1 showed the highest expression in breast cancer of the basal subtype, but the correlation between T stage and N stage according to PD-L1 expression was not statistically significant. To determine the functional importance of PD-L1 in breast cancer, we established 4T1-PD-L1-overexpressing breast cancer cell lines. We observed that the overexpression of PD-L1 promoted cell proliferation, migration, and invasion. In the orthotopic tumor mouse model, PD-L1 showed no significant difference in tumor growth compared to the control group, but anti-PD-L1 treatment showed a significant antitumor effect.
Conclusion: We confirmed that overexpression of PD-L1 in an orthotopic breast cancer model did not induce increased tumor growth. Above all, it was confirmed that a high PD-L1 level enhances the antitumor effect of immune checkpoint inhibitors. Our findings show that the expression level of PD-L1 in breast cancer has a significant effect on the immune checkpoint inhibitor effect. We need to further investigate the role of PD-L1 in breast cancer.

#6655

A real world analysis: Impact of clinical trial eligibility criteria on clinical outcomes among patients with advanced non-small cell lung cancer (aNSCLC) receiving second line (2L) immune checkpoint inhibitor (ICI) therapy

Hina Mohammed[1], Miso Kim[2], Mahder Teka[1], Monika Izano[1], Frank Wolf[1], Thomas Brown[1]. *[1]Syapse, San Francisco, CA,[2]Seoul National University Hospital, Seoul, Korea, Republic of*

Background. Clinical trials (CT) include patients (pts) satisfying eligibility criteria including normal organ function and low comorbidity. Real-world outcomes for pts with aNSCLC receiving ICIs in 2L were compared based on whether pts met CT eligibility criteria.
Methods. 2L- associated outcomes were compared between pts with aNSCLC diagnosed between 04/01/2015 - 12/31/2020 in US community health systems that fulfilled or failed to fulfill CT eligibility criteria. CT-eligible (CTE) pts had at 2L: performance status of 0-1; normal renal, hepatic, and bone marrow function; no evidence of Hepatitis B or C, HIV, rheumatic diseases, or interstitial lung disease. Pts were CT-ineligible (CTI) if they failed to meet one or more of these criteria. Follow-up spanned 2L start to the first of: outcome of interest, death, or study end on 06/30/2021. Outcomes were evaluated in pts receiving ICI monotherapy (monotherapy) or ICI + chemotherapy (combination).
Results. Of the 505 pts in this analysis, 81% and 19% received monotherapy and combination, respectively; 19% of pts were CTE (76% monotherapy, 24% combination, **Table)**. Overall, in ICI subgroups among monotherapy pts, pembrolizumab-treated pts had longer OS and TTNT; time to treatment discontinuation (TTD) was less variable across subgroups. CTE pts in the monotherapy group had longer OS, shorter TTNT, and similar TTD compared to CTI. Among combination pts, CTE had similar OS and TTD, but shorter TTNT compared to CTI.
Conclusions. CTE pts appear to have longer survival than CTI pts with aNSCLC receiving ICI monotherapy, but not among pts receiving combination. TTNT was longer for CTI pts in both groups. In addition to CTE pts, some CTI pts appear to benefit from 2L ICI therapy.

Expression pattern and clinicopathological implication of B7 family immune checkpoints, VTCN1 and HHLA2, in non-small cell lung cancer
Sojung Lim[1], Jaemoon Koh[1], Seung Geun Song[1], Jeemin Yim[1], Bogyeong Han[1], Young A Kim[2], Doo Hyun Chung[1], Yoon Kyung Jeon[1]. *[1]Pathology, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Pathology, Seoul Metropolitan Government Boramae Hospital, Seoul, Korea, Republic of*

Background: Efforts are needed to discover novel immunotherapeutic targets in non-responders of current immunotherapies. VTCN1 (B7-H4/B7x/B7S1) and HHLA2 (B7-H7/B7y) are B7 family co-inhibitory molecules reported to be expressed in PD-L1-negative or *EGFR*-mutant lung adenocarcinoma (LUAD). To elucidate the clinicopathological implications of these two immune checkpoints, we checked their detailed expression patterns including intratumoral heterogeneity.
Methods: VTCN1 and HHLA2 expression were evaluated in public single-cell RNA sequencing (scRNAseq) and The Cancer Genome Atlas (TCGA) dataset. Their immunohistochemistry (IHC) was performed on tissue microarrays of 413 LUAD and 382 lung squamous cell carcinoma (LUSC) specimens. Intratumoral heterogeneity was evaluated by IHC on representative sections of 59 surgically resected LUAD and 49 LUSC specimens.

Results: In LUAD scRNAseq, VTCN1 and HHLA2 were predominantly expressed on epithelial cells and were not co-expressed with PD-L1. However, IHC showed their expression in both tumor and immune cells. In TCGA analysis, there was a negative correlation between VTCN1 and PD-L1 (LUAD, r = -0.094, $p = 0.033$; LUSC, r = -0.227, $p < 0.001$). VTCN1 and HHLA2 showed positive correlations in both TCGA (LUAD, r = 0.211, $p < 0.001$; LUSC, r = 0.182, $p < 0.001$) and IHC analysis (LUAD, $p < 0.001$; LUSC, $p = 0.016$). They were more frequently expressed in *EGFR*-mutant LUAD (52.9% vs. 40.3%, $p = 0.015$ for VTCN1 in *EGFR*-mutant vs. wildtype; 59.8% vs. 40.5%, $p < 0.001$ for HHLA2). $CD8^+$ T-cell infiltration was significantly higher in VTCN1- or HHLA2-positive *EGFR*-mutant LUAD, but there was no significant relationship in *EGFR*-wildtype. In 60% of cases expressing both VTCN1 and HHLA2, the two showed spatially concordant expression (15 out of 24 LUAD; 3 out of 6 LUSC). However, VTCN1 and PD-L1 showed concordant expression in 37.2% of cases expressing both (6 out of 16 LUAD; 10 out of 27 LUSC). HHLA2 expression was associated with better overall survival in LUSC, but there was no significant difference in survival according to VTCN1 expression.
Conclusions: VTCN1 and HHLA2 are frequently co-expressed in PD-L1-negative NSCLC, especially *EGFR*-mutant LUAD rich in $CD8^+$ T-cells and can serve as potential novel immunotherapeutic targets.

Phase I trial of first-in-class anti-PVR mAb NTX1088: Restoration of DNAM1 expression as MOA for enhanced antitumor immunity

Anas Atieh[1], Akram Obiedat[1], Alon Vitenshtein[1], Guy Cinamon[1], Keren Paz[1], Tihana lenac[2], Paola Kucan[2], Marija Mazor[2], Ofer Mandelboim[3], Stipan Jonji[2], Pini Tsukerman[1]. *[1]Nectin Therapeutics, Ltd., Jerusalem, Israel,[2]MEDRI, Rijeka, Croatia,[3]HUJI, Jerusalem, Israel*

NTX1088, a first-in-class anti-PVR (CD155) monoclonal antibody (mAb), is currently evaluated in a Phase 1, open-label, multi-center study (NCT05378425), initiated at MD Anderson Cancer center. Study objectives are safety, dose-finding, and efficacy with focus on pharmacokinetics, pharmacodynamics, and biomarker discovery. NTX1088 will be investigated as a single agent and combined with the anti-PD1 mAb, pembrolizumab (Keytruda) in patients with locally advanced and metastatic solid malignancies.NTX1088 is a humanized, IgG4-S228P mAb that binds PVR with sub-nM affinity and blocks all known interacting receptors with a single nM EC_{50}. PVR, is a membranal protein, highly upregulated on tumor cells, across multiple cancer types. PVR expression has been associated with worse patient outcomes, due to its role in immune suppression. PVR's impact on immune cells is mediated through interaction with the key stimulatory receptor, DNAM1 (CD226), on T and NK cells, leading to internalization and degradation of DNAM1. Additionally, PVR is the ligand for the inhibitory immune checkpoint receptors, TIGIT, CD96 and KIR2DL5A. Blocking PVR by NTX1088, therefore, has a multi-faceted immune-stimulating role, through restoration of DNAM1 expression and its immune activation function, while simultaneously neutralizing TIGIT, CD96 and KIR2DL5A inhibitory signals in immune cells. Importantly, DNAM1 downmodulation was recently identified as a key resistance mechanism to approved immune checkpoint inhibitors (ICIs), and its restoration by NTX1088 is a novel MoA, not demonstrated by other therapies.In vitro, as a monotherapy, NTX1088 significantly increased immune cell activation, and was superior to TIGIT, CD112R, and PD1 antibody blockade, leading to greater immune-mediated tumor cell killing, IFNγ secretion, and CD137 induction. Importantly, only NTX1088 was able to restore DNAM1 to the surface of immune cells in all experimental settings. Synergy was observed when NTX1088 was combined with PD1 blockers, or with the anti-CD112R mAb, NTX2R13, in line with the restoration of DNAM1 expression.Numerous humanized murine xenograft models were investigated. NTX1088 exhibited robust tumor growth inhibition as a standalone and in combination with PD1 blockade. Syngeneic models of $PVR^{K.O}$ resulted in complete immune-mediated tumor regression, including hard to treat colorectal tumors. In conclusion, PVR blockade by NTX1088 has a remarkable pre-clinical efficacy, suggesting a potential clinical breakthrough, based on the ability of simultaneously overcome multiple tumor escape mechanisms. First-in-human (FIH) trial is currently ongoing and biomarker data is analyzed to assess clinical impact of the drug and prepare for patient stratification.

#6658

Prevalence of PD-L1 expression and its correlation with tumor biomarkers in the Chinese muscle invasive urothelial bladder carcinoma patients

Yu Fan[1], Tao Dai[2], Dahong Zhang[3], Hongqian Guo[4], Fangjian Zhou[5], Benkang Shi[6], Shaogang Wang[7], Zhigang Ji[8], Chunxi Wang[9], Xudong Yao[10], Qiang Wei[11], Nanhui Chen[12], Jinchun Xing[13], Jinjian Yang[14], Chuize Kong[15], Jian Huang[16], Dingwei Ye[17], Liqun Zhou[1]. *[1]Department of Urology, Peking University First Hospital, Beijing,*

China,[2]Department of Urology, The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University and Hunan Cancer Hospital, Changsha, China,[3]Department of Urology, Zhejiang Provincial People's Hospital, Hangzhou, China,[4]Department of Urology, Drum Tower Hospital, Medical School of Nanjing University, Institute of Urology, Nanjing University, Nanjing, China,[5]Department of Urology, Sun Yat-sen University Cancer Center, Guangzhou, China,[6]Department of Urology, Qilu Hospital, Cheeloo College of Medicine, Shandong University, Jinan, China,[7]Department of Urology, Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China,[8]Department of Urology, Peking Union Medical College Hospital, Chinese Academy of Science, Beijing, China,[9]Department of Urology, First Hospital of Jilin University, Jilin, China,[10]Department of Urology, Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, China,[11]Department of Urology, Institute of Urology, West China Hospital, Sichuan University, Shanghai, China,[12]Department of Urology, Meizhou People's Hospital, Meizhou, China,[13]Department of Urology Surgery, The First Affiliated Hospital of Xiamen University, Xiamen, China,[14]Department of Urology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China,[15]Department of Urology, The First Hospital of China Medical University, Shenyang, China,[16]Department of Urology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China,[17]Department of Urology, Fudan University Shanghai Cancer Center, Shanghai, China

The association of programmed cell death-ligand 1 (PD-L1) expression with the activity of immune checkpoint inhibitor therapy setting has encouraged us to study the prevalence of PD-L1 in muscle invasive urothelial bladder cancer (MIUBC) patients. Since, the prevalence of PD-L1 expression and its prognostic role in MIUBC is unclear in China, we conducted a multi-center, prospective, epidemiological study to investigate prevalence of high PD-L1 expression and its correlation with other exploratory biomarkers including CD8+ T cells and tumor mutation burden (TMB) in Chinese MIUBC patients (NCT03433924). The study enrolled newly diagnosed, untreated MIUBC patients from 17 hospitals in China. High PD-L1 expression by Ventana PD-L1 [SP263] assay was defined as 1) ≥25% tumor cell (TC) + or 2) tumor associated immune cell (IC) area >1%: ≥25% IC+; 3) IC area=1%: 100% IC+. The primary outcome was prevalence of high PD-L1 expression; secondary outcome was PD-L1 expression profile in TC or IC in patients. An exploratory study was conducted to investigate the percentage of patients with high infiltration of CD8+ T cells and elevated TMB using immunohistochemistry and next generation sequencing, respectively. High CD8+ and TMB status was considered if it refers to > median value (3%) and >10 mut/Mb, respectively. Association of PD-L1 expression with demographic and baseline characteristics was evaluated by logistic regression model while PD-L1 with tumor biomarkers were evaluated by spearman's rank correlation coefficient. Overall, 248 MIUBC patients were enrolled and 229 patients with PD-L1 data were included. High PD-L1 expression was observed in 52.4% patients. High PD-L1 expression was positive in 59 (25.8%) patients of TC and 82 (35.8%) patients of IC. CD8+ T cell and TMB showed high expression in 44.5% and 54.1% patients, respectively, with mean TMB of 14.14 mut/Mb. The exploratory analysis showed no significant association of PD-L1 expression with age, gender, primary tumor site, metastatic disease, regional lymph node, tobacco use or AJCC stage. Further a weak and positive correlation was observed between percentage of TC with membrane PD-L1 positivity and CD8+ T cells (0.34, 95%Cl, 0.22 - 0.45, $p<0.001$), IC with membrane PD-L1 positivity and CD8+ T cells (0.44, 95%Cl, 0.33 - 0.54, $p<0.001$), TC with membrane PD-L1 positivity and TMB (0.05, 95%Cl, -0.08 - 0.19, $p=0.441$), IC with membrane PD-L1 positivity and TMB (0.16, 95%Cl, 0.02 - 0.29, $p=0.020$). In conclusion, our study showed high prevalence of PD-L1 expression in patients with MIUBC along with their weak, positive correlation with CD8+ T cells and TMB. These findings are consistent with other studies that show that PD-L1 and TMB stand as the most robust predictive biomarkers, but may be uncorrelated. With subsequent follow-up time, the effect of biomarkers on survival will be assessed in future study.

Immune Monitoring and Responses to Therapy

#6662

Studying immune responses against human endogenous retroviruses in immune checkpoint blockade-treated lung adenocarcinoma

Khaled Sanber[1], Sydney Connor[1], Steven Vensko[2], Christopher Cherry[1], Zhen Zeng[1], Drew Pardoll[1], Patrick Forde[1], Benjamin Vincent[2], Kellie Smith[1]. *[1]Sidney Kimmel Comprehensive Cancer Center, Bloomberg-Kimmel Institute for Cancer Immunotherapy at Johns Hopkins University, Baltimore, MD,[2]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Clinical response to immune checkpoint blockade (ICB) is predicated upon the existence of tumor-reactive T cells, but their precise targets remain poorly defined. Some patients with low tumor mutational burden (TMB) lung adenocarcinoma (LUAD) derive clinical benefit from ICB, suggesting that non-mutated antigens may serve as T cell targets. Human endogenous retroviruses (hERVs) can be differentially expressed in malignant cells due to epigenetic dysregulation and can be targeted by T cells. We hypothesize that the detection of T cell responses against hERVs correlates with a favorable clinical response to ICB in LUAD.
Methods: Tumor tissues from patients with Stage I-III LUAD who underwent upfront surgical resection were enzymatically digested. Viable $CD45^{-}EPCAM^{+}$ cells were sorted. Total RNA was extracted and RNA sequencing was performed. The hervQUANT workflow was used to bioinformatically identify differentially-expressed, open reading frame (ORF)-encoding hERV transcripts. Publicly available RNAseq datasets derived from human medullary thymic epithelial cells (mTECs) and normal tissues were queried to exclude hERV transcripts expressed in these tissues. Overlapping peptide libraries (OPLs) spanning the shared hERV ORFs were synthesized and used in Functional Expansion of Specific T Cells (FEST) assays to detect hERV-specific T cell clones in the peripheral blood of a cohort of patients who met these criteria: (1) had advanced/metastatic LUAD, (2) were treated with ICB, (3) had peripheral blood mononuclear cells isolated at 4-8 weeks post-initiation of ICB and (4) had formal radiographic assessment of response to ICB.
Results: We identified 41 differentially-expressed, ORF-encoding hERV transcripts that were shared by ≥4 (out of 11) $CD45^{-}EPCAM^{+}$ LUAD samples. OPLs covering hERV ORFs with mean expression of ≥ 3 CPM in $CD45^{-}EPCAM^{+}$ LUAD cells and <3 CPM in mTECs were synthesized. Low expression in normal tissues was also confirmed (<3 CPM). A total of 318 patients were screened and 30 patients (22 radiographic responders and 8 non-responders) met the inclusion criteria. The median age was 66.5 years for responders and 58 years for non-responders. The median PD-L1 TPS was 72.5% and 70%, respectively. The median TMB was 8 and 2.55, respectively. FEST assays utilizing hERV OPLs revealed 4 potential hERV-reactive T cell clonotypes in the peripheral blood of 2 patients with LUAD treated with ICB. Studies are ongoing to validate and characterize these clonotypes. Testing of the remainder of the selected patient cohort is also ongoing.
Conclusions: Potential hERV-reactive T cell clonotypes are detectable in ICB-treated patients with LUAD. Correlation with clinical response to ICB will be evaluated upon validation of these clonotypes, but these results are promising findings in the ongoing efforts to identify immunogenic sources of non-mutated antigens in cancer.

Immunostimulatory gene therapy targeting CD40/4-1BB in combination with chemotherapy induces an inflammatory gene profile in tumors from patients with advanced disease

Jessica Wenthe[1], Emma Eriksson[2], Sedigheh Naseri[1], Linda Sandin[3], Amanda Hahn[1], Sandra Irenaeus[1], Anders Sundin[1], Justyna Leja-Jarblad[3], Gustav Ullenhag[1], Tanja Lövgren[1], Angelica Loskog[2]. *[1]Uppsala University, Uppsala, Sweden,[2]Uppsala University/Lokon Pharma AB, Uppsala, Sweden,[3]Lokon Pharma AB, Uppsala, Sweden*

In the LOKON002 phase I/II clinical trial (NCT03225989), therapy with LOAd703 (delolimogene mupadenorepvec) is investigated in combination with gemcitabine-based chemotherapy in patients with advanced cancer. LOAd703 is an immunostimulatory gene therapy utilizing an oncolytic adenovirus that is engineered to express two transgenes (trimerized membrane-bound CD40L (TMZ-CD40L) and 4-1BBL), which are key players in the induction of an anti-tumor immune response. Herein, we present the preliminary immunological evaluation of the first 27 patients enrolled in the trial. The primary tumor was pancreatic cancer (n=16), colorectal cancer (n=5), ovarian cancer (n=3) or biliary cancer (n=3). Patients received a maximum of eight intratumoral LOAd703 treatments, given biweekly, and chemotherapy was administered at the same time according to standard protocol. Matched tumor biopsies from the injected tumor lesion were taken at baseline and after six LOAd703 treatments, and analyzed for gene expression with nCounter® PanCancer Immune Profiling Panel from NanoString (n=12; 7 patients analyzed so far). Blood samples were collected for isolation of serum samples and peripheral blood mononuclear cells, and these were analyzed with multiplex assays (Meso Scale Diagnostics) (n=15) and flow cytometry (n=27), respectively. Preliminary results indicate that after treatment, most tumors displayed a strong inflammatory profile with an upregulation of gene profiles, which have been shown to predict responses to immune checkpoint inhibitor therapy (T cell inflamed profile (Ayers et al.) & T effector and IFNγ associated profile (Fehrenbacher et al.)). We also noted an upregulation of genes connected to dendritic cell activation and antigen presentation (MHC class I and II, CD80, CD86, TAP1/2), as well as adenoviral-response genes. Moreover, we observed systemic treatment effects after three LOAd703 treatments, as shown by an increase in serum levels

of pro-inflammatory cytokines and chemokines (IFNγ, IL-15, CXCL10, CCL2, IL-8, IL-6), as well as an increased percentage of CD8+ effector memory T cells (CD45RA-CCR7-) and PD-1+ CD8+ T cells in the blood. The fractions of natural killer (NK) cells (CD14-CD3-CD56+CD16+) and M2-like macrophages (CD11b+CD163+) were reduced in the blood at that time point. In conclusion, LOAd703 therapy in combination with chemotherapy generated an inflamed tumor microenvironment in tumors that are normally seen as immunologically "cold". Hence, LOAd703 may be able to prime tumors for immune checkpoint inhibitors or other immunotherapies, such as adoptive T or NK cell transfer.

Comprehensive immunoprofiling of peripheral blood reveals five conserved immunotypes with implications for immunotherapy in cancer patients

Daniiar Dyikanov, Iris Wang, Tatiana Vasileva, Polina Shpudeiko, Polina Turova, Arseniy A. Sokolov, Olga Golubeva, Evgenii Tikhonov, Anna Kamysheva, Ilya Krauz, Mary Abdou, Madison Chasse, Tori Conroy, Nicholas R. Merriam, Boris Shpak, Anastasia Radko, Anastasiia Kilina, Lira Nigmatullina, Linda Balabanian, Christopher J. H. Davitt, Alexander A. Ryabykh, Olga Kudryashova, Cagdas Tazearslan, Ravshan Ataullakhanov, Alexander Bagaev, Aleksandr Zaitsev, Nathan Fowler, Michael F. Goldberg. *BostonGene, Corp., Waltham, MA*

Recent advances in immunotherapy demonstrate the need to further understand the characteristics of an individual cancer patient's immune system and how it influences responses to cancer treatment. Here, we developed an immunoprofiling platform to evaluate the features in the blood of cancer patients to test the hypothesis that peripheral immune cell heterogeneity could be used to stratify these patients into different categories or immunotypes to monitor disease progression and treatment response.
To that end, we established a unique diagnostic immunoprofiling assay and analytical framework based on the analysis of leukocytes in the peripheral blood using multiparameter flow cytometry. Supervised manual gating of flow cytometry data from a cohort of 50 healthy donors identified 415 cell types and immune activation states that were used to train and later independently validate machine learning models to automatically identify immune cell subsets from raw cytometry data. By applying this tool to peripheral blood samples from a mixed cohort of 299 healthy donors and 323 cancer patients, we developed a machine-learning classification model that can differentiate between these two groups with 93% accuracy. This model was further refined using spectral clustering with bootstrapping, revealing 5 clusters, or immunotypes, characterized by specific physiological immune profiles: (1) Myeloid-derived suppressor/NK cell, (2) Terminally-differentiated $CD8^+$ T cells, (3) Mixed $CD4^+$ T helper cells, (4) $CD4^+$ Th1 & $CD8^+$ T cell memory, and (5) Naive T and B lymphocytes. Interestingly, very few healthy donors could be found in clusters 1 and 2 but were assigned most frequently to cluster 5. Matched RNA-seq was used to further validate these profiles using the cellular deconvolution algorithm, Kassandra, and differential gene expression analysis revealed immunotype-specific signatures that are consistent with immune response potential. Patients in the terminally-differentiated $CD8^+$ T cell cluster had a narrower range of HLA-types than the other clusters, and TCR repertoire analysis indicated significantly increased clonality and reduced clonotype diversity. Within this cluster there was a high degree of overlap between TCR sequences in the peripheral blood and the tumor, indicating a relationship between peripheral blood immunotype and tumor infiltration. Altogether, the establishment of these immunotypes using peripheral blood immunoprofiling represents a promising signature that can be used to identify and stratify cancer patients that will benefit from immune-based therapies.

A spatiotemporal cell atlas of human gastric malignancy reveals mechanisms underlying metastasis and immunotherapy response

Yikai Luo[1], Muxing Kang[2], Wei Liu[3], Shiping Jiao[4], Lie Wang[2], Jian Chen[2], Han Liang[3]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Zhejiang University School of Medicine, Hangzhou, China,[3]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[4]The Affiliated Hospital of Nanjing University Medical School, Nanjing, China*

Cellular heterogeneity in the tumor immune microenvironment (TIME) of gastric cancer (GC) is progressively molded in pre- and early-malignant lesions and has a profound impact on disease progression and responses to therapeutics, in particular those based on immune checkpoint blockade (ICB). To date, no study has been conducted to characterize the single-cell kinetics of tumor-infiltrating immune populations in gastric cancer

patients treated with ICB. Here, we generated for the first time single-cell RNA sequencing (scRNA-seq) and TCR sequencing (scTCR-seq) profiles of ICB-treated primary GC tumors, as well as liver and ovary metastases. When integrated with public scRNA-seq datasets, our data capture a full trajectory of GC malignancy comprising more than 300,000 cells derived from 73 samples. We further performed bulk TCR-seq, cytometry by time of flight (CyTOF), and multiplex immunofluorescence (mxIF) on independent GC samples to orthogonally validate the key observations from the scRNA-seq cohort and unbiasedly search for more in-depth and spatial-relationship-focused features of ICB-responsive immune populations. Built upon this multi-omic atlas of GC cell states, we identified remarkable transformation of the abundance and clonal dynamics of distinct immune populations and their population-specific transcriptional programs. Most importantly, we observed the rejuvenation of exhausted CD8+ T cells induced by anti-PD-1 treatment, which is associated with the enhanced immunogenicity of gastric cancer cells. In addition, we found the enrichment of NK-like terminally differentiated CD8+ T cells in metastases independent of migration destinations. Our single-cell ICB-perturbed spatiotemporal GC landscape reveals how neoadjuvant checkpoint blockade induces local and systemic tumor immunity. As a cellular and molecular reference, it also enables high-resolution interpretation of future single-cell omics data in gastric cancer that may be masked by de novo analysis.

Multispectral imaging to detect immune phenotypes in pre and post therapy breast cancer patient specimens

Bhavika Patel, Stephanie Allen, Brenna Dennison, Jacob Stapleton, Roni Archuleta, Mary Lou Rath, Navi Mehra, Sameer S. Talwalkar. *Lanterne Dx, Broomfield, CO*

The immune microenvironment is an important component in cancer therapy. Immune cells can encourage tumor growth, leading to disease progression. A high number of immune cells may be predictive of disease prognosis and response to therapies. Therefore, understanding the immune cell phenotypes present within cancerous tissue can be valuable in developing strategies that aid in the treatment of cancer. In this study, we analyzed pre-and post-therapy samples from breast cancer patients, treated with neoadjuvant chemotherapy, using a 6-plex immunofluorescence assay which included clinically relevant immuno-oncology biomarkers (FoxP3, PD-L1, PanCK, CD4, CD8 and CD163). This assay was developed and optimized in-house prior to testing the cohort. Endpoints for this analysis were characterization of the tumor microenvironment and analysis of the individual immune cell subsets pre and post treatment. Staining was completed on the Leica Bond RX autostainer (Leica Biosystems) and slides were scanned using the PhenoImager™ Fusion (Akoya Biosciences). Using Visiopharm® software, the multiplex phenotyping module was used to analyze the high dimensional human tissue and cell phenotypes were detected using artificial intelligence. Qualitative and quantitative results revealed a change in immune cell phenotypes between pre- and post-therapy samples. These included an increase in intra-tumoral and stromal T cells, no significant difference in PD-L1 positive cells, and an increase in the FOXP3 positive T cells in post-treatment samples. Our data provides insights into the development and application of multispectral imaging for characterization of tumor microenvironment and its dynamics before and after treatment in breast cancer. This can be applied to other cancer types and can aid in making treatment decisions.

Pan-cancer assessment of tumour and peripheral T-cell receptor repertoire dynamics in patients treated with immune checkpoint inhibitors

Shirin Soleimani[1], Ben X. Wang[2], Stephanie Pedersen[2], Jenna Eagles[2], Jacob Brick[2], Marcus O. Butler[3], Scott V. Bratman[2], Lillian L. Siu[3], Pamela S. Ohashi[2], Trevor J. Pugh[2]. *[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, Toronto, ON, Canada,[3]Division of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Introduction: Clinical benefit from Immune Checkpoint Blockade (ICB) is a function of local T-cell specificity for tumor-associated antigens. However, overcoming local T-cell dysfunction necessitates systemic immunity engagement. Therefore, studying the dynamics of both local and peripheral T-cell repertoires in response to ICB is required to identify features of T-cell repertoires associated with pathological response.
Methods: We conducted TCRβ-sequencing on tumor-residing T-cells (n=59), Peripheral Blood Mononuclear Cells (PBMCs) (n=306) and cell-free DNA (cfDNA) (n=73) from pre- and multiple on-ICB timepoints collected from patients enrolled in the pan-cancer INvestigator-initiated Phase II Study of Pembrolizumab Immunological Response Evaluation (INSPIRE; NCT02644369) trial. To assess specificity-agnostic shifts in TCR repertoires, we

first compared TCR diversity and clonal expansion in longitudinal tumor and PBMC samples. Then, to temporally track the specificity-associated features of local and systemic TCR repertoires, we leveraged a Graph Neural Network (GNN) model that took in unique TCRβ chains as nodes. The connectivity between the nodes was defined by multi-relational edges that represented VJ-gene usage and GLIPHII-identified (Grouping Lymphocyte Interactions by Paratope Hotspots) specificities derived from a compendium of TCR sequences with empirically confirmed specificities. **Results:** While absolute diversity and clonal expansion values in baseline tumor (n=33) were not associated with response to ICB, changes in these values were informative between pre- and on-ICB tumors. All patients (n=4) with low baseline tumor TCR diversity and lack of clonotypic re-structuring in tumor TCR repertoire on-ICB had either progressive or short-term stable disease. Furthermore, pairwise comparison of pre- and on-ICB tumors for each patient (n=17) revealed that all the patients, irrespective of their pathological response, experienced emergence of new TCR clonotypes (i.e., clonal replacement) in response to ICB, suggesting only a minority of these TCRs might consist of tumor-associated clonotypes. Patients with clinical benefit also had higher degree of GLIPHII-identified clustering at baseline tumor, highlighting the role of both specificity-agnostic and specificity-centric TCR analysis in determining the response to ICB. Analysis of TCR sequences in blood plasma found cfDNA contains a small number of TCR sequences (median 32, range 12-89) enriched for TCRs found in matched tumor tissues, suggesting that cfDNA TCR repertoire may provide an indirect measurement of tumor-residing T-cells.
Conclusions: TCR diversity and functional clonal annotation are emerging biomarkers of ICB response and cfDNA TCR repertoire can potentially be exploited for clinical diagnostics and monitoring.

#6668

Immune infiltrate co-occurrence and neoantigen similarity are prognostic factors in early stage NSCLC

Martina M. Sykora[1], Jason Pugh[2], Bailiang Li[2], Finn O. Mildner[1], Hubert Hackl[3], Arno Amann[1], Fabienne I. Nocera[1], Rachel M. Pyke[2], Lee McDaniel[2], Charles W. Abbott[2], Sean M. Boyle[2], Richard O. Chen[2], Dominik Wolf[1], Sieghart Sopper[1], Gabriele Gamerith[1]. *[1]Internal Medicine V, Hematology and Oncology, Medical University of Innsbruck, Innsbruck, Austria,[2]Personalis Inc, Menlo Park, CA,[3]Medical University of Innsbruck, Innsbruck, Austria*

The prevalence of early-stage non-small cell lung cancer (NSCLC) with curative treatment options is expected to increase with recent implementation of annual screening programs. Predictors and molecular drivers of disease relapse, especially the role of intra-tumoral immune dysfunction, remains unclear but critical for the refinement of therapeutic decisions. By leveraging a comprehensive individual portrait of each patient's immune system potential novel mechanisms associated with tumor relapse in early-stage NSCLC may be identified. We profiled 11 non-relapsed (at least 2 year FU) lung adenocarcinoma patients and 11 covariate-matched (gender, age, stage) relapsed patients, who underwent curative treatment in stage IA-IIIB disease. We used NeXT Summit^{TM} for variant and CNA calling, gene expression quantification, neoantigen prediction, HLA profiling (typing, mutation, and loss of heterozygosity), T-cell receptor and tumor microenvironment (TME) profiling. Neoantigen peptide sequences were subjected to further filtering and clustering based on between-patient similarity scores, with the goal of identifying shared clusters of relapse-associated neoantigens in each possible pair of patients. Differential network analyses were applied to the TME composition estimates to investigate relapse-associated patterns of cellular co-occurrence and interaction. When considering neoantigens selected on the basis of similarity, we found that those belonging to non-relapsed patients had significantly lower HLA binding rank (17.8 points) compared to that of relapsed patients ($P=0.02$), indicating weaker binding for relapsed cases. Clustering of both the most similar and frequently shared neoantigens correlated with relapse ($P < 0.002$). In the TME, we observed differential immune cell co-occurrence associated with relapse status, such as Tregs are positively correlated with B and CD4 T cells only in relapsed patients (Pearson's $R=0.7$ and 0.74, both $P<0.02$ vs. $R=0.18$ and 0.35, both $P>0.2$ in non-relapsed patients), indicating suppressive anti-tumor immunity. Relapsed patients did not share significant enrichment of mutations in any biological pathway. Surprisingly, mutation purity (less mutations than expected by chance) was observed in relapsed patients, suggesting selective killing and escape. In this pilot cohort, we used an integrated platform to broadly characterize both the tumor and immune system, enabling identification of relapse-associated neoantigens that may share universal features which enhance HLA binding. Relapses in early-stage LUAD patients were associated with neoantigens with lower immunogenicity and an immunosuppressive TME. These findings demonstrate that deeper profiling of shared neoantigen features has the potential to become an early biomarker of relapse, informing patient therapy selection and surveillance.

#6669

Antigen features are associated with response and survival after neoadjuvant chemo-immunotherapy for muscle-invasive bladder cancer

Wolfgang Beckabir, Steven Vensko, Alec Wilkinson, Gatphan Atassi, Mi Zhou, Kenneth Fowler, Leah Flick, Hsing-Hui Wang, Mark Woodcock, Karen McKinnon, Jonathan Serody, Tracy Rose, Matthew Milowsky, William Kim, Benjamin Vincent. *UNC-Chapel Hill, Chapel Hill, NC*

In the Phase II LCCC1520 trial, neoadjuvant chemo-immunotherapy (pembrolizumab with gemcitabine plus cisplatin) induced response in 22 of 39 muscle-invasive bladder cancer patients[1]. In this correlative analysis, we identify molecular features associated with response and survival. Associations of molecular subtype, TMB, and antigen presentation and immune checkpoint gene expression with response and survival were evaluated pre-and post-treatment. Neoantigens were predicted in 4 immuno-oncology data sets (LCCC1520, IMvigor210 cohorts 1[2] and 2[3], and Hugo[4]) using Landscape of Effective Neoantigens Software[5]. Effective neoantigen count (ENC) was calculated by binning predicted neoantigens by expression, binding affinity, binding stability, and tumor PD-1 and PD-L1 expression, then identifying the bin in which neoantigen count was most strongly associated with response in the discovery set. Using elastic net modeling with 10-fold cross-validation, survival was predicted from immune gene signature expression, clinical variables, TMB and ENC. Response was associated with pre-treatment molecular subtype and immune checkpoint expression. Pre-treatment ENC was associated with response in Hugo (discovery set, p = 0.020) and the three validation sets (p = 0.011, 0.042, 0.049). The final elastic net model (Cox P-H p = 5.6e-5) predicted survival significantly better than TMB (p = 0.055) or ENC (p = 0.141) alone. Post-treatment antigen presentation gene expression was associated with survival among non-responders. We identify pre-and post-treatment features associated with response and survival in the LCCC1520 trial and propose that tumor antigen presentation is a major driver of neoadjuvant chemo-immunotherapy outcomes. *[1] Rose JCO 2022 [2] Balar Lancet 2017 [3] Mariathasan Nature 2018 [4] Hugo Cell 2016 [5] Vensko bioRxiv 2022*

Association between circulating CD4 memory T cell levels and severe immune-related adverse events in melanoma patients treated with immune checkpoint blockade

Abul Usmani[1], Noah Earland[1], Wubing Zhang[2], Peter K. Harris[1], Antonietta Bacchiocchi[3], Aishwarya Nene[3], David Y. Chen[1], Mario Sznol[3], Ruth Halaban[3], Aaron M. Newman[2], Aadel A. Chaudhuri[1]. *[1]Washington University in St. Louis, St. Louis, MO,[2]Stanford University, Stanford, CA,[3]Yale University School of Medicine, New Haven, CT*

Introduction: Severe immune-related adverse events (irAEs) occur in up to 60% of melanoma patients treated with immune checkpoint inhibitors (ICIs), causing substantial treatment-related morbidity and in the most severe cases, death. There is no clinical assay to predict who will develop severe ICI-induced irAEs and who will not. Using single-cell profiling assays applied to a retrospective melanoma cohort treated with ICIs, we recently showed that higher baseline levels of circulating CD4 effector memory T (TEM) cells were associated with severe irAE development, independent of the affected organ system (Lozano et al. *Nature Medicine*, 2022). As part of a prospective validation study of 100 melanoma patients, here we report our initial findings on the first 24 patients accrued to date.

Methods: We prospectively collected pre-ICI blood from 24 metastatic melanoma patients from two academic medical centers from February 2021 onward. Peripheral blood was collected pre-treatment on the day of immunotherapy (cycle 1 day 1). We then isolated peripheral blood mononuclear cells (PBMCs) and applied mass cytometry by time of flight (CyTOF) to profile 38 leukocyte markers including markers specific to CD4 TEM cells. Cellular subpopulations were quantified using Cytobank v9. Patients underwent routine medical oncology follow-up during and after ICI treatment including grading of irAEs using the Common Terminology Criteria for Adverse Events v5.

Results: Median follow-up time after pre-ICI blood collection was 9.1 months (range 2.6-18.5). Fifteen (63%) patients received combination (anti-PD1 / anti-CTLA4) ICIs while the remainder received anti-PD1 monotherapy. Eight patients developed severe (grade 3+) irAEs at a median of 8.5 weeks (range 4-21) after treatment initiation, including 4 who developed life-threatening (grade 4) irAEs. Severe and life-threatening irAE development spanned 9 separate organ systems, most commonly gastrointestinal, dermatological, and hepatic. Using CyTOF, we found that circulating CD4 TEM cells were more abundant in patients who developed severe irAEs compared to those who did not ($P = 0.01$; AUC = 0.81), irrespective of the involved organ systems. Moreover, median-

splitting the patient cohort into two groups based on pretreatment CD4 TEM levels revealed that patients with low CD4 TEMs had significantly longer freedom from severe irAE than those with high CD4 TEMs (not reached vs. 4.6 months; $P = 0.013$; HR = 6.7). There was no significant difference in pretreatment CD4 TEM levels between patients with and without durable clinical benefit to ICIs ($P = 0.75$).
Conclusion: Circulating CD4 TEM levels measured by CyTOF were associated with severe irAE development, independent of response status, in patients with advanced melanoma. These findings could form the basis for pretreatment ICI risk stratification in the future.

Simplifying high-parameter phenotypic and functional characterization of cancer immune cells
Deeqa Mahamed, Michael Cohen, Stephen Li, Lauren Tracey, Huihui Yao, Christina Loh, Leslie Fung. *Standard BioTools, Markham, ON, Canada*

Interrogating immune cell composition and function in patients with cancer is critical for making disease prognoses, monitoring clinical efficacy of tumor immunotherapies, identifying novel therapeutic targets, and discovering predictive biomarkers of disease. Both the adaptive and innate arms of the immune system play important roles in generating pro- or anti-tumor milieus. In particular, natural killer (NK) cells are gaining increasing attention as potential cell-based therapies in immuno-oncology, including in adoptive transfer of chimeric antigen receptor (CAR) and iPSC-derived NK cells or off-the-shelf NK cell lines to target multiple myeloma. Since NK cells can also indirectly impact CAR T cell or antibody-based immunotherapies, characterizing these cells using optimized and reproducible assays is critical. CyTOF® is a high-plex flow cytometry technology that exploits metal-isotope-tagged antibodies to probe cellular phenotypes and functions. In contrast to fluorescence-based conventional and spectral flow cytometry, CyTOF experimental workflows are streamlined as autofluorescence is not an issue and signal spillover is minimal, allowing rapid design and application of 40-plus-marker panels. To expand on the increasing clinical and preclinical utility of the 30-marker Maxpar® Direct™ Immune Profiling Assay™ (Maxpar Direct Assay), we developed nine add-on Expansion Panels for deeper phenotyping of specific cell types and activation states, including panels designed to characterize *ex vivo* and activated myeloid cells, T cells, and NK cells. Peripheral blood mononuclear cells from healthy donors and donors with multiple myeloma were stimulated *in vitro*, then stained in the 30-antibody Maxpar Direct Assay tube with the NK Cell Expansion Panel (CD181, NKp30, NKp46, PD-1, NKG2A, ICOS, and TIGIT) or the T Cell Panel 3 (OX40, TIGIT, CD69, PD-1, Tim-3, ICOS, and 4-1BB) as drop-in antibodies. Surface staining was followed by intracellular staining with the Basic Activation Expansion Panel antibodies (IL-2, TNFα, IFNγ, perforin, granzyme B) after cell fixation and permeabilization. Anti-CD107a was added during stimulation to measure degranulation. Samples were acquired on a CyTOF XT™ instrument in automated batch acquisition mode. Automated analysis was performed with Maxpar Pathsetter™ software to enumerate immune cell types and quantify marker expression. In addition to the 37 populations identified by Pathsetter with the base Maxpar Direct Assay, the new Expansion Panels allowed deeper profiling of NK and T cells, while the Basic Activation Panel revealed their cytokine responsiveness and cytotoxic potential. Thus, the optimized single-tube Maxpar Direct Assay is a powerful tool that can be further expanded and customized with predefined panels or antibodies to comprehensively study immune cells in health and disease.

#6673
Simultaneous detection of IGH VDJ rearrangements and JH translocations via Ring-Seq, a novel multiplex PCR technology for targeted sequencing of translocations with novel gene partners or breakpoints
Shannon Owens, Katherine Fichter, Richard Que, Sabrina Shore, Timothy Looney. *Singular Genomics, San Diego, CA*

Introduction: Next-generation sequencing (NGS) of B cell receptor rearrangements is a leading method for clonality assessment and measurable residual disease (MRD) monitoring of B cell malignancies. Current methods rely upon multiplex PCR (mPCR) amplification of rearranged IGH, IGK or IGL loci via variable and joining gene targeting primers followed by NGS to assess rearrangements. Limitations include a need for reflex testing owing to somatic hypermutation (SHM) mediated loss of sensitivity and an inability to detect clinically relevant translocations of the IGH locus. Here we apply Ring-Seq, a novel technology for the targeted detection gene fusions with unknown partners, to simultaneously detect IGH VDJ rearrangements and translocations in a single

reaction. We demonstrate detection of clinically relevant translocations and VDJ rearrangements from highly degraded gDNA.
Methods: The method begins with a highly efficient circularization of DNA fragments followed by a multiplex inverse PCR of joining genes that preferentially amplifies breakpoint junction containing templates. Amplicon libraries are sequenced on the G4 platform and analyzed to detect translocations and VDJ rearrangements. We pooled gDNA from reference cell lines harboring marker IGH VDJ rearrangements and BCL1/2-JH translocations. Pooled reference gDNA was spiked into a background of healthy donor PBL gDNA to evaluate performance over a range of marker frequencies. To simulate performance with degraded materials, gDNA input was fragmented to ~200bp by sonication prior to analysis.
Results: BCL1-JH and BCL2-JH translocations and marker IGH VDJ rearrangements were detected from 50ng pooled reference gDNA. Translocations and marker VDJ rearrangements were also detected in 50ng samples consisting of reference gDNA spiked at 10% and 1% frequency into a background of healthy donor PBL gDNA. Sequencing of healthy donor PBL gDNA yielded IGH repertoire features that were highly concordant with results obtained from BIOMED-2 mPCR analysis of the same samples.
Conclusions: We have applied Ring-Seq to enable the simultaneous detection of B cell receptor rearrangements and JH translocations relevant to the diagnosis of MCL and FL while minimizing loss of sensitivity owing to SHM. Traditional mPCR often fails to detect JH translocations owing to variation in the breakpoint region. Consequently, suspected MCL and FL diagnostic samples are assessed for translocations by FISH, while separate material is submitted for NGS-based VDJ clonality analysis via traditional mPCR. Ring-Seq may streamline this process by consolidating separate tests into a single rapid NGS assay for the G4 platform. Looking ahead, we envision broad applicability of the technology to mPCR-based variant detection.

Integration of associations of immune profiles in peripheral blood and tumor microenvironment with bladder cancer outcomes

Ji-Qing Chen[1], Lucas A. Salas[1], John K. Wiencke[2], Devin C. Koestler[3], Annette M. Molinaro[2], Angeline S. Andrew[4], John D. Seigne[5], Margaret R. Karagas[1], Karl T. Kelsey[6], Brock C. Christensen[1]. *[1]Epidemiology, Dartmouth College, Hanover, NH,[2]Neurological Surgery, University of California San Francisco, San Francisco, CA,[3]Biostatistics & Data Science, University of Kansas Medical Center, Kansas City, KS,[4]Neurology, Dartmouth College, Hanover, NH,[5]Surgery, Dartmouth College, Hanover, NH,[6]Epidemiology and Pathology and Laboratory Medicine, Brown University, Providence, RI*

Immune cell profiles in peripheral blood have been associated with bladder cancer outcomes, however, their association with response to immunotherapy and the tumor microenvironment is a major unresolved issue. Although tumor growth can be attenuated via the activation of tumor-infiltrating effector T cells, the relationship between tumor infiltration and immune activation remains unclear. This study explored the interaction between bladder cancer outcomes and immune profiles within peripheral blood and a tumor microenvironment (TME) based on DNA methylation profiles. Peripheral blood and the matched tumor FFPE DNA methylation profiles of 60 non-muscle-invasive bladder cancer (NMIBC) and 12 muscle-invasive bladder cancer (MIBC) patients. Cell-type deconvolution approaches were applied to estimate 12 peripheral immune cell-type proportions and 17 cell-type proportions within TME. We found a positive correlation between dendritic cell proportions in the TME with peripheral CD8T memory cell proportions ($r = 0.35$, $P = 0.003$) and a negative correlation between dendritic cell proportions in the TME with peripheral regulatory T cell proportions ($r = -0.28$, $P = 0.021$). In addition, monocyte cell proportions in TME had a positive correlation with peripheral B memory ($r = 0.37$, $P = 0.002$) and CD8T memory cell proportions ($r = 0.43$, $P = 0.0002$). To investigate associations of bladder cancer outcomes with immune cell profiles, using Cox proportional hazard models, we observed an association between the fraction of dendritic cells and the hazard of death (HR = 1.27, 95% CI = 1.06-1.53). Further, a high endothelial cell proportion was significantly associated with an increased hazard of death and tumor recurrence (HR = 1.06, 95% CI = 1.01-1.13) in TME. In addition, the peripheral neutrophil-to-lymphocyte ratio (HR = 1.49, 95% CI = 1.01-2.22), monocyte (HR = 1.17, 95% CI = 1.05-1.31), neutrophil (HR = 1.04, 95% CI = 1.01-1.07), and basophil (HR = 1.35, 95% CI = 1.01-1.81) cell proportions were associated with an increased hazard of death and tumor recurrence. Our results integrated the information on bladder cancer outcomes and cell profiles in TME and peripheral blood, providing biomarkers for estimating bladder cancer prognosis using genome-scale DNA methylation measures.

Exploratory biomarker analyses in phase 1 study of regorafenib, ipilimumab, and nivolumab (RIN) in chemotherapy resistant microsatellite stable (MSS) metastatic colorectal cancer (mCRC)

Jian Ye[1], Chongkai Wang[2], Colt Egelston[1], Weihua Guo[1], Peter P. Lee[1], Marwan Fakih[2]. *[1]Beckman Research Institute of the City of Hope, Duarte, CA,[2]City of Hope National Medical Center, Duarte, CA*

Background: We recently reported an objective response rate of 36.4% in a phase I trial of RIN in MSS mCRC patients without liver metastases, while no response was noted in patients with liver metastases. Here we characterized kinetics in local and systemic immune responses associated with clinical outcomes, liver metastasis, and immune related toxicity during RIN treatment.
Methods: Patients with chemotherapy-resistant MSS mCRC received RIN at (R) at 80 mg QD x 21 days in 4-week(w) cycle, (I) at 1mg/kg Q6w and (N) at 240 mg Q 2w (n=29). Needle biopsies were collected at baseline (n=8) and 4 weeks (n=6) after treatment. Blood samples were collected at baseline (n=29), 4 weeks (n=29) and 8 weeks (n=25) after treatment. Alterations in the tumor microenvironment (TME) were characterized by RNA sequencing. We analyzed the immune cell composition and activities in the blood, including 90 subpopulations of leukocytes and 29 activation/suppression/proliferation markers, with high-dimensional spectral flow cytometry.
Results: The clinical responses are positively correlated with the induction of local anti-tumor immunity. Patients with better clinical outcomes exhibited higher levels of lymphocyte infiltration, chemokine production, and antigen-presentation potential in the local TME following one cycle of RIN treatment. The duration of progression-free survival (PFS) was correlated with a higher baseline STING signal in the TME. In the peripheral blood, the responders have more circulating CD4 T cells, B cells, and cDC1, while expressing lower immune activation markers, especially in T cells with type 1 immunity at baseline. At 4 weeks, immune activation and proliferation markers were higher in responders than non-responders. Interestingly, immune effectors (non-Tregs, $CD45RA^-$ CD8 T cells, NKT cells, and M1 monocytes) in the blood were proportionally reduced in responders at 4 weeks, coincident with their enrichment in the local TME. We also compared peripheral immune signatures between patients with and without liver metastases, liver metastases (n=7) were associated with a significantly lower ratio of CD4/CD8 T cells in the blood, a phenomenon of immunosenescence, both at baseline and after RIN treatment. Lastly, the occurrence of immune-related toxicities was closely correlated with the induction of immune activities in both acellular and cellular components in the circulation.
Conclusions: Clinical benefit of RIN was correlated to more robust immune activation of the TME and peripheral blood following one cycle of treatment. A higher baseline STING signal in the TME was associated with longer PFS. Liver metastasis was associated with a lower ratio of peripheral CD4/CD8 T cells which may contribute to the resistance to immunotherapy in those patients.

Preliminary immune correlatives from BCA101 trial show favorable modulation of tumor immune microenvironment

Patrick H. Lizotte[1], Paul Paik[2], Liviu Niculescu[3], Seng-Lai H. Tan[3], David Bohr[3], Elham Gharakhani[3], Ralf Reiners[3], Rachel Salazar[3], Avanish Varshney[3], Shiv Ram Krishn[4], Pradip Nair[4], Cloud Paweletz[1]. *[1]Dana-Farber Cancer Institute, Boston, MA,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Bicara Therapeutics, Cambridge, MA,[4]Syngene International Limited Biocon, Bangalore, India*

Background: BCA101 is a bispecific antibody targeting EGFR and TGF-β. TGF-β pathway activation is a hallmark of human immune-excluded tumors, and TGF-β expression is associated with resistance to anti-PD-1 blockade. Neutralization of TGF-β removes an immunosuppressive signal that drives accumulation and polarization of myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAMs) in solid tumors, while EGFR inhibition targets tumor cell-intrinsic oncogenic signaling. Co-targeting of EGFR and TGF-β directly impacts tumor progression while enhancing the immunogenicity of tumors.
Methods: Patients with multiple solid tumor types (CRC, pancreatic, HNSCC, SqNSCLC, and others) were treated with escalating doses of either single agent BCA101 or in combination with anti-PD-1 (pembrolizumab) enrolled on NCT04429542 trial. We performed a variety of immune correlatives on pre- and on-treatment tumor biopsies, including Nanostring-based transcriptomic profiling and IHC for immunophenotypic markers, as well as multiparametric flow cytometric profiling of circulating PBMCs.
Results: Our preliminary evidence suggests that neutralization of TGF-β positively alters the systemic immune state (PBMCs) and tumor immune phenotype (mRNA, IHC). Circulating HLA-DR+ monocytes were significantly

increased in on-treatment PBMC samples relative to screening. Pathway analysis of on-treatment tumor biopsies revealed enhanced costimulatory signaling, cytokine and chemokine signaling, immune infiltration, and interferon signaling. Top differentially regulated genes in on-treatment biopsies included CCL21, CXCL9, CXCL11, and CXCL13, which recruit T and NK cells. HDAC11, which negative regulates type-I interferon signaling, was significantly reduced in on-treatment biopsies. Notably, two patients with EGFR-amplified squamous non-small cell lung cancer, who both progressed on first-line immunotherapy treatment, were treated with BCA101 at 1250 mg and 1500 mg qw and achieved a partial response (ongoing for 10 months at the time of the data cutoff) and a prolonged stable disease for 11 months, respectively. They exhibited increased CD8+ T cell infiltration and a reduction in TAMs following treatment.
Conclusions: Increased abundance of circulating HLA-DR+ monocytes following treatment indicated polarization towards a more positive, Th1-like systemic immune state. We observed enhanced immunogenicity of tumors as assessed by a targeted IO transcriptomic analysis. The results of the pathway analysis were supported by IHC on post-treatment biopsies from a subsequent cohort showing enhanced CD8+ T cell infiltration and stable, or reduced expression of TAM marker CD163. These results indicate that neutralization of TGF-β induces a more permissive tumor immune microenvironment.

XNA increases assay sensitivity in sanger sequencing, qPCR, NGS and CRISPR mutant screening
Wei Liu, Robert Brown, Andrew Fu, Shuo Shen, Michael Sha, Aiguo Zhang. *DiaCarta, Pleasanton, CA*

The proprietary XNA (xeno nucleic acid) technology has wide applications in sensitive detection of rare mutations in different genomic platforms. These target-specific DNA oligo analogs increase assay sensitivity by blocking the polymerase-dependent amplification of wildtype sequence so only amplification of the mutant sequence occurs. Here we show that the XNA technology helps enrich rare somatic mutations in different human specimen types such as FFPE and plasma samples, using technology platforms such as Sanger sequencing, TaqMan qPCR, and NGS. XNA increases assay sensitivity to 0.1% for Sanger sequencing and qPCR. For NGS, XNA allows detection of the mutant sequence at a lower sequencing depth, thus combining XNA technology with NGS for MRD (molecular residual disease) detection could improve cancer management. In addition, We also show CRISPR mutant screening using a target-specific XNA in a SYBR Green qPCR assay. XNA can be used for rapid CRISPR mutant screening for DNA from pool or individual clones generated from gene editing experiments. In summary, XNA technology is a powerful tool when combined with existing genomic mutation detection platforms to screen for rare somatic mutations and for rapid CRISPR mutant screening. The technology is customizable as a service for easy integration with current technology platforms and applications.

A patient-specific, tumor-informed, circulating tumor DNA (ctDNA)-based minimal residual disease (MRD) assay in surgical patients with biliary tract cancer
Tianqiang Song, Qiang Wu, Yunlong Cui, Huikai Li, Wei Zhang, Feng Fang, Qingqing Xiong. *Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: Biliary tract cancer (BTC) refers to malignancies arising from the bile ducts, gallbladder, and ampulla of Vater. ctDNA-based MRD testing has shown promise in identifying surgical patients at high risk of recurrence, although there is a paucity of evidence on its utility in BTC. In this study, we prospectively evaluated the performance of Burning Rock Patient-specific pROgnostic and Potential tHErapeutic marker Tracking (brPROPHET), a patient-specific, tumor-informed MRD assay.
Methods: Surgical specimens and two serial blood biopsies (before and approximately 4 weeks after surgery) were collected. The brPROPHET MRD assay (Burning Rock Biotech, China) uses whole exome sequencing for detecting patient-specific somatic alterations from tumor tissues and for blood a personalized panel designed to target up to 50 variants. For head-to-head comparison, the samples were also subjected to a tumor-informed, fixed-panel assay using 520- and 168-gene panels respectively for tumor and blood samples.
Results: A total of 17 patients were analyzed. Most were men (11, 64.7%), had extrahepatic cholangiocarcinomas (13, 76.5%), or stage II disease (15, 88.2%). Median age was 64 years (range 57-68). Disease-free survival (DFS) was available for 14 patients at a median follow-up of 11.5 months (range 6.5-16.0). Baseline and postoperative ctDNA positivity rates were 64.7% (11/17) and 11.8% (2/17) with brPROPHET and 17.7% (3/17) and 5.8% (1/17)

with the fixed-panel assay using 520- and 168-gene panels. Moreover, of the 3 patients who have relapsed, 1 was postoperatively ctDNA-positive by both assays and 1 only by brPROPHET. These findings suggested superior technical sensitivity of patient-specific over fixed-panel approach in detecting tumor-associated aberrations, and this advantage could translate into more sensitive identification of surgical BTC patients at high risk of recurrence. Furthermore, ctDNA positivity determined brPROPHET by was significantly associated with shorter DFS (log-rank p = 0.003), while that by fixed-panel was not (log-rank p = 0.113), suggesting a stronger association between the patient-specific approach with clinical outcomes. brPROPHET-derived postoperative ctDNA positivity also showed higher negative predictive value (91.7% vs 84.6%) and accuracy (92.9% vs 85.7%) in predicting recurrence. Together, these results supported a better performance of brPROPHET than the fixed panel approach for MRD detection.
Conclusions: This prospective study demonstrated the clinical performance of brPROPHET, a patient-specific tumor-informed ctDNA-based MRD test for surgical patients with BTC. Compared with the fixed-panel approach using 520- and 168-gene panels respectively for tumor and blood samples, brPROPHET yields higher sensitivity, accuracy, and negative predictive value in predicting relapse.

Genetic alterations of circulating tumor DNA in advanced pancreatic cancer patients receiving 5-fluorouracil based chemotherapy
SooBeen Heo[1], Sunhwa Park[1], Jung Won Chun[1], Yun-Hee Kim[1], Jun-Kyu Kang[2], Hwang-Phill Kim[2], Sang Myung Woo[1], Sun-Young Kong[1]. *[1]National Cancer Center, Goyang, Korea, Republic of,[2]IMBdx, Seoul, Korea, Republic of*

Background: Pancreatic cancer remains one of the most devastating malignancies due to lack of target therapeutic options for advanced disease. Liquid biopsy which analyzes tumor-related biomarkers in blood, has emerged as an innovative technology. The aim of this study was to identify circulating tumor DNA (ctDNA) mutations in pancreatic adenocarcinoma(PDAC) patients using multi-gene panels.
Methods: Total of 45 patients (27 male, median age 63 years) blood samples were obtained at baseline then follow-up after 2 months samples were acquired in 16 patients at National Cancer Center, Korea from November 2021 to April 2022. CtDNA were analyzed by next-generation-sequencing (NGS) panel of 118 genes and the varient allele frequency (VAF) of detected genes were analyzed. Then the association between outcomes of 5FU treated response and survival (overall survival and progression-free survival; OS and PFS) and VAF reduction at follow-up were analyzed.
Results: Total of 35 genes with 114 genetic alterations were detected and frequent mutations were as follows: KRAS (29.9%), TP53 (14.9%), GNAS(4.4%), SMAD4(4.4%), AR(3.5%), RNF434(3.5%), ATM(3.5%), BRCA2(2.6%) and PIK3CA(2.6%). The mean VAF level considering all pathogenic variants of 45 patients was 8.9%(range, 0 - 87.2) including 8 patients who were not detected ctDNA mutations in baseline, and the mean VAF was 4.2% (0 - 50.0) at follow-up in 16 patients. With association of clinical response, patients with partial response (PR) and stable disease (SD) were decreased VAF from 11% at baseline to 10% after 2 months, and three (60%) of patients showed clearance of ctDNA. Progressive disease (PD) patients were also decreased VAF 67% after 2 months, however, clearance of ctDNA was only observed in one patient (12.5%). Reduction of ctDNA more than 50% were associated with longer survival as PFS (> 50% reduction groups vs. no reduction group; 5 vs. 3 months, p value=0.903, OS (undefined vs. 6 months, p value =0.180).
Conclusions: This study showed most common mutation was KRAS with several other mutations of ctDNA in PDAC, and outcomes represented association with ctDNA.

Detection of PD-L1, HER2 and EGFR on circulating tumor cells in carcinoma patients
Jayant Khandare[1], Atul Bharde[1], Sreeja Jayant[1], Gourishankar Aland[1], Meghana Garbhe[1], Sayali Gosavi[1], Apoorva Janorkar[1], Purva Tikekar[1], Mrunmayi Patil[1], Vikas Jadhav[1], Ganesh Khutale[1], Amrut Ashturkar[1], Aravindan Vasudevan[1], Kumar Prabhash[2], Nirmal Raut[3], Pankaj Chaturvedi[4]. *[1]Actorius Innovation and Research USA and India, Pune, India,[2]Tata Memorial Hospital, Mumbai, India,[3]Bhaktivedanta Hospital And Research Institute, Mumbai, India,[4]Tata Memorial Hospital, Tata Memorial Hospital, Mumbai, India*

Background: Small molecular inhibitors and immunotherapy has emerged as a novel alternative treatment regime for a variety of epithelial cancers. Large number of clinical trials are in progress to gauge efficacy of tyrosine

kinase inhibitors or immune checkpoint inhibitors against actionable targets such as receptor tyrosine kinases and program death ligand 1 (PD-L1). Although highly effective, the outcome of PD-L1 based ICI or TKI against RTKs is vitally contingent on the presence of PD-L1 or RTK expression on circulating tumor cells. We report validation of CTCs with PD-L1, HER2 and EGFR expression in different epithelial cancers.
Methods: We retrospectively evaluated 134 carcinoma patients blood for presence of CTCs expressing PD-L1, HER2 or EGFR markers respect. 45 % patients had lung cancer, while 25 % and 20 % were presented with breast and GI and CRC malignancies. Remaining were gallbladder, ovarian, prostate, and head and neck cancers. CTCs were isolated from DCGI approved OncoDiscover platform with immunomagnetic targeting of EpCAM. CTCs were confirmed with expression of CK18, absence of CD45 and presence of DAPI nucleus. Presence/absence of biomarkers was determined using fluorescence imaging. Expression of PD-L1, HER2 or EGFR was detected by fluorescence microscopy using fluorescently labelled anti PD-L1, HER2 or EGFR antibodies respect. Based on fluorescence intensity CTCs were binned as PD-L1, HER2 or EGFR negative for no detectable fluorescence signal or weakly or strongly positive based on low or high fluorescence signal.
Results: Among the evaluated cohort, 51% of CTCs showed presence of PD-L1 expression. While 63% showed HER2 positive CTCs (breast cancer). 20% from the PD-L1 positive population showed stronger PD-L1 expression. 78% of CTCs from lung cancer patients showed presence of detectable PD-L1 signal, while 66% breast, GI and CRC patients showed CTCs with PD-L1 expression. CTCs from HNC and gall bladder cancer patients showed low PD-L1 expression (25% and 50% respect.). Among CTCs originating from different cancer types, breast cancer CTCs showed higher mean expression of PD-L1 compared to CTCs from CRC patients. A clear subset of CTCs for PD-L1 and Her2 expression was observed in lung and breast cancer patients respect, suggesting the heterogeneity in expression or presence of different subclones within the same tumor type. CTCs evaluated for EGFR expression, 50% showed presence of detectable EGFR compared to the cut-off signal.
Conclusions: CTC can be used as a real-time surrogate for molecular profiling of PD-L1, HER2 and EGFR expression. These CTC cell surface markers offer alternative for immunotherapy or targeted therapies decisions in a adenocarcinomas.

#6685
Targeted liquid biopsy mutation profiling and genome-wide cfDNA copy-number landscape in 3000 samples from six major cancer indications
Billie Gould, Lu Tan, Chao Dai, Tiantian Zheng, Wei Mo, Xianghong Wang, Michael Sneddon, Shidong Jia, Kemin Zhou, Pan Du. *Predicine Inc., Hayward, CA*

Introduction. PredicineCARE is a CLIA-certified targeted next-generation sequencing (NGS) assay that provides comprehensive, non-invasive genomic profiling of circulating tumor DNA (ctDNA) in blood and urine. Here we present liquid biopsy mutational profiles and genome-wide cell-free DNA (cfDNA) copy-number burden levels for historical cancer cohorts analyzed with PredicineCARE. We include a total of 3,147 samples from six major cancer indications: prostate (n=1681), lung (n=630), breast (n=300), colorectal (n=217), pancreatic (n=190), and bladder (n=129).
Methods. PredicineCARE employs a 152 targeted gene panel covering all major guideline-recommended alterations for patient care and clinical drug development including targeted therapies and immunotherapies. The assay detects single nucleotide variants (SNVs), small insertions and deletions, gene-level copy number loss/gain, and targeted re-arrangements/fusions. Concurrent low-pass whole-genome sequencing (without the need for additional sample volume) is performed to measure blood-based genome-wide copy-number burden (bCNB) and tumor fraction, providing important complementary molecular insights to variant detection.
Results. We present data from a representative cohort of blood and urine samples processed at Predicine lab in Hayward California (n=3,147). Sequencing was performed using a minimum of 5 ng total cfDNA input from 1-5 mL of plasma or 20-40mL of urine, at one or more clinical timepoints per patient. Samples were sequenced at ~20,000X target panel coverage and the majority also had ~2.5X low-pass whole genome sequencing. Using the Predicine in-house DeepSea bioinformatics pipeline, we report variants as low as 0.05% allele frequency and estimate genome-wide CNVs and bCNB from low-pass data. We compare the mutational and CNV profiles of important genes in each liquid biopsy cancer cohort to variants reported in solid tumor tissues from several large public data sets including Project GENIE (n=71,817 patients) and 136 additional study programs including TCGA (n=38,619 patients, www.cBioPortal.org).
Conclusion. PredicineCARE is a highly sensitive and robust assay for detecting cancer variants in blood and urine. The cfDNA mutation profiles are mostly consistent with public tissue datasets. A small but significant portion of the detected ctDNA variants have been shown to be important for treatment selection or are currently

being tested for targeted drug development. Increased bCNB provides a useful measure to monitor treatment response and disease progression. PredicineCARE has been CE-marked and received breakthrough device designation from FDA. A harmonized PredicineCARE assay is available in the US and China to support patient testing in the clinic, global clinical trials and CDx development.

Tumor suppressor miRNA-665 based serum biomarker for detecting pancreatobiliary cancer

Shuichi Mitsunaga[1], Makoto Ueno[2], Masahiro Tsuda[3], Takamichi Kuwahara[4], Yukiko Takayama[5], Keiji Hanada[6], Hitoshi Yoshida[7], Kenji Takahashi[8], Kohei Nakata[9], Hideaki Iwama[10], Masafumi Ikeda[11], Satoshi Kobayashi[2], Ikuya Miki[3], Kazuo Hara[4], Ryota Higuchi[12], Akinori Shimizu[6], Tomohiro Nomoto[7], Hidetaka Iwamoto[8], Masafumi Nakamura[9], Etsuro Hatano[10], Hiroko Sudo[13], Satoko Takizawa[13], Atsushi Ochiai[14]. *[1]Division of Biomarker Research, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Kashiwa, Japan,[2]Department of Gastroenterology, Kanagawa Cancer Center, Yokohama, Japan,[3]Department of Gastroenterological Oncology, Hyogo Cancer Center, Akashi, Japan,[4]Department of Gastroenterology, Aichi Cancer Center, Nagoya, Japan,[5]Department of Gastroenterology, Tokyo Women's Medical University, Tokyo, Japan,[6]Department of Gastroenterology, Onomichi General Hospital, Onomichi, Japan,[7]Department of Medicine, Division of Gastroenterology, Showa University School of Medicine, Tokyo, Japan,[8]Department of Medicine, Asahikawa Medical University, Asahikawa, Japan,[9]Department of Surgery and Oncology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan,[10]Department of Gastroenterological Surgery, Hyogo College of Medicine, Nishinomiya, Japan,[11]Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan,[12]Department of Surgery, Institute of Gastroenterology, Tokyo Women's Medical University, Tokyo, Japan,[13]Toray Industries, Inc., Kamakura, Japan,[14]Research Institute for Biomedical Sciences, Tokyo University of Science, Noda, Japan*

Background: MicroRNA-665 (miR-665), an intracellular inhibitor of pancreatic cancer (PC) cells, might be a potential biomarker to detect pancreatobiliary cancer (PBca). We sought to determine the diagnostic ability of miR-665 as a serum biomarker for PBca, and to explore the role of miR-665 in PC.
Methods: This multicenter study enrolled patients with treatment-naïve PBca and healthy participants. PBca-related serum miRNAs were determined using weighted co-expression network analysis of a comprehensive serum miRNA microarray dataset in an exploratory cohort. Using various combinations of PBca-related serum miRNAs, Fisher's linear discriminant analyses provided miRNA signatures to discriminate PBca from healthy controls. MiRNA signatures with a sensitivity/specificity (SN/SP) of ≥80/80% and high AUC in comparison with the AUC of CA19-9 were defined as the diagnostic miRNA signature in exploratory, validation and independent validation cohorts, whose accuracy was confirmed by 5-fold cross validation. Biology of the diagnostic miRNAs was evaluated using biopsy samples from liver metastasis of PC patients and human PC cells.
Results: We analyzed 496 of 1487 enrolled subjects (150 healthy and 134 PBca, 50 healthy and 47 PBca, and 50 healthy and 46 PBca subjects in the exploratory, validation and independent validation cohorts, respectively). Among miRNA signatures from 82 PBca-related miRNAs, a five serum miRNA combination containing miR-665 was identified as the diagnostic miRNA signature in all three cohorts. SN/SP and AUC in the validation and independent validation cohorts were 92/88% and 0.95 (CA19-9: 81/92% and 0.94) and 87/80% and 0.91 (CA19-9: 80/98% and 0.87), respectively. In sub-population analysis for detecting 48 resectable PCs, the discriminative ability of the diagnostic miRNA signature plus CA19-9 (SN/SP: 90/78%) was superior in sensitivity to that of CA19-9 alone (60/94%). In seven PC patients with liver metastasis, high expression of intratumor miR-665 tended to correlate with high serum miR-665 level ($r = 0.56$) and low expression of intratumor phospho-Erk expression ($r = 0.57$). Transfection of miR-665 to a human PC cell led to cell growth suppression.
Conclusions: This study identified the diagnostic ability of a tumor suppressor miR-665-based serum miRNA signature for PBca. For detecting resectable PC, a miR-665-based serum miRNA signature plus CA19-9 is a superior biomarker to CA19-9 alone.

#6687

Prevalence of four major gene mutation classes in a survey of ctDNA recovery from early and advanced stage NSCLC

Claire Gould, Leisa Jackson, Colin Cochran, Audrey Audetat, Brittany D'Alessio, Amanda Weaver, Janice Riley, Gary A. Pestano. *Biodesix, Inc., Boulder, CO*

Introduction: Circulating tumor DNA (ctDNA) has emerged as a powerful biomarker with many applications in oncology including early and late-stage disease prognosis and in treatment decision making. Liquid biopsies have become critical in non-small cell lung cancer (NSCLC) given the patient risks associated with biopsies. It is well established that circulating nucleic acid levels representative of all solid tumors are increased in advanced stages of the disease. Less well characterized is the status of cfDNA levels in the earliest stages of solid tumor progression. We used validated methods for quantitative fluorometry and a high sensitivity amplicon based NGS method to survey cfDNA recovery and prevalence for the four major mutation classes (copy number amplifications (CNAs), single nucleotide variations (SNVs), fusions, and insertions/deletions (INDELs)) from patients previously diagnosed with NSCLC.
Methods: Cell-free nucleic acid was extracted from 1,139 late-stage and 185 early-stage NSCLC plasma specimens. cfDNA was quantified using fluorometry, and the 52 gene GeneStrat NGS Test was used for the detection of CNAs, SNVs, fusions and INDELs. We evaluated cfDNA concentration (normalized to plasma input volume), quantity in circulation, and the prevalence of the four classes of mutations in early-stage (I-IIIA) versus late-stage (IIIB-IV) NSCLC.
Results: We observed significantly lower average concentrations of cf nucleic acids in plasma recovered from early versus late-stage NSCLC specimens (early-stage: 13.7 ng/mL; range (3.14, 118.65); n = 185; late-stage: 18.3 ng/mL; range (0.67, 187.2); n =1,139; p=0.00176). We also evaluated total cfDNA recovered for the sample set and observed significantly lower average measurements for early-stage specimens versus late-stage (early-stage: 101.4 ng; range (18.38, 652.6); n=185; late-stage: 140.5 ng; range (9.802, 1534); n=1,139; p=0.00692). We do note that there were overlaps at the low end of the ranges. Also significant was the finding that all mutation classes were more prevalent in late versus early-stage NSCLC. Specifically, 56 of 58 CNAs (96.6%); 737 of 805 SNVs (91.6%); 42 of 43 INDELs (97.3%) and 12 fusions (100%) were associated with late-stage specimens.
Conclusion: In this observational study cohort, cfDNA yields were significantly higher in late-stage NSCLC patients compared to early-stage. We also observed significantly more and varied mutations in plasma from late-stage patients. These initial findings need to be extended to additional cancers and refined by stage at diagnosis. We are currently expanding our study to include additional technologies and panels to assess ctDNA mutations especially for the early-stage patients. Quantitative cfDNA data may be of utility in diagnosis, monitoring and recurrence of cancer.

#6688
Development of a liquid biopsy cfDNA assay for detection of multiple HPV types in cervical neoplasias
Johanna Herbst[1], Vanessa Vohl[1], Maroje Krajina[2], Katharina Prieske[3], Anna Jaeger[3], Markus Leffers[1], Leticia Oliveira-Ferrer[3], Yvonne Goy[4], Klaus Pantel[1], Alexander Sartori[2], Caren Vollmert[2], Linn Wölber[3], Katharina Effenberger[1], Harriet Wikman[1]. *[1]Tumor Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Agena Bioscience GmbH, Hamburg, Germany,[3]Gynecology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[4]Radiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Over 95% of cervical cancers and their precancerous lesions are caused by human papillomavirus (HPV). Molecular screening approaches for HPV detection are gaining promising data over cytologic analysis. Similarly, liquid biopsy-based approaches are becoming a powerful tool for cancer detection and monitoring.
Materials and Methods: An HPV panel detecting 24 HPV types was developed suitable for liquid biopsy approaches. Here, HPV measurement was performed with an iPLEX multiplex PCR-based workflow combined with mass spectrometry-based analysis (MassARRAY System, Agena Bioscience). The assay was validated on HPV positive plasmid controls and cell lines. Furthermore, 52 cervical smear samples from HSIL positive women and 40 cfDNA samples (peripheral blood) from cervical cancer patients were screened using this approach.
Results: According to already published ring trial results, the HPV types HPV6, 11, 16, 18, 31, 33, 35, 39, 45, 51, 52, 58 and 59 were considered proficient with the required detection level of 50 and 5 international units (IU)/5 µl for HPV 16 and 18, and 500 and 50 HPV genome equivalents (GE)/5µl for the other HPV types (Arroyo Mühr et al., 2022). Further analyses showed a sensitivity of 0.03% for HPV16 and 0.33% HPV18 and 0.33% for the other tested HPV types. HPV DNA was detected in 94% of (49/52) smear samples analyzed. 86.5% were found positive for at least one of the high-risk HPV (hrHPV) types in the study cohort. Two of the three HPV negative samples were truly negative according to clinical data. In 15 samples, multiple HPV types were found, with positivity in up to five different HPV types. For smear samples a sensitivity of 98.14% and a positive predictive value of 0.98 (49/50) were thus obtained. The overall agreement between the MassARRAY and Seegene (from clinical records) HPV tests was 97.2% (κ=0.84). 27 of 40 (67.5%) cfDNA cervical cancer samples were tested positive for any

HPV type. The distribution of HPV types showed most infections being due to hrHPV (25/27 plasma HPV positive). HPV positive samples were found in all FIGO stages, with 56.5% positivity in FIGO stage I and 87.5% in FIGO stage III and IV.
Conclusions: The HPV assay showed reliable results for detecting a large number of HPV types in a multiplex mass spectrometry-based assay. A high sensitivity was achieved for both, cervical smear samples of HSIL patients as well as cfDNA from blood samples of cervical cancer patients.

Whole genome cell-free tumor DNA mutational signatures from blood for early detection of recurrence of low stage lung adenocarcinoma

Ivy Tran[1], Alejandro Vargas[1], Reid Wilkins[1], Isabella Pizzillo[1], Kenneth Tokoro[2], Danielle Afterman[3], Tomer Lauterman[3], Maja Kuzman[4], Santiago Gonzalez[4], Dunja Glavas[4], James Smadbeck[4], Dillon Maloney[4], Jurica Levatic[4], Samuel Phillips[4], Sunil Deochand[4], Michael Yahalom[4], Ryan Ptashkin[4], Iman Tavassoly[4], Zohar Donenhirsh[3], Eric White[4], Ravi Kandasamy[4], Ury Alon[3], Paz Polak[4], Boris Oklander[3], Asaf Zviran[4], Matija Snuderl[1], Harvey I. Pass[2]. *[1]Pathology, NYU Langone Health, New York, NY,[2]Department of Cardiothoracic Surgery, NYU Langone Health, New York, NY,[3]C2i Genomics, Haifa, Israel,[4]C2i Genomics, New York, NY*

Introduction: Lung cancer remains the leading cause of cancer-related deaths. Surgery is the best option for early lung cancer, and the role of adjuvant therapy remains controversial. Liquid biopsy offers a noninvasive approach to monitor cancer burden. Targeted sequencing of circulating cell free tumor DNA (ctDNA) in blood has shown success for diagnosis; however, low tumor burden and dynamic evolution of low stage disease is challenging for targeted panels. Thus, we hypothesized that a whole genome sequencing (WGS)-derived patient specific mutational signature from a matched tumor-normal WGS can provide sensitive and specific approach to detect mutations and copy numbers in ctDNA for monitoring of lung adenocarcinoma patients.
Methods: We successfully profiled 50 Stage 1 or 2 lung adenocarcinomas. ctDNA was extracted from 1-2 mL of plasma, tumor DNA was extracted from pathology tissue and normal germline DNA from the white blood cells. WGS using was performed on matched tumor and normal DNA, and ctDNA extracted from plasma. WGS coverage was 40x for matched tumor-normal and 20x for ctDNA. We derived a personalized mutational pattern for each tumor and used an AI-based error suppression model for quantification and ultra-sensitive detection of ctDNA in plasma samples. A patient-specific personalized genome-wide compendium of somatic mutations and copy numbers was established and ctDNA tested at 3 to 18 available time points during the therapy or follow up. A personalized mutational signature for detection ctDNA from WGS was quantified and the ctDNA Tumor Fraction (TF) was compared to the clinical status and time to recurrence.
Results: Tumor specific signatures were derived from matched tumor-normal samples with >5% tumor purity and <30% duplications rate. Out of all patients, 33 patients showed no recurrence and 12 recurred. Tumor-specific signatures detected the presence of the tumor signature in plasma with TF as low as 10^{-5}. Based on positive minimal residual disease in plasma, the recurrence prediction sensitivity was 0.75 and specificity 0.82, with positive predictive value of 0.6 and negative predictive value 0.9. WGS ctDNA predicted recurrence with a median lead time of 508 days before clinical/imaging recurrence. In one case we were able to identify the second primary by deconvoluting known and novel ctDNA mutations. ctDNA mutational profiles enabled identification of smoking mutational signature matching clinical history, and APOBEC and ageing signatures as well as tumor mutational burden.
Conclusions: Patient-specific WGS tumor signature from plasma derived ctDNA enables specific and ultrasensitive tracking of minimal residual disease in low stage lung adenocarcinoma patients. Molecularly positive status can be used to predict recurrence and identify patients with clinical low stage disease that may benefit from adjuvant therapy.

Monitoring response and resistance to EGFR inhibition with circulating tumor DNA in a non-small cell lung cancer patient-derived xenograft

Long H. Do, Raffaella Pippa, Warren Andrews, Yuan Chien, Jantzen Sperry, Jonathan Nakashima. *Certis Oncology Solutions, San Diego, CA*

Circulating tumor DNA (ctDNA) has been shown as a clinically relevant biomarker for non-invasive monitoring of therapy response, disease burden and disease progression in cancer patients. Patient-derived xenografts (PDX) are

essential translational models used for evaluating therapeutic response and identifying novel biomarkers, but analysis of ctDNA in these models remains understudied. Here, we report the use of ctDNA for the monitoring of therapeutic response and secondary resistance of a Non-Small Cell Lung Cancer PDX treated with EGFR inhibitors. We demonstrate measurable ctDNA changes correlate with disease burden and therapeutic response. Altogether, the isolation of ctDNA from PDX models is a robust methodology for interrogating therapeutic efficacy, response, and resistance in a preclinical setting that can be translated as a viable biomarker for non-invasive monitoring in patients.

#6691

Paired comparison of routine molecular screening of patient samples with advanced non-small cell lung cancer in circulating cell-free DNA using OncoBEAM™ EGFR V2, targeted next-generation sequencing Plasma-SeqSensei™ Solid Cancer IVD Kit and custom-validated NGS assay

David Barthelemy[1], Emmanuel Grolleau[1], Gaelle Lescuyer[1], Florence Geiguer[1], Arnaud Gauthier[1], Julie Balandier[1], Margaux Raffin[1], Claire Bardel[1], Bruno Bouyssounouse[2], Claire Rodriguez-Lafrasse[1], Sébastien Couraud[1], Anne-Sophie Wozny[1], Lea Payen-Gay[1]. *[1]Centre Hospitalier Lyon Sud - HCL, Pierre Benite, France,[2]Inovotion, Grenoble, France*

Background: Noninvasive genotyping using plasma cell-free DNA (cfDNA) has the potential to obviate the need for some invasive biopsies in cancer patients. We sought to validate an ultra-deep plasma Next-Generation Sequencing (NGS) assay for patients with Non-Small-Cell Lung Cancers (NSCLC) for detecting Minimal Residual Disease (MRD) following curative-intent NSCLC treatment or EGFR detection at an early stage.
Patients and Methods: We carried out targeted NGS using the Plasma-SeqSensei™ Solid Cancer IVD Kit on cfDNA extracted from plasma. Somatic alterations were filtered, removing somatic mutations attributable to clonal hematopoiesis. Sensitivity and specificity for plasma detection of known oncogenic drivers were calculated. In a subset of cases, validation was carried out using an orthogonal OncoBEAM™ EGFR V2 assay, as well as with a custom-validated NGS assay.
Results: In comparison with the OncoBEAM™ EGFR V2 kit, we observed a 75% concordance with the Plasma-SeqSensei™ Solid Cancer IVD Kit. The 25% genomic discordances were respectively observed in 5%, 7% and 13% linked to the limit of coverage of the OncoBEAM™ EGFR V2 kit, the limit of EGFR sensitivity of the Plasma-SeqSensei™ Solid Cancer IVD Kit and the larger *KRAS, PIK3CA, BRAF* coverage of the Plasma-SeqSensei™ Solid Cancer IVD Kit. In comparison with the custom-validated NGS assay, we observed a 68% concordance with the Plasma-SeqSensei™ Solid Cancer IVD Kit. The 32% genomic discordances were respectively observed in 5%, 11% and 16% linked to the limit of coverage of the Plasma-SeqSensei™ Solid Cancer IVD Kit, the limit of covered sensitivity of the custom-validated NGS assay and the additional oncodrivers analysis only covered by the custom-validated NGS assay. Benefitting from the higher coverage from targetable *BRAF, KRAS, PIK3CA* targetable alterations, the plasma targeted NGS Plasma-SeqSensei™ Solid Cancer IVD Kit showed 13% additional discordances with the Plasma OncoBEAM™ EGFR V2 kit. Most of these additional somatic alterations were cross-validated in our orthogonal custom-validated NGS assay, used in the routine management of patients. The custom-validated NGS assay sensitivity is determined for MAF at 1%, explaining the limit of sensitivity with the Plasma-SeqSensei™ Solid Cancer IVD Kit.
Conclusions: Plasma-SeqSensei™ Solid Cancer IVD Kit resulted in *de novo* detection of targetable oncogenic drivers and resistance mechanisms in patients with NSCLC, including when tissue biopsies were inadequate for genotyping with high sensitivity and accuracy for low and high cfDNA inputs.

Identification of circulating tumor cells based on machine learning

Jae Hyuk Lee[1], Sung Ho Park[2], Jihoon Kang[2], Jihyun Lee[1], Soee Kim[1], Jungwon Kim[1], Young Woong Sohn[1], Jong Kil Lee[1]. *[1]CytoGen, Inc., Seoul, Korea, Republic of,[2]Tech University of Korea, Siheung-si, Korea, Republic of*

Circulating tumor cells (CTC) are tumor cells that have shed into the bloodstream from primary tumor and circulate in the blood. CTC could provide better understanding of tumor metastasis and show the possibility as promising biomarker for early detection of cancer, cancer prognosis, noninvasive monitoring of treatment response, and personalized medicine. However, the isolation and characterization has been a major technological challenge due to their rareness among the massive blood cells. CytoGen's Smart BiopsyTM CTC platform

comprised of CTC isolator, IF (Immunofluorescence) Stainer, and Cell Image Analyzer is a unique and competitive technology platform for the isolation and analysis of CTC from blood. Intact live CTC could be isolated gravity-based filtration via high-density micro-porous (HDM) chip with minimized cellular damage and high retrieval rate. For the more accurate and quick analysis of CTC after isolation with Smart BiopsyTM CTC platform, we are developing the analysis method of CTC identification using machine learning technologies. Preliminary results of machine learning showed the accurate separation of CTC and PBMC (peripheral blood mononuclear cells) based on the specific markers of them. CTC identification based on machine learning technologies might be reliable analysis method and give secure information of CTC.

Stability of urinary cell-free DNA and detection of T790M variant

Carolin Münch[1], Saikal Shamkeeva[1], Mitja Heinemann[1], Berend Isermann[1], Sabine Kasimir-Bauer[2], Bahriye Aktas[1], Ivonne Nel[1]. *[1]University of Leipzig, Leipzig, Germany,[2]University Hospital Essen, Essen, Germany*

Background: The so-called “liquid biopsy” has become a powerful tool for cancer research in the recent years, with circulating cell-free DNA (cfDNA) that originates from tumors as one of the most promising analytes. In contrast to plasma derived cfDNA, only a few studies were performed investigating urinary cfDNA. One reason might be quick degradation and hence relatively low concentrations of urinary cfDNA. This study focused on examining the stability of cfDNA in urine using different ways of preservation under various storage conditions.
Methodology: To mimic patient samples, a pool of healthy male and female urine donors was spiked with a synthetic cfDNA reference standard (fragment size 170 bp) containing the T790M mutation in the EGFR gene and preserved with three different buffers and no buffer over four different storage periods (0; 4; 12; 24 h) at room temperature vs. fridge. Preservatives used were the Urinary Analyte Stabilizer (UAS, Novosanis), the Urine Conditioning Buffer (UCB, Zymo) and a self-prepared buffer called “AlloU”. The cfDNA was extracted with the QIAamp MinElute ccfDNA Mini Kit (Qiagen) and the concentration measured with the Qubit™ 4 fluorometer (Thermo Fisher Scientific). Droplet digital PCR (ddPCR) was used for detection and quantification of the T790M mutation (Bio-Rad)
Results: From the model samples with no preservation buffer, almost no spiked cfDNA could be recovered and the T790M variant could not be detected using ddPCR, indicating that without preservation cfDNA was degraded below the detection limit by the nucleases present in urine. The most effective stabilizing buffer over all storage periods and at room as well as fridge temperature was the UAS, resulting in accurate detection of the T790M variant using ddPCR.
Conclusion: From a technical point of view, urinary cfDNA might be useful for non-invasive disease monitoring when the samples are stabilized and stored adequately during clinical routine.
