Introduction: Advancements in DNA sequence detection technology and assay design have enabled molecular residual disease (MRD) assays to detect cancer earlier and with greater sensitivity. In Tumor-Informed (TI) strategies, mutations from the tumor are used to define a set of patient-specific markers that are tracked in the blood as circulating tumor DNA (ctDNA). Whereas tumor-naïve (TN) approaches do not require prior genomic information from the tumor and instead employ a fixed panel of marker(s). Methylated DNA Markers (MDMs) can be used to distinguish cancer from non-cancer and can be found in plasma. We have developed a proprietary TN MRD platform for colorectal cancer (CRC) capable of measuring as few as 1-5 strands of MDM target. Additionally, we are actively developing a TI MRD assay platform. Here we describe the evaluation of both TI and TN approaches for the detection of circulating tumor DNA (ctDNA) in blood across all stages of colorectal cancer and explore the complementarity of these two approaches in the context of MRD monitoring. Procedures: A 20-sample cohort of paired tumor/normal and pre-surgery plasma specimens from stage I (6/20), stage II (7/20), stage III (6/20), and stage IV (1/20) CRC patients and 20 demographically matched non-cancer controls were acquired for our study. All cancer plasma samples were collected prior to tumor resection. Neat and diluted plasma samples were tested for the presence of ctDNA containing short variants specifically derived from the corresponding primary tumor and for a pre-defined set of MDMs and protein cancer biomarkers. Tumor-specific short variants were characterized by whole exome sequencing of the primary tumors. MDMs were detected from bisulfite converted cfDNA by Target Enrichment Long probe Quantitative Amplified Signal (TELQAS) for 35 MDMs. A cancer detection classifier for the TN assay was trained and validated using a separate cohort of non-cancer and CRC plasma samples and employed for this study. Protein was detected by high throughput ELISA.Results: Tumor sequencing of the 20 CRC samples identified between 122 and 7146 (median = 230) somatic mutations per tumor sample.

The combination of features from TI and TN assays achieved 95% accuracy, demonstrating an improvement over either assay in isolation. Indeed, 5 “positive” calls were made for cancer samples for which only one of the two methods met pre-defined RUO thresholds for ctDNA detection. Comparison of median variant allele fraction from the TI assay with median percent methylation of CRC markers for these CRC samples had a Pearson’s correlation of 0.967. Conclusion: TI and TN assays show high concordance in cancer detection, but also complement each other. Additionally, ctDNA quantifications produced from TI and TN assays are linearly correlated. The combination of data from both assays can be used to further differentiate cancer samples from non-cancer samples.

Utility of circulating tumor DNA in breast cancer clinical research and practice: systematic review and meta-analysis

Xuezheng Sun[1], Nicholas Ballew[2], Linda Kalilani[1], Kelesitse Phiri[3], Kelly Bell[2], Alexander Slowly[4], Magdalena Zajac[4], Erin Hofstatter[5], Angela Silvestro[5], Zebin Wang[6], Jeanne Schilder[2]. *[1]GSK, Research Triangle Park, NC,[2]GSK, Philadelphia, PA,[3]GSK, Collegeville, PA,[4]GSK, London, United Kingdom,[5]GSK, Waltham, MA,[6]GSK (at the time the analysis was conducted), Waltham, MA*

Background: Circulating tumor DNA (ctDNA) has been increasingly used in the clinical care of patients with cancer. This systematic review summarizes current data on the utility of ctDNA in breast cancer clinical research and practice and provides insights for integrating ctDNA into drug development and patient treatment.
Methods: The Embase database was used to identify original clinical research articles of ctDNA in breast cancer published from 2015 to 2020. ctDNA clinical utilities were reviewed and summarized, focusing on 3 areas: early diagnosis, prognostication, and monitoring disease progression/treatment response. Associations of ctDNA with disease-free survival (DFS) and overall survival (OS) were estimated in the embedded meta-analysis. Pooled estimates were calculated using fixed-effect or random-effect models depending on study heterogeneity.
Results: After screening and review, 72 articles were included. ctDNA studies have increased in recent years, with 59.7% of included articles

published in 2019 or 2020. Overall, 61.1% of the studies were in patients with advanced stage/metastatic cancer; 45.8% were restricted to patients with specific cancer subtypes. ctDNA was minimally used in diagnosis; it was predominantly used in clinical outcome prediction with differences by stage. In patients with early-stage disease, the meta-analyses found that overall ctDNA detection/positivity was associated with shorter DFS (n=697; HR, 5.37; 95% CI, 2.94-9.80) and OS (n=238; HR, 4.60; 95% CI, 2.56-8.26). Specific gene mutations in ctDNA were mainly assessed in patients with advanced/metastatic disease, with mutations of *ERBB*, *ESR1*, and *TP53* linked to shorter DFS in the meta-analyses (P<0.05). Moreover, current studies provided evidence that ctDNA reflects the dynamics of breast tumors in the patient treatment journey, acting as a biomarker to monitor tumor evolution and drug resistance.
Conclusions: Recent studies demonstrate ctDNA application in breast cancer prognostication/monitoring, suggesting an important role in patient stratification, molecular relapse identification, and personalized treatment. Large, multicenter clinical trials and real-world longitudinal data sets are needed to validate findings and to address challenges related to ctDNA to improve clinical utility and to integrate ctDNA testing into clinical practice and drug development.

Genomic alterations associated with early-onset and late-onset colorectal cancer

Eric M. Lander[1], Samuel Rivero-Hinojosa[2], Vasily N. Aushev[2], Jesús Izaguirre-Carbonell[2], Adham Jurdi[2], Minetta C. Liu[2], Cathy Eng[1].
[1]Department of Medicine, Vanderbilt University Medical Center, Nashville, TN,[2]Natera, Inc., Austin, TX

Background: The causes of the rising incidence of early-onset colorectal cancer (EOCRC), defined as CRC in patients aged <50, remain unknown. In this study, we evaluated tumor genomic differences in patients with EOCRC versus late-onset CRC (LOCRC, age >60).
Methods: The international cohort included 13,262 patients diagnosed with stages I-III colon or rectal cancer who had ctDNA testing using a personalized and tumor-informed multiplex PCR assay (Signatera™ 16-plex bespoke mPCR NGS assay), from which whole-exome sequencing

(WES) on the surgically resected tumor was performed. Tumor mutational burden (TMB) and microsatellite instability (MSI) status were derived from WES analysis. The prevalence of gene-wide mutations, pathogenic gene variants, and mutations in known oncogenic pathways was compared between EOCRC and LOCRC groups, stratified by TMB and MSI status. Fisher's exact test was used to test significance between the groups and p-values were adjusted using the FDR method for multiple test correction.
Results: A total of 3,093 patients with EOCRC (70.8% colon, 27.4% rectal, 1.9% unknown) and 10,169 patients with LOCRC (79.9% colon, 18.3% rectal, 1.7% unknown) were included, where 9.0%/37.3%/53.7% were AJCC stages I, II, and III, respectively. Early-onset patients compared to late-onset patients had fewer cases of stage II CRC (30.7% vs. 39.3%, $p<0.01$) and more cases of stage III CRC (60.9% vs 51.6%, $p<0.01$). Adjusted by stage, patients with EOCRC were less likely to be MSI-H compared to patients with LOCRC (10% vs. 17%, $p<0.01$), or have high tumor mutational burden (TMB-H) (15% vs. 19%, $p<0.01$). Genes of the Hippo, NOTCH, WNT, and RTK-RAS oncogenic pathways were less commonly mutated in the EOCRC cohort ($p<0.01$). The BRAF V600E mutation was less prevalent in the EOCRC group (3% vs. 15%, $p<0.01$), regardless of TMB and MSI status. In the TMB-low/MSS group, TP53 mutations were more common in EOCRC (8% vs. 5%, $p<0.01$), but APC gene mutations were less common in EOCRC (56% vs. 66%, $p<0.01$). When comparing EOCRC and LOCRC in the TMB-H/MSI-H group, BRAF V600E (4% vs. 60%), RNF43 G659V (16% vs. 45%), and WNT1 G619A (6% vs. 20%) mutations were less prevalent in EOCRC ($p<0.01$ for all mutations); however, patients with EOCRC had more mutations in PIK3CA H1047R (22% vs. 9%), APC R1468* (11% vs. 3%), and KRAS A146T (7% vs. 2%) gene variants ($p<0.01$ for all mutations). In the TMB-H/MSS group, EOCRC patients were more likely to have driver mutations in the PI3K pathway (74% vs. 56%, $p<0.01$). Further, POLE P286R mutations were more common in TMB-H/MSS patients with EOCRC compared to LOCRC (38% vs. 13%, $p<0.01$), whereas ACVR2A K437R was less common (11% vs. 30%, $p<0.01$).
Conclusion: Patients with LOCRC were more likely to have pathogenic gene variants and mutations in established pathways of CRC carcinogenesis. Tumors in EOCRC cases harbored unique genomic

alterations that varied between the TMB-low/MSS, TMB-H/MSI-H, and TMB-H/MSS subpopulations.

Deep learning algorithm for cancer detection using multimodal characteristics of whole methylome sequencing of cf-DNA

Juntae Park[1], Minjung Kim[1], Sook Ryun Park[2], Ki-Byung Song[3], Eunsung Jun[3], Dongryul Oh[4], Jeong-Won Lee[5], Young Sik Park[6], Ki-Won Song[7], Jeong-Sik Byeon[8], Bo Hyun Kim[9], Chang-Seok Ki[1], Eunhae Cho[1]. *[1]GC Genome, Yongin, Korea, Republic of,[2]Asan Medical Center, Seoul, Korea, Republic of,[3]Department of Surgery, Asan Medical Center, Seoul, Korea, Republic of,[4]4.Department of Radiation Oncology, Samsung Medical Center, Seoul, Korea, Republic of,[5]Department of Obstetrics and Gynecology, Samsung Medical Center, Seoul, Korea, Republic of,[6]Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[7]Department of Surgery, Song, Asan Medical Center, Korea, Republic of,[8]Department of Gastroenterology, Asan Medical Center, Seoul, Korea, Republic of,[9]Center for Liver and Pancreatobiliary Cancer, National Cancer Center, Goyang, Korea, Republic of*

Background Various cell-free DNA (cfDNA) features including methylation and genomic profiles have been investigated for their potential use in early cancer detection. We developed deep learning models based the data generated by the enzymatic conversion based whole methylome sequencing of cfDNA.

Methods Cell-free whole genome Enzymatic Methyl sequencing(cfWEMseq) data were generated from 198 cancer patients (stage I: 11%, II: 17%, III: 22%, IV: 20%, unknown: 31%) and 69 healthy controls. The cancer types were consisted of breast (n=31), liver (n=24), esophageal (n=38), pancreatic (n=30), colon (n=34), ovarian (n=18), and lung (n=23). Sequence data was produced on average of 200 million reads using Novaseq 6000 (Illumina). For model training and evaluation, data partitioning was stratified by cancer type, and 5-fold cross validation was used. Coverage and methylation beta values were calculated by binning at fixed size of 100K, 1M, and 5M base and variable size from Topologically Associated Domains (TAD). Genome Coverage (GC), Genome Methylation

Beta values (GMB), and Mutation Signature (MS) features were trained using a one-dimensional convolutional neural network (1D-CNN). The performance of the model was evaluated by measuring the average value of the results measured in each test set of 5 fold.
Results We tested the cancer detection performance of various feature combinations using all data from cfWEMseq (n=267). Regardless of the bin size, the GMB single model achieved higher performance than the GC single model. The best-performing model is the ensemble model of GMB (100k bin) and MS. The cancer detection performance of this ensemble model reached an accuracy 96% (CI: 93.6% to 98.1%), AUC 0.99 (CI: 0.97 to 1.0) and sensitivity 98.0% (CI: 92.4% to 99.5%) with a specificity of 90%.
Conclusions These results provide an opportunity for higher accuracies by integrating methylation information and genomic data using cfWEMseq.
This research was supported through the National Research Foundation (NRF) funded by the Ministry of Science and ICT (2020M2D9A3094213).

Combinatorial genomic and epigenomic cell-free DNA analysis of high-risk metastatic castration resistant prostate cancer reveals prognostic liquid biopsy signatures

Irfan Alahi[1], Pradeep S. Chauhan[1], Alexander L. Shiang[1], Jace Webster[1], Ha X. Dang[1], Lilli Greiner[1], Breanna yang[1], Elisa M. Ledet[2], Ramandeep K. Babbra[3], Wenjia Feng[1], Peter K. Harris[1], Ellen B. Jaeger[2], Patrick J. Miller[2], Sydney A. Caputo[2], Giordano Cittolin Santos[1], Oliver Sartor[2], Russell K. Pachynski[1], Christopher A. Maher[1], Aadel A. Chaudhuri[1].
[1]Washington University in St. Louis, Saint Louis, MO,[2]Tulane University School of Medicine, New Orleans, LA,[3]Wilmot Institute Cancer Center, University of Rochester Medical Center, Rochester, NY

Background: Androgen receptor signaling inhibitors (ARSI) such abiraterone and enzalutamide have significantly improved clinical outcomes in metastatic castrate-resistant prostate cancer (mCRPC) patients. However, patients with genomic alterations in the androgen receptor (*AR*) and its enhancer region do not respond well and acquire resistance to these inhibitors. Here, we applied our previously developed cell-free DNA

(cfDNA) liquid biopsy assay (EnhanceAR-Seq) to detect these high-risk mCRPC patients prior to the administration of first-line AR-directed therapy and correlated with survival. We also interrogated the plasma methylome to identify differentially methylated regions (DMRs) across these high-risk patients. **Methodology**: We applied EnhanceAR-Seq to plasma cfDNA isolated from 99 mCRPC patients enrolled from two institutions (n=52 Tulane; n=47 WashU). Plasma samples were collected prior to ARSI initiation (n=63) or during treatment (n=36). We also performed Enzymatic Methyl-seq in pre-treatment plasma from 43 patients. We split these 43 patients into cell-free genomically high-risk and low-risk groups using our EnhanceAR-seq results, and conducted DMR analysis using metilene. To identify significant DMRs, we performed multiple hypothesis testing and required $q<0.05$ using the Benjamini-Hochberg procedure, and further required at least 5 CpGs per DMR. **Results**: EnhanceAR-Seq detected *AR*/enhancer alterations in 35% of all plasma samples. Cell-free *AR*/enhancer detection was highly prognostic (PFS HR=2.80, p=0.0002; OS HR=2.6, p=0.01). When considering only pre-treatment plasma, *AR*/enhancer alterations detected in 44% (28/63) of samples correlated significantly with worse PFS (HR=2.21, p=0.009) and OS (HR=2.60, p=0.02). *AR*/enhancer alterations detected in 19% (7/36) of samples collected during ARSI were also associated with worse PFS (HR=15.6, p=0.0002) and OS (HR=8.09, p=0.05). Plasma methylome analysis revealed that for cell-free genomically high-risk mCRPC patients (based on *AR*/enhancer alterations detected in cfDNA), significantly hypomethylated DMRs were found in the *AR* promoter, upstream *AR* enhancer, and in *AR*-associated genes including *FOXP1* and *FOLH1*. Significantly hypomethylated DMRs were also observed in DNA damage repair and cell cycle genes including *MSH6*, *MSH3*, *FANCD2*, *CDK12* and *RAD51B*. Hypermethylated DMRs were seen in tumor suppressor genes including *ZBTB16*, *BRCA2*, *WT1* and *GNAS*. **Conclusions***: AR*/enhancer alterations detected in plasma cfDNA predicted inferior survival in mCRPC patients. Cell-free genomically high-risk mCRPC patients could be distinguished from low-risk patients based on distinct methylation signatures.

What are the characteristics of mutations to use as targets in tumor-informed ctDNA analysis?

Marijana Nesic, Mads H. Rasmussen, Tenna V. Henriksen, Christina Demuth, Amanda Frydendahl, Iver Nordentoft, Lars Dyrskjøt, Claus L. Andersen. *Aarhus University, Århus, Denmark*

Introduction: Tumor-informed, mutation-based approaches for the detection of circulating tumor DNA (ctDNA) are among the most common and widely used ctDNA detection approaches. To identify the mutations to be used as ctDNA targets, tumor tissue is often mutation-profiled using broad panel sequencing strategies. Optimally, the strategy for mutation profiling should enable assessment of clonality and copy number of the identified mutations. Hereby, it will be possible to rank the mutations and select those that are clonal and present in multiple copies per cancer cell. Theoretically, this should increase the ctDNA detection likelihood. However, there is no consensus on how best to identify and select the targets. Here, we propose a bioinformatic pipeline for an easy and robust selection of target mutations for ctDNA detection from tumor whole-exome sequencing (WES) profiles.

Methods: The pipeline consists of Mutect2 and PureCN, which were both applied to paired tumor and normal WES profiles. The output from the pipeline is a list of somatic mutations, each with estimated measures of clonality, in the form of a cancer cell fraction (CCF), and multiplicity (local mutation copy number). Mutations with CCF above 0.9 were considered clonal. The performance of the pipeline was assessed using matched WES and ctDNA data from 98 colorectal cancer (CRC) and 30 bladder cancer patients. For CRC patients, 1-5 mutations per patient within a pre-defined CRC panel were used as ctDNA targets, while an average of 41 selected mutations per patient were used for bladder cancer patients. The performance measure was the mutation detection rate in pre-operative plasma samples, stratified for clonality (CCF), multiplicity, and the combination of CCF and multiplicity.

Results: For CRC patients, 51% of mutations with CCF > 0.9 were detected compared to only 17% when CCF < 0.9 (p= 4.3e-09). In bladder cancer patients 21% of mutations with CCF > 0.9 were detected compared to 2 % when CCF < 0.9 (p=1.2e-09). For CRC patients the ctDNA detection rate was 58% when mutation multiplicity was higher than 1 and 31% when

multiplicity was 1 (p= 9.175e-06). For bladder cancer, the same numbers were 22% and 16% (p=4.635e-03). Mutations with CCF > 0.9 and multiplicity >1 had significantly increased ctDNA detection rate compared with mutations with CCF < 0.9 and multiplicity 1, in both CRC (p= 1.486e-09) and bladder cancer (p=1.077e-09).
Conclusion: The CCF and multiplicity measures provided by the pipeline are highly useful when selecting ctDNA targets. By selecting mutations with CCF> 0.9 and multiplicity >1 the likelihood of detecting ctDNA in plasma cfDNA is significantly improved.

Characterizing circulating tumor DNA release kinetics and fragment length in a chemotherapy resistant model of esophageal adenocarcinoma
Alexandra Bartolomucci[1], Sarah Tadhg Ferrier[1], Thupten Tsering[1], Xin Su[1], Jonathan Cools-Lartigue[2], Julia V. Burnier[1]. *[1]McGill University Health Centre Research Institute, Montreal, QC, Canada,[2]McGill University Health Centre, Montreal, QC, Canada*

Background: While the incidence of esophageal adenocarcinoma (EAC) is rapidly increasing, the 5-year survival rate of this disease remains poor at less than 25%, with a substantial number of patients exhibiting inherent or acquired resistance to chemotherapy. Circulating tumor DNA (ctDNA) isolated from liquid biopsies of EAC patients holds clinical biomarker potential in this disease, but our understanding of how chemotherapy affects ctDNA release remains limited.
Methods: In order to study the impact of cancer treatment on ctDNA emission *in vitro*, we first sought to establish a chemo-resistant model of EAC. As such, the EAC cell line OE19 was exposed to discontinuous cisplatin treatments for three months in order to establish drug resistance. Following this, established chemo-resistant OE19 cells and parental (chemo-sensitive) OE19 cells were exposed to five daily cisplatin treatments, and cell culture supernatant was collected every day throughout treatment. ctDNA was subsequently isolated from cell culture supernatant and quantified by Qubit fluorometer dsDNA HS assay. ctDNA quantities were additionally assessed by droplet digital PCR (ddPCR) assay using primers and probes targeting the *TP53* N310K mutation in the OE19 cell

line. Finally, ctDNA fragment lengths were analyzed using the Agilent Bioanalyzer 2100.
Results: A chemo-resistant model of the OE19 cell line was established, as exemplified by marked morphological changes in the cells and significantly increased cell viability determined by CCK8 assay after 48-hour treatments of various doses of cisplatin ($p<0.05$). ctDNA levels, as measured by both Qubit fluorometer and mutant copies detected by ddPCR assay, increased after chemotherapy treatment for both chemo-sensitive and resistant cells. Notably, ctDNA emission was higher with larger amounts cell death, with chemo-sensitive cells emitting significantly higher levels of ctDNA compared to chemo-resistant cells throughout treatment ($p<0.05$). Fragmentomics analysis revealed ctDNA peaks corresponding to apoptosis (~167 bp) and necrosis (~10,000 bp). Moreover, chemotherapy treatment caused a shift in average fragment size, with larger fragments being observed during chemotherapy treatment in both chemo-sensitive and resistant cells.
Conclusion: This study reveals that *in vitro* cancer models can be used to successfully study ctDNA emission during pre-clinical drug analyses. ctDNA release was found to be correlated to cytotoxicity and cell death, providing us with valuable insight into how clinical liquid biopsy data should be interpreted. Finally, fragment size analysis of ctDNA reveals a potential novel biomarker for treatment response in cancer patients.

6-color Crystal Digital PCR for the high-plex detection of 10 *ESR1* mutations in breast cancer

Stavroula Smilkou[1], Aliki Ntzifa[1], Dimitra Stergiopoulou[1], Quentin Blache[2], Myrtille Remy[2], Cecile Jovelet[2], Allison Mallory[2], Evi Lianidou[1].
[1]University of Athens, Athens, Greece,[2]Stilla Technologies, Villejuif, France

Introduction. *ESR1* mutations have emerged as a key mechanism of resistance to endocrine therapy in estrogen-receptor-positive (ER+) breast cancer, thus detection of *ESR1* mutations is crucial to monitor during patient treatment. We evaluated a novel 12plex breast cancer assay for the detection of 10 *ESR1* mutations and *AKT1* E17K in plasma cell-free DNA (cfDNA) using 6-color Crystal Digital PCR™ (naica® system, Stilla Technologies, France). We further compared the results with our previously

reported *ESR1* NAPA assay for D538G, Y537S, Y537C and Y537N mutations (Stergiopoulou et al, Cancers, 2021).
Patients and Methods. Using the 6-color Crystal Digital PCR™ breast cancer 12plex assay, we analyzed 35 plasma cfDNA samples from ER+ breast cancer patients and 10 plasma cfDNA from healthy donors (HD). We also analyzed the same cfDNA samples using the *ESR1* NAPA assay.
Results. The Stilla 6-color breast cancer assay revealed in 5/35 (14,3%) ER+ cfDNA samples the *AKT1*_E17K and *ESR1* D538G mutations. *ESR1* D538G was detected in 4/35 ER+ cfDNA samples with the *ESR1* NAPA assay. Direct comparison between Crystal Digital PCR™ and the *ESR1* NAPA assay revealed a high concordance (97.1%) for 34/35 samples tested, for the detection of the D538G mutation, and with a higher sensitivity for the Stilla 6-color breast cancer assay. The *ESR1* mutations Y537S, Y537C and Y537N were not detected by either method in any of the plasma-cfDNA samples. No *AKT1* E17K or *ESR1* mutations were detected in cfDNA from HD plasma.
Conclusions. The naica® system 12plex *ESR1* assay is quantitative, highly sensitive and easy to perform using plasma-cfDNA samples. The use of highly multiplexed Crystal Digital PCR™ shows great promise for clinical utility for ER+ breast cancer patient monitoring.
Key words: Circulating tumor DNA; Crystal Digital PCR™, *ESR1* mutations; liquid biopsy; mutation monitoring, 6-color multiplexing;

The clinical characteristics and outcomes of NSCLC patients with genomic alterations detected by blood-based NGS ctDNA assay
Hsin-Yi Wang[1], Chao-Chi Ho[2], Yen-Ting Lin[3], Wei-Yu Liao[2], Chung-Yu Chen[1], Jin-Yuan Shih[2], Chong-Jen Yu[2]. *[1]National Taiwan University Hospital, Yun-lin Branch, Yunlin, Taiwan,[2]National Taiwan University Hospital, Taipei, Taiwan,[3]National Taiwan University Cancer Centre, Taipei, Taiwan*

Background: The Blood First Assay Screening Trial (BFAST) (NCT03178552) is a prospective study screening for actionable genetic alterations using NGS of ctDNA among patients with treatment-naive advanced or metastatic NSCLC. We aimed to perform a more systematic

investigation of genomic alterations in Asia/Taiwan NSCLC patients through the BFAST database at NTUH.
Materials and Methods: There was a total of 269 patients enrolled and receiving FoundationOne Liquid Companion Diagnostic (F1LCDx) assay at cancer diagnosis between Feb, 2019 and Mar, 2022 in NTUH. The concordance of tissue-based genetic testing in the real-life clinical setting and the blood-based NGS testing in the clinical trial were analyzed. The co-occurrence of genomic alterations detected with blood-based NGS ctDNA assay were also interpreted.
Results: A total of 206 patients (76.5%) detected driver mutations. Tissue-based genetic testing in the real-life clinical setting missed driver mutations in 67 (24.9%) patients with a sensitivity of 67.32%. Liquid NGS detected 38 (14%) patients with RET, KRAS, Met or ErbB2 mutations which were beyond the scope of current genetic testing in the clinical settings. Also, the F1LCDx assay detected more uncommon EGFR mutations than the Roche Cobas EGFR Mutation Test V2 ($P < 0.0001$). Thirty-four (12.6%) patients had non-detected results in the F1LCDx assay which produced a sensitivity of 83.41%. By multivariate analysis, the predictors associated with discordant blood-based NGS ctDNA results were T stage (odds ratio [OR] 0.35, 95% confidence interval [CI] 0.15-0.79, $p = 0.012$) and M stage (OR 0.21, 95% CI 0.09-0.49, $p < 0.0001$). The most common co-occurring mutations in the blood-based NGS ctDNA assay were TP53, DNMT3A, TET2, PIK3CA and CTNNB1. Among the EGFR mutant population, first-generation compared to third-generation TKI use (hazard ratio [HR] = 0.43, 95% CI 0.22-0.85, P=0.02) and co-occurring genomic alterations in TET2 (HR = 2.35, 95% CI 1.15-3.48, P=0.02) were associated with shorter progression free survival of EGFR TKIs treatment in multivariate analysis. Disease stage was the only factor associated with overall survival in the EGFR mutant population.
Conclusion: NGS ctDNA analysis provided a more comprehensive genetic testing than conventional single gene testing kits. The lower stage which could imply lower or lack of ctDNA shedding into the blood was associated with a discordant result of the blood-based NGS ctDNA assay. Co-occurring mutations might have an impact on the treatment duration of EGFR-TKI.

Objective qualification of cell-free DNA by applying the cfDNA quality metric

Annika Dorn. *Agilent Technologies, Inc., Waldbronn, Germany*

Next Generation Sequencing (NGS) of cell-free DNA (cfDNA) has the potential to reveal new biomarkers for various conditions. Despite the establishment of low input library protocols, library preparation of cfDNA samples remains a challenge due to restricted amount of starting material and variable size distribution of cfDNA fragments. The yield and quality of cfDNA can vary and a lot of care is required to obtain appropriate cfDNA starting material for downstream applications. Further, cfDNA samples may contain high molecular weight (HMW) DNA that can negatively affect library yield and sequencing quality. Therefore, quality control of cfDNA starting material is essential to ensure the success of downstream experiments. The Agilent Tapestation system with the Cell-free DNA ScreenTape Assay is based on automated electrophoresis and thereby offers an objective and reliable qualification of cfDNA samples by applying the %cfDNA quality score. By comparing different samples with varying total DNA yield and HMW contamination, the additional level of information gained by the %cfDNA score is highlighted. While other QC methods might miss critical information on HMW DNA contamination, this could result in flawed yield estimations, ultimately threatening the successful outcome of downstream experiments. Therefore, accurate quantification of cfDNA starting material, taking also HMW DNA contamination into account is essential for NGS library preparation and generating reliable NGS results.

#6704

A digital-PCR primer/probe library for pan-cancer ctDNA monitoring established from public databases for somatic mutations

Hayato Hiraki, Akiko Yashima-Abo, Takeshi Iwaya, Satoshi S. Nishizuka. *Iwate Medical Univ., Iwate, Japan*

Background: Circulating tumor DNA (ctDNA), a new class of tumor marker, has been demonstrated the clinical validity of: 1) early relapse prediction, 2) therapeutic efficacy evaluation, and 3) relapse-free corroboration in the context of cancer treatment. Variant allele frequencies

(VAFs) of ctDNA were under 0.1% even in most advanced cancer patients. Since the detection limit of next-generation sequencing (NGS) is above 1%, higher sensitivity is needed for sensitive ctDNA monitoring. Digital PCR (dPCR) offers excellent sensitivity at an affordable cost compared with NGS. A mutation-specific primer/probe (P/P) is required for the dPCR assay, but a limited number of P/Ps are commercially available.
Materials and Methods: To provide essential probes for the rapid monitoring of sensitive ctDNA, we developed an off-the-shelf (OTS) dPCR P/P library (OTS-Probes) that includes probes that can detect >1,000 mutations found in human cancer. The majority of the mutations to be detected by these P/P sets have been selected using an originally developed statistical scoring from hot spot mutations reported in the Catalogue of Somatic Mutations in Cancer (COSMIC) database. To evaluate the coverage of OTS-Probes in human cancer specimens, the Cancer Genome Atlas (TCGA) and the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) datasets were used. TCGA is an international landmark cancer genomic program in the U.S., and C-CAT is a Japanese cancer genome profiling database.
Results: At least one mutation was matched to the OTS-Probes for ctDNA monitoring in lung, colorectum, stomach, liver, pancreas, breast, uterus, and prostate from TCGA and C-CAT cancer specimens, reflecting 63% and 77% of corresponding tumor types, respectively. The mutation coverage of the OTS-Probes tends to be lower in TCGA than in C-CAT, partially due to the fact that information about the *TERT* promoter mutation is absent in TCGA. We found that some *ARID1A* deletion mutations that have a high count in COSMIC were not observed in either the TCGA or the C-CAT database. We also analyzed the coverage of the OTS-Probes in different organs and driver genes. Currently, more than 250 P/P sets have been designed, synthesized, and validated with human tumor DNA or synthesized DNA fragments. Importantly, nearly 98% of P/P sets work with the same PCR condition. With our proprietary oligo synthesis method with modified bases, only a small percentage of P/P sets required optimization of the annealing temperature.
Conclusion: We developed a dPCR P/P library called OTS-Probes. Our analysis suggests that 60-80% of cancer patients could immediately apply at least one P/P set for sensitive ctDNA monitoring by dPCR. A quarter of the P/P library has already been validated by tumor DNA or synthesized DNA

fragments. OTS-Probes is a great tool for ctDNA- related studies and for clinical use when a higher sensitivity than NGS can offer is required.

Molecular detection of circulating cancer cells with cancer stem cell or mesenchymal characteristics in esophageal squamous cell carcinoma

Zhen Tan, Josephine Mun-Yee Ko, Valen Zhuoyou Yu, Hoi Yan Ng, Simon Law, Maria Li Lung. *The University of Hong Kong, Hong Kong, China*

Esophageal squamous cell carcinoma (ESCC) is a clinically challenging disease that requires a multidisciplinary approach. Unfortunately, the scarcity of ESCC genomic data hinders the understanding of ESCC biology, disease progression and rational therapy design. Circulating tumor cells (CTCs), which are shed from the primary and metastatic tumors and then circulate within the peripheral vasculature, reflect the existing tumor heterogeneity. Here, we utilized the non-biased size-based CTC enrichment strategy in combination with the real-time RT-PCR to molecularly characterize the CTCs with cancer stem cell (CSC) or mesenchymal properties in ESCC. Comprehensive data from ESCC cell lines, mouse ESCC xenograft models and clinical ESCC peripheral blood samples emphasize the importance of *TWIST1* (Twist Family BHLH Transcription Factor 1) in ESCC progression. Gain-of-function and loss-of-function analyses demonstrate that TWIST1 promotes cell migration, invasion and colony formation in ESCC cells. Moreover, positive TWIST1 expression is responsible for the chemoresistance of ESCC cells to Cisplatin and is correlated with poor overall survival in ESCC patients. In addition, we show that TWIST1 promotes malignant potential, including tumor growth, invasion and chemoresistance via the TWIST1-TGFBI-ZEB1 signaling pathway in ESCC. Meanwhile, the TWIST1-TGFBI-ZEB1 signaling pathway confers immunosuppressive conditions to the tumor microenvironment, which in turn contributes to EMT to promote tumor progression. Collectively, these findings indicate that TWIST1 has a novel role in ESCC carcinogenesis by regulating tumorigenicity and cancer stem cell properties that may be useful as a prognostic monitoring biomarker and a promising therapeutic target in clinical ESCC treatment.

Co-culture of circulating tumor cells (CTCs)-derived 3D organoids and autologous cytotoxic CD8+ T cells: A new functional precision oncology platform

Lanlan Zhou, Leiqing Zhang, Lindsey Carlsen, Kelsey E. Huntington, Vida Tajiknia, Andrew George, Arielle De La Cruz, Arunasalam Navaraj, Praveen Srinivasan, Maximilian Schwermann, Benedito A. Carneiro, Wafik S. El-Deiry. *Pathology and Laboratory Medicine, Legorreta Cancer Center at Brown University, Providence, RI*

Greater than 10 million patients succumb to cancer each year. Cancer metastasis is responsible for more than 90% of all cancer-associated deaths due to treatment resistance and increased tumor burden. As a seed for metastases, circulating tumor cells (CTCs) present a new dimension and horizon for clinical doctors in diagnosis, prognosis prediction, treatment monitoring, disease mechanism, and drug development. CTCs could gradually replace tissue biopsies which are painful and may be difficult to obtain depending on tumor location. CTC isolation is feasible after minimally invasive liquid biopsy and provides the basis for a multitude of *ex vivo* and *in vivo* studies including establishment of CTCs-derived 2D and 3D cultures. Organoids are miniscule models of tissues that grow in a 3D semisolid extracellular matrix medium with specific growth factors supplied. CTCs-derived 3D organoids play a vital role in precision oncology because they can preserve tumor heterogeneity, imitate the tumor microenvironment (TME), mimic cancer hypoxia in the TME, and maintain cancer and metastasis phenotypes. Cytotoxic $CD8^+$ T cells are the most powerful effectors in the anticancer immune response. We hypothesized that co-culture of CTCs-derived 3D organoids and autologous cytotoxic $CD8^+$ T cells could maximize patient-relevance of laboratory assessment of cancer-treatment immune-system interactions to facilitate precision oncology practice. TellBio's novel TellDx CTC technology allows for isolation of viable and intact CTCs in liquid biopsies, regardless of cancer type. Unlabeled CTCs were cultured in growth factor reduced Matrigel with organoid culture WENRAS medium. Magnetic beads labeled white blood cells (WBCs) were cultured with T cell culture medium - WBCs and magnetic beads usually separate in three days - cytotoxic $CD8^+$ T cells were isolated with the EasySep™ Human $CD8^+$ T Cell Isolation Kit. CTCs-derived 3D organoids and autologous cytotoxic $CD8^+$ T cells were co-

cultured with or without different drug treatments - cytotoxicity was measured with CellTiterGlo® 3D Cell Viability Assay and imaging, and further mechanistic studies were feasible. Our co-culture platform enables us to utilize a patient's peripheral blood or pleural effusions to create a patient-specific, *in vivo*-like TME and immune microenvironment to model and assess *ex vivo* responses to investigational and FDA-cleared cancer therapies, and potentially provide oncologists with insights to improve clinical outcomes.

Optimization of miRNA isolation from plasma biopsies of proton therapy prostate cancer patients

Johnny I. Velasquez[1], Andrew Bass[2], Moein Rajaei[3], Curtic Bryant[4], Nancy Mendenhall[4], Luisel Ricks-Santi[5]. *[1]Florida-California Cancer Research Education and Engagement Health Equity Center (CaRE2 Center), Gainesville, FL,[2]University of Florida, Gainesville, FL,[3]Department of Pharmacotherapy and Translational Research, College of Pharmacy, University of Florida, Gainesville, FL,[4]University of Florida Health Proton Therapy Institute, Jacksonville, FL,[5]Cancer Center, University of Florida, Gainesville, FL*

Introduction: Radiotherapy (RT) is a treatment option for men with Prostate Cancer (PCa). While minimizing damage to proximal healthy tissue, RT can still result in severe toxicities. Studies have shown that exposure to ionizing radiation leads to changes of miRNA expression at the cellular level, making cells more radioresistant or radiosensitive which could result in toxicity, recurrence, and metastatic spread. Importantly, RT induced miRNA changes have been found to be associated with RT response in clinical contexts and may serve as diagnostic tools to assess PCa risk stratification that inform precision medicine approaches. However, miRNAs have not been assessed in patients treated with proton therapy (PT), a type of particle-based RT which purports improved dose distribution and reduced toxicity. This is attributed to the proton’s unique ability to deposit most of its energy at a narrow bragg peak with minimal energy deposition beyond the peak, into surrounding organs. Because miRNAs are ubiquitous in the human body, they are stable in many environments including the bloodstream and are becoming attractive biomarkers of treatment response,

including RT. Still, blood-derived biomarkers for diagnosis, prognosis, and therapy response is an emerging field and there remains a lack of standardization and normalization of sample preparation and protocol for isolating human derived miRNA from plasma. The objective is to optimize RNA isolation procedures so that it is achievable to accurately identify miRNA biomarkers in PCa patients undergoing PT.
Methods: The results of 2 RNA isolation kits were compared. To assess the effectiveness of each optimization strategy performed, a number of metrics were used to quantitate and determine the quality of the RNA: fluorometry (Qubit 2.0 and 4.0), spectrophotometry (nano-drop), and qRT-PCR amplification (Taqman).
Results: Fluorometry methods were not sensitive enough for RNA quantification for either kit. Of the two RNA isolation kits, Kit A outperformed Kit B in every metric output when 100 uL of plasma was initially used. Furthermore, amelioration of metric output was observed when the original starting plasma amount of 100 uL was increased to 200 uL in Kit A. Nanodrop quantities ranged from 8.85 - 32.65 ng/uL and -72.82 - 4.98 ng/uL using Kit A and Kit B, respectively. The quality (260/280 ratios) ranged from -7.65 - 3.17 and -41.65 - 6.13 for Kit A and Kit B, respectively. Taqman amplification was achieved for both kits.
Conclusions: Although total RNA isolation was effectively performed, there is a need for properly optimizing miRNA detection in these blood-based biopsies. Enhancing miRNA detection to determine treatment outcomes may result in miRNA's becoming a powerful predictive biomarker. The goal is to utilize miRNAs as a diagnostic tool for real time monitoring of individualized therapy response, detecting developing metastases, and predicting relapse.

#6709

Utility of RNA sequencing for transcriptome analysis of small extracellular vesicles derived from blood sera of colorectal cancer patients

Tana Machackova[1], Petra Vychytilova-Faltejskova[1], Marie Madrzyk[1], Karolina Trachtova[1], Marketa Pavlikova[1], Jan Kotoucek[2], Jana Halamkova[3], Dagmar Al Tukmachi[1], Jiri Sana[1], Petra Pokorna[1], Milana Sachlova[3], Ondrej Slaby[4]. *[1]Molecular Medicine, Central European Institute of Technology, Brno, Czech Republic,[2]Pharmacology and Toxicology,*

Veterinary Research Institute, Brno, Czech Republic,[3]Comprehensive Cancer Care, Masaryk Memorial Cancer Institute, Brno, Czech Republic,[4]Biology, Masaryk University, Faculty of Medicine, Brno, Czech Republic

Introduction: Currently used molecular diagnostic tests for colorectal cancer (CRC) are underperforming and more sensitive, non-invasive biomarkers are needed. Long non-coding RNAs (lncRNA) and microRNA (miRNA) have shown potential as diagnostic biomarkers. Unfortunately, the identification of non-coding RNA circulating biomarkers in blood serum is significantly burdened by abundant RNA specimens from disrupted blood cells. Recently, small extracellular vesicles (sEVs) emerged as potential reservoirs of clinically relevant biomarkers, including lncRNAs and miRNAs. In theory, sEVs protect RNAs from degradation and might serve as a source of intact RNA for further analyses. However, there is a lack of evidence supporting the superior quality of RNA extracted from sEVs over RNA from whole blood serum. This study aimed to analyze the RNA content of blood serum and the sEVs derived from the blood serum of CRC patients and healthy controls using RNA sequencing. Moreover, small RNA sequencing was used to evaluate the difference in miRNA profiles of sEVs and corresponding blood sera of CRC patients and healthy controls.
Methods: Spin-column chromatography (Exiqon), precipitation-based method (Norgen), and size-exclusion chromatography (iZON) were used to extract sEVs from blood sera. The concentration of sEVs was measured by dynamic light scattering (DLS), the size was evaluated by electron microscopy (EM), and sEV-specific content was analyzed by western blot and qRT-PCR. RNA was extracted using the column-based method. Next-generation sequencing (NGS) analyses of blood serum and sEVs extracted from blood serum included samples from 10 CRC patients and 10 healthy controls for RNAseq, and 5 CRC patients and 5 healthy controls for small RNAseq. Differential expression analysis was carried out in R using DESeq2 package.
Results: DLS and EM showed that size-exclusion chromatography yielded the purest population of sEVs characterized according to ISEV recommendations. Extraction of sEVs and subsequent RNA extraction and sequencing library preparation from ultra-low input samples were optimized. Over 30k different RNAs were identified in the sEVs derived

from blood sera of CRC patients and healthy controls, including lncRNAs, miRNAs, and protein-coding RNAs. A detailed comparison of the transcriptome of blood sera and corresponding sEVs is a part of the poster. **Conclusion:** sEVs could serve as a source of RNA biomarkers; however, proper characterization and optimal methodology are necessary.

Myc-regulated miR17, 20a modulate RANK expression in osteosarcoma

Bikesh Kumar Nirala[1], Lyazat Kurenbekova[1], Tajhal Patel[1], Ryan Lane Shuck[1], Atreyi Dasgupta[1], Nino Carlo Rainusso[1], Jason T. Yustein[2]. *[1]Texas Children's Hospital Cancer & Hematology Ctr., Houston, TX,[2]Pediatrics, Emory University School of Medicine, Atlanta, GA*

Osteosarcoma (OS) is the most common primary bone tumor in children and adolescents. Approximately 25-30% of these tumors carry amplification of chromosome 8q24, which harbors the oncogene c-Myc, and correlates with a poor prognosis in patients with OS. To understand the mechanisms that underlie the ability of Myc to alter both the tumor and its surrounding tumor immune microenvironment (TiME), we generated and molecularly characterized an osteoblast-specific Cre-Lox-Stop-Lox;(LSL)-c-MycT58A;p53f/+ knockin genetically engineered mouse model (GEMM). Phenotypically, the Myc knockin-GEMM had rapid tumor development with a high incidence of metastasis. Myc-dependent gene signature in our murine model demonstrated significant homology to the human Myc-amplified OS.Interestingly, we noticed a significant reduction in the osteoclast (OCL) cell population in the Myc knockin OS tumor compared to the p53-driven. We found the expression of RANK was significantly downregulated in the Myc knockin tumor compared to the Non-knockin

p53 heterozygous tumors. The RANK/RANKL pathway is vital in OCL maturation and bone modeling/remodeling. To understand the involvement of Myc in RANK regulation, we used murine-derived OS cell lines and transiently knocked down of Myc expression using siRNA. We observed a significant upregulation in RANK expression after Myc knockdown. To decipher the molecular mechanism behind the Myc-dependent regulation of RANK expression in OS, we looked into the Myc-mediated microRNAs. Myc regulates the expression of several microRNAs, including the polycistronic miR-17-92 cluster. The expression of miR17-5p and Mir20a-5p was significantly higher in the GEMM tumor tissue samples isolated from the Myc knockin compared to the p53-driven. Further, we validated the Myc-dependent regulation of miR-17-5p/20a-5p expression using transient knockdown of Myc in mouse Myc knockin-derived cell lines. To examine the role of miR17-5p/20a-5p on the RANK regulation, we performed both gain and loss-of-function studies using microRNA-17/20a mimics and inhibitors. After the treatment with miR-17-5p/20a-5p inhibitors, the expression of RANK was significantly upregulated whereas in
the case of miR17/20a mimics reversed these effects and led to a downregulation of RANK expression. We established that miR-17-5p/20a-5p is causally responsible for at least part of the mechanism by which Myc regulates the RANK expression in OS.We concluded that the Myc-regulated miR17/20a modulates the RANK expression that is involved in the OCL cell population regulation and function in the OS.

ALCAM promotes neuroblastoma proliferation, migration, and immune evasion

Jarrett Lindsay, Minu Samanta, Nathan Kendsersky, Jonathan Gaither, Molly Christie, Kyabeth Torres-Rodriguez, Catherine Wingrove, John M. Maris. *Children's Hospital of Philadelphia, Philadelphia, PA*

BACKGROUND: Neuroblastoma is a cancer arising from the developing sympathetic nervous system. Less than half of children diagnosed with high-risk neuroblastoma survive five years. Two transcriptional subpopulations have been identified: aggressive, chemotherapy-sensitive adrenergic (ADRN) and indolent, chemotherapy-resistant mesenchymal

(MES). ALCAM is a cell adhesion molecule that is overexpressed in neuroblastoma. ALCAM is a cancer stem cell marker in colorectal and small cell lung cancer and promotes bone metastasis in prostate cancer. ALCAM also interacts with the CD6 receptor on T cells, which facilitates adhesion in the immunological synapse and inhibits T cell activation.
METHODS: We characterized ALCAM expression in 24 neuroblastoma cell lines using immunoblotting. We investigated ALCAM expression in ADRN and MES neuroblastoma using RNA-sequencing data from two patient datasets. Next, we developed doxycycline (dox)-inducible ALCAM depletion cell lines using CRISPR inhibition (CRISPRi) in three high-ALCAM cell lines with relevant oncogenic aberrations. Using the Incucyte® SX5 Live-Cell Analysis System, we interrogated the effects of ALCAM depletion on proliferation and scratch wound migration. To determine the mechanism of ALCAM overexpression, we leveraged ChIP-sequencing data for MYC and MYCN in 9 cell lines. We probed the effects of the MYC(N)-MAX disrupter MYCi975 on ALCAM expression using immunoblotting. To investigate the effects of the ALCAM-CD6 interaction on T cells, we stimulated CD4+ and CD8+ T cells with CD3/28 antibodies in the presence or absence of recombinant ALCAM and measured activation by ELISA for IFN-γ, and TNF-α and flow cytometry for CD69 expression.
RESULTS: ALCAM is highly expressed in most neuroblastoma primary tumors and cell lines. ALCAM mRNA expression is higher in the ADRN subpopulation ($p \leq 0.0045$), although both ADRN and MES tumors and cell lines express high levels of ALCAM. Dox-inducible CRISPRi mediated robust ALCAM depletion in all three cell lines, and ALCAM knockdown significantly delayed proliferation ($p \leq 0.0025$) and impaired scratch wound migration. ChIP-sequencing showed robust MYC(N) peaks at the ALCAM promoter, and treatment with IC_{50} concentrations (3.5 - 9.0 μM) of MYCi975 depleted MYC(N) and ALCAM. Activation of CD4+ and CD8+ T cells in the presence of recombinant ALCAM mediated dose-dependent reduction in expression of T cell activation marker CD69 after 3 days and inhibited IFN-γ and TNF-α release.
CONCLUSIONS: ALCAM is overexpressed in neuroblastoma and its expression is driven, at least in part, by MYC(N). ALCAM is a mediator of cellular proliferation and migration and may contribute to immune evasion by inhibiting T cell activation. Ongoing *in vivo* studies will characterize the

effects of ALCAM depletion on tumor growth and metastasis. We propose ALCAM is a tractable immunotherapy target through multi-specific antibodies or the ALCAM-CD6 interaction.

CLIC1 and CLIC4 ion channels as bioelectric targets for tumor treating fields in pediatric high-grade glioma

Michaela Griffin, Paul Smith, Raheela Khan, Surajit Basu, Stuart James Smith. *University of Nottingham, Nottingham, United Kingdom*

Background: High Grade Glioma is a lethal brain cancer with an average survival of 14 months. Due to the scarcity of effective treatment, and aggressive nature of the tumor, pediatric High Grade Glioma (pHGG) forms a leading cause of CNS cancer-related death in children. Optune™ is a non-invasive therapy that uses alternating electric fields - coined Tumor Treating Fields (TTFields) - to disrupt cancer cell division. Increasing evidence shows that ion channels not only regulate electrical signaling of excitable cells, but also play a crucial role in the development and progression of brain tumors. Ion channels are essential in cell cycle control, invasion and migration of cancer cells and therefore present as valuable therapeutic targets.
Methods: CLIC channel expression patterns were identified via multivariate analysis of in-house and publicly available data sets and RNA sequencing of in-house patient tissues. siRNA depletion of CLIC1 and CLIC4 was assessed using cell cycle, clonogenic, migration and proliferation assays, alone and concomitant with TTFields and or CLIC channel inhibitors, IAA94 or metformin. Whole transcriptome gene expression analysis (Human Clariom™ Array) of pHGG cells treated with TTFields was carried out. Whole cell and cell attached patch clamp protocols were used to assess ion channel activity in pHGG and normal astrocytes.
Results: Clinical correlation determined that CLIC4 and CLIC1 deficiency was associated with increased overall survival ($p=<0.03$), with siRNA depletion propagating a reduction in the proliferation, migration and invasion of pHGG cell lines associated with cell cycle arrest. Furthermore, CLIC1 and CLIC4 deficiency exacerbated the killing capacity of TTFields, reducing clonogenic and proliferative capabilities. Concomitant application of either IAA94 or metformin, and TTFields increased the sensitivity of

cells to TTFields. Whole transcriptome gene expression analysis of pHGG cell lines treated with TTFields and found that cells treated with TTFields exhibited a down-regulation in CLIC1 and CLIC4 compared to untreated cells. Furthermore, neurophysiological patch clamp experiments revealed increasingly depolarized membrane potential readings in pHGG cell lines compared to normal astrocytes, with unique ion channel activity (including chloride channel function) observed and the potential for further pharmacological exploitation.
Conclusions: These data provide rationale that genetic, electrical, and pharmacological manipulation of ion channels can reduce the capacity of childhood brain tumors to proliferate and invade. CLIC channels may be a suitable target to enhance the treatment efficacy of TTFields and help optimize this non-invasive therapy in pediatric HGG patients.

Preclinical evaluation of nano-liposomal irinotecan in pediatric solid tumor patient-derived xenografts

Elizabeth Stewart[1], Kaley Blankenship[1], Burgess Freeman[2], Sara Federico[1], Michael Dyer[3]. *[1]Oncology, St. Jude Children's Research Hospital, Memphis, TN,[2]Preclinical PK Shared Resource, St. Jude Children's Research Hospital, Memphis, TN,[3]Developmental Neurobiology, St. Jude Children's Research Hospital, Memphis, TN*

Background: Pediatric solid tumors are rare and the use of well characterized preclinical models can be a helpful tool to prioritize novel drug combinations and formulations which are challenging to test in a limited patient population. Irinotecan (IRN) has shown efficacy in diverse pediatric cancers where children are often treated on an extended low-dose schedule rather than a single large dose commonly used in adults. The use of nano-liposomal irinotecan (nal-IRI) is a promising strategy as 95% of the drug remains encapsulated during systemic exposure while maintaining prolonged exposure in the tumor. Adult clinical trials have shown reduced side effects without compromising efficacy but nal-IRI has had limited use thus far in pediatric cancers.
Methods: Orthotopic xenograft models of Ewing sarcoma (EWS, 4 models) and rhabdomyosarcoma (RMS, 2 models) were generated by injecting luciferase labeled cells into the femur and hind-leg muscle of nude mice

respectively. Pharmacokinetic (PK) studies on normal and tumor-bearing mice were performed for both nal-IRI and standard IRN to determine matched human AUC-guided dosing and schedule of chemotherapy agents. Mice were randomized to single agent and relevant combinations of nal-IRI with PARP inhibitors and temozolomide (EWS) and with vincristine and temozolomide (RMS) and compared to the same regimens using standard IRN. Therapy was given on a clinically relevant schedule with each course consisting of 21 days and tumor response was measured weekly using bioluminescence.
Results: PK studies showed that plasma levels of the active metabolite of IRN (SN-38) drop quickly for both standard IRN and nal-IRI single dosed mice while the levels of SN-38 were maintained in the tumor for several days using the nal-IRI formulation. In all 6 models tested, nal-IRI combinations were as or more effective when compared to regimens using standard IRN. No significant toxicity was seen in mice treated with nal-IRI combinations.
Conclusions: The substitution of nal-IRI for standard IRN remains a promising strategy in pediatrics with the potential to reduce side effects as well as hospital visits due to the dosing schedule with nal-IRI given once per cycle where standard IRN is often given for 5 or 10 days in children. Our preclinical PK data confirmed the liposomal formulation resulted in sustained SN-38 levels in the tumor and efficacy was maintained or improved in pediatric cancer models. The combination of nal-IRI with temozolomide and talazoparib is now being tested in a multi-center randomized phase I/II trial for children with relapsed solid tumors and this data supports consideration for use in other pediatric cancer trials both in the upfront and relapse setting.

Extracellular vesicles in diagnostic retinoblastoma aqueous humor correlate with disease stage and clinical outcome: a pilot study

Sarah Pike[1], Chen-Ching Peng[1], Paolo Neviani[2], Jesse L. Berry[1], Liya Xu[1].
[1]The Vision Center, Children's Hospital Los Angeles, Los Angeles, CA,[2]Extracellular Vesicle Core, Children's Hospital Los Angeles, Los Angeles, CA

Introduction: Retinoblastoma (RB), a pediatric retinal malignancy, is unique in that it cannot be biopsied, impeding biomarker discovery. Aqueous humor (AH) is an ocular fluid that is an established source of tumor information, serving as a surrogate liquid biopsy. Extracellular vesicles (EVs) are promising biomarker candidates, and were recently established in RB AH. EVs are membrane-enclosed secretory vesicles carrying bioactive molecular information, which can be phenotyped using validated tetraspanin protein markers. Currently, relationships between EVs and RB clinical features are unknown, but establishing such relationships is necessary to determine the utility of EVs as RB biomarkers. Methods: We quantified and phenotyped EVs in 37 AH samples from 18 RB eyes with varying International Intraocular Retinoblastoma Classification (IIRC) stages and explored clinical correlations. Samples were collected from 10 eyes at diagnosis (DX) and 27 eyes during treatment (Tx). By outcome, 6 DX eyes were enucleated and 4 were salvaged. DX samples were collected from one A, one B, six D and two E eyes by IIRC group. 10μL of unprocessed AH underwent Single Particle-Interferometric Reflectance Imaging Sensor (SP-IRIS) (Exoview R100) analysis for fluorescent-based particle count and immunophenotyping of tetraspanin expression (CD63/81/9). Counts were converted to percentages. Statistics were done with Mann-Whitney U, ANOVA, and Tukey's tests. Results: Samples from DX eyes (n=10) contained a higher number of EVs than samples from Tx eyes (n=27) (1.68 x 107 ± 4.28 x 107 per mL vs. 2.10x 106 ± 1.33 x 106 per mL) by SP-IRIS analysis. By percentage, DX samples were enriched with CD63/81+ EVs ($P<0.001$) while Tx samples had more homogenous mono-CD63+ dominant EV populations ($P=0.007$). Enrichment of CD63/81+ EVs was significantly higher in enucleated AH (n=6) than salvaged AH (n=4) when compared by count ($P=0.038$) and marginally higher when compared by percentage ($P=0.067$). The CD9/81+ EV population percentage was significant in salvaged eyes ($P=0.01$). By IIRC, CD63/81+ EVs were most abundant in Group E eyes (n= 2) when compared to Group D eyes (n=6) by count ($P<0.001$), and when compared to Group A+B eyes (n=2) by count ($P=0.01$) and percentage ($P=0.019$). Group A+B eyes had a larger percentage of CD9/81+ EVs than did Group E eyes ($P=0.043$). Conclusions: EV quantity in RB AH decreases with treatment, and phenotypic expression profiles vary by treatment status and clinical outcome. TheCD63/81+ EV subpopulation is higher in eyes with advanced

Group E disease and those requiring enucleation, while the CD9/81+ subpopulation is higher in eyes with less advanced Group A+B disease and those salvaged with treatment. Our data suggests that EV phenotypes correlate with RB clinical features, and further research into these subpopulations offers the prospect of establishing critical RB biomarkers.

Exploiting metabolic vulnerabilities of pediatric rhabdomyosarcoma with novelnicotinamide phosphoribosyltransferase (NAMPT) inhibitor OT-82

Grace McKay-Corkum[1], Victor J. Collins[1], Choh Yeung[1], Takeshi Ito[2], Sameer H. Issaq[2], Arnulfo Mendoza[1], Kazutoshi Yamamoto[3], Murali Cherukuri[3], Len Neckers[2], Christine M. Heske[1]. *[1]Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD,[2]Urologic Oncology Branch, National Cancer Institute, Bethesda, MD,[3]Radiation Biology Branch, National Cancer Institute, Bethesda, MD*

Purpose: A hallmark of cancer cells is altered metabolism. Therapeutically, these alterations may be exploited by targeting metabolic vulnerabilities specific to cancer cells. Efficient production of NAD through the NAD salvage pathway is one such potential vulnerability, as some tumor cells demonstrate a high need for rapid NAD turnover. Nicotinamide phosphoribosyltransferase (NAMPT) is the pharmacologically targetable rate-limiting enzyme in this pathway. We report on the effect of targeting NAMPT in models of pediatric rhabdomyosarcoma (RMS), a cancer for which novel therapeutics remain an unmet need.
Experimental Procedures: The relative sensitivity of RMS cell lines to NAMPT inhibitors was first compared to NAMPT inhibitor sensitivity of other cancer cell lines using viability assays. A panel of ten molecularly diverse RMS cell lines was used for the remainder of the evaluations. *In vitro* activity of NAMPT inhibition was evaluated using assays of proliferation and cell death. Measurements of NAD and functional assessment of NAD-dependent processes, such as glucose metabolism, were used to study the mechanistic activity of NAMPT inhibition in these models. *In vivo* studies included assessments of toxicity, efficacy, and mechanism of action of a clinical NAMPT inhibitor, OT-82, in four orthotopic RMS models.

Results: RMS cells showed striking sensitivity to NAMPT inhibition with IC-50 values in the low nanomolar range. *In vitro,* NAMPT inhibition resulted in NAD depletion and impaired cellular proliferation. Effects on glucose metabolism included decreases in glycolytic activity and glycolytic capacity in all cell lines tested, as well as decreased oxidative phosphorylation in a subset of cell lines. The majority of cell lines exhibited ATP depletion and irreversible necrotic cell death. Apoptotic cell death was not observed. *In vivo*, the effects of OT-82 treatment delivered on the human clinical schedule replicated those seen *in vitro,* including loss of glycolytic activity as measured using hyperpolarized ^{13}C MRI spectroscopy. In all four xenograft models, complete tumor regressions were observed at multiple doses and with minimal toxicity.
Conclusions: NAMPT inhibition with OT-82 was highly effective in decreasing RMS proliferation and impairing glucose metabolism both *in vitro* and *in vivo*. Given these results, there is a critical need for further clinical study of this class of agents for RMS.

Using proteasome inhibition to hyperactivate the integrated stress response in aggressive pediatric brain tumors
Orlandi Valencia Novak, Tyler Findlay, Jeffrey Rubens, Charles Eberhart, Eric H. Raabe. *Johns Hopkins University School of Medicine, Baltimore, MD*

H3K27-altered diffuse midline glioma (DMG) and atypical teratoid/rhabdoid tumor (AT/RT) are aggressive pediatric brain tumors with dismal outcomes. DMG and AT/RT have increased baseline activation of the integrated stress response (ISR), an evolutionarily conserved system that enables cells to tolerate various forms of stress. This activation is manifested by elevated levels of ATF4 and NRF2 in DMG and AT/RT, respectively. Transient or low-level expression of these transcription factors protect cells from stress, while sustained, high-level activation leads to cell death. Ixazomib is an orally bioavailable proteasome inhibitor that causes endoplasmic reticulum stress, which is a major upstream activator of the ISR. We hypothesized that the high baseline level of ATF4 in DMG and NRF2 in AT/RT would make these tumors susceptible to ISR activators such as ixazomib. After determining the IC50 of ixazomib, DMG and

AT/RT cell lines (JHH-DIPG1, JHH-DIPG16A, and CHLA06) were treated with increasing concentrations of the drug. Cleaved caspase 3 immunofluorescence showed a significant increase of apoptosis in all cell lines (JHH-DIPG16A and CHLA06 $p<0.0001$, JHH-DIPG1 $p=0.0008$ by ANOVA). Additionally, western blots for cleaved PARP and phospho-Rb expression detected induction of apoptosis and suppression of cell proliferation in JHH-DIPG1 treated with ixazomib. We are currently testing ixazomib in combination with idarubicin, a brain-penetrant anthracycline, and gemcitabine, a brain-penetrant nucleoside analog. Synergy testing in CHLA06 showed an overall zero-interaction-potency (ZIP) synergy score of 23.464 with inhibitory concentrations of ixazomib and idarubicin in the low nanomolar range (scores of 10 or above indicate synergy). Similarly, ixazomib and gemcitabine synergized to suppress CHLA06 growth and induce apoptosis (67% Annexin V+ cells in combination compared to 14 and 24% Annexin V+ with single agent treatment). In the future, we will determine if ixazomib selectively kills DMG and AT/RT while sparing normal cells in iPSC brain organoids. We will also test ixazomib singly and in combination with traditional chemotherapy in orthotopic xenografts of AT/RT. These results suggest that ixazomib, especially in combination with idarubicin, gemcitabine or other ISR activators, has the potential to serve as an effective therapy for aggressive pediatric brain tumors.

β3-adrenergic receptor correlates with tumor growth and progression in neuroblastoma

Alessia Boaretto, Gennaro Bruno, Nicoletta Nastasi, Claudio Favre, Maura Calvani. *Meyer Children's Hospital Florence, Firenze, Italy*

Neuroblastoma (NB) is a heterogeneous, often aggressive, extracranial tumor and the most common malignancy to be diagnosed in the first year of life. It has been already demonstrated that the specific antagonism of the β3-adrenergic receptor (β3-AR) on NB tumor cells affects tumor growth. To confirm the results obtained with the pharmacological approach on the crucial role played by the β3-AR receptor in influencing different pro-tumoral signaling pathways, here we investigated the effect of CRISPR/Cas9-mediated knock-out of β3-AR gene (ADRB3) on human NB cell line BE(2)-C *in vitro* and *in vivo*. Inoculation of BE(2)-C β3-AR$^{-/-}$ cells

in athymic nude mice (NU(N-Cr)-Foxn1nu) showed a strong reduction of NB tumor growth compared to wild type cells, and in some cases β3-AR knock-out tumor cells failed in producing a tumor mass. RNA Sequencing on these tumor masses showed alterations of signaling pathways related to various tumor mechanisms, such as proliferation, cell motility and cell differentiation. Furthermore, we evaluated by flow cytometry the expression of β3-AR in circulating tumor cells (CTCs) from NB patients with different degrees of disease. Following depletion with anti-CD45 magnetic beads, tumor cells were identified through the expression of specific tumor markers, CD56 and GD2. Results showed that a high expression of β3-AR correlates with poor prognosis, characterized by metastatic or recurrent tumors, compared to patients with a favorable clinical outcome that instead show a low expression of β3-AR. Overall, our results demonstrate the β3-AR involvement in supporting NB tumor growth and suggest a possible role in regulating the metastatic potential of this tumor.

RNAScope *in situ* hybridization as a novel approach for the spatiotemporal assessment of RD3 mRNA expression in neuroblastoma

Dinesh Babu Somasundaram[1], Sheeja Aravindan[2], Zhongxin Yu[1], Ashley Baker[1], Natarajan Aravindan[1]. *[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]OU Health Stephenson Cancer Center, Oklahoma City, OK*

Our recent investigations unveiled the transcriptional and translational loss of Retinal degeneration Protein 3 in neuroblastomas (NB) when compared to the healthy adult and fetal tissues. Further, our preclinical studies with patient derived cellular systems and mouse model of high-risk NB (HR-NB) demonstrated that RD3 loss orchestrates disease progression. More importantly, we defined the therapy pressure driven acquired loss of RD3 in neuroblastomas, its crucial function in the evolution of progressive disease (PD), and further defined the prognostic and predictive significance of RD3 loss in NB. In this study, we investigated the use of RNAScope as a sensitive and specific method for the evaluation of spatiotemporal RD3 transcriptional loss in NB. We investigated the expression of RD3 mRNA in FFPE NB (n = 100) tissues utilizing RNAScope with custom archived RD3

specific probes comparing it with the matched RD3 protein (IHC) expression patterns. With positive (PPIB) and negative (DapB) controls in place, our results displayed definite and specific RD3 mRNA expression in NB. We observed a statistically significant association of RD3 mRNA loss to the disease progression and poor clinical outcomes. Further, we observed significant correlation to the loss of RD3 transcription to the evolution of progressive disease. More importantly, the expression gradients of RD3 mRNA observed with RNAScope assay (compared in terms of no treatment vs progressive disease, primary vs metastatic disease, relapsed vs no relapse, favorable to unfavorable disease) illustrate the concordance with the RD3 IHC outcomes. Our results provide a reference basis for better RD3 mRNA readouts in NB, and more importantly identify the technically sound, adaptable (high throughput/single event, manual/automatic) RNAScope *in situ* hybridization assay as an alternate approach to detect spatiotemporal expression of RD3 mRNA. Together, the results provide a new, descriptive, and efficient platform, RNAScope for assessing spatiotemporal RD3 mRNA expression that could better inform disease prognosis and therapy response in children with NB.

Application of in vitro drug screening of circulating tumor cells in pediatric glioma therapy

Yen-Lin Liu[1], Yin-Ju Chen[2], Shu-Huey Chen[3], Yu-Mei Liao[4], Wu Shih-Pei[5], Yi-Hsuan Chen[1], Wan-Ling Ho[1], Liang-Yi Juo[1], Chia-Yau Chang[1], Jinn-Li Wang[6], Min-Yu Su[7], Pei-Chin Lin[4], Shih-Chung Wang[8], James S. Miser[9], Tai-Tong Wong[10], Yuan-Hung Wu[11], Peng Yuan Wang[12], Thierry Burnouf[2], Jeng-Fong Chiou[13], Long-Sheng Lu[13]. *[1]Departments of Pediatrics, Taipei Medical University Hospital, Taipei, Taiwan,[2]Graduate Institute of Biomedical Materials & Tissue Engineering, Taipei Medical University, Taipei, Taiwan,[3]Departments of Pediatrics, Taipei Medical University-Shuang Ho Hospital, New Taipei, Taiwan,[4]Division of Pediatric Hematology/Oncology, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan,[5]CancerFree Biotech Ltd., Taipei, Taiwan,[6]Departments*

of Pediatrics, Taipei Municipal Wanfang Hospital, New Taipei, Taiwan,[7]Department of Pediatrics, China Medial University Children's Hospital, Taichung, Taiwan,[8]Division of Pediatric Hematology/Oncology, Changhua Christian Children's Hospital, Changhua, Taiwan,[9]Taipei Cancer Center, Taipei Medical University, Taipei, Taiwan,[10]Pediatric Neurosurgery, Taipei Medical University Hospital, Taipei, Taiwan,[11]Division of Radiation Oncology, Department of Oncology, Taipei Veterans General Hospital, Taipei, Taiwan,[12]Key Laboratory of Alzheimer's Disease of Zhejiang Province, Institute of Aging, Wenzhou Medical University, Zhejiang, China,[13]Radiation Oncology, Taipei Medical University Hospital, Taipei, Taiwan

Twenty-one gliomas in patients aged 0-21 years were evaluated for drug sensitivity by *ex vivo* expanded circulating tumor cells (CTC). The results were correlated with clinical outcomes. Venous blood samples were obtained prior to drug treatment. Peripheral blood mononuclear cells were processed in a 3D cell culture system (EVA Select™, Cancer Free Biotech Ltd., Taipei, Taiwan) and cultured for 3 weeks. Expanded CTCs were successfully cultured into organoids from 18 out of 21 patients and were analyzed for ATP abundance. Staining with CD45, a marker for blood cells, and pancytokeratin, a marker for keratinocytes, was performed on the cultured cells. Staining of GFAP, a marker of glioma cells, was performed in a subset of samples. These cells were then tested in cytotoxicity assays in triplicate with a panel of chemotherapeutic and targeted agents at clinically relevant concentrations. The surviving fraction was normalized to a buffer-only control. Based on the percentage of cell viability, the agent was chosen for clinical treatment. Comparing the results among low-grade glioma (LGG; $n = 6$), diffuse midline glioma (DMG; $n = 4$), and high-grade glioma (HGG, $n = 8$; including glioblastoma multiforme [GBM; $n = 5$]), the mean surviving fraction to temozolomide was similarly high across the three tumor types (LGG *vs*. DMG *vs*. HGG = 57.5% *vs*. 50.6% *vs*. 49.5%, respectively). 6 of 6 patients in the LGG group showed CTC sensitivity to at least one chemotherapeutic agent tested. The clinical response of patients treated with selected agents was evaluated with the RANO criteria at 6 months after initiation of treatment. Among the 24 agents tested with clinical correlation, the CTC surviving fraction after exposure to the agent

was significantly higher in patients who had progressive disease within 6 months (n = 11; 68%) *vs*. in patients with no progression at 6 months (n = 13; 39%; P = 0.039). Treating CTCs with histone deacetylase inhibitors *in vitro* resulted in a consistently lower surviving fraction (15.1% ± 12.0%) for DMG and HGG/GBM; however, clinical correlation was not available. The 1 patient with clinical correlation with HGG had a 34.9% surviving fraction to a Tyrosine kinase inhibitor (TKI) *in vitro* and showed a 42.9% shrinkage at 6 months after treatment with the TKI. The expansion of CTCs in patients with relapsed/refractory pediatric gliomas provides the ability to test drug sensitivity of patient-derived organoids. Our data suggest a correlation between the *ex vivo* drug sensitivity of CTCs and clinical response.

Targeting urea cycle dysfunction to prevent and treat osteosarcoma

Rachel Offenbacher[1], Paul Ciero[2], David Loeb[1]. *[1]The Children's Hospital at Montefiore, Bronx, NY,[2]Albert Einstein College of Medicine, Bronx, NY*

Introduction: Osteosarcoma (OS) is the most common primary malignant bone tumor in adolescents and young adults. Intensive multimodal treatment cures almost 75% of patients who present with localized disease; however, only 25% of patients who present with metastases become long term survivors, and those who suffer a metastatic relapse are almost never cured. Polyamine metabolism and signaling play important roles in multiple cancers but have not previously been studied in osteosarcoma. D, L-alpha-difluoromethylornithine (DFMO) is an irreversible inhibitor of ornithine decarboxylase (ODC), the initial, rate-limiting enzyme within the polyamine biosynthetic pathway, and has been studied in a number of different cancers as either a therapeutic or a chemopreventive agent. We investigated the role of polyamines in OS proliferation and metastasis and whether blocking the polyamine synthetic pathway with DFMO had therapeutic potential in the treatment of OS.
Methods: We evaluated proliferation, apoptosis, clonogenic growth and the ability to grow under nonadherent conditions in vitro using established OS lines. To investigate the effect of DFMO on tumor growth in vivo, we implanted fragments of patient derived xenograft into the tibias of NOD/SCID/IL-2Rγ null mice. Upon confirmation of tumor growth, mice

were randomized to either receive drinking water or drinking water supplemented with 2% DFMO. A third cohort of mice received water supplemented with 2% DFMO only after hindlimb amputation.
Results: DFMO has a profound effect on the proliferation of OS cell lines in vitro. Utilizing caspase assays, we determined that DFMO does not induce apoptosis, but is cytostatic and inhibits proliferation. We found that DFMO prevents the clonogenic growth of 3 different OS cell lines in soft agar and prevents spheroid formation under non-adherent conditions. Interestingly, once established, spheroidss were not disrupted by the addition of DFMO. In vivo, administration of 2% DFMO after hindlimb amputation decreased local recurrence and limited metastasis ($p=0.02$).
Conclusion: DFMO inhibits proliferation and clonogenic growth in vitro, and decreases distant metastasis in vivo. Since pediatric dosing and safety data are already established, our findings are readily translatable to clinical trials.

Effectiveness of irinotecan plus trabectedin in a desmoplastic small round cell tumor patient-derived xenograft
Valentina Zuco, Sandro Pasquali, Monica Tortoreto, Stefano Percio, Valentina Doldi, Marta Barisella, Paola Collini, Gianpaolo Dagrada, Silvia Brich, Patrizia Gasparini, Marco Fiore, Michela Casanova, Anna Maria Frezza, Alessandro Gronchi, Silvia Stacchiotti, Andrea Ferrari, Nadia Zaffaroni. *Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy*

Desmoplastic small round cell tumor (DSRCT) is a ultra-rare pediatric scarcoma with poor overall survival. This tumor is dependent on the continued expression and activity of its pathognomonic molecular lesion, the EWS-WT1 transcription factor. DSRCT is often treated with multimodal approach of chemotherapy, surgery, and radiotherapy. Given the rarity of the disease, there have not been clinical studies to establish an effective therapeutic regimen. Indeed, the development of fully characterized preclinical models, able to reproduce the molecular characteristics of clinical tumors, appears instrumental for testing novel therapeutic strategies and accelerating the translation of preclinical findings to the clinical practice. In this study we exploited a novel DSRCT patient-derived xenograft (PDX), which reproduces histomorphological, genomic

(CNV) and transcriptomic characteristics of the paired clinical tumor, to comparatively assess the activity of cytotoxic and targeted anticancer agents. Anti-tumor effect was moderate for single-agent doxorubicin, pazopanib and larotrectenib [maximum tumor volume inhibition (max TVI): 55-66%], trabectedin had a higher effect (max TVI: 82%) while irinotecan and eribulin almost complete inhibited tumor growth (max TVI: 96% and 98%, respectively). Interestingly, combination of irinotecan with either eribulin or trabectedin resulted in complete responses which were maintained until the end of the experiment for irinotecan + trabectedin. The trabectedin + irinotecan combination markedly reduced the expression of anti-apoptotic proteins and caused caspase-3 cleavage, consistent with an apoptotic response, and also induced the accumulation of phospho-RIP1 (Ser166) and phospho-RIP3 (Ser227), indicating the occurrence of necroptosis, a type of programmed cell death with necrotic morphology. In line with these findings, transcriptomic profile analysis of ex-vivo tumor samples obtained from mice exposed to trabectedin ± irinotecan revealed a reduced expression of the biological pathways related to apoptosis and cell proliferation in tumor exposed to the drug combination. Mechanistically, we found that these effects were mediated, at least in part, by the down-regulation of EWS-WT1 chimeric protein and its downstream targets, as assessed by PCR and western blotting. Overall, this study emphasizes the importance of patient-derived pre-clinical models to explore new treatments in DSRCT and fosters clinical investigation in the activity of irinotecan plus trabectedin, providing a step forward for developing more effective trabectedin-based combinations for DSRCT to be tested in clinical trials.

Therapeutic targeting of BET bromodomain proteins increases DNA damage and potentiates salvage therapy in osteosarcoma xenografts derived from patients with replication stress signatures

Niknam Riyahi, Pankita H. Pandya, Barbara J. Bailey, Erika A. Dobrota, Courtney Young, Harlan E. Shannon, Farinaz Barghi, Rada Malko, Khadijeh Bijangi-Vishehsaraei, Melissa A. Trowbridge, Kathy Coy, Felicia M. Kennedy, Anthony L. Sinn, Steve Angus, Michael J. Ferguson, M. Reza Saadatzadeh, Karen E. Pollok. *Indiana University School of Medicine, Indianapolis, IN*

Osteosarcoma (OS) is an aggressive cancer of the bone with high metastatic potential in pediatric as well as adolescent and young adults. The survival rate for metastatic and relapsed OS patients is <30% and there is currently no effective standardized salvage therapy. Lack of efficacy is attributed to genetic complexity present in OS that is partly due to moderate levels of replication stress (RS). While high levels of RS can induce cell death, moderate RS levels may cause genomic instability that contributes to OS progression. Therefore, induction of RS to high levels that cause cell death could be a promising therapeutic strategy. Bromodomain and extra-terminal domain [BET proteins (BRD2,3, and 4)] are a family of epigenetic readers that not only regulate gene expression networks, but also regulate DNA replication and RS. Thus, we tested the hypothesis that BET inhibition will potentiate the efficacy of salvage therapy through exacerbation of RS in xenograft models of aggressive OS. The effect of the bivalent BET inhibitor (BETi), AZD5153, as a single agent and in combination with cytotoxic agents such as topotecan and ifosfamide was evaluated. Combination index and Bliss independence analyses demonstrated additive to synergistic cell growth inhibition in OS cell lines upon treatment with clinically relevant concentrations of AZD5153+ topotecan/ifosfamide. Treatment with PROTAC ARV825 that degrades BET proteins, resulted in similar growth inhibitory effects. Significant increase in PARP cleavage was observed following AZD5153+topotecan treatment compared to single agent, indicating enhancement of apoptosis. In addition, western blot and comet assays showed that BETi+topotecan induces its effect, at least partly, through increased DNA damage and RS *in vitro*. *In vivo* efficacy and safety studies focused on patient-derived xenografts (PDXs) of naive and pre-treated OS that harbor RS signatures. AZD5153 as a single agent significantly suppressed tumor growth in both naïve (PDX96) and pretreated (TT2) OS PDX models compared to vehicle ($p<0.05$, Two-way ANOVA; Holm-Sidak). Anti-tumor effect correlated with increased γ-H2AX following AZD5153 exposure in PDX, indicative of increased RS. Moreover, RNA-seq analysis integrated with kinome profiling data from BETi-treated PDX exhibited deregulation of factors involved in RS. Combination treatments of BETi+topotecan/ifosfamide indicated that AZD5153 potentiated the anti-cancer effect of salvage therapy in TT2 OS PDX, was well tolerated, and increased the probability of survival in mice. Efficacy in an OS RS+ metastatic lesion model is in progress. These data

collectively suggest that BET inhibition as a single agent and in combination with low-dose salvage therapy holds promise as novel treatment strategies for inducing RS-mediated cell death in aggressive OS.

Osteosarcoma patient-derived xenografts derived from naive and pretreated metastatic patients with high-risk CDK4/6 hyperactivation signatures are sensitive to dual inhibition of CDK4/6 and PI3K/mTOR

Farinaz Barghi[1], M. Reza Saadatzadeh[2], Erika Dobrota[3], Rada Malko[1], Barbara J Bailey[2], Courtney Young[4], Harlan E. Shannon[4], Ryli Justice[4], Niknam Riyahi[4], Khadijeh Bijangi-Vishehsaraei[5], Melissa Trowbridge[6], Kathy Coy[6], Felicia M Kennedy[6], Anthony L Sinn[6], Amber Mosley[7], Steve Angus[4], Michael J. Ferguson[8], Pankita H. Pandya[5], Karen E. Pollok[1].
[1]Indiana University School of Medicine, Department of Medical and Molecular Genetics, Indianapolis, IN,[2]Indiana University School of Medicine, .Herman B Wells Center for Pediatric Research, Indianapolis, IN,[3]Indiana University School of Medicine, Herman B Wells Center for Pediatric Research, IUSM, Indianapolis, IN,[4]Indiana University School of Medicine, Herman B Wells Center for Pediatric Research, Indianapolis, IN,[5]Indiana University School of Medicine, Department of Pediatrics, Hematology/Oncology, Indianapolis, IN,[6]Indiana University School of Medicine, In Vivo Therapeutics Core, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN,[7]Indiana University School of Medicine, Indianapolis, IN,[8]Indiana University School of Medicine, Department of Pediatrics, Indianapolis, IN

Precision genomics studies have demonstrated hyperactivation of cyclin-dependent kinases 4 and 6 (CDK4/6) as a top actionable marker in children, as well as adolescents and young adults (AYA) with osteosarcoma (OS). CDK4/6 binds to cyclin D resulting in a complex that mediates RB phosphorylation leading to cell cycle progression. Preclinical modeling approaches are critical for identification of tumor adaptive responses to CDK4/6 inhibitors (CDK4/6i) as well as validation of alternative or combination therapies. Although CDK4/6i are clinically well-validated, cytostatic effects make combination treatments essential. Moreover, concomitant dysregulation of CDK4/6 and PI3K/mTOR pathways are

observed in aggressive OS. Multiple positive feedback loops between these pathways exacerbate the hyperactivation of CDK4/6 and PI3K/mTOR signaling. Thus, we hypothesize that dual inhibition of CDK4/6 and PI3K/mTOR will be efficacious in RB+ OS PDXs. In this study, OS PDX models TT2-77 (pretreated patient) and HT96 (treatment-naïve patient) with molecular signatures indicative of therapeutic sensitivity to palbociclib (RB+, CDKN2A null, CCND3 amplified) were treated long-term with CDK4/6i (palbociclib) (50 mg/kg), PI3K/mTOR inhibitor (PI3K/mTORi; voxtalisib) (50 mg/kg) or combination palbociclib+voxtalisib. In both PDXs, growth was significantly reduced in single-agent and combination groups compared to vehicle ($p<0.05$, two-way ANOVA). Importantly, combination palbociclib + voxtalisib was more efficacious than single-agents following prolonged treatment and well tolerated based on histological analyses. Kinome profiling analysis of long-term treated HT96 PDX demonstrated that compared to single agents, dual inhibition of CDK4/6+PI3K/mTOR significantly decreased PI3K pathway activity, including downregulation of Pik3ca, mTOR, and the G2 to M transition regulator CDK1 (-log10[p] ≥1.3). OS metastatic lesion 143B model indicated increased survival based on body scoring criteria in combo versus single agent. In RB+ OS cell lines and TT2-77 xenoline, palbociclib+voxtalisib caused additive-to-synergistic cell growth inhibition, G1 arrest, and minimal apoptosis at clinically relevant doses. Increased activity of senescence biomarker beta-galactosidase indicated that inhibition of CDK4/6 but not PI3K/mTOR induced significant levels of senescence in OS cells. Mechanistic siRNA RB studies indicated CDK4/6i effect was partially dependent on RB status. These data provide evidence that combination palbociclib+voxtalisib therapy is safe, efficacious, and increases CDK4/6i efficiency in both pretreated and naive PDX models of OS. These studies provide rationale for earlier therapeutic intervention in pediatric and AYA OS patients with CDK4/6 hyperactivation signatures.

Urea cycle metabolism is disturbed in Fibrolamellar carcinoma

Mahsa Shirani[1], Solomon Levin[1], Michael D. Tomasini[1], James Knox[2], Bassem Shebl[1], David Requena[1], Jackson Clark[1], Søren Heissel[3], Hanan Alwaseem[3], Rodrigo Surjan[4], Ron Lahasky[5], Henrik Molina[3], Barbara Lyons[1], Rachael D. Migler[6], Philip Coffino[1], Sanford M. Simon[1].

[1]Laboratory of Cellular Biophysics, Rockefeller University, New York, NY,[2]Rockefeller University, New York, NY,[3]Proteomics Resource Center, Rockefeller University, New York, NY,[4]General Surgery Division, Surgery Department, Hospital Nove de Julho, São Paulo, Brazil,[5]Lahasky Medical Clinic, Abbeville, LA,[6]The Fibrolamellar Registry, New York, NY

In fibrolamellar hepatocellular carcinoma (FLC), hyperammonemic encephalopathy is a common occurrence and occasionally causes death. Using mass spectrometry, we quantitatively analyzed the proteomes of FLC patient's tumor and adjacent normal, to find pathways that are changed in FLC. These data identified multiple proteins that were altered in the proteome, among these, enzymes involved in metabolism of ammonia. These results were confirmed with immunofluorescence demonstrating that these alterations occur in all tumor cells. These results suggest that FLC cells have defects in the two primary ammonia detoxification pathways in the liver, which are responsible for detoxification of 70% of the ammonia in the body: 1) consumption of ammonia by glutamine synthetase (GLUL), and 2) addition of ammonia by ornithine carbamoyltransferase (OTC) to the urea cycle. Additionally, they also generate extra ammonia because of upregulation of glutaminase (GLS). This was tested with a targeted metabolomics of the reactants and products of these enzymes. The results were consistent with both a loss of the two pathways for consumption of ammonia activation of a pathway for generating ammonia. This production of ammonia is consistent with the observation that surgical resection of fibrolamellar reduces the ammonia in patients. All FLC patients with hyperammonemic encephalopathy and documented urine test results showed increased urinary orotic acid, evidence of blockage of the OTC pathway. This study implies that hyperammonemic encephalopathy in FLC may require alternatives to commonly used therapies.

#6730

Preclinical testing of lestaurtinib (CEP701) as a single and combination agent for the treatment of Ewing sarcoma

Samet Dayi[1], Christiane Schaefer[1], Anne Albers[2], Kiruthiga Balusamy[2], Marc Hotfilder[2], Maximilian Kerkhoff[1], Leonhard Koch[1], Hatice Önder[1], Claudia Rössig[2], Uta Dirksen[1], Stefan K. Zöllner[1]. *[1]Pediatrics III,*

University Hospital Essen, Essen, Germany,[2]Pediatric Hematology and Oncology, University Hospital Münster, Münster, Germany

Background: Multimodality treatment of Ewing sarcoma (EwS), a highly malignant bone and soft tissue tumor, provides a cure in most patients, but in the metastatic stage the prognosis remains bleak; new systemically effective therapeutic options are urgently needed. The multikinase inhibitor lestaurtinib (CEP701) is an orphan drug that has been clinically studied in various carcinomas, refractory neuroblastoma, and acute myeloid leukemia, but has not yet established itself as a standard therapy.
Methods: We performed an in vitro screening of 142 compounds with different mechanisms of action at two different concentrations and measured cell viability 120 hours after the first of two days of treatment. Lestaurtinib was further tested as a lead compound in various cell biology assays in a group of EwS cell lines genetically representing clinically predominant tumor characteristics.
Results: Lestaurtinib was among the 21 of 142 (14.8%) compounds tested that were sensitive, i.e., reduced cell viability to below 20% at 1 μM and/or 10 μM in at least four of five EwS cell lines tested. In an expanded group of six other EwS cell lines, 72 hours of treatment with lestaurtinib resulted in significantly reduced cell growth compared to human mesenchymal stem cells. In several colony formation assays, a significant reduction in the number or size of colonies was observed, both when treatment occurred prior to colony growth and when colonies that had already formed were treated. Lestaurtinib induced apoptosis with a significant increase in PI+/FTIC+-driven cells, significantly promoted anoikis, and prevented cell migration by FACS, low adherence flow cytometry analysis, and scratch assays, respectively. Cell cycle analyses by FACS showed significant G_2-M cell cycle arrest after 24 hours of treatment. Lestaurtinib also displayed a synergistic cytotoxic effect with doxorubicin, an established agent for the treatment of EwS, and exhibited a favorable dose-reduction index in all EwS cell lines tested. Notably, treatment with lestaurtinib significantly reduced doxorubicin dose at high efficacy levels (Fa 0.97) and low combination index values.
Conclusion: Our results highlight the *in vitro* efficacy of lestaurtinib in EwS and warrant further testing in an *in vivo*model as a single agent and in combination with doxorubicin.

Gut microbiome associated with the psychoneurological symptom cluster among children with solid tumors receiving chemotherapy

Jinbing Bai[1], Melissa Martin[2], Kathryn S. Sutton[1], Christie Powell[2], Thomas Olson[1], Hye In Noh[1], Maria C. Swartz[3], Deborah Watkins Bruner[1].
[1]Emory University, Atlanta, GA,[2]Children's Healthcare of Atlanta, Atlanta, GA,[3]University of Texas MD Anderson Cancer Center, Houston, TX

Background: Children with cancer (CWC) receiving chemotherapy (chemo) report significant suffering from a cluster of psychoneurological symptoms (PNS), including pain, fatigue, anxiety, depression, and cognitive dysfunction. Continuous or severe PNS reduce a child's quality of life. Chemo can disturb the gut microbiome (GM), which is associated with PNS based on the gut-brain axis. This study aimed to examine associations of GM with PNS and the PNS cluster in CWC undergoing chemo.
Methods: An observational prospective study was conducted in 21 CWC enrolled from Children's Healthcare of Atlanta. Children with at least 1 cycle of chemo were consented pre-cycle 2 chemo (T1) and followed at the end of chemo (T2). At T1, parents reported children's demographics; at T1 and T2, PNS (pain, fatigue, anxiety, depression, cognitive dysfunction) were reported by children by the Pediatric PROMIS scales and fecal specimens were collected for GM. T-score of the PROMIS scales was computed; an average of T-scores of the five PNS was computed for the PNS cluster. T-score >50 indicates a significant symptom or symptom cluster. 16S rRNA V4 gene from fecal specimens was sequenced for GM. QIIME 2 was used to examine associations of α- and β-diversity with PNS. Linear discriminant analysis effect size identified microbial taxa associated with each PNS and the PNS cluster.
Results: We analyzed 21 CWC with a mean age of 13 years, 67% male, and 67% white. Children at T2 had higher fatigue (54% vs. 43%), cognitive dysfunction (69% vs. 43%), depressive symptoms (23% vs. 19%), and multiple PNS (62% vs. 48%), but lower pain interference (31% vs. 38%) and anxiety (23% vs. 38%) than those at T1. No association was found for α-diversity at T1; higher α-diversity was associated with lower cognitive dysfunction (Faith's phylogenetic diversity, p=0.04) and anxiety (Pielou's_e, p=0.08) at T2; β-diversity (Jaccard distance) showed the GM

dissimilarities by levels of pain interference (moderate vs. severe, p=0.02) and levels of anxiety (mild vs. moderate, p=0.07). After controlling for study timepoint, children with low pain interference had an enriched *Bacteroides*; those with low fatigue had enriched *Bacteroides* and *Turicibacter*; those with normal cognitive function had enriched *Parasutterella, UBA1819, NK4A214, Sellimonas*, and *Ruminococcaceae*. Children without the PNS cluster had enriched *Bacteroides, while* those with the PNS cluster had enriched *Enterobacteriaceae*. Children without multiple PNS had enriched *UCG_003*.
Conclusions: Children with low PNS showed a higher α-diversity and a higher abundance of taxa involved in nutrition and vitamin metabolism (eg, *Bacteroides*), reducing inflammation (eg, *Turicibacter*), and producing short chain fatty acids (eg, *Ruminococcaceae*). These findings provide potential solutions to treat PNS. Further work is needed to corroborate these associations in CWC.

#6732

Identifying novel combination therapies for Ewing sarcoma

Maria Ana Isabel C. De Los Santos[1], Anne-Florence Blandin[1], Alejandra E. Aguilar[1], Matthew Hall[2], Min Shen[2], Ya-Qin Zhang[2], Brian D. Crompton[1].
[1]Dana-Farber Cancer Institute, Boston, MA,[2]National Center for Advancing Translational Sciences, Bethesda, MD

Ewing sarcoma is the second most common pediatric bone cancer in children and young adults. The standard of care therapy consists of chemotherapy, surgery, and radiation. Despite therapeutic advances, metastatic and relapsed Ewing sarcoma have poor outcomes. This is partially because transcription factors, such as the Ewing sarcoma oncoprotein *EWS-FLI1,* are difficult targets for the development of small molecules. Novel synergistic combination treatments are needed, and drug repurposing efforts can fast track potential therapies into clinical trials. To identify synergistic anti-Ewing combinations of targeted cancer agents, we conducted an initial library screen of 26 tyrosine kinase inhibitors, cell cycle inhibitors, and chemotherapies on two Ewing cell lines. While the screening results revealed multiple synergistic combinations of tyrosine kinase inhibitors and cell cycle inhibitors, we focused our follow-up validation studies on combinations that met at least one of the following

criteria: 1) agents that exhibited additivity when combined with VEGFR inhibitors, a class of agents already shown to having clinical efficacy in Ewing sarcoma and 2) combinations involving approved FDA drugs that could be rapidly translated into early phase trials for patients with Ewing sarcoma. Efficacy of selected synergistic combinations were then tested in vitro on a larger collection of Ewing cell lines. Based on these results, two combinations, one with a VEGFR inhibitor and one combination of FDA approved agents, was tested in an aggressive Ewing sarcoma xenograft mouse model for efficacy and impact on survival. We demonstrated that the combination of ribociclib, a CDK 4/6 inhibitor, and regorafenib, a VEGFR inhibitor, exhibited additivity and synergy in Ewing cell lines. Xenografted mice treated with this combination had significantly impaired tumor proliferation in a subcutaneous tumor model and prolonged survival (median 35 days) compared to mice treated with vehicle (median 28 days) or single-agent therapy. Similarly, cell lines treated with copanlisib, a PI3K inhibitor, and ribociclib, two FDA-approved drugs, synergistically inhibited cell line viability in vitro and impaired xenograft proliferation in vivo. This combination also significantly improved survival (median 48 days) in a mouse xenograft compared to treatment with vehicle (median 27 days) or either drug alone. This work demonstrates that CDK 4/6 inhibitors show synergistic activity with both VEGFR inhibitors and PI3K inhibitors in Ewing Sarcoma by impairing the growth of cultured Ewing cells and improving the survival of mice with Ewing sarcoma. We believe that pre-clinical validation of novel approved drug combinations in Ewing sarcoma will accelerate the development of early phase trials for patients with relapsed refractory disease, a group of patients greatly in need of new therapeutic opportunities.

#6733

Targeting Sp1 in Ewing sarcoma: a multi-approach method for the utilization of mithramycin

Christoffer Lambring, Riyaz Basha, Umesh Sankpal. *University of North Texas Health Science Ctr., Fort Worth, TX*

Purpose: Ewing Sarcoma (ES) is a bone and soft tissue cancer affecting young adults and children. Localized ES presents with a 5-year survival rate of 70%, while metastatic cases range from 15-30%. Our laboratory

investigates combination treatments using less toxic agents to induce sensitization to chemotherapy in ES. The anti-cancer activity of an antineoplastic antibiotic, Mithramycin (Mit), against ES cells has been shown. Mit inhibits Specificity protein 1 (Sp1) a marker associated with aggressive cancer cell growth and resistance to chemo/radiation therapies. However, its mechanistic effects on other oncogenic proteins have yet to be elucidated in ES. The purpose of this study is to evaluate the effectiveness of Mit and combination with other chemotherapeutic agents, Etoposide and Vincristine, to inhibit ES cell growth and assess the effect on cancer related proteins regulated by Sp1. Future studies will expand upon Mithramycin's mechanism of action in Ewing Sarcoma utilizing RNA sequencing and computational methods.
Methods: Anti-proliferative activity of Mit and/or Vincristine and Etoposide against ES cell lines, TC205 and CHLA10, was evaluated using CellTiterGlo kit. Dose curves and IC50 values were determined by Sigma-Plot software. The expression of Sp1 and survivin was determined by Western blot analysis. Cell lines were obtained from Children's Oncology Group. The specific type of drug effect of the combination treatments were determined by analyzing the combination index obtained via Calcusyn software. Nude mice were injected with TC-205 cells and treated over two weeks with either Mit (1mg/kg per week) and/or Etoposide (5mg/kg per week) and tumor volume was compared. Protein models were obtained from RCSB PDB and homology tests were performed in the Swiss-model workspace.
Results: Mit significantly decreased ES cell line viability and tumor volume in nude mice. Mit showed the ability to reduce the expression of Sp1 and offered differing effects on survivin expression, indicative of anti-apoptotic mechanisms being implemented in the ES cell lines. IC50 values of both chemotherapeutics and Mit were decreased by nearly 50% when used in combination and this effect was mirrored in further decreases in Sp1 expression. Synergistic drug responses were shown in the combination of Mit with both Vincristine and Etoposide. Sp1 and survivin protein models were established and homology verification using Ramachandran plots and QMEAN Z-scores indicated quality protein models for further computational studies.
Conclusions: Mit may effectively sensitize ES cells and improve the response of chemotherapy while lowering necessary effective dosages.

Studies to understand the mechanism of action of Mit on Sp1, survivin, and other proteins involved in Ewing Sarcomagenesis are underway. This study is partially supported by a grant from the Cancer Prevention and Research Institute of Texas (Award#: RP210046)

Identification of the novel *TENM3-ALK* fusion in an AYA case with *ALK* rearranged neuroblastoma

Mitsuteru Hiwatari[1], Masafumi Seki[2], Ryosuke Matsuno[3], Kenichi Yoshida[4], Takeshi Nagasawa[2], Aiko Sato-Otsubo[2], Shohei Yamamoto[5], Motohiro Kato[2], Kentaro Watanabe[2], Masahiro Sekiguchi[2], Satoru Miyano[6], Seishi Ogawa[4], Junko Takita[7]. *[1]Pediatrics, Teikyo University School of Medicine, Tokyo, Japan,[2]Pediatrics, University of Tokyo, Tokyo, Japan,[3]Pediatrics, Kansai Medical University, Osaka, Japan,[4]Pathology and Tumor Biology, Kyoto University, Kyoto, Japan,[5]Pediatrics, Tokai University School of Medicine, Isehara, Japan,[6]Tokyo Medical and Dental University, M&D Data Science Center, Tokyo, Japan,[7]Pediatrics, Kyoto University, Kyoto, Japan*

Neuroblastoma is the most common extracranial solid tumor that occurs in childhood and the most common cancer in infancy. Fewer than 5% of neuroblastomas occur in adolescents and young adults (AYAs), for whom the disease has an indolent and fatal course. Chen et al. previously reported that missense mutations in the protein- tyrosine kinase domain of *anaplastic lymphoma kinase* (*ALK*) occur in approximately 10% of cases of sporadic neuroblastoma, and these missense mutations result in the activation of the ALK protein kinase domain, which plays a key role in the tumorigenic process as seen in ALK fusion proteins. Since the initial discovery of the NPM-ALK fusion protein in human anaplastic lymphoma cell lines, more than 24 different ALK fusion proteins have been discovered in various malignancies. Till date, ALK-containing chimeric proteins have not been reported in neuroblastoma. In this study, a translocation within chromosome 2p and 4q was found to bring about the formation of an in-frame fusion gene that was composed of portions of the *teneurin transmembrane protein 3* (*TENM3*) gene and *ALK* gene in tumor cells from an AYA patient with neuroblastoma. The patient was 19-year-old female diagnosed with stage 4

neuroblastoma (unfavorable histology, poorly differentiated subtype, MYCN DNA not amplified). Computed tomography revealed a mass in the left adrenal gland with bone, spine, liver, and lung metastasis. *ALK* rearrangement was confirmed via FISH analysis. Crizotinib resulted in no disease progression for 5 months, except for metastatic spinal disease, but it did not exhibit high efficacy compared with its effects against lymphoma and lung cancer. This 5′ in-frame fusion partner gene in neuroblastoma has not yet been identified, and its role is not well-known in oncogenesis. We generated the cell line with the expression of the full length *TENM3-ALK* cDNA in NIH-3T3 cells led to the formation of a fusion protein. A cell-based evaluation of this predicted ALK protein variant revealed activation of downstream targets-STAT3, AKT and ERK- and ALK inhibitors, crizotinib or lorlatinib, treatment inhibited the growth of xenograft tumors with stable TENM3-ALK expression. We determined whether TENM3-ALK affects transformation and proliferation using a soft agar colony formation assay. As expected, the cells that expressed an empty vector and wild type ALK line did not produce a considerable number of colonies, whereas TENM3-ALK transfected cells showed anchorage-independent growth, resulting in the production of a higher number of colonies .The evidence for the role of ALK receptor signaling in stimulating neuroblastoma tumor cell growth and the demonstrated *in vitro* and *in vivo* efficacy of the ALK selective inhibitors in this study provide biological and clinical justification for the further exploration of this combination and testing in patients with recurrent or refractory neuroblastoma.

Identifying the role of novel driver TREX subcomplex in medulloblastoma growth and progression

Shahad M. Abdulsahib, Santosh Timilsina, Manjeet Rao. *UT Health Science Center at San Antonio, San Antonio, TX*

Background: Medulloblastoma (MB) is the most common malignant brain cancer in children. Despite the progress made in treating MB, the 5-year survival rate for high-risk tumors remains poor and risk of recurrence within 2 years of treatment is still high. Almost all MB deaths are attributed to leptomeningeal dissemination (LMD) as MB spreads exclusively through cerebrospinal fluid (CSF) to spinal and intracranial leptomeninges.

Unfortunately, patients who do survive have reduced quality of life because of the highly toxic side effects of radiation and chemotherapy. *Those facts underline the importance of identifying new drivers of medulloblastoma and understanding the mechanism by which those drivers may promote medulloblastoma.* Towards that goal, I aim to identify novel drivers of MB and characterize novel therapies for treating (LMD-MB). Using an unbiased genome-wide screen, we discovered THO complex as one of the highly differentially expressed genes that may provide survival advantage to MB cells. THO is a subcomplex of the TREX complex, is known to couple mRNA transcription, processing and nuclear export associated with spliced mRNA.

Methods: Recent work in our lab utilizing various genomes and proteomics identified THO complex as a possible target. Transfection agents were used to knockdown part of the TREX subcomplex expression in several MB cells. Western blot and qPCR verified the knockdown. The cell viability was measured using Cell Titer Glo, and cell proliferation was evaluated with an IncuCyte. Cells were seeded at a low density and cultured until colonies formed then were fixed and stained with crystal violet. In addition, cells were seeded in a serum-free medium and allowed to migrate to complete media before being fixed and stained. Flow cytometry was used to examine cells for apoptosis and cell cycle. For apoptosis, cells were stained with propidium iodide (PI) and Annexin FTIC, and for the cell cycle, cells were stained and followed by PI.

Results: The Cancer Dependency Map (Dep-Map) meta-analysis revealed that MB strongly depends on The TREX subcomplex. Significantly, increased THO complex expression was associated with a worse overall survival rate in MB patients. Our findings indicated that part of the TREX subcomplex depletion decreased MB cell survival in the short- and long-term proliferation, migration, and invasion. Furthermore, part of TREX subcomplex depletion promoted apoptosis in MB cells. I propose that THO complex may be a new driver of MB and that strategies aiming to reduce part of TREX subcomplex levels and activity might benefit MB patients.

Conclusion: TREX subcomplex parts depletion has been demonstrated to reduce MB cells in vitro in various experiments. Future research, including CRISPR-CAS9-based knockout models, single-cell sequencing, and metabolomics, will further elucidate the mechanism(s) and utility of the TREX subcomplex axis in LMD-MB.

Suppression of antigen presentation is a hallmark of pediatric rhabdomyosarcoma

David Milewski, Meijie Tian, Yong Kim, Jun Wei, Javed Khan. *National Cancer Inst. - Bethesda Campus, Bethesda, MD*

Background: Rhabdomyosarcoma (RMS) is the most common soft tissue tumor in children and young adults, accounting for approximately 350-400 new cases annually in the US. These tumors are diagnosed based on their expression of skeletal muscle lineage markers. Clinical trials testing conventional immunotherapies such as cancer vaccines or immune checkpoint blockade (ICB) therapy have found no activity in RMS, although the root causes of failure are largely unexplored. A recent study by our group found that RMS tumors have a lack of immune infiltrate, consistent with previous reports. However, we made an unexpected observation that RMS tumors had a near absence of antigen processing and presentation (APP) gene expression, a key requisite for anti-tumor CD8+ T lymphocytes. In this study, we investigate the root causes of the lack of APP in RMS and evaluate implications for immunotherapy.
Methods: Publicly available DNA sequencing datasets were used to evaluate APP gene mutations in RMS tumor samples. RNAseq from reporter iPSC cell lines demarcating specific stages of skeletal muscle differentiation were used to evaluate APP gene expression during myogenesis. Surface MHC class I expression was evaluated using flow cytometry against a panel of pediatric sarcoma cell lines. RMS PDX and cell line APP protein levels were measured by western blot. Stimulation of APP in RMS cell lines was tested using IFNγ or sub-cytotoxic doses of different epigenetic therapeutics (DNMTi, HDACi, EZH2i) before analyzing surface MHC class I expression by flow cytometry.
Results: RNAseq analysis of the differentiation states across the normal human skeletal muscle lineage revealed a myoblastic cell state which transiently downregulates the APP pathway. RNA expression of *HLA-A,B,C* genes were lower in RMS than any other pediatric extracranial solid tumor histology studied. RMS cell lines and PDX models also displayed low APP pathway gene expression by western blot and flow cytometry, with *FOXO1* fusion positive RMS having a near absence of expression. RMS tumor

exome sequencing data from RMS patients showed a lack of enrichment of APP gene mutations. Instead, we found that APP could be induced in nearly all samples tested using IFNγ or epigenetic stimulation with Decitabine, Entinostat, or Tazemetostat.
Conclusions: We uncovered a previously unappreciated lack of antigen presentation in RMS which phenocopies myoblasts in normal skeletal muscle development. The downregulation of MHC class I antigen presentation is not due to APP pathway mutations but rather a partially reversible downregulation mirroring this specific stage of normal skeletal muscle development. Our findings suggest that pharmacological reversal of the APP pathway downregulation may enhance immunotherapies targeting MHC class I antigens in RMS.

Exposure-response and age subgroup analyses to support body-weight (BW) dosing of brentuximab vedotin (BV) in newly diagnosed high-risk classical Hodgkin lymphoma (cHL) in children and young adults (aged 2-21 years [y]): A randomized children's oncology group phase 3 trial (AHOD1331)

Zufei Zhang[1], Daping Zhang[1], Wenchuan Guo[2], Keenan Fenton[2], Sujata Narayanan[3], Shweta Jain[3], Joy Jiang[4], Sharon M. Castellino[5], Kara M. Kelly[6], Peter D. Cole[7], Frank G. Keller[5], Amit Garg[8], Yen Lin Chia[8].
[1]Quantitative Pharmacology and Disposition, Seagen Inc., Bothell, WA,[2]Biometrics, Seagen Inc., Bothell, WA,[3]Clinical Development, Seagen Inc., Bothell, WA,[4]Safety Evaluation & Risk Management, Seagen Inc., Bothell, WA,[5]Emory University School of Medicine, Atlanta, GA,[6]Roswell Park Comprehensive Cancer Center, University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY,[7]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[8]Quantitative Pharmacology and Disposition, Seagen Inc., San Francisco, CA

Introduction: High-risk cHL in pediatric patients (pts) is typically treated with chemotherapy and radiation. BV, an antibody-drug conjugate (ADC) directed to CD30, is approved in six adult indications including cHL and in children with previously untreated high-risk cHL. In AHOD1331, BV was incorporated into the standard chemotherapy backbone treatment regimen

of doxorubicin (Adriamycin®), bleomycin, vincristine, etoposide, prednisone & cyclophosphamide (ABVE-PC) for cHL to replace bleomycin and its expectant toxicity. BV-AVEPC treatment resulted in a statistically significant improvement in efficacy compared to ABVE-PC; safety profiles were comparable. We sought to examine the exposure-response (E-R) relationships in this pediatric population.
Methods: Pts in the BV-AVEPC arm received 1.8 mg/kg BV (max: 180 mg) every 3 weeks (Q3W) for a max of 5 cycles. Pharmacokinetics (PK) evaluation focused on pts aged <13 y (n=26), as lower BV exposure was previously reported in pts with lower BW. Age and BW subgroup analyses were conducted on the primary efficacy endpoint, event-free survival (EFS); key secondary efficacy endpoints included early response rate (ERR) and key AEs of interest: peripheral neuropathy (PN) and neutropenia. E-R was evaluated in the PK population.
Results: In all, 593 pts (aged 2 to 21 y) with previously untreated high-risk cHL (Ann Arbor Stage IIB with bulk/IIIB/IVA/IVB) were randomized to ≥1 cycle of ABVE-PC (n=297) or BV-AVEPC (n=296). Compared to adults, BW dosing provided similar BV exposure in pts aged 12 to <18 y (median: 54 kg) but numerically lower ADC exposure (31%) in pts aged 2 to <12 y due to their lower BW (median: 21 kg). However, EFS was comparable between pts aged 2 to <12 y and 12 to <18 y in the BV-AVEPC arm (EFS rate at 36 mo: 96.2% [91.1-100%] vs. 92.0% [88.5-95.7%]). Similarly, in the exploratory E-R no trends were observed for ERR.
Similar PN rates (Grade [Gr] ≥3: 5.8% vs 6.4%) and neutrophil count decrease (Gr ≥3: 53.8% vs 48.6.%) with BV-AVEPC were observed between pts aged <12 y and 12 to <18 y. There were no apparent trends in neutropenia across BW groups but slightly elevated PN in pts with BW ≥70 kg (Gr ≥3: 11.3% vs ≤8.2%). Overall, there was no consistent evidence that PN and neutropenia were exposure or age-driven in this pediatric population.
Conclusions: Consistent efficacy was observed in pediatric pts in the BV-AVEPC arm across age groups despite lower exposure in pts 2 to <12 y, with no evidence of exposure-driven PN and neutropenia. For pediatric pts with previously untreated cHL,1.8 mg/kg Q3W BV + AVEPC ≤5 cycles demonstrated a favorable risk-benefit profile. These data support the 1.8 mg/kg Q3W BV dosage and do not indicate a need for dose adjustment by age or BW subgroups. ZZ and DZ contributed equally.

Number of prescription drugs and overall survival in metastatic castrate resistant prostate cancer

Martin W. Schoen[1], Carley Pickett[1], Daniel B. Eaton[2], Brendan T. Heiden[3], Su-Hsin Chang[3], Yan Yan[3], Melanie P. Subramanian[3], Varun Puri[3]. *[1]Saint Louis University, Saint Louis, MO,[2]VA St. Louis Healthcare System, Saint Louis, MO,[3]Washington University in St. Louis, Saint Louis, MO*

Background: Assessment of comorbid diseases is essential to clinical research and may risk-stratify patients for adverse events and death. Total number of prescription medications and drug classes could be an easy-to-use tool for estimating patient risk independent of established methods such as the Charlson Comorbidity Index (CCI) that is created from administrative data. Additionally, clinicians have access to prescription medication lists, facilitating assessment of comorbidities in clinical settings.
Methods: Retrospective observational study of US Veterans treated for metastatic castrate resistant prostate cancer in the Veterans Health Administration who received treatment with abiraterone or enzalutamide between May 2011-June 2, 2017. We determined number of unique drugs and anatomic therapeutic chemical (ATC) drug classes prescribed in the year prior up to 14 days before initiation of treatment. Multivariable logistic regression and Cox proportional hazard modeling was used to assess the association between number of drugs with all-cause 90-day mortality and overall survival (OS) while accounting for important covariates including age, CCI, body-mass index, prostate specific antigen, race, prior docetaxel, hemoglobin, albumin, bilirubin, and creatinine.
Results: Among 11,021 Veterans, a median (IQR) of 11 (6,18) unique medications and 10 (5,15) unique ATC medication classes were filled in the year prior to treatment. The median age was 75 years with median CCI of 3 and 2,550 were black (23.1%). Increasing age was associated with increased CCI across age strata with mean CCI of 3.7 in age <70, 4.2 in age 70-79, and 4.3 in age 80+ ($p<0.001$). Increased age was associated with decreased number of unique medicines with mean 14.7 in age <70, 12.7 in age 70-79, and 11.2 in age 80+ ($p<0.001$). Black race was associated with

increased mean number of medications compared to white race (15.5 vs. 12.0, $p<0.001$). After adjusting for relevant patient, tumor, and treatment factors, the number of medications and drug classes were each independently associated with increased 90-day mortality with adjusted OR (95% CI) of 1.021 (1.011,1.030) and 1.024 (1.012,1.036) respectively. Both number of medications and number of classes were also associated with decreased OS with adjusted Hazard Ratio of 1.015 (1.013,1.018) and 1.018 (1.014,1.021) respectively. Within subgroups of patients with comparable CCI, increased number of medications was associated with increased risk of death.
Conclusion: The number of prescription medications and drug classes are independently associated with short- and long-term outcomes in patients undergoing treatment for metastatic castrate resistant prostate cancer, even after accounting for important covariates including age and CCI. Assessment of patient medications may provide a simple, yet reliable tool to assess comorbidities, risk of adverse events, and death.

Genomic profiling and sites of metastasis in non-small cell lung cancer (NSCLC)

Kok Hoe Chan, Ji Lin, Arthi Sridhar, Syed H. Jafri. *Internal Medicine, The University of Texas Health Science Center at Houston, Houston, TX*

Introduction: Molecular genotyping of metastatic NSCLC adenocarcinoma subtypes using next generation sequencing (NGS) is currently the standard practice. However, there is limited data on the biological predisposition to site of metastasis in patients with NSCLC based on their molecular profiling. We sought to identify any association between metastatic site and molecular profile in NSCLC patients.
Method: This is a retrospective analysis conducted at UTHealth Houston/Memorial Hermann Cancer Center from January 2014 to June 2022. Clinical characteristics, pathology, NGS panel reports, and imaging were retrieved and reviewed. The χ^2 test was used for categorical variables. Continuous variables were compared using Kruskal-Wallis one-way analysis of variance. Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier test.

Results: After excluding patients who did not have complete clinical data, a total of 143 patients were included, and their NGS panels analyzed. Median age was 65 years, with an equal number of men (n=71) and women (n=72). The most common histology was adenocarcinoma (81.8%), followed by squamous cell cancer (11.9%) and large cell carcinoma (3.5%). At least one genetic mutation was discovered in 100 patients. Mutations with a targetable drug were found in 86 patients, and many patients had >1 genetic mutation. The most common mutations were TP53 (25.2%), EGFR (24.5%), KRAS/NRAS (20.3%), and CDKN2A/2B (7.7%). Patients with any mutation were significantly more likely to have metastatic disease to the brain (57% vs 37%, p=0.03), but there was no difference in metastatic disease to bone (34% vs 26%, p=0.32). Patients without a discoverable mutation were significantly more likely to have metastatic disease to other sites (e.g., adrenal gland, liver; 91% vs 66%, p=0.002). There was no difference in PFS or OS between those with versus without mutations. Median PFS was significantly longer in patients with EGFR mutation than those with KRAS/NRAS or TP53 mutations (36 vs 16.2 vs 11.9 months, p=0.03). Median OS for patients with EGFR mutation was not reached and was significantly longer than in patients with TP53 (28.7 months) or KRAS/NRAS (26 months) mutations (p=0.003).Patients with PDL-1 >1% or TP53 were significantly more likely to have metastatic disease to organs other than bone or brain (p=0.047 and p=0.023, respectively). There was also no difference between rates of brain and bone metastasis with regards to mutational profile.
Conclusion: Metastatic lung cancer patients with discoverable mutations on NGS are more likely to have metastatic disease to the brain. PDL-1 expression and TP53 mutation tend to lead to disease metastatic to organs other than brain or bone. Patients with EGFR mutations, despite having a great propensity to brain metastasis, have significantly better PFS and OS than patients with KRAS/NRAS and TP53 mutations, likely due to targeted therapy options.

#6743
Clinical outcomes with pembrolizumab-based therapies in relapsed/refractory NSCLC after definitive chemoradiation and durvalumab

Lukas Delasos, Wei Wei, Khaled A. Hassan, Nathan Pennell, Pradnya Patil, James Stevenson. *The Cleveland Clinic, Taussig Cancer Institute, Cleveland, OH*

Background: More than 50% of patients (pts) with unresectable non-small cell lung cancer (NSCLC) experience relapsed/refractory (R/R) disease within 2 years of starting chemoradiation (CRT) and durvalumab. Based on current national guidelines, these patients are offered treatment for metastatic disease as definitive therapy is no longer feasible. Immunotherapy +/- chemotherapy is typically initiated if a driver-oncogene is absent. The addition of programmed cell death protein-1 (PD-1) antibody pembrolizumab to chemo has resulted in improved progression-free survival (PFS) (8.8 vs 4.9 mos) and overall survival (OS) (69.2% vs 49.4% 12-mos OS) compared to chemotherapy alone. Although this treatment strategy has been incorporated for R/R NSCLC, there remains a paucity of data regarding its efficacy within this population. Here we present clinical outcomes data with pembrolizumab-based regimens for R/R NSCLC following definitive CRT and durvalumab.
Methods: This was a retrospective analysis of pts treated between January 2016 to November 2022 at the Cleveland Clinic Foundation in Cleveland, OH. Eligibility criteria included pts age ≥ 18 years with unresectable NSCLC who had received definitive CRT and durvalumab consolidation followed by pembrolizumab for R/R disease. The primary objective was to estimate OS and PFS in this distinct cohort and to compare these findings to historical outcomes. Secondary objective was to compare OS and PFS between specific groups including age, sex, smoking history, combined chemo, histology, *KRAS*-mutation, and PD-L1 expression. OS and PFS were estimated by Kaplan-Meier method and compared using log rank test.
Results: 62 pts were identified, of whom 50 met full eligibility criteria and were included for data analysis. Median follow-up time was 11.3 months (0.7 - 38.2 mos). Median OS was 10.6 months (95% CI; 7.9 mos - NA) with a 1-year OS rate of 48% (95% CI; 35 - 67%). Median PFS was 6.1 months (95% CI; 4.8 - 9.9 mos) with a 1-year PFS rate of 26% (95% CI; 16-45%). Current smokers had significantly better median OS and PFS rates as compared to former smokers (NA vs 10.5 and 9.9 vs 6.0 mos, respectively; P = 0.036 and 0.028). An OS benefit in pts who received chemo with pembrolizumab (median OS 12.9 vs 6.0 mos) was noted but was not

statistically significant. No other statistically significant difference was detected.
Conclusion: Patients with R/R NSCLC after definitive CRT and durvalumab consolidation represent a distinct cohort with apparent inferior outcomes as compared to those with *de novo* stage IV disease when treated with pembrolizumab-based therapies. Although improved survival was observed with the addition of chemo to pembrolizumab, further investigation is warranted to optimize treatment strategies for this patient population. Given the limited sample size of our analysis, larger studies with matched real-world treatment cohorts are planned.

Cell-free DNA detection of alterations in the MAPK pathway in metastatic hormone receptor positive breast cancer: A multi-institutional analysis of incidence and clinical outcomes

Arielle J. Medford[1], Andrzej Niemierko[2], Whitney L. Hensing[3], Andrew A. Davis[3], Katherine Clifton[3], Jennifer C. Keenan[4], Lesli Kiedrowski[5], Ami N. Shah[6], Lorenzo Gerratana[7], Massimo Cristofanilli[8], Aditya Bardia[2].
[1]Hematology/Oncology, Massachusetts General Hospital, Harvard Medical School, Broad Institute, Boston, MA,[2]Hematology/Oncology, Massachusetts General Hospital, Harvard Medical School, Boston, MA,[3]Hematology/Oncology, Washington University in St Louis, St Louis, MO,[4]Hematology/Oncology, Massachusetts General Hospital, Boston, MA,[5]Guardant Inc, Palo Alto, CA,[6]Hematology/Oncology, Northwestern University, Chicago, IL,[7]Hematology/Oncology, Centro di Riferimento Oncologico, Aviano, Italy,[8]Hematology/Oncology, Weill Cornell Medicine, New York, NY

Background Alterations in the MAPK pathway are known mechanisms for tumorigenesis in multiple solid tumors. While not major drivers in early breast cancers, activating MAPK pathway alterations have been invoked as potential resistance mechanisms in advanced hormone receptor positive (HR+) breast cancer. While MAPK pathway mutations are believed to be relatively rare in breast cancer, the accessibility of cell-free DNA (cfDNA) analysis allows for evaluation of their prevalence, co-occurring mutations, and associated clinical outcomes. In this study, we evaluated the incidence

of MAPK pathway alterations and impact on clinical outcomes among patients with metastatic breast cancer (MBC).
Methods Plasma was collected in patients with HR+ MBC at the Massachusetts General Hospital and Washington University in St. Louis, and cfDNA was analyzed via the Guardant 360 assay, a 74-gene next generation sequencing panel. The impact of MAPK pathway alterations on progression-free survival (PFS) and overall survival (OS) was analyzed using multivariable Cox regression analysis, adjusting for age, number of prior therapies, visceral metastases, de novo metastases, and *PIK3CA* alterations. PFS and OS were evaluated in the overall study population, as well as in subgroups that received endocrine therapy + CDK4/6 inhibitor, endocrine monotherapy and chemotherapy.
Results Out of 647 HR+ MBC patients, 103 (16%) had non-synonymous mutations in the MAPK pathway detected in cfDNA. Median age was similar (61.9 and 60.7) in MAPK-altered and non-altered patients, respectively. Both groups had received a median of 2 prior lines of therapy (p=0.08). MAPK pathway alterations included *NF1* (n = 45, 7.0%), *KRAS* (n = 22, 3.4%), *BRAF* (n = 22, 3.4%), *MAPK1* (n = 8, 1.2%), *MAP2K1* (n = 6, 0.9%), *NRAS* (n = 5, 0.8%), *RAF1* (n = 5, 0.8%), *HRAS* (n = 4, 0.6%), *ARAF* (n = 4, 0.6%), *MAP2K2* (n = 4, 0.6%), *RIT1* (n = 3, 0.5%), and *MAPK3* (n = 2, 0.3%). Mutant allele fractions ranged from 0.03 to 26. Co-alterations in *PIK3CA* occurred in 49% (n = 51), *TP53* in 41% (n = 42), and *ESR1* in 27% (n = 28). In multivariable analysis, patients with MAPK-altered HR+ MBC had significantly poorer median PFS, 7.6 months vs 11.5 months (HR: 1.6; p = 0.005; 95% CI: 1.2-2.2). There was no statistically significant impact on outcomes when stratifying by treatment type.
Conclusions MAPK pathway alterations are associated with a significantly poorer PFS among patients with HR+ MBC. Further research is needed to independently validate these observations and evaluate the impact of genotype-directed therapy targeting MAPK-altered, HR+ MBC.

#6745
Prognostic indicators and outcomes of hepatocellular carcinoma (HCC) in an Appalachian population
Michelle Hartzell[1], Gary Monroe[1], Jon Shakesprere[1], Sijin Wen[2], J. Wallis Marsh[3], Jacob Fuqua[4], Robert Grammer[5], Beau Toskich[6], Midhun Malla[4].
[1]Medicine, West Virginia Univ. School of Medicine, Morgantown,

WV,[2]Epidemiology and Biostatistics, West Virginia University Health Science Center, Morgantown, WV,[3]Surgery, West Virginia Univ. School of Medicine, Morgantown, WV,[4]West Virginia University Cancer Institute, Morgantown, WV,[5]Radiology, West Virginia Univ. School of Medicine, Morgantown, WV,[6]Division of Vascular/Interventional Radiology, Mayo Clinic, Jacksonville, FL

Introduction: The development of hepatocellular carcinoma (HCC) is associated with underlying chronic liver disease from viral hepatitis or nonviral etiologies, such as nonalcoholic fatty liver disease (NAFLD) and alcoholic liver disease. An area of current research interest is the relationship between etiology of chronic liver disease in HCC patients and the response to specific treatment modalities. The purpose of this study is to identify prognostic indicators and compare survival outcomes among HCC patients within an Appalachian patient population.
Methods: A single-institution, retrospective chart review was conducted for all patients diagnosed with HCC between August 2009 and March 2017 at West Virginia University Hospital. Patient demographics, tumor characteristics, laboratory data and treatment information were obtained from the electronic medical record (EMR). Survival analyses were performed using Kaplan-Meier method and multivariable Cox regression analysis.
Results: The study sample (n=100) had a mean age of 62 years and was comprised of 82% males and 18% females. Nonviral etiologies of chronic liver disease were predominant (55%) over chronic viral hepatitis (45%). Significant adverse prognostic indicators of overall survival (OS) were Child-Pugh class C and tumor size >5 cm at diagnosis ($p<0.0001$, log-rank test). Patients who received liver-directed therapy (LDT) or liver resection had greater OS compared to those not treated with either modality (15.5 vs. 2.0 months, $p<0.0001$). Liver ablation or resection as initial modes of treatment had greater OS compared to those who initially received transarterial chemoembolization (TACE) or transarterial radioembolization (TARE) (17.2 vs 14.9 months, $p<0.05$). Patients who received TACE or TARE (n=60) as initial treatment had characteristics of advanced disease, with 45% having a tumor greater than 5 cm in size and 77% having multifocal unilobar or bilobar tumors. Among all patients who received LDT or resection, post-treatment albumin-bilirubin grade (ALBI) of 1 or 2

correlated with greater OS than grade 3 (22.5 vs 6.2 months, $p<0.0001$). In the multivariate Cox analysis, tumor size, Child-Pugh class and mode of initial treatment (resection/ablation vs. TACE/TARE) were independent predictors of OS ($p<0.05$).
Conclusions: Treatment with LDT or liver resection correlated with greater overall survival in this predominantly nonviral cohort of HCC patients. Post-treatment ALBI grade correlated with overall survival and may have prognostic value in guiding clinical management. Mode of initial treatment was a predictor of overall survival, but further studies are needed to compare tumor characteristics between groups. Research is ongoing to evaluate the relationship between chronic liver disease etiology and survival among HCC patients treated with LDT, immunotherapy or a combination of both.

Academic facility is associated with improved survival in patients with leiomyosarcoma: a national cancer database analysis
Steven Stanley, Marco Braaten, Peter Silberstein. *Creighton University School of Medicine, Omaha, NE*

Background: Leiomyosarcoma is a malignant sarcoma of smooth muscle that comprises 10-20% of all sarcomas with a predilection to the uterus and peritoneum. [1] Prior studies have shown treatment at Academic facilities is associated with improved outcomes in cancer treatment.[2] The objective of this study was to investigate the effect of treatment at an Academic facility on overall survival in patients with leiomyosarcoma.
Methods: The National Cancer Database (NCDB) was used to identify patients with leiomyosarcoma from 2004-2019 using the ICD-O-3 histology codes 8900 and 8901. Facility types used were assigned by the Commission on Cancer Accreditation program. Categorical Academic and Non-Academic variables were created. Data was analyzed using SPSS with a statistical significance of $\alpha = 0.05$.
Results: Of the 7950 patients included in this study, 3122 were treated at Academic facilities with a median survival of 77.6 months compared to 61.0 months for patients treated at a Non-Academic facility, which was statistically significant on long-rank testing ($p<0.001$). Compared to patients treated at Non-Academic facilities, patients at Academic facilities

experienced delay in the average surgical initiation time (p<0.001), however, they were more likely to have surgery (88.1% vs. 74.1%; p<0.001), have no residual tumor margins on resection, (63.4% vs. 53.3%; p<0.001) and receive adjuvant chemotherapy (15.2% vs. 12.4%; p<0.001). Academic facility patients also had a younger mean age and were more likely to come from highest median income quartile (36.9% vs. 33.2; p<0.001).
Conclusions: Patients with leiomyosarcoma treated at Academic facilities experienced improved survival compared with patients with the same disease treated at Non-Academic facilities. These patients experienced higher rates of surgery, adjuvant therapy and wider excisional margins. It is possible that treatment discrepancies and/or differences in surgical technique vary by facility type and contribute to the observed differences in survival.

Sites of metastases prior to systemic treatment influence progression patterns and survival in stage IV melanoma patients

Ismael A. Vergara[1], Serigne N. Lo[2], Isabel Li[2], Alexander M. Menzies[3], Matteo S. Carlino[4], Richard A. Scolyer[5], Georgina V. Long[6], Ines Pires da Silva[7]. *[1]Melanoma Institute Australia, Charles Perkins Centre, The University of Sydney, Camperdown, Australia,[2]Melanoma Institute Australia, The University of Sydney, Sydney, Australia,[3]Melanoma Institute Australia, The University of Sydney, Royal North Shore and Mater Hospitals, Sydney, Australia,[4]Melanoma Institute Australia, The University of Sydney, Blacktown Hospital, Crown Princess Mary Cancer Centre, Camperdown, Australia,[5]Melanoma Institute Australia, Charles Perkins Centre, The University of Sydney, , Royal Prince Alfred Hospital and NSW*

Health Pathology, Sydney, Australia,[6]Melanoma Institute Australia, Charles Perkins Centre, The University of Sydney, Royal North Shore and Mater Hospitals, Sydney, Australia,[7]Melanoma Institute Australia, Charles Perkins Centre, The University of Sydney, Blacktown Hospital, Sydney, Australia

Background: Different metastatic sites have distinct response rates to immune checkpoint inhibitors (ICI), suggesting that anatomical locations play a role in treatment response and survival. This project investigated the impact that sites of metastases present at baseline - *ie.* before starting treatment - have on the anatomical patterns of progression and their association with survival in patients (pts) exposed to ICI and BRAF/MEK inhibitors (BRAF/MEKi) as first line treatment.
Methods: We curated the progression history of distant metastases of 568 stage IV pts; 352 pts had first line treatment with antiPD1 +/- antiCTLA4, and 216 pts had first line BRAF/MEKi. We sought to investigate the association between sites of metastases at baseline and (a) sites of progression in pts who failed first line anti-PD1 vs first line BRAF/MEKi, (b) sites of progression in pts who failed first line anti-PD1 with innate vs acquired resistance, and (c) survival of all pts, from time of first line treatment to last follow-up.
Results: Using a sophisticated mathematical graph representation of anatomical disease progression, we unveiled sites of metastases at baseline that impacted where new sites of metastases developed on treatment failure. In pts with brain metastasis at baseline, pts who failed anti-PD1 had higher progression in the brain compared to BRAF/MEKi progressors (68.1% in anti-PD1 progressors vs 62.5% in BRAF/MEKi progressors). In contrast, the opposite trend was observed in the progression to the brain in pts with no brain metastasis at baseline, which was lower in anti-PD1 progressors compared to BRAF/MEKi progressors (20.6% in anti-PD1 progressors vs 32.6% in BRAF/MEKi progressors).Within pts who failed anti-PD1, pts with innate resistance (n=95) had a higher rate of progression in the brain (42.1%) compared to pts with acquired (n=36) resistance (25%). Among pts with innate resistance who had brain metastasis at baseline (n=36), 80.6% progressed in the brain. In contrast, among pts with innate resistance without brain metastasis at baseline (n=59), only 18.6% progressed to the brain.Sites of metastases at baseline also had an impact on the survival of

pts. In BRAF/MEKi pts, brain metastasis at baseline was not associated with survival (log-rank p-value=0.6). In contrast, anti-PD1 pts with brain metastasis at baseline had worst survival (2-yr survival 56%) compared to pts without brain metastasis at baseline (2-yr survival 73%, log-rank p-value=0.005).
Utilisation of this graph representation for the development of a time-dependent predictor of brain metastases will be presented.
Further associations of metastatic sites of disease at baseline with progression and survival will be discussed.
Conclusions: Different sites of metastases at baseline have a distinct effect on the progression patterns and survival of pts who received BRAF/MEKi or anti-PD1 as first line treatment.

#6749
Histiocytic sarcoma descriptors and clinicopathologic determinants of survival: Analysis of a pooled database
Dinesh Keerty, Philip A. Haddad. *LSUHSC-S, Feist-Weiller Cancer Center/Overton Brooks VAMC, Shreveport, LA*

Background Histiocytic sarcoma (HS) is an aggressive, rare malignant neoplasm of cells with histiocytic differentiation. It can occur de novo or develop in the context of other malignant disorders. HS can present as disseminated or localized lesions in the skin, lymphatics, gastrointestinal tract, central nervous system, or other organs. Little is known about factors that impact HS clinical outcomes. We conducted this pooled database analysis to delineate key clinicopathological characteristics, prognostic indicators, and treatment modalities that affect survival in this rare histiocytic entity.
Methods To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 146 cases of HS. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS).
Results A total of 146 patients with confirmed HS were identified. The median age was 52, with bimodal peaks between 14-28 and 56-70 years. There was a male preponderance with M:F of 1.3. Primary sites of

involvement were CNS (21%), GI(16%), soft tissues (12%), H&N and bones (9% each), skin (8%), liver (7%), spleen (5%), lung (4%), and breast (1%). Lymphadenopathy and bone marrow (BM) were involved in 21% and 42%, respectively. Constitutional symptoms were present in 6%. The median size of the HS tumor was 4.45cm. The median OS of the whole group was 16 months. Age younger than 55 had better median OS (NR vs. 6 months, p=0.038). The primary site of involvement also impacted the median OS, where soft tissues and visceral disease had longer OS than those with CNS and spleno-lymphatic disease (60 vs. 7 vs. 6 months, p=0.03). Stage 1 disease had better median OS than stages 2-4 (p=0.06). Furthermore, unifocal had better median OS than multifocal/multicentric disease (60 vs. 9 months, p=0.007). The presence of inflammatory background positively impacted OS (p=0.01). Compared to no treatment, localized therapies such as surgery (S) and radiation therapy (RT), and systemic combination chemotherapy (CT) were statistically superior, with a median OS of 1, 204, and 21 months, respectively (p=0.003). With HS not amenable to complete resection, CT and CT+S were superior to RT+S (15 vs. 60 vs. 7 months, p=0.008). While BM involvement and size >10 cm were associated with worse OS, the latter did not reach statistical significance. There was no difference in median OS with respect to sex. **Conclusion** This study presents updated clinicopathologic data from a pooled cohort of patients with HS. It identifies age, the primary site of the disease, stage and extent of the disease, the inflammatory background status, and treatment approach as key determinants of OS.

Primary effusion lymphoma descriptors and clinicopathologic determinants of survival: Analysis of a pooled database

Supriya Gupta, Christopher Graham, Philip A. Haddad. *LSUHSC-S, Feist-Weiller Cancer Center/Overton Brooks VAMC, Shreveport, LA*

Background Primary effusion lymphoma (PEL) is a rare and aggressive type of B-cell non-Hodgkin lymphoma presenting primarily as lymphomatous effusions in body cavities and less often as solid extracavitary masses. It is typically associated with human herpesvirus 8 (HHV8) infection and occasionally with Epstein-Barr virus (EBV) co-infection. It is commonly seen in immunocompromised states, such as

human immunodeficiency virus (HIV) infection, organ transplantation, immunosuppressive therapy, or advanced age. Due to our limited understanding of this disease, we conducted this pooled database analysis to delineate key clinicopathological characteristics, prognostic indicators, and treatment modalities that affect survival in this rare and unique lymphoma subtype.
Methods To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 303 cases of PEL. All cases with an unequivocal expression of CD19 and CD20 expression were excluded. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS).
Result A total of 304 patients with confirmed PEL were identified. The median age was 49, with a peak incidence between 42 and 56 years. There was a male preponderance with M:F of 10. The majority (71%) was associated with HIV infection, with a median CD4 count of 108. Sixty-eight percent were cavitary with the pleural, pericardial, and peritoneal cavities involved in 56%, 20%, and 30%. The median duration of symptoms before diagnosis was 1.5 months. Patients presented with constitutional symptoms, hepatosplenomegaly, lymphadenopathy, and bone marrow involvement in 31%, 10%, 20%, and 16%. The median OS of the whole group was 6.5 months. Presentation with constitutional symptoms ($p=0.026$), extracavitary/solid tumors ($p=0.03$), and normal platelet counts ($p=0.04$) were associated with better median OS. Cavitary disease with effusions restricted to the thoracic cavity had also better median OS ($p<0.0001$). PEL occurrence in the context of immunosuppression due to transplantation had poor median OS ($p=0.004$). While having Kaposi sarcoma tended to impact OS negatively ($p=0.08$), Castleman's disease did not. Compared to no treatment, combination chemotherapy alone, chemotherapy with anti-retroviral therapy, and stem cell transplant were statistically superior with a median OS of 1.5, 8, 30, and 16 months, respectively ($p<0.0001$).
Conclusion This study presents updated clinicopathologic data from a pooled cohort of patients with PEL. It identifies the type of clinical setting contributing to immunodeficiency, disease presentation, the primary location of cavitary disease, and treatment approach as key determinants of OS.

Provisional prognostic score for primary effusion lymphoma

Philip A. Haddad, Supriya Gupta, Christopher Graham. *LSUHSC-S, Feist-Weiller Cancer Center/Overton Brooks VAMC, Shreveport, LA*

Background Primary effusion lymphoma (PEL) is a rare and aggressive type of B-cell non-Hodgkin lymphoma presenting primarily as lymphomatous effusions in body cavities and less often as solid extracavitary masses. It is typically associated with human herpesvirus 8 (HHV8) infection and occasionally with Epstein-Barr virus (EBV) co-infection. It is commonly seen in immunocompromised states, such as human immunodeficiency virus (HIV) infection, organ transplantation, immunosuppressive therapy, or advanced age. Survival remains poor, and an optimal regimen has yet to be identified. However, the disease presents a diverse spectrum of survival outcomes. We conducted this study to develop a provisional PEL prognostic score (PPS) for this rare disease.
Methods We used our constructed PEL database, which contains retrospective data on 302 cases. Such data included demographics such as sex, age, and race. It also included disease presentation symptoms, duration of symptoms before diagnosis, site(s) of the disease, blood counts, coexisting comorbidities, disease immunohistochemical and molecular phenotype, types of treatment, and survival outcomes. Of the 302 cases, only 238 had complete survival and outcomes data, the sample chosen for this study. Cox proportional-hazards model and Log-rank tests were used to assess the influence of clinicopathologic factors on overall survival (OS). Due to the relatively small training cohort, we included factors that statistically impacted OS and those that numerically trended that way.
Results The median OS of the cohort was 6.5 months. The following dichotomous variables were identified as impactful prognostic factors in this cohort: the absence of constitutional symptoms (5 vs. 18 months), cavitary effusion disease (6 vs. 66 months), peritoneal cavity disease (3.5 vs. 11 months), transplant context (4 vs. 7 months), male sex (6 vs. 40 months), and detectable HHV8 viremia (7 vs. 66 months). A prognostic model was devised using these variables to identify different levels of risk. Each variable was assigned a score of 1 when present, except for peritoneal cavity disease and transplant context, which were assigned 2 points as they

had the highest hazard ratio of all the other variables. In this exploratory cohort, low risk was assigned a score of 0-1, intermediate risk a score of 2-3, and high risk a score of 4-8. This prognostic score system led to our cohort's most optimal risk discriminatory model, where low, intermediate, and high risk had a median OS of 66, 28, and 4 months, respectively ($p<0.0001$).
Conclusion This PPS is a promising new tool for risk-stratifying patients with PEL. However, it still needs prospective validation.

Patient (pt) characteristics, diagnostic journey, and cancer enrichment among pts with nonspecific signs and/or symptoms (s/sx) in the US community oncology setting: a real-world retrospective study
Christopher Benton[1], Ding He[2], Karen Todoroff[2], Marie V. Coignet[3], Ying Luan[3], Kathryn N. Kurtzman[3], Ira Zackon[4]. *[1]Rocky Mountain Cancer Centers, Englewood, CO,[2]Ontada, The Woodlands, TX,[3]GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc. under the terms of the Interim Measures Order of the European Commission dated 29 October 2021, Menlo Park, CA,[4]New York Oncology Hematology, Albany, NY*

Of the >1.6 million people diagnosed with cancer in the US each year, >60% are diagnosed after symptomatic presentation, including nonspecific s/sx. These nonspecific s/sx may cause pts to undergo unnecessary diagnostic evaluation while the possibility of cancer and search for its origin is explored, causing delayed treatment and poor outcomes. Additionally, pts who do not have cancer are often subjected to various undirected/misdirected procedures due to initial cancer suspicion. Our objective was to examine pt characteristics, diagnostic journey, and cancer incidence of pts with nonspecific s/sx within The US Oncology Network. This retrospective observational cohort study included pts aged ≥40 with ≥1 of the following nonspecific s/sx in their problem list at their first visit within The US Oncology Network (index date) during the identification period from 1/1/2016 to 12/31/2020: anemia, venous thromboembolism, general malaise, weight loss, nonspecific abdominal symptoms, new and unexplained breathlessness, unexplained worsening pain, and abnormal lab test results. Pts were excluded if diagnosed with any cancer (except basal

cell carcinoma and squamous cell carcinoma skin cancer) within 3 years prior to or on index date. Pts were followed longitudinally with data from electronic health records for initial cancer diagnosis (dx), death, end of study observation period, or 12 months, whichever occurred first. Demographic and clinical characteristics were assessed descriptively. 103,984 pts were identified. The median age was 65.7, 64% were female, 65% were White, 41% were obese, 47% were never smokers, and 48% were from a southern practice region. 6,774/103,984 pts (7%) were diagnosed with cancer and 6,537/6,774 (97%) with 1 primary cancer: 3,825/6,537 (59%) were diagnosed with a hematologic malignancy and 2,712/6,537 (41%) with a solid tumor cancer. Among pts diagnosed with primary solid tumors, 31% had gastrointestinal, 15% genitourinary, 15% respiratory, 13% breast, and 11% gynecologic cancer. Among pts diagnosed with cancer, median time to cancer dx after being referred to secondary care within The US Oncology Network with nonspecific s/sx was >5 wks (solid: >7 wks; hematologic: >4 wks); by 17 and 34 wks, 75% and 90% of pts received a cancer dx, respectively.
Within this population of pts most frequently presenting with nonspecific hematologic s/sx and subsequent cancer dx, 40% were diagnosed with solid tumor cancers within 1 year. This speaks to the unmet need for more tools such as a multi-cancer detection test that could aid in detection of multiple cancers and faster diagnostic resolution of nonspecific s/sx. Given the impact of delayed cancer dx and timely treatment on outcomes, such a test could potentially substantially improve cancer care and diagnostic evaluations.

#6753

Non-HIV cryptococcal patients with hematological malignancies: A retrospective analysis of a ten-year study from a Peruvian oncologic center

Kelly Meza, Luis E. Cuellar. *Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru*

Background Globally, cryptococcal infection has become a public health challenge. However, relatively little is known about cryptococcal infection in people with hematological disorders.

Methods We developed a retrospective cohort study that includes hematological patients who had cryptococcosis infection seen in the Instituto Nacional de Enfermedades Neoplasicas between 2007 and 2017.
Results During the 11-year study period, a total of 21 cases of cryptococcosis (incidence rate of 13,4 per 1000 hematological malignancies). The time of diagnosis of cryptococcosis since hematologic malignancy diagnosis was 42 (18-161) days. Non-Hodgkin lymphoma (NHL) was the most frequent malignancy (47.6%), followed by leukemias (23.8%), multiple myeloma in (19.1%), and HL (9.5%). Three cases of adult T-cell leukemia/lymphoma associated with HTLV-1 infection were identified in the NHL. Cryptococcemia was the most frequent diagnosis (85.7%) followed by pulmonary (52.4%) and CNS (38.1%) involvement. Regarding clinical presentation, f ever was the most common symptom in meningeal cryptococcosis (76.2%) and dyspnea in pulmonary cryptococcosis (61.9%). The use of immunosuppressant chemotherapy within a month before the diagnosis of cryptococcosis was the most common risk factor. The main characteristics between patients with cryptococcosis and type of neoplasms (NHL vs other hematological neoplasms) such as age at admission, site of presentation of cryptococcosis, and lymphocyte count at admission were different significantly between these groups. In the NHL group, there was less involvement of the lungs. Overall survival (OS) in 15 and 120 days were 70% (95%CI: 0.43-0.86) and 51% (95%CI: 0.26-0.72), respectively. OS for patients with NHL was 57% at 15 days (95% CI: 0.17-0.83) and 42% at 120 days (95%CI:0.09-0.73). OS for other hematological malignancies was 90% at 15 days (95%CI:0.47-0.98) and 60% at 120 days (95%CI: 0.25-0.82).
Conclusions CNS cryptococcal infection was more frequent in patients with NHL.

#6754

Clinical characteristics, real-world treatment patterns, and clinical outcomes among patients with previously treated metastatic or unresectable EGFR-mutated non-small cell lung cancer in the United States

Jyoti D. Patel[1], Jie Meng[2], Sudarshan Phani[3], Aaron Crowley[4], Summera Zhou[4], Maribel Salas[3], Yoko Tanaka[3], Hoa Le[3], Jeffrey Anderson[4], Karen L. Reckamp[5]. *[1]Northwestern University, Chicago, IL,[2]Daiichi Sankyo*

Europe GmbH, München, Germany,[3]Daiichi Sankyo, Basking Ridge, NJ,[4]Genesis Research, Hoboken, NJ,[5]Cedars-Sinai Medical Center, Los Angeles, CA

Background: A consensus on preferred treatment for patients with EGFR-mutated (EGFRm) advanced or metastatic non-small-cell lung cancer (a/mNSCLC) who have progressed on osimertinib and platinum-based chemotherapy (PBC) has yet to be established. The study objectives were to describe patient characteristics and treatment patterns in this context and assess corresponding clinical outcomes in the US real-world setting.
Methods: This study was a retrospective analysis of data sourced from Flatiron's de-identified database, which included electronic health records and curated cancer data from approximately 280 US cancer clinics (~800 US sites of care). The index line of therapy (LOT) was defined as initiation of a new treatment regimen after osimertinib and PBC. Adults were eligible for inclusion if they: 1) were diagnosed with a/mNSCLC on or after January 1, 2011; 2) had evidence of an activating EGFR mutation (exon 19 or L858R); 3) initiated a new LOT between November 13, 2015, and June 30, 2021, after treatment with osimertinib and PBC. Treatment regimens in the index LOT were summarized, and real-world overall survival (rwOS, defined as the time from initiation of index LOT to death) and real-world progression-free survival (rwPFS, defined as the time from initiation of index LOT to disease progression or death) were assessed.
Results: Among 273 study patients included, the majority were ≥65 years (57%), female (67%), Caucasian (65%; Asian, 17%; Black or African American, 6%), with no history of smoking (58%), performance status 0-1 (82%), and >2 prior LOT (64%). Median follow-up duration was 7.3 months. Index treatment regimens were classified as tyrosine kinase inhibitor (TKI) monotherapy (15%) or TKI in combination with non-immuno-oncologic agents (12%), non-platinum-based chemotherapy (23%), immuno-oncologic monotherapy (17%) or combination therapy (15%), PBC (12%), a regimen containing a clinical study drug (4%), or other NSCLC therapy (1%). Deaths occurred in 203 patients (74%) during follow-up; median rwOS was 8.6 months (95% confidence interval [CI], 7.4-9.8). Real-world progression occurred in 235 patients (86%); median rwPFS was 3.3 months (95% CI, 2.8-4.4).

Conclusions: For patients with EGFRm a/mNSCLC, third-generation EGFR TKIs such as osimertinib can provide disease control, however progression is common. After disease progression, chemotherapy is often the next treatment of choice. Results of this real-world study show that treatment patterns after EGFR TKI and PBC are highly variable and suggest poor clinical outcomes, highlighting the need for more efficacious treatments among patients with previously treated a/mNSCLC.

#6755

The impact of renin-angiotensin system inhibitors on survival outcomes of pancreatic adenocarcinoma patients

Kuan-Yu Tseng, Cheng-Wei Chou. *Taichung Veterans General Hospital, Taichung, Taiwan*

Introduction Pancreatic adenocarcinoma (PDAC) is a highly aggressive malignancy with significant morbidity and mortality. RAS (renin-angiotensin system) inhibitors have been used for hypertension, and the potential role of using RAS inhibitors in pancreatic adenocarcinoma have been investigated in pre-clinical models by enhancing drug delivery and reducing hypoxia. However, the clinical benefit of RAS inhibitors in pancreatic cancer patients was still unclear.
Methods We retrospectively investigated the impact of RAS inhibitors on survival outcomes of pancreatic adenocarcinoma patients in Taichung Veterans General Hospital between January 2014 and July 2021. Patients with histologically proven pancreatic adenocarcinoma were included in the study. Clinical feature with drugs exposure and survival outcome were analyzed.
Results A total of 384 pancreatic cancer patients were analyzed. Among them, 70 patients had concurrent use of RAS inhibitors and 314 patients had no concurrent medication use. Among patients with RAS inhibitors use, the diagnosed age was significantly older (70.0 vs. 68.0, $p = 0.023$), and a higher proportion of hypertension (100.0% vs. 51.0%, $p < 0.0001$), chronic kidney disease (27.5% vs. 9.1%, $p < 0.0001$), and diabetes (64.3% vs 39.5%, $p < 0.0001$) than those without RAS inhibitors use. The 12-month progression-free survival were 22.9% and 13.7% in the RAS inhibitors and control group ($p = 0.008$), respectively. The Overall survival was not significantly different in the both groups ($p = 0.356$). In the multivariate

analysis, the use of RAS inhibitors had a significantly better progression-free survival outcome (Hazard ratio = 0.025, CI:0.52-0.96). The advanced disease status, poor ECOG performance status and the elevated level of CA19-9 were correlated with poor progression-free survival.
Conclusion In our study, although higher percentage of existed comorbidities in the RAS inhibitor group, we demonstrated that the use of RAS inhibitors among pancreatic cancer patients might provide a better progression-free survival outcome. Further prospective study and investigation are warranted.

Ramucirumab plus paclitaxel as second-line treatment in patients with advanced gastric cancer who previously treated with first-line nivolumab plus chemotherapy

Youngkyung Jeon, Sun Young Jeong, Jaeyeon Jang, Ye Ji Jung, Daeho Choi, Joohyun Hong, Seung Tae Kim, Won ki Kang, Jeeyun Lee. *Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, Korea, Republic of*

Background: For human epidermal growth factor receptor 2 (HER2)-negative advanced gastric cancer (AGC), a combination of fluoropyrimidines and platinum agents was the standard first-line treatment. After the failure of the first-line therapy, ramucirumab plus paclitaxel was the standard second-line treatment. In the CheckMate 649 study, nivolumab plus chemotherapy has been considered a new standard first-line treatment in previously untreated AGC. However, the role of ramucirumab plus paclitaxel as 2nd line after the failure of nivolumab plus chemotherapy is not confirmed.
Methods: We analyzed AGC patients with ramucirumab plus paclitaxel as second-line therapy, who failed the nivolumab plus chemotherapy (capecitabine plus oxaliplatin (XELOX) or 5-fluorouracil plus oxaliplatin (FOLFOX)) as frontline therapy at Samsung Medical Center, South Korea.
Results: Under the routine clinical practice, 23 AGC patients, who progressed after first-line chemotherapy with nivolumab plus chemotherapy, were treated with ramucirumab plus paclitaxel between Dec 2021 to Sep 2022. The median age was 56 (range, 24-76), and 18 (78.3%) patients received nivolumab plus XELOX, while 5 (21.7%) patients

received nivolumab plus FOLFOX. The overall response rate (ORR) to ramucirumab plus paclitaxel was 10.0% (2 of PR) and the disease control rate was 55.0%. At the median follow-up of 4.5 months, the median progression-free survival (PFS) from second-line ramucirumab plus paclitaxel commencement was 2.7 months (95% confidence interval (CI), 1.7-3.7); 6.9 months (95% CI, not calculated) in the first nivolumab plus chemotherapy responders(n=7), and 2.3 months (95% CI, 1.6-3.0) in non-responders(n=15) (p=0.232). At the time of data cutoff, 6 patients continued to receive ramucirumab plus paclitaxel and the median OS was 6.3 months (95% CI, 4.9-7.7).
Conclusions: This analysis showed that ramucirumab plus paclitaxel as 2nd line therapy was not sufficient in AGC patients after the failure for nivolumab plus chemotherapy. The new innovative 2nd line therapy might be needed in AGC patients after nivolumab plus chemotherapy.

#6757

Identification of predictive factors for early relapse in patients with unresectable stage III NSCLC receiving consolidation durvalumab after concurrent chemoradiation

Chang Dong Yeo[1], Hye Seon Kang[2], In Kyoung Kim[1], Sang Haak Lee[1], Jin Woo Kim[3]. *[1]St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of,[2]St. Mary's Hospital, The Catholic University of Korea, Bucheon, Korea, Republic of,[3]St. Mary's Hospital, The Catholic University of Korea, Uijeongbu, Korea, Republic of*

Background: Patients with locally advanced, unresectable, non-small cell lung cancer (NSCLC) receiving definitive concurrent chemoradiation (CCRT) benefit from durvalumab consolidation therapy. However, predictive factors for early relapse during durvalumab maintenance were not identified.
Patients and Methods: The present study used the lung cancer cohort of the Catholic Medical Centers at the Catholic University of Korea from 2018 to 2021. In all, 51 NSCLC patients that were treated with durvalumab consolidation therapy after definitive CCRT. Early relapse was considered if it occurred within 6 months of starting initial durvalumab therapy.
Results: During study period, 15 (29.4%) relapsed among 51 included patients. Median time from initial therapy of durvalumab to progression

was 107.73 ± 47.69 days in early relapse group. In mutivariate analysis, younger age (HR 0.713, 95% CI 0.572-0.888, *P*=0.003), higher pack years (HR 1.311, 95% CI 1.109-1.549, *P*=0.001), non-COPD (HR 0.030, 95% CI 0.001-0.677, *P*=0.027), anemia (HR 23.30, 95% CI 2.030-267.48, *P*=0.011) and stage IIIC (vs. stage IIIA) (HR 17.890, 95% CI 1.997-160.243, *P*=0.010) were independent predictive factors for early relapse during durvalumab consolidation therapy.
Conclusion: Younger age, higher pack years, non-COPD, anemia and stage IIIC were independent predictive factors for early relapse during durvalumab consolidation therapy in patients with unresectable stage III NSCLC after definitive CCRT. Careful patient selection and clinical attention are needed for high-risk individuals.

Tumor immune microenvironment &genomic features of non-small cell lung carcinomas in patients with HIV (PWH)

Shruti Desai[1], Kishu Ranjan[1], Syim Salahuddin[2], Ramsey Yusuf[2], Jianlei Gu[3], Daiwei Tang[3], Yong Kong[3], Barani Kumar Rajendran[1], Hongyu Zhao[3], Yuval Kluger[1], Sarah Goldberg[2], Brinda Emu[2], Kurt Alex Schalper[1].
[1]Department of Pathology, Yale University School of Medicine, New Haven, CT,[2]Department of Internal Medicine, Yale University School of Medicine, New Haven, CT,[3]Department of Biostatistics, Yale University School of Medicine, New Haven, CT

Introduction: Lung cancer is the leading cause of cancer-related death among PWH with a relative risk that is over 3-fold higher compared to the uninfected population. In addition, HIV-infected patients with non-small cell lung cancer (NSCLC) have a significantly worse prognosis. The determinants for these associations remain uncertain.
Methods: We investigated the immune contexture of 18 primary NSCLCs from PWH and 19 clinicopathologically matched NSCLCs from HIV-negative cases represented in tissue microarrays using 37-plex Imaging Mass Cytometry (IMC) panels including cell phenotype markers (CK,CD4,CD8,CD20,CD45RO,CD25,etc), immunomodulatory targets (PD-L1,PD-L2,B7-H3,B7-H4,B2M,etc) and DNA damage response/repair

(DDR) indicators (γH2AX, RAD51,BRCA1,53BP1,etc). The samples were analyzed using single-cell tissue segmentation and spatial analysis. A subset of cases was also studied using whole exome DNA sequencing (WES) and mRNA sequencing (RNAseq).
Results: NSCLCs from PWH showed comparable levels of tumor infiltrating lymphocytes (TILs) relative to HIV-negative cases with a trend towards a lower CD4+/CD8+ cell ratio. However, CD4+ and CD8+ TILs in PWH showed higher levels of markers associated with T-cell activation and dysfunction including GZB, CD25, Ki-67, PD-1, LAG-3, and TIM-3 than non-HIV tumors. The epithelial tumor cells in HIV-associated cases showed higher levels of the immunomodulatory ligands PD-L1, CD47, B7-H4 and VISTA; and altered levels of the DDR markers γH2AX, BRCA1 and 53BP1 relative to the non-HIV controls. Differences were also seen in tumor-associated macrophages consistent with an immune regulatory environment. The spatial analysis of tumor and immune cells revealed a distinct topographic distribution of these cells in HIV-associated malignancies. WES analysis showed a higher nonsynonymous tumor mutational burden in HIV-associated tumors (400 vs 202 mean mutations/exome) with increased predicted HLA class-I neoantigens and a numerically higher immunoediting score than the non-HIV group. Exploratory analysis identified enrichment in RYR2 and KIAA1671 gene mutations in HIV-associated malignancies. RNAseq revealed distinct mRNA expression profiles of HIV-positive and negative NSCLCs with a fraction of transcripts showing differential expression associated with tumor suppressor functions, interleukin signaling and DDR.
Conclusion: NSCLCs in PWH display profound immunological and genomic alterations suggesting defective immunosurveillance. Our study reveals novel characteristics of HIV-associated NSCLC with possible clinical implications for this growing and understudied population.

Spatial profiling of cancer-associated fibroblasts in non-small cell lung cancer
Yunhe Liu, Guangchun Han, Enyu Dai, Guangsheng Pei, Jiahui Jiang, Humam Kadara, Linghua Wang. *UT MD Anderson Cancer Center, Houston, TX*

Cancer-associated fibroblast (CAF) is an unique component of the tumor microenviroment (TME). CAFs heterogeneous have been identified by recent single-cell studies. However, their spatial distribution, orgnization patterns and neighbors remain incompletely understood. Deep profiling of CAFs in tissue context may provides new insights into improved understanding of their functions and identify targets for the development of CAF-targeted therapies.We obtained the open-source CosMx SMI dataset generated on 8 tissue sections from 5 non-small-cell lung cancer (NSCLC) tissues *(He, S. et al. Nat Biotechnol. 2022)*. We extracted the cells' spatial locations and transcriptome data for subsequent analyses. Quanlity filtering, data normalization, batch correction and clustering analysis was performed by Seurat package. Cell type was defined based on canonical immune markers and curated gene sets. In addition, we applied NMF clustering approach to define the spatial subtypes of CAFs based on the composition of neighboring cells. After that, Four spatial subtypes of CAFs were defined, exhibiting distinct spatial distribution patterns and compositions of neiboring cells, including CAFs that are clustered with tumor cells, CAFs localized within stromal, CAFs co-localized with B cells and T cells within the tertiary lymphoid structures, and CAFs localized within myeloid-enriched areas. Notably, we observed an intimate link between their spatial location and tarnscriptioanl states, i.e., these different spatial CAF subtypes showed clearly distinct expression profiles, may suggest their heterogeneous functions in the tumor microenviroment. For example, tumor-enriched CAFs showed high expression of contractile (e.g., *ACTA2, TAGLN*) and extracellular matrix (*COL1A1*) related genes, resembling myofibroblast (myCAFs), whereas the TLS-niches CAFs showed high expression of genes involved in antigen presentation such as major histocompatibility complex class II molecules and CD74, suggesting their antigen presentation function and were identified as apCAFs. Consistently, we observed high expression of inflammation related genes such as interleukin and PDGFRA in the myeloid-enriched CAFs suggesting an inflammatory phenotype (iCAFs). In addition, these CAFs in different spatial subtypes showed differential expression of molecular pathways

regulating stress and inflammation response, likely reflecting their complex interactions with other components of the tunmor microenvironment. We also included single-cell RNA sequencing (scRNA-seq) and spatially resolved whole transcriptomics datasets for cross validation of our novel discoveries in additional cohorts.In summary, by applying a novel approach to classify CAFs in the spatial context, this study provided novel insights into an improved understanding of the phenotypic and functional heterogeneity of CAFs in the tunmor microenvironment of NSCLC.

Multi-parametric comparison of scRNA-seq with CITE-seq and ultrahigh-plex spatial phenotyping of proteins in FFPE head and neck tumor biopsies: An opportunity to generate uniquely comprehensive multi-omic single cell datasets to investigate the tumor microenvironment.

Aditya Pratapa[1], Shawn M. Jensen[2], Niyati Jhaveri[1], Yoshinobu Koguchi[2], Venkatesh Rajamanickam[2], Brady Bernard[2], Tanisha Christie[2], Brian Piening[2], Rom S. Leidner[2], Oliver Braubach[1], Bernard A. Fox[2]. *[1]Discovery Applications, Akoya Biosciences, Marlborough, MA,[2]Providence Cancer Institute, Earle A. Chiles Research Institute, Portland, OR*

Single cell RNA-seq (scRNA-seq) performed on cell suspensions isolated from tumor biopsies provides substantial insights into the transcriptional state of the cells in the tumor microenvironment (TME). Complementing this work with multi-omic Cellular Indexing of Transcriptomes and Epitopes (CITE-seq), which adds barcoded antibodies to label the surface of isolated cells, allows us to additionally characterize surface proteins. While information gleaned from these studies is dramatically expanding our understanding of the evolving immune response and tumor-immune interactions, it lacks an appreciation of the many spatial relationships that are present within the TME. Spatial phenotyping with the power of single cell resolution and whole slide imaging provides a valuable tool for identifying the cellular architecture and organization of spatial neighborhoods that perform critical roles in tumor progression, resistance, and clinical responses. Here, we explore bioinformatic strategies aimed at combining scRNA-seq and CITE-seq data with single-cell spatial protein data obtained with the PhenoCycler-Fusion (PCF) imaging platform. To this

end, we performed whole-slide spatial phenotyping with an ultrahigh-plex PCF panel on FFPE human head and neck tumors. The same biopsies were also enzymatically digested and subjected to CITE-seq and scRNA-seq analysis. The combined multi-omic, single cell dataset provides a uniquely comprehensive account of the cellular states, functional significance and spatial neighborhoods that govern the TME. This study represents a novel approach to integrate high dimensional data from bulk tissue and single-cell spatial technologies to provide deeper insights into tumor biology and, in turn, to develop more informed strategies for combination immunotherapy trials and improved patient outcomes.

Spatial insights into tumor immune evasion illuminated with 1000-plex RNA profiling with CosMx Spatial Molecular Imager

Claire Williams, Jason W. Reeves, Patrick Danaher, Shanshan He, Sean Kim, Michael Patrick, Julian Preciado, Mark Gregory, Zach Reitz, Justin Jenkins, Rachel Liu, Sarah Murphy, Christine Kang, Byron Hartman, Vikram Devgan, Michael Rhodes, Joseph Beechem. *NanoString Technologies, Inc., Seattle, WA*

Patient response to immunotherapy has been revolutionary but remains limited due to the inability to convert excluded or cold tumors into ones which would be permissive to therapeutic intervention. To treat patients that evade immune therapy, comprehensive understanding of their tumor microenvironment (TME) is needed. To date, most profiling efforts have lacked the ability to capture high-plex ‘omics data while retaining the spatial architecture of the TME. We developed the CosMx™ Spatial Molecular Imager (SMI) for analyzing formalin-fixed paraffin-embedded (FFPE) or fresh-frozen (FF) tissue and capturing the expression of over 1000 RNA targets simultaneously with subcellular resolution from a single histopathology slide. We profiled a cohort of 16 slides with CosMx using the Human Universal Cell Characterization (UCC) Panel across a range of solid tumors. This cohort represents a diverse array of patients which include both infiltrated and excluded tumors. We included technical replicates for 5 of the samples to better understand reproducibility of the assay. We were able to characterize over 4.5 million cells and detected on average over 80% of the panel per patient and assigning more than 95% of

the transcripts profiled to unique cells across these samples. We were able to robustly identify more than 20 cell types by integrating our data with previous single-cell sequencing projects from the human cell atlas. We demonstrate robust delineation of critical immune cell populations from across lymphoid and myeloid lineages, as well as stromal cell populations inclusive of cell types frequently missed using dissociated cell sequencing, such as vascular endothelium associated with immune cell migration into the tumor bed. We leveraged 450+ genes from our panel dedicated to cell lineage, cell-cell interaction, and ligand-receptor signaling to identify unique interactions occurring at different scales between the tumor and the TME. We find that diverse mechanisms of immune evasion can be captured, and a clear role for cell types such as SPP1+ Macrophages emerges in multiple cancer types. Utilizing the CosMx platform to profile tissues allows for robust resolution of critical immunogenic signaling cascades and cellular interactions that are necessary to truly understand the tumor architecture. By maintaining the tissue structure, we can directly measure cellular interactions and capture cells commonly missed during dissociative studies. With this new platform, we are better poised than ever to truly understand the molecular mechanisms that drive tumor response to intervention. FOR RESEARCH USE ONLY. Not for use in diagnostic procedures

#6766

Pan-cancer characterization of tumor-immune interactions using spatially resolved transcriptomics

Guangsheng Pei[1], Jingjing Wu[1], Enyu Dai[1], Yunhe Liu[1], Guangchun Han[1], Jian Hu[2], Fuduan Peng[1], Kyung S. Cho[1], Jiahui Jiang[1], Daiwei Zhang[2], Ansam F. Sinjab[1], Boyu Zhang[1], Shumei Song[1], Junya Fujimoto[1], Luisa M. Solis Soto[1], Anirban Maitra[1], Jaffer Ajani[1], Mingyao Li[2], Humam Kadara[1], Linghua Wang[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Pennsylvania, Philadelphia, PA*

The development of immunotherapy drugs, such as immune checkpoint inhibitors (ICIs) has changed the environment of cancer treatment tremendously by providing efficacious therapeutic options for many cancer patients. However, only a minority of patients experience durable clinical benefit and increasing evidence has linked the efficacy of ICIs to tumor cell

heterogeneity, the complex tumor immune microenvironment and their interactions, which remains poorly understood, particularly in the tissue context. Recent advances in spatially resolved transcriptomics (SRT) has provided great opportunity to better understand spatial tumor-immune interactions. In this study, we obtained public and in-house SRT data on a total of 136 tissue sections across 11 different cancer types, representing to date, the largest collection of SRT on human cancer. Sample and spot-level quality filters were applied, batch effects were assessed and properly handled. High-quality SRT data were pre-processed uniformly to comprehensively interrogate the spatial heterogeneity and architectures of the 3 major compartments (malignant, stroma, and immune) as well as relationships among them. Transcriptome data was integrated with region- and/or spot-level annotations from pathologists. For regions enriched with malignant cells, we inferred somatic copy number alterations, clonal structure of tumor cells, and profiled the transcriptional hallmarks of intra-tumor heterogeneity (ITH) including a number of curated gene sets and meta-programs, and systematically characterized tumor cell heterogeneity under the spatial modality. We observed a great variation in aneuploidy levels and transcriptome profiles within and across patients and cancer types and notably in molecular processes regulating tumor cell responses to stress, hypoxia and interferon signals and other key processes such as epithelial-mesenchymal transition. In addition, we performed cell-type deconvolution analysis using available tools including RCTD and cell2location, based on expression of curated cell-type specific gene signatures, we inferred levels of immune infiltration in each tissue section in both tumor core and invasive edges, and classified tumors into “cold”, “warm”, “hot”, and “mixed” immune phenotypes. We further quantified the abundance and spatial distribution of stromal cells and key TME structures such as tertiary lymphoid structures and lympho-myeloid aggregates, as well as their spatial neighbors with oncogenic features which revealed multiple interesting interplay patterns. Together, this study provide novel insights into our improved understanding of spatial tumor heterogeneity and tumor-immune interactions and revealed potential exploitable targets, and great resource for the community.

Cancer-associated fibroblasts promote T-cell exclusion and resistance to immunotherapy in non-small cell lung cancer with tertiary lymphoid structures

Florent Peyraud[1], Jean-Philippe Guegan[2], Christophe Rey[2], Oren Ngouala[2], Ophélie Odin[2], Emma Clot[1], Lucile Vanhersecke[1], Maxime Brunet[1], Thomas Grellety[3], Marie Del Castillo[4], Sylvestre Le Moulec[5], François Le Loarer[1], Alban Bessede[2], Antoine Italiano[1]. *[1]Institute Bergonié, Bordeaux, France,[2]Explicyte, Bordeaux, France,[3]Centre Hospitalier de la Côte Basque, Bayonne, France,[4]Atlantic Pathologie, Saint Pierre d'Irube, France,[5]Clinique Marzet, Pau, France*

Background: We and others have reported the major role of mature tertiary lymphoid structures (TLS) in the efficacy of PD-L1 blockade in NSCLC. The objective response rate (ORR) to inhibition of PD1/PDL1 used as single agents observed in TLS-positive NSCLC is similar to ORRs observed in all-comers NSCLC treated with a combination of immune checkpoint inhibitor (ICI) and chemotherapy. However, a substantial proportion of patients with TLS-positive NSCLC did not display clinical benefit. The aim of our study was to identify the determinants of response to ICI in TLS-positive NSCLC.

Methods: We spatially profiled the expression of >18,000 protein-coding genes across six patients with mature TLS-positive NSCLC (three with objective response and three with progressive disease as the best response) using the GeoMx whole-transcriptome atlas (WTA) assay. Using two consecutive slides stained with CD3/CD20 and CD45/PanCK markers, a first set of regions of interest (ROIs) selected the TLS (CD3+/CD20+) as an entire area of illumination (AOIs). A second set of ROIs was selected outside the TLS region and further segmented into 'tumor' (PanCK+/CD45-) versus 'stroma' (PanCK-/CD45+) AOIs. To further validate our findings, we performed multiplex immunofluorescence (mIF) on 70 mature TLS-positive NSCLC tumors.

Results: Comparative transcriptomic analysis of TLS between non-responders and responders revealed upregulation in responders of CCL21 which plays a crucial role in T cell recruitment, and of IGHM indicating the presence of unswitched B cells. Outside of TLS, in the stromal compartment, the most significantly differentially expressed genes between

responders and non-responders were those belonging to a subset of cancer associated fibroblasts (CAFs) expressing both FAP and αSMA markers, and recently described as linked to more inflammatory activated immune cells and involved in T cell exclusion in NSCLC. We then used FFPE tissue mIF to histologically profile CAF subset composition and spatial distribution of T cells in a cohort of 70 mature TLS-positive NSCLC. In tumor lesions enriched in FAP+αSMA+ CAFs, the tumor-to-stroma ratio of infiltrating CD8+ cells was significantly lower, consistent with a decreased infiltrating CD8+ T cell density in the tumor. Strikingly, ORR and survival of patients with mature TLS NSCCLC enriched in FAP+αSMA+ CAFs were significantly lower than those of patients with low abundance of CAFs. Conclusions: We report here the first study investigating the mechanisms of resistance to immunotherapy in TLS-positive tumors. Our analysis of human tumor samples suggests a crucial role of FAP+αSMA+ CAFs in excluding T cells and in driving resistance to immune checkpoint inhibition in mature TLS-positive NSCLC. The development of novel CAF-targeting strategies may be particularly relevant in this subset of tumors.

#6768

The potential predictive role of spatial phenotyping in non-small cell lung cancer

Ning Ma[1], Aditya Pratapa[1], James Monkman[2], Ken O'Byrne[3], Oliver Braubach[1], Arutha Kulasinghe[2]. *[1]Akoya Biosciences, Menlo Park, CA,[2]University of Queensland, Brisbane, Australia,[3]Princess Alexandra Hospital, Brisbane, CA*

Background Lung cancers are the leading cause of cancer-related deaths with a 5-year-survival of only ~20%. Whilst immunotherapies have led to durable and prolonged survival, only a subset of patients remain responsive. Additional biomarkers are thus needed to better predict if patients will respond or develop resistance against immune checkpoint inhibitor (ICI) therapies. Spatial phenotyping of the tumor microenvironment (TME) is now recognized as a proxy for ICI therapy outcomes. Our study employs an end-to-end spatial biology strategy to survey non-small-cell lung cancer (NSCLC) tissues for new biomarkers that could guide immunotherapy treatments.

Methods We phenotyped pre-treatment biopsies from non-small-cell lung cancer (NSCLC) patients treated with single-agent Nivolumab. We first performed 57-plex whole-slide Single Cell Spatial Phenotyping on the PhenoCycler®-Fusion platform. Next, we developed the spatial analysis of a larger NSCLC cohort using customizable PhenoCode Signature Panels (PSP) for high-throughput immune profile (CD3/CD8/CD20/CD68/PanCK + CD4 add-in) and immuno-contexture (CD8/CD68/PD-L1/FoxP3/PanCK + PD-1 add-in) imaging. The PSP panel content combines the barcode-based antibody chemistry from the PhenoCycler platform with the signal amplification of Opal chemistry from the PhenoImager platform. PSP panels were profiled across n=27 NSCLC biopsies and provided a wider breadth of tissue profiling.
Results Our whole-slide single-cell spatial phenotyping analyses revealed high phenotypic diversity in the TME of patients responsive and resistant to ICI therapy. However, higher-throughput analyses of the same tissues using targeted PSP panels revealed no significant differences in quantities of immune cell lineages, including T-cells and macrophages. On the contrary, we discovered multiple quantifiable and statistically significant spatial signatures that appear to be predictive of treatment benefit, which confirms the potential biomarker value of spatial associations in patient tissues.
Conclusions This study amounts to a uniquely comprehensive Single Cell Spatial Phenotyping analysis of pre-treatment NSCLC biopsies from a single-agent Nivolumab study. Our data catalogue the diversity in the immune microenvironment of NSCLC but highlighted that immune cell quantification is insufficient to stratify patient cohorts. Single-cell spatial phenotyping, on the other hand, promises to reveal new biomarkers that may aid in better stratification of patients in pre-treatment evaluations.

Precise spatial multiplexing of protein biomarkers for immune profiling in tissue samples with chip cytometry
Karen Kwarta, Thomas Campbell, Adam Northcutt, Spencer Schwarz.
Canopy Biosciences, St. Louis, MO

Immunohistochemistry is the most widely used diagnostic technique in tissue pathology. However, IHC is associated with several limitations including the labeling of just a few markers per tissue section and limited

quantification of cell populations. As a result of plex limitations, key insights about tumor biology are missed, which could be important for advancing our understanding of tumor biology and ultimately improving patient outcomes. Chip Cytometry is a novel image-based platform for precise spatial multiplexing that addresses these challenges by combining iterative immuno-fluorescent staining with high-dynamic range imaging to facilitate quantitative phenotyping with single-cell resolution. The platform enables simultaneous detection of dozens of markers on a single tissue section and enables accurate quantification of protein expression levels necessary to deeply profile single cells, understand interactions between key immune cells, and identify topographic biomarkers. Here we demonstrate how standard FCS files are generated from multichannel OME TIFF images, enabling identification of cellular phenotypes via flow cytometry-like hierarchical gating. Quantification of results reveal precise expression levels for each marker in the assay in each individual cell in the sample, while maintaining spatial information about each cell. Chip Cytometry has the potential to advance precision medicine in immuno-oncology and inform the discovery of novel biomarkers by enabling quantitative analysis of cellular phenotypes in the spatial context. The Chip Cytometry platform enables simultaneous detection of multiple protein markers on a single tissue section for deep immune cell profiling in the tumor microenvironment. Combined with the single-cell spatial information, such data sets provide an opportunity for the discovery of new complex multiplexed biomarker signatures to inform therapeutic development.

Spatial characterization of immune microenvironment from early onset metastatic colorectal cancer (EOmCRC) showed a dual prognostic role for IDO1 expression

Raghavendar Thyagaraja Nagaraju[1], Jakub Franczak[1], Markus Möhler[2], Elisa Fontana[3], Anne Giraut[4], Lieve Dirix[4], Jose Casas-Martin[4], Beatrice Borelli[5], Florian Lordick[6], Elizabeth Smith[7], Sabine Tejpar[8], Gunnar Folprecht[9], Jorge Barriuso[1]. *[1]Division of Cancer sciences, University of Manchester, Manchester, United Kingdom,[2]Mainz-University Medical Center, Mainz, Germany,[3]Sarah Cannon Research UK, London, United*

Kingdom,[4]Headquarters, EORTC, Brussels, Belgium,[5]Azienda Ospedaliera Universitaria Pisana, Pisa, Italy,[6]Universitaetsklinikum Leipzig UCCL-Krebszentrum, Leipzig, Germany,[7]Royal Marsden Hospital, London, United Kingdom,[8]Digestive Oncology Unit, University Hospital Gasthuisberg, Leuven, Belgium,[9]Medical Department I, University Cancer Center, University Hospital Carl Gustav Carus, Dresden, Germany

Background: Epidemiological studies demonstrate that the incidence of CRC in young adults is continually rising in both Europe and the USA. The differences between the spatial distribution of immune related markers (IRM) and their prognostic role in EOmCRC compared to late onset (LOmCRC) remains to be elucidated.
Methods: Forty paraffin embedded formalin fixed unstained sections from patients (pts) diagnosed with either EOmCRC (≤45) or (≥50) LOmCRC, matched for chemotherapy (chx) and molecular features, all with microsatellite stable disease were included. All tissue samples were obtained from pts enrolled in SPECTAcolor (EORTC-40CRC-GITCG) platform trial. The expression of IRM was studied using the GeoMX Digital Spatial Profiler (DSP). Fifty-seven IRMs were used and three morphology markers (MMs) anti-CD45, pan-cytokeratin and SYTO 13. Three 300 μm regions of interest (ROIs) were selected within the core of the tumour and further 3 ROIs within the active margin of the tumour. Each ROI was segmented based on MMs to obtain a tumour microenvironment (TME) and a tumour (T) mask. The analysis used the GeoMX DSP Advanced Analysis Suite software, R and IBM SPSS. Control for multiple comparisons use a false discovery rate (FDR) threshold of 0.05.
Results: Samples from 40 pts were collected; 19 (47.5%) were EOmCRCs; 16 (40%) were female; 23 (57.5%) with pathological stage IV. The majority being, 23 (57.5%) grade ≥ 2, left sided 26 (65%), oxaliplatin based first line chx 23 (57.5%). Ten (25%) were KRAS mutant (mt), 1 (2.5%) NRAS mt and 1 (2.5%) BRAF mt. The median overall (OS) and progression free survival (PFS) for the entire cohort was 36.6 months (m) 95%CI (33.5 - 39.7) and 11.7 m (8.1 - 15.3), respectively.The <0.05 FDR differential expression analysis based on tissue segmentation uncovered 9 hits when comparing the TME between different age groups and 2 hits when comparing T segments, all overexpressed in LOmCRC. Indoleamine 2,3-dioxygenase 1 (IDO1) was differentially overexpressed in TME (adjusted

p=0.043) and T (adjusted p=0.042) for LOmCRC.In the EOmCRC group IDO1 relative high expression in T was an independent marker associated with worse survival outcomes after multivariate cox regression corrected for the rest of significant markers (MVCC) for OS, HR: $7.01*10^5$ 95%CI ($9.08*10^5$-$5.41*10^{10}$), p=0.003 and PFS, HR:$7.7*10^5$ 95%CI (1.96-$30.3*10^6$), p=0.029. However, interestingly high IDO1 in TME was an independent marker associated with better OS, HR: 0.02 95%CI (0.01-0.46), p=0.015.
Conclusion: Differential expression analysis of IRMs found IDO1 as differentially expressed in both segments (T and TME). Furthermore, high IDO1 expression seemed to have a dual prognostic role depending on the segment analysed, showing worse OS when found in the tumour but better OS when found in tumour microenvironment for early onset mCRC.

Interrogating the tumor-immune landscape with a novel automated RNAscope™ assay for multiplexed detection of RNA and protein
Anushka Dikshit, Sayantani Basak, Vasudha Murlidhar, Ge-Ah Kim, Julia Yu, Sonali Deshpande, Li-Chong Wang, Maithreyan Srinivasan. *Bio-Techne Corporation, Newark, CA*

Understanding tissue heterogeneity is critical for elucidating cell-cell interactions with important implications in immuno-oncology, inflammation, and neuroscience. Tissue heterogeneity poses immense challenges to understanding underlying molecular mechanisms using techniques such as qRT-PCR or bulk sequencing. While single-cell RNA sequencing can provide information about precise cellular composition of tissues, data analysis can be cumbersome and spatial context is lost. With single-cell spatial platforms such as RNAscope, target gene and protein expression can be visualized to characterize cell types and tissue neighborhoods. Here, we demonstrate a novel method for the simultaneous detection of RNA and protein using a modified co-detection assay. This novel co-detection assay enables visualization of a combination of up to 12 RNA and/or protein targets on the same sample. We used a set of antibodies targeting key immune and tumor cell markers- PD1, CD3, CD4, CD8, CD68, FOXP3 and KRT17, along with RNA biomarkers to interrogate the tumor microenvironment (TME) in human FFPE tumor samples. Using a

combination of RNA and protein targets, we characterized different cell types such as T cells, macrophages, and tumor cells in the TME. We also developed a novel method for visualizing intercellular interactions between PD1 and PD-L1, offering insights into popular checkpoint mechanisms that are targeted for therapeutic intervention in cancer treatment. The assay offers a powerful technique for visualizing target RNA biomarkers in specific cell-types identified by cell-marker protein expression. This is a valuable tool for multi-omic analysis and accurate interrogation of complex tissues to obtain insights into novel biomarkers and therapeutic targets.

#6772

Powerful background reduction in fluorescent tissue stains with an improved proximity-based technology for detection of protein-protein interactions

Hampus Elofsson, Doroteya Raykova, Agata Zieba Wicher. *Navinci Diagnostics AB, Uppsala, Sweden*

Immunofluorescent staining of tissues via *in situ* proximity ligation assay (isPLA) is now a well-established tool for highly sensitive detection of protein-protein interactions and their localization. It finds versatile applications in basic research, understanding of cellular processes, visualization of tissue architecture, and identification of biomarkers, among others. However, standard IF and isPLA techniques alike may suffer from high background. Tissues are particularly affected by background problems caused by autofluorescence and tissue infiltration of various cell types (e.g., immune, endothelial) where the fluorescently labelled oligos used for detection in isPLA may bind unspecifically. To address this, we developed a next generation isPLA-based technology for fluorescent detection of protein interactions in FFPE and fresh frozen human and mouse tissues, called NaveniFlex Tissue. In contrast to previously available protocols, it can visualize signal that would otherwise be obscured by background, thereby increasing sensitivity. Here, we compare the ability of NaveniFlex Tissue and similar commercial kits to detect the interaction between low abundance proteins Podocalyxin and Ezrin in the glomeruli of healthy kidney and in breast cancer, where co-expression is a prognostic marker for increased metastatic potential. While other kits generate high background which masks isPLA signal entirely, NaveniFlex Tissue dramatically reduces

cell-based background and visualizes the interaction in its specific localization. Furthermore, in a TMA staining for the Mucin 16/Mesothelin interaction, our method successfully demonstrates strong and clear signal in stage III ovarian cancer. Moreover, it sensitively detects even low abundance interaction in a stage Ia tumor. In contrast, a different commercial kit detects significantly less interactions in the stage III tumor, while in the lower grade tumor it does not generate signals above background level. Therefore, NaveniFlex Tissue improves detection in tissues with varying disease progression, thus adding information and prognostic value to the staining. Taken together, our data illustrate that NaveniFlex Tissue outperforms current isPLA-based techniques by efficiently reducing background, which improves visualization of signal and signal-to-noise ratios in various healthy and diseased tissues.

Spatial dynamics of cytotoxic T lymphocyte exhaustion in reactive and tumoral tissue

Maxim De Schepper[1], Asier Antoranz[2], Nikolina Dubroja[2], Giuseppe Floris[2], Frederik De Smet[2], Francesca Bosisio[2]. *[1]Laboratory for translational breast cancer research, Department of Oncology, KU Leuven, Leuven, Belgium,[2]Translational Cell and Tissue Research, Department of Imaging and Pathology, KU Leuven, Leuven, Belgium*

Background The study of cytotoxic T-lymphocytes (Tcy) has shown increased attention from the scientific community in the last years because of their predictive role in anti-cancer therapy with specific interest in immune check point blocking therapy. However, most of these studies have used bulk or dissociation-based single-cell technologies to draw their biological insights. Lately, new spatial -omics technologies are increasing our knowledge on this population by adding the spatial location of these cells in-situ in the native structure of the tissue. In this study, we have compared the activation of Tcy in reactive and cancerous conditions at single cell level and in the micro-anatomical context of the tissue.
Experimental procedures One tissue micro array slide containing: reactive tonsil, inflammatory liver disease, breast cancer, glioblastoma and melanoma was stained using the COMET™ instrument (Lunaphore Technologies SA) for a multiplex panel of 20 markers. The derived

multiplexed images were analyzed using the DISSCOVERY software platform developed by the MILAN Unit at KU Leuven (Belgium). 12/20 markers were specifically aimed at identifying the main cell populations in the tissue (CD11b, CD163, CD20, CD3, CD31, CD4, CD56, CD68, CD8, CK, FOXP3, S100) while the remaining 8 markers were aimed at adding functional information on immune cell types of interest (CD69, HLA-DR, Ki67, LAG3, OX40, PD-1, PD-L1, TIM3).
Results The general activation levels of the Tcy in the reactive conditions were higher than in the three cancer subtypes. When looking at Tcy activation as a function of the distance from the vascular structures (identified via CD31+ endothelial cells), we observed an orderly distribution of activated Tcy around CD31+ endothelial cells with a gradient of increasing exhaustion levels with increasing distance from the vessel in the reactive conditions. In the cancer samples, on the contrary, a patchy disorderly organized pattern of exhausted and activated Tcy was observed around the vessels.
Conclusion The spatial location of inflammatory cells plays a critical role to understand their functional behavior and thanks to technological progress it is now possible to start doing this at scale. The study of the dynamics of exhaustion of Tcy in the tissue will help clarify the interplay between cancer cells and immune environment. These results will be crucial to better select patients who may benefit the most of immune check point blockade.

The development of a spatial metabolic map of immunotherapy sensitive and resistant cutaneous skin carcinoma

Niyati Jhaveri[1], Dmytro Klymyshyn[1], Bassem B. Cheikh[1], James Monkman[2], Dan Winkowski[3], James Mansfield[3], Subham Basu[4], Michael Prater[4], Nadine Nelson[4], Gabrielle Belz[2], Oliver Braubach[1], Arutha Kulasinghe[2]. *[1]Akoya Biosciences, Menlo Park, CA,[2]The University of Queensland, Brisbane, Australia,[3]Visiopharm A/S, Horsholm, Denmark,[4]Abcam, Cambridge, United Kingdom*

Background: Cutaneous squamous cell carcinoma (cSCC) is the second most common skin cancer and represents a major global health burden. Approximately 50% of cSCC patients develop primary resistance and 20% will develop secondary resistance to immune checkpoint inhibitors (ICI).

There are limited biomarkers that reflect the tumor dynamics predictive of response to ICI therapy, and therefore we need to explore new biomarkers that can better understand the cSCC tumor microenvironment (TME).
Methods: Our retrospective study profiled pre-treatment cutaneous skin cancer tissues from patients with immunotherapy sensitive and resistant diseases. In this exploratory study, we designed a high-dimensional > 50-plex antibody panel identifying cell lineages, activation states, and immune checkpoints. In addition, we deployed a combination of antibodies for a novel multiplexed metabolic readout, to enhance our *in situ* profiling beyond well-known TME targets. Whole-slide spatial phenotyping was conducted on the PhenoCycler-Fusion spatial biology platform. Highplex image analysis was performed using Phenoplex (Visiopharm), including tissue segmentation and cellular phenotyping. Here, we used a deep learning approach to discriminate tumor regions and margins based on their morphology. Spatial analyses including phenotypic composition, cell-to-cell localization, and cellular neighborhoods were performed and compared to clinicopathological findings and responses to ICI therapy.
Results: We have profiled the TME of cSCC via ultrahigh-plex, single-cell spatial analyses of whole tissues. Our data have revealed unique cell phenotype compositions and metabolic states within the TME of different patient cohorts. Areas of metabolic activity were visualized and compartmentalized to determine spatial distributions of inherent sensitivity and resistance to ICI therapy. Additionally, a comparison of the phenotypic expression patterns between immunotherapy sensitive and resistant cohorts in the tumor, stromal and margin regions showed relevant differences in the immune content. Taken together, this high-dimensional imaging approach of the cSCC TME has revealed new tissue insights.
Conclusion: There is a need to understand the contexture of the cSCC immune microenvironment. Here we identify distinct cellular phenotypic compositions and metabolic states in tissues from immune-competent and immunocompromised cSCC. We thereby confirm biological differences in tissue composition and cellular interactions between these tissues and provide putative new biomarkers for cSCC patient stratification.

Combination of spatial transcriptomics and multiplex IHC as valuable multi-omics tool for biomarker discovery

Nicole Kerstedt, Monika Schoeppler, Bita Motamedi-Baniassad, Antonia Hirt, Julia Ploetzky, Mirja Kastein, Laura Thoms, Malik Khenkhar, Hartmut Juhl, Kerstin A. David. *Indivumed, Hamburg, Germany*

Colorectal cancer (CRC) is one of the most common cancers worldwide and shows heterogenous molecular subtypes making personalized medicine as well as identifying new targets highly important to provide individual patients with the most appropriate treatment.
To gain more insight into the visualization of potential molecules or pathways for targeting CRC we used a multi-omics approach for the simultaneous analysis of gene and protein expression within a sample. In this study we combined fluorescent multiplex immunohistochemistry (mIHC) for the detection of proteins (4-plex panel) with the Visium Spatial Transcriptomics technology (10x Genomics) that enables the detection of the whole transcriptome in the histological context.
A formalin-fixed paraffin-embedded (FFPE) tumor tissue sample from a patient diagnosed with CRC was selected according to our quality standards. For this multi-omics approach, serial sections were prepared. The first section was used for fluorescent mIHC staining visualizing the protein expression of Ki67 (proliferation marker), p53 and p21 (both tumor suppressor genes). The second section was stained for hematoxylin and eosin (H&E) to evaluate the tissue morphology. On the third section the Visium FFPE Spatial Gene Expression workflow was applied, and gene expression patterns were analyzed by using the software Space Ranger and Loupe Browser.
Our data showed on the one hand a good correlation of protein and gene expression of Ki67, p53 and p21 within the analyzed sample and on the other hand a clear difference of expression patterns between tumor cell areas and regions with corresponding normal mucosa cells. Moreover, by comparing Spatial Transcriptomics gene expression patterns of tumor cell and corresponding normal mucosa cell areas, we also identified genes that were linked to other cancer types and/or are still only poorly described in cancer, especially for CRC. Corresponding protein expression will be verified by chromogenic IHC in the next steps.
The combination of fluorescent mIHC and Spatial Transcriptomics has been shown to be a valuable approach not only to visualize already described relations as proof of principle, but more importantly to enable the discovery

of new biomarkers or pathways predominantly linked to colorectal tumor tissue that may serve as new targets for cancer treatment.

#6776

Spatial transcriptomics of response to tepotinib treatment in a patient with NSCLC

Manon A. Simard[1], Felix Geist[1], Carlos Cabrera[2], Santiago Viteri[2], Joachim Albers[1], Michael Zuehlsdorf[1], Niki Karachaliou[1]. *[1]Research Unit Oncology, Merck KGaA, Darmstadt, Germany,[2]UOMI Cancer Center, Barcelona, Spain*

Background: While cancer therapies are becoming increasingly more targeted, our understanding of the genomic changes occurring during these treatments is lacking. Moreover, the tumoral heterogeneity and its spatial distribution remain important obstacles in predicting tumor evolution and treatment responses. In recent years, genomic spatial profiling techniques have shed light on this complexity by detecting gene expression changes in heterogenous tumor regions and their microenvironment over the course of treatment.
Methods: Tepotinib is a highly selective and potent MET class Ib inhibitor, approved for the treatment of patients with NSCLC with *MET* exon 14 skipping alterations. To detect genomic changes during neoadjuvant treatment with tepotinib, a GeoMx® digital spatial profiler (DSP; Nanostring Technologies) analysis was conducted in paired baseline and on-treatment patient samples. GeoMx® DSP was performed by selecting regions of interest with nuclear, TTF-1, CD3 and CD33 morphology markers followed by next-generation sequencing (NGS) using the Cancer Transcriptome Atlas RNA panel (>1,800 cancer-related genes).
Results: Following a poor response to chemotherapy, neoadjuvant tepotinib treatment was initiated in a 54-year-old female, never-smoker with NSCLC harboring a *MET* exon 14 alteration. Owing to a good response to tepotinib, surgical resection of the tumor was decided by the tumor board given the downgrading (from IIIB to IA1) and resulting in a major pathological response. This resection allowed spatial transcriptomics to be compared to a baseline biopsy from the same patient. MET signaling inhibition by tepotinib treatment increased immune cell infiltration in the tumor microenvironment compared to the baseline sample. This enhanced tumoral

immune cell density was shown by the fluorescent morphology markers and confirmed through spatial deconvolution of the NGS results. It was further characterized by the significantly altered gene expression levels between the two samples. Gene ontology (GO) assessment of the differentially expressed genes revealed GO terms associated with tumorigenesis in the basal sample, such as cell mobility and motility, vascular epithelial growth factor production and cell communication. In turn, the tepotinib-treated tissue mainly exhibited tumor-clearing characteristics, including antigen processing and presentation through major histocompatibility complex classes I & II, T cell-mediated toxicity, and granulocyte and leukocyte activation.
Conclusion: This is the first spatial genomic characterization of the effect of tepotinib on the tumor and its microenvironment in a patient with NSCLC over time. Results from this case report highlight the impact of MET inhibition by tepotinib on the tumor immune microenvironment, likely enabling the recruitment of antigen-presenting cells for tumor clearance, while reducing the expression of tumor-promoting genes.

Digital Spatial Profiler highlights a T and B cells inflamed tumor microenvironment in brain metastases derived from melanoma vs. non-melanoma solid tumors

Alberto Mendoza-Valderrey[1], Daria M. Kessler[2], Ethan Dettmann[3], Xinmin Li[4], Sierra Thompson[5], Steven E. Kolker[5], Kim A. Margolin[6], Maria L. Ascierto[1]. *[1]Translational Cancer Immunology and Immunotherapy, Saint John's Cancer Institute, Providence Saint John's Health Center; Rosalie and Harold Rae Brown Cancer Immunotherapy Research Program; Borstein Family Melanoma Program, Santa Monica, CA,[2]Bioinformatic Department, Saint John's Cancer Institute, Providence Saint John's Health Center, Santa Monica, CA,[3]Translational Cancer Immunology and Immunotherapy, Saint John's Cancer Institute, Providence Saint John's Health Center, Santa Monica, CA,[4]Technology Center for Genomics and Bioinformatics, UCLA, Los Angeles, CA,[5]Dermatopathology Section, Saint John's Cancer Institute, Providence Saint John's Health Center, Santa Monica, CA,[6]Melanoma Program, Saint John's Cancer Institute,*

Providence Saint John's Health Center; Borstein Family Melanoma Program, Santa Monica, CA

Introduction**:** Systemic immunotherapies (IO) have recently shown activity in melanoma and non-small cell lung cancer metastatic to the brain, but minimal activity in the treatment of other brain metastases. Further, only a limited percentage of melanoma or lung cancer (MBM/NSCLC)-brain metastasis (BrMs) patients respond to IO. The aim of this study is to explore the differences in the tumor microenvironment (TME) among BrMs from different tumor types including melanoma, NSCLC, breast, and renal cell carcinoma (RCC).
Methods: Formalin-fixed paraffin-embedded (FFPE) tumor from 13 MBM and 43 non-MBM [18 NSCLC-BrMs, 20 breast-BrMs and 5 Renal RCC-BrMs] and primary tissue from 7 melanoma, 4 NSCLC and 3 breast cases were identified. RNA was isolated from tumor regions and subjected to whole gene expression profiling (GEP) by RNA-seq. Microenvironment Cell-Populations counter method estimated the abundance of immune and stromal infiltrated cell subpopulations. Inter- and intra-tumor heterogeneity was evaluated in selected regions of interest using a 59-plex immune related protein panel assessed by GeoMx Digital Spatial Profiling (DSP) technology.
Results: Whole GEP revealed 3650 transcripts differentially expressed between MBM and non-MBM (False Discovery Rate, FDR, ≤0.01). MBM showed increased expression of genes involved in B cell function, cytolytic activity associated with CD8 and NK cells and complement signaling (*C1QA*/*B*/*C*). Conversely, overexpression of genes involved in epithelial signaling, cell adhesion and neurovascular coupling was observed in non MBM vs MBM. Spatial protein profiling revealed in the TME of MBM vs non-MBM, an increased expression ($p < 0.1$, $FC > 1.5$) of the tumor antigen MART-1, together with a higher infiltration of CD8+ cytotoxic cells ($CD8^+$, $41BB^+$), antigen presenting cells (HLA-DR^+, $B2M^+$, $CD40^+$) and cells involved in the formation of tertiary lymphoid structures ($CD20^+$, $CD11c^+$). Conversely, increased infiltration of Tregs ($CD25^+$, $CD127^+$), neutrophils ($CD66b^+$) and epithelial cells ($EpCAM^+$, $PanCK^+$) was observed in non-MBM vs MBM. Interestingly, $LAG3^+$and PD-$L2^+$cells were also observed to be more enriched in non-MBM vs MBM. GEP in primary tumors (FDR≤0.01) showed limited immune-related signals but revealed

overexpression of genes associated with NK cells functions and immune chemoattraction (*CCL18*/*20*, *CXCL2*/*5*/*17*) to be overexpressed in PM vs other primary tumors.
Conclusion: TME interrogation at molecular and protein levels has shown that MBM are more immune infiltrated than brain metastases derived from non-melanoma solid tumors. Particularly, a cytotoxic and B cells - enriched TME was observed in MBM vs brain metastases derived from NSCLC, breast and RCC. These findings will be validated in larger cohorts and incorporated in therapeutic investigations.

Spatial analysis of genomic signatures on colorectal cancer pathogenesis using the GeoMx® Digital Spatial Profiler
Xiang Li[1], Qinqin Zha[1], Brigitte Lovell[2], Jane Reed[2], Anna Juncker-Jensen[1], Tricia Peters[2], Lakshmi Chandramohan[2]. *[1]NeoGenomics, Aliso Viejo, CA,[2]NeoGenomics, Houston, CA*

Background: The development of colorectal cancer (CRC) is a complex process, involving multiple sequential molecular aberrations that contribute to disease progression. Understanding the immunopathogenesis of CRC particularly within the spatial context of tumor microenvironment (TME) may elucidate the genomic and biological changes to improve patient prognosis for adjuvant therapies and identifying potential drug targets. However, this can be challenging, as genomic signatures from sub-cellular populations and varying levels of immune cell infiltration in TME may be lost in bulk sequencing. In this study, we used the NanoString GeoMx® Digital Spatial Profiler (DSP) to spatially select epithelial, proximal stromal and distal stromal regions of TMEs on a total of 10 FFPE samples (5 colon cancer patients and 5 healthy donor samples) and profiled up to 1,800 genes included in the Cancer Transcriptome Atlas (CTA) panel.
Methods: Selection of regions of interest (ROI) were guided by pathology assessment of H&E images and fluorescent markers (CD45, PanCK, Syto13). Tumor and stroma (proximal and distal) regions were profiled through geometric ROI selection in PanCK+ (epithelial) and CD45+ (stromal/immune) enriched areas respectively, followed by collection of indexed oligonucleotides and sequencing on NextSeq 550 Illumina instrument. Differential expression and pathways enrichment analyses was

performed using R BioConductor package DESeq2 and DSP GeoMx analysis suite. A subset of samples were tested for bulk RNA expression using PanCancer IO360 panel on NanoString nCounter Flex system and data analyzed using nSolver software 3.0 and TIS algorithm App.
Results: The CTA panel is designed to profile the global immune response and all aspects of tumor microenvironment biology. From differential gene expression analysis of epithelial and distal/proximal stromal ROIs, we have identified biomarkers such as SOX9, IRAK2 and NLRP3 that are specifically upregulated in CRC samples compared to the healthy cohort. Comprehensive pathways analysis revealed an over activation of NF-kB signaling, extracellular matrix organization and interferon signaling pathways in the CRC cohort. Suppression of the NF-kB signaling pathway is a potential therapeutic approach in the treatment of colon cancer.
Conclusion: With this spatial study using GeoMx CTA panel, we have highlighted key genes and pathways involved in CRC in order to provide a much-needed understanding of the underlying mechanisms as well as immune signatures in the development of colon cancer.

Spatial and single-nucleus transcriptomics of human glioblastoma

Yue Hao[1], Angela Baker[1], Brian Hilbush[2], Marcos Otero[2], Chris Streck[2], Karen L. Fink[3], George J. Snipes[3], Bruce E. Mickey[3], Michael Berens[1].
[1]Cancer and Cell Biology Division, TGen (The Translational Genomics Research Institute), Phoenix, AZ,[2]Veranome Biosystems LLC, Mountain View, CA,[3]Baylor Scott & White Medical Center, Dallas, TX

Glioblastoma (GBM) multiforme is the most aggressive type of brain cancer. These lethal brain tumors are characterized by the inter- and intra-tumor molecular heterogeneity and diverse cell plasticity. We sought to interrogate the immune landscape of GBM, tease out the distinct biological and therapeutic niches in GBM and to understand how the tumor microenvironments mediated the heterogeneity of GBM. We have collected six human GBM samples for spatial profiling and single-nucleus RNA sequencing. Multiple sets of spatial gene panels were designed to capture the cell identities (cancer stem cells, astrocytes, oligodendrocytes, microglia, macrophages, endothelial cells, etc.) and the spatially-resolved expression patterns of genes indicative of different functional states. We

also aim to find altered neurovascular units by examining the spatial correlation between cells that highly express angiogenesis markers such as VEGFA with tumor-associated macrophages, which could be recruited to the angiogenic niche by GBM tumor cells. From the spatial RNA dataset of the first two samples, we observed close proximity of tumor-associated macrophages and endothelial cells that form the microvasculature. Our preliminary results from the single-nucleus RNA sequencing and spatial transcriptomics of two samples shed light on the complex cell landscape and the dynamic interaction between tumor cells and infiltrating or resident immune cells in the GBM tumor tissue.

Characterization of immunological heterogeneity in the tumor microenvironment by integrated analyses using single cell RNAseq, spatial RNAseq and multiplex IHC

Seul Lee[1], Jae-Hwan Kim[2], Kwangmin Na[2], Seung Min Yang[2], Dong Kwon Kim[1], Sujeong Baek[3], Seong-san Kang[4], Yu Jin Han[2], Chun-Bong Synn[1], Mi hyun Kim[2], Heekyung Han[2], Young Taek Kim[2], Sungwoo Lee[4], Youngseon Byeon[2], Young Seob Kim[2], Ji Yun Lee[5], Jii Bum Lee[5], Chang Gon Kim[5], Min Hee Hong[5], Sun Min Lim[5], Kyoung-Ho Pyo[2], Byoung Chul Cho[5]. *[1]Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Seoul, Korea, Republic of,[4]JEUK Institute for Cancer Research, JEUK Co., Ltd, Gumi-city, Korea, Republic of,[5]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of*

Heterogeneity in resistant to immunotherapies of tumor microenvironment (TME) has been implicated in immunotherapies to cause immune evasion or drug resistance. This study was conducted to explore the heterogeneity of TME through multiplex IHC, spatial and RNA sequencing analysis. We selected a sample from a lung adenocarcinoma patient without EGFR-activating mutation and expressing 30% of PD-L1. For quantitative analysis

by multiplex IHC, various markers including CD4, CD8, FoxP3, granzyme B, CD20 and pan-cytokeratin were stained with 7 different fluorescence dyes, which was imaged with Vectra Polaris (Akoya). For scRNAseq and spatial RNAseq, we used 5' chromium library kit (10X Genomics) to make library construction. Integrated raw data was generated using Cell ranger, Seurat pipeline and Azimuth package. The tumor area was divided into 16 clusters in which we selected 2 clusters based on CD3/45 expression. There was a noticeable distinction between the two clusters which were defined as the 'High' region ($CD45^{high}CD3^{high}$ cluster) and the 'Low' region ($CD45^{low}CD3^{low}$ cluster). By multiplex IHC, percentage of $CD8^{+}$T cells was higher in the 'High' region than in the 'Low' region (8.5% vs. 0.8%, respectively). Subsequent analysis of two clusters using spatial and single cell RNA seq, the 'Low' region was characterized by increased hypoxia-associated gene expressions including HIF1A, HIF3A and VEGFA. Various immune cells were abundant in the 'High' region and CD45 expression level was 11-fold higher in the 'High' region compared to the 'Low' region. Cytokine/chemokine network analysis via spatial RNAseq revealed that gene expression of tumor necrosis factor (TNF) family-associated factors increased in the 'High' region compared to the 'Low' region (TNF, FAS, TRAIL, RANKL and CD40), which is well-known to promotes apoptosis, programmed cell death, or necrosis of certain cancer. Additionally, the 'High' region also had elevated levels of the PD-1/PD-L1, CD155, CD122/TIGIT, Siglec10/CD24, LAG3/LAGLS3, and CD47/CD172a axes, suggesting active immune responses. Intriguingly, combined analyses showed that 'High' region showed enhanced level of *CD44* expression as the leading-edged gene, which suggests the metastatic potential of tumor cells. Furthermore, scRNA analysis confirmed that *CD44* expression was mainly higher in macrophages, suggesting that tumor-associated macrophages partially affected tumor cell metastasis in the 'High' region. Our finding suggests that understanding the intratumoral immunological heterogeneity of lung adenocarcinoma can help to study the mechanism of tumor heterogeneity by integrated spatial RNAseq and scRNAseq analyses. This type of technique could be applied to understand complex networks of anti-tumor immune activities, drug resistance mechanisms and immunotherapeutic response of cancer.

#6781

Spatial omics using spatially-resolved laser-activated cell sorting for cancer biomarker discovery

Amos C. Lee, Sumin Lee, Sunghoon Kwon. *Seoul National University, Seoul, Korea, Republic of*

Cancer is spatially heterogeneous in terms of genetic molecules. Revealing genomic, epigenomic, transcriptomic, and epitranscriptomic features that are unique to the malignant cell populations within cancer lead to cancer biomarker discoveries that can be translated into diagnostic or therapeutic tools. Here, we introduce spatially-resolved laser-activated cell sorting (SLACS) technology coupled to next generation sequencing and mass spectrometry that analyzes genetic molecules from regions of interest within spatial context. Specifically, we demonstrate application of SLACS in various cancers such as breast cancer, glioblastoma, glioma, meningioma, multiple myeloma, and leukemia. Examples of discovering cancer biomarker and their mechanism of action within spatial context are also provided. Specifically, we describe Select-seq which isolates the regions of interest as small as single cells from the immunofluorescence stained tissue and obtains the full-length transcriptome data. We demonstrated Select-seq on tumor tissue section from triple negative breast cancer patient who have received neoadjuvant chemotherapy. Select-seq produced full-length spatial transcriptome data, with which we analyzed the transcriptomic and epitranscriptomic features including alternative splicing variant, complementarity-determining region analysis of B cells, and even adenosine-to-inosine base editing. We were also able to analyze the immune- and stem-cell-like microniches, in which the complex mechanisms behind ferroptosis inhibition might suggest therapeutic options for the TNBC patients. Bridging spatial technologies to omics technologies, the discovery of specific markers within spatial context will provide insights into the next generation diagnostics and cancer therapeutics such as cancer vaccines.

Spatial transcriptomics of serous tubal intraepithelial carcinoma and its putative precursor lesions

Rahul Krishnan[1], Lisa Schweizer[2], Agnes Bilecz[1], Aasa Shimizu[1], Rachelle Mendoza[3], Diane Yamada[1], Ricardo Lastra[3], Matthias Mann[2], Ernst

Lengyel[1]. [1]*Gynecologic Oncology, Obstetrics & Gynecology, The University of Chicago, Chicago, IL,*[2]*Max Planck Institute of Biochemistry, Munich, Germany,*[3]*Pathology, The University of Chicago, Chicago, IL*

Background: Increasing evidence over the past two decades has implicated serous tubal intraepithelial carcinoma (STIC) of the fallopian tube (FT) epithelium as the putative precursor lesion for high-grade serous ovarian cancer (HGSC). Additional atypical lesions of the FT known as p53 signature lesions and serous tubal intraepithelial lesions (STIL) have been proposed as early precursors in the carcinogenic sequence based on morphology, histochemical and genetic studies. Little however is known about the molecular events that drive FT epithelial cells to transform into HGSC.Methods: To elucidate the molecular changes that underlie the progression from p53 signature to STIL to STIC, we performed spatial transcriptomics on formalin-fixed paraffin embedded (FFPE) tissue sections using the Nanostring GeoMx Whole Transcriptome Atlas panel (18,000 protein-encoding gene panel). Our study cohort consisted of 16 representative cases (3 p53 signature cases, 3 STIL cases, 3 STIC lesions, and 7 STIC cases with matched HGSC).Results: We characterized gene expression to a depth of over 9400 genes in these rare precursor cell populations. Our analysis demonstrated that by gene expression profiles, p53 signatures and STIL lesions bear close resemblance to normal FT secretory cells compared to FT ciliated cells or even STIC and invasive HGSC. We identify for the first time, several pathways altered in expression between normal fallopian tube epithelium and early p53 signature lesions including those related to signaling pathways (Trop-2), Wnt pathway (LGR5), identifying new pathways observed in the progression from normal FT cells to precursor intraepithelial lesion. Our data show that STIC lesions bear significant similarities to invasive HGSC by gene expression, especially compared to the earlier precursor lesions (p53 signature and STIL). We observed several alterations in cell-adhesion(EGR1) and signaling pathways, transcription factors (Trop-2) and metabolism that mark the transition from STIC to HGSC, representing possible mechanisms by which these intraepithelial lesions transform into disseminated invasive disease. Conclusion: Our data profile HGSC precursor lesions in high-depth with characterization of over 9400 genes providing new insight into the molecular alterations that characterize these intraepithelial lesions. Our

future direction is to pair transcriptomics data with our established spatial proteomics platform (Deep Visual Proteomics) to measure matched spatial protein expression in our cohort.

Introduction: Multiple myeloma (MM), a clonal disorder of terminally differentiated plasma cells, is the second most common hematologic malignancy with ~57.9% 5-year survival rate. Current MM therapies are not curative and in most patients MM relapse. Aiming to restore antitumor immunity and counteract MM evolution, we have developed a personalized dendritic(DC)/MM cell fusion vaccine, whereby several tumor antigens are presented in the context of DC mediated co-stimulation. BMT CTN 1401 is a multicenter randomized phase II clinical trial (NCT02728102) evaluating the efficacy of the DC/MM vaccine combined with lenalidomide maintenance (Len) after autoHCT. 203 patients were enrolled from 18 centers. **Aim:** To evaluate the impact of the DC/MM vaccine on the establishment of anti-MM immune response we profiled the peripheral blood (PB) immune landscape at the single-cell level, with particular focus on the T cell compartment.
Method: We performed single-cell immunoprofiling (gene expression + V(D)J sequencing) on 40 patients (3xDC/MM vaccine/Len/GM-CSF: N=20; Len/GM-CSF: N=10; Len: N=10). 160 PB mononuclear cells (PBMC) samples were collected at enrollment, prior to Len, after 1 and 3 vaccines and were processed using the 10x Genomics single cell 5' assay. Here we present the analysis relative to 52 PBMC samples from 13 vaccinated patients included in the initial study cohort. The remaining 108 PBMC samples have already been subjected to single-cell immunoprofiling and the analysis is ongoing.
Results: 309,423 cells passed quality-check identifying 47 cell populations, corresponding to 20 major compartments. The T cell compartment (146,373 cells) was divided into 14 different cell populations including activated CD8, CD4, and NKT cells that exhibited a gradual increase during the course of the study. Relatively, TCR sequencing demonstrated a recovery of T cell clonal diversity and a progressive rise in the frequency of expanded clonotypes within the activated CD4 and cytotoxic T cell populations after vaccination. Consistently, we observed a progressively raised number of shared TCR clonotypes within the activated CD8 and CD4 T cell subsets. The identification of common epitope/paratope hotspots among the expanded clonotypes and the different patients revealed a higher proportion of shared TCR clonotype groups across patients after vaccination compared to the early post-transplant period, predominantly after 3 vaccinations.

Conclusions: Assessment of PBMC samples from 13 vaccinated patients provided a detailed picture of the PBMC landscape. The constant T cell expansion in patients following vaccination coupled with the shared paratope/epitope hotspots and TCR signatures among patients indicated the TCR cross-reactivity and suggested for the establishment of an anti-MM immune response.

NT-I7 as an adjuvant to DNA neoantigen vaccination enhances and prolongs neoantigen-specific anti-tumor immunity

Michael Y. Chen[1], Ina Chen[1], Suangson Supabphol[1], Alexandra A. Wolfarth[2], Sara F. Martinez[2], Byung Ha Lee[2], Lijin Li[1], Xiuli Zhang[1], Peter S. Goedgebuure[1], William E. Gillanders[1]. *[1]Surgery, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]NeoImmuneTech, Inc., Rockville, MD*

Background: IL-7 is an essential cytokine in the development and maintenance of antigen-specific T cells. NT-I7 (efineptakin alfa; NeoImmuneTech, Inc, Rockville, MD), is a long acting IL-7 composed of recombinant human IL-7 (rhIL-7) fused to a hybrid Fc antibody platform that has significantly improved *in vivo* stability and half-life compared to rhIL-7. DNA cancer neoantigen vaccines are a promising personalized cancer immunotherapy capable of generating strong anti-tumor immunity, but limited by a short-lived neoantigen-specific T cell response. We hypothesize NT-I7 as an adjuvant to a DNA neoantigen vaccine will enhance the magnitude and duration of neoantigen-specific anti-tumor immunity.

Methods: C57BL/6 mice were vaccinated with DNA vaccine encoding neoantigens present in E0771 murine breast cancer model on days 0, 3, and 6. NT-I7 (5 mg/kg) was administered intravenously on day 4 or 13 during T cell expansion or contraction phase respectively. Primary T cell responses to neoantigens were assessed by IFN-γ ELISPOT. Tumor protection was evaluated by inoculating mice with 5×10^5 E0771 cells subcutaneously after receiving DNA vaccine with or without NT-I7. Duration of neoantigen-specific CD8 T cell immunity was determined by *in vivo* CFSE killing assay.

Results: NT-I7 administered during the T cell contraction phase following the DNA vaccine increases the magnitude of neoantigen-specific T cell responses on day 20 compared to DNA vaccine alone. DNA vaccination and NT-I7 alone prior to tumor inoculation confers partial protection against tumor growth compared to control while DNA + NT-I7 during contraction phase rejects 100% of tumors. Compared to DNA vaccine alone, DNA vaccine + NT-I7 during contraction phase induces greater neoantigen-specific killing on day 41 (34.6% vs. 11.97%, p=0.03).
Conclusion: NT-I7 as an adjuvant to a DNA neoantigen vaccine increases the magnitude and duration of neoantigen-specific anti-tumor immunity in a murine model. Clinical application of NT-I7 may help overcome immunologic shortcomings of current neoantigen vaccines.

#6787
Vaccinia virus harboring TRAIL (vTRAIL) for in vivo lung cancer therapy
So Young Yoo. *Pusan National University, Busan, Korea, Republic of*

While oncolytic virotherapy has shown promising results for uncured patients with cancer, its effects on lung cancer remain unclear. Lung cancer is mostly unlikely to respond to conventional anticancer drug, therefore, oncolytic virotherapy can be the best option. Herein, we evaluated the anti-cancer activity of the previously developed three oncolytic vaccinia viruses encoding TNF-related apoptosis-inducing ligand (TRAIL), angiopoietin 1 (Ang1) and both genes, especially on killing lung cancer (LC). In this study, we confirmed that our engineered vaccinia viruses showed overall higher anti-cancer activity on lung cancer cells, compared to WT. Vaccinia virus engineered with both Ang1 and TRAIL (vTRAN) showed the highest oncolytic activity and selectivity in vitro (WT < vTRAIL < vAng1 < vTRAN). However, In vivo LLC1 murine lung cancer syngeneic model showed highest attenuated tumor growth when vTRAIL was treated (WT < vAng1 < vTRAN < vTRAIL), which was in accordance with $CD8^{high}$ $PD1^{low}$ expression levels in the tissues. It concludes that engineered vaccinia virus harboring TRAIL (vTRAIL) is the promising therapeutic option for in vivo lung cancer therapy.

hNIS imaging data from a first-in-human trial of the oncolytic virus CF33-hNIS-antiPD-L1 in patients with triple negative breast cancer

Jamie Green Rand[1], Dave Yamauchi[1], Shyambabu Chaurasiya[1], Jianying Zhang[1], Raju Pillai[1], Colt Egelston[1], Jonathan Kessler[1], Badri Modi[1], Leslie Chong[2], Amanda Seiz[2], Giovanni Selvaggi[2], Nick Ede[2], Mireya Murga[1], Norma Martinez[1], Wichanee Borisuthirattana[1], Hans Meisen[1], Susan Yost[1], James Waisman[1], Daphne Stewart[1], Joanne Mortimer[1], Yuman Fong[1], Yuan Yuan[3]. *[1]City of Hope Comprehensive Cancer Center, Duarte, CA,[2]Imugene Limited, Sydney, Australia,[3]Cedars-Sinai Medical Center, Los Angeles, CA*

Background: CF33-hNIS-anti-PD-L1 is a novel chimeric orthopoxvirus shown to have anti-cancer activity in triple negative breast cancer (TNBC) xenografts. For clinical tracking of the oncolytic virus (OV), human sodium iodide symporter (hNIS) transgene was inserted into the virus. hNIS gene expression allows cells to take up iodine and be visible by non-invasive imaging techniques. Animal studies showed that tumor cells infected with CF33-hNIS-anti-PD-L1 express functional hNIS and are visible by single-photon emission computed tomography (SPECT) or positron emission tomography (PET). The current report describes imaging results from an ongoing first-in-human trial.

Methods: This is a phase I, single center, single arm clinical trial evaluating the safety and tolerability of CF33-hNIS-anti-PD-L1 intratumoral (IT) injections in patients with metastatic TNBC. Key eligibility criteria include patients with unresectable or metastatic TNBC; progressed on at least 2 prior chemotherapies; ECOG 0-2; RECIST 1.1 measurable disease; and at least one tumor amenable to repeated IT injections. Eligible patients receive CF33-hNIS-anti-PD-L1 IT at 1 of 8 assigned dose levels (from 1×10^5 PFU to 3×10^8 PFU) on Days 1 and 15 of each 28-day cycle for a total of 3 cycles of treatment. The primary objective is to evaluate the safety and tolerability of CF33-hNIS-anti-PD-L1. Secondary objectives are to determine optimal biological dose, recommended phase II dose, and response rates. Exploratory objectives include assessing feasibility of non-invasive hNIS imaging as a method of tracking viral infection and replication. SPECT whole body imaging was performed at Cycle 1 Day 8 (C1D8).

Results: From October 2021 to October 2022, 8 patients were enrolled in this ongoing study and received at least 1 dose of CF33-hNIS-anti-PD-L1 injection at one of the first 3 dose levels (1 x 10^5, 3 x 10^5, or 1 x 10^6 PFU). All 8 patients underwent SPECT imaging at C1D8 with 6/8 patients (75%) having uptake at the site of injection on the SPECT imaging study. Four of 4 patients (100%) with injection sites at metastatic subcutaneous nodules, intramuscular masses, or axillary lymph nodes and 2/4 patients (50%) with injection sites at matted dermal metastatic lesions had uptake on SPECT. Conclusion: SPECT imaging successfully showed enhancement at the injected lesions in 75% of patients treated with CF33-hNIS-anti-PD-L1, even at current low doses, suggesting local viral replication and hNIS expression. Further analysis will evaluate the correlation of SPECT imaging results with pathologic immune cell infiltrate, viral staining, and tumor response. This is the first known report of hNIS-based imaging to track oncolytic poxvirus replication in humans and gives promise that this technology may be used for noninvasive tracking of systemically administered OV and other therapies.

#6789

The oncolytic virus VET3-TGI both blocks TGF-beta signaling and activates type 2 IFN responses, resulting in potent therapeutic responses in multiple mouse models

Ravikumar Muthuswamy, Steve Thorne. *Immunology, Kalivir Immunotherapeutics LLC, Pittsburgh, PA*

Background: TGFB1 mediated immune resistance is one of the major mechanisms of immune suppression utilized across multiple tumor types. Immune resistance imparted by TGFB1 is mediated through its pleiotropic effects on vasculature, fibrogenesis and regulatory/effector immune cells within the tumor microenvironment. Blockade of TGFB1 (TGFBi) will likely improve response to immunotherapy. IL-12 is a cytokine that through IFNg induction, promotes type 1 inflammatory response, M1 macrophages and effector CD8 T cell response. Combining TGFB1 blockade with IL-12 may maximize therapeutic benefits through simultaneously reducing immunosuppression and enhancing anti-tumor immune response. Current studies have developed a vaccinia-based immunotherapy, combining enhanced systemic virus delivery to CXCR3 ligand rich tumors and locally

expressed IL-12 and TGFBi within the tumor microenvironment, for efficient control of multiple tumor models.
Methods: An oncolytic vaccinia virus expressing CXCR3, IL-12 and a TGFB1 antagonizing mini-monomer was constructed (VET3-TGI) and the expression and function of the transgenes were confirmed. Using *in vivo* mouse RENCA, EMT-6 and MC38 tumor models, the functionality and therapeutic efficacy of VET-TGI were tested with comparison to control virus. Post-mortem analysis was used to analyze the impact of VET3-TGI on immune/stromal/endothelial milieu of the tumors and to determine toxicity profile.
Results: VET3-TGI infected cells expressed CXCR3 and showed enhanced migration to CXCR3 ligands *in vitro* and improved systemic delivery to tumors expressing CXCR3 ligands *in vivo*, even in the face of pre-existing anti-viral immunity. IL-12 expression and TGFBi blockade of TGFB1 mediated suppression of CD8 T cell proliferation were confirmed *in vitro*. *In vivo* mouse studies using EMT6, RENCA and MC38 tumor models demonstrated potent therapeutic activity, including 100% CRs, even at doses several logs below equivalent clinical doses and in multiple models. Mechanism of activity studies suggested that the therapeutic efficacy of VET3-TGI is associated with considerable modification of the tumor microenvironment. In addition, preliminary toxicity studies demonstrated the safety of VET3-TGI in mouse models.
Conclusions: VET3-TGI demonstrated an ability to reduce immunosuppression and dramatically enhance antitumor immune response leading to safe and potent therapeutic activity in multiple mouse tumor models. This data led to the selection of VET3-TGI as our lead clinical candidate. A human version of the virus is currently undergoing clinical manufacture and toxicology testing.

The peptide vaccine revived in cancer immunotherpay: a novel peptide vaccine platform for effective cancer immunotherpay
Dongho Kim, SeungHwan Lee. *NA Vaccine Institute, Seoul, Korea, Republic of*

The production of tumor-specific T cells is essential for cancer immunotherapy. Due to the low cost and ease of CMC, peptide vaccines

have been suggested as effective immunotherapy for cancer. A variety of peptide vaccines have been designed and tested in clinical trials for decades. However, most clinical trials of peptide vaccines have failed for several reasons. Poor stability of peptides, use of inappropriate adjuvants, lack of co-delivery of peptides and adjuvants, and immunosuppression by the tumor microenvironment. We tried to solve the problems that lead to failure and developed effective platform technologies for them. The first problem was the choice of vaccine adjuvants. Poly IC and its derivatives are known to induce antigen-specific Th1 and CTL responses. Since Th1-type immunity is essential for the elimination of intracellular pathogens or tumors, they may be suitable as the adjuvant for peptide vaccines. Despite several limitations of poly IC and its derivatives, such as high heterogeneity, inconsistent activity, poor stability, and unpredictable in vivo kinetics, they still serve as major adjuvants in numerous clinical trials. A novel and defined TLR3 agonist called NexaVant (NVT) was developed as an alternative to them. NVT induces a stronger anti-cancer efficacy compared to the known TLR agonists through multiple advantages of homogeneity, stability, and quantitative in vivo kinetics. Second, the stability of peptides was dramatically improved by a peptide/adjuvant complex formation. When a cationic peptide domain is introduced into the epitope together with an epitope processing domain, the peptide and adjuvant can form a nanocomplex by a simple charge interaction. And this complex improves the stability of the peptide which leads to improvement of the T cell immunity. Third, suppression of T cell immunity in cancer was mitigated by Treg modulation in the presence of a known chemotherapeutic drug. When this combination therapy of the vaccine and chemical was applied to various animal models, a strong anticancer effect was obtained by increasing T cell immunity and suppressing Treg. The same therapeutic effect was shown in several terminal stage tumor models with strong T cell memory regardless of whether the epitope was self or foreign originated.

Inovative *in vivo* (i*n ovo*) CAM model to predict efficacy and mode of action of a new antitumor vaccine stc-1010 on human colorectal adenocarcinoma

Yan Wang[1], Arnaud Peyronnier[1], Benoit Pinteur[2], Lionel Chalus[2], Corinne Tortorelli[2], Paul Bravetti[2], Jean Viallet[1], François Ghiringhelli[3], Philippe

Fornies[1]. *[1]Inovotion, La Tronche, France,[2]Brenus Pharma, Issoire, France,[3]Team Inserm 1231 TIRECs « Therapies and Immune REsponse in CancerS », Inserm, Dijon, France*

BACKGROUND: Colorectal cancer (CRC) is the second-most deadly cancer. Therapeutic resistance to immuno-oncology drives the need for new treatments. Stimulated tumor cell (STC) vaccine (Brenus Pharma) is composed of selected tumor cell lines, stimulated to overexpress tumor-associated or tumor-specific antigens and neoantigens including resistance factors. Haptenization of these proteins forms an immunogenic complex which stimulate the immune system to recognize and target the patient's tumor cells expressing same resistance factors. We report *in vivo* results of STC-1010 vaccine, on human CRC adenocarcinoma from HT29 cell using chorioallantoic membrane (CAM) assay developed by Inovotion in immune reactive model.
METHODS: This study was carried out in 2 steps: Firstly, three batches of naïve chicken embryos were stimulated by injections of STC1010 at Embryo Development Day (EDD) 11 and EDD13. At EDD18 of each batch, chicken peripheral blood mononuclear cells (PBMCs) were collected and used as anti-tumor reagent to treat respectively, at EDD 11, EDD 13 and EDD16 chicken embryos xenografted with HT29 cells. Activation of PBMCs was evaluated by IL2 and IL12 secretion quantified by ELISA. At EDD18, i.e., 9 days post-graft, *in ovo* anti-tumor efficacy was evaluated by tumor weight, metastatic invasion (qPCR analysis of human Alu sequence in lower CAM) and quantification of tumor-infiltrating by CD8, CD4, IFN-gamma, Perforin and TNF-alpha.
RESULTS: Compared to negative control, STC-1010 vaccine induced: 1) significant increase of IL-12 and IL-2 secretion in peripheric blood during the generation of all three batches of PBMCs, confirming previous results (IL-12: +52%, p=0.0003 ; IL-2: +482%, p=0.0033); 2) a significant expression of IFN-gamma in tumor (+130,83%, p=0.0185); 3) a tendency to increase infiltrating cells: CD4+: +79,2%, CD8+: +29,4% , Perforin: +105,5%, TNFα : +78,63% confirmed by immunohistochemistry and translated into 4) a significant increase of tumor necrosis (p = 0.0267); and 5) a tendency of metastasis regression (-49%); with 6) no embryonic toxicity/mortality (daily evaluation of embryonic viability) induced by STC-1010.

CONCLUSION: This *in ovo* study confirms efficacy of the STC-1010 observed in previous CRC syngeneic models and gives more insight about STC mechanism of action with the activation and maturation of dendritic cells, induction of CD8+ and LTh1 against tumor as the main driver of the response, all without toxicity. Inovotion's CAM model could be used for indication screening and as a pre-proof-of-concept before syngeneic model study.

Targeting immunosuppressive adenosine to enhance vaccinia virus renal cancer oncolysis *in vivo*

Valery A. Chavez[1], Floritza Bustamante[1], Carolina Merchan-Mendes[2], Shannon Saigh[3], Patricia Guevara[3], Eric Wieder[4], Jaime Merchan[5].
[1]Hematology, Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[2]Miami Dade Colege, Miami, FL,[3]Flow Cytometry Facility, Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[4]Cellular Therapy, Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[5]Medical Oncology, Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL

Background: The oncolytic vaccinia virus (VV) is a promising biotherapy undergoing clinical development in human cancer, including renal cell carcinoma (RCC). While VV induces potent tumor oncolysis and immunomodulation, clinical experience has shown that OV therapy alone leads to limited benefit. Moreover, OVs and checkpoint inhibitor combinations, do not significantly improve clinical responses, underscoring the need to identify new tumor microenvironment targets to overcome OV resistance in vivo. The adenosine pathway is a biologically and clinically relevant target in RCC and is associated with adaptive resistance to immunotherapy. The objectives of this study are to characterize the role of the adenosine axis in tumor escape mechanisms to vaccinia virus in RCC, and to determine the efficacy of novel OV-immunotherapy combinations targeting adenosine.
Methods: The in vitro oncolytic effects of JX-594 and mJX-594 (oncolytic VVs expressing human or murine GMCSF, respectively) in human (786-0, ACHN, CAKi-1, UOK262) and murine (RENCA) renal cancer cell lines were assessed. Proteomic analysis of 786-0 lysates treated with JX-594 was performed for mechanistic studies. The effects of JX-594 and mJX 594 on

CD73 and CD39 expression were determined in human and murine RCC. In vivo antitumor effects of mJX-594 alone, and in combination with A2AR, A2BR and Dual Adenosine receptor inhibition was determined in the RENCA model in immunocompetent mice.
Results: Potent in vitro oncolysis and efficient viral replication were observed in human and murine RCC cells after infection with vaccinia virus. VV oncolysis was associated with significant modulation of proliferation, survival, and ER stress pathways, as determined by functional proteomics. JX-594 and mJX-594 treatment induced increased expression of CD39 and CD73 in RCC cell lines and in renal tumors in vivo. While no significant enhancement of vaccinia oncolysis was observed with combinations with A2AR and A2BR inhibitors *in vitro*, a significant improvement on *in vivo* tumor control and survival were observed when mJX594 given intravenously was combined with A2AR and A2BR inhibitors (triplet), at a higher degree than single agents or doublets (mJX-594 in combination with single A2AR or A2BR inhibitors). Characterization of treatment mediated changes in immune signatures (nanostring) is underway and will be presented at the meeting.
Conclusion: Vaccinia virus potently induces in vitro oncolysis in RCC cell lines, while also increasing expression of adenosine rate limiting enzymes in vitro and in vivo, which could explain tumor escape to oncolytic VV. MJX-594 combination with A2AR and A2BR inhibition safely and significantly improves renal cancer oncolysis and tumor control in vivo. Our studies uncover a novel, translationally relevant strategy to improve OV efficacy in vivo, in RCC and other cancers.

***In vivo* effects and molecular mechanisms of Minnelide mediated enhancement of measles virus oncolysis in human colorectal cancer**

Valery A. Chavez[1], Floritza Bustamante[1], Carolina Merchan-Mendes[2], Ashok Saluja[3], Jaime Merchan[4]. *[1]Hematology, Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[2]Miami Dade College, Miami, FL,[3]Department of Biochemistry & Molecular Biology, Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL,[4]Medical Oncology, Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL*

Background: The development of novel biotherapies for metastatic colorectal cancer (CRC), a fatal disease when advanced, is an urgent medical need. Oncolytic viruses (OVs) are novel cancer biotherapies, and the oncolytic measles virus (MV) has demonstrated safety and antitumor activity in early clinical studies. Triptolide (TRP), a diterpenoid epoxide extracted from the thunder god vine, and Minnelide (MN), its water-soluble compound, are novel agents associated with potent antitumor, anti-proliferative, pro-apoptotic, antiangiogenic, and ER stress inducing effects. The objectives of this study are to characterize the in vitro and in vivo effects and molecular mechanisms of measles virotherapy in combination with TRP and MN in CRC.
Methods: The in vitro effects of TRP, MV-GFP (Edmonston strain of Measles virus expressing eGFP), MV-CD46-muPA (dual targeted MV against the murine uPA receptor and human CD46), or virus-triptolide combinations on tumor cell cytotoxicity were assessed on HT-29, HCT116 and SW620 CRC cells. Molecular and mechanistic characterization of TRP's effects alone and combination with MV in HT29 cells was analyzed by the Reverse Phase Protein Array (RPPA) and validated by western blot analysis. In vivo effects (tumor progression and survival) of MN alone and in combination with MV vectors using different treatment schemes were assessed in HT-29 tumor bearing NSG mice, and tumor correlative studies were performed.
Results: MV and TRP had single agent antitumor activity against human CRC cell lines. MV-TRP combinations were associated with increased in vitro cytotoxicity compared to single agent treatments. Functional proteomics analysis showed that TRP-MV combinations were associated with inhibition of survival and proliferation pathways, such as AKT, ERK, inhibition of HSP70 as well as induction of autophagy, at a higher level than each agent alone. In vivo, both a 7-days MN treatment and a 21-days MN treatment significantly improved long term tumor control and significantly improved survival, compared to each agent alone. Tumor studies showed that MN increased MV tumor deposition, as well as enhancement in apoptosis and inhibition of proliferation. Molecular characterization of oncogenic pathways modulated by MV-Minnelide combinations (Nanostring) are underway and will be presented at the meeting.

Conclusions: Our results demonstrated that, in human CRC xenografts, Minnelide safely and significantly enhances measles virus oncolysis in vivo, leading to improved antitumor effects and prolonged survival. These effects were associated with enhanced antiproliferative and pro-apoptotic effects with the MV-Minnelide combination, suggesting in vivo synergy. Studies characterizing the molecular mechanisms of in vivo synergy and assessing this promising combination in immunocompetent CRC models are underway.

#6794

SETD2 loss in renal cell carcinoma generates peptides from aberrantly translated retained introns

Marya T. Kozinova[1], Alexander Metz[1], Robert Uzzo[2], Janusz Franco-Barraza[1], Michael Slifker[1], Jessica Peskin[2], Angel Fernández Sanromán[3], Samra Turajlic[3], Edna Cukierman[1], Phillip Phillip Abbosh[1]. *[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Penn State University, Philadelphia, PA,[3]Francis Crick Institute, London, United Kingdom*

Introduction: SETD2, a histone H3-K36 trimethyltransferase, is necessary for regulation of proper intron splicing. SETD2 is frequently inactivated in kidney cancer. We hypothesized that SETD2 deficiency would cause aberrant translation of retained introns (ATaRI) that could serve as potential immunotherapeutic targets in *SETD2*-mutant states.

Methods and Results: We detected increased presence of retained introns in *SETD2*-mutant vs WT tumors in two publicly available renal cell carcinoma RNA-seq data sets. We hypothesized that if intronic sequences translated into proteins, accumulation of misfolded proteins would activate the Unfolded Protein Response (UPR). The UPR pathway was strongly transcriptionally enriched as measured by GSEA, as were several immunotherapy-relevant pathways, suggesting that tumors are inflamed, possibly related to the antigenic nature of translated introns. To investigate this further, we generated Setd2-isogenic mouse renal cancer cells using CRISPR in the RENCA cell line. RNAseq followed by GSEA confirmed upregulation of UPR pathway transcriptional signature in the Setd2-null condition, supporting our observation in human tumors. Indicators of UPR activation such as cleavage of ATF6 and increase in ATF4 and Xbp1 levels in Setd2 deficient vs. unedited RENCA cells, as well as nuclear

translocation of ATF6 in *SETD2*-mutant human kidney cancer samples validates these findings. We then measured the presence of ATaRI-derived peptides in *Setd2*-mutant RENCA cells using mass spectrometry, detecting 47 such peptides. Using publicly available proteomics data from one human data set, we preliminarily identified peptides translated from 151 introns that are retained in *SETD*2-mutant cases. Applying netMHCpan to both the human and murine data, we found that detectable ATaRI peptides were predicted to generate multiple 10-amino acid-long peptides which strongly bind to the 8 murine MHC or to the 20 most common human HLA receptors. We propose that these presentable peptides might activate an immune response to SETD2-mutant renal cell carcinoma.
Conclusions: We identified intron retention which may cause activation of the UPR as a feature of *SETD2*-mutant kidney cancer. ATaRI peptides are detectable and should be presented to the adaptive immune system. These features may represent a new therapeutic vulnerability for exploitation as a rationale for personalized medicine.

PoxSTG, a novel chimeric poxvirus with improved oncolytic potency

Philippe Erbs, Annie Findeli, Johann Foloppe, Juliette Kempf, Isabelle Farine, Baptiste Moreau, Julie Hortelano, Christelle Pichon, Jules Deforges, Eric Quemeneur. *Transgene S.A., Illkirch Graffenstaden, France*

Oncolytic virus (OV) therapy has emerged as a promising approach for cancer treatment with the potential to be less toxic and more efficient than classic cancer therapies. Various types of OVs in clinical development, including Vaccinia virus (VACV)-derived OVs, have shown good safety profiles, but limited therapeutic efficacy as monotherapy in some cancer models. Many different methods have been employed to improve the oncolytic potency of OVs. We used a directed evolution process, pooling multiple species of orthopoxviruses to generate chimeric poxviruses with increased oncolytic properties. Through selective pressure by successive passages on human tumor cells, a new chimeric oncolytic poxvirus, named PoxSTG, was derived. The chimeric viral genome contains, in addition to sequences from several strains of Vaccinia virus, sequences of Rabbitpox virus and Cowpox virus. Compared with its parental viruses, PoxSTG has demonstrated superior oncolytic characteristics, and was notably attenuated

in normal primary cells. PoxSTG has superior secretion of extracellular-enveloped virus (EEV) compared to all parental strains inducing higher dissemination of the virus into the tumors and more resistance to neutralization. PoxSTG was saved and showed potent antitumor effects in several syngeneic and xenograft mouse models of cancers. Furthermore, PoxSTG exerted low-dose antitumor effects in virus-injected and non-virus-injected distant tumors in a CRC xenograft model, demonstrating strong virus spread to distant tumors. All these data demonstrate the potential of PoxSTG as a novel therapeutic agent for cancer treatment.

#6797

Oncolytic virotherapy with non-human viruses to improve anti-myeloma effect

Valentina Marchica[1], Rosanna Vescovini[1], Valentina Franceschi[2], Paola Storti[1], Nicolas Thomas Iannozzi[1], Vincenzo Raimondi[1], Oxana Longu[1], Jessica Burroughs Garcia[3], Denise Toscani[1], Anna Benedetta Dalla Palma[3], Gaetano Donofrio[2], Nicola Giuliani[1]. *[1]Department of Medicine and Surgery, University of Parma, Parma, Italy,[2]Department of Medical-Veterinary Science, University of Parma, Parma, Italy,[3]Department of Hematology, Azienda Ospedaliero-Universitaria di Parma, Parma, Italy*

Multiple myeloma (MM) is an incurable hematological malignancy characterized by remission and relapse with drugs resistance. Therefore, new therapeutic approaches are needed. Oncolytic viruses (OVs) represent a new strategy to augment the spectrum of cancer therapeutics. Several studies reported that, in MM, the OVs act through tumor-specific oncolysis and generation of an antitumor immune response. The main viruses that have been tested for MM setting are human viruses, this approach is highly restricted by pre-existing anti-virus humoral immunity that neutralize the anti-tumor effect of OVs. Recently, our group have demonstrated for the first time the role of a bovine virus, non-pathogen for the human, Bovine Viral Diarrhea Virus (BVDV) in direct MM cell killing suggesting its possible use as alternative strategy in MM oncolytic virotherapy. The aim of this study was to increase the bovine oncolytic viruses's spectrum for anti-MM treatment investigating the role of another bovine virus, Bovine Herpes Virus type 1 (BoHV-1), in the direct effect on MM cells. Firstly, after virus preparation, we treated human MM cell lines (HMCLs) for 24,

48 and 72 hours with BoHV-1 at 1 and 2 multiplicity of infection (MOI). We showed a significant increase of cell mortality, checked by flow cytometry analysis, already after 48 hours of infection in JJN3 (BoHV-1 1 MOI *vs* untreated $p< 0.001$; BoHV-1 2 MOI *vs* untreated $p< 0.001$) and in MM1.S (BoHV-1 1 MOI *vs* untreated $p= 0.025$; BoHV-1 2 MOI *vs* untreated $p= 0.002$). Interestingly, the cytotoxic effect of BoHV-1 treatment in HMCLs was associated by a significant increased expression of apoptotic markers as Apo2.7, evaluated by flow cytometry (JJN3 at 48 hours: BoHV-1 1 MOI *vs* untreated $p= 0.007$; BoHV-1 2 MOI *vs* untreated $p= 0.001$. MM1.S at 48 hours: BoHV-1 1 MOI *vs* untreated $p< 0.001$; BoHV-1 2 MOI *vs* untreated $p< 0.001$). Subsequently, we infected bone marrow mononuclear cells (BMMNCs) obtained from MM patients with BohV-1 for 48 and 72 hours. Already after 48 hours of infection, we found that MM cells had significantly increased cell mortality in BoHV-1-treated BMMNCs compared with untreated conditions. Overall, our data indicate that BoHV-1, as BVDV, was able to exert a direct anti-tumor effect on both HMCLs and primary cells from MM patients. In addition, data from ongoing studies will characterize the role of immune microenvironment in bovine oncolytic virotherapy. Focusing on monocytes, NK cells and CD8+ T cells we will explore a possible bovine virus-induced immune response to enhance anti-MM virotherapy. This study will highlight the possible use of non-human OVs as new anti-MM strategy.

CD8α+ dendritic cells potentiate the antitumor and immune activities against murine ovarian cancers

Shin-Wha Lee[1], Dasol Oh[1], Hyunah Lee[2], Kyung-Won Lee[3], Min-Je Kim[3], Sung Wan Kang[3], Young-Jae Lee[1], HyunSoo Kim[2], Yong-Man Kim[1].
[1]Obstetrics and Gynecology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Pharmicell Co. Inc., Seongnam, Korea, Republic of,[3]Asan Institute for Life Sciences, Seoul, Korea, Republic of

Objectives: Dendritic cell (DC) based immunotherapies have been shown to be a potential treatment option for various cancers; however, the exact strategies in ovarian cancer remain unknown. This study aimed to evaluate the effectiveness of mouse CD8α+ dendritic cells (DCs), corresponding to

human CD141+ DCs, derived from bone marrow (BM) hematopoietic stem cells (HSCs) in a syngeneic and orthotopic mouse ovarian cancer model.
Methods: Stem-DCs from HSCs and Mono-DCs from monocytes were generated from the bone marrow mononuclear cells (BM-MNCs) of C57BL/6 mice in condition of pulsing with ID8 tumor cell lysates. C57BL/6 mice were intraperitoneally injected with 5×10^6 ID8 cells. They were treated with vehicle, low/medium/high dose pulsed Stem-DCs, Mono-DCs, and unpulsed Stem-DCs. At 8 to 9 weeks, the treated mice were sacrificed, and tumor responses and immune responses, such as lymphocyte proliferation and cytokine secretion, were analyzed.
Results: Mono-DCs and Stem-DCs were characterized by CD11c+CD80+CD86+ and CD8α+Clec9a+ expression, respectively. They were confirmed by the secretion of immunostimulatory cytokines, such as interleukin (IL)-12 and interferon (IFN)-γ, and T cell proliferation was observed after maturation. Despite a lower dose compared with Mono-DCs, mice treated with pulsed Stem-DCs showed a reduced amount of ascitic fluid and lower body weights compared with those of vehicle treated mice ($P = 0.0021$ and $P = 0.0092$, respectively). These mice treated with pulsed Stem-DCs appeared to have fewer tumor implants which were usually confined in the epithelium of ovaries, diaphragm and peritoneum. All mice injected with DCs demonstrated longer survival than the vehicle group ($P = 0.0187$), especially the medium/high dose pulsed Stem-DC treatment groups. Moreover, these favorable tumor responses were associated with a low proportion of myeloid-derived suppressor cells (MDSCs) and regulatory T cells, high IL-12 and IFN-γ levels, and accumulation of several tumor-infiltrating lymphocytes.
Conclusions: We demonstrated that mouse CD8α+ DCs derived from BM HSCs could decrease tumor progression and enhance antitumor immune responses against murine ovarian cancer. Further studies are necessary to develop potent DC vaccines using human CD141+ DCs.

A porous silicon particle based particulate anti-cancer vaccine for immunotherapy

Junhua Mai, Yongbin Liu, Dongfang Yu, Haifa Shen. *Houston Methodist Research Institute, Houston, TX*

Background: Anti-cancer vaccine is a widely-studied strategy that activates innate and adaptive host immunity via its adjuvant components and tumor antigens against cancer. Unfortunately, its response rate in clinical trials was not promising. On the vaccine part, sufficient stimulation of strong and long-lasting local and systemic immunity and efficient promotion of intratumoral infiltration of cytotoxic T lymphocytes are among the critical issues determining the therapeutic efficacy of cancer vaccines in addition to the innate features of tumor. Our project aims to develop a porous silicon particle based particulate vaccine against cancer, and investigate the therapeutic mechanism and combinational effects with current first-line strategies.
Method: We first screened the combinations of ligands of Toll-like receptors (TLRs) expressing on antigen presenting cells (APCs) and selected the most powerful combo for immune stimulation. We then loaded the identified adjuvants in addition to antigen peptides to produce vaccine particles. Stimulation and licensing of APCs were tested in vitro, and its therapeutic efficacies were evaluated on multiple orthotopic and systemic metastasis cancer murine models of breast and colon cancers. Furthermore, we investigated the vaccine's synergistic effects and impacts on tumor microenviroment (TME) with an immunogenic chemotherapeutic oxaliplatin on a CT26 colon cancer model.
Result: According to the adjuvant screening assays, we identified a capable combination of CpG1826 (CpG) and 2'3'-cGAMP (cGAMP), which extensively stimulated the activation, maturation and type-I interferon secretion of APCs. A μGCVax formulation composed by these two adjuvants and antigen peptides was then applied on primary and metastatic HER2+ breast cancer TUBO bearing mice. μGCVax potently promoted the activation and lymph node migration of $CD8^+$ and $CD103^+$ dendritic cells in vivo. Distal metastatic tumor nodules in all different tissues vanished after two vaccinations. Functional cure of cancer and extension of animal survival were achieved. Moreover, oxaliplatin treatment on colon cancer caused immunogenic cell death and generated an immune favorable TME in a subcutaneous CT26 colon cancer model. The combination of μGCVax with the oxaliplatin effectively blocked the progression of large tumor mass. We finally revealed that the reprogramming of TME and the promotion of efficacy were mostly achieved from diminishing myeloid-derived suppressor cells (MDSCs) in tumor.

Conclusion: μGCVax is an effective and board-spectrum formulation for cancer immunotherapy. It effectively induces APC activation and licensing, and stimulates the innate and adaptive immunity against multiple cancers. The combination with oxaliplatin further promotes the therapeutic efficacy of μGCVax by decreasing tumor MDSCs.

Unique autologous cancer vaccine comprised of irradiated whole tumor cells and MBTA (rWTC-MBTA) triggers antitumor immune response to prevent metastasis

Juan Ye[1], Herui Wang[1], Mitchell Sun[1], Ondrej Uher[1], Mark R. Gilbert[1], Karel Pacak[1], Zhengping Zhuang[1], Rogelio Medina[2], Samik Chakraborty[3], Jan Zenka[4]. *[1]National Institutes of Health (NIH), Bethesda, MD,[2]Northwestern Memorial Hospital, Chicago, IL,[3]NE1 Inc, New York, NY,[4]University of South Bohemia, České Budějovice, Czech Republic*

Despite the advances made in cancer treatment over the past decades, one statistic has remained unchanged: metastatic cancer accounts for 90 percent of annual cancer deaths in the United States. Our group previously demonstrated that an autologous whole tumor cell vaccine (rWTC-MBTA: irradiated autologous whole tumor cells pulsed with Mannan-BAM, TLR ligands, and anti-CD40 antibody) had a potent anti-tumor immune response and prolonged survival in a mouse colon carcinoma model. To investigate whether rWTC-MBTA would work in “cold” tumor models, we evaluated the vaccine’s effect on preventing and treating tumor metastasis in 4T1 breast tumors. Our data showed that vaccinated mice could significantly prevent lung metastasis in both intravenous injection and mammary pad subcutaneous implantation animal models. Further, we used another metastasis model that more closely mimics clinical practice by resecting the primary tumor after metastasis development. The data showed that vaccinated mice could prevent tumor recurrence, increase T-cell infiltration in the metastatic tumor, and prolong the survival curve. The mechanistic investigation by immunophenotyping revealed that rWTC-MBTA vaccination induced both effector memory ($CD44^+CD62L^-$) and center memory ($CD44^+CD62L^+$) T cells as well as increased overall $CD4^+$ and $CD8^+$ T-cell count while depletion experiments demonstrated that $CD8^+$ T

cells were required for vaccine efficacy. Isolated splenocytes co-cultured with 4T1 cells showed rWTC-MBTA significantly increased T-cell mediated cytotoxicity through TNF-a and IFN-γ in $CD107a^{+}CD4^{+}$ T cells and Granzyme B and IFN-γ in $CD107a^{+}CD8^{+}$ T cells. In all experiments, vaccination exerted negligible systemic toxicity. Collectively, our study demonstrates that the rWTC-MBTA vaccine is a safe and promising therapeutic option to prevent and treat tumor metastasis by triggering an antitumor immune response.

UCP2 inhibitor eradicates cancer stem-like population in trastuzumab-resistant HER2-positive breast cancer

Minsu Park, Soeun Park, Juyeon Seo, Dongmi Ko, Seongjae Kim, Yong Koo Kang, Kee Dal Nam, So Ra Seuk, Tae-Min Cho, Eunsun Jung, Yoon-Jae Kim, Ji Young Kim, Jae Hong Seo. *Korea University Guro Hospital, Seoul, Korea, Republic of*

Purpose: Uncoupling protein 2 (UCP2) is a member of the mitochondrial anion carrier protein family that plays an important role in stabilizing the inner mitochondrial membrane potential (MMP, ΔΨm) and controlling reactive oxygen species (ROS) production. A selective UCP2 inhibitor, genipin is known to elicit cytotoxicity in several cancers, however, its effects on cancer stem cells (CSCs)-like properties and trastuzumab resistance in HER2-positive breast cancer cells have not been fully elucidated. In the present study, we sought to investigate the mechanism of action of genipin responsible for the induction of apoptosis and its effects on CSC-like features, expression of HER family member and trastuzumab resistance in HER2-positive breast cancer cells *in vitro* and *in vivo*.
Experimental Designs: The effects of genipin on trastuzuamb-sensitive [BT474 and SKBR3] and trastuzumab-resistant [JIMT-1 and MDA-MB-453] HER2-positive breast cancer cell lines *in vitro* were evaluated for cell viability, Sub-G1, ROS, MMP, ALDH1 activity, CD44+/CD24- subpopulation and mammosphere formation. To confirm the physiological

relevance of our *in vitro* observations, we explored the impact of genipin on tumor growth and angiogenesis and expression of p95HER2 and ALDH1A1 in trastuzumab-resistant xenograft model *in vivo*.
Results: HER2-positive breast cancer cells harbored a higher level of UCP2, when compared to their counterparts. Genipin significantly downregulated UCP2 and mitochondrial dysfunction coinciding with increased ROS generation and disruption of MMP. These phenomena were accompanied with upregulation of the Bax/Bcl-2 ratio and activation of caspase-3 and caspase-7. Genipin treatment led to significant reduction in levels of truncated p95HER2, p-HER2, p-HER3 and p-Akt levels in both trastuzumab-sensitive and -resistant lines. Marked decline of CD44 and ALDH1A1 expression by genipin treatment was associated with attenuation of mammosphere-forming ability. UCP2 level is predominantly upregulated in CSC-enriched populations, while its knockdown significantly suppressed CSC-like characteristics concomitant with decreased ALDH1A1 and CD44 expression as well as impairment of ALDH1 activity. Genipin administration significantly retarded tumor growth and angiogenesis in trastuzumab-resistant JIMT-1 xenograft tumors. The antitumor effect occurred concomitantly with a decrease in Ki-67 proliferating index and enhancement of apoptosis. Furthermore, individuals receiving genipin exhibited markedly lower levels of p95HER2, full-length p185HER2, CD44 and ALDH1A1 expression compared to their control counterparts.
Conclusion: To our knowledge, our findings are the first reported instance of genipin-induced suppression of CSC-like properties and HER2/HER3/Akt axis, implying that genipin treatment may have application in addressing trastuzumab resistance.

Targeting mutant p53 and KRAS for novel pancreatic cancer therapy by combination treatment of simvastatin and imipridones
Xiaobing Tian, Wafik S. Deiry. *Brown University, Providence, RI*

KRAS mutation is found in 95% pancreatic ductal adenocarcinoma (PDAC). TP53 is altered in 70% of patients with PDAC that co-occur with KRAS mutations. Enhanced de novo cholesterol biosynthesis is a hallmark of cancer cells. P53 inhibits the mevalonate pathway to mediate tumor repression. p53 mutations drive de novo cholesterol pathway activation and

are required for the proliferation of KRAS-mutant cancers. Inhibition of the mevalonate pathway leads to feedback activation of SREBP-2, which restores mevalonate pathway and leads to re-activation of KRAS and restoration of mutant p53 GOF. Imipridones induced ATF4 through the action of mitochondria protease ClpP. Simvastatin triggers ATF4 activation through inhibition of mevalonate pathway. We hypothesize that combined treatment with imipridones can overcome the resistance to simvastatin by two different mechanisms: (1) Imipridones inhibit oxidative phosphorylation through ClpP hyperactivation and result in AMPK activation. AMPK phosphorylates and inhibits SREBP-2 transcriptional function, which blocks the feedback activation of SREBP-2. (2) Enhanced ATF4 and CHOP induction through different pathways leads to cancer cell death. We also expect that the combined treatment through sustained induction of ATF4 and CHOP can sensitize cancer cells to imipridone treatment.

Mouse and human PDAC cell lines (KPCY, HPAF-II, and PANC-1) with p53 and KRAS mutations were used to test the effects of combination treatment of simvastatin and imipridones. The combined treatments synergistically inhibited the proliferation of p53 and KRAS co-mutant cell lines. For example, the synergy scores of simvastatin and ONC201 combination are 75 (KPCY), 15 (HPAF-II), and 14 (PANC-1). Enhanced cell death is consistent with sustained and enhanced induction of ATF4 and CHOP compared to single drug treatment alone. Imipridones activated AMPK in the tested PDAC cell lines. Imipridones potently inhibit AKT and ERK1/2 activation at 72-hour time point, which might also contribute to block above mentioned feedback activation of KRAS. We also observed that cell lines with a structural mutant of p53 are more sensitive to the combination treatments than a cell line with a DNA-contact mutant of p53, which is consistent with the fact that simvastatin treatment leads to degradation of structural p53 mutants. Surprisingly, our data indicated that simvastatin potently inhibits kinase WEE1 and leads to CDK1 dephosphorylation and activation, which has not been reported before. Together, our data is consistent with publications that p53 mutated cancer cell lines are sensitive to statin treatments. In short, combination treatment may overcome simvastatin resistance and/or imipridone resistance by modulating ATF4/CHOP and SREBP-2 activity.

Characterization of the synergistic tumor cytotoxicity of agonistic DR5 IgM antibody IGM-8444 with chemotherapeutic agents

Beatrice T. Wang, Thomas J. Matthew, Poonam Yakkundi, Miho Oyasu, Mélanie Desbois, Susan E. Calhoun, Ling Wang, Tasnim Kothambawala, Devinder K. Ubhi, Marvin S. Peterson, Eric W. Humke, Maya F. Kotturi, Bruce A. Keyt, Angus M. Sinclair. *IGM Biosciences, Inc., Mountain View, CA*

Death receptor 5 (DR5) is a tumor necrosis factor receptor (TNF) superfamily member that requires multimerization to activate the extrinsic apoptotic pathway and is broadly expressed on solid and hematologic cancers. IGM-8444 is a multivalent IgM DR5 agonist that efficiently multimerizes DR5 to induce tumor cell apoptosis while maintaining a favorable in vitro and in vivo safety profile. The universal mechanism of apoptotic cell death and the safety profile of IGM-8444 makes it an attractive combination partner with standard of care treatment regimens. Here we describe the characterization of single agent and combinatorial cytotoxicity with different classes of chemotherapeutic agents. IGM-8444 was first evaluated as a monotherapy across a panel of human solid tumor cell lines in vitro and xenograft tumor models in vivo. IGM-8444 responses ranged from highly sensitive to resistant. In a sensitive Colo205 model IGM-8444 additionally showed rapid intratumoral pharmacodynamic (PD) activity, inducing maximal caspase-3 cleavage at 6 hours post-dose. Next a panel of solid tumor (including colorectal, gastric, non-small cell lung cancer, and pancreatic) cell lines were selected to evaluate IGM-8444 in combination with standard of care chemotherapeutic agents. Synergistic cytotoxicity was observed when IGM-8444 was used in combination with certain classes of chemotherapeutic agents including topoisomerase inhibitors, microtubule inhibitors, nucleoside analogs, and platinum-based agents. Enhanced anti-tumor activity was also observed in xenograft mouse models where IGM-8444 was dosed in combination with these classes of chemotherapeutic compounds. Mechanistically, this synergistic combinatorial cytotoxicity may be explained by the reported increase in DR5 expression on tumor cells following treatment with many of these classes of chemotherapeutic agents. In summary, IGM-8444 shows in vitro cytotoxicity and in vivo PD and anti-tumor efficacy responses in preclinical

models, with enhanced activity in combination with several classes of chemotherapies reported to upregulate DR5 expression. IGM-8444 combination with FOLFIRI standard of care is currently under evaluation in a Phase 1 study in patients with metastatic colorectal cancer (NCT04553692).

Recombinant apurinic/apyrimidinic endonuclease-1/redox factor-1 plus acetylsalicylic acid combination therapy inhibits tumorigenesis in an orthotopic xenograft murine model of triple-negative breast cancer

Yu Ran Lee, Hee Kyoung Joo, Eun-Ok Lee, Sungmin Kim, Hao Jin, Yeon Hee Choi, Eun Ju Choi, Byeong Hwa Jeon. *College of Medicine, Chungnam National University, Daejeon, Korea, Republic of*

Triple-negative breast cancer (TNBC) is characterized with hormone receptor negative and frequently exhibits inherently aggressive clinical behavior, resulting in poor prognoses. TNBCs are highly heterogenic, leading to obstacles in identifying new therapeutic targets and performing targeted therapy. Apurinic/apyrimidinic endonuclease 1/redox factor-1 (APE1/Ref-1), a multifunctional protein, is mainly involved in DNA repair and redox regulation; it is upregulated in various cancers and is extracellularly secreted because of hyperacetylation. We previously reported that hyperacetylation induced APE1/Ref-1 release causes apoptosis in TNBCs. In the current study, we aimed to assess the therapeutic efficacy of combination treatment involving recombinant human APE1/Ref-1 (rhAPE1/Ref-1) plus acetylsalicylic acid (ASA) in TNBC xenograft mice. ASA co-treatment was used to induce and lasting acetylation of rhAPE1/Ref-1. For in vivo analysis, we constructed an orthotopic xenograft in vivo model of TNBC by using MDA-MB-231 cells. We performed combination therapy involving intravenous injection of purified rhAPE1/Ref-1 (1 mg/kg) and oral administration of ASA (20 mg/kg) thrice a week for 6 weeks in TNBC xenograft mice. This rhAPE1/Ref-1 plus ASA combination therapy inhibited tumor formation and growth, without damaging liver or kidney tissue, and decreased plasma levels of the cancer marker CEA and breast cancer-specific markers CA27-29 and CA15-3 in the TNBC xenograft mice. The TNBC group, which underwent combination therapy, had more apoptotic cells and greater inflammatory

cell infiltration in tumor tissues than the vehicle group did. Additionally, in tumor tissue of TNBC with combination therapy exhibits increased apoptosis following upregulation of Bax, cleaved-caspase-3, and cleaved-PARP. Thus, we found that rhAPE1/Ref-1 plus ASA combination therapy enhanced antitumor effects in TNBCs via inflammatory cell infiltration and apoptosis signaling pathways. Our findings indicate the therapeutic potential of rhAPE1/Ref-1 plus ASA combination therapy for TNBC.

Induction and modulation of apoptosis in pancreatic ductal carcinoma PANC-1 cells by Chinese medicinal herbs *Scutellaria barbata* and *Oldenlandia diffusa*

MinSeo Kang[1], Allana Benjamin[2], Christine Choi[2], Rekha Isaac[3], Sarah Wolf[2], Jasmine Cha[2], Elim Choi[2], Jessica Yi[2], Padma T. Uppala[4], Ryan Hayes[5], Brian Yuen Yau Wong[6]. *[1]Mathematics, Andrews University, Berrien Springs, MI,[2]Biology, Andrews University, Berrien Springs, MI,[3]Biochemistry, Andrews University, Berrien Springs, MI,[4]Public Health, Nutrition & Wellness, Andrews University, Berrien Springs, MI,[5]Chemistry, Andrews University, Berrien Springs, MI,[6]Andrews University, Berrien Springs, MI*

Pancreatic cancer is a devastating disease with a poor prognosis. It is usually symptom-free during development and is advanced by the time of diagnosis. PANC-1 is a pancreatic ductal carcinoma cell derived from a 56-year-old male with adenocarcinoma in the head of the pancreas and metastasized to the duodenal wall. Apoptosis is a controlled program cell death process that the body uses to combat cancer development. *Scutellaria barbata* (SB) has been used in traditional Chinese medicine for treating liver, lung, and rectal cancers. SB and *Oldenlanida diffusa* (OD) are included in most of the herbal cancer treatment formulas in Taiwan hospitals. We previously showed that aqueous extracts of SB and OD selectively induced apoptosis in colon HCT 116 cancer cells but not in colon CCD 841 CoN normal epithelial cells by modulating the pro-apoptotic and anti-apoptotic proteins. These two herbs also effectively modulated apoptosis in MDA-MB-157 and 93B breast cancer cells. Green synthesis of gold nanoparticles (AuNPs) of SB demonstrated effective

anticancer activity against this PANC-1 cell. This study used the green/red/blue fluorescent Apoptosis /Necrosis Detection Kit and the Human Apoptosis Antibody Array - Membrane [43 Targets] Test (Abcam). Our fluorescent apoptosis data showed that a 2-hour treatment with 1.5 mg and 3.0 mg aqueous extract of SB and OD induced a statistically significant percentage of apoptosis in PANC-1 cells (SB: 57.5 ± 2.5%, 68.0 ± 0.0% > 11.5% ± 3.5%, $p < 0.05$; OD: 62.0 ± 9.0%, 67.0 ± 11.0%> 11.5% ± 3.5%, $p < 0.05$) as compared to the negative control respectively. Similar results were obtained with the 4-hour incubation period (SB: 73.5 ± 0.5%, 72.0 ± 2.0% > 18.2% ± 2.0%, $p < 0.05$; OD: 59.0 ± 1.0%, 73.5 ± 13.5%> 18.2% ± 2.0%, $p < 0.05$). From the antibody array-membrane experiments, modulation of various apoptosis markers by SB and OD such as the pro-apoptotic proteins Bid, Bim, Bad, Bax, p27, and p53 as compared to the negative controls were observed; and regulation of anti-apoptotic proteins Bcl-2, FasL, IGF-I, and p21 were also revealed. These results suggest that SB and OD contain phytochemicals that induce apoptosis in pancreatic ductal carcinoma PANC-1 cells via the modulation of various apoptotic protein productions. Further study of their specific modulation effects of apoptosis is warranted to reveal their potential chemopreventive and therapeutic properties against pancreatic and other cancers.

Antitumor effect of Iso-mukaadial acetate in MCF-7 human cancer xenograft models

Portia Raphela-Choma[1], Lesetja R. Motadi[2], Mpho S. Choene[2]. *[1]University of Johannesburg, Johannesburg, South Africa,[2]Biochemistry, University of Johannesburg, Johannesburg, South Africa*

Antitumor drugs used today have shown significant efficacy and are derived from natural products such as plants. Iso-mukaadial acetate has previously been shown to possess anticancer properties by inducing apoptosis. The purpose of this study was to investigate the therapeutic effect of Iso-mukaadial acetate in the breast cancer xenograft mice model. Female athymic mice were used and were inoculated with breast cancer cells subcutaneously after culturing. Group one served as a negative control group (no treatments) and group two positive control group (cisplatin) which was administered intravenously. Iso-mukaadial acetate treatment was

administered orally to group three(100 mg/kg) and group four (500 mg/kg). Blood was collected (70 μL) from the tail vein on day zero, day seven and day 14. Tumor regression was measured, and a pharmacokinetic study was conducted. Estimation of Serum Parameters for Hepatic and Renal Indices were examined using an Automated Chemistry Analyzer. Histopathological analysis was conducted to evaluate morphological changes before and after treatment under a light microscope. Tumor shrinkage was observed after treatment. In conclusion, Iso-mukaadial acetate inhibited tumor progression in breast cancer athymic mice without major side effects.

#6127

MDM2 inhibition in combination with MEK inhibition in pre-clinical models of lung adenocarcinomas with *MDM2* amplification

Arielle Elkrief[1], Vladimir Markov[1], Álvaro Quintanal-Villalonga[1], Rebecca Caeser[1], Pawel Sobczuk[1], Emily Cheng[1], Alexander Drilon[1], Gregory J. Riely[1], William W. Lockwood[2], Elisa de Stanchina[1], Charles M. Rudin[1], Igor Odintsov[1], Romel Somwar[1]. *[1]Memorial Sloan Kettering Cancer Center, New York City, NY,[2]University of British Columbia, Vancouver, BC, Canada*

The eventual development of resistance to single-agent targeted therapies in lung adenocarcinomas (LUAD) is inevitable, and new strategies are needed. We hypothesize that combination therapies aimed at a known driver and a distinct targetable alteration could prolong time on oral targeted therapy. In an analysis of 7636 patients with LUAD who underwent MSK-IMPACT large panel NGS testing, 5.5% (416/7636) harbored *MDM2* amplification (*MDM2*amp), a known mechanism of TP53 inactivation. *MDM2*amp was over-represented among tumors with alterations in *MET*ex14 (34.4%, $p<0.001$), *EGFR* (10%, $p<0.001$), *RET* (11%, $p<0.05$), and *ALK* (9.9%, $p<0.002$). The small molecule MDM2 inhibitor milademetan (mila) caused growth inhibition as a single-agent in *MDM2*amp patient-derived cell lines with concurrent kinase alterations including ECLC5-GLx (*MDM2*amp/*TRIM33::RET*/*TP53* wildtype (WT)) and LUAD12c (*MDM2*amp/*MET*ex14/*KRAS*^{G12S}/*TP53* WT). Mila also caused growth inhibition in a cell line with *KRAS*^{G12C} and WT *TP53* without *MDM2*amp (SW1573 (*KRAS*^{G12C}/*TP53*^{WT})), but not in cell lines with *TP53* mutations

(LUAD-002AS1 (*KIF5B::RET/TP53*^{P128fs}*, H1792 (KRAS*^{G12C}*/TP53 splice site mut*)). Treatment of ECLC5-GLx and LUAD12c with mila resulted in restoration of ERK phosphorylation, confirming a previous report of ERK activation upon MDM2 inhibition. At 48 hours, ERK phosphorylation was suppressed by concurrent mila and MEK inhibition using trametinib (tram). In contrast, ERK phosphorylation was not suppressed by concurrent mila and KIF5B::RET inhibition using selpercatinib (in ECLC5-GLx) or MET inhibition using capmatinib (in LUAD12c). The combination of mila+tram was synergistic in slowing growth of ECLC5-GLx, LUAD12c, and SW1573 cells, and increased expression of pro-apoptotic proteins PUMA and BIM, beyond that achieved by either agent alone. In ECLC5-GLx, mila+tram also caused increased apoptotic cells measured by Annexin-V compared to either agent alone (combination $p<0.01$ compared to mila, $p<0.001$ compared to tram). In *vivo*, combination mila+tram was more effective than mila or tram alone in ECLC5-GLx ($p<0.0001$ and $p<0.0001$, respectively), LX-285 (*EGFR*ex19del/*MDM2*amp) ($p<0.0001$ and $p<0.0001$, respectively), and L-13BS1 (model resistant to capmatinib) (*MET*ex14/*MDM2*amp) ($p<0.05$ and $p<0.0001$, respectively). These results suggest that combined MDM2/MEK inhibition is effective in patient-derived LUAD models harboring *MDM2*amp. This combination, potentially applicable to LUADs with a wide variety of oncogenic driver mutations and kinase fusions will be investigated as part of a phase 1/2 clinical trial.

Deubiquitinating enzyme Inhibitor PR-619 inducesendoplasmic reticulum stress-related apoptosisin human chondrosarcoma

Kuan-Lin Kuo, Chen-Hsun Hsu, Shih-Ming Liao, Kuo-Yuan Huang.
National Taiwan University Hospital, Taipei, Taiwan

It is reported that PR-619 is a deubiquitination enzyme inhibitor that can exert anti-tumor effects on a variety of malignancies. We conducted this study to explore the antitumor effects of PR-619 on chondrosarcoma in vitro and in vivo by using two different classes of human chondrosarcoma cell lines SW-11353 and JJ012. To determine these effects, we measured cell viability (MTT), apoptosis (detection of Annexin V-FITC labeling using flow cytometry) and western blot to evaluate molecules associated with apoptosis and cell stress. In addition, we used a nude mouse xenograft

mouse model to determine the effect of PR-619 on tumor growth. As our data revealed, in addition to inducing BAD and activating Capase-7, Caspase-8, and PARP, PR-619 also has a dose-effect that induces cytotoxicity, proliferation restriction, and apoptosis in these human chondrosarcoma cells. PR-619 has also been found to activate endoplasmic reticulum pressure-related molecules (caspase-4 and CHOP) and other stress responses (activation of JNK and c-Jun). We conclusively demonstrated the ability of PR-619 to inhibit tumor growth while achieving minimal general toxicity in a developed xenograft mouse model of chondrosarcoma. Therefore, we conclude that PR-619 exacts an antitumor effect in conjunction with cellular and endoplasmic reticulum pressure in human chondrosarcoma. These findings suggest that PR-619 may provide a novel therapeutic strategy for chondrosarcoma.

#6129

The proapoptotic peptide PEP-010 is efficient on several models of different tumor origins and it can be monitored by pharmacodynamic biomarker candidates in clinical practice

Rayan Farhat[1], Laura Dadon[1], F. Nemati[2], A. Rebollo[3], D. Decaudin[2], Joelle Wiels[4], Catherine Brenner[4], Diego Germini[1]. *[1]PEP-Therapy, Paris, France,[2]Translational Research Department, Laboratory of Preclinical Investigation, PSL University, Paris, France,[3]Unité de Technologies Chimiques et Biologiques pour la Santé, Paris, France,[4]CNRS UMR9018, Villejuif, France*

In cancer cells, the proapoptotic proteins caspase-9 and PP2A interaction prevents them to play their role in apoptosis. PEP-010, a drug candidate developed by PEP-Therapy, a French Biotech company, is a proapoptotic peptide targeting and disrupting this interaction leading to restoration of the apoptotic cascade. PEP-010 is an innovative bifunctional peptide. It penetrates into cells thanks to its cell penetrating part and specifically disrupts the caspase-9/PP2A interaction thanks to its interfering part. PEP-010 is currently in Phase I a/b multicenter clinical trial for the treatment of advanced solid tumors.To the aim of screening different potential therapeutic targets, to investigate the molecular mechanism-of-action of PEP-010 and to identify potential pharmacodynamic biomarkers, we have tested PEP-010 efficacy on several cell models of different tumor origins.

By the Annexin V/Propidium Iodide staining and flow cytometry analysis, we found that PEP-010 induces apoptosis in most of the tested models. One possible mechanism-of-action is an involvement of the PP2A which, once released by PEP-010, could regulate expression and/or activity of different intracellular factors leading to caspases activation and cell death.The identification of the major molecular features involved in PEP-010 mechanism-of-action, were instrumental to identify different pharmacodynamic biomarker candidates (e.g. active caspase-3). Hence, such biomarkers could be useful in clinical practice to monitor the effect of PEP-010 at molecular level. We have compared specific features related to the mechanism-of-action of PEP-010 in sensitive (MDA-MB-231, IGROV1) and not sensitive cell models of different tumor origins and in tissue sections derived from Patient-Derived Xenografts models of breast cancer treated or not with PEP-010. Widely used techniques as immunofluorescent staining and immunohistochemistry were employed, making these results easily transferable in clinical routine.Taken together, our pre-clinical data showed the potential of PEP-010 as an anti-cancer peptide on a wide variety of malignancies and enabled the identification of pharmacodynamic biomarker candidates, important to ease the clinical development.

#6130

Cancer sensitivity to therapy is constrained by apoptosis regulation in cells of origin

Cameron Fraser[1], Xingping Qin[1], Kenichi Shimada[2], Johan Spetz[1], Mary Heather Florido[1], Rumani Singh[1], Stacey Yu[1], Adam Presser[1], Zintis Inde[1], Gaurav Joshi[1], Jennifer Guerriero[3], Francisco Sanchez-Rivera[4], Alison Karst[5], Omar Lopez[6], Chendi Li[7], Peter Winter[4], Ying Yue[2], Peter Sorger[2], Jingwei Cheng[8], Izidore Lossos[9], Aaron Hata[7], Ronny Drapkin[10], Adam Palmer[11], James Decaprio[8], Manisha Thakuria[3], Charles Yoon[3], Ursula Matulonis[8], Matthew Meyerson[8], Elizabeth Stover[8], Diana Cardona[6], Kris Wood[6], Shayna Sarosiek[8], David Kirsch[6], Joseph Mancias[8], Andrew Cherniack[12], Anthony Letai[8], Kristopher Sarosiek[1]. *[1]Harvard School of Public Health, Boston, MA,[2]Harvard Medical School, Boston, MA,[3]Brigham and Women's Hospital, Boston, MA,[4]Massachusetts Institute of Technology, Boston, MA,[5]Gilead Sciences, Seattle, WA,[6]Duke University,*

Durham, NC,[7]Massachusetts General Hospital, Boston, MA,[8]Dana-Farber Cancer Institute, Boston, MA,[9]University of Miami Miller School of Medicine, Miami, FL,[10]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA,[11]University of North Carolina at Chapel Hill, Chapel Hill, NC,[12]Broad Institute of Harvard and MIT, Cambridge, MA

Many chemotherapeutic agents target cellular components or processes that are present in all cancers, yet clinical responses to these agents vary greatly between cancer types and even patient age - the basis for these broad-scale differences are unclear. The vast majority of targeted and cytotoxic cancer therapies including ionizing radiation produce pro-apoptotic signaling in exposed cells, suggesting that the mitochondrial apoptosis sensitivity of cancer cells could act as a central signaling “node” to broadly impact therapy outcomes. To test this, we used BH3 profiling and complementary chemosensitivity assays to analyze hundreds of primary cancer specimens across twelve major cancer types. We find that cancers with typically favorable outcomes including certain hematologic malignancies, testicular cancer, and some pediatric cancers contain mitochondria that are highly primed for apoptosis, which renders them hypersensitive to cytotoxic as well as targeted agents and radiation therapy. Priming levels in many epithelial cancers including ovarian cancer and non-small cell lung cancer are highly heterogeneous, mirroring their variability in clinical outcomes. Finally, many tumor types that are typically chemoresistant including adult soft tissue sarcomas, hepatocellular carcinoma and pancreatic cancer are almost completely resistant to pro-apoptotic signaling. By analyzing in vitro and in vivo pancreatic, ovarian, hepatocellular and sarcoma tumorigenesis models, we find that apoptotic priming generally increases during neoplastic transformation, in part due to consistent upregulation of pro-apoptotic proteins BAX and BAK. However, the level of apoptotic priming in cancer cells is constrained by the baseline apoptosis sensitivity of normal cells prior to transformation. Remarkably, we find that apoptotic priming is dynamically regulated by cell lineage and differentiation state but can also be modulated by oncogenes. For instance, Myc activation typically increases apoptotic priming while activation of mutant Ras signaling decreases it - these changes in priming alter the chemosensitivity of cancer cells. Finally, we use inducible mouse tumor models to demonstrate that neoplastic transformation of cells from developmentally immature tissues

yields pediatric tumors that are more primed for apoptosis than equivalent tumors arising in adults. This difference in priming causes pediatric tumors to be more sensitive to front-line therapies and BH3 mimetics targeting pro-survival BCL-2 family proteins in vitro and in vivo. Thus, lineage-determined regulation of apoptosis prior to and during neoplastic transformation leads to broad-scale differences in cancer cell chemosensitivity and can be exploited therapeutically by targeting BCL-2 family proteins.

#6131

Extracellular vesicles containing p53 of xenogeneic origin as a therapeutic strategy

Alex Tendler[1], Gil Shalev[1], Harel Kasuto[1], Lana Volokh[1], Albina Lin[1], Yevgeny Tendler[1], David Sidransky[2]. *[1]ExoProTher Medical, Haifa, Israel,[2]Israel Biotech Fund, Rehovot, Israel*

Introduction: It was recently discovered that extracellular vesicles (EVs) containing p53 are actively secreted by corneal epithelial cells into the corneal extracellular space and tear film. These EVs are re-captured by neighboring epithelial cells and play a pivotal role in local anti-cancer defense because the corneal epithelium (As an immuno-privileged tissue site), lacks classic critical pathways of innate and adaptive immunity. We took advantage of the local corneal mechanism of anti-cancer defense to develop a novel therapeutic approach based on EVs delivery of WT p53 protein to tumors. In order to avoid the inhibition of newly delivered WT p53 through the known dominant negative effect of mutant p53, we utilized p53 containing EVs produced by corneal epithelial cells of chicken origin. The C-terminal domain responsible for oligomerization is sufficiently diverse between chicken and human p53 to preventing suppression of the delivered WT p53.
Methods: The functional consequences of chicken tissue derived p53 containing EVs in human malignancies was assessed in vitro in variety of p53 mutated panels through the Annexin/PI potency assay, cell cycle arrest assessment, cell counting and IncuCyte. Confirmation of the p53 driven mechanism of action (MoA) was achieved using RT-PCR of p53 downstream responsive genes such as p21, YPEL3, BAX and PIDD. In

vivo testing was performed using the Colo320 DM human colon cancer xenograft model in nude mice.
Results: Following treatment with avian p53 containing EVs multiple tested human malignant cell lines exhibited cell cycle arrest and/or massive apoptosis within 24h. Transcription levels of the YPEL3 and BAX genes were increased significantly in human LN18 cells (p53 mut GBM) post treatment. Moreover transcription levels of the YPEL3 and PIDD genes were increased significantly in human HCT116 p53wt cells (p53 WT colorectal carcinoma) while BAX and PIDD genes are increased significantly in human HCT116 p53ko cells (p53 KO colorectal carcinoma) after treatment. In vivo results showed significant inhibition of growth in Colo320DM xenografts with further histopathological findings of reduced proliferation (Ki-67) and increased apoptosis (TUNEL) in treated group.
Conclusions: Upregulation of key p53 responsive genes is direct evidence of p53-driven response in human cancer cells triggered by p53-containing avian EVs. Further functional evidence of activity was observed through documented apoptosis and cell cycle arrest in multiple cell lines and in-vivo model. Additional relevant in-vivo models are being treated and assessed for tumor growth inhibition and functional p53 downstream activity. These preliminary preclinical results show promise for this novel therapeutic concept in targeting a hallmark genetic alteration that poses a major challenge in human cancer therapy.

Impact of treatment with agents targeting different members of HER family, CDKs and downstream cell signaling molecules on growth and migration of stomach cancer cells.

Tina Al-Janaby[1], Narmin Nahi[1], Said A. Khelwatty[1], Alan Seddon[1], Izhar Bagwan[2], Helmout Modjtahedi[1]. *[1]School of Life Science, Pharmacy and Chemistry, Kingston University London, Kingston upon Thames, United Kingdom,[2]Berkshire Surrey Pathology Services, Royal Surrey County Hospital, Guildford, United Kingdom*

Stomach cancer ranks fifth and fourth for the incidence and mortality rate for cancer worldwide, respectively. In recent years, several inhibitors with specificity to one or more members of human epidermal growth factor receptor (HER) family have been approved for the treatment of patients

with different cancer types. Of these, only the anti-HER2 monoclonal antibody (mAb) Herceptin/trastuzumab and the antibody-drug conjugate trastuzumab deruxtecan has been approved for the treatment of patients with stomach cancer. However, the duration of response may be short in many patients and with tumor heterogeneity being one contributing factor. In this study, we investigated the effect of various types of targeted agents on the growth *in vitro* of a panel of human stomach cancer cells (HSCCLs) and the impact of stomach cancer proliferation rate on the anti-tumor activities of these agents. Moreover, we investigated the cell surface expression of the HER family members, other biomarkers such as C-Met, Alk-7 and cancer stem cell makers CD44 and CD133 by flow cytometry and the effect various targeted agents on tumor migration using Incucyte. Of the 18 agents examined, the CDK 1/2/5/9 inhibitor dinaciclib was the most effective and inhibited the growth of all human HSCCLs at IC50 values between 1nM to 9nM. Of various HER inhibitors, the irreversible pan-HER family inhibitors (e.g., afatinib) were more effective than the reversible dual EGFR/HER2 TKI lapatinib and the EGFR specific TKI erlotinib in inhibiting the growth of HSCCLs. Interestingly, the HER-2 overexpressing cells lines NCI-N87 (Mean Fluorescence Intensity =596) was most sensitive to the HER inhibitors. Of agents targeting different downstream cell signaling molecules, dasatinib targeting Ab1/Src/C-Kit, trametinib targeting MERK1/2 and miransertib targeting AKT1/2/3 inhibited growth of majority of HSCCLs and with the IC50 values ranging from 2nM to 7uM. Interestingly, many of these agents were more effective in inhibiting the growth of HSCCLs when proliferating at slower rate. Of the agent examined, neratinib, afatinib, dinacicilib, dasatinib, stattic and miransertib also inhibited the migration of stomach cancer cells. Finally, treatment with a combination of afatinib with dinaciclib, capmatinib, dasatinib, stattic, ponatinib or miransertib resulted in synergistic and additive growth inhibition of stomach cancer cells. As stomach cancer cells are heterogenous in nature, our results support further research on the therapeutic potential of the CDK dinaciclib in combination with a pan-HER inhibitor in stomach cancer.

Growth response and migration of brain cancer cell lines to treatment with agents targeting different members of the HER family, CDKs and

other signalling pathways

Ermira Mulliqi[1], Said A. Khelwatty[1], Anna L. Morgan[1], Keyoumars Ashkan[2], Helmout Modjtahedi[1]. *[1]School of Life Science Pharmacy and Chemistry, Kingston Univ. London, Kingston upon Thames, United Kingdom,[2]Department of Neurosurgery,, Kings College Hospital, London, United Kingdom*

Glioblastoma (GB) is one of the most frequent primary brain tumors in adults with an extremely poor prognosis and a very high demand for novel therapies. Poor prognosis has been linked to its complex biology, tumor heterogeneity and an increased activation of signaling pathways through various growth factor receptors signaling pathway. In particular, aberrant expression and activation of epidermal growth factor receptor (EGFR) expression has been found to be common in patients with GBM. However, no EGFR inhibitor has yet been approved for the treatment of patients with brain tumor and there is currently no comprehensive study of all members of the HER family in the progression brain tumors. The aim of this study was to investigate the role of all members of the HER family (EGFR, HER2 HER3 and HER4), other growth factor receptors (e.g., C-MET) and downstream cell signaling pathways in the growth of a panel of human brain cancer cell lines (HBCCLs) and response to therapeutic interventions. Using Sulforhodamine B colorimetric assay, the growth response of four HBCCLs to treatment with 18 agents targeting different members of the HER family and other growth receptors (e.g. C-met/ALK 7, PDGFRs, FGFRs, C-kit), cyclin dependent kinases inhibitors (e.g. CDKs 1/2/5/9, CDK4/6) and downstream signaling molecules (e.g. STAT3, Src, Abl) was examined. We determined the expression level of all members of the HER family in brain cancer cells by flow cytometry and Western blot and the effect of these agents on migration of brain cancer cells were determined using Incucyte. Of the targeted agents examined, the CDK 1/2/5/9 inhibitor dinaciclib was the most potent and inhibited growth for all four HBCCLs with an IC50 below 10nM. Of the HER inhibitors, neratinib and afatinib were more effective than erlotinib and lapatinib and inhibiting the growth of all HBCCLs at IC50 values below 700nM and 1.9 μM, respectively. Treatment with Src/Abl/c-kit inhibitor dasatinib, STAT3 inhibitor static, Abl/PDGFRα/VEGFR2/FGFR1 inhibitor Ponatinib and the TRK/ROS/ALK inhibitor entrecitinb also inhibited the growth of HBCCLs

with IC50 value ranging from 0.06 - 2.96 μM, 1 - 3.8μM, 0.19- 0.42 μM and 2.85- 3.47μM, respectively. Interestingly, these agents were more effective in inhibiting growth of HBCCLs when proliferating at a slower rate. In addition to inhibiting the proliferation of HBCCLs, treatment with neratinib, dinaciclib, dasatanib, static and trametinib inhibited the migration of brain tumor cells. Finally, treatment with neratinib in combination with Palbociclib, AZD4547, trametinib and miransertib inhibited the growth of HBCCLs synergistically. Taken together, our results support further investigation on the therapeutic potential of irreversible pan HER in combination with the CDK inhibitor dinaciclib and other targeted agents in brain cancer.

Exploiting the oncogenic state of colorectal cancer for therapeutic development

Felipe de Sousa e Melo. *Genentech, Inc., South San Francisco, CA*

Over the past two decades, only incremental progresses have been made in the therapeutic management of colorectal cancer (CRC). This is in part attributed to the fact that the Wnt pathway, the oncogenic pathway that initiates the transformation of CRC and sustains tumor maintenance, has been largely undruggable. While most efforts targeting Wnt signaling have revolved around interfering with Wnt target genes that regulate cell growth, we turned our attention to a subset of genes encoding for negative regulators of the pathway. Of particular interest are the cell-surface E3 ubiquitin ligases, ring finger protein 43 (RNF43) and ZNRF3, two known negative regulators of Wnt signaling that promote the turnover of Wnt receptors Frizzled/low-density lipoprotein receptor-related proteins (FZD/LRPs) via ubiquitination-mediated degradation. Given their exposed extracellular domains (ECDs), we set out to explore whether this intrinsic cellular degradative machinery could be repurposed for an antibody-based targeted protein degradation platform. More specifically, we have devised a technology that exploits the elevated expression of ZNRF3 and RNF43 in colon cancer by generating bispecific antibodies that can tether these E3 ubiquitin ligases to a variety of cell surface receptors to promote tumor receptor degradation. Most notably, these antibody degraders are highly active in vivo and can degrade receptors in a tumor specific manner while

sparing normal tissues. This platform, that we have been dubbed Proteolysis Targeting Antibodies (PROTABs) describes a strategy for the rapid development of potent, bioavailable and tissue-selective degraders of cell-surface proteins.

Dynamics of ligand-induced epidermal growth factor receptor internalization in cancer cell lines

Mandy W. E. Smeets, Eef F. P. Smits, Janneke J. T. M. Melis, Dimitri Pappaioannou, Guido J. R. Zaman. *Oncolines B.V., Oss, Netherlands*

Antibody-drug conjugates (ADCs), comprised of cancer cell-specific antibodies linked to cytotoxic drugs, represent an innovative and promising class of anticancer agents. Due to its amplified expression in various tumor types, the epidermal growth factor receptor (EGFR) presents an attractive target for ADC therapy, and three anti-EGFR ADCs are currently studied in clinical trials. As ADCs depend on receptor internalization for intracellular release of drugs in the targeted cancer cells, studying the dynamics of receptor internalization can aid in their development and optimization. We studied the internalization of EGFR induced by its ligand EGF, as a mimic of ADCs, in cell lines with different surface receptor densities.
BxPC-3 (pancreas) and RT-112 (bladder) cancer cells were seeded in 6-well plates and allowed to adhere for 24 hours. Cells were serum-starved overnight, followed by stimulation with 150 ng/mL EGF for 2, 4, 6, 24 and 48 hours. Internalization was studied by quantification of the number of surface-expressed receptors using flow cytometry with Quantibrite PE beads and EGFR-PE antibody. Moreover, incorporation of the ligand-receptor complex into acidic endo-lysosomes was studied using EGF conjugated to the fluorescent pH sensor pHrodo™ Green. Total EGFR and EGFR phosphorylation levels were assessed by western blot analysis. RNA was isolated and converted into cDNA to perform TaqMan qPCR.
Unstimulated BxPC-3 cells showed higher numbers of EGFR per cell compared to unstimulated RT-112 cells. Since high receptor expression is key for some ADCs to induce effective endocytosis, this may indicate BxPC-3 cells as a more attractive model to study EGFR internalization.
Stimulation with EGF induced a strong decrease in surface receptor density for both BxPC-3 and RT-112 cells during the first two hours, suggesting

receptor internalization. Accordingly, treatment of BxPC-3 cells with pHrodo™ Green EGF demonstrated the incorporation of ligand-receptor complexes into endo-lysosomes. During following hours, the cell surface expression of EGFR remained stable, whereas it partially recovered after 24 to 48 hours. In contrast, the lysosomal incorporation of EGF-EGFR complexes was not decreased at 24 or 48 hours, suggesting that the increase in surface EGFR may be due to *de novo* protein synthesis rather than recycling. No increase of EGFR mRNA was, however, detected. Finally, increased phosphorylation of EGFR was observed after two to six hours of stimulation, whereas total EGFR levels were highest in unstimulated and 24- or 48-hour-stimulated cells, which is in concordance with the flow cytometry data.
In conclusion, both BxPC-3 and RT-112 cells show dynamic changes in EGFR internalization upon EGF stimulation, despite differences in EGFR expression levels. These cell lines can therefore successfully be used for internalization studies, which may contribute to future ADC development.

Cell Death Pathways and Treatment / Molecular Classification of Tumors for Diagnostics, Prognostics, and Therapeutic Outcomes

Clinical implication of EZH2 inhibitors in hepatocellular carcinoma
Bo Hwa Sohn[1], Sung Hwan Lee[2], Yun Seong Jeong[1], Ju-Seog Lee[1].
[1]Systems Biology, UT MD Anderson Cancer Center, Houston, TX,[2]Surgery, CHA Bundang Medical Center, Seongnam, Korea, Republic of

Background & Aim: Aberrant upregulation of EZH2 is frequently observed in hepatocellular carcinoma (HCC) and significantly associated with poor prognosis of HCC patients. While EZH2 inhibitors (EZH2i) are recently approved for treatment of lymphoma and sarcoma, their antitumor effect alone is not optimally efficacious against solid tumors like HCC. Ferroptosis is a newly discovered nonapoptotic type of cell death characterized by the iron-dependent accumulation of lipid hydroperoxides in cell membrane to lethal levels. Owing to anti-cancer effects of ferroptosis, many oncogenes are known to suppress ferroptosis. However, their mechanisms in HCC are currently unknown. We aim to uncover a novel mechanism for EZH2-mediated resistance to ferroptosis in HCC.

Methods: Multi-step analyses were performed with genomic data from mouse models (*Ezh1*/*2* KO), cancer cell lines treated with EZH2i GSK126, and primary tumors including HCC to identify genetic networks or signaling/metabolic pathways associated with EZH2 in cancer cells. Functional connection of identified networks or pathways from the prediction analyses was tested in cell line models with various molecular biology approaches including western blots, colony forming assay, overexpression and/or depletion of genes of interest.
Results: Gene network analysis predicted that ferroptosis pathway is inhibited by EZH2. Interestingly, lipid biosynthesis is also identified as an inhibited metabolic pathway by EZH2. Since polyunsaturated fatty acid (PUFA) is essential for executing ferroptosis, we hypothesize that EZH2 suppresses ferroptosis by inhibiting synthesis of PUFA. HCC cells with high EZH2 expression have higher IC50 values to erastin, a ferroptosis inducer, than those with low EZH2 expression. Moreover, inhibition or depletion of EZH2 sensitize HCC cells to erastin-induced ferroptotic cell death, strongly suggesting that EZH2 accounts for resistance to ferroptosis. Mechanistically, EZH2 increases H3K27me3 methylation near PUFA gene promoters, leading to suppression of PUFA gene expression and subsequently low cellular PUFA level. Most interestingly, treatment of EZH2i significantly sensitized HCC cells with high EZH2 expression to erastin-induced ferroptosis, suggesting potential therapeutic opportunity for treatment of HCC patients with high EZH2 expression.
Conclusion: EZH2 is a novel suppressor of ferroptosis by negatively regulating lipid metabolism. Thus, our study provides scientific evidence for developing a novel therapeutic strategy for treatment of HCC patients with co-treatment of ferroptosis inducers and EZH2 inhibitors.

Caspase-3 mediated cleavage of GSDME enhances the antitumor efficacy of HER2-targeted therapy in HER2-positive gastric cancer

Qiuyun Luo, Zengfei Xia, Jing Yang, Wentao Pan, Fan Luo, Jiaxin Cao, Yuting Sun, Liqiong Yang, Lin Zhang, Miaozhen Qiu, Dajun Yang. *Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Gasdermin E (GSDME) is one of the gasdermin family proteins, which induces a new type of programmed cell death - pyroptosis

after cleavage by caspase-3. Previous researches have shown that the overexpression of GSDMB, another gasdermin family protein, is associated with poor prognosis in HER2 breast cancer and attributed to HER2-targeted therapy resistance through mediating protective autophagy. However, the role of GSDME in the anti-HER2 treatment of HER2-positive gastric cancer remains unclear. In this study, we sought to explore the function of GSDME in response to anti-HER2 treatment of HER2-positive gastric cancer and investigate the combination treatment strategies.
Methods: GSDME overexpressed vector and siRNA interference were applied to evaluate the function of GSDME in HER2-positive gastric cancer. The correlation between the expression of GSDME and survival in HER2-positive and negative gastric cancer was analyzed in the Kaplan Meier plotter database. Flow cytometry, LDH release assay and western blotting were used to determine apoptosis and pyroptosis. Moreover, the phospho-tyrosine kinase array was applied to explore the synergistic mechanism of combination therapy. GSDME overexpressed NCI-N87 xenograft model was established to evaluate the synergistic antitumor effect in vivo.
Results: We found that anti-HER2 agents upregulated the expression level of GSDME in a dose- and time-dependent manner. The bioinformatics analysis showed that a higher level of GSDME was correlated with poor overall survival both in HER2-negative and HER2-positive gastric cancer. We further demonstrated that GSDME upregulation in response to anti-HER2 treatment is associated with anti-HER2 therapy resistance. In order to validate whether cleavage of GSDME may render the cancer cells more sensitive to anti-HER2 agents, we applied a novel BCL-2/BCL-XL dual target inhibitor APG-1252 to test the combination antitumor effect with anti-HER2 agents. We found that APG-1252 could enhance the antitumor effect of lapatinib by promoting cell apoptosis and pyroptosis. Mechanistically, the combination treatment synergistically inhibited the phosphorylation of AKT/GSK-3β, subsequently inducing depolarization of the mitochondrial membrane and caspase-3-dependent cleavage of GSDME, which consequently triggered cell apoptosis and pyroptosis. Finally, in the HER2-positive GC cells xenotransplantation models, both lapatinib and APG-1252 monotherapy could delay tumor growth, while the combination therapy significantly suppressed tumor growth.

Conclusions: Taken together, our data indicated that anti-HER2 agents could upregulate the expression of GSDME, and the combination of lapatinib and APG-1252 showed a synergistic antitumor effect against HER2-positive gastric cancer through inducing caspase-3/GSDME mediated apoptosis and pyroptosis.

Mechanisms by which Mito-lonidamine inhibits *EGFR* mutant lung cancer

Katherine M. Weh[1], Connor Howard[1], Yun Zhang[1], Jean-Jack Riethoven[2], Jennifer Clarke[2], Gang Cheng[3], Balaraman Kalyanaraman[3], Ming You[4], Laura Kresty[1]. *[1]University of Michigan, Ann Arbor, MI,[2]University of Nebraska-Lincoln, Lincoln, NE,[3]Medical College of Wisconsin, Milwaukee, WI,[4]Houston Methodist, Houston, TX*

Lung cancer remains the leading cause of cancer mortality. Efficacious targeted therapy options are urgently needed for lung cancer prevention and treatment. Epidermal growth factor receptor (EGFR) mutant lung cancer represents about 15% of lung cancer cases generally occurring in patients with minimal to no smoking history and with higher prevalence in females. Linkages to environmental exposures have been postulated. Our group synthesized Mito-lonidamine (Mito-LND), a mitochondrial targeted analog of lonidamine which inhibits aerobic glycolysis in cancer cells. We previously identified that Mito-LND induces mitophagy in *KRAS* mutant lung cells and inhibits lung tumorigenesis and brain metastasis *in vivo*. Yet, the cancer inhibitory capacity of Mito-LND in *EGFR* mutant lung cancer has not been investigated. Viability staining assessed Mito-LND induced cell death in *EGFR* mutant cell lines PC9 (parent) and PC9BrM3 (brain metastatic). Transcriptomic profiling was conducted following Mito-LND treatment and results analyzed in Metacore to assess molecular changes. Deconvolution analysis interrogated alterations in immune cell populations. To discern cell death mechanisms, we evaluated FDA-approved inhibitors for autophagy (chloroquine, CQ), mitophagy/apoptosis (cyclosporin A, CsA) and necrosis (Ponatinib) in *EGFR* mutant cell lines using viability assays with Mito-LND treatment. In PC9 cells, the IC50 for Mito-LND at 24h and 48h was 1.5μM and 0.5μM, respectively and in PC9BrM3 cells at 24h and 48h was 1.5μM and 0.7μM, respectively. These data support that

EGFR mutant cell lines are >2-fold more sensitive to Mito-LND induced cell death compared to *KRAS* mutant lung cell lines H2030 and H2030BrM3. Transcriptomic profiling results show that Mito-LND treatment upregulated pathway maps linked to heat shock protein and HIF-1A signaling in both PC9 and PC9BrM3 cells. Process networks linked to unfolded protein response, response to hypoxia and oxidative stress, apoptosis and the immune response were upregulated with Mito-LND treatment. Deconvolution analysis revealed monocytes and macrophages were upregulated in Mito-LND treated *EGFR* mutant cell lines, with CD8+ T cells increased in PC9BrM3 cells and regulatory T cells increased in PC9 cells. Last, CsA significantly inhibited Mito-LND induced cell death in both cell lines, while CQ had no effect suggesting blocking apoptosis, but not late autophagy inhibits cell death induction in EGFR mutant cell lines. Further, necrosis inhibition with Ponatinib synergistically increased Mito-LND induced cell death in *EGFR* mutant cell lines. These results begin to define the cancer inhibitory mechanisms of Mito-LND in *EGFR* mutant lung cancer cells which appear to differ from those observed in *KRAS* mutant lung cancer cells. Future directions include dissecting apoptotic and necrosis driven Mito-LND induced cell death using additional pharmacological inhibitors and genetic approaches.

Inhibition of both MAPK and AKT pathways overcomes resistance of NRAS-mutant melanoma stem cells to apoptosis

Ryyan Alobaidi, Nusrat Islam, Yanjun R. Zhang, Mathew M. Shamo, Samuel Allsup, Cynthia M. Simbulan-Rosenthal, Dean S. Rosenthal.
Biochemistry and Molecular & Cellular Biology, Georgetown Univ. School of Medicine, Washington, DC

Malignant melanoma is a lethal skin cancer containing melanoma-initiating cells (MIC) implicated in tumorigenesis, invasion, and drug resistance, and characterized by elevated expression of stem cell markers, such as CD133. We have shown that siRNA knockdown of CD133 enhanced apoptosis induced by the MEK inhibitor trametinib in melanoma cells. The current study investigates the underlying mechanisms of CD133's anti-apoptotic activity in patient-derived BAKP melanoma, harboring the difficult-to-treat $NRAS^{Q61K}$ driver mutation, after either CRISPR-Cas9 CD133 knockout or

Dox-inducible expression of CD133. CD133 knockout in BAKP cells increased trametinib-induced apoptosis by reducing anti-apoptotic BCL-xL, p-AKT, and p-BAD and increasing pro-apoptotic BAX. Conversely, Dox-induced CD133 expression diminished apoptosis in trametinib-treated cells, coincident with elevated pro-survival p-AKT, p-BAD, BCL-2, and BCL-xL and decreased activation of BAX and caspases-3 and -9. Inhibition of MEK with trametinib, in combination with pan-AKT inhibitor capivasertib (AZD5363) in BAKP cells with either CD133 overexpression or knockout *in vitro* reduced cell survival as measured by XTT, FACS analysis and colony formation assays. Further, *in vivo* studies with nude mice xenografted with Dox-inducible BAKP melanoma cells, showed significantly decreased tumor growth after xenografted mice were treated with trametinib alone or in combination with AZD5363. CD133 may therefore activate a survival pathway where (1) increased AKT phosphorylation and activation induces (2) BAD phosphorylation and inactivation, (3) decreases BAX activation, and (4) reduces caspases-3 and -9 activity and caspase-mediated PARP cleavage, leading to apoptosis suppression and drug resistance in melanoma. Targeting nodes of the AKT and MAPK survival pathways with both trametinib and AZD5363 highlights the potential for combination therapies for NRAS-mutant melanoma stem cells for the development of more effective treatments for patients with high-risk melanoma.

Novel multiplexed assays of ferroptosis, pyroptosis and necroptosis biomarkers for translational studies

William G. Herrick[1], Jeevan Govindharajulu[1], Ralph E. Parchment[1], James H. Doroshow[2], Apurva K. Srivastava[1]. *[1]Applied and Developmental Research Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Background: The recent discovery that multiple chemo- and immuno-therapies activate non-apoptotic cell death pathways such as necroptosis, pyroptosis, and ferroptosis in cancer cells has necessitated development of pharmacodynamic biomarker assays to study their novel mechanisms of action. We describe the development, analytical validation, and proof-of-

concept demonstration of assays for potential biomarkers of ferroptosis, pyroptosis and necroptosis pathways to support anti-cancer drug development.
Methods: We developed multiplex sandwich immunoassays on the Luminex platform to quantify transferrin receptor (TfR), glutathione peroxidase 4 (GPx4), active caspase-3, cleaved and full-length gasdermins D and E (GSDMD, GSDME), MLKL oligomers, and MLKL heterodimers with RIPK1 and RIPK3. Novel antibodies to gasdermin cleavage neoepitopes were generated and their specificity validated with knockout (GSDMD) or non-expressing (GSDME) cell lines. We utilized well-established in vitro cancer cell line models (NCI-H522, THP-1, MV411, MB231, HT29) and inducers/inhibitors of pyroptosis, necroptosis and ferroptosis to test for expected directional changes of biomarker modulation.
Results: Analytical validity of the measurements is demonstrated with acceptable reproducibility, precision, dilutional linearity, dilutional recovery, spike recovery, sample freeze-thaw and temperature stability. The fitness-for-purpose of the assays is demonstrated by increased cleavage of GSDME, loss of full-length GSDME, and activation of caspase-3 in NCI-H522 cells treated with doxorubicin; similarly, cleavage of GSDMD and loss of full-length GSDMD is shown in THP-1 cells primed with LPS and treated with nigericin, and in MV-4-11 cells treated with val-boroPro. HT29 cells treated with ZVAD + birinapant + TNFα were used to demonstrate increased MLKL oligomerization or heterodimer formation with RIPK1/RIPK3. Modulation of ferroptosis biomarkers TfR and GPx4 (SU-DHL-5, MDA-MB-231) in response to imidazole ketone erastin (IKE) or RSL3 was cell line-dependent. Studies are underway to validate modulation of select ferroptosis biomarkers using orthogonal LC-MS methods.
Conclusions: We describe development and translational readiness of novel multiplex assays to interrogate drugs inducing ferroptosis, pyroptosis and necroptosis cell death pathways. Our data demonstrate utility of biomarkers of pyroptosis and necroptosis, whereas biomarkers of ferroptosis require further appraisal. In vivo pharmacodynamic studies of pyroptosis, ferroptosis and necroptosis inducers are ongoing to verify assay fitness-for-purpose with tumor biopsy specimens. This project was funded with federal funds from the NCI, NIH, under contract no. HHSN261201500003I.

Polyploidization enables initial survival of chemotherapy but a progressively increased susceptibility to ferroptosis

Luke Loftus. *Johns Hopkins University School of Medicine, Baltimore, MD*

Once cancer has metastasized it remains incurable owing to evolved resistance to nearly all systemic therapies. Classical views of therapeutic resistance include tumor heterogeneity and genetic instability, but our group and others have identified an unappreciated cancer cell phenotype, the polyaneuploid cancer cell (PACC) state, that provides an alternative model. The PACC state is induced upon exposure to a variety of applied stressors, including multiple different classes of chemotherapy, and is characterized by polyploidization of the aneuploid cancer genome. We have shown that this polyploidization is accomplished through endocycling that leads to an enlarged cell size with increased transcriptomic and protein content, higher oxidative buffer capacity, and increased autophagy. We have demonstrated that PACCs are present in a variety of cell lines, arise in response to multiple stressors *in vitro,* and are resistant to subsequent treatment with several classes of chemotherapy. Thus, we hypothesize that the PACC state is driving therapeutic resistance to current treatment regimens. Elimination of this overlooked phenotype is critical for sustained anticancer therapy response. Cancer cells, including those in the PACC state, control canonical cell cycle and cell death programs to evade apoptosis from external stressors including chemotherapy, highlighting an opportunity to leverage cell cycle-independent death pathways as an alternative therapeutic strategy[1]. Ferroptosis is a cell cycle agnostic immunogenic form of cell death that is an ideal pathway for elimination of cells in the PACC state. Characterization of ROS levels, glutathione content, labile iron homeostasis, and lipid content indicate that cells in the PACC state have a mounting susceptibility to ferroptosis. Our data suggests that cells in the PACC state keep ferroptosis in check through elevated levels of reduced glutathione and proficient redox activity, including turn over of GPX4, the sole enzyme counteracting lipid peroxidation. Direct inhibition of GPX4 is highly toxic to cells in the PACC state, particularly at later timepoints post therapy removal when the immediate stress response is largely resolved. These studies will directly lead to development of a therapeutic strategy specifically targeting the PACC state with the intention of eliminating cancer resistance.

Alternative splicing of GSDMB modulates killer lymphocyte-triggered pyroptosis

Qing Kong[1], Shiyu Xia[2], Xingxin Pan[3], Kaixiong Ye[4], Zhouyihan Li[5], Haoyan Li[5], Nidhi Sahni[5], S. Stephen Yi[3], Xing Liu[6], Hao Wu[7], Judy Lieberman[7], Zhibin Zhang[5]. *[1]Department of Immunology, UT MD Anderson Cancer Center, Houston, TX,[2]California Institute of Technology, Pasadena, CA,[3]The University of Texas at Austin, Austin, TX,[4]University of Georgia, Athens, GA,[5]UT MD Anderson Cancer Center, Houston, TX,[6]Institut Pasteur of Shanghai, Shanghai, China,[7]Boston Children's Hospital, Boston, MA*

Killer lymphocyte-mediated tumor cell killing is a vital and final step of anti-tumor protective immunity. Killer cells, including cytotoxic CD8 T cells and Natural Killer (NK) cells, deliver granzymes (Gzm) into target cells, which normally activates noninflammatory cell death, but becomes inflammatory when target cells express the gasdermin (GSDM) proteins responsible for pyroptosis. GzmA and GzmB cleave and activate GSDMB and GSDME, respectively. However, the role of GSDMB in anti-tumor immunity is unclear - GSDMB pore formation is controversial and GSDMB expression has been linked to both anti- and pro-tumor functions. Here we found that GSDMB splicing variants are functionally distinct. Cleaved N-terminal (NT) fragments of isoforms 3 and 4 caused pyroptosis, but isoforms 1, 2 and 5, which deleted or modified exon 6, did not. Structural analysis based on AlphaFold predictions and the cryoEM structures of GSDMA3 and GSDMD showed that pore formation required the formation of a functional stabilizing belt structural element near the C-terminus of the cleaved N-terminal fragment, which was disrupted in the non-cytotoxic alternatively spliced isoforms. NK attack of GSDMB3-expressing cells caused pyroptosis, but GSDMB4 cells died mostly by apoptosis, and GSDMB1/2 cells died only by apoptosis. GSDMB4 partially resisted NK cell-triggered cleavage, suggesting that only GSDMB3 is fully functional.

GSDMB1-3 were the most abundant isoforms in tested cells and were similarly induced by IFNγ and a chemotherapy drug methotrexate. Expression of cytotoxic GSDMB3/4, but not GSDMB1/2, was associated with better outcome in bladder and cervical cancer, suggesting GSDMB-mediated pyroptosis was protective in those tumors. Our study uncovers a novel role of alternative splicing in modulating caner-associated pyroptosis, and suggests that tumors may manipulate GSDMB splicing to avoid pyroptosis. Thus, modulating GSDMB splicing to increase cytotoxic GSDMB variants but suppress non-cytotoxic GSDMB isoforms could improve anti-tumor immunity and have therapeutic utility.

#6146

Tumor suppressor p73 primes extrinsic apoptosis via transcriptional activation of DR5 and c-FLIP

Shengliang Zhang, Wafik S. El-Deiry. *Pathology and Laboratory Medicine, Brown University, Providence, RI*

The tumor suppressor p73 is a member of p53 family. p73 transcriptionally activates p53-targeted genes involved in cell cycle regulation and apoptosis. It is well known that p73 induces cellular apoptosis via the intrinsic apoptotic pathway upon cellular stresses. However, the role of p73 in extrinsic apoptosis is poorly studied. We observed cell cycle arrested at the G1 phase in cells infected with a p73-expressing recombinant adenovirus (Ad-p73). We observed that overexpression of p73 upregulated c-FLIP at the protein level, in addition to DR5 and p21. c-FLIP is an anti-apoptotic factor that inhibits caspase 8/10 activation, thus blocking extrinsic pathway apoptosis. We demonstrated that c-FLIP is a transcriptional target of p73 based on our observations that: 1) p73 increases c-FLIP at mRNA level, 2) p73 binds to the c-FLIP promoter and 3) p73 enhances c-FLIP promoter-driven luciferase expression. We sought to explore whether the upregulation of c-FLIP prevents extrinsic apoptosis in cancer cells following p73 activation. To address this question, p73 was overexpressed in cells by adenovirus infection and c-FLIP was knocked down by siRNA. Overexpression of p73 induced cellular apoptosis in the cells with knockdown of c-FLIP and this effect was blocked by knockdown of caspase 8. Our results suggest that p73 induces extrinsic apoptosis when c-FLIP is depleted in cancer cells. We further found that the knockdown of DR5

inhibited p73-induced apoptosis in c-FLIP-deficient cancer cells. By contrast, PUMA knockdown did not block p73-induced apoptosis. Our results suggest that DR5 is required for cell extrinsic apoptosis in c-FLIP-deficient cancer cells upon p73 activation. p21 is the cyclin dependent kinase inhibitor that leads to cell cycle arrest at the G1/S phase. Knockdown of p21 enhanced cleaved-caspase 8 and cleaved-PARP in c-FLIP-depleted cancer cells treated with Ad-p73. Our results, taken together, suggest that the p73 primes extrinsic apoptosis via DR5 and the priming level appears to be titrated at the level of c-FLIP. Upregulation of c-FLIP decreases the priming level, resulting in cells converting to cell cycle arrest and survival via p21 whereas reduction of c-FLIP leads the primed cancer cells to undergo extrinsic apoptosis upon p73 treatment in cancer cells. Our discovery of p73 transcriptional upregulation of c-FLIP provides a rationale for depleting c-FLIP to improve antitumor efficacy of p73-targeting cancer therapy.

MCL1 inhibitor PRT1419 demonstrates anti-tumor activity in PBRM1-altered clear cell renal cancer and synergizes with standard of care agents

Norman Fultang, Brian Vidal, Ashley M. Schwab, Alexander Grego, Stephanie Rodgers, Diane Heiser, Kris Vaddi, Neha Bhagwat, Peggy Scherle. *Prelude Therapeutics, Wilmington, DE*

Induced myeloid leukemia cell differentiation protein (MCL1) is a member of the B-cell lymphoma-2 (BCL2) family of apoptosis regulators, which plays a critical role in maintaining cellular homeostasis and promoting cancer cell survival. Increased expression of MCL1 in various cancers has been associated with poor prognosis and resistance to chemotherapeutic and targeted agents. We previously described PRT1419, a novel, potent, selective MCL1 inhibitor that demonstrates anti-tumor efficacy in various preclinical models of solid and hematologic malignancies. PRT1419 is currently under evaluation in Phase I clinical trials in patients with relapsed/refractory hematologic malignancies and advanced solid tumors. To identify novel biomarkers that might predict sensitivity to MCL1 inhibition, we conducted a gene essentiality analysis using publicly available human cancer cell line gene dependency data generated from

genome-wide CRISPR/Cas9 cell viability screens. We observed that clear cell renal cancer (ccRCC) cell lines with deleterious alterations in *PBRM1* (*Polybromo 1*) displayed a strong dependency on *MCL1*. PBRM1, also known as BAF180, is a chromatin-targeting subunit of mammalian pBAF (SWI/SNF-B) complexes. PBRM1 is frequently altered in various human cancers but it has a particularly high alteration rate in ccRCC with ~40% of tumors harboring damaging PBRM1 alterations. We had previously described alterations in other mammalian SWI/SNF factors as biomarkers of MCL1 inhibitor sensitivity.We observed potent inhibition of tumor growth as well as induction of apoptosis by PRT1419 in various preclinical models of PBRM1-mutant ccRCC but not in PBRM1-WT tumor models. Depletion of PBRM1 via RNAi in PBRM1-WT ccRCC induced sensitivity to PRT1419. Mechanistically, PBRM1 depletion coincided with increased expression of pro-apoptotic factors, priming PBRM1-loss cells for caspase-mediated cell death following MCL1 inhibition. Increased MCL1 activity has previously been described as a resistance mechanism to Sunitinib and Everolimus, two approved targeted agents for ccRCC. To investigate if MCL1 inhibition could potentiate the anti-tumor effects of these agents, we evaluated PRT1419 in combination with Sunitinib or Everolimus in PBRM1-loss ccRCC. PRT1419 synergized with both Sunitinib and Everolimus in inhibiting tumor growth in various models. Taken together, these findings suggest PBRM1 loss is associated with sensitivity to MCL1 inhibition in ccRCC and provide rationale for the evaluation of PRT1419 for the treatment for PBRM1-deficient ccRCC

Disulfide isomerases AGR2, ERp44, and PDIA1 maintain death receptor 5 in an auto-inhibited, monomeric form

Brian K. Law[1], Mary E. Law[1], Elham Yaaghubi[1], Amanda Ghilardi[1], Brad J. Davis[1], Renan Ferreira[1], Samantha Eggleston[1], Jade Nguyen[1], Grace Alexandrow[1], Jin Koh[1], Sixue Chen[1], Chi-Wu Chiang[2], Coy Heldermon[1], Peter Norgaard[3], Ronald K. Castallano[1], Zaafir M. Dulloo[1]. *[1]University of Florida, Gainesville, FL,[2]National Cheng Kung University, Tainan, Taiwan,[3]Copenhagen University Hospital, Herlev, Denmark*

Previous studies indicated that compounds termed Disulfide bond Disrupting Agents (DDAs) exhibit anti-cancer activity that is associated

with downregulation of EGFR/HER1, HER2, and HER3, and activation of Death Receptors 4 and 5 (DR4/5). DDA-induced HER1-3 downregulation is preceded by disulfide-mediated oligomerization. In contrast, DDA-mediated DR4/5 oligomerization results in DR5 upregulation, and activation of DR4/5 pro-apoptotic signaling through Caspases 8 and 3. However, the precise mechanisms by which altered disulfide bonding stabilizes and activates DR5 are unknown. A recent report indicated that the extracellular domain of DR5 acts in an auto-inhibitory manner to prevent DR5 oligomerization and pro-apoptotic signaling in the absence of its ligand, TRAIL. A subsequent paper showed that the DR5 auto-inhibitory domain is a positive patch consisting of three basic residues. Importantly, the structure of the auto-inhibitory loop is formed by two disulfide bonds. We hypothesize that DDAs disrupt the disulfide bonds that make up the auto-inhibitory loop, resulting in DR5 oligomerization, and activation of Caspase 8/3-driven apoptosis in a TRAIL-independent manner. Due to their novel mechanisms of action, DDAs may overcome the pharmacological liabilities that have limited the efficacy of TRAIL analogs and DR5 agonist antibodies. Another unanswered question is how precisely DDAs alter DR5 and EGFR disulfide bonding. The direct targets of DDA action were revealed through affinity purification studies with biotinylated-DDA analogs. These studies identified the protein disulfide isomerases AGR2, ERp44, and PDIA1 as DDA target proteins, explaining how DDAs alter DR5 and EGFR disulfide bonding patterns. Consistent with this interpretation, knockdown of AGR2 or ERp44, or expression of catalytically null AGR2 or ERp44 mutants, mimicked DDAs in inducing disulfide-mediated DR5 oligomerization and Caspase 8 activation. Together, these results demonstrate a fundamentally novel, ligand-independent mechanism for activation of DR5 through DDA-mediated inhibition of the PDIs AGR2, ERp44, and PDIA1. Significantly, DDAs are the first identified active site inhibitors of AGR2 and ERp44.

STAT3 activation promotes invasiveness and cancer stemness in lung cancer

Sai Fung Yeung, Sze Man Chan, Chun Ho Law, Hoi Yin Chan, Kwok Wing Tsui. *School of Biomedical Science, The Chinese University of Hong Kong, Shatin, NT, Hong Kong*

Lung cancer is the leading cause of cancer-related death worldwide, featuring a high incidence and low 5-year survival rate. Nearly 40% of patients are diagnosed with metastatic disease when they are first presented to the clinic. However, drug intervention targeting established metastatic tumors remains challenging, a better understanding of therapeutically exploitable mechanisms is urgently needed. This present study aims to explore novel therapeutic intervention against metastatic lung cancer. To understand the tumor-cell-intrinsic pathway that drives metastatic progression, we generated a highly invasive subline of lung cancer cell - A549 (ATCC, USA) by serial selections for Matrigel-coated transwells. The invasive subline A549-i3 shows about 5 times higher invasion potential than the parental cell line A549-Par ($p<0.05$, Student t-test). Colony-formation Assay and suspension growth in ultra-low attachment plates were used to measure the 2D proliferation ability and anoikis resistance, albeit with no difference. The differential efficacies between A549-Par and A549-i3 against multiple pathway inhibitors were screened using MTT assay *in vitro*. Notably, A549-i3 is more sensitive towards napabucasin (STAT3 inhibitor) and tipifarnib (FTase inhibitor) when compared with A549-Par, suggesting their potency in targeting cancer stemness and addicted oncogenic driver. Furthermore, napabucasin reduced the migration and invasion abilities of A549-i3 to similar extent as their parent counterpart. Overall, our preliminary data identified STAT3 as a potential therapeutic vulnerability in highly invasive cancer cells. Future work will be focused on identifying pathways responsible to sensitize highly invasive NSCLC cells toward STAT3 inhibition using multiomics approach. This project was supported by the Research Impact Fund (Ref. No.: R4015-19) from the Research Grants Council in Hong Kong.

AZD0466, a dual BCL-2/XL targeting nanomedicine, is active in small cell lung cancer models

Courtney L. Andersen[1], Giulia Fabbri[1], David Jenkins[1], Zumla Cader[2], Shringi Sharma[3], Areya Tabatabai[1], Srividya Balachander[1], Jordan Roebuck[4], Melanie Galvin[4], Kathryn Simpson[4], Caroline Dive[4], Jordi Rodon Ahnert[5], Jamal Saeh[1]. *[1]AstraZeneca, Waltham, MA,[2]AstraZeneca, Cambridge, United Kingdom,[3]AstraZeneca, South San Francisco,*

CA,[4]CRUK Manchester Institute, Manchester, United Kingdom,[5]MD Anderson Cancer Center, Houston, TX

Small cell lung cancer (SCLC) is an aggressive malignancy with critical need for new therapies. While currently treated as a single disease, SCLC is heterogenous, comprised of several transcriptional subtypes. Each of these subtypes has distinct drivers and may warrant unique therapeutic targets. Two potential therapeutic targets for SCLC are the pro-survival proteins BCL-2 and BCL-XL. BCL-2 is overexpressed in ASCL1 (A) and POUF3 (P) subtypes of SCLC. We therefore sought to evaluate efficacy of the dual BCL-2/XL inhibitor AZD0466 in SCLC models and to determine whether transcriptional subtype would predict response. AZD0466 is a novel drug-dendrimer conjugate. The active moiety, AZD4320, is a potent dual inhibitor of BCL-2 and BCL-XL. AZD4320 is covalently conjugated to a 5th-generation PEGylated poly-lysine dendrimer through a hydrolytically labile linker to make AZD0466. AZD0466 has been optimized to deliver efficacy while mitigating potential Cmax-driven on-target toxicities of AZD4320. AZD4320 was active (IC50 $\leq$0.1 μM) in 9/27 SCLC cell lines. AZD4320 in vitro sensitivity was enriched in cell lines that represented A and P subtypes of SCLC compared to NEUROD1 and YAP1 subtypes. We next profiled AZD0466 in a panel of SCLC patient-derived models: 14 patient-derived xenografts and 10 circulating tumor cell-derived xenografts. AZD0466 monotherapy dosed weekly IV was active in 12/24 SCLC xenografts, driving regressions in 8 models. AZD0466 drove efficacy and cleaved caspase-3 induction in a dose-dependent manner. Similar to in vitro, AZD0466 in vivo efficacy was enriched in subtype-A, driving responses in 10/14 ASCL1 models (7 regression, 3 stable disease). AZD0466 response also correlated strongly with BCL-2 mRNA expression ($P<0.0001$). AZD0466 outperformed the selective BCL-2 inhibitor venetoclax in 6/10 models. Notably, AZD0466 was active in models resistant to platinum/etoposide chemotherapy, the standard-of-care for SCLC. Together, these data suggest BCL-2/XL inhibition has therapeutic potential in SCLC. AZD0466 is in clinical development. The first-in-human study treated 9 patients with advanced solid tumors (NCT04214093) at doses from 50-200mg, all of which were well-tolerated. The BOR was SD observed in 3 patients (100mg) with 1 patient receiving treatment for 5.5 months. AZD0466 is now under evaluation in patients with hematologic

malignancies (NCT04865419 and NCT05205161). AZD0466 has been dosed in 33 patients up to 2400mg. No DLTs have been reported to date. Initial clinical activity has been observed through reduction of bone marrow blasts following AZD0466 treatment. AZD0466 exhibits linear PK, consistent across solid tumor and leukemia patients. The doses tested are in line with preclinical studies in SCLC.

Loss of GPR54 inhibits tumor growth by suppressing AKT/DDC signaling pathway in KRAS-mutant non-small cell lung cancer

Seo Yeon Lee, Yu-Jeong Choi, Hyun-Ha Hwang, Sooyeon Kang, Kangwook Lee, Seong-Gyu Ko. *Kyung Hee University, Seoul, Korea, Republic of*

Therapeutic targeting of KRAS-mutant lung cancers has remained a challenge. There are increasing evidence that KISS1/GPR54 signaling pathway is associated with the development of various cancer. Although KISS1 and GPR54 are expressed in the lung, their biological role in the lung tumorigenesis remains unclear. In this study, using the genetically engineered mouse models, we have identified that loss of Gpr54 inhibited Kras-driven lung tumorigenesis by suppressing pathways in oncogenesis such as the MAPK and AKT pathways and inducing apoptosis. Similarly, genomic inhibition of GPR54 suppressed cell proliferation, decreased ERK and AKT signaling pathway, and increased apoptotic cell death in NSCLC cells. RNA-sequencing analysis revealed that DDC expression and glycolysis gene sets were significantly changed in Gpr54 deficient mice. Interestingly, HIF-1α expression is regulated by GPR54/AKT/DDC signaling pathway in NSCLC cells, leading to glycolytic change. Genomic inhibition of DDC suppressed cell proliferation and enhanced apoptotic cell death in NSCLC cell lines. Also, pharmacological inhibition of GPR54 and DDC lower glucose consumption and lactate production in NSCLC cell lines. Taken together, we demonstrate GPR54, as a potential therapeutic target, suggesting a new strategy to cure for lung cancer patients.

Exploiting ferroptosis in mutant BAP1 uveal melanoma

Camille J. Cunanan. *Pharmacology and Physiology, MCBG, Drexel University College of Medicine, Philadelphia, PA, PA*

Uveal melanoma (UM) arises from melanocytes of the uveal tract in the eye and is the most common intraocular malignancy in adults. Primary UM lesions often harbor mutations in G-proteins, GNAQ or GNA11, and are successfully treated by radiotherapy or enucleation. However, 50% of patients develop metastases. Of these metastatic UM (MUM) patients, 80%develop metastases to the liver, an effect strongly correlated with the loss of function of BAP1,a nuclear deubiquitinase. BAP1-mutant MUMs are less responsive to conventional treatments, such as chemotherapy and immune checkpoint inhibitors, with 50% of these patients having an overall survival of only 1 year. We propose that the unique metabolic intermediates found in liver microenvironment may dictate MUM tropism, aggressiveness, and poor therapeutic response. Here, using a combination of *in vitro* and *ex vivo* liver slice cultures, we found that the liver microenvironment induces gene expression alterations consistent with limiting the toxicity of reactive oxygen species (ROS). Importantly, we note that mutant BAP1 UM displayed improved ROS detoxification compared to its wildtype counterparts. Furthermore, publicly available datasets suggest patients with mutant BAP1 UM, the subset of patients with liver metastases, have corresponding ROS detoxification gene expression patterns. These findings suggest that the liver microenvironment and BAP1 loss directs MUM to mitigate ROS-associated toxicity. This compensatory mechanism may be therapeutically exploited and pair well as a combination treatment with the recently approved bispecific agent, Tebentafusp, to selectively target liver MUM.

Triple negative breast cancer targeted by Ophiobolin A: Epithelial-mesenchymal transition take the lead

Santhalakshmi Ranganathan[1], Alexander Kornienko[2], Antonio Evidente[3], Daniel Romo[4], Joseph Taube[1]. *[1]Baylor University - Department of Biology, Waco, TX,[2]Department of Chemistry and Biochemistry, Texas State University, San Marcos, TX,[3]Department of Chemical Sciences, University of Naples Federico II, Complesso Universitario Monte Sant'Angelo, Naples, Italy,[4]Department of Chemistry and Biochemistry, Baylor University, Waco, TX*

Triple negative breast cancer (TNBC) has fewer treatment options than other types of invasive breastcancer. Moreover, Epithelial to Mesenchymal Transition (EMT) helps enrichment of cancer stem cells(CSCs) which promotes resistance to chemotherapy. Ophiobolin A (OpA), a drug like small molecule wasrecently found to have anti-CSC properties. Our current study investigated the cell death mechanism(s)induced by OpA in various breast cancer cell lines with respect to epithelial-mesenchymal transition(EMT).The mechanism of cell death elicited by OpA was analyzed by applying inhibitors for specific pathwaysincluding apoptosis, necroptosis and paraptosis and by analyzing markers of cell death using flowcytometry and western blotting. HMLE(R) and HMLE(R)-Twist cell lines were used to assay the role of EMT.The formation of necrosomes was analyzed with exogeneous expression of RIPK3 tagged with greenfluorescence protein (GFP) in HeLa cell line which lacks endogenous RIPK3 expression. The necrosomeformation was identified by formation of puncta using confocal microscopy. Immune compromised SCIDmice were used to analyze the effect of OpA *In vivo*.The data obtained in the present study indicates that OpA has an increased anticancer effect in TNBCcompared to the estrogen receptor (ER) positive breast cancer cells. Cells having undergone EMT wereshown to have more sensitivity towards OpA when compared to -uninduced cell lines, which is sensitiveto Necrostatin-1, an inhibitor of necroptosis. OpA also diminished the $CD44^{hi}/CD24^{lo}$ population in TNBCcells. However, apoptosis and paraptosis inhibitors failed to rescue cell death which clearly confirms thatOpA induces necroptosis cell death pathway in EMT undergone cells. An increased phosphorylation ofRIPK, a necroptosis protein marker, was observed on OpA treatment compared to the control. OpAtreatment significantly increased puncta TNBC compared to the untreated control cells, furtherconfirming the necroptotic cell death in TNBC. OpA treatment showed a significant tumor regression intumor bearing SCID mice. All together our findings identify that OpA induce necroptosis in EMT-enrichedTNBC. The study further needs an in-depth analysis of involvement of EMT in necroptotic cell death inTNBC.**Key words: Triple-negative breast cancer, EMT, Ophiobolin A, Necroptosis, cell deathmechanism**

Imipramine induces apoptosis and inhibits metastasis via suppression of EGFR signaling pathway in bladder cancer

Tsai Lin Lo[1], Jai-Jen Tsai[2], Fei-Ting Hsu[1], Yuan Chang[3]. *[1]Department of Biological Science and Technology, China Medicial University, Taichung, Taiwan,[2]Division of Gastroenterology, Department of Medicine, Taipei Veterans General Hospital, Yuanshan/Su'ao Branch, Su'ao, Taiwan,[3]Department of Medical Imaging, Taipei Medical University-Shuang Ho Hospital, Ministry of Health and Welfare, New Taipei City, Taipei, Taiwan*

Bladder cancer (BC) is one of the most common malignant diseases of the urinary system, with poor prognosis and high recurrence and metastasis rate. Recent literatures suggested that BC patients have proportionately worse depression and mental health, as well as being at increased risk of suicidal death when compared to the general population, while relatively sane BC patients have a 2.2 times higher mortality rate, which means that depression can make BC worse. Imipramine is a tricyclic antidepressant, was used to treat neuropathic pain, nocturnal enuresis, and depression. Recently, imipramine has been reported to owns anti-tumor efficacy in various type of cancer. However, the effects and underlying mechanisms of imipramine on BC is remaining unclear. First, we indicated that imipramine may induce cytotoxicity of BC by MTT assay. Flow cytometry also showed that imipramine may trigger the loss of mitochondrial membrane potential, the accumulation of oxidative stress (ROS), and the activation of cleaved-caspase-3, -8 and -9. Our western blotting assay and immunofluorescence translocation staining also verified that imipramine markedly inhibited BC progression by inhibiting both EGFR/AKT/NFKB and EGFR/ERK/NKB signaling pathways. Furthermore, transwell and wound healing assay indicated that imipramine effectively reduced the metastatic ability of BC. In addition, the anti-tumor effect of imipramine was also validated by MB49 bearing animal model. Most importantly biochemistry level and pathology was not affected by imipramine. In conclusion, imipramine may not only suppressed BC progression by inactivation of EGFR/AKT/NFKB and EGFR/ERK/NFKB signaling pathways and induction of apoptosis pathways. These results suggested that imipramine has the opportunity to be a new therapeutic strategy for BC patients.

#6155

Lurbinectedin exhibits combinatorial activity with BCL2/BCL2L1 inhibitors *in vitro* and *in vivo* by modulation of MCL1 expression

Kedar S. Vaidya, Aparna Gupta, Robert Hauptschein, Robin C. Humphreys.
Jazz Pharmaceuticals, Palo Alto, CA

Lurbinectedin (Zepzelca) is a marine-derived anti-tumor agent currently approved for metastatic small cell lung cancer (SCLC). Lurbinectedin has been previously shown to exert its anti-tumor effect by binding to the minor groove of DNA and inhibition of nucleotide excision repair. In addition, lurbinectedin inhibits transcription by inducing degradation of RNA polymerase II. While these activities hint towards a general mechanism, specific molecular targets for lurbinectedin remain obscure. We demonstrate that *in vitro*, Lurbinectedin specifically induced downregulation of MCL1 protein, a member of the BCL2 family of pro-survival proteins, in a dose- (0-30 nM) and time-dependent manner (0-24 h) by Western analysis. Expression of other pro-survival proteins BCL2 and BCL2L1 were not affected. The downregulation of MCL1 was consistent in all nine tumor cell lines tested regardless of indication. Increased activity or expression of MCL1 is a known compensatory mechanism to offset loss of BCL2 or BCL2L1. We therefore hypothesized that lurbinectedin induced MCL1 loss, along with inhibition of the pro-survival proteins BCL2 and BCL2L1 would lead to an enhancement in cell killing. Consistent with the dominant pro-survival role of BCL2 in SCLC, the combination of lurbinectedin with a specific BCL2 inhibitor (venetoclax) *in vitro* induced synergistic cytotoxicity (measured by Bliss Sum analysis) in a panel of small cell lung cancer lines. In solid tumor lines other than SCLC, the combination of lurbinectedin with a specific BCL2L1 inhibitor (A-1331852) was also synergistic. Correspondingly *in vivo*, enhancement in the efficacy of lurbinectedin was observed in combination with venetoclax in SCLC models, while in solid tumor models other than SCLC the combination with a specific BCL2L1 inhibitor enhanced efficacy. Collectively, these data identify MCL1 as a specific lurbinectedin target and suggest that combinations that target other pro-survival proteins may represent a viable strategy to enhance the anti-tumor activity of lurbinectedin.

MALT1 protease inhibition overcomes BTK inhibitor resistance and shows synergistic activity with venetoclax in models of B cell lymphoma and leukemia

Joshua P. Plotnik[1], Raghuveer S. Mali[2], Velitchka Bontcheva[1], Colleen Dowell[1], Jun Chen[2], Adam E. Richardson[1], Ryan A. McClure[1], Paul Jung[1], Lan Pham[2], Andrew J. Souers[1], Jonathan A. Meulbroek[1], William N. Pappano[1]. *[1]Oncology Discovery Research, AbbVie, North Chicago, IL,[2]Oncology Discovery Research, AbbVie, South San Francisco, CA*

Introduction: Specific B cell malignancies, including CLL and the aggressive non-GCB subtype of DLBCL, are driven by constitutive activation of the B cell receptor (BCR) pathway and the transcription factor NF-κB. Pharmacological inhibition of MALT1 protease, a key mediator of the BCR/NF-κB signal transduction pathway, may therefore provide an attractive treatment option for patients with these cancers. Further, as combination therapy is often required for the treatment of aggressive B cell malignancies, the identification of therapies that synergistically combine with MALT1 inhibitors could afford additional and promising treatment options.

Experimental Procedures: A highly potent and orally bioavailable MALT1 protease inhibitor (ABBV-MALT1) was used to test the hypothesis that MALT1 inhibition will abrogate the proliferation of preclinical models of B cell malignancies in vitro and in vivo. Tumors treated with ABBV-MALT1 were subjected to transcriptomic and functional proteomic assays to elucidate molecular mechanisms of action and rational combination partners.

Results: Mechanistic studies reveal that ABBV-MALT1 effectively inhibits signal transduction of the BCR pathway and reduces NF-κB gene activation in non-GCB DLBCL cell lines resulting in cell cycle arrest and diminished viability. In vivo, oral administration of this compound demonstrates robust tumor growth inhibition in several models of B cell tumors, including non-GCB DLBCL models that are resistant to Bruton's tyrosine kinase (BTK) inhibitors. NF-κB target genes include the pro-survival family members BCL-X_L and BCL2-A1, which aid in regulation of the intrinsic apoptosis pathway. As ABBV-MALT1-induced inhibition of the NF-κB pathway resulted in downregulation of these genes, we hypothesized that the

associated tumor models would become increasingly dependent on the pro-survival family member BCL-2. To test this hypothesis, combination studies of ABBV-MALT1 and the selective BCL-2 inhibitor venetoclax were performed in both cell line and patient-derived xenograft models of DLBCL. Herein we show that concomitant administration of ABBV-MALT1 and venetoclax results in dramatic antitumor activity in all models tested in vivo. This efficacy also translates to primary patient CLL cells in vitro where the combination confers greater levels of apoptosis compared to either agent alone.
Conclusion: ABBV-MALT1 demonstrates robust single agent anti-tumor activity in malignant B cell models that are resistant to BTK inhibitors. Moreover, combination of ABBV-MALT1 with the BCL-2 inhibitor venetoclax shows synergistic cell killing of B cell tumors in vitro and dramatic tumor regression in vivo. Together, these data indicate that MALT1 inhibition may overcome BTK inhibitor resistance and combine with venetoclax to effectively treat patients with B cell malignancies.

USP7 is a promising therapeutic target for neuroblastoma
Christophe Le Clorennec[1], Karen Lee[2], Peter Zage[3]. *[1]UCSD Moores Cancer Center, La Jolla, CA,[2]Hematology/Oncology, Rady Children's Hospital, San Diego, CA,[3]Pediatrics, UCSD Moores Cancer Center, La Jolla, CA*

Background: The ubiquitin-proteasome system (UPS) plays an essential role in post-translational modification of proteins to maintain proteostasis. Ubiquitination of target protein is coordinated by different enzymes, which add and link ubiquitin to each other in specific ways that determine the fate of the protein for to be degraded or to be included into protein complex to induce signaling pathways. Ubiquitination is further regulated by deubiquitinases, which remove ubiquitin and rescue target protein from being degraded or diverted from it signaling role. UPS dysregulation has been linked to many human diseases, including cancer. Ubiquitin-specific protease 7 (USP7) is a deubiquitinase that plays a critical role in immune response, tumor suppression and DNA repair. USP7 overexpression has been associated with tumor aggressiveness in a variety of tumors, including in neuroblastoma (NB). Therefore, USP7 is a potential therapeutic target for

NB. Some new specific USP7 inhibitors are highly potent and selective and have demonstrated significant antitumor activity in preclinical models of adult cancer. We hypothesize that inhibition of USP7 alone or in combination with epigenetic drugs like HDAC inhibitors will be more effective against NB tumor growth. To evaluate the efficacy of USP7 inhibition with specific USP7 inhibitors alone or with combination with epigenetic drugs like HDAC inhibitors (Saha) or chemotherapy against NB tumor growth, NB cell lines were treated with increasing concentrations of USP7 inhibitors alone or in combination with chemotherapy or with HDAC inhibitors. Cell proliferation was measured using continuous live cell imaging and cell viability using AlamarBlue assay. Apoptosis was measured by caspase cleavage using Caspase 3/7 apoptosis assay as well as by PARP cleavage by Western Blotting (WB). Changes in various proteins were measured by WB and co-immunoprecipitation were performed to analyze the ubiquitin status of specific protein targets regulated by USP7. Pharmacologic inhibition of USP7 resulted in significant decreases in both cell proliferation and cell viability *in vitro* only in p*53* wild-type NB cell lines. There was no correlation seen between *MYCN* amplification status and treatment response. USP7 inhibition induced apoptosis as well as necroptosis with dose-dependent increase. Treatment with USP7 inhibitors led to decrease p53 ubiquitination leading increased of p53 protein expression in all sensitive cell lines tested and decreased MYCN protein level in *MYCN*-amplified cell lines. EZH2, which is a predominant target of USP7 is significantly downregulated with increasing dose of USP7 inhibitors. In addition, the combination of USP7 inhibitors with chemotherapy commonly used in NB or with combination with HDAC inhibitors showed enhanced efficacy. Our data suggests that USP7 inhibition may be a promising therapeutic strategy for children with high-risk and relapsed neuroblastoma.

#6158

BGB-24714, a novel oral IAP antagonist, displayed significant anti-tumor activities in preclinical models as a monotherapy and in combination with paclitaxel

Jie Li[1], Nan Hu[2], Yilu Zhang[2], Xiaolong Yang[2], Minjuan Deng[2], Wenfeng Gong[2], Longbo Yin[2], Yong Liu[2], Yajuan Gao[2], Wei Wei[2], Xing Wang[2], Xinyi Liang[2], Yanwen Ma[2], Xuxing Sang[2], Chang Liu[2], Jingyuan Wang[2],

Qianqian Lu[2], Fengtao Song[2], Xi Yuan[2], Yibing Wang[1], Jing Li[2], Wei Jin[2], Xuesong Liu[2], Xiaomin Song[2]. *[1]BeiGene Ltd., Shanghai, China,[2]BeiGene Ltd., Beijing, China*

Background: Evasion of apoptosis is identified as one of the essential hallmarks of cancer and upregulation of inhibitor of apoptosis proteins (IAPs) is one of the mechanisms by which tumor cells evade apoptosis. An oral SMAC mimetic and antagonist of cellular IAP1 (cIAP1) and X-linked IAP (XIAP), BGB-24714, is currently investigated in a phase 1a/1b oncology trial in patients with advanced or metastatic solid tumors (NCT05381909). Here, we evaluated the anti-tumor activity of BGB-24714 as a single agent or in combination with paclitaxel in preclinical models. Results: BGB-24714 effectively inhibited cIAP1 by inducing its degradation in MDA-MB-231 cells, with an EC50 of 2.5 nM. BGB-24714 also potently antagonized the inhibitory interaction of XIAP with caspase-9 and induced caspase-9 autoactivation in MDA-MB-231 cells, with an EC50 of 23 nM. In a total of 25 breast cancer cell lines treated with TNFα, BGB-24714 potently inhibited the in vitro proliferation of 5 breast cancer cells with EC50 < 100 nM. In pharmacodynamics studies, single dose administration of BGB-24714 significantly induced degradation of cIAP1 and antagonism of the XIAP: Smac interaction in the MDA-MB-231 xenograft model in a dose dependent manner. Using the same model, BGB-24714 exhibited dose-dependent anti-tumor activities as a single agent. The tumor growth inhibition rates were 30%, 52% and 73% in low to high dosage treatment groups. Furthermore, BGB-24714 at medium dosage level demonstrated synergized anti-tumor activity in HCC1806 xenograft model when used in combination with paclitaxel. In intermittent dosing study, BGB-24714 with the intermittent dosing schedule demonstrated significant but slightly less effective anti-tumor activity than the continuous dosing schedule. In summary, BGB-24714, as a novel oral IAP antagonist, showing significant anti-tumor activities in preclinical models, which is promising and warrants the testing of the compound in human.

#6160

Targeting RNA N^6-methyladenosine methyltransferase, METTL3 activates p53 and apoptosis pathways in osteosarcoma cells

Seungjae Shin[1], Yumi Oh[2], Yoojin Yang[1], Sung-Yup Cho[1]. *[1]Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Medical Research Center, Genomic Medicine Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of*

Osteosarcoma (OS) is a malignant tumor which is mesenchymal origin from bone stroma. The 5-year overall survival of localized OS is approximately 70%, however patients who have metastasis to other organs, mostly lung, have a poor 5-year survival rate, approximately 20%. Recently, oncogenic role of Methyltransferase-like 3 (METTL3), which is the only catalytic subunit of RNA N^6-Methyladenosine methyltransferase complex, has been suggested, but its mechanism in OS is still unclear. To elucidate the roles of METTL3 in OS, we generated METTL3 knock-out U2OS osteosarcoma cell lines by CRISPR knock-out system. Knock-out of METTL3 decreased cell proliferation on U2OS cells, which was assessed by WST-1 assay and manual cell counting assay. Also, RNA-sequencing was conducted in METTL3 wild type and knock-out cell lines. Gene set enrichment analysis (GSEA) revealed that gene sets of 'Programmed cell death' in gene ontology (GO) category, 'p53 pathway' and 'Apoptosis' in HALLMARK gene sets, and 'p53 signaling pathway' and 'Apoptosis' in KEGG pathway were enriched in METTL3 knock-out cells. To validate the result of GSEA in our METTL3 knock-out cells, mRNA and protein levels of GADD45A and CDKN1A, which are downstream targets of p53, and BAX and BAK, which are apoptosis-related molecules induced by p53, were detected by real-time PCR and western blot, respectively, and these genes were upregulated in METTL3 knock out cell lines. Collectively, these results suggest that inhibition of METTL3 is potential therapeutic targets against OS by activating p53 and apoptosis pathways.

Targeting endogenous and therapy-induced dependence on BCL-X_L in high grade serous ovarian carcinoma

Lissah Johnson[1], Xingping Qin[1], Cameron Fraser[1], Elizabeth Stover[2], Yang Yang[3], Daohong Zhou[4], Bo Rueda[5], Kristopher Sarosiek[1]. *[1]John B. Little Center for Radiation Sciences, Harvard T.H. Chan School of Public Health, Boston, MA,[2]Division of Gynecologic Oncology, Dana-Farber Cancer*

Institute, Boston, MA,[3]College of Pharmacy, University of Florida, Gainesville, FL,[4]Department of Biochemistry and Structural Biology, Long School of Medicine, University of Texas Health San Antonio, San Antonio, TX,[5]Division of Gynecologic Oncology, Department of Obstetrics and Gynecology, Vincent Center for Reproductive Biology, Massachusetts General Hospital, Boston, MA

Though most patients diagnosed with high-grade serous ovarian carcinoma (HGSOC) have favorable initial responses to therapy, approximately 80% will experience tumor recurrence and develop chemoresistant disease. This highlights the urgent need for more effective therapeutic strategies and a better understanding of the mechanisms that drive therapy resistance. Altered expression of BCL-2 family proteins that control the intrinsic apoptosis pathway is a prominent mechanism by which tumor cells can develop therapy resistance. Therefore, we sought to elucidate how changes in apoptotic regulation may contribute to chemoresistance in HGSOC in order to uncover potential opportunities for improving treatment outcomes. We used well-established HGSOC cell lines and human primary tumors to measure sensitivity to inhibitors of pro-survival BCL-2 family proteins as single agents and in combination with the front-line ovarian cancer chemotherapy drugs carboplatin and paclitaxel. Based on BH3 profiling, flow cytometry-based cell death analysis and colony formation assays, we found that HGSOC cells are particularly sensitive to BCL-X_L inhibitors including the first-generation BH3 mimetics ABT-263 and A1331852 as well as novel proteolysis-targeting chimeras (PROTACs) that degrade BCL-X_L. Clinical use of first-generation BCL-X_L inhibitors has been hampered by thrombocytopenia resulting from platelet dependence on BCL-X_L for survival. PROTACs have been developed to avoid this toxicity by degrading BCL-X_L using the VHL E3 ligase, which is expressed at very low levels in platelets. We tested BCL-X_L targeting in vivo using HGSOC xenografts in immunocompromised mice and found these tumors to be highly sensitive to BCL-X_L inhibitors as single agents and in combination with chemotherapeutic agents. BCL-X_L inhibitors reduced xenograft tumor growth and prolonged overall mouse survival. Importantly, thrombocytopenia was observed with in vivo use of first-generation BCL-

X_L inhibitors but not with use of BCL-X_L targeting PROTACs. Transcriptional profiling demonstrated that expression levels of pro-apoptotic BAX and BAK, which initiate apoptosis by causing mitochondrial outer membrane permeabilization, increase during ovarian tumorigenesis, as do levels of BCL-X_L. These changes are consistent with the increased BCL-X_L dependence evident in HGSOC cells. We also detected BCL-X_L dependence in ovarian cancer tumorigenesis models utilizing human fallopian tube secretory epithelial cells, the putative cell of origin for HGSOC. Overall, we find that BCL-X_L inhibitors, especially PROTACs, can safely enhance the chemosensitivity of HGSOC cells in vitro and in vivo and may therefore prevent tumor recurrence in women diagnosed with this disease.

High resolution detection of HER2 copy number variation in admixed breast cancer cell lines and HER2+ FFPE donor tissue using a digital PCR multigene reference panel

Tyler Landrith[1], Samantha Smith[1], Jennifer Chan[1], Mari Christensen[1], Yu Chuan Tai[1], Megan Gonzales[1], William Yee[1], Nicolas Newton[1], Wouter Pattje[2], Patrick Bogard[1], Wei Yang[1]. *[1]Roche Diagnostics Solutions, Inc, Pleasanton, CA,[2]Roche Diagnostics International AG, Rotkreuz, Switzerland*

The measurement of *HER2* (*ERBB2*) gene amplification guides both the prognosis and treatment of breast cancer, as amplification correlates with worse outcomes and the recommendation for anti-*HER2* treatment. Digital PCR (dPCR) can serve as a useful tool for the direct quantification of copy number variants (CNV) in this gene, without the need for calibration standards as required for qPCR, or labor-intensive histological techniques such as FISH. Furthermore, increasing the number of available partitions in a digital PCR reaction can yield substantial gains in precision, thus offering the potential for ultra-high resolution discrimination of copy number changes. In this study, we evaluated the utility of a multiplex dPCR assay for the high-resolution detection of HER2 copy number variation in clinically relevant samples. The precision achievable by digital PCR correlates with the number of partitions, and the resolution of small CNV

differences greatly relies on high precision. We utilized a dPCR setup with ~100,000 physical partitions per reaction, which allowed for a theoretical precision (relative confidence) of 1%, assuming optimal input and template. Five single-plex primer and probe sets, published by the National Institute of Standards and Technology, were assembled and optimized into a multiplex configuration. The final 5-plex consisted of four reference genes and *HER2* as the target of interest. The accuracy and precision of the optimized five-plex assay was tested in nine breast cancer cell lines with established *HER2* amplification ratios, ranging from 1.3 to 70 fold. The assay demonstrated the precise and accurate measurement of the *HER2* amplification ratio across all nine cell lines over a wide dynamic range of sample input. Along with increasing the reaction partition number, the use of multiple reference genes also improved the precision of the *HER2* amplification ratio measurement and avoided inaccurate copy number calls due to outlier references. The resolution of the assay was evaluated using admixed samples simulating low tumor fraction. A minimum of a 1.03 fold difference (3% difference from wild type) was detected with statistical significance. Assay concordance was evaluated against IHC-characterized HER2+ FFPE donor tissue with concordant FISH/CISH results. The assay demonstrated robust performance in clinically relevant sample types, supporting further investigation of dPCR as a complementary or even alternative diagnostic approach to current methods.

Background: Fusions (Fs) are major molecular biological abnormalities in acute leukemias (ALs), and all well-known Fs in leukemias are founder variations are routinely used as molecular markers for the diagnosis, classification, risk stratification, and targeted therapy but there is a considerable part of ALs that are not screened for other known/unknown transcripts. For example in B-Other B Acute Lymphoblastic Leukemia (B-ALL) [Ph**-/-/-;** negative for t(9;22)*;* t(1;19); t(4;11); 61% of adult B-ALL], many chimeric genes have been identified leading to a refined classification of B-ALL and to, in some cases, tailored therapies. At this point, a RNA-seq approach is needed but challenging for many aspects, among them a not standardized and very heterogeneous F data analysis.
Aims: We developed and validated our integrated pipeline in order to assess targetable biomarkers and to better classify patients (pts).
Methods: we performed 1385 gene RNAseq (Illumina) of 224 adult AL samples (112 Ph-/-/-, 41 Ph+, 6 t(1;19), 16 T-LBL/T-ALL and 49 AML). Starting from Ph-/-/-, we developed a combined 4 tool analysis that is further implemented with a filtering strategy with a specific ALs fusion literature filter (Patent PCTEP2021-065692 and 749 ALL Fs database copyright) (Fig.1A). We validate our strategy using: RT-PCR, FISH SNP Arrays; MLPA and total RNA-seq.
Results: From 3022 candidate Fs, we retained 160 of them (5.3%; excluding WHO canonical Fs) not otherwise detected, in 120 pts with a

high Fs rate in T-LBL/T-ALL, Ph-/-/- and Ph+ (62.5%, 62.2% and 61% respectively) denoting that ALs are not deeply characterized (Fig 1B). The lower rate was found in AML (26.5%), but we were able to identify new *ETV6* rearrangement (r) and a FISH cryptic F in a 46,XY pt (*TBL1XR1-MECOM*). We validated 98 Fs that have been already reported in the literature and 43 novel F transcripts. We obtained a validation rate of 81%. The majority of fused samples (65.2%) had only one detectable F while a smaller group was characterized by multiple Fs. Many of these Fs were previously described in B/T-ALL and AML (e.g. *KMT2A-MLLT1, ABL1/2-RCSD1, IGH-MYC, NUP214-SET, ETV6-MECOM*). In our bigger sub-cohort (Ph-/-/-), 44 Fs out of 109 (40.3%) were never been reported in Ph-ALL cases. In 15 Ph-like pts, we identified and validate 11 new transcripts. Ph-/-/- F detection help to sub-classify our fused pts in Ph-/-/- subgroups (ZNF384r-11.8%; Ph-like-19.1%; DUX4r- 4.4%; HLFr, MLLr and BCL2/MYC in 2.9%; MEF2Dr-1.5%).
Conclusions: we identified pivotal transcripts in all ALs and an unexpected high rate of secondary Fs in adult ALs subgroups (52.4%) that are not characterized with conventional diagnostic methods. The use of an NGS approach and a powerful pipeline permit us to detect Fs useful for a better classification, prognostic identification (e.g. *TBL1XR1-MECOM)* and in some cases to find targetable Fs (e.g. *ABL1-2/RCSD1, NUMA1-CSF1R, ZMYM2-FLT3*). Supported by: L3P2505.

NF-κB and NRF2 signaling pathways affect prognosis in HPV-associated head and neck cancer

Aditi Kothari[1], Travis Parke Schrank[2], Wendell Gray Yarbrough[3], Natalia Isaeva[3]. *[1]University of North Carolina at Chapel Hill, Durham, NC,[2]Otolaryngology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC*

Incidence of HPV associated head and neck squamous cell carcinoma (HNSCC) is on the rise, displaying a significantly favorable prognosis and overall better survival as compared to HPV negative HNSCC. Intense radiotherapy is the primary medical care leading to treatment associated morbidity in patients, thereby generating a need for de-intensification strategies. Biomarkers that can identify patients with less aggressive tumors

as candidates for de-escalation therapy would revolutionize treatment. We applied an unbiased approach (weighted gene correlation network analysis (WGCNA)) that allows detection of autocorrelated gene sets on 3 independent cohorts of HPV+ HNSCC and created 22 consensus transcriptional modules by selecting genes that grouped together in WGCNA analyses from all 3 cohorts. Interestingly, only 1 module intrinsically divided HPV+ HNSCC into 2 subtypes, displaying different mutational profiles, mutational signatures, HPV gene expression patterns, HPV integration status, and patient survival. Gene set enrichment analysis revealed that this module was enriched in NF-kB genes and strongly associated with NF-κB signaling, confirming our prior findings that defined HPV+ HNSCC subtypes by presence or absence of NF-kB regulators, *TRAF3* or *CYLD* defects and by the NF-κB activity classifier. Our studies show that *NF-* κ*B* -driven intrinsic tumor characteristics contribute to increased sensitivity of *NF-* κ*B* active HPV+ head and neck tumors to radiation, providing patients survival benefits. Indeed, *TRAF3* or *CYLD* deletion activated NF-kB and dramatically increased radiation sensitivity of HPV+ head and neck cancer cells. In line with our RNA seq analysis, we found that activation of NF-κB via TRAF3/CYLD deletion significantly correlated with marked downregulation of NRF2 activity and reduced nuclear localization in in HPV+ HNSCC cells. Interestingly, *TRAF3* CRISPR KO cells had lower NRF2 protein levels that were restored by MG132 treatment, indicating an involvement of KEAP1/CUL3 mediated proteasomal degradation of NRF2. In summary, our data unveils a unique relation between *NF-κB* pathway and radiosensitivity in HPV+ HNSCC. The distinct biological characteristics that separate patients into two subclasses associated with favorable prognosis could serve as a biomarker for personalized therapy.

Identification of biomarkers of early onset colorectal cancer from transciptome and whole genome data

Yejin Ha[1], Yun-Jae Shin[2], Ka Hee Tak[1], Jong-Lyul Park[2], Jeong-Hwan Kim[2], Jong Lyul Lee[1], Seon-Young Kim[2], Chan Wook Kim[1]. *[1]Asan Medical Center, Seoul, Korea, Republic of,[2]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of*

Colorectal cancer (CRC) is not only the third most commonly occurred cancer worldwide, but it is the leading cause of cancer deaths in 2018. However, the overall incidence of CRC and death from CRC has declined since 1998, the case of early-onset CRC (EOCRC) defined as CRC diagnosed under age 50 has been increasing. Including the etiology of EOCRC, the reasons underlying this upward trend are not well understood. Moreover, some suggested that EOCRC patients have difficulty in early diagnosis compared to late-onset colorectal cancer (LOCRC). For this reason, EOCRC patients tend to be diagnosed at advanced stages. In addition to the clinical feature, EOCRC tumors have different features in pathology and molecularity compared with LOCRC tumors. With these distinct characteristics of EOCRC, there is necessary to characterize EOCRC compared to LOCRC patients. In this study, patients under 50 years (from hereon referred to as ‘‘early-onset’’) and over 70 (‘‘late-onset’’) were considered for comparison. Whole transcriptome sequencing (WTS) for profiling gene expression and whole genome sequencing for mutations were carried out with tumor tissues of early-onset (n=49) and late-onset (n=50) CRC patients. Subsequently, we performed bioinformatic analysis to identify genomic and transcriptomic features. For the precise selection of differentially expressed genes, we selected constantly differentially expressed genes (DEG) in TCGA COAD and READ data. Genes up-regulated in both data set were CPS1, CCL19, CHGB, GLDC, WASF3, RPL39L and MAP9. The down-regulated were PRSS33, ANPEP, DKK4 and NTS. To identify whether CMS classification had different feature in each type if age onset was different, we classified CMS subtypes using transcriptome data. The ratio of each CMS subtypes both early and late-onset group had no significant difference. In terms of somatic mutations reported for driving colorectal cancer, three genes (ATM, BCL9L, NF1) had significantly mutated in early-onset group. Moreover, Non-synonymous mutation frequency had no significant difference while total mutation frequency had significantly difference between early and late-onset group. Lastly, Mutational signature had difference in both groups, assuming that the early-onset group had been through different event attributing to mutational changes. Although these findings should be further validated by detailed functional experiments, our genomic and transcriptomic analysis provide additional insights into understanding of young CRC patients.

#6166

TBL1, a multifunctional transcriptional regulator, is highly expressed in osteosarcoma and correlates with activated beta catenin

Kimberly R. Holloway[1], Taku Yamamichi[2], Bikesh Nirala[2], Nino Rainusso[2], Jason T. Yustein[2], Stephen Horrigan[1]. *[1]Iterion Therapeutics, Houston, TX,[2]Dept. of Pediatrics, Texas Children's Cancer Center/Baylor College of Medicine, Houston, TX*

Background: Osteosarcoma (OS) is the most common primary bone cancer in children and adolescents. Two-thirds of OS patients are cured through chemotherapy and tumor resection. However, survival rates have plateaued over the past 30 years, especially for patients with relapsed and/or metastatic disease, with overall long-term outcomes of less than 30%. Transducin beta-like protein 1 (TBL1) protects beta-catenin from nuclear degradation and mediates Wnt targeted transcription by forming a TBL1-beta-catenin complex. Overexpression of TBL1 and nuclear beta-catenin are positively correlated to adverse clinicopathological features and poor prognosis for osteosarcoma patients. Functional experiments reveal that down-regulation of TBL1 and nuclear beta-catenin activity inhibit proliferation, migration, and invasion of osteosarcoma cells. The objective of this study was to determine TBL1 levels within a panel of OS patient-derived xenograft (PDX) tumors.
Methods: TBL1 and beta-catenin protein levels were measured via western blot and immunohistochemistry in OS samples. We examined protein levels in OS PDX cell lines collected at distinct clinical stages of metastatic OS and OS primary tumor samples. TBL1, total beta-catenin, and activated beta-catenin levels were measured by immunohistochemical (IHC) staining in tissue microarray (TMA) derived from patient derived xenograft (PDX) tumor and clinical samples. Each tumor sample were formalin fixed, paraffin embedded, and spotted in triplicate on the TMA.
Results: Beta-catenin and TBL1 protein were detected in OS samples, and we found higher TBL1 protein levels in cells derived from advanced disease stages. Assessment of TBL1 protein was expanded to OS tissue microarray where TBL1, total beta-catenin, and active beta-catenin were independently stained in a TMA. TBL1, total beta-catenin, and activated beta-catenin were present in 100% of OS PDX cores. Finally, a majority of

OS cores were shown to have high expression for both TBL1 and active beta-catenin.
Conclusion: Elevated TBL1 levels have been associated with metastatic disease and poor survival. We have measured TBL1 and activated beta-catenin protein levels in a variety of osteosarcoma samples and identified a large percentage of osteosarcoma that co-express both proteins. These results indicate that metastatic OS represents a TBL1 enriched patient population and is a candidate for therapeutics that target TBL1.

#6167

Targeting TBL1 with tegavivint promotes anti-tumor and immunomodulatory responses in preclinical models of hepatocellular carcinoma

Kimberly R. Holloway[1], Thomas Drake[2], Thomas Bird[2], Stephen Horrigan[1]. *[1]Iterion Therapeutics, Houston, TX,[2]CRUK Beatson Institute, Liver Disease and Regeneration Laboratory, Glasgow, United Kingdom*

Background: Hepatocellular cancer (HCC) is the 3rd leading cause of death worldwide with approximately 30% of patients possessing a beta-catenin activating mutation. Despite recent progress in combination with VEGF inhibition, resistance to immune checkpoint inhibitors (ICI) still occurs in a majority of HCC patients. Recent studies suggest that activated beta-catenin regulates both tumor metabolism and immune microenvironment in CTNNB1-mutated HCCs. Transducin beta-like protein 1 (TBL1) is necessary for canonical Wnt -regulated gene transcription by binding nuclear beta-catenin, which prevents its nuclear degradation and promotes recruitment to Wnt-target gene promoters. The TBL1 inhibitor, tegavivint, disrupts the TBL1-beta-catenin complex and inhibits beta catenin signaling. This study measures TBL1 levels and determines tegavivint response within preclinical models of HCC.
Methods: Tegavivint cytotoxicity (GI_{50}) was determined in an HCC cell line panel. Tegavivint activity was measured in a syngeneic mouse model of HCC. Tumors were collected for FACS analysis of cell subpopulations of interest from the vehicle and tegavivint group at study termination. Efficacy and tolerability were measured and evaluated by tumor growth curve and body weight change in treatment groups. Liver and tumor tissue were collected at study termination. TBL1 levels were measured in HCC cells

and mouse tumors via western blot and immunohistochemical (IHC) staining.
Results: Tegavivint sensitivity was measured in a of HCC cell line panel resulting in GI_{50} values ranging from 0.03 μM - 0.20 μM. Correlation between cell sensitivity and activating beta-catenin mutational status was identified and further characterized by measurement of active beta-catenin and TBL1 expression in cell lysates. In an HCC syngeneic mouse model with reported elevated levels of beta-catenin, tegavivint significantly inhibited tumor growth in comparison to vehicle control and demonstrated a significant change in PD-1+ CD3+ and PD-1+ CD4+ subpopulations. TBL1 and active beta-catenin levels were also characterized in tumor mouse tissue relative to tegavivint response.
Conclusion: Tegavivint monotherapy demonstrated antitumor activity in a range of HCC preclinical models. In vitro studies show correlation between tegavivint potency and beta-catenin mutation. In a syngeneic HCC mouse model with elevated beta-catenin, tegavivint reduces tumor growth and induces an activated T-cell subpopulation. We are currently characterizing potential biomarkers of TBL1/beta-catenin activity to identify HCC patient populations that will be most responsive to tegavivint in a clinical setting.

Despite a detailed understanding of the genes mutated in myelodysplastic syndromes (MDS), diagnostic and treatment decisions for patients with MDS rely primarily on clinical and cytogenetic variables as considered by

the Revised International Prognostic Scoring System (IPSS-R). Here we describe the recently developed Molecular IPSS (IPSS-M), a clinico-genomic risk stratification system that considers clinical, cytogenetic and genetic parameters; the implementation of a web portal to facilitate its adoption, a strategy to handle missing variables, and the worldwide utilization of the web calculator as a clinical support tool.

The IPSS-M was trained on 2,957 clinically annotated diagnostic MDS samples profiled for mutations in 156 driver genes. To maximize the clinical applicability of the IPSS-M and account for missing genetic data (i.e genes missing from a sequencing panel), we implemented a strategy to calculate a risk score under three scenarios: best, worst and average. Last, we developed an online calculator as a standalone single-page web application using VueJs, and D3Js for the interactive visualizations, deployed through a CI/CD pipeline on AWS, where collection of anonymous usage analytics allows to track adoption and usability of the new proposed model.

The model incorporates clinical, morphological, genetic variables informed by cytogenetics and constructed from the presence of oncogenic mutations in 31 genes. It delivers a unique risk score for each individual patient, as well as an assignment to one of six IPSS-M risk strata. Compared to the IPSS-R the IPSS-M re-stratified 46% of MDS patients. The model was validated in an external dataset of 754 MDS patients. We released an open-access IPSS-M web calculator available at https://mds-risk-model.com. By specifying the patient clinical and molecular profiles, the tool returns the patient-specific IPSS-M risk score and category, and the probability estimates over time for three clinical endpoints, i.e. leukemia free survival (LFS), overall survival, and incidence of leukemic transformation. Since its launch in June 2022, the calculator has been used by >6000 users in >75 countries, reaching a daily average of 100 users per day. Risks have been calculated for >45,000 patient profiles. 99.28% of the sessions initiated reach an IPSS-M score, suggesting that the calculator is intuitive and easy to use.

We trained and validated the IPSS-M on 3,711 patients, a patient tailored risk stratification tool for patients with MDS that considers clinical, morphological and genetic variables inclusive of cytogenetics and mutations in one of 31 genes. The development of a web based tool was instrumental to the global dissemination of the model, enabling non-expert

users to leverage the power of molecular biomarkers in risk stratification for patients with MDS.

Characterization of a novel series of highly selective PARP1 inhibitors

Phillip M. Cowley, Barry E. McGuinness, Gillian M. Campbell, Alan Wise.
Duke Street Bio Limited, London, United Kingdom

First-generation PARP1 inhibitors have provided significant therapeutic benefit to patients whose tumors exhibit homologous repair deficiencies, including BRCA mutations, however their use has been associated with hematological toxicities that have restricted their application, particularly in combination with standard-of-care chemotherapy. All four FDA-approved PARP1 inhibitors are largely non-selective for the closely related enzyme PARP2, inhibition of which has been shown to drive hematotoxicity. Hence, the development of second-generation molecules highly selective for PARP1 over PARP2 offers a significant opportunity to 1) dramatically enhance therapeutic index, 2) enable additional precision medicine / combination approaches with chemotherapy, radiotherapy, immunotherapy and targeted agents and 3) expand the addressable patient population to those whose tumors harbor additional DDR defects. Utilizing X-ray crystallography and structure-based drug design, we describe the characterization of a novel chemical series of highly selective PARP1 inhibitors. These molecules demonstrate high potency in multiple biochemical and cell-based assays, including viability and colony forming unit read-outs in BRCA-deficient cancer cells, whilst sparing isogenically-paired BRCA wild-type cells and non-transformed primary cell lines. The molecules are potent PARP1-DNA trappers and exhibit high affinity, high selectivity and prolonged residence time in biophysical surface plasmon resonance (SPR) binding assays. The molecules also demonstrate exceptionally high selectivity for PARP1 over PARP2, and across the mono and polyPARP family, using a cell-based NanoBRET target engagement assay. This chemical series generally exhibits highly desirable physico-chemical and in vitro ADME properties, coupled with an excellent in vitro safety profile, which translate to high oral bioavailability and low clearance

in rodent PK studies. Lead molecules yield deep and durable anti-tumor efficacy in a BRCA1m MDA-MB-436 breast cancer xenograft model with responses continuing after cessation of treatment. Percent tumor regression and post-dose tumor control was superior to olaparib at $1/10^{th}$ of the dose. Importantly, our molecules demonstrate prolonged tumor residence time and a markedly superior tumor:plasma ratio compared to competitor PARP1-selective inhibitors. Taken together, these data predict low therapeutic dosing with the potential to demonstrate improved efficacy and tolerability compared to marketed PARP inhibitors. In summary, we describe the characterization of novel potent and selective PARP1 inhibitors. These molecules demonstrate excellent in vitro ADMET and in vivo PK, coupled with profound anti-tumor efficacy and tumor-targeting properties in a genetically-defined mouse model, supporting their progression into clinical studies.

AKT1 prevents aberrant R-loops accumulation via regulating DHX9 and suppresses transcription-replication collision in PARP inhibitor-resistant ovarian cancer

Tzu-Ting Huang[1], Chih-Yuan Chiang[2], Jayakumar R. Nair[1], Chi-Ting Shih[1], Kelli Wilson[2], Ken Chih-Chien Cheng[2], Jung-Min Lee[1]. *[1]National Cancer Institute, Bethesda, MD,[2]National Center for Advancing Translational Sciences, Rockville, MD*

Background: Acquired resistance to PARP inhibitors (PARPis) is a pressing problem in high-grade serous ovarian cancer (HGSC), highlighting the development of novel therapeutic options. To address this unmet need, we conducted high-throughput drug combination screens in PARPi-resistant HGSC cells using ATR inhibitor (ATRi), given that ATR/CHK1 signaling activation is one of the main mechanisms of PARPi resistance. In the screens, PI3K/AKT pathway inhibitors were synergistic with ATRi. Mechanistically, ATR signaling plays a major role in R-loop dynamics and replication stress (RS) response pathways, but the role of AKT is unclear. Here, we aim to investigate AKT's role in R-loop-mediated RS in PARPi-resistant HGSC cells. We also hypothesize that AKT inhibitor (AKTi) would augment ATRi-induced R-loop formation by reducing the expression of helicases.

Methods: We used PARPi-resistant variants and parental PEO1 as a negative control. ATRi (ceralasertib) and AKTi (capivasertib) were used for further mechanistic studies. Induction of RS, DNA double-strand break, and R-loop were evaluated using immunofluorescence staining for markers pRPA, γH2AX, and S9.6, respectively. We measured multiple nuclear helicases and *in situ* DHX9-R-loop interaction by western blot and proximity ligation assay. DHX9-AKT1 interaction was confirmed by co-immunoprecipitation. All data were repeated in triplicate, analyzed using one-way ANOVA test, and shown as mean ± SD. $P < 0.05$ was considered statistically significant.
Results: The ATRi and AKTi combination induced greater RS, as evidenced by a 1.7-12.0-fold increase in pRPA+/γH2AX+ population relative to each drug alone. Adding AKTi to ATRi significantly increased R-loops compared to monotherapy alone (signal intensity 14-19 x 10^5 vs. 9.9-14.6 x 10^5, $P < 0.001$), suggesting that AKT also contributes to R-loop dissolution. Moreover, the combination showed a higher percentage of cells with γH2AX and R-loops relative to monotherapy (54.7-75.4% vs. 33.3-49.0%, $P < 0.001$) in the presence of pan-caspase inhibitor, indicating the increased DNA damage is unlikely caused by increased apoptosis but by R-loop accumulation. Also, AKTi addition to ATRi significantly reduced the nuclear DHX9 among other helicases. Moreover, we found that AKT1 directly binds with DHX9 via its kinase domain and couples with DHX9 to resolve R-loops.
Conclusion: Our data suggest ATRi and AKTi combination could be a new therapeutic combination in HGSC with PARPi resistance. Mechanistically, our data reveal a previously unknown direct role of AKT1 and its interaction with DHX9 in R-loop resolution besides ATR.

#6174
ATX-101, a peptide drug targeting PCNA, enhances the effect of gemcitabine in liposarcoma and leiomyosarcoma
Elgilda Musi, Tahir Sheikh, Matthew Ingham, Sminu Bose, Gary K. Schwartz. *Columbia University Irving Medical Center, New York, NY*

Soft tissue sarcomas are heterogeneous mesenchymal neoplasms and account for 1% of all cancers in adults. Over 50 sarcomas subtypes have been classified and many have very limited treatment options which include

surgery, chemotherapy and radiation. Two of the most common sarcomas are liposarcoma and leiomyosarcoma which are often treated with chemotherapies such as doxorubicin, dacarbazine and gemcitabine with low response rates. There is now more than ever an urgent need for new therapies for sarcoma. PCNA (Proliferating Cell Nuclear Antigen) is considered to be a key regulator of DNA and cell cycle control. In addition, it has been implicated to have roles in metabolism, cellular signaling and some immunological functions. PCNA forms complexes with proteins bearing a novel PCNA-interacting Peptide Motif called APIM (AlkB homolog 2 PCNA Interacting Motif). This binding usually occurs during stress responses such as those achieved during cancer therapy or cancer development. By preventing stress proteins from repairing or defending themselves, cancer therapies can be made more effective. We examined the in vitro effects of ATX-101, a PCNA-APIM protein interaction blocking peptide, on liposarcoma cell lines LS141, DDLS, SW872, 93T449 and 94T778 and leiomyosarcoma cell lines SK-LMS, SK-UT1 and SK-UT-1B. Cell survival, as measured by cell proliferation assays, indicated IC50s of 7.5-15μM with ATX-101. Enhanced combination effects with ATX-101 and chemotherapies such as doxorubicin, irinotecan and gemcitabine were also observed by proliferation assay. Synergism, with ATX-101 and gemcitabine, was indicated with SynergyFinder analysis. Cell cycle changes exhibited increases of S and G2 phases when treated with ATX-101 and gemcitabine. This correlated with increase of cell cycle proteins, cyclin B1 and cyclin A2. Western blot observations included increase of apoptotic marker, cleaved caspase 3, and DNA damage marker, pH2A.X. In addition, immunofluorescence assay showed increasing pH2A.X with ATX-101 and gemcitabine. In vivo studies revealed ATX-101 enhanced gemcitabine decrease of tumor volume in leiomyosarcoma cell line xenograft, SK-UT1. Tumor target inhibition by western blot showed increased pH2A.X and cleaved PARP along with decreased RAD51 API protein with combination treatment. Taken these observations and results, there is strong evidence of combining gemcitabine with ATX-101 in liposarcoma and leiomyosarcoma.

CDK8 inhibition potentiates the efficacy of niraparib in homologous recombination proficient cancer cell lines

Karen A. Simon-Crevatis[1], Shailesh R. Metkar[1], Justin T. Hardcastle[1], Keith Jansson[2], Usman Shabon[2], Rajarshi Choudhury[2], Euan A. Stronach[3], Kevin G. Coleman[1], Asli Muvaffak[1]. *[1]Synthetic Lethality Research Unit, GlaxoSmithKline LLC, Cambridge, MA,[2]Genomic Sciences, GlaxoSmithKline LLC, Collegeville, PA,[3]Genomic Sciences, GlaxoSmithKline LLC, Stevenage, United Kingdom*

While cyclin dependent kinases (CDKs) were originally implicated in cell cycle regulation, several CDKs including CDK7, CDK8, and CDK9 play critical roles in transcription through regulation of RNA polymerase II (Pol II) activity. In addition to expected phosphosite targets associated with DNA-binding transcription factors, chromatin regulators, or other known regulators of pol II activity, a phospho-proteomics study on a CDK8/19 inhibitor (Cortistatin A) also identified DNA replication and repair proteins, i.e., namely BRCA1 and MDC1, as substrates for CDK8. RVU120, a first in-class CDK8/19 inhibitor in phase I clinical trial demonstrated preclinical efficacy in acute myeloid leukemia PDX models. A robust relationship has also been observed between the exposure to RVU120 and inhibition of pSTAT5, a pharmacodynamic marker, in solid tumor indications in a recent clinical trial. Additionally, preclinical data suggested RVU120 reduced expression of genes related to interferon-related DNA damage signature (IRDS) suggesting a potential role of CDK8 in DNA repair signaling. CDK8 loss was identified as a synthetic lethal hit in two internal, orthogonal screens that surveyed targets which can synergize with niraparib inhibition. Niraparib inhibits PARP enzymatic activity and promotes PARP trapping on ssDNA breaks which lead to replication stress-induced dsDNA breaks that require BRCA-dependent homologous recombination repair (HRR). Combination with other therapeutic agents is anticipated to improve the efficacy of niraparib in HR proficient (HRP) and BRCA1/2.WT tumors. This work describes our proof-of-concept data from in vitro validation of combination synergy response of RVU120 with niraparib in a panel of 129 HRR.WT and HRR mutant cancer cell lines across ovarian, breast, lung, and colorectal cancer indications. Our results indicated that the niraparib+RVU120 combination was synergistic, and a strong synergy response, i.e., a SS (Synergy Score) ≥ 5 was detected by Loewe modelling across the entire surface of the combination matrix in ~26% of Horizon Discovery OncoSignature™ panel cell lines that were largely resistant to

niraparib monotherapy. The study findings indicated the potential of CDK8/19 inhibitors to enhance niraparib activity in both HRR.WT and HRR mutant populations. The potential benefit of CDK8/19i+niraparib combination will be further explored in PARPi-resistant models. Molecular studies are underway to explore potential biomarkers associated with synergy response, and to analyze the downstream effects on DNA Damage Response.

Enhancing treatment efficacy of glioblastoma cell lines by adding tumor treating fields (TTFields) to temozolomide and lomustine

Hila Fishman, Roni Monin, Eyal Dor-On, Adi Haber, Moshe Giladi, Uri Weinberg, Yoram Palti. *Novocure Ltd, Haifa, Israel*

Background: Tumor Treating Fields (TTFields) are electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression, ultimately leading to cell death. Concurrent maintenance temozolomide (TMZ) with TTFields was approved by the FDA in 2014 for treatment of patients with newly diagnosed glioblastoma (ndGBM). Recently, the addition of lomustine (CCNU) to TMZ demonstrated clinical benefit in ndGBM patients. The aim of the current study was to examine in GBM cells the effect of TTFields concurrent with TMZ and CCNU.
Methods: Human GBM cell lines (U-87 MG, LN229, U118, and LN18) with various MGMT expression levels were treated with TTFields (intensity of 0.83 V/cm RMS; frequency of 200 kHz) using the inovitro system. Effectiveness of TTFields concomitant with TMZ and/or CCNU was tested by measuring cell count and colony formation. Levels of DNA repair proteins in control and TTFields-treated cells were measured using Western blot.
Results: The cell lines displayed different sensitivity to TMZ, in accordance with their MGMT expression level, but showed a comparable response to TTFields. TTFields concomitant with TMZ displayed an additive effect on cell numbers, irrespective of MGMT expression levels. The effect of TTFields concomitant with CCNU was additive in cell lines expressing MGMT, whereas it trended toward synergy in cell lines not expressing MGMT. Application of TTFields to the cells downregulated expression of proteins from the Fanconi Anemia-BRCA pathway for DNA repair.

TTFields concurrent with both TMZ and CCNU provided higher efficacy relative to TMZ plus CCNU or TTFields apart.
Conclusions: Efficacy of TMZ and CCNU may be enhanced by TTFields, with synergism seen for the latter case in cells with limited MGMT expression. The BRCAness state induced by TTFields rationalizes these outcomes, as DNA damage induced by CCNU requires the BRCA pathway for repair, especially in the absence of MGMT. The results suggest a potential benefit for concomitant TTFields with the TMZ/CCNU combination in ndGBM.

#6177

ATRN-119 and ATRN-W1051: Novel and potentially well tolerated ATR and WEE1 inhibitors for targeted cancer treatment

Joseph Vacca[1], Stephen Rocca[2], Justin Frye[2], Steven J. Schnell[2], Molly Hansbarger[2], Gregory Korbel[2], Fiona Simpkins[3], Eric J. Brown[3], Oren Gilad[2]. *[1]Aprea Therapeutics, Dolyestown, PA,[2]Aprea Therapeutics, Doylestown, PA,[3]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Previous studies have demonstrated the promise of ATR and WEE1 inhibitors (ATRi and WEE1i) as cancer treatments. Inhibition of these DNA replication checkpoint kinases disrupts normal DNA synthesis and causes replication fork collapse, and these effects are accentuated by numerous cancer-associated mutations. However, a key limitation to this approach in clinical trials has been the occurrence of adverse hematological effects, including anemia, neutropenia, and thrombocytopenia. Herein, we describe two novel inhibitors, ATRN-119 (ATRi) and ATRN-W1051 (WEE1i), that exhibit increased target selectivity that potentially decreases these dose-limiting toxicities. ATRN-119, the first macrocyclic ATRi to enter clinical trials, is highly specific for inhibition of ATR relative to other phosphatidylinositol kinase-related kinases (PIKKs), such as ATM, DNA-PK, and MTOR. This specificity correlates with increased tolerability, which permits continuous dosing in animal models. Importantly, dose scheduling of ATRN-119 that suppresses tumor growth in xenograft mouse models of colon, pancreatic, and prostate cancers causes no appreciable loss of body weight or hematologic toxicity (anemia, neutropenia or thrombocytopenia). Daily dosing is also tolerated in combination with

PARP inhibition, which causes significant tumor reduction in a BRCA2-defient PDX model of high-grade serous ovarian cancer. These findings have led a biomarker-driven Phase I clinical trial of ATRN-119 with daily dosing for ovarian and other cancers (Simpkins, PI). To potentially reduce the toxicity of WEE1i, a new potent and selective WEE1 inhibitor, ATRN-W1051, was developed. *In vitro*, ATRN-W1051 inhibits WEE1 with an IC50 of 2.2 nM and limits the proliferation of ovarian cancer cell lines in the 100 nM to 200 nM range. Importantly, ATRN-W1051 exhibits low off-target inhibition of the PLK family of kinases (PLK1, PLK2 and PLK3), which are substantially inhibited by the leading WEE1i in the clinic (AZD1775 and ZN-c3)[1]. In addition, ATRN-W1051 also has potentially favorable pharmacokinetic properties that permits 3-8 times lower dosing than AZD1775 or ZN-c3 to achieve similar exposure (AUC_{0-24}) levels[2]. Notably, daily oral dosing of ATRN-W1051 is well tolerated in mice and suppresses the growth of CCNE1-amplified HGSOC xenografted tumors. These preclinical data suggest that ATRN-W1051 may be a potential therapeutic candidate for CCNE1-overexpressing HGSOC. Together, ATRN-119 and ATRN-W1051 provide promising alternative DNA replication checkpoint inhibitors for the treatment of a variety of cancers.

#6178

A novel second-generation nano-fluoropyrimidine to treat metastatic colorectal cancer and overcome 5-fluorouracil resistance

Naresh Sah[1], Pamela Luna[1], Chinnadurai Mani[1], William Gmeiner[2], Komaraiah Palle[1]. *[1]Cell Biology and Biochemistry, Texas Tech University Health Sciences Center, Lubbock, TX,[2]Department of Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC*

Colorectal cancer (CRC) is the 3rd leading cause of cancer-related mortality. The mortality associated with colon cancer results notably from metastatic disease (mCRC), with a 5-year survival rate for patients with stage IV CRC being < 14%. Despite extensive efforts towards developing personalized therapies, limited success has been achieved and chemotherapeutic regimens that include the fluoropyrimidine (FP) drug 5-fluorouracil (5-FU) are central to patient management. While using 5-FU-based regimens such as FOLFOX and FOLFIRI in combination with biologics confer a survival

benefit, their ineffectiveness at promoting long-term survival in a substantial fraction of mCRC patients and associated toxicities limits their use. This underscores the pressing need to develop improved FP drugs. To overcome the limitations of 5-FU that include resistance due to elevated expression of thymidylate synthase (TS) and inefficient anabolic metabolism to FdUMP, the TS-inhibitory/active metabolite, we are developing FP polymers consisting of single-stranded DNA with FdUMP (only active metabolite) as the repeating nucleotide unit. Our therapeutic objective is to initiate a Phase I clinical trial with a new 2nd generation nanoscale FP polymer (CF10) that demonstrates promising anticancer effects in several preclinical models and significantly lower systemic toxicity. We observed that CF10 displayed significantly higher anti-tumor activity than 5-FU in flank and syngeneic tumor models. Additionally, CF10 treatment improved survival (84.5 days *vs* 32 days; $P < 0.0001$) relative to 5-FU in an orthotopic HCT-116-*luc* colorectal cancer mice model that spontaneously metastasized to the liver. Interestingly, a reduction in metastatic tumor burden in the CF10 treatment group led us to hypothesize that CF10 could inhibit the TS-mediated EMT phenotype and pro-metastatic activities in colorectal cancer cells (CRCs). This was supported by increased vimentin, decreased E-cadherin expression, and increased cell migration and invasion in TS-overexpressing CRC cells ("Tet-on" system). Alkaline comet assay, immunofluorescence imaging, and immunoblot identified significantly higher replication stress with CF10 treatment than 5-FU in mouse, rat, and human-established CRC cell lines and primary CRC cells. Strikingly, we also discovered that CF10 attenuates the growth of TS-overexpressing primary colonoids. In conclusion, CF10 induces increased replication stress compared to a similar concentration of conventional drugs. Our findings suggest the significance of elevated TS in CRC metastatic progression and 5-FU resistance and demonstrate that CF10 may be effective at inhibiting CRC metastatic progression. CF10 may be a successful candidate for early-phase clinical trials to treat mCRC.

Comparative study of Polθ helicase and polymerase inhibitor biochemical and cellular potency

Johanna K. Ahlskog[1], Antti Pohjakallio[2], Ralf Paul[1], Martin Augustin[3], Elisabeth Schneider[3], Sakshi Johri[3], Tuomas Tervahauta[2], Hans-Georg

Beisel[1], Lars Neumann[3], Julia Lindqvist[1], Anu Moilanen[1]. *[1]Orion Corporation, Turku, Finland,[2]Orion Corporation, Espoo, Finland,[3]Proteros Biostructures GmbH, Martinsried, Germany*

Background: DNA Polymerase θ (Polθ) is active in Theta-mediated end joining (TMEJ), a repair pathway that utilizes resected 3' ends and micro-homology sequences to repair double strand breaks. Polθ contains an N-terminal helicase domain and a C-terminal polymerase domain. The helicase domain facilitates stripping of RPA/RAD51 from single stranded DNA and is involved in DNA-end recognition, and micro-homology search and pairing. The polymerase domain performs DNA synthesis following micro-homology pairing. Lack of Polθ is synthetic lethal in homologous recombination deficient (HRD) cells. In this study, we utilized existing small molecule inhibitors targeting either helicase or polymerase domain of Polθ, to assess their translational potential in HRD *in vitro* cancer cell models.
Methods: Small molecules inhibiting either the helicase or polymerase activity of Polθ were studied with biochemical and cellular assays. For the biochemical studies, recombinant helicase or polymerase domains were purified. The helicase activity of Polθ was analyzed using ADP-Glo and the polymerase activity by primer extension assay. Binding assays confirmed inhibitor binding to recombinant proteins. To study inhibitor efficacy in cellular models, we probed cell viability of BRCA2-deficient cell lines.
Results: Both helicase and polymerase inhibitors showed good potency in inhibiting Polθ enzymatic activity in ATPase or primer extension assays, respectively, with IC50 values in low-nanomolar range. However, the viability of BRCA2-deficient cell lines was not significantly affected after treatment with either helicase or polymerase inhibitors. The measured compound properties (stability, efflux, solubility) did not explain the lack of efficacy in cellular viability assays. Combining Polθ inhibitor treatment with ionizing radiation led to a modest enhancement of radiation-induced decrease in cell viability.
Conclusions: Recently, significant advances have been made in Polθ inhibitor development prompted by the synthetic lethal interaction between Polθ and HRD discovered in several screening efforts. Both helicase and polymerase inhibitors are highly potent in biochemical assays. However, without exogenous genotoxic stress, the potential of Polθ inhibitors as

therapeutic target may not be reached *in vitro.* Additional studies are required to understand the translational gap between biochemical and biological read-outs.

#6180

Antitumor activity of the ATR inhibitor Elimusertib in patient-derived xenograft models with DNA damage response pathway alterations

Kaushik Varadarajan[1], Christian X. C. Pico[1], Kurt Evans[1], Maria G. Raso[1], Yasmeen Rizvi[1], Xiaofeng Zheng[1], Timothy P. Diperi[2], Bailiang Wang[1], Stephen Scott[1], Ming Zhao[1], Argun Akcakanat[1], Antje M. Wengner[3], Timothy A. Yap[1], Funda Meric-Bernstam[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Cedars Sinai Medical Center, Los Angeles, CA,[3]Bayer AG, Berlin, Germany*

Introduction: The ataxia telangiectasia and RAD3-related (ATR) kinase is a key component of the DNA damage response (DDR) and functions in conjunction with ataxia telangiectasia mutated (ATM). ATM loss or functional deficiency may enhance reliance on ATR signaling. Preclinical and clinical studies have pointed to a potential synthetic lethality of ATR inhibition and ATM loss. In this study, we sought to further elaborate potential candidates for ATR inhibition by testing the anti-tumor effect of elimusertib (BAY 1895344) in patient-derived tumor xenograft (PDX) models with DDR alterations including ATM loss.

Methods: Patient derived xenograft (PDX) models were implanted into athymic nu/nu mice. Once tumors reached an appropriate size of approximately 200-400mm^3 treatments were started. Mice were randomized (N= 3-8) to different treatment arms for assessment of anti-tumor activity of elimusertib as monotherapy and in combination therapy with copanlisib. Monotherapy treatment was performed with 20 mg/kg and 40 mg/kg doses, applied twice daily for 3 days with 4 days treatment break (BID 3 days on/4 days off). Efficacy read-out was either Event-Free Survival (EFS-2), defined as time for doubling of tumor volume relative to baseline, or response based on RECIST criteria:(partial response [PR]= >30% decrease, stable disease [SD]= between 20% increase and 30% decrease, and progressive disease [PD]= >20% increase). For assessment of pharmacodynamic effects, tumors were harvested 10 days after treatment

start and analyzed by immunohistochemistry (IHC) and RPPA (Reverse Phase Proteomics Array).
Results: Elimusertib was tested in 21 PDX models with various DDR alterations. Of those 11 showed a statistically significant prolongation of event free survival compared to control. In 4 PDX models elimusertib reached a partial response (PR), and another 4 models showed stable disease (SD). Amongst the 5 models with ATM protein Ioss (IHC), one was PR and another one SD. In 3 of 5 PARP inhibitor resistant there was statistically significant prolongation of EFS upon elimusertib treatment vs control. We found an increase in DNA damage in tumors, as indicated by increased level of YH2AX (on IHC and RPPA). We also detected an increase in PI3K/mTOR pathway signaling as determined by p-MTOR and pS6 (RPPA) in 2 of 4 models (PR and PD model) with different sensitivity to ATRi and PARPi alone. We tested the combination of elimusertib with the PI3K inhibitor copanlisib achieved a statistically significant increase of EFS compared to monotherapy in 3 of 11 models tested.
Conclusion ATR inhibition shows potent monotherapy activity in selected PDX models that harbor DDR defects, including models with intrinsic and acquired PARPi resistance. Further work is needed to identify markers predicting sensitivity or resistance that providing rationale for synergistic combination therapies.

Dynamic changes in monocyte and reticulocyte counts predict mechanism-based anemia development and recovery during ATR inhibitor treatment in phase I/II trials
Natalie Y. L. Ngoi, Heather Y. Lin, Ecaterina Dumbrava, Siqing Fu, Daniel D. Karp, Aung Naing, Shubham Pant, Sarina A. Piha-Paul, Jordi Rodon, Vivek Subbiah, Apostolia M. Tsimberidou, Erick Campbell, Samuel Urrutia, David S. Hong, Funda Meric-Bernstam, Ying Yuan, Timothy A. Yap. *UT MD Anderson Cancer Center, Houston, TX*

Introduction: Clinical trials are exploring ATR inhibitors (ATRi) in genomically selected contexts. However, dose-dependent anemia has limited the therapeutic index of this class. We hypothesized that monocytes and reticulocytes are more vulnerable to ATRi due to their lack of base excision repair and high levels of oxidative stress, respectively. We sought

to examine the kinetics of decline and recovery of red blood cell (RBC) and reticulocyte indices, in relation to hemoglobin (Hb), in the first 28 days after ATRi initiation.
Methods: We retrospectively retrieved peripheral blood cell indices from complete blood count (CBC) reports of patients (pts) pre- and during treatment with an oral ATRi on phase I/II trials at our center. Pts received ATRi monotherapy or in combination with a PARP inhibitor (ATRi+PARPi) in dose-escalation and expansion cohorts, which included ATRi at potentially toxic doses. We applied linear mixed effect models to evaluate the joint evolution of Hb and other RBC or reticulocyte indices over time via bivariate analysis. A random intercept was included in the model to account for the longitudinal nature of the data and a variance component option for the covariance structure was specified to model a different variance component for each index of interest. To assess if Hb decline was preceded by decline in the index of interest from baseline, piecewise regression models were used to estimate break points, defined as the time point where the fitted functions intersect, of each index. Log transformed data with a base of 2, were noted to have more symmetric distributions, and were used in the analyses. The time variable assessed was days from cycle 1 day 1 of ATRi. A two-sided p value <0.05 was considered statistically significant.
Results: 35,007 indices from 1,843 CBC of 119 pts treated with an ATRi from 10/2017 to 1/2022 were analyzed. 110 (92.4%) pts received ATRi, 9 (7.6%) received ATRi+PARPi. Monocytes (-0.120 vs -0.022, $p <0.0001$) and reticulocytes (-0.140 vs -0.022, $p <0.0001$) declined at a faster rate compared with Hb. Time to monocyte and reticulocyte nadir after ATRi initiation was 8.9 and 5.8 days, respectively, while time to Hb nadir was 19.5 days. Conversely, RBC (-0.020 vs -0.023, $p=0.410$), MCV (-0.002 vs -0.022, $p <0.0001$) and MCH (-0.001 vs -0.022, $p<0.0001$) declined at a slower rate than Hb. Time to RBC, MCV and MCH nadir after ATRi initiation was 26.3, 18.7 and 15.0 days, respectively. After reaching their individual index nadir, monocytes (0.004 vs 0.001, $p <0.0001$) and reticulocytes (0.005 vs 0.0005, $p <0.0001$) increased more quickly than Hb.
Conclusions: Charting the kinetics of CBC index evolution in relation to Hb identified peripheral monocytes and reticulocytes as relevant blood indices that herald Hb decline. Our findings may inform patient monitoring strategies to mitigate hematologic toxicity on future ATRi trials.

#6182

Tumor treating fields (TTFields) concomitant with PARP inhibitors or carboplatin for treatment of ovarian cancer cell lines

Antonia Martinez-Conde, Hila Ene, Roni Frechtel-Gerzi, Eyal Dor-On, Adi Haber, Moshe Giladi, Uri Weinberg, Yoram Palti. *Novocure Ltd, Haifa, Israel*

Purpose/Objectives: Ovarian cancer continues to be the leading cause of death among gynecological malignancies. Platinum-based chemotherapy is recommended after surgery for most patients with ovarian cancer; and PARP inhibitors (PARPi) are suggested as maintenance therapy. Both therapies induce DNA damage that require the proper activity of the Fanconi Anemia (FA)- BRCA pathway for its resolution, and hence are most beneficial in cancers with a BRCA mutation. However, 75% of patients with ovarian cancer do not harbor BRCA mutations, and thus may experience limited benefit from these treatments. TTFields are electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression, ultimately leading to cancer cell death. Recently, TTFields have been shown to induce a state of BRCAness in various cancer types, and to be effective in ovarian cancer pre-clinical models. The objective of the current study was to examine the effect of TTFields concomitant with carboplatin or PARPi on ovarian cancer cell lines.
Materials/Methods: A2780 (BRCA wild type) and OVCAR3 (BRCA mutated) ovarian carcinoma cells were treated with TTFields (72 h, 1 V/cm RMS, 200 kHz), alone or with concomitant application of carboplatin or the PARP inhibitors olaparib or niraparib. Efficacy was examined via measurements of cell count, colony formation, and induction of apoptosis. The overall effect was calculated by multiplying cell count with colony formation.
Results: Application of TTFields to A2780 or OVCAR3 cells resulted in reduced cell count, increased overall effect, and elevated apoptosis. Carboplatin, olaparib, and niraparib each displayed dose dependent effects in both cell lines, with higher sensitivity demonstrated in the BRCA mutated cells. Concomitant application of TTFields with any of these drugs displayed a synergistic interaction in the BRCA wild type A2780 cells and an additive effect in the BRCA mutant OVCAR-3 cells.

Conclusions: The data suggest potential benefits for TTFields concomitant with platinum-based chemotherapy and PARPi in ovarian cancer, even in the absence of background BRCA mutations, in accordance with the BRCAness state induced by TTFields. As such, TTFields may enhance the efficacy of treatment for ovarian cancer in both the adjuvant and maintenance settings.

Somatic heterozygous mutations in genes encoding for RNA splicing factors (SF) *SRSF2*, *U2AF1*, and *SF3B1* are frequently mutated in patients with hematologic malignancies, representing a unique genetic vulnerability for targeted therapy. In the current study, we performed a focused drug screen with inhibitors targeting different DNA damage response and DNA metabolic pathways to identify novel therapeutic vulnerabilities generated by SF mutations. We generated a murine leukemia model by overexpressing the MLL-AF9 fusion oncogene on an $Srsf2^{P95H/+}$ background, a mutational combination that is found in ~10% of *MLL*-rearranged leukemias. We surprisingly found that MLL-AF9 $Srsf2^{P95H/+}$ mutant leukemias are sensitive to inhibitors targeting ADP-ribosyltransferases (PARP). PARP

inhibitor sensitivity was also observed in isogenic murine MLL-AF9 *U2af1*$^{s34/+}$ cells compared to MLL-AF9 *U2af1*$^{+/+}$ cells. Second, murine Srsf2^{P95H} leukemias showed improved prolonged survival when treated with olaparib (PARPi) compared to vehicle treatment *in vivo*. Third, human primary AML patient samples that harbor SF mutations are sensitive to PARPi compared to non-SF mutant samples. These data highlight that both *SRSF2*^{P95H} and *U2AF1*^{S34F} mutations create a common vulnerability that is dependent on PARP activity for survival. To evaluate PARP activity, we used isogenic K562 leukemia cells expressing *SRSF2*^{P95H} and *U2AF1*^{S34F} mutations from their endogenous loci and monitored ADP-ribosylation (ADPr) levels, a marker of PARP activity. Both SRSF2^{P95H} and U2AF1^{S34F} cells exhibited elevated levels of ADPr compared to wildtype cells in a PARP1- dependent manner. PARPi preferentially induced DNA damage and cell death in SF mutant cells. Surprisingly, we found that SRSF2^{P95H} and U2AF1^{S34F} cells are not defective in homologous recombination repair. Instead, the increased PARP1-mediated ADPr in SF-mutant cells is caused by accumulated R loops, a group of transcription intermediates containing RNA:DNA hybrids and displaced single-stranded DNA. To determine whether PARPi sensitivity is due to R-loop accumulation, we overexpressed RNase H1, an enzyme that specifically cleaves the RNA moiety within RNA:DNA hybrids in U2AF1^{S34F} cells. Overexpression of RNase H1 significantly reduced ADPr levels and suppressed the PARPi-induced U2AF1^{S34F} cell growth inhibition. Collectively, these results suggest that spliceosome mutants induce R-loop accumulation and elicit an R-loop-associated PARP1 response to promote cell survival. In summary, our data establish a previously unknown link between R-loop-induced PARP1 response and RNA splicing perturbation and provide a mechanistic rationale to evaluate the clinical efficacy of PARP inhibitors in spliceosome-mutant malignancies. Furthermore, our study highlights a new therapeutic potential of targeting the R-loop tolerance pathways caused by different spliceosome gene mutations.

Pre-clinical study of SYX3759, a novel PARG inhibitor for the treatment of homologous recombination deficient malignancies

Xuzhen Tang, Yaqi Cui, Lanqiao Zhang, Huihui Jin, Zeqiong Xu, Hu He, Chongxun Ge, Song Liu, Xiaochun Yu, Song Shi. *SynRx Therapeutics, Hangzhou, China*

Although PARP inhibitors (PARPi) are very successful on the treatment of BRCA-mutant cancer, the tumor spectrum targeted by PARPi is quite narrow. Interestingly, Poly(ADP-ribose) Glycohydrolase (aka PARG), the major dePARylation enzyme, has emerged as a promising therapeutic target for cancer treatment. Here, we have developed a cell membrane permeable PARG inhibitor with subnanomolar IC_{50}. SYX3759 directly binds to the catalytic domain of PARG and induces significant accumulation of PARylation at DNA lesions, where it traps numerous DNA repair factors, such as XRCC1. Compared to PARPi, such as Olaparib, SYX3759 shows selective and potent cytotoxicity on a broader spectrum of homologous recombination deficient (HRD) tumors both in vitro and in vivo. Moreover, SYX3759 is well tolerated at the highest dose tested without obvious adverse effect on hematopoiesis. Collectively, SYX3759 is a potent PARG inhibitor both in vitro and in vivo warranting future clinical trials for the treatment of HRD cancers and beyond.

#6185

Debio 0123 is a selective WEE1 inhibitor that effectively penetrates the brain and demonstrates anti-tumor activity in preclinical models of glioblastoma

Luke Piggott, Noemie Luong, Frederic Massiere, Annett Kunze, Christophe Chardonnens, Anne Vaslin. *Translational Medicine, Debiopharm International S.A., Lausanne, Switzerland*

Background: Glioblastoma (GBM) is one of the most aggressive and hard-to-treat cancers with a 5-year survival rate of 5.8%, in part due to the presence of the blood brain barrier (BBB) that prevents most therapeutics from reaching the tumors at efficacious concentrations. Debio 0123 is a WEE1 inhibitor that has previously shown significant preclinical efficacy in combination with DNA damaging agents or radiotherapy and is currently being investigated in phase 1 clinical studies either as a monotherapy or in combination with carboplatin. Herein we present data that demonstrates Debio 0123 effectively penetrates in to the brain and subsequently leads to

anti-tumor activity in GBM models both in vitro and in vivo as a monotherapy or in combination with standard-of-care therapies (SOC).
Methods: Radio- and chemo-sensitizing effects of Debio 0123 were evaluated in GBM cell lines in vitro using standard clonogenic assays or cytotoxicity assays. In vivo, distribution and bioanalysis studies were performed to determine the amount of Debio 0123 present in the different parts of the brain and intracranially implanted tumors. Efficacy of Debio 0123 as monotherapy or in combination with the SOC, temozolomide (TMZ), was further assessed in vivo in U87MG-luc intracranial or subcutaneous xenograft models.
Results: In vitro, Debio 0123 in combination with radiation enhanced cell death in GBM cell lines and reduced TMZ IC50 in primary GBM cell lines. In vivo studies demonstrated substantial Debio 0123 brain penetration in mice, rats and monkeys, with mean brain-to-plasma concentration ratios of ~0.6 and 1.52 and 4, respectively. Furthermore, a mean tumor-to-plasma ratio of 0.62 was determined in orthotopically implanted brain tumors in mice. In efficacy studies, Debio 0123 administered at 30 or 60mg/kg every day for 28 days displayed significant anti-tumor activity in a GBM xenograft model U87-MG implanted in immunodeficient mice either subcutaneously, with up to 57.5% tumor growth inhibition, or orthotopically in the brain, with up to 73.7% tumor growth inhibition. Finally, efficacy of Debio 0123 in combination with TMZ was also assessed in intracranially transplanted U87-MG tumors. Here, TMZ was highly active, however, the combination of Debio 0123 and TMZ resulted in significantly enhanced anti-tumor activity leading to sustained complete regressions in 75% of animals for up to 100 days and was well tolerated throughout the 28-day treatment.
Conclusion: These results demonstrate that following oral administration, Debio 0123 effectively crosses the BBB, has significant efficacy as a monotherapy and improves response to standard-of-care chemo or radiotherapy in preclinical models. Collectively, these data highlight Debio 0123 as a promising candidate for further clinical development in GBM patients that may provide improved response to SOC therapy.

#6186
Patient-derived tumor organoids with p53 mutations, and not wild-type p53, demonstrate synergistic sensitivity to treatment with

temozolomide in combination with talazoparib PARP inhibitor

Florencia P. Madorsky Rowdo[1], Gu Xiao[2], Melissa B. Davis[1], Laura Martin[1], Olivier Elemento[1], Jill Bargonetti[2]. *[1]Weill Cornell Medicine, New York, NY,[2]Biological Sciences Hunter College, City University of New York, New York, NY*

Mutations in the *TP53* gene can be found in more than 50% of tumors. We recently showed in 2D breast cancer cell lines that mutant p53 (mtp53) proteins tightly associate with replicating DNA, chromatin and Poly (ADP-ribose) polymerase (PARP) protein. In addition, missense mtp53 R273H causes an increase in the chromatin association of replication proteins including PARP, and mini-chromosome maintenance complex 2-7 (MCM2-7). The expression of mtp53 R273H enhances overall MCM2 levels, promotes cell proliferation, and improves the synergistic cytotoxicity of treatment with the alkylating agent temozolomide in combination with the PARP inhibitor (PARPi) talazoparib. Currently, PARPis are indicated for patients that present BRCA1/2 mutations, but there might be patients with other alterations associated with DNA damage repair that could benefit from PARPi treatment; this includes expression of mtp53. Patient-derived Tumor Organoids (PDTO) are 3D culture models that retain cell-cell and cell-matrix interactions and are shown to reproduce drug responses observed in patients. Here, we evaluated the sensitivity of wild-type BRCA1/2 breast and lung PDTO with either mtp53 or wild-type p53 (wtp53) to the combination of DNA damaging agent temozolomide plus the PARPi talazoparib. First, we tested the sensitivity of the organoids to talazoparib and temozolomide individually. To determine if there was synergy between the two treatments, the organoids were treated with an inhibitor matrix to evaluate multiple combinatorial concentrations. Three breast cancer and two lung cancer PDTO with mtp53 presented synergistic cytotoxicity of the combination treatment. Two breast organoid lines with wtp53 showed no synergistic interaction between the two drugs, and the same was observed in a wtp53 lung organoid line. We analyzed wtp53 and mtp53 PDTO cell extracts by western blot to assess the activation of downstream p53 effectors and DNA damage markers after treatment with temozolomide and/or talazoparib. Combination of talazoparib and temozolomide induced higher DNA double-strand breaks in mtp53 organoids as shown by increased gamma-H2AX expression. The results

obtained demonstrated that in mtp53 PDTO synergism is achieved with combined talazoparib-temozolomide treatment supporting the idea that tumors expressing mtp53 may be potential candidates for this combination PARPi treatment.

The combination of Trifluridine/Tipiracil and a WEE1 inhibitor is an effective and tolerable candidate strategy against ESCC

Hoang Trang Nguyen Vu, Osamu Kikuchi, Tomoki Saito, Yukie Nakai, Tomomi Ida, Yuki Kondo, Shigeki Kataoka, Yosuke Mitani, Shinya Ohashi, Manabu Muto. *Therapeutic Oncology, Kyoto Univ. Graduate School of Medicine, Kyoto, Japan*

Background: Recently we reported that trifluridine (FTD)/ Tipiracil (TPI) is tolerable for unresectable Esophageal squamous cell carcinoma (ESCC) patients although the anti-tumor effect was modest (Mori Y, et al. Esophagus 2022). Therefore, we aimed at developing a combination therapy with FTD/TPI with another small molecule to achieve better efficacy against ESCC. CHK1 inhibitor was considered to be the candidate, because combination treatment with FTD/TPI and prexasertib showed potent antitumor effects in p53-mutant ESCC cells through the synthetic lethality (Ohashi S, et al. Mol Cancer Ther 2020); however, CHK1 inhibitors are not clinically available for further clinical development. Here we explored the concept of synthetic lethality with CHK1 perturbation to the whole ATR-CHK1-WEE1 pathway, especially to the downward WEE1 which directly targets a cell cycle regulator CDK1. The aim of this study is to elucidate the efficacy of the combination of a WEE1 inhibitor (WEE1i) MK1775 with FTD/TPI in ESCC.
Methods: ESCC cells (TE-8 and TE-11) are used for *in vitro* assay, with compounds including FTD, MK1775 (WEE1i). Mitosis assay (flowcytometry with phospho-Histone H3 [p-hH3] antibody), cell viability assay (WST-1 and clonogenic assays), cytotoxicity assay (CytoTox-Glo assay), and western blotting (double-strand DNA break [γ-H2AX], DDR activity [phospho-CHK1], and CDK1 activity [phospho-Tyr15-CDK1]) were performed. Antitumor effects and tolerability were observed *in vivo* with TE-8 xenograft model with nu/nu nude mice.

Results: FTD induced activation of CHK1 and inhibition of CDK1 sequentially in ESCC cells. FTD also decreased the proportion of p-hH3 positive cells in mitosis assay. Combination treatment with WEE1i and FTD had activated CDK1, increased p-hH3 positive cells, and induced γ-H2AX. The WST-1 cell viability assay showed significant sensitizing effect of WEE1i to FTD in ESCC cells. The cytotoxicity assay also revealed the significant increase of dead cells by the combination treatment ($p = 0.003$). Furthermore, we confirmed the combination treatment significantly suppressed xenografted tumor growth (-86%) without major adverse events *in vivo* (two-way ANOVA and Tukey post-hoc analyses: FTD/TPI vs. control, $P < 0.05$; MK1775 vs. control, $P < 0.05$, without significant interaction between the FTD/TPI treatment and MK1775 treatment). Conclusion: FTD/TPI and WEE1i combination showed potent cytotoxicity, and is considered as a candidate treatment strategy against ESCC.

Exportin 1 inhibition synergizes with lurbinectedin by altering the response to DNA damage in neuroendocrine lung tumors

Esther Redin Resano[1], Charles Rudin[2], Alvaro Quintanal-Villalonga[1].
[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Memorial Sloan Kettering Cancer Center/Weill Cornell Graduate School of Medical Sciences, New York, NY

Background: Neuroendocrine lung cancer carcinomas (Lung NECs), which include large cell neuroendocrine carcinomas (LCNECs) and small cell lung cancer (SCLC) tumors, are particularly aggressive lung neoplasms with limited clinical therapeutic options. Patients with lung NECs are treated with platinum-based chemotherapy as the first line of treatment, but they promptly develop resistance. Lurbinectedin has recently been approved by the FDA as a second-line treatment for SCLC due to its efficacy in metastatic chemorelapsed SCLC patients. However, there is still a large percentage of SCLC patients who do not respond to lurbinectedin and the overall survival of those who benefit from it remains very low (<6 months). Previous work from our group had shown that exportin-1 (XPO1) was a driver of chemoresistance in SCLC and its inhibition with selinexor resentitized to first- and second-line chemotherapies in naïve and chemorelapsed SCLC patients derived xenografts, respectively. Importantly,

selinexor is an FDA-approved drug for the treatment of relapsed multiple myeloma and is currently undergoing clinical testing in multiple solid tumors.
Methods: We performed synergy proliferation assays *in vitro*. DNA damage/repair pathways were analyzed by western blotting. Cell cycle and apoptosis were analyzed by flow cytometry.
Results: We explored the cytotoxic capacity of the combination of lurbinectedin with selinexor in cell linesfrom both SCLC (N=2) and LCNECs (N=3) in synergy *in vitro* assays. Selinexor strongly synergized with lurbinectedin in both SCLC and LCNEC settings and induced a potent increase in the DNA damage marker γ-H2A, reflective of increased DNA damage induced by the combination treatment. Mechanistically, this combination altered DNA damage and DNA repair mechanisms by decreasing CHK1 and CHK2 protein levels in short-term treatments, suggestive of the impairment of DNA response. Additionally, selinexor reduced the expression of MLH, a key regulator of DNA mismatch repair in monotherapy and in combination with lurbinectedin. Consistent with these results, selinexor in combination with lurbinectedin also induced a significant increase in apoptotic cells and promoted cell cycle arrest.
Conclusions: These data indicates that inhibition of exportin 1 with selinexor in combination with lurbinectedin is a promising therapeutic strategy in lung NECs. Subsequent *In vivo* testing in patient-derived xenograft to study efficacy and toxicity of this combination will provide preclinical rationale for clinically exploring this combination in patients with lung NECs who have failed chemotherapy regimen.

#6189
Targeting DNA damage responsive pathways in cancer therapy
Junjie Chen. *Experimental Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX*

DNA double strand breaks (DSBs) result in activation of several key DNA damage response (DDR) kinases including ATM, ATR, and DNA-PK. These protein kinases not only promote DNA damage-induced checkpoint control, but also facilitate DSB repair in humans. Thus, these DDR kinases have become promising drug targets for cancer therapy. However, the benefits of targeting DDR kinases remain to be realized, in part due to the

lack of predictive biomarkers. By undertaking CRISPR screens with inhibitors targeting key DDR kinases, we obtained a global and unbiased view of genetic interactions with DDR inhibition. Additionally, we compared the synergistic effects of combining different DDR inhibitors and found that an ATM inhibitor plus a PARP inhibitor induced dramatic levels of cell death, probably through promoting apoptosis. Our results provide a better understanding of DDR pathways, which may facilitate the use of these DDR-targeting agents in cancer therapy. Moreover, To provide comprehensive and unbiased perspective of DDR signaling pathways, we performed 30 fluorescence-activated cell sorting-based genome-wide CRISPR screens with antibodies recognizing distinct endogenous DNA damage-signaling proteins to identify new regulators involved in DNA damage response (DDR). We discovered that proteasome-mediated processing is an early and prerequisite event for cells to trigger camptothecin- and etoposide-induced DDR signaling. Furthermore, we identified PRMT1 and PRMT5 as new modulators that regulate ATM protein level. Moreover, we discovered that GNB1L is a master regulator of DDR signaling via its role as a co-chaperone for PIKK proteins. Collectively, these screens offer a rich resource for further investigation of DDR, which may provide insight into strategies of targeting these DDR pathways to improve therapeutic outcomes.

Polymerase theta inhibition activates the cGAS-STING pathway and cooperates with immune checkpoint blockade in BRCA-deficient cancers

Jeffrey Patterson-Fortin[1], Heta Jadhav[1], Constantia Pantelidou[1], Tin Phan[1], Carter Grochala[1], Anita K. Mehta[2], Jennifer L. Guerriero[2], Gerburg M. Wulf[3], Brian M. Wolpin[1], Ben Z. Stanger[4], Andrew J. Aguirre[1], James M. Cleary[1], Alan D. D'Andrea[1], Geoffrey I. Shapiro[1]. *[1]Dana-Farber Cancer Institute, Boston, MA,[2]Department of Surgical Oncology, Brigham and Women's Hospital, Boston, MA,[3]Hematology and Oncology, Beth Israel Deaconess Medical Center, Boston, MA,[4]University of Pennsylvania, Philadelphia, PA*

Cancers deficient in homologous recombination (HR) repair secondary to mutations in genes such as *BRCA1* or *BRCA2*, are dependent on alternative DNA damage response (DDR) pathways to maintain genomic integrity, rendering them susceptible to synthetic lethal targeting of these pathways. Recently, inhibitors of polymerase theta (POLθ, encoded by *POLQ*), the critical enzyme in microhomology-mediated end-joining (MMEJ), have been shown to be synthetic lethal with HR repair deficiency (*Zhou et al. Nature Cancer 2021*). Both HR and MMEJ require nucleolytic DNA end-resection to allow for DSB repair, and we have previously shown that MMEJ acts as a barrier to DNA end-resection at DSBs (*Patterson-Fortin et al. Cancer Research 2022*). Given the synthetic lethality between HR and MMEJ leads to unrestrained DNA end-resection generating chromosomal abnormalities and the release of nuclear DNA into the cytoplasm, we hypothesized that POLθ inhibition in HR-deficient cancers would activate the cGAS/STING innate immune response pathway and facilitate immunotherapy. To investigate the interactions of POLθ inhibition with the immune microenvironment in HR-deficient cancers, we used human cell lines and genetically modified mouse models representative of BRCA1-deficient triple-negative breast cancer (TNBC) and BRCA2-deficient pancreatic ductal adenocarcinoma (PDAC). Genetic or pharmacological inhibition of POLθ using novobiocin, a first-in-class inhibitor of the POLθ ATPase domain, induced significantly increased cytosolic dsDNA contained in micronuclei. This free DNA was sensed by the cytosolic DNA sensor cyclic GMP-AMP (cGAMP) synthetase (cGAS), increasing synthesis of cGAMP, in HR-deficient tumor cells but not in HR-proficient tumor cells. Increased cGAMP bound to and activated stimulator of interferon genes (STING), triggering phosphorylation of TBK1 and ultimately of IRF3. Activation of the cGAS/STING pathway by POLθ inhibition drove the expression of type I interferon response elements, including PD-L1. Depletion of *STING* by siRNA or by CRISPR abrogated this pro-inflammatory signaling and abolished the anti-tumor efficacy of novobiocin-mediated POLθ inhibition. Pharmacologic inhibition of POLθ enhanced Granzyme B+ CD8+ T-cell tumor infiltration. Importantly, antibody-mediated depletion of CD8+ T-cell severely compromised the anti-tumor efficacy of novobiocin-mediated POLθ inhibition, whereas anti-tumor activity of POLθ inhibition was augmented with the addition of either anti-PD-1 or anti-CTLA-4 antibodies. These results demonstrate that

POLθ inhibition in HR-deficient cancers mediates a pro-inflammatory response in HR-deficient TNBC or PDAC tumor microenvironments, and that immune checkpoint blockade inhibition enhances the therapeutic efficacy of POLθ inhibition.

#6191

Temozolomide-associated DNA damage processes related to glioblastoma-immune interactions

Elizabeth Y. Choe, Forest M. White. *Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA*

How do cancer cells convert an external perturbation into an interaction with the immune system? The processes associated with antigen presentation remain largely unknown, especially in cancer cells responding to treatment. These intracellular changes may be critical in cancers where immunotherapies need significant optimization, such as glioblastoma. Glioblastoma is also a particularly relevant cancer to characterize the cellular response to perturbations, since all patients currently receive temozolomide, an alkylating agent, regardless of their prognosis.

We used mass spectrometry methods to quantify temozolomide-associated changes to the repertoire of peptides presented on MHC class I molecules in vitro over time, as well as the associated changes that occur in DNA damage signaling and protein synthesis. We treated U87-MG cells with temozolomide and directly profiled the peptide-MHC repertoire, ATM/ATR kinase substrate phosphorylation, and newly-synthesized proteins via isotopically labeled and non-canonical amino acid-tagged proteins after 24, 48, and 72 hours.

These proteomics approaches identified several MHC-peptides, including phosphorylated peptides, whose presentation changes over time after treatment with temozolomide. We also found that the temporal dynamics of the DNA damage response mirrored that of immunopeptidome remodeling. Additionally, temozolomide alters translation at these time points, with newly-synthesized proteins reflecting internal cell stress processes.

These findings suggest potential treatment-associated antigens against which to design vaccines as well as particular signaling nodes that could be modulated with combination therapies to improve presentation of these peptides.

MSI2 regulates DNA damage response signaling and tumor progression in murine NSCLC

Igor Bychkov[1], Alexander Deneka[2], Iuliia Topchu[1], Rajendra P. Pangeni[1], Christopher Lengner[3], Evgeny Izumchenko[4], Jyoti Patel[1], John Karanicolas[2], Petr Makhov[2], Yanis Boumber[1]. *[1]Northwestern University - Chicago, Chicago, IL,[2]Fox Chase Cancer Center, Philadelphia, PA,[3]University of Pennsylvania, Philadelphia, PA,[4]University of Chicago, Chicago, IL*

Lung cancer is one of the most frequently diagnosed cancers and is the leading cause of cancer-related death worldwide, accounting for >2.2 million of new cancer diagnoses and 1.8 million cancer-related deaths in 2020. Non-small cell lung cancer (NSCLC) is the most common type of lung cancer, including adenocarcinomas and squamous cell carcinomas. Many lung adenocarcinomas have activating driver mutations in *KRAS* (~32% tumors), often co-occurring with mutations inactivating the *TP53* tumor suppressor. Expression of the RNA-binding protein Musashi-2 (MSI2) MSI2 regulates target mRNA translation, and its expression is progressively elevated along with tumor stage in lung cancers. We previously showed that MSI2 actively promotes lung cancer growth, invasion, and metastasis, in part through promoting expression and activity of the TGFβR1/SMAD3 and EGFR signaling cascades. We now find that genetic *MSI2* deficiency in a murine lung tumor model, $Kras^{mut}/Trp53^{KO}/Msi2^{KO}$ (KPM2) decreases both the total tumor number and tumor burden in comparison to control $Kras^{mut}/Trp53^{KO}$ (KP) mice. Using a panel of KPM2 and KP cell lines we established from tumors from these mice, we found KPM2 cell lines demonstrate a significant decrease in proliferation compared to KP cell lines. Interestingly, reverse phase protein array (RPPA) comparison analysis of KPM2 and KP cell lines showed that MSI2 strongly and positively regulates expression of Ataxia-Telangiectasia Mutated (ATM) protein, with lower levels observed in KPM2 cells. The ATM serine/threonine protein kinase is a key transducer of DDR signaling in cases of double-strand breaks; ATM activation causes G1/S cell cycle arrest, contributes to efficiency of DNA repair, and triggers apoptosis in

cases of repair failure. Notably, KPM2 cells showed significantly higher levels of γH2AX, suggesting inefficient DDR. Finally, untreated or cisplatin-treated KPM2 cells demonstrated G2/M arrest and had increased level of apoptosis as demonstrated by increase in caspase 3 cleavage, consistent with ATM loss and compensatory activation of Ataxia-telangiectasia and Rad3-related protein (ATR). Taken together, our data suggests that one of the consequences of MSI2 upregulation in NSCLC includes maintenance of an efficient DDR. Targeting MSI2 and its downstream signaling would be of therapeutic interest.

A bifunctional inhibitor of PARP and HDAC enzymes with activity in Ewing sarcoma 3D spheroid and metastasis models

Sarah Truong[1], Louise Ramos[1], Beibei Zhai[1], Jay Joshi[1], Fariba Ghaidi[1], Michael M. Lizardo[2], Taras Shyp[2], John Langlands[3], Dennis Brown[3], Jeffrey Bacha[3], Poul Sorensen[4], Wang Shen[3], Mads Daugaard[4]. *[1]Vancouver Prostate Centre, Vancouver, BC, Canada,[2]British Columbia Cancer Research Centre, Vancouver, BC, Canada,[3]Rakovina Therapeutics, Vancouver, BC, Canada,[4]University of British Columbia, Vancouver, BC, Canada*

Introduction: Poly(ADP-ribose) polymerase (PARP) plays a major role in DNA repair and PARP inhibitors (PARPi) have shown promise in pre-clinical studies for the treatment of Ewing sarcoma (ES). While a clinical trial using olaparib as a single agent failed to show significant response against ES, combination therapies with PARPi have emerged as an area of interest. Deacetylation of histones, controlled by histone deacetylases (HDACs) is a key regulatory event in DNA repair and inhibition of HDACs has been shown to reduce ES tumor growth *in vitro* and *in vivo*. PARP inhibition combined with HDAC inhibition has demonstrated enhanced efficacy in pre-clinical studies in various tumor indications, and a clinical trial of olaparib and vorinostat combination therapy against metastatic breast cancer is currently ongoing. However, combination therapies can be limited in clinical utility due to overlapping toxicities and different pharmacokinetic profiles. Here, we report the efficacy of a novel bifunctional small-molecule compound, kt-3283, designed to have both PARP and HDAC inhibitory activities.

Materials and methods: PARP1 and PARP2 activity were measured using Trevigen Universal Colorimetric PARP Assay Kit, BPS Bioscience PARP2 Colorimetric PARP2 Assay Kit, and PARylation assay. HDAC activity was measured using HeLa cell nuclear extracts and a fluorogenic peptide-based biochemical assay. Cell survival EC_{50}s were determined using live cell imaging with an Incucyte® S3 system and CellTiter Glo viability assay. Cell cycle analysis was performed by flow cytometry with propidium iodide staining. DNA damage was investigated by western blot, immunofluorescence, and comet assay. Spheroid assays were performed using the Incucyte® S3 spheroid analysis module and inhibition of metastases was assessed in a PUMA ES mouse model.
Results and discussion: Kt-3283 showed potent inhibition of PARP1/2 activity and PAR synthesis with IC_{50} values comparable to olaparib. Kt-3283 also showed inhibition of HDACs with an IC_{50} value in the low μM range. Cell survival EC_{50} values for the compound were also superior to those of olaparib and vorinostat in ES cell lines. Cell cycle and DNA damage analyses indicated S/G2/M cell cycle arrest and strong DNA damage upon treatment with kt-3283 at lower concentration range compared to olaparib and vorinostat. This compound also exhibited potent inhibition of 3D spheroid growth of ES cells with low μM EC_{50} values, and inhibited metastatic growth in a PUMA mouse model.
Conclusion: Kt-3283 shows potent inhibition of PARP1/2 and HDAC activities. It induces S and G2/M cell cycle arrest and DNA damage, and inhibits 3D spheroid growth and metastatic potential of ES cells. Further investigation of this bifunctional single-molecule inhibitor may offer a novel treatment opportunity for ES and other solid tumors with limited responses to PARPi.

Assessing replication stress as an actionable therapeutic opportunity in chordoma

Nindo Punturi[1], Lee Dolat[1], Wendy Leung[2], Joan Levy[1], Lee Zou[2], Daniel M. Freed[1], Gregory M. Cote[2]. *[1]Chordoma Foundation, Durham, NC,[2]Massachusetts General Hospital, Charlestown, MA*

Chordoma is a rare bone cancer with a high rate of disease recurrence and no approved systemic therapies. Tumor profiling studies indicate a significant number of chordomas are characterized by alterations in SWI/SNF chromatin remodeling and DNA damage repair genes, which have been associated with replication stress in other cancer types. We demonstrate here that preclinical chordoma models exhibit a replication stress phenotype and dependence on ATR activity. To assess the effect of ATR inhibition on cell viability, a panel of chordoma cell lines were treated with the ATR inhibitor elimusertib (BAY 1895344). In a subset of cell lines, elimusertib inhibited viability with low-nanomolar IC50 values. Upon treatment with the ATR inhibitor ceralasertib (AZD6738), DNA fiber assays revealed a mild decrease in replication fork speed and a significant increase in fork asymmetry in cells sensitive to ATR inhibitor, suggesting possible fork stalling or collapse in response to ATR inhibition. To assess genomic instability as a consequence of ATR inactivation and fork stalling or collapse, alkaline and neutral comet assays were performed to determine the presence of genome-wide ssDNA and/or dsDNA breaks, respectively. In a panel of chordoma PDX models, striking differential sensitivity to ATR inhibition was observed. In sensitive models, elimusertib (50 mg/kg, po, bidx3) promoted 85-90% tumor growth inhibition, in contrast to resistant models, where elimusertib treatment had no effect on tumor growth. Moreover, PDX models sensitive to ATR inhibition were sensitive to other therapies that exacerbate replication stress; for example, gemcitabine promoted multiple complete responses in a pediatric chordoma PDX model. Coupled with preclinical efficacy data, genomic and transcriptomic sequencing of differentially-sensitive chordoma models provided insight into the molecular factors associated with the replication stress phenotype in chordoma - illuminating potential biomarkers for patient selection. Finally, we explore various combination therapies and show that combining elimusertib with cisplatin or gemcitabine synergistically inhibits the viability of chordoma cell lines. Collectively, our data indicate that a subset of chordomas are characterized by intrinsic replication stress that can be therapeutically exploited by inhibiting ATR.

Proteasome inhibitors induce DNA damage and mitotic catastrophe in acute lymphoblastic leukemia via autophagy-mediated degradation of WEE1

Chun-fung Sin, Rahman Ud Din, Anan Jiao, Kei-ching Yuen. *Department of Pathology, The University of Hong Kong, Hong Kong, Hong Kong*

Acute lymphoblastic leukemia (ALL) is an aggressive hematolymphoid malignancy and the prognosis is poor in adults with long-term survival of only 30% due to the high prevalence of high-risk subtypes. Therefore, there is an urgent need to develop novel treatment for ALL. Carfilzomib is a second-generation proteasome inhibitor which is more potent than its first-generation counterpart, bortezomib, with an excellent activity against bortezomib-resistant plasma cell myeloma. However, pre-clinical and clinical studies of carfilzomib in ALL are limited. Targeting DNA damage and mitotic defects of cancer cell is a major treatment strategy of cancer. WEE1 kinase prevents mitosis of cells with unrepaired DNA through inhibiting cyclin B. Pharmacological inhibition of WEE1 was effective in treating T-ALL with induction of DNA damage. Thus, targeting WEE1 kinase is an attractive approach of novel therapy in ALL. However, there are no studies to evaluate the mechanism of action of carfilzomib in ALL, especially in the aspect of DNA damage and mitotic catastrophe. Moreover, the role of WEE1 modulation by carfilzomib and its underlying mechanism has not been studied in ALL. In view of these unmet clinical needs and research gap, we conducted the study with the aims: 1). To show that carfilzomib induces DNA damage and mitotic catastrophe; 2). To show that carfilzomib induces WEE1 downregulation and delineate underlying mechanisms. ALL cell lines representing a spectrum of high-risk ALL including TOM-1, SEM, LOUCY, CCRF-CEM, KE-37 and PEER were treated with various doses of carfilzomib. Cell viability was reduced, and percentage of apoptotic cells was increased in a time and dose-dependent manner, measured by trypan blue assay and flow cytometry analysis by annexin V/PI staining respectively, upon treating with carfilzomib for 24 & 72 hours. Comet assay showed evidence of DNA damage after treating with carfilzomib for 24 hours. Fluorescence microscopy also demonstrated evidence of mitotic catastrophe upon treating with carfilzomib. Western blot analysis showed downregulation of WEE1 upon treatment of carfilzomib

for 24 hours, with evidence of autophagy induction as shown by western blot analysis of LC3-1 and LC3-II. Quantitative PCR showed the upregulation of ER-stress related gene, CHOP while the mRNA level of WEE1 remained unchanged. Co-treatment of carfilzomib with autophagy inhibitor, bafilomycin A1, reversed the process of WEE1 downregulation. Herein, we proved that carfilzomib induced DNA damage and mitotic catastrophe with WEE1 downregulation. Moreover, carfilzomib trigger autophagy-mediated degradation of WEE1 in ALL via induction of ER-stress. The findings provide mechanistic insights of carfilzomib in ALL and rationalize the introduction of novel approach of combination treatment of carfilzomib with other DNA damaging agents.

PARP1 hyperactivation by the decoy oligodeoxynucleotide OX425 mediates DNA repair abrogation and unleashes the anti-tumor immune response

Vlada Zakharova[1], Claudia Galassi[2], Chloé Doizelet[1], Vincent Hayes[1], Lorenzo Galluzzi[2], Wael Jdey[1]. *[1]Onxeo S.A., Paris, France,[2]Weill Cornell Medical College, New York, NY*

Background: Poly (ADP-ribose) polymerase inhibitors (PARPis) lead to synthetic lethality when used in cancers with homologous recombination deficiency (HRD). However, the development of resistance to PARPis is a recurrent problem thus limits the duration of response and hence the clinical utility of these agents. Here, we describe the antineoplastic and immunomodulatory effects of OX425, a first-in-class oligodeoxynucleotide that operates as a PARP1 decoy, resulting in constitutive PARP1 hyperactivation and consequent exhaustion of the DNA damage response.
Methods: OX425-induced PARP trapping, hyperactivation and cell cytotoxicity were examined *in vitro* in HRD and homologous recombination proficient (HRP) human cancer cells, as well as in non-transformed cell lines. DNA repair efficacy was monitored by analyzing repair protein recruitment to damage sites. OX425 effects on the innate and adaptive immune responses were assessed by following STING activation and T-cell mediated anti-tumor cytotoxicity. RNAseq analysis in HRP/HRD tumor cells treated with OX425 or PARP inhibitors was employed to uncover the molecular mechanisms underlying OX425 effects. The

anticancer efficacy of OX425 was assessed *in vivo* in different HRD and HRP tumor models. OX425-induced PARP activation and tumor infiltration by immune cells were analyzed by flow cytometry.
Results: At odds with conventional PARP inhibitors, OX425 bound to and hyperactivated PARP1 with high affinity in a dose-dependent manner, resulting in elevated cytotoxicity to multiple cancer cells (breast, ovarian, prostate, colon, hematological, endometrial cancers) irrespective of HR status. Interestingly, long-term treatment with OX425 did not show any mutagenicity compared to PARPi. The activity of OX425 was specific to tumor cells, as no significant effect on cell viability was observed for normal cells, at odds with PARP inhibitors. In line with *in vitro* results, OX425 mediated considerable anticancer effects *in vivo*. Moreover, OX425 triggered activation of the STING pathway and CCL5 secretion in the EMT6 mouse mammary carcinoma model. The anticancer effect of OX425 was coupled with tumor-targeting T cell responses. In MPA/DMBA-driven mammary tumors, OX425 mediated considerable anticancer effects in monotherapy and synergistic effects in combination with PD1 inhibition. Moreover, OX425 treatment significantly delayed acquired resistance to olaparib in *BRCA1* mutated MDA-MB-436 cell-derived xenografts.
Conclusions: Our results provide preclinical rationale for using OX425 to trigger DNA damage exhaustion and STING activation in cancer cells and initiate inflammatory responses that can be actioned by immune checkpoint inhibitors in patients bearing HRD or HRP tumors

Identification of SP-002, a highly selective USP1 inhibitor effectively inhibits HRD tumor growth and displays low hematotoxicity risk
Feng Zhou[1], Zhengtao Li[2], Lei Zhou[3], Wei Zhu[4], Jiyan Zhang[5], Wenqing Yang[1], Liting Xue[1], Xiaokang Qin[6], Ping Chen[6], Renhong Tang[1]. *[1]State Key Laboratory of Translational Medicine and Innovative Drug Development, Jiangsu Simcere Pharmaceutical Co. Ltd., Nanjing, China,[2]State Key Laboratory of Translational Medicine and Innovative Drug Development, Hainan Sparkle Therapeutics Co., Ltd., Hainan, China,[3]Jiangsu Simcere Pharmaceutical Co. Ltd., Nanjing, China,[4]Hainan Sparkle Therapeutics Co., Ltd., Hainan, China,[5]Jiangsu Simcere Pharmaceutical Co. Ltd., Hainan, China,[6]Simcere Pharmaceutical Co. Ltd., Hainan, China*

Tumors with homologous repair deficiencies (HRD) are sensitive to agents interrupting DNA repair. The deubiquitinase USP1 involves in the DNA damage response by translesion synthesis and Fanconi anemia pathway. And the synthetic lethality of USP1 and HRD is well reported. Moreover, deficiency of USP1 or its downstream pathway leads to hypersensitivity of HRD tumors to PARP inhibition. In addition, target-related hematotoxicity is widely observed in serval DNA Damage Response (DDR) pathway inhibitors, including PARP and ATR inhibitors, which limits the combination therapy. Here, we reported SP-002, a highly selective USP1 inhibitor, displayed monotherapy potential and combination activity with PARP inhibitor in HRD cancers. In the biochemical assay, SP-002 strongly inhibited USP1 enzyme with IC_{50} of 15.7 nM, and potently inhibited proliferation of *BRCA1*-mutant MDA-MB-436 breast cell (GI50, 47.4 nM). SP-002 demonstrated synergistic anti-proliferation effects in combination of olaparib, a PARP inhibitor, in MDA-MB-436 cells. And further results revealed that the combination significantly enhances the DNA damage burden and cells apoptosis. Moreover, synergistic activities of SP-002 and olaparib also were observed in a panel of HRD cell lines, such as UWB1.289, Capan-1, MDA-MB-453 and NCI-H292. In a human hematopoietic stem cells based *in vitro* hematotoxicity assay, SP-002 showed no significant inhibition on lineage-specific (myeloid, erythroid, and megakaryocytic) cell differentiation and survival. In comparison, positive controls, 5-fluorouracil and olaparib significantly attenuated those primary cells both on differentiation and survival, which was consistent with the hematological toxicity observed in human. Oral administration of SP-002 led to completely tumor growth inhibition in MDA-MB-436 xenograft model, and combination of SP-002 and olaparib resulted in tumor regression. In conclusion, SP-002, a selective and potent USP1 inhibitor without significant hematotoxicity, that demonstrated excellent efficacy on treatment of HRD cancers.

6-Phosphofructo-2-kinase in regulating DNA damage and repair in EGFR-driven lung cancer

Nadiia Lypova, Lilibeth Lanceta, Susan Dougherty, Jason Chesney, Yoannis Imbert-Fernandez. *Medical Oncology, James Graham Brown Cancer*

Center, University of Louisville, Louisville, KY

Activating mutations of epidermal growth factor receptor (mutEGFR) are established drivers of lung tumor development, aggressiveness, and resistance to targeted therapies. While targeting mutEGFR with small-molecule tyrosine kinase inhibitors (EGFR-TKIs) dramatically improved progression-free survival in patients with non-small cell lung cancers (NSCLCs), intrinsic or acquired resistance to TKI therapy limits the duration of an effective response to TKIs. Alteration in DNA damage response (DDR) plays a vital role in genomic stability and cancer progression and helps cells to escape apoptosis, limiting the efficacy of targeted therapies.

Interestingly, lung cancer cells exposed to EGFR-TKIs demonstrate attenuated glycolytic flux - one of the major providers of precursors for *de novo* nucleotide synthesis. A key regulator of glycolysis is the enzyme 6-phosphofructo-2-kinase (PFKFB3). PFKFB3 synthesizes fructose 2,6-bisphosphate (F2,6BP), which is a potent allosteric activator of the glycolytic rate-limiting enzyme, 6-phosphofructo-1-kinase (PFK1). Accordingly, F2,6BP controls flux throughout the entire glycolytic pathway. In preliminary studies, we provide evidence that PFKFB3 plays multiple roles in regulating the efficacy of DDR in lung cancer cells exposed to EGFR-TKIs. We show that PFKFB3 is required for EGFR-driven glucose metabolism, which provides a list of intermediates utilized in nucleotide synthesis. PFKFB3 regulates the expression of ribonucleotide reductase small subunit M2 (RRM2) of the ribonucleotide reductase (RNR), which is important for *de novo* onsite synthesis of deoxynucleotide triphosphate (dNTP) during DNA replication and repair. Moreover, a PFKFB3 inhibitor, PFK-158, increases oxidative stress in mutEGFR lung cancer cell lines and, as a result, promotes DNA damage. Importantly, we found that PFKFB3 plays an important role in the chromatin binding of scaffold proteins regulating the assembly of DNA repair complex.

Our studies suggest that PFKFB3 plays an important role in DDR and provide a clear rationale to propose the use of PFKFB3 inhibitors in combination with EGFR inhibitors to increase the efficiency and/or overcome resistance to EGFR-TKIs.

CTC1-STN1-TEN1 (CST) complex-independent roles for STN1 in DNA double-strand break repair in pancreatic ductal adenocarcinoma

Changxian Shen[1], Linlin Yang[1], Sergio Corrales-Guerrero[2], Sindhu Nair[1], Terence Williams[1]. *[1]City of Hope National Medical Center, Duarte, CA,[2]College of Medicine, The Ohio State University, Columbus, OH*

KRAS mutation occurs in 90-95% of pancreatic ductal adenocarcinoma (PDAC) and is a driver of PDAC; however, the underlying molecular mechanisms by which *KRAS* mutation maintains survival and promotes progression of PDAC need further refinement. We herein report that *KRAS* mutations increase *STN1* (also named *OBFC1*) expression leading to enhanced repair of DNA double strand breaks (DSBs) in PDAC. Analysis of The Cancer Genome Atlas databases reveal that *STN1* is significantly upregulated in PDAC tissue and, is associated with *KRAS* mutation and poor survival. Silencing *KRAS* or pharmacologic inhibition of KRAS signaling decreased *STN1* expression in PDAC cells. Canonically, STN1 forms a CST (CTC1-STN1-TEN1) complex, which is important for telomere duplication and maintenance. Intriguingly, siRNA-mediated depletion of STN1 (but not CTC1 or TEN1) sensitized PDAC cells to ionizing radiation and chemotherapy as assessed by radiation clonogenic assay and alamarBlue assay, respectively. Consistently, immunoblotting and immunofluorescence analyses of γH2AX (marker of DNA damage) demonstrated that depletion of STN1 (but not CTC1 or TEN1) resulted in DNA damage. To explore the underlying molecular mechanisms, we performed proteomic analysis and found that STN1 physically interacts with many proteins important for DNA repair, replication and cell cycle progression. Of note, we revealed unreported interactions of STN1 with ATM, ATR and DNA-PKcs, key components of DNA damage response signaling. Furthermore, homologous recombination and non-homologous end joining repair reporter assays demonstrated that STN1 silencing reduced both homologous recombination and non-homologous end joining repair of DSBs in U2OS and PDAC cells. Moreover, flow cytometry and immunofluorescence analyses showed that knockdown of STN1 by siRNA impaired cell cycle arrest at S and G2/M phases which was accompanied with mitotic catastrophe in response to ionizing radiation. Our findings have revealed novel CST complex-independent roles for STN1 in DSB repair

and suggest STN1 is a novel biomarker for PDAC as well as potentially other cancers.

DNA-PK inhibition augment the cancer specific cytotoxicity of mitotic MTH1 inhibitor OXC-101

Akhilesh Nagesh Danda[1], Helge Gad[1], Martin Scobie[1], Laura Martínez-López[2], Nuria Pastor Carrillo[2], Manuel Luis Orta[2], Thomas Helleday[1], Ulrika warpman berglund[1], Kumar Sanjiv[1]. *[1]Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden,[2]Department of biology, University of Sevilla, Sevilla, Spain*

DNA-dependent protein kinase (DNA-PK) plays an important role in the repair of DNA double-strand breaks via the non-homologous end joining (NHEJ) pathway. In addition to its role in the NHEJ pathway, DNA-PK is also known to have an emerging role in cell cycle progression and mitosis. Some studies have shown that depletion or inhibition of DNA-PK inhibitors leads to a delay in the transition from metaphase to anaphase. The mitotic MTH1 inhibitor OXC-101(TH1579, karonudib) is a dual inhibitor that both targets MTH1 and disrupts tubulin polymerization in cancer cells, causing DNA damage and mitotic catastrophe in cancer cells. Based on the involvement of DNA-PK in mitosis, we hypothesized that depletion/inhibition of DNA-PK might enhance the DNA damage and mitotic catastrophic effect of OXC-101.To test our hypothesis, we performed an in vitro drug combination experiment using the DNA-PK inhibitor nedisertib with OXC-101 in non-small cell lung carcinoma NSCLC (H460,A549), uveal melanoma (MP -38, MP -41 and MP46), osteosarcoma (U2OS) and) and neuroblastoma (IMR32, Kelly, SKNFI) cancer cell lines and non-cancerous foreskin fibroblasts(VH-10, BjhTERT). We found cancer-specific synergistic drug interactions between nedisertib and OXC-101. Combined treatment of nedisertib and OXC-101 to H460 and MP46 increased expression of s10H3 (mitotic marker) and the apoptosis marker (cPARP) compared with single treatment. However, there was no additional increase in expression of the DNA damage markerγH2AX with combined treatment. We also performed annexin V staining by FACS on MP38 andMP48 cells and observed a significant increase in the apoptotic population with combination treatment compared

with single treatment. Imaging live cells, we observed a significant delay or arrest in the mitotic phase followed by death of cancer cells in mitosis in response to combination treatment, whereas cells treated individually with nedisertib or OXC-101 continued to proliferate and progress to the next phase of the cell cycle. These data suggest that the DNA-PK inhibitor may enhance the cytotoxic effect of OXC-101specifically in cancer cells. In addition, we will conduct an in-depth mechanistic study of how depletion/inhibition of DNA-PK enhances the cytotoxicity of OXC-101 and validate the drug combination in an appropriate preclinical mouse model.

Visualizing dynamics of long non-coding RNA TUG1 in live glioblastoma cells

Ayaka Minematsu. *Nagoya University, Nagoya, Japan*

Long non-coding RNAs (lncRNAs) are transcripts longer than 200 nucleotides that are not translated into proteins. lncRNA TUG1 (taurine upregulated gene 1) is highly expressed in various cancers, including glioblastoma. Previously we found that TUG1 is an essential molecule for cancer cells to cope with excessive replication stress in the S phase. Albeit its importance to cell cycle-related function, how it is dynamically regulated during the cell cycle is entirely unknown. Here, we established a system visualizing endogenous TUG1 molecules in live cells. TUG1 was tagged with stem-loop motifs recognized by a specific binding protein fused with GFP. We tracked TUG1 RNA by the GFP signal for 22 hours in T98G glioblastoma cells and found that the expression started from the later G1 phase. When cells were treated with Hydroxy Urea, a chemical that interferes with replication and increases replication stress, the expression of TUG1 was further upregulated in the S phase within 20 mins. We also observed some TUG1 molecules accumulated in several nuclear locations. It may indicate that TUG1 assembles to protect damaged DNA loci efficiently. Our results suggest that the expression of TUG1 is regulated in a cell cycle-dependent manner and is strongly connected with its function of TUG1. The current live-cell imaging system could help further discover the critical roles of TUG1 in cancer cells.

Combined inhibition of AXL and ATR enhances replication stress, cell death and immune response in small cell lung cancer

Kavya Ramkumar, C. Allison Stewart, Azusa Tanimoto, Qi Wang, Yuanxin Xi, Benjamin B. Morris, Runsheng Wang, Li Shen, Robert J. Cardnell, Jing Wang, Carl M. Gay, Lauren A. Byers. *UT MD Anderson Cancer Center, Houston, TX*

Small cell lung cancer (SCLC) is an aggressive neuroendocrine lung tumor. Despite high initial responses to frontline chemo-immunotherapy, therapeutic resistance develops rapidly. There are limited treatment options in the relapsed setting, where the prognosis remains dismal. SCLC tumors experience continuous and high levels of replication stress (RS) due to ubiquitous loss of key cell cycle checkpoints, *RB1* and *TP53*. Frequent amplification and high expression of the transcription factor *cMYC* further contribute to increased RS. Thus, high levels of RS expose a potential SCLC vulnerability and provide a therapeutic opportunity. Our group and others have shown that AXL, a TAM family receptor tyrosine kinase that is highly expressed in mesenchymal tumors, mediates resistance to chemotherapy, radiation and targeted therapies in SCLC, non-small cell lung cancer and other cancers, through its role in driving epithelial to mesenchymal transition (EMT). More recently, a novel role for AXL in DNA damage repair and tolerance has emerged. Therefore, we hypothesize that AXL targeting may be a potential therapeutic approach in SCLC. We first investigated the transcriptomic expression profile of *AXL* in SCLC clinical cohorts. *AXL*-high tumors were seen in a subset of treatment-naïve SCLC tumors, frequently among, but not limited to, the inflamed SCLC subtype. *AXL* expression was also seen in many relapsed SCLC tumors. As expected, tumors with high *AXL* expression also expressed several mesenchymal genes and higher EMT scores. Interestingly, among the treatment-naïve SCLC tumors, *AXL* expression was inversely correlated with a RS signature (rho=-0.54, $p<0.001$). Next, we tested the effects of AXL inhibition in SCLC *in vitro* and *in vivo* models. In a panel of 30 SCLC cell lines, bemcentinib, a selective AXL inhibitor in clinical trials for various advanced solid tumors, exhibited a range of antiproliferative activity, with IC_{50} values ranging from 41 nM to 10 μM (median IC_{50} 3.1 μM). Bemcentinib also significantly delayed tumor growth in *in vivo* SCLC models. Biomarkers associated with sensitivity to bemcentinib in SCLC cell

lines included markers of RS (cMYC, replication stress score) and DNA damage response (phospho CHK1^{S345}, phospho CHK2^{T68}). Bemcentinib also induced RS, indicated by the activation of ATR/CHK1-mediated RS response pathway, and DNA damage, and the combination with an ATR inhibitor (ceralasertib) showed a greater than additive effect. In a syngeneic model of SCLC, the combination of bemcentinib, ceralasertib and an anti-PDL1 antibody induced significant tumor regression. Together, these promising findings demonstrate that AXL inhibition may be an effective strategy to target the RS vulnerability common in SCLC.

Targeting DNA polymerase theta and ATM leads to synergistic killing of mantle cell lymphoma cells

Jithma Prasad Abeykoon[1], Shuhei Asada[2], Kalindi Parmar[2], Xiaosheng Wu[1], Thomas Witzig[1], Geoffrey Shapiro[2], Alan D. D'Andrea[2]. *[1]Mayo Clinic, Rochester, MN,[2]Dana-Farber Cancer Institute, Boston, MA*

Introduction: Rapid cell proliferation requires intact and faithful DNA damage repair mechanisms. DNA polymerase theta (POLQ) plays a key role in repairing DNA double-strand breaks through the microhomology-mediated end-joining (MMEJ), which is one of the three main pathways involved in repairing replication-induced double-strand breaks. Limited data have suggested that concurrent depletion of POLQ and ataxia-telangiectasia mutated (ATM) could be embryonic lethal. Hence, this phenomenon has the potential to be exploited for therapeutic benefit in cancers where ATM mutations are commonly seen. Mantle cell lymphoma (MCL) is a non-Hodgkin lymphoma marked by (11;14) translocation with ATM alterations seen in 40-50% of patients. There is an unmet need to find novel therapeutic strategies, especially in relapsed and/or refractory (R/R) MCL. Here, we investigated whether targeting POLQ and ATM could be a potential therapeutic strategy in MCL.
Methods: *In vitro* studies were conducted by using MCL cell lines. CRISPR-Cas9 system was used to genetically deplete POLQ and ATM genes and sgRNAs co-expressing fluorescence markers were used to track the cell population with respective genotypes over time. Cell viability was assessed by CellTiter-Glo assay and flow cytometry. All cell lines were profiled for ATM expression and activity. A p-value of < 0.05 was

considered statistically significant. The combination index of <1 was defined as synergistic.
Results: CRISPR-Cas9-mediated depletion of POLQ significantly decreased cell proliferation in multiple MCL cell lines. In particular, Granta-519, which possesses a single copy of kinase-dead ATM that is reduced in expression, was most sensitive to POLQ depletion. Concurrent genetic depletion of ATM and POLQ resulted in a synergistic antiproliferative effect in ATM-proficient MCL cell lines. Subsequently, this cellular phenotype caused by the genetic intervention was recapitulated by using two POLQ inhibitors (novobiocin and ART558) and an ATM inhibitor (AZD0156). *In vitro*, single-agent treatment with novobiocin or ART558 caused a significant cytotoxic effect at physiologically relevant concentrations in ATM-deficient cells and co-treatment of novobiocin or ART558 with AZD0156 was synergistic in killing ATM-proficient MCL cells. Importantly, POLQ inhibitors significantly decreased the cell viability of MCIR1, which is an ibrutinib-resistant MCL cell line. Mechanistically, novobiocin or ART558 treatment induced gH2AX and cleaved PARP upregulation, which was further enhanced by ATM depletion, suggesting that co-inhibition of POLQ and ATM caused apoptosis due to the accumulation of unrepaired DNA damage.
Conclusion: POLQ is a promising target in MCL, especially in ATM-deficient setting. In ATM-proficient MCL, targeting ATM and POLQ is synergistic. Our data has the potential to uncover novel biomarker-driven drug therapy of POLQ inhibitors in R/R MCL.

#6209
O6-methylguanine as the junction of MGMT and PARP1-mediated repair pathways
Jodie D. Cropper, Dauren S. Alimbetov, Kevin T. G. Brown, Andrew Robles, Rostislav I. Likhotvorik, James T. Guerra, Yidong Chen, Youngho Kwon, Raushan T. Kurmasheva. *Greehey Children's Cancer Research Institute, San Antonio, TX*

Temozolomide is the first-choice DNA alkylating agent and has been commonly used in oncology over the last several decades. The cytotoxicity that temozolomide elicits through the methylation of guanine and adenine residues often becomes the limiting factor in effective treatment. Despite

growing evidence of dysregulated alkylating DNA damage repair as a driving force of genome instability leading to cancer, neurological diseases, and premature aging, little is currently known about the coordinated role of PARP1 and MGMT (O6-methylguanine methyltransferase) enzymes in the repair of temozolomide-induced methylated DNA lesions. A major PARP1 function in DNA damage is facilitation of repair of the methylated DNA lesions, N6-methyladenine and N7-methylguanine, via base excision repair (BER); while MGMT restores guanine in O6-methylguanine (O6meG), the most cytotoxic adduct, by a one-step catalysis. It is generally thought that BER and MGMT represent two distinct mechanisms for removing DNA damage induced by alkylating agents; however, using a number of advanced cell-free and cell-based approaches, we provided evidence for direct (DNA-independent) and indirect (through PARylation) interaction between PARP1 and MGMT and demonstrated a functional crosstalk between these repair pathways. Particularly, O6meG repair activity is increased once PARP1 PARylates MGMT. Further, longer (more clinically relevant) exposure to temozolomide induced stronger MGMT PARylation in cells, indicating that the PARP1-MGMT interaction is important for enhanced O6meG repair and cell survival. As PARP1-MGMT complex forms in a variety of cancer cell types, our findings have strong implications for the development of an effective cancer therapy for cells dependent on PARP1 and MGMT mediated DNA repair.

#6210

Combination of M1774 and niraparib can overcome ATR and PARP inhibitor resistance in BRCA1 mutated ovarian cancer models

Jie Hao[1], Arindam Bose[2], Golbahar Sadatrezaei[2], David B. Martignetti[2], Yuqing Jiao[2], Alexandre André B. A. da Costa[2], Jean-Bernard Lazaro[2], Bose Kochupurakkal[2], Huy Nguyen[2], Kalindi Parmar[2], Alan D. D'Andrea[2], Geoffrey I. Shapiro[1]. *[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Radiation Oncology, Dana-Farber Cancer Institute, Boston, MA*

PARP inhibitors are being used in maintenance treatment of *BRCA*-mutated high-grade serous ovarian cancer (HGSOC). However, *de novo* and acquired resistance to PARP inhibitors, resulting from restoration of homologous recombination repair or stabilization of replication forks, is a

pressing clinical problem. ATR inhibitors are known to reverse both of these mechanisms of PARP inhibitor resistance and are currently in clinical development. In this study, we assessed the activity of a novel ATR inhibitor, M1774, as a monotherapy and in combination with PARP inhibition in HGSOC preclinical models. M1774 exhibited single-agent activity across a panel of ovarian cancer cell lines with induction of DNA damage. We used a panel of *BRCA1*-mutated patient-derived xenograft (PDX) models of HGSOC with acquired PARP inhibitor resistance and identified two M1774-sensitive models and one M1774-resistant model. M1774 monotherapy demonstrated anti-tumor activity in mice bearing sensitive PDX models of HGSOC with PARP inhibitor resistance. In the M1774-sensitive models, the combination of M1774 and niraparib augmented the degree and durability of response compared with M1774 monotherapy. The combination of M1774 and niraparib also demonstrated synergistic anti-tumor activity in the M1774-resistant model, indicating that the combination could overcome monotherapy resistant to either agent. We also generated organoid cultures from these PDX models. Treatment of the organoid models with M1774, niraparib or the combination faithfully recapitulated the anti-tumor activities seen in vivo. Mechanistically, M1774-resistant organoid cultures demonstrated stable replication forks and an absence of replication stress. The combination of M1774 with niraparib resulted in destabilization of the replication forks. In contrast, M1774-sensitive organoids exhibited unstable replication forks, which were further destabilized by the niraparib combination. In addition, the sensitive models demonstrated higher basal levels of replication stress, as detected by increased levels of phospho-RPA. Collectively, these results indicate that the combination of M1774 and niraparib can overcome PARP inhibitor resistance and ATR inhibitor resistance in *BRCA1*-mutant ovarian cancer PDX models and demonstrate the utility of organoid cultures for discerning mechanisms of resistance and strategies to restore drug sensitivity. Combined M1774-mediated ATR inhibition and PARP inhibition may be a promising therapeutic strategy for the treatment of ovarian cancer.

Development and validation of a novel sSTRIDE-MMR functional assay to study the efficiency of MMR inhibitors

Kamil Solarczyk, Karolina Uznańska, Olga Wójcikowska, Maja Białecka, Agnieszka Waligórska, Szymon Koman, Magdalena Kordon-Kiszala.
intoDNA, Kraków, Poland

Mismatch repair (MMR) is considered to be one of the fundamental pathways that guards genome stability and mutations in genes encoding for crucial MMR proteins have been shown to promote cancer initiation. On the other hand, inactivation of MMR components in cancer cells leads to increased neoantigen formation and in consequence, exposes the tumor to the immune system. Therapeutic strategies aiming at inhibiting MMR are thus under development, yet methods reporting on the status of MMR are lacking. We report here the development, optimization and validation of a first MMR-specific functional assay. The assay, which is based on the STRIDE platform technology, detects DNA nicks localized in close proximity to PMS2 protein and can thus be utilized as a direct reporter of inhibition of PSM2 itself or upstream acting proteins. The optimization phase of assay development was performed in U2OS cells. First, in untreated cells we have shown that the sSTRIDE-MMR signals constitute ca. 10-15% of total single-strand DNA breaks foci detected by the classic sSTRIDE assay variant. In a series of technical negative controls we have then shown that the number of false-positive foci never exceeds 10% of the total number of signals, with as little as 2% for the isotype controls. The assay was further validated in HAP1 wild-type and PMS2-KO isogenic cell line pair. As expected, the number of sSTRIDE-MMR foci in the PMS2-KO cell line was significantly lower than in wild-type cells and additionally, no response to the treatment with 6TG, a known inducer of MMR, was detected in PMS2 null cells. Finally, the assay was used to verify the efficiency of first-in-class small-molecule MMR inhibitors. After treatment with the compounds, the number of detected sSTRIDE-MMR foci was significantly lower when compared to the number of foci in untreated cells. In conclusion, we show here that sSTRIDE-MMR is an assay characterized by high specificity, low false positives rate and a high-dynamic range. We believe that sSTRIDE-MMR can prove to be a very useful cell-based solution to study the efficiency of MMR inhibitors.

#6212

Inhibition of ATM-dependent checkpoint control and DNA double-strand break repair enhances the efficacy of ATR inhibitors

Audrey Turchick[1], Astrid Zimmermann[2], Li-Ya Chiu[1], Heike Dahmen[2], Brian Elenbaas[1], Frank T. Zenke[1], Andree Blaukat[2], Lyubomir T. Vassilev[1]. *[1]Research Unit Oncology, EMD Serono, Billerica, MA,[2]Research Unit Oncology, Merck KGaA, Darmstadt, Germany*

Ataxia telangiectasia and Rad3 related (ATR) and ataxia telangiectasia mutated (ATM) protein kinases play key roles in the DNA damage response (DDR) by responding to replication stress and double-strand DNA breaks respectively to pause the cell cycle and promote DNA repair. ATR kinase inhibition in cancer cells disrupts cell cycle control and causes unrepaired DNA lesions and cytotoxicity. Accordingly, several ATR inhibitors (ATRi) are in clinical development as monotherapies and in combination with DNA damaging chemotherapies and poly(ADP-ribose) polymerase (PARP) inhibitors. Here we show that while treatment of cancer cells with an ATRi inhibits the ATR pathway, it simultaneously activates the ATM signaling pathway as shown by increased levels of p-ATM, p-CHK2, p-KAP1 and p-p53. In p53 wild-type cancer cells, ATR inhibition causes an ATM-mediated G1 cell cycle arrest which diminishes the DNA lesions and cytotoxic effects of ATR inhibition. Combination of an ATRi with a selective ATM inhibitor (ATMi) synergistically potentiated efficacy in cancer cells *in vitro* and increased efficacy *in vivo* at doses that did not show overt toxicities. In a panel of patient-derived xenograft (PDX) models of triple-negative breast cancer treated with an ATRi/ATMi combination, substantial improvement in efficacy was observed. Thus, activation of the ATM pathway by an ATRi acts as a compensatory resistance pathway for ATR inhibition. These results suggest a novel and efficacious combination approach for cancer therapy by dual inhibition of these two key DDR kinases.

Disruption of XPF function by HPV promotes alternative end joining and sensitivity to cisplatin in HNSCC

Qi Liu[1], Nan Zuo[1], Lin Ma[2], Lanlan Wei[3]. *[1]Shenzhen Bay Laboratory, Shenzhen, China,[2]Department of Stomatology, General Hospital, Shenzhen*

University, Shenzhen, China,[3]The Second Affiliated Hospital of Southern University of Science and Technology, Shenzhen, China

Human papillomavirus (HPV) positive head and neck squamous cell carcinoma (HNSCC) usually show a tremendous better clinical outcome compared to their HPV-negative counterparts. Although the HPV associated survival advantage is partially explained by the enhanced cisplatin sensitivity in HNSCC (Clin Ca Res 2018, 24(23): 6001), the underlying mechanisms are still poorly elucidated. Cisplatin causes DNA interstrand crosslinks (ICLs) that requires Fanconi anemia (FA) pathway for DNA repair. Consistently, our study showed that HPV-positive HNSCC cells exhibited a FA defective cellular phenotype. In clonogenic cell survival assay, 1h treatment with 5μM cisplatin eliminated approximately 56.7% more HPV-positive HNSCC cells than HPV-negative ones. Furthermore, HPV-positive cells treated with cisplatin showed prolonged G2/M cell cycle arrest and more 53BP1 foci, indicating profound deficiency in repairing ICLs. Consistent with these findings, increased aberrant chromosome formation was observed in HPV-positive cells following Mitomycin C treatment. In order to reveal the mechanism, we further interrogated HPV-labeled HNSCC samples in TCGA database, and identified XPF, an endonuclease protein in FA pathway, was downregulated in HPV-positive HNSCC. Further analysis of cellular and clinical samples confirmed that both mRNA and protein expressions of XPF were significantly lower in HPV-positive HNSCC ($P<0.001$). To test the importance of XPF in HPV-induced cisplatin sensitivity, we performed a cell viability assay, and found that knock-down of XPF increased the effects of cisplatin on HPV-negative HNSCC by 39.54% (± 4.42%), while no significant change was observed in HPV-positive HNSCC ($P>0.05$). Notably, inhibition of XPF function by a small molecule inhibitor recapitulated the effect of HPV, resulted in enhanced error-prone DNA repair with alternative end-joining (alt-EJ). In a probe-based ddPCR assay, XPF inhibition increased 32.02% (± 5.80%, $P<0.001$) alt-EJ events in HPV-negative HNSCC cells, while little difference was detected in HPV-positive cells. Thus, we speculated that combined inhibition of XPF and alt-EJ may improve clinical outcome in the difficult-to-treat, HPV-negative HNSCC, which worth further research efforts.

FANCA promotes transcription-coupled homologous recombination by catalyzing R-loops formation

Fang Li. *University of Miami Miller School of Medicine, Miami, FL*

R loops arise from hybridization of RNA transcripts with template DNA during transcription, which are not only cause DNA damage in certain contexts as cancer hallmarks but also be important regulators of cellular processes. Recent findings revealed that DNA double-strand breaks (DSBs) elicit RNA-DNA hybrid formation. The RNA moiety of the R-loop displays an extraordinary potential to regulate multiple steps of homologous recombination (HR) by substituting for the double-stranded DNA (dsDNA) substrate on which DSB repair processes naturally occur. Here, we use the Damage At RNA Transcription assay to reveal colocalization of FANCA with R-loops in a highly transcribed genomic locus upon DNA damage. We further demonstrate FANCA participates in forming R-loops in the initial DSBs repair stage and assists in removing R-loops later. Besides, we find that highly purified human FANCA anneals synthetic single-stranded RNA (ssRNA) and ssDNA species to R-loops and binds R-loop substrates with high affinity, preferring guanine-rich sequences in vitro. Importantly, we illustrate that FANCA promotes HR efficiency via catalyzation of DNA: RNA hybrids at DSBs sites. Finally, a series of RNA and R-loop substrates are found to stimulate ID2 monoubiquitination, with activity corresponding to remove transient R- loops in later HR stage. In summary, our results support a mechanism whereby FANCA promotes the formation of temporary R-loops by annealing ssRNA and ssDNA species at DSBs in transcribed regions, thereby stimulating HR.

Peposertib, a DNA-PK inhibitor, enhances the antitumor efficacy of anthracyclines in triple-negative breast cancer models in vitro and in vivo

Steffie Revia[1], Christian Sirrenberg[1], Antonia Schach[1], Astrid Zimmermann[1], Frank T. Zenke[2], Joachim Albers[1]. *[1]Merck Healthcare KGaA, Darmstadt, Germany,[2]EMD Serono, Billerica, MA*

Background: Triple-negative breast cancer (TNBC) is the most lethal breast cancer subtype, exhibiting poor response rates toward current chemotherapy regimens and lacking additional effective treatment options. Approximately 30% of patients with TNBC respond well to anthracycline/taxane-based standard-of-care chemotherapy regimens. However, remaining patients demonstrate limited improvements in clinical outcomes, highlighting the critical need for effective strategies to improve anthracycline/taxane-based chemotherapy (1, 2). DNA-dependent protein kinase (DNA-PK), a member of the phosphoinositide 3-kinase-related kinase protein family, promotes nonhomologous end joining (NHEJ) as part of the DNA damage response. Peposertib is a potent, selective, and orally bioavailable DNA-PK inhibitor that strongly potentiates the antitumor effects of ionizing radiation and DNA double-strand break-inducing agents, including anthracyclines, in preclinical models. Here we report the synergistic antitumor effects of peposertib combined with topoisomerase II (TOPO II) inhibitors, particularly anthracyclines, in TNBC models in vitro and in vivo.
Methodology: Combinations of peposertib with TOPO II inhibitors were evaluated in TNBC cell lines by viability assays, immunoblotting, and flow cytometry. Gene expression analysis was performed using the nCounter PanCancer pathways panel and results were confirmed by quantitative polymerase chain reaction (qPCR). In vivo efficacy was assessed in cell-line derived and patient-derived xenograft models.
Results: When administered in combination with doxorubicin, epirubicin, and etoposide, peposertib exhibited synergistic antiproliferative activity in TNBC cell lines in vitro. The downstream analysis of pharmacodynamic biomarkers revealed induction of NHEJ mediated repair upon TOPO II inhibitor treatment and provided mechanistic insights into the synergistic antitumor effects of peposertib combined with TOPO II inhibitors. Furthermore, this combination treatment induced ataxia telangiectasia mutated (ATM)-dependent compensatory signaling and inflammatory responses, potentially creating a proinflammatory tumor microenvironment. To evaluate whether peposertib enhanced the antitumor effects of TOPO II inhibitors in vivo, we established a well-tolerated preclinical treatment schedule for the combined use of peposertib and pegylated liposomal doxorubicin, which was capable of achieving tumor regression in patient- and cell line-derived xenograft models of TNBC.

Conclusion: Our findings suggest that cotreatment with the DNA-PK inhibitor peposertib can enhance the efficacy of anthracycline/TOPO II-based chemotherapies. *This work was supported by the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).*

Pre-ribosomal RNA mediates HR repair via the BRCA1/BARD1 complex

Duo Wu[1], Huang huang[1], Tenglong Chen[1], Xiaochen Gai[1], Song Liu[2], Hu He[2], Song Shi[2], Xiaochun Yu[1]. *[1]Westlake University, Hang Zhou Shi, China,[2]SynRx Therapeutics, Hang Zhou Shi, China*

The BRCA1/BARD1 complex plays a key role in DNA double-stand break (DSB) repair in both somatic cells and germ cells. However, the underlying molecular mechanism by which this complex mediates DSB repair remains elusive. Here, we show that the recruitment of the BRCA1/BARD1 complex to the unsynapsed axis of the XY body in male germ cells is mediated by pre-rRNA. Similarly, the BRCA1/BARD1 complex associates with pre-rRNA in somatic cells, which targets the BRCA1/BARD1 complex to DSBs. The interactions between the BRCT domains of the BRCA1/BARD1 complex and pre-rRNA induces liquid-liquid phase separations, which may be the molecular basis of DSB-induced nuclear foci formation of the BRCA1/BARD1 complex. Pre-rRNA also mediates BRCA1-dependent homologous recombination (HR). Cancer-associated mutations in the BRCT domains of BRCA1 and BARD1 abolish the interaction with pre-rRNA. We developed novel RNA pol I inhibitors to suppress pre-rRNA biogenesis, which not only abolished HR repair but also sensitized tumor cells to PARP inhibitor treatment. Collectively, this study reveals that pre-rRNA is a functional partner of the BRCA1/BARD1 complex in the DSB repair. It is also a potential therapeutic target for cancer therapy.

#6217

Inhibiting ataxia-telangiectasia mutated and RAD3-related (ATR) by BAY 1895344 overcomes chemoresistance to oxaliplatin and promotes synergistic anti-tumor effect in pancreatic cancer

Hye Won Shon[1], Jung Won Chun[2], Jeong Eun Gong[2], Mi Rim Lee[1], Yu-Sun Lee[2], Sumin Kang[1], Sunshin Kim[2], Sang Myung Woo[2], In Rae Cho[3], Woo Hyun Paik[3], Woo Jin Lee[2], Ji Kon Ryu[3], Yong-Tae Kim[3], Sang Hyub Lee[3], Yun-Hee Kim[2]. *[1]National Cancer Center Graduate School of Cancer Science and Policy, Goyang, Korea, Republic of,[2]Research Institute and Hospital, National Cancer Center, Goyang, Korea, Republic of,[3]Department of Internal Medicine and Liver Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of*

Pancreatic Ductal Adenocarcinoma (PDAC) is a highly aggressive disease with a poor prognosis and a limited response to most of the treatments. Despite a platinum-based drug such as oxaliplatin or cisplatin is one of the most effective chemotherapy drugs for PDAC, resistance to it is a major limiting factor in PDAC treatment, indicating an urgent need for new approaches. Recently, targeting major DNA damage response (DDR) regulators such as ATM (Ataxia-telangiectasia mutated) or ATR (Ataxia telangiectasia mutated and Rad3-related) kinase has shown therapeutic potential in cancer treatment. This shows that it may be possible to enhance the responsiveness of platinum medicines via a DDR inhibition strategy. The most recently developed ATR inhibitor with the greatest potency, BAY 1895344, showed an anti-proliferative effect in clinical trials. Here, we aimed to evaluate the effect of ATR inhibition using BAY 1895344 on responsiveness to oxaliplatin in pancreatic cancer, for the first time. CFPAC-1 and Capan-2 are selected among six kinds of pancreatic cancer cell lines as oxaliplatin-sensitive and -resistant cells, respectively. According to BRAID analysis, combining the BAY 1895344 and oxaliplatin resulted in strong synergistic effects in both cell lines, particularly in Capan-2. The synergism is also confirmed in all four organoids derived from PDAC patients. We found that p-Chk1, coordinating DDR and cell cycle checkpoint, was considerably suppressed by the combined treatments, which was associated with elevated γ-H2AX intensity, cell cycle arrest and apoptosis. Moreover, we investigated the in vivo synergistic anti-tumor efficacy of combination therapy using a tumor-

bearing nude mice model with CFPAC-1 and Capan-2 cells, demonstrating a substantial reduction of tumor growth in combination therapy when compared to single treatment. In conclusion, ATR inhibition enhanced the anticancer effect of oxaliplatin, and this combined therapeutic strategy may be effective in overcoming chemo-resistance in PDAC. (This study is supported by National Cancer Center, Republic of Korea (No. 2212470, 2010330))

NKX3.1 immunohistochemistry and methylome profiling in mesenchymal chondrosarcoma: additional diagnostic value for a well defined disease?

Salome Glauser[1], Baptiste Ameline[1], Vanghelita Andrei[1], Dorothee Harder[2], Chantal Pauli[3], Marcel Trautmann[4], Wolfgang Hartmann[4], Daniel Baumhoer[1]. *[1]Bone Tumour Reference Centre, Institute of Medical Genetics and Pathology, University Hospital Basel, Basel, Switzerland,[2]Department of Radiology, University Hospital Basel, Basel, Switzerland,[3]Department of Pathology and Molecular Pathology, University Hospital Zurich, Zurich, Switzerland,[4]Gerhard-Domagk-Institute of Pathology, University Hospital Munster, Munster, Germany*

Background: Mesenchymal chondrosarcoma (MCS) is a high-grade sarcoma characterized by a biphasic histological appearance. However, more often than not, only the poorly differentiated component is present on a biopsy, thus more entities enter the differential diagnosis. Since the small cell component is morphologically non-specific, the differential diagnoses are broad, such as Ewing sarcoma, rhabdomyosarcoma, poorly differentiated synovial sarcoma small cell carcinoma, lymphoma and also melanoma. Morevoer, although the *HEY1::NCOA2* gene fusion is present in almost all MCS, some studies have shown alternative alterations in the absence of the *HEY1::NCOA2* fusion, suggesting genomic heterogeneity in at least a small subset of MCS. Thus, new diagnostic aids would be helpful to confirm the diagnosis. While most of the immunohistochemical profile overlaps between these tumours, NKX3.1 was recently proposed as a useful diagnostic marker for MCS. Furthermore, studies using DNA-methylation profiling show that MCS forms a distinct methylation cluster. The aim of this study is to evaluate the utility of these new diagnostic tools.

Methods: Slides from 45 samples with MCS were stained with NKX3.1 antibody (EP356, Cell Marque, Roche) and were also investigated by methylome analysis (Mehylation Epic BeadChips, Illumina). Depending on tissue availability, the cases were subjected to *HEY1::NCOA2* gene fusion testing.
Results: The methylation profile showed a distinct cluster for mesenchymal chondrosarcoma, in line with the previous studies. Moreover, these findings were reproduced even when submitting tissue solely from one component, either the cellular or the cartilaginous one. In addition, the copy number profile derived from the methylome analysis proves its utility in distinguishing MCS from its mimics. On the other hand, only 32.6% of cases were positive for NKX3.1. Four samples initially diagnosed as MCS were histologically re-evaluated due to an atypical methylome profile, a high amount of CNV and/or lack of validation of the gene fusion. Methylation profiling led to the re-classification of three cases, whereas the fourth sample could not be further classified.
Conclusions: We conclude that the methylation analysis, along with the copy number profile, are reliable tools in terms of diagnosing MCS. On the contrary, the immunomarker NKX3.1 shows contradicting results, proving itself as an unreliable marker in this setting.

Endogenous human retroviruses in epithelial ovarian cancers: An exploratory analysis
Jill Alldredge[1], Vinay Kumar[2], Brook Sanders[1], Farahnaz Rahmatpanah[2].
[1]University of Colorado Anschutz Medical Campus, Aurora, CO,[2]University of California, Irvine, Orange, CA

Objectives: Endogenous human retroviruses (ERVs) are remnants of exogenous retroviruses that gained access to germline cells allowing integration into the human genome. Emerging data suggest that some ERVs may become activated allowing epigenetic alterations through DNA methylation or histone modification, which can further alter gene regulation. This may serve as a targeted therapeutic opportunity in modulating oncogenesis, through aberrant oncogene activation or tumor suppressor gene inactivation. This is an emerging area of exploration in ovarian cancer.

Methods: We applied our ERV mapping tools (1) to RNA-seq data from 24 female patients with ovarian, fallopian tube, or primary peritoneal cancers to investigate expression of ~550,000 ERV elements from the Human Endogenous Retrovirus database (HERVd) (2, 3). Univariate Cox regression models were constructed with normalized ERV expression data and the most significantly differentially expressed ERVs were then filtered using a penalized Lasso-Cox proportional-hazards model. ERV expression, alongside the available clinical data (including age, histotypes, and tumor stage) were provided as inputs and linear predictors generated by the model separated samples into either high or low risk categories. We identified a panel of 15 predictive ERVs and these risk evaluations allowed for Kaplan-Meier analyses of survival by clinical parameters alone versus combined with ERV signature. We also performed a secondary analysis of platinum resistant ovarian cancers using RNA-seq data (GSE102118) to investigate the effect of demethylating agent guadecitabine on ERV expression (n=9) (4).

Results: Exploratory analyses of ERVs demonstrated significantly different expression between histologies (clear cell, mucinous, endometrioid, high grade serous) and FIGO disease stage. In our prognostic model, Kaplan-Meier survival analysis using only clinical parameters resulted in a significance level of 0.0013, however the supplemented model combining the 15-ERV panel and the clinical data discriminated the two risk groups for time to recurrence at a much higher significance level of $p = 7.076 \times 10^{-8}$. Included in the 15 ERV panel are HERVK, HERV3, and several putative ERV promoters including LTR12, LTR7, LTR3 and LTR4 (5). In our secondary analysis of platinum-resistant patients, the ERV transcripts were compared for each patient pre- and post-guadecitabine treatment and there were several ERVs with risk-predictive values induced in patients receiving guadecitabine including LTR7, LTR12 and HERVK.

Conclusions: In summary, ERV RNA expression in ovarian cancer is significantly different between histologies and disease stages. The ability to successfully classify patients as either high-risk or low-risk for disease progression is of considerable value for patient management and ERVs may improve prognostication and guide future therapeutic targeting.

#6220

Development of a mutation profiling NGS assay to facilitate clinical decisions in hematologic malignancies.

Grant Hogg[1], Tong Liu[1], Helen Cao[1], Adib Shafi[1], Ashraf Shabaneh[1], John Howitt[2], Amanda Williamson[2], Rachel Dango[2], Xiaojun Guan[3], Heidi Hoffmann[4], Michael Mooney[5], John Pruitt[2], Scott Parker[2], Stan Letovsky[4], Li Cai[2], Eric A. Severson[2], Shakti Ramkissoon[2], Anjen Chenn[2], Marcia Eisenberg[6], Eyad Almasri[1], Taylor Jensen[5]. *[1]Oncology, Labcorp, San Diego, CA,[2]Labcorp, Durham, NC,[3]Labcorp, San Diego, CA,[4]Labcorp, Westborough, MA,[5]Oncology, Labcorp, Durham, NC,[6]Labcorp, Burlington, NC*

Introduction: Accurate diagnosis, prognosis and treatment of hematologic disorders from both myeloid and lymphoid origin requires assessing somatic mutation status in an increasingly large number of genes. Here we present the results of the assay development and validation of a targeted next generation sequencing panel which provides full exon sequencing of 141 genes associated with myeloid and lymphoid malignancies, as well as the ability to detect clinically relevant copy number alterations (CNAs) and certain sub-gene level CNAs.

Methods: Based on review of clinical guidelines, 141 genes including 72 myeloid and 84 lymphoid associated genes were selected. The assay interrogates all coding exons of the 141 genes to detect single nucleotide variants (SNVs) and insertions/deletions (indels). The assay also identifies CNAs in 16 genes, *FLT3* internal tandem duplicates (ITDs), and select non-coding pathogenic variants. The custom hybrid capture-based assay utilizes genomic libraries created from 250 ng gDNA extracted from peripheral blood or bone marrow followed by sequencing on Illumina sequencers. Concordance studies were performed on clinical samples previously assessed using an orthogonal NGS-based laboratory developed test for SNVs/Indels or digital multiplexed ligation-dependent probe amplification for CNAs. In addition, analytical sensitivity was assessed using cell line dilution series and specificity by reference samples from Genome in a Bottle (GIAB). Small indels were defined as <25bp while long indels are ≥ 25bp.

Results: Interim estimates of positive percentage agreement (PPA) and specificity have been determined for SNV/Indels, *FLT3*-ITDs, and CNVs,

with further testing ongoing. PPA of SNVs was 100% (218/218 SNVs; n = 134 samples). PPA was also 100% for both small indels (21/21; n = 14 samples) and long indels (6/6; n = 6 samples). A dilution series of 8 positive clinical samples at 4 different dilutions showed SNV and small indel detection of 100% at allele frequency (AF) ≥ 3%. Long indel detection was 87.5% at AF ≥ 5%. *FLT3*-ITD was evaluated with 2 cell line samples at 5 different dilutions with 100% detection at AF ≥ 5%. PPA of CNAs were 95.7% (157/164) in 46 clinical samples. CNA detection was also evaluated with 8 cell line samples at 4 different dilutions showing 92.3% detection at a copy number ratio threshold ± 0.15. A preliminary estimate of specificity was determined using 4 replicates of the GIAB sample, NA12878, and was >99.99% for SNVs and small indels (n=6.9 x 10^5). Finally, a model for gender classification was created using a training cohort of 70 clinical samples. The performance was evaluated on a test set of 144 clinical samples with 100% PPA (144/144).
Conclusions: Taken together, these data demonstrate that the developed NGS assay is a sensitive, specific, and accurate assay with high clinical utility to inform treatment decision making in hematologic malignancies.

#6221
Support for targeted therapy selection in triple negative breast cancer patients using aberrant signal transduction pathway activity profiles
Diederick M. Keizer, Yvonne J. W. Wesseling, Dianne A. M. van Strijp, Saskia M. J. Vermeer, Eveline C. A. den Biezen. *InnoSIGN B.V., Eindhoven, Netherlands*

Introduction: Success of therapeutic interventions largely rely on the pathological and biological characteristics of the tumor and varies due to the heterogeneous nature of breast cancers. Triple negative breast cancers (TNBC) stain IHC negative for both hormone receptors (ER, PR) and HER-2. TNBC is usually treated with chemotherapy because of absence of any molecular target. This study is initiated to characterize TNBC based on a new methodology that measures and quantifies signal transduction pathways (STPs) activities to reveal potential tumor-driving STPs in TNBC and create new options for targeted therapy.
Method: Using the mRNA-based OncoSIGNal pathway activity profiling PCR test (InnoSIGN) STP activities of 7 pathways (AR, ER, PI3K, MAPK,

HH, TGFβ and Notch) in 39 samples from normal breast tissue and 12 TNBC patients were quantified and expressed on a scale from 0-100. Normal healthy breast tissue was obtained from breast reduction surgery and areas where epithelial cells content was at least 50% were annotated and harvested for mRNA isolation and STP analyses. The normal STP activity is representing the normal physiological activity and is used as reference value. Aberrant high pathway activity in a patient tumor sample was concluded when this score was higher than twice the standard deviation above the mean of normal breast tissue STP activity.
Results: STP thresholds for interpretation of high aberrant activity were determined from 39 normal breast samples. Using these thresholds, STP activities in 12 TNBC samples were analyzed. In these TNBC samples, MAPK was in 75%, HH in 67%, PI3K in 58%, and AR, Notch and TGFβ were in 17% of the cases above the thresholds. In 50% of the cases a combination of MAPK and HH or a combination of PI3K and HH were found above thresholds. In 42% of the cases MAPK in combination with PI3K were above thresholds. Increased activity of AR was never observed in combination with increased HH activity.
Conclusion: By using the OncoSIGNal test high aberrant STP activities could be determined in TNBC patient samples. Results show that different pathways are aberrantly active, depending on the patient sample, which opens the opportunity for personalized targeted treatment of individual TNBC patients.
Next steps: The TNBC data set will be extended to further profile the STP activity in relation to different clinical outcomes and to investigate new opportunities for targeted therapies.

#6222

Clinical impact of p53 and AXL immunostaining on the efficacy of immune checkpoint inhibitor-based therapy after osimertinib treatment in patients with epidermal growth factor mutant non-small cell lung cancer

Kenji Morimoto, Tadaaki Yamada, Shinsaku Tokuda, Koichi Takayama.
Pulmonary Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan

Background: Current evidence indicates that immune checkpoint inhibitors (ICIs) have a limited efficacy in patients with lung cancer harboring epidermal growth factor receptor (*EGFR*) mutations. However, there is a lack of data on the efficacy of ICIs after osimertinib treatment, and the predictors of ICI efficacy are unclear.
Methods: We retrospectively assessed consecutive patients with *EGFR*-mutant NSCLC who received ICI-based therapy after osimertinib treatment at 10 institutions in Japan, between March 2016 and March 2021. Immunohistochemical staining was used to evaluate the expression of p53 and AXL. The deletions of exon 19 and the exon 21 L858R point mutation in *EGFR* were defined as common mutations; other mutations were defined as uncommon mutations.
Results: A total of 36 patients with advanced or recurrent *EGFR*-mutant NSCLC were analyzed. In multivariate analysis, p53 expression in tumors was an independent predictor of PFS after ICI-based therapy ($p = 0.002$). In patients with common *EGFR* mutations, high AXL expression was a predictor of shorter PFS and overall survival after ICI-based therapy (log-rank test; $p = 0.04$ and $p = 0.02$, respectively).
Conclusion: The levels of p53 in pretreatment tumors may be a predictor of ICI-based therapy outcomes in patients with *EGFR*-mutant NSCLC after osimertinib treatment. High levels of AXL in tumors may also be a predictor of ICI-based therapy outcomes, specifically for patients with common *EGFR* mutations. Further prospective large-scale investigations on the predictors of ICI efficacy following osimertinib treatment are warranted.

Evaluating peroxiredoxins 1-6 and their potential as prognostic biomarkers for uterine corpus endometrial carcinoma
Lauren Lambros, Vien Sturm, Calli A. Davison-Versagli. *Biology, Saint Mary's College, Notre Dame, IN*

Introduction: Uterine corpus endometrial carcinoma (UCEC) is one of the most commonly diagnosed cancers in women in the United States, where the death rate continues to climb by 1.9% every year due to poor prognostic and therapeutic methodologies. Recently, altered expression patterns of peroxiredoxins (PRDX) (1-6), a family of antioxidant enzymes comprised of six known isoforms, has been connected to overall outcome in many

cancers. While recent studies have begun to unravel the potential of PRDXs as prognostic biomarkers in other cancers, PRDX expression patterns and their use as prognostic biomarkers in UCEC have yet to be explored. This study aimed to determine the value of PRDX1-6 as potential prognostic biomarkers for UCEC patients.
Methods: To determine the impacts of PRDX1-6 expression on overall survival (OS) and relapse-free survival (RFS), UCEC samples (n=543) from the TCGA database available on the Pan-Cancer RNA seq platform on Kaplan-Meier Plotter (KM plotter) were utilized. The patient cohort was split into groups according to high PRDX expression status and low PRDX expression status using the autoselect best cutoff function in KM plotter where all possible cutoff values between the lower and upper quartiles of PRDX expression were computed. The best-performing threshold was used as the cutoff and data was plotted in a Kaplan-Meier plot. Hazard ratio (HR), 95% confidence interval (95% CI), and log-rank P value were calculated using the KM plotter platform. For molecular analyses, a total of 507 UCEC samples obtained from the PanCancer Atlas on the cBioportal platform were analyzed for PRDX1-6 copy number alterations (CNAs), and mRNA expression Z-scores relative to all samples were used to evaluate the association between CNAs and transcriptional levels of PRDXs.
Results: Favorable OS associated with high PRDX2 (P=0.044, HR=0.65, 95% CI: 0.43-0.99) and high PRDX4 (P=0.01, HR=0.56, 95% CI: 0.36-0.88) mRNA levels. High PRDX2 (P=0.029, HR=0.56, 95% CI: 0.33-0.95) and high PRDX3 (P=0.034, HR=0.56, 95% CI:
0.33-0.96) expression in UCEC tumor samples correlated with favorable RFS. Shallow deletions were identified in PRDX2 (9.8%), PRDX3 (9.6%), and PRDX4 (14%) of the UCEC samples analyzed in cBioportal. Compared to diploid cells, shallow deletions in PRDX2 and PRDX3 correlated with decreased PRDX2 ($P=1.33 \times 10^{-12}$) and PRDX3 ($P=8.17 \times 10^{-13}$) mRNA levels, respectively. High expression of PRDX6 correlated with unfavorable OS (P=0.0021, HR=1.9, 95% CI: 1.25-2.88) and unfavorable RFS ($P= 4.3 \times 10^{-5}$, HR=2.88, 95% CI: 1.69-4.88). Notably, 41.2% of UCEC patients displayed PRDX6 copy number gain that correlated with increased PRDX6 mRNA levels ($P= 8.69 \times 10^{-24}$) compared to diploid cells.
Conclusion: High PRDX2, PRDX3, and PRDX4 expression could serve as favorable UCEC prognostic biomarkers, while high PRDX6 expression may be a novel unfavorable prognostic biomarker.

#6224

Exploring the integration of CMS subtyping and other omics in colorectal cancer classification and its reflection in stool miRNome and metagenome for non-invasive precision medicine

Amedeo Gagliardi[1], Giulia Francesca[1], Giulio Ferrero[2], Sonia Tarallo[1], Giulia Piaggeschi[1], Antonio Francavilla[1], Carla Di Battista[1], Enrico Berrino[3], Caterina Marchiò[3], Francesca Cordero[4], Barbara Pardini[1], Alessio Naccarati[1]. *[1]Italian Institute for Genomic Medicine (IIGM), Candiolo, Italy,[2]Department of Clinical and Biological Sciences, University of Turin, Turin, Italy,[3]Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy,[4]Department of Computer Science, University of Turin, Turin, Italy*

Background: The Consensus Molecular Subtypes (CMS) is a subtyping system used for colorectal cancer (CRC) to facilitate traditional tumor classification and clinical translation. Relying on RNA-seq data, the system classifies patients into four molecular subtypes (CMS 1-4). Each subtype is enriched with several mutations, but no genetic aberrations are peculiar to a single CMS. A more in-depth characterization of each subtype's genomic and epigenomic background by integrating different omics may help in refining this classification, including the missing assignment of a subgroup of tumors. The possible translation of this improved classification to surrogate tissues, such as stool, has never been investigated.
Aims: We aim to comprehensively characterize the CMS by the integrative analysis of target genomic sequencing, RNA-Seq, small RNA-Seq, and immune infiltrate profiling data of a cohort of CRC patients. These data will be used to identify integrative CMS-specific signatures and to characterize those tumors not assigned to any CMS. In addition, differences in stool miRNome and metagenomic profiles will be explored to identify potential specific signatures characterizing each subtype.
Methods: Tumor tissue and adjacent mucosa were collected from 87 CRC patients and preserved in RNA later. mRNA and other non-coding RNA expression levels were evaluated with ribosomal depleted RNA-seq and small RNA-seq. Tumors were assigned to a CMS subtype using the CMScaller algorithm and genomically characterized with the TruSight Oncology 500 (TSO500) cancer panel. Differential expression analyses were performed using the DESeq2 package for the R software to identify

CMS-specific expression signatures. Small RNA-seq and shotgun metagenomic analyses were performed on stool samples collected from the same patients.
Preliminary Results: Tumors were assigned to CMS1 (n=9), CMS2 (n=24), CMS3 (n=26), and CMS4 (n=22), except for six samples. Differential expression analyses between paired tumor samples and adjacent mucosa within each CMS revealed 1096 differentially expressed genes in CMS1, 4218 in CMS2, 27 in CMS3 and 190 in CMS4.From the genomic point of view, CMS3 cases showed 384 unique missense variants, while CMS1 included almost all samples with microsatellite instability. Small RNA-seq on the same tissue sample identified 380 dysregulated miRNAs (215 up and 165 downregulated) in the tumor compared to adjacent mucosa.
Conclusions: A more in-depth CMS subtyping by integrating different omics analyses could help refine this classification system. Moreover, the possible CMS reflection in stool miRNome and metagenomic could shed new light on the host gut-microbiota interactions and allow a non-invasive classification applicable for a routine personalized clinical management of CRC.

#6225

SERPINB3 promotes the aggressive basal-like/squamous subtype and correlates with poor prognosis in pancreatic ductal adenocarcinoma through metabolic reprogramming

Yuuki Ohara[1], Wei Tang[1], Liu Huaitian[1], Shouhui Yang[1], Peijun He[1], Helen Cawley[1], Paloma Valenzuela[1], Lin Zhang[1], Jochen Gaedcke[2], B. Michael Ghadimi[2], Matthias M. Gaida[3], Frank Bergmann[3], H. Richard Alexander[4], Nader Hanna[5], Stefan Ambs[1], S. Perwez Hussain[1]. *[1]National Cancer Institute, Laboratory of Human Carcinogenesis, National Institutes of Health, Bethesda, MD,[2]Department of General, Visceral and Pediatric Surgery, University Medical Center Göttingen, Göttingen, Germany,[3]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany,[4]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[5]Division of General & Oncologic Surgery, University of Maryland School of Medicine, Baltimore, MD*

In this study, we aimed to find genes with a key function in the development of molecular subtypes in pancreatic ductal adenocarcinoma (PDAC). Through transcriptome analysis, we discovered that the endogenous serine/cysteine proteinase inhibitor SERPINB3 (squamous cell carcinoma antigen 1, SCCA1) was distinctively upregulated in the basal-like/squamous subtype, known as an aggressive subtype, and this upregulation associated with decreased patient survival in both a test (N=123) and a validation cohort (N=84). In additional investigations of the tumor metabolome and transcriptome using PDAC patient tumors and cell lines, SERPINB3 and the basal-like/squamous subtype showed a robust relationship with upregulated levels of amino acids (e.g., hydroxyproline) whereas SERPINB3 promoted a gene signature indicative of the basal-like/squamous subtype. Additional mechanistic studies revealed that SERPINB3 and hydroxyproline promoted the migration/invasion of PDAC cells. Moreover, SERPINB3 also promoted metastasis in an orthotopic mouse model of PDAC through stromal factors that increased tumor microvessel density. To conclude, inhibiting SERPINB3 function may attenuate disease progression of the basal-like/squamous subtype in PDAC through changes to the tumor stroma and tumor metabolism.

Therapeutic vulnerability of *MTAP*-deleted nasopharyngeal carcinoma by MAT2A inhibitors

YUK-Yu Chan[1], Chi-Man Tsang[1], Grace T.Y. Chung[1], Ka-Fai To[1], Yi Zhang[2], Xiaodong Zhang[2], Jun Tang[2], Kwok Wai Lo[1]. *[1]Department of Anatomical & Cellular Pathology, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]ScinnoHub Pharmaceutical Co., Ltd., Chengdu, China*

Introduction: EBV-associated nasopharyngeal carcinoma (NPC) is a distinct type of head and neck cancer that is prevalence in southern China and Southeast Asia. While radiotherapy or concurrent chemo-radiotherapy are efficient for the patients with early disease, more than 60% of NPC patients are diagnosed at an advanced stage and frequently develop local failure and distant metastases. The lack of druggable targets is a challenge for controlling this common cancer. By whole-genome sequencing and FISH analysis, we have defined the frequent homozygous deletion of 9p21.3 in

NPC. The loss of *MTAP* that encodes methylthioadenosine phosphorylase on this region was found in 32% and 34% of primary and recurrent NPC respectively, indicating vulnerability to targeted-therapies for MAT2A/PRMT5 axis.
Methods: The preclinical efficacy of MAT2A inhibitors, FIDAS-5 and BT115386 was elucidated in a panel of *MTAP*-deleted EBV-positive NPC cell lines and patient-derived xenografts. *In vitro* and *in vivo* growth inhibition of NPC cells by these compounds were determined. In addition to the suppression of PRMT5 activity, the effects of MAT2A inhibitor treatment on activating p53 pathway, inducing EBV lytic genes and modulating expression of proteins involved in cellular differentiation, apoptosis and lipogenesis in NPC were accessed.
Results: *In vitro* study has revealed that treatment of the MAT2A inhibitors markedly reduced PRMT5 activity and cell growth in all MTAP-deleted NPCs. Compared to the MTAP-wild type NPC cells, the MTAP-deleted cells, either with wild type or mutated *TP53*, showed heightened sensitivity (>9 fold more sensitive) to the MAT2A inhibition by FIDAS-5 and BT115386. The potent *in vivo* growth inhibitory effect of BT115386 were observed in the *MTAP*-deleted xenografts, but not in that with wild type *MTAP*. In the *MTAP*-deleted NPC treated with MAT2A inhibitors, activation of p53 pathway and induction of BAX apoptotic protein were consistently found. The treatment also promoted differentiation, suppressed stemness transcription factors and inhibited lipogenesis. Notably, the MAT2A inhibitors also disrupted EBV latency in the *MTAP*-deleted NPC, induction of multiple EBV lytic genes including *BZLF1* and *BMRF1* were demonstrated.
Conclusion: Selective sensitivity of *MTAP*-deleted NPC to the treatment of MAT2A inhibitors including FIDAS-5 and BT115386 was demonstrated. To facility its growth inhibitory effects, the compounds targeted PRMT5 activity, subsequently modulated multiple cellular mechanisms and induced EBV lytic reactivation. The potent antitumor effect of BT115386 was demonstrated in the *in vivo* MTAP-deleted NPC mouse models. The findings warrant future assessments of *MAT2A* inhibitors in clinical studies for NPC, which might well impact a large subset of patients.

Tumor cell heterogeneity may cause treatment failure of GPA33-targeted therapy in colorectal cancer

Teresa Börding, Tobias Janik, Markus Morkel, Christine Sers, David Horst.
Charité - Universitätsmedizin Berlin, Berlin, Germany

Purpose: Glycoprotein A33 (GPA33) is a membrane protein almost exclusively expressed in intestinal epithelia and in more than 95% of colorectal cancers (CRCs). This renders GPA33 a promising antigen for targeted therapy, but trials did not meet pre-specified response rates. We investigated intratumoral heterogeneity as a reason for low treatment efficacy, GPA33 regulation and the potential for pharmacological induction of GPA33 expression *in vitro* and *in vivo* to enhance treatment response.
Methods: We assessed intratumoral heterogeneity of GPA33 in tissue specimens of 223 stage II CRCs using immunohistochemistry and immunofluorescence, and obtained scRNAseq transcriptomic analysis from 12 primary CRCs. We then manipulated WNT and PPARγ signaling pathways and transcription factor expression in colon cancer cells using specific inhibitors, siRNAs or inducible dominant negative TCF4 (dnTCF4), and analyzed the effects on GPA33 protein and RNA expression. Furthermore, we investigated the effects of WNT inhibition on GPA33 *in vivo* in NOD/SCID xenografts. Additionally, we developed anti-GPA33 CAR-T cells and measured their activation after co-cultivation with colon cancer cells using flow cytometry.
Results: In the CRC cohort we found that GPA33 expressing cells had a differentiated phenotype and low WNT activity. GPA33-negative subpopulations were located at the infiltrative tumor edge and showed increased nuclear β-catenin. Downregulation of WNT pathway activity using inhibitors, siRNAs or inducible dominant negative TCF4 (dnTCF4), as well as activation of PPARγ signaling induced GPA33 expression *in vitro*. Forced expression of dnTCF4 also enhanced GPA33 expression *in vivo* in previously GPA33-negative tumor cell subpopulations in colon cancer xenografts. siRNA mediated knockdown of CDX1 and KLF4, two transcription factors that were previously implicated in GPA33 regulation, only moderately reduced GPA33 expression levels *in vitro*. Anti-GPA33

CAR-T cells activated in response to co-culture with GPA33-expressing CRC cells *in vitro*.
Conclusion: Our analysis highlights a heterogenous expression of GPA33 *in vivo* as a limiting factor for anti-GPA33 therapy. WNT inhibition or PPARγ activation induced GPA33 expression *in vitro* and *in vivo*. Depletion of CDX1 and KLF4 had moderate effects on GPA33 only, indicating a complex regulation in colon cancer. We suggest that pharmacological induction of GPA33 expression may increase the efficacy of anti-GPA33 targeted therapy in patients with CRC.

DNA-reactive Agents, HDAC and Methyltransferase Inhibitors, and Tubulin Agents

Activation of GCN2 by HC-7366 results in significant antitumor efficacy as monotherapy and in combination with multiple standard of care agents in various solid cancer models

Feven Tameire[1], Paulina Wojnarowicz[1], Crissy Dudgeon[1], Sho Fujisawa[1], Sharon Huang[1], Owen B. Reilly[1], Nicholas Collette[1], Jeremy Drees[1], Kathryn Bieging-Rolett[1], Takashi O. Kangas[1], Weiyu Zhang[1], Maria Fumagalli[1], Iman Dewji[1], Yunfang Li[1], Anissa SH Chan[1], Xiaohong Qiu[1], Ben Harrison[1], Ashley LaCayo[1], Ricardo A. Cordova[2], Kirk A. Staschke[2], Alan C. Rigby[1], Savithri Ramurthy[1], Eric S. Lightcap[1], David Surguladze[1], Nandita Bose[1]. *[1]HiberCell, New York, NY,[2]Department of Biochemistry and Molecular Biology, Indiana University School of Medicine, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN*

The integrated stress response (ISR) is an adaptive signaling pathway that cells utilize to respond to a wide range of extrinsic and intrinsic stresses, which are important for tumorigenesis. Activation of ISR is suggested to play a dual role in cell fate decisions. While the ISR promotes survival, prolonged activation of ISR induces apoptosis. We are developing HC-7366, a first-in-class, first-in-human GCN2 activator, and are currently evaluating it in a phase 1 clinical trial in solid tumors (NCT05121948). In

this study, we present the characterization of the antitumor effects of HC-7366 in solid tumors.
In vivo efficacy studies using HC-7366 montherapy showed significant tumor growth inhibition (TGI%) in preclinical cancer models of colorectal (78-95%), head and neck (33% regression), sarcoma (80%) and prostate (65%). HC-7366 activated the ISR in tumors from treated mice as evidenced by induction of the ATF4 target genes ASNS and PSAT1. Additionally, HC-7366 induced the proapoptotic protein PUMA and reduced HIF1α and HIF2α levels. Furthermore, HC-7366 showed significant benefit in colorectal models when combined with DC101 (anti-VEGFR2 antibody), 5-fluorouracil (chemotherapy), alpelisib (PI3Kα inhibitor), or trametinib (MEK1/2 inhibitor). Using GCN2 CRISPR-knockout cells, we confirmed that the HC-7366 mediated reduction of cell growth and induction of ISR markers was dependent on GCN2. We performed multi-omics analyses to further understand the mechanism of action. Metabolomics analysis of tumors treated with HC-7366 revealed that HC-7366 altered several metabolites involved in amino acid metabolism, oxidative stress, the urea cycle, and pyrimidine biosynthesis. Additionally, proteomics analysis showed that HC-7366 significantly reduced proteins involved in oxidative phosphorylation. Analysis of the transcriptome in tumors from treated mice demonstrated that HC-7366 reduced the activity of HIF and E2F1-driven transcription, including expression of metaphase-anaphase transition genes, consistent with decreased Ki67 staining in tumors. ATF4 and JUN transcriptional activity was enhanced with HC-7366 treatment consistent with activation of ISR. Collectively, our *in vitro* and *in vivo* results demonstrate that HC-7366 is a potent GCN2 activator with strong antitumor activity across multiple solid tumor models as a monotherapy or in combination with standard of care agents.

Ulipristal acetate, a selective progesterone receptor modulator, induces cell death via inhibition of STAT3/CCL2 signaling pathway in uterine sarcoma

Jae Ryoung Hwang[1], Young-Jae Cho[1], Ji-Yoon Ryu[1], Ju-Yeon Choi[1], Jung-Joo Choi[2], Jeong-Won Lee[2]. [1]*Sungkyunkwan University School of*

Medicine, Seoul, Korea, Republic of,[2]Samsung Medical Center, Seoul, Korea, Republic of

Purpose: Ulipristal acetate (UPA) is used for the treatment of uterine leiomyoma as a selective progesterone receptor modulator. Until now, there has been no experimental research on the effect of UPA on uterine sarcoma. In this study, we examined the efficacy of UPA in uterine sarcoma with *in vitro* and *in vivo* animal models.
Experimental Design: The cytotoxicity of UPA was determined in uterine sarcoma cell lines (MES-SA, SK-UT-1, and SK-LMS-1) by MTT and caspase-3 activity assays. A migration assay was done using a Transwell chamber, and MMP-2 was measured with its specific ELISA kit. Apoptotic genes and signaling pathways affected by UPA were analyzed by complementary DNA (cDNA) microarray of uterine sarcoma cell lines and western blot, respectively. The *in vivo* efficacy of UPA was examined in uterine sarcoma cell line- and patient-derived xenograft mice models.
Results: UPA inhibited cell growth and increased apoptosis in cell lines including uterine sarcoma (MES-SA) and leiomyosarcoma (SK-UT-1 and SK-LMS-1) in a dose-dependent manner. UPA also inhibited cell migration and the expression of MMP-2. cDNA microarray analysis revealed that CCL2 was commonly down-regulated by UPA in investigated cell lines. The UPA-mediated inhibition of CCL2 expression was confirmed by ELISA. The phosphorylation and the total expression of STAT3, downstream from the CCL2 signaling pathway, was also inhibited by UPA. We also found that UPA reduced cell growth and increased caspase-3 activity in primary culture cells from leiomyosarcoma patient-derived xenografts (PDX-C). Moreover, we found that STAT3/CCL2 inhibition by UPA was independent of the expression of progesterone receptor. *In vivo* studies with MES-SA and SK-UT-1 cell line-derived xenografts and a PDX model with leiomyosarcoma demonstrated that UPA significantly decreased tumor growth.
Conclusions: UPA had significant anti-tumor effects in uterine sarcoma through the STAT3/CCL2 signaling pathway and might be a potential therapeutic agent to treat this disease.

Omacetaxine reduces c-MYC expression and demonstrates antitumor effects in osteosarcoma

Kristen B. Farrell, Douglas H. Thamm. *Colorado State University, Fort Collins, CO*

Omacetaxine mepesuccinate (OMX), also known as homoharringtonine, is a protein translation inhibitor approved for use in chronic myeloid leukemia. Recent studies suggest OMX may be effective against other cancer types with high rates of protein translation, and may be successful against protein targets that are difficult to inhibit by reducing their translation rates. Using both canine and human osteosarcoma (OS) cell lines, we have investigated the efficacy of OMX against osteosarcoma and expression of c-MYC. OMX provides significant growth inhibition of OS cells with IC_{50} values in the low nanomolar range. OMX also reduces migration and invasion capabilities of OS cells. Strikingly, we observed reduction in levels of c-MYC protein in most canine and human OS cell lines after OMX exposure. This reduction was both dose and time dependent. We also investigated the efficacy of OMX against OS in an orthotopic mouse OS model. OMX is a promising candidate for treatment of OS in both dogs and humans, and potentially additional cancers dependent on c-MYC.

Targeting integrin alpha V beta 5 heterodimer stability using a novel small molecular inhibitor for tumor suppression

Nicole Mattson, Kazuya Miyashita, Anthony Chan, Lu Yang, Sheela Pangeni Pokharel, Wei Liu, Mingli Li, Qiao Liu, Xiaobao Xu, Priyanka Singh, Leisi Zhang, Mingye Feng, Chun-Wei Chen. *Systems Biology, Beckman Research Institute of The City of Hope, Monrovia, CA*

Integrins have long been sought as therapeutic targets in cancer, but there are no FDA approved drugs to target this gene family. Since integrins require the dimerization between an alpha and beta subunit to function, we developed a CRISPR library targeting all 26 alpha and beta subunits to identify which pair is the most important. We found a strong correlation between ITGAV and ITGB5 (Integrin Beta 5), which form a known heterodimer, in solid tumors. CRISPR targeting either ITGAV or ITGB5 led

to attenuated cell proliferation with increased cell cycle stalling and apoptosis. As the more essential partner, we designed a CRISPR tiling scan targeting the entire coding region of ITGAV and determine the essential nature of each amino acid. We found a sub-domain within the beta propeller to be important for ITGAV function, the CRISPR identified pocket (CIP). Genetic targeting of this pocket disrupted the ability to detect the heterodimer signal of ITGAV-ITGB5 by a specific antibody. Furthermore, we confirmed that essential amino acids within the CIP responsible for the heterodimer stability by the NanoBRET energy transfer system. Knowing the role of the CIP in heterodimer stability we searched for a small molecule to bind in the CIP to phenocopy our genetic findings. A combined *in-silico* and *in-vitro* high throughput drug screen started tested compounds for cell killing and disruption of the ITGAV-ITGB5 heterodimer. "Compound 2" (cpd_2) showed both strong cell killing and dissociation of the heterodimer. Disruption was measured by detection by flow cytometry and through the NanoBRET system. Cpd_2's binding was confirmed with thermal shift studies with purified ITGAV beta propeller, validating that this compound is behaving and binding as we expect at the CIP. Next, we sought to understand how the ITGAV-ITGB5 heterodimer controls cancer cell survival. From the Dependency Map Public database (DepMap) we found that Rac1 dependency is significantly correlated only with ITGAV and ITGB5. We hypothesized that this meant that ITGAV-ITGB5 regulated Rac1 activity. Loss of Rac1 phenocopies knock out of ITGAV or ITGB5 and loss of either Rac1 or ITGAV led to dysregulation of the actin cytoskeleton, a known downstream feature of Rac1. A constitutively Rac1 (CA_Rac1) rescues the effects of targeting of ITGAV or treatment with cpd_2. Altogether this data suggests that ITGAV-ITGB5 signals to Rac1 and that attenuation of their function can be reversed by an active Rac1 In summary, our study highlights a novel strategy of targeting the integrin heterodimer ITGAV-ITGB5 with a small molecule binding to a novel subdomain, CIP, of ITGAV. The CIP is responsible for the heterodimer stability of ITGAV and ITGB5. Disruption of this heterodimer led to the dysregulation of Rac1 and destabilization of the actin cytoskeleton. This mechanism highlights a novel strategy for targeting integrins as a therapeutic target in cancer.

Discovery of novel HDAC6 inhibitors that enhance proteasomal activity to boost antigen presentation and trigger anti-myeloma T-cell immunity

Priyanka S. Rana[1], James Ignatz-Hoover[2], James J. Driscoll[2]. *[1]Hematology and Oncology, Case Western Reserve University, Cleveland, OH,[2]University Hospitals - Seidman Cancer Center, Cleveland, OH*

Transformative success of cancer immunotherapy has revolutionized cancer treatment and can induce long lasting responses in patients with cancers from a wide range of histologies. However, only a fraction of patients respond to immunotherapy and cancer cells escape immunosurveillance through molecular mechanisms that remain elusive. Proteasomes play a central role in the immune response by generating peptides from intracellular antigens which are presented on the cell surface for recognition by $CD8^+$ cytotoxic T lymphocytes (CTLs). Malignant cells employ strategies to downregulate antigen presentation and impair CTL-mediated tumor recognition and lysis. Recently, we discovered that HDAC6-specific inhibitors increased intracellular proteasome activity and the generation of antigenic class I MHC peptides. However, current HDAC6 inhibitors have pharmacologic liabilities that limit efficacy, e.g., low potency and solubility, poor pharmacokinetic properties and potential genotoxicity. Therefore, we performed a cell-based, high-throughput screen (HTS) of 9,600 HDAC-specific compounds to identify novel compounds that increased proteasomal activity in myeloma cells. We identified 8 hits that increased proteasomal activity at least two-fold. Importantly, two novel molecules identified in the HTS increased proteasome activity more potently and more rapidly than the HDAC6-specific inhibitors Tubastatin-A and ACY-1215 (Ricolinostat) with comparatively low cytotoxicity. Proteasomes degrade chicken ovalbumin (Ova) to generate the immunodominant antigen SIINFEKL presented at the cell surface complexed with the MHC-class I molecule H-$2K^b$. Treatment of tumor cells with Tubastatin-A and ACY-1215 increased levels of the MHC-class I-SIINFEKL complex by ~3-fold. Tumor cells were pretreated with Tubastatin-A and ACY-1215 and then co-cultured with CTLs that had been genetically-engineered to express a SIINFEKL-restricted T-cell receptor (TCR). Pre-treatment of lymphoma or multiple myeloma cells with novel HDAC6 inhibitors also increased tumor lysis by CTLs that expressed the SIINFEKL-restricted TCR by 2-fold.

Taken together, our results support repositioning pharmacologics that inhibit HDAC6 to activate proteasomal generation of antigenic peptides and boost antigen presentation as cancer immunotherapeutics.

#6236

Stellettin B induces apoptosis and autophagy in human bladder cancer RT112 cells

Mei-Chuan Chen, Chun-Han Chang. *Taipei Medical University, Taipei, Taiwan*

Bladder cancer is one of the most prevalent cancers worldwide. Although most of the patients have good prognosis and good life expectancy with standard treatments, recurrence rate and five-year survival rate have not been significantly improved in patients with bladder cancer, demonstrating there is an urgent need for development of a novel therapeutic strategy for the treatment of bladder cancer. Stellettin B (SP-2), a triterpene isolated from marine sponge *Jaspis stellifera ,* suppresses cell viability in bladder cancer RT112 cells without severe toxicity toward normal uroepithelial SV-HUC-1 cells. Our results showed that SP-2 induces accumulation of cells at subG1 phase in parallel with increase of early apoptotic cells via annexin V/PI staining and activation of cell apoptotic death proteins. Moreover, non-cytotoxic concentrations of SP-2 induces LC3-II formation and p62 downregulation to activate autophagy in RT112 cells, suggesting autophagy may play a role in SP-2 -induced cell death. Inhibition of autophagy by pharmacological inhibitors (3-MA and chloroquine) or ATG5 knockout protects stellettin B-induced apoptosis and cell viability suppression, indicating SP-2 induces autophagy to promotes cell death. Taken together, stellettin B may be a promising therapeutic agent for bladder cancer treatment.

#6237

Small molecule screen identifies pyrimethamine as an inhibitor of NRF2-driven esophageal hyperplasia

chorlada Paiboonrungruang. *North Carolina Central University, Durham, NC*

Objective: NRF2 is a master transcription factor that regulates the stress response. NRF2 is frequently mutated and activated in human esophageal squamous cell carcinoma (ESCC), which drives resistance to chemotherapy and radiation therapy. Therefore, a great need exists for NRF2 inhibitors for targeted therapy of $NRF2^{high}$ ESCC.
Design: We performed high-throughput screening of two compound libraries from which hit compounds were further validated in human ESCC cells and a genetically modified mouse model. Mechanism of action of one compound was explored by biochemical assays.
Results: Using high-throughput screening of two small molecule compound libraries, we identified 11 hit compounds as potential NRF2 inhibitors with minimal cytotoxicity at specified concentrations. We then validated two of these compounds, pyrimethamine and mitoxantrone, by demonstrating their dose- and time-dependent inhibitory effects on the expression of NRF2 and its target genes in two $NRF2^{Mut}$ human ESCC cells (KYSE70 and KYSE180). RNAseq and qPCR confirmed the suppression of global NRF2 signaling by these two compounds. Mechanistically, pyrimethamine reduced NRF2 half-life by promoting NRF2 ubiquitination and degradation in KYSE70 and KYSE180 cells. Expression of an $Nrf2^{E79Q}$ allele in mouse esophageal epithelium (*Sox2CreER;LSL-*$Nrf2^{E79Q/+}$) resulted in an $NRF2^{high}$ phenotype, which included squamous hyperplasia, hyperkeratinization, and hyperactive glycolysis. Treatment with pyrimethamine (30mg/kg/day, *p.o.*) suppressed the $NRF2^{high}$ esophageal phenotype with no observed toxicity.
Conclusion: We have identified and validated pyrimethamine as an NRF2 inhibitor that may be rapidly tested in the clinic as a radiation and chemotherapy sensitizer for $NRF2^{high}$ ESCC.

#6238
ABM-2752, a potent and selective HPK1 inhibitor with excellent efficacies as a single agent or in combination with a PD-1 antibody
Chen Chen, Charles Huang, Min Xu, Xiuquan Chen, Xiaobing Lv, Chen Yang, lanjiao Zhao, YouQin Chen, jizhi li, li zhao. *ABM Therapeutics, San Diego, CA*

Hematopoietic Progenitor Kinase 1 (HPK1, MAP4K1) is predominantly expressed in hematopoietic cells and is a negative immune regulator of T-cell and B-cell activation through phosphorylating adaptors. Loss of HPK1 kinase function suppresses tumor growth in preclinical tumor models, and therapeutic co-blockade of HPK1 kinase and PD-1 enhances anti-tumor responses. Therefore inhibition of HPK1 is an attractive approach for the immunotherapy of cancers. ABM-2752 has a unique chemical structure that was potent on the HPK1, and selective over other MAP4K family members. It showed dose-dependent inhibition of SLP-76 phosphorylation and induction of IL-2, with good ADME and animal PK properties. In vivo efficacy was demonstrated in murine colorectal MC38 and CT26 syngeneic models as a single agent, enhanced by aPD-1. Treatment of ABM-2752 in these two models also improved animal overall survival. Other efficacy studies in murine melanoma B16F10 model and glioblastoma GL261 orthotopic model showed good efficacy and safety, demonstrating its good brain penetration in animals. Preliminary tox studies indicated a good safety window. Based on these preclinical results we plan to file IND in 2023.

#6239

PM534 is a novel microtubule-destabilizing agent with high affinity and potent antineoplastic properties

Maria Ángela Oliva[1], Beatriz Álvarez-Bernad[2], Daniel Lucena-Agell[1], Marta Martínez Diez[3], María José Guillén[4], Gema Santamaría Nuñez[3], María José Muñoz-Alonso[3], Eva M. Garrido-Martin[3], Pablo Avilés[5], Carmen Cuevas[6], J. Fernando Díaz[7]. *[1]Structure, Function and Pharmacology of Cytoskeleton, Centro de Investigaciones Biológicas CSIC, Madrid, Spain,[2]Structure, Function and Pharmacology of Cytoskeleton, Centro de Investigaciones Biologicas CSIC, Madrid, Spain,[3]Cell Biology and Mechanism of Action, Pharma Mar, S.A., Madrid, Spain,[4]Pharmacology, Pharma Mar, S.A., Madrid, Spain,[5]Pharmacology and Toxicology, Pharma Mar, S.A., Madrid, Spain,[6]Research and Development, Pharma Mar, S.A., Madrid, Spain,[7]Structure, function and pharmacology of cytoskeleton, Centro de Investigaciones Biológicas, Madrid, Spain*

Background: Microtubule targeting compounds are a successful class of anticancer agents in the clinic. Although highly potent, the currently approved antitumor agents targeting tubulin present some drawbacks such as the development of acquired resistances, which remain an obstacle for an effective prolonged anticancer treatment. In this work, we present a novel microtubule destabilizing agent with an optimized interaction for the colchicine site and a novel mechanism of action which confers it a high affinity binding for tubulin.
Methods and Results: We have determined the X-ray crystallographic structure of the complex T_2R-TTL with PM534 at a resolution of 2.45 Å. We unequivocally found PM534 ligand density at the intra-dimer interface between α and β tubulin of both tubulin dimers (the colchicine domain) within the complex. The colchicine domain of tubulin can be divided into three zones: a central pocket and two accessories. Whereas other colchicine site-ligands only bind to two of the zones, we found that PM534 binds extensively along the three zones, making multiple contacts with β-tubulin N terminal domain, central hinge helix, and the intermediate domain. PM534 interaction did not affect the overall curved conformation of tubulin and its mechanism of action consists on precluding the curve-to-straight conformational transition required for tubulin to assemble intro microtubules and thus, to perform its cellular functions. In competition assays we found that the compound displaces a bona fide high-affinity colchicine-probe with a binding affinity of 5.1 ± 0.3 x10^7 M^{-1} at 25ºC. Moreover, PM534 shows potent antineoplastic activity *in vitro*, with GI_{50} values in the low nanomolar range, observed in different human tumor cancer cell lines. An *in vivo* Proof of the Concept (PoC) was performed in athymic *nu/nu* mice bearing H460 (NSCLC) tumors that were treated (intravenous, on days 0, 7, 14) with different doses (ranging from 0.75 mg/kg to 2.5 mg/kg) of PM534. Results demonstrated strong, dose-related PM534-induced antitumor activity in this *in vivo* model.
Conclusions: The mechanism of action of PM534 involves an optimized interaction with the colchicine site, which is reflected in its high affinity for the substrate, being this the ultimate reason for the observed cellular activity. Additionally, PM534 presents a potent antitumor activity *in vitro* that was translated into a clear positive *in vivo* PoC that resulted in strong antitumor effect.

#6240

The potent quadruplex-binding compound QN-302 shows anti-tumor activity as a monotherapy in an orthotopic *in vivo* model of pancreatic cancer

Nicole Williams[1], Danielle Santos[1], Jenny Worthington[1], Ahmed Ahmed[2], Tariq Arshad[3], Stephen Neidle[2]. *[1]Axis Bioservices, Coleraine, United Kingdom,[2]University College London (UCL), London, United Kingdom,[3]Qualigen Therapeutics Inc, San Diego, CA*

The compound QN-302, a tetra-substituted naphthalene diimide derivative has single-digit nM anti-proliferative activity in a panel of human pancreatic cancer (PDAC) cell lines (Ahmed et al., ACS Med Chem Lett, 2020, 11, 1634-1644). It has significant anti-tumor activity in the MIA-PACA2 xenograft model for PDAC and in the genetic KPC model. We now report that this compound also shows significant mono-therapy anti-tumor activity in an orthotopic model for PDAC. Female athymic nude mice bearing orthotopically implanted pancreatic BxPC-3 cells were dosed with 1 x weekly IV QN-302 at 0.5 and 1.0 mg/kg, over a period of 21 days. A separate group of mice was treated with Gemcitabine twice weekly IV during this period, at a dosage of 15 mg/kg. Blood samples from animals were collected on a weekly basis and were used to detect and quantify circulating tumor DNA as a method of following treatment efficacy. In line with previous studies QN-302 was well-tolerated at 0.5 and 1.0 mg/kg with no adverse effects on animal health or behavior noted during the study. Circulating tumor DNA levels were significantly less than vehicle controls in gemcitabine-treated animals from day 7 and QN-302 (1.0 mg/kg) treated animals from day 14 of treatment. Survival was significantly increased in gemcitabine and QN-302 (1.0 mg/kg) QW treatment groups. Statistically significant efficacy was observed in gemcitabine and QN-302 (1.0 mg/kg) treated animals. Examination of blood chemistry and biochemistry of treated animals did not indicate any adverse effects due to QN-302. This orthotopic model is the 4th *in vivo* study in a pancreatic cancer model showing anti-tumor activity for QN-302, further confirming the potential of this compound for human disease. QN-302 is currently in an advanced stage of pre-IND development by Qualigen Inc.

#6241

LP-184, an acylfulvene class small molecule therapeutic, is synthetically lethal in DNA damage repair deficient cancers

Aditya Kulkarni, Jianli Zhou, Neha Biyani, Kishor Bhatia, Panna Sharma.
Lantern Pharma Inc., Dallas, TX

As many as one third of solid tumors (ovarian, breast, pancreatic, prostate cancers) harbor deficiency in some DNA Damage Repair (DDR) pathways. Such cancers become dependent on alternative DDR pathways to maintain genome integrity, making them selectively vulnerable to DDR inhibitors. The concept of synthetic lethality has been successfully applied to develop strategies to treat subsets of such tumors. Clinically, PARP inhibitors (PARPi) have been successful particularly in Homologous Recombination Deficiency (HRD) cancers. Other agents have also been designed to target these DDR deficiencies in cancer cells and have potential to be clinically beneficial. LP-184 is a next generation acylfulvene prodrug metabolized to an active compound by prostaglandin reductase 1 (PTGR1) that is often elevated in multiple tumors. LP-184-induced DNA lesions are likely repaired by the Nucleotide Excision Repair (NER) and Homologous Repair (HR) pathways. Reduced activities of multiple DDR-related pathways in solid tumor models correlated with increased sensitivities to LP-184 as indicated by Gene Set Enrichment Analysis. Chinese Hamster Ovary cells with NER mutations (ERCC1/2/6) were at least 4 fold more sensitive to LP-184 relative to otherwise isogenic parental cells. ERCC2 or BRCA2 depletion enhanced LP-184 sensitivity 5-8X in a metastatic prostate cancer cell line. LP-184 showed ~120 fold higher potency (IC50 77 nM) compared to Olaparib in HRD prostate cancer organoid model LuCaP 96 (BRCA2/ CHEK2 inactivating mutations). Across 14 patient-derived pancreatic, lung and prostate tumor models harboring HR mutations (BRCA1/2, CHEK1/2, ATM/ATR, PALB2, PARP1/2, RAD51, FANCA/B), LP-184 showed ex vivo IC50s in the range of 30-300 nM, whereas Olaparib IC50s ranged from 1700-6900 nM. LP-184 treatment resulted in complete tumor regression (107-141% TGI) in 10/10 HR deficient triple negative breast cancer PDX models of which 7/10 were resistant Olaparib/ Niraparib and to Doxorubicin/ Cyclophosphamide. LP-184 treatment resulted in complete and durable tumor regression in HRD (BRCA1/ATR mutant) pancreatic cancer PDX models (112-140% TGI). In the ovarian cancer cell line OVCAR3 having HRD/NERD phenotype, LP-184 IC50 was 13 nM,

Olaparib IC50 was 145 nM and their combination Bliss Synergy Score was 16 indicating synergy. LP-184 is synthetic lethal resulting from its abilities to cause unresolvable DNA damage if tumor cells express high PTGR1 and are deficient in NER/HR genes. Unlike PARPi, LP-184 has striking activity in both NERD as well as HRD cancers. These strong data have prompted the development of a soon to be launched clinical trial to translate the broad preclinical anticancer activity of LP-184 in solid tumors with HR/NER pathway defects, such as pancreatic, prostate, ovarian and breast cancers.

Inhibition of BIRC5/survivin by LQZ-7I inhibits neuroblastoma growth while hemizygosity of *BIRC5* does not: implications for therapy of neuroblastoma

Carmen Dorneburg[1], Celimene Galliger[1], Voker Rasche[2], Andre Lechel[3], Thomas F. E. Barth[3], Klaus-Michael Debatin[1], Christian Beltinger[1].
[1]University Children's Hospital, Ulm, Germany,[2]Experimental Cardiovascular MRI, University Medical Center Ulm, Ulm, Germany,[3]Innere Medizin, University Medical Center Ulm, Ulm, Germany

Overexpression of survivin, a crucial regulator of the mitotic spindle checkpoint, is associated with poor prognosis in neuroblastoma (NB). Transcriptional inhibitors of survivin have been tested in clinical trials. However, results have been disappointing. We thus investigated the small molecules LQZ-7I and S12 that inhibit dimerization of survivin protein and compared their growth-inhibiting efficacy with that of markedly decreased survivin expression in a novel transgenic NB mouse. Mice hemizygous for *BIRC5* were crossed with TH-MYCN mice to generate BIRC5$^{+/-}$/MYCN$^{tg/+}$ mice. NB incidence, growth and retransplantation capacity were assessed. In vitro, LQZ-7I and S12 were used to inhibit survivin protein interactions and the effects on proliferation and cell cycle of NB cells were investigated. *BIRC5* hemizygous mice developed NB although mRNA and protein expression of survivin was markedly decreased. Surprisingly, incidence and latency of the NB that developed in the BIRC5$^{+/-}$/MYCN$^{tg/+}$ mice did not differ from the NB in the TH-MYCN mice, and tumor growth and survival of the mice was not affected. In stark contrast, the survivin interaction inhibitors LQZ-7I and S12 abolished anchorage-independent growth and proliferation of NB cell lines. Reduced growth of NB cells resulted from

defects in mitosis induced by LQZ-7I or S12 or. LQZ-7I was the more efficient inhibitor of NB cells while S12 was not able to reduce tumor growth in a xenograft model. Taken together, these results support the notion that inhibiting survivin interaction is more efficacious in NB than inhibiting survivin transcription.

The novel antitubulin agent PM534 exhibits potent antitumoral and antiangiogenic properties in vitro and in vivo

Marta Martínez Diez[1], María José Muñoz-Alonso[1], Gema Santamaría Nuñez[1], María José Guillén[2], María Ángela Oliva[3], Eva Maria Garrido-Martin[1], Pablo Avilés[4], J. Fernando Díaz[3], Carmen Cuevas[5]. *[1]Cell Biology and Mechanism of Action, Pharma Mar, S.A., Madrid, Spain,[2]Pharmacology, Pharma Mar, S.A., Madrid, Spain,[3]Structure, function and pharmacology of cytoskeleton, Centro de Investigaciones Biológicas CSIC, Madrid, Spain,[4]Pharmacology and Toxicology, Pharma Mar, S.A., Madrid, Spain,[5]Research and Development, Pharma Mar, S.A., Madrid, Spain*

Background: Microtubule targeting agents have demonstrated to be very effective antitumoral drugs. The development of novel anti-tubulin agents with more efficient mechanisms of action presents several challenges due to their poor solubility, troublesome synthesis or purification, and toxicities. In this work, we present the novel anti-tubulin agent PM534, a synthetic small molecule that shows efficient antitumoral and antiangiogenic properties *in vitro* and *in vivo*.

Methods and Results: PM534 exhibits a potent antitumor activity *in vitro* with a mean GI_{50} value in the low nanomolar range in several different human cancer cell lines. Washout *in vitro* experiments show irreversible cellular effects after 1h in contact with the compound, compelling the cells to apoptotic cell death likely due to PM534 induced disorganization of the tubulin cytoskeleton. PM534 inhibits migration and invasion of tumor cells *in vitro*, and arrests the cell cycle in the G2/M phase, forcing them to apoptosis. In addition, PM534 presents potent antiangiogenic effects *in vitro*, robustly inhibiting endothelial cells proliferation and migration, and the formation of angiotubes. The *in vivo* antitumor activity of PM534 was

characterized in human-derived tumors xenografted in athymic *nu/nu* mice, namely breast (MDA-MB-231), and pancreas (Mia-Paca-2). PM534 was intravenously administered once per week for three consecutive weeks at 5.0 mg/kg. *In vivo* PM534-induced antitumor activity (vs. placebo) was seen in MDA-MB-231 (T/C, 0.3% on Day 28; TV, $p<0.0001$) and Mia-Paca-2 (21.3% on Day 21; TV, $p<0.0001$). Also, PM534 treatment increased with statistical significance (vs. placebo) the median survival time of mice bearing MDA-MB-231 (82 vs. 33 days; $p<0.0001$) and Mia-Paca-2 (51 vs. 30 days; $p=0.0008$). Of note, complete tumor remissions were observed in 2/10 (lasting 11 days and 161 days, each), and 10/10 (lasting 45 days in 9/10 and 140 days in 1/10) PM534-treated animals bearing Mia-Paca-2 and MDA-MB-231 and tumors, respectively.
Conclusions: Based on *in vitro* activity against different human tumor cell lines, *in vivo* activity in xenografted human tumors, as well as on its anti-angiogenic properties, the safety, pharmacology and preliminary antitumor activity of PM534 will be evaluated in a first-in-human clinical trial to be conducted in patients with advanced solid tumors.

#6244

Design, synthesis, and structure-activity relationships of substituted pyrido[3,2-*d*]pyrimidines as microtubule targeting agents and anti-cancer agents

Yesha Vijaykumar Shah[1], Ruoli Bai[2], Ernest Hamel[2], Aleem Gangjee[1].
[1]Medicinal Chemistry, Duquesne University School of Pharmacy, Pittsburgh, PA,[2]Frederick National Laboratory for Cancer Research, National Cancer Institute, Frederick, MD

Microtubules (MTs) are composed of *αβ*-tubulin heterodimers and are essential components of the cellular cytoskeleton involved in critical cellular functions, including mitosis, cell migration and signaling, intracellular trafficking, and angiogenesis. Microtubule targeting agents (MTAs) are highly successful chemotherapeutic agents because they target MT dynamics and interfere with MT-dependent cellular processes. The clinical efficacy of MTAs is limited by multidrug resistance due to expression of the P-glycoprotein (Pgp) drug efflux pump or increased expression of *β*III-tubulin. This necessitates the development of novel MTAs effective against cell lines expressing these forms of drug resistance,

which could offer potential advantages in patients who fail to respond to current MTAs, such as paclitaxel. Previously, we reported colchicine site (CS) binding compound **1** with a pyrido[3,2-*d*]pyrimidine scaffold and a 2-H substitution and *N*4-4'-methoxyaniline substitution inhibited colchicine binding and tubulin assembly (87% inhibition at 5 μM and IC_{50} = 1.3 μM, respectively). Compounds **2-9** were designed with a 2-CH_3 substitution to evaluate the structure-activity relationships at the 4-position by using conformational restriction and isosteric replacements. Compounds **2-9** were synthesized, and the biological evaluation showed that compounds **2-9** inhibited tubulin assembly (**7**, IC_{50} = 0.72 μM) and binding of colchicine to tubulin (**7**, 97% inhibition at 5 μM, 81% at 0.5 μM). Compound **7** was found to be highly potent in the MCF-7 breast cancer cell line with an IC_{50} of 2.5 nM which was ~3.5-fold better than combretastatin-A4 (CA4). Compound **7** inhibited the growth of the human ovarian cancer cell line OVCAR-8 with an IC_{50} = 3.0 nM. For the Pgp overexpressing cell line NCI/ADR-RES, **7** was equally potent (IC_{50} = 3.0 nM), whereas paclitaxel was almost inactive (IC_{50} = 1,500 nM). Thus, we have identified 2-CH_3 substituted pyrido[3,2-*d*]pyrimidines as a novel structural scaffold for inhibition of tubulin assembly and colchicine binding that have potent cytotoxic activity against the breast cancer cell line MCF-7 and against both the parental ovarian cancer cell line OVCAR-8 and its derivative Pgp overexpressing cell line NCI/ADR-RES. These compounds thus merit further study as potential cancer chemotherapeutic agents.

Selective HDAC6 inhibition by ITF3756 modifies the landscape of gene and protein expression in human monocytes: Possible identification of a specific biomarker signature

Chiara Ripamonti, Valeria Spadotto, Monica Forino, Christian Steinkuhler, Gianluca Fossati. *Italfarmaco S.p.A., Cinisello Balsamo, Italy*

Histone deacetylase 6 (HDAC6) modulates tumor immunogenicity through several pathways, such as the control of PD-L1 expression on tumor and on lymphoid cells. Thus, HDAC6 is a potential pharmacological target for cancer treatment. In humans, HDAC6 inhibition can be monitored by measuring the ratio between tubulin and histone acetylation. However, the

identification of biomarkers to be used as a signature for patient stratification that correlates with the treatment efficacy is missing. Since we have previously demonstrated that the activity of the selective HDAC6 inhibitor ITF3756 on myeloid cells plays a role in the antitumor immune response in the TME, we reasoned that an ITF3756-specific signature could be identified in unstimulated monocytes treated with the compound. Monocytes were purified from healthy donors, treated with ITF3756 and RNAseq and proteomic analyses were performed. Gene Ontology analysis shows that ITF3756 has a widespread effect on monocyte transcriptome and proteome. We observed the down-modulation of genes and proteins involved in inflammatory pathways and in transcription regulation. Up-regulation of neutrophil-mediated immunity, metabolic pathways and protein phosphorylation was also identified. Focusing on genes that could be relevant in the tumor context, we selected a panel of genes from the most up- (SCL27A1, ANXA6 and IRF6) and down-modulated (CD84, RANK, CXCL2, CXCL3, STAB-1, CD163, PD-L1, CD206 and ADA). Interestingly, we found among the downmodulated genes markers of M2 macrophages, genes related to the tumor associated macrophages, and STAB-1, whose targeting is currently in clinical trials for cancer immunotherapy. Peripheral Blood Mononuclear Cells (PBMCs) could be a less expensive starting material for biomarker identification to be collected during a clinical trial when compared to purified monocytes. Thus, to ascertain whether the regulation by ITF3756 of our selected genes was detectable also in PBMCs we performed gene expression analysis after ITF3756 treatment and we confirmed that all selected genes were reproducibly modulated. Surface protein expression of M2 macrophages biomarkers in our panel, were determined by flow cytometry and all of them were significantly modulated in PBMCs. These data show how our approach successfully led both to the identification of a biomarker signature that could be used in clinical trials to monitor the pharmacodynamic effect of ITF3756, and to the discovery of previously unknown targets of HDAC6 inhibition.

#6246

The MTA-cooperative PRMT5 inhibitor AM-9747 exhibits robust antitumor activity in combination with clinically relevant chemotherapies and targeted agents in MTAP null tumor models

Katherine Slemmons, Brian Belmontes, Siyuan Liu, Jodi Moriguchi, Antonia Policheni, Paul E. Hughes. *Discovery Research, Amgen Inc., Thousand Oaks, CA*

Homozygous deletion of chr9p21, containing genes *CDKN2A* and *MTAP*, occurs in about 15% of cancers. MTAP loss, a key enzyme in the methionine and adenine salvage pathways, leads to the accumulation of its substrate MTA. MTA competes with the methyl donor SAM for binding to type II arginine methyltransferase PRMT5, placing PRMT5 in a hypomorphic state and vulnerable to further PRMT5 inhibition. MTA-cooperative PRMT5 inhibitors are an emerging class of therapeutics targeting MTAP null tumors. AMG 193, currently in Phase 1 trials, and its representative analog AM-9747 have broad spectrum activity in MTAP null tumor models across hematologic and solid tumor indications. Mechanistically, AM-9747 induces DNA damage, shown by increased phosphorylated H2AX, resulting in cell cycle arrest and senescence. Exploration of clinically relevant therapeutic combinations with standard of care (SOC) chemotherapies or targeted agents that could potentiate this DNA damage or target orthogonal pathways is a rational therapeutic approach. Here, we evaluated AM-9747 in combination with SOC chemotherapies and assessed synergy using the Chou-Talalay Method to generate Combination Index (CI) scores. SOC agents representing a variety of mechanisms of action (paclitaxel, carboplatin, gemcitabine, pemetrexed, irinotecan, 5-FU) were evaluated and results ranged from strongly synergistic ($CI<0.3$) to additive ($CI=1$) in a panel of non-small cell lung carcinoma (NSCLC) and pancreatic cancer cell lines. The SOC combinations augmented AM-9747 induced DNA damage resulting in increased cell cycle arrest and nuclear count assays confirmed the synergistic antiproliferative effects of the combinations. Combinations of AM-9747 and one strongly synergistic agent (carboplatin) and one moderately synergistic agent (paclitaxel) were evaluated in H292 NSCLC xenografts. Significant reductions in tumor burden compared to single agent treatments were observed with AM-9747 + paclitaxel (67% TGI) and AM-9747 + carboplatin (82% TGI). Additionally, roughly 2-3% of NSCLC tumors harbor both *MTAP* loss and a KRAS G12C mutation. To target both pathways we combined the FDA-approved KRAS G12C inhibitor sotorasib with AM-9747 and observed synergy ($CI<0.6$) in MIAPACA2 cells.

Nuclear counts confirmed a greater cell growth inhibition in the combination and immunoblots confirmed on target inhibition of both pathways. Combination treatment of AM-9747 and sotorasib in LU99 NSCLC xenografts resulted in significant tumor regression compared to each single agent with 10/10 mice tumor free. This combination is being tested in additional MTAP null KRAS G12C mutant models. Overall, our data suggests that combining MTA-cooperative inhibitor AM-9747 with SOC or clinically relevant targeted agents is a compelling therapeutic strategy for the treatment of *MTAP* null cancers.

Lurbinectedin shows potent activity in all four molecular subtypes of small cell lung cancer (SCLC) and POU2F3 and SLFN11 are biomarkers for a better response

Marta Martínez Diez[1], Gema Santamaría Nuñez[1], María José Guillén[2], Daniel Rueda[3], Eva Maria Garrido-Martin[1], Pablo Avilés[4], Carmen Cuevas[5]. *[1]Cell Biology and Mechanism of Action, Pharma Mar, S.A., Madrid, Spain,[2]Pharmacology, Pharma Mar, S.A., Madrid, Spain,[3]Biomarkers and Translational Studies, Pharma Mar, S.A., Madrid, Spain,[4]Pharmacology and Toxicology, Pharma Mar, S.A., Madrid, Spain,[5]Research and Development, Pharma Mar, S.A., Madrid, Spain*

Background - SCLC is the most aggressive lung cancer type and with the worst prognosis. There are four molecular subtypes based on the high expression of distinct transcription factors and with different therapeutic vulnerabilities. However, all share transcriptional addiction as pathogenic mechanism. Lurbinectedin is a novel oncogenic transcription inhibitor, approved in the United States and other countries for the treatment of adult patients with metastatic SCLC with disease progression on or after platinum-based chemotherapy. The aim of this study was to analyze the activity of lurbinectedin in the different SCLC molecular subtypes and to investigate new biomarkers of response.
Methods and Results - We have characterized a panel of 20 SCLC human cell lines based on the expression of ASCL1, NEUROD1, YAP1 and POU2F3, where lurbinectedin yielded a mean IC_{50} value of 6.52 nM, which is considerable greater than the activity exerted by topotecan, irinotecan,

carboplatin, etoposide, olaparib, alisertib and navitoclax (IC_{50} 100 μM-100 nM). Lurbinectedin potency is high in the four molecular subtypes, with IC_{50} values of 4.1, 14.9, 7.2, and 0.2 nM for SCLC-A, -N, -I and -P, respectively. However, high expression of POU2F3 correlated with better responses. In fact, mean IC_{50} was 0.28 nM for $POU2F3^{high}$ cells versus 12.1 nM for all $POU2F3^{low}$ cells (p=0.0443). Additionally, basal SLFN11 levels were evaluated, observing that $SLFN11^{high}$ cells responded better to lurbinectedin, with IC_{50} values of 1.1 nM versus 11.8 nM for $SLFN11^{low}$ (p=0.05). Likewise, lurbinectedin treatment induced greater antitumor activity in $SLFN11^{high}$ tumor-bearing mice (H526: T/C, 18% on day 11) than in $SLFN11^{low}$ tumor-bearing mice (H82: T/C, 65% on day 7) after intravenous treatment at 0.18 mg/kg (on days 0, 7 and 14). Finally, SLFN11 expression was evaluated by IHC in FFPE tumor samples from SCLC patients participating in a multicenter phase II clinical trial in advanced solid tumors (NCT02454972), which allowed lurbinectedin accelerated approval in this indication by FDA. Patients with higher expression of SLFN11 had a slightly better overall survival (OS at 6 months: 68.4% (<15%, N=20) vs. 98.7% (≥15%, N=20) p=0.0261)), especially in the refractory/resistant subgroup (OS at 6 months: 33.3% (<15%, N=9) vs. 100.0% (≥15%, N=6) p<0.0001).
Conclusions - Lurbinectedin is highly effective in all molecular subtypes of SCLC *in vitro* and *in vivo*, with IC_{50} values at least two logs more potent than for other antitumoral agents and its activity is even greater in tumors with high POU2F3 expression and/or high SLFN11 expression.

#6248

Inhibiting β-catenin in AML by targeting DDX5

WEI NI[1], Swati Garg[1], Fen Zhu[1], Ellen L. Weisberg[1], Basudev Chowdhury[1], Martin Sattler[1], Amulya Jakkani[1], Suiyang Liu[1], Dana M. Sanchez[1], Lizi Wu[2], Richard M. Stone[1], Matthew S. Davids[1], James D. Griffin[1]. *[1]Medical Oncology, DFCI/Harvard Medical School, Boston, MA,[2]Molecular Genetics & Microbiology, University of Florida, Gainesville, FL*

Despite the use of high-dose chemotherapy and HSCT, less than 70% of adult AML patients enter complete remission and most patients relapse in less than two years. These poor outcomes have motivated intensive searches for effective and safe targeted agents. Asp-Glu-Ala-Asp (DEAD)-box protein DDX5 was found to be highly expressed in several solid cancers. DDX5, especially its phosphorylated form at Y593, has been reported to promote β-catenin cytoplasm-to-nucleus shuttling and subsequently facilitate the transcriptional activities of the β-catenin/T-cell factor (TCF) complex leading to enhanced expression of genes that are critical for growth, including *MYC* and *CCND1*. Knockdown of *DDX5* has also been reported to reduce the growth of AML cells, indicating that DDX5 is a potential therapeutic target in AML. However, it remains unknown whether the growth dependence of AML on DDX5 is mainly mediated by β-catenin signaling. Importantly, drugs that selectively target DDX5 have not been tested in AML. In this study, we first analyzed the TCGA AML dataset and found that *DDX5* gene is significantly overexpressed in the AML cohort compared to normal bone marrow samples. High *DDX5* expression is associated with worse overall survival in AML patients. Moreover, *DDX5* correlates with *CTNNB1* which encodes β-catenin, at transcript levels. We further found that DDX5 is constitutively phosphorylated at Y593 and predominantly present in the nucleus of 10 AML cell lines tested. These results indicate the clinical relevance of DDX5 whose functional impact may link to β-catenin signaling in AML. We then determined the therapeutic efficacy of targeting DDX5 in human AML using RX-5902, a quinoxalinyl-piperazine compound. RX-5902 was previously shown to interfere with the interaction between phosphorylated DDX5 and β-catenin, inhibiting β-catenin signaling in some solid tumors. We found that RX-5902 attenuated phosphorylation of DDX5 at Y593, led to accumulation of β-catenin in the cytoplasm and consequently downregulated c-MYC in human AML cells within 24 hours. Treatment with RX-5902 dramatically increased cellular ROS level, induced cleaved-caspase3 mediated apoptosis and eventually inhibited cell growth of most human AML cell lines and primary AML cells in culture. These results mirrored what we observed following DDX5 depletion by shRNAs in AML cell lines. Also, dosing of RX-5902 *in vivo* significantly suppressed the growth of AML xenotransplants in immunocompromised mice and prolonged survival. Finally, we performed dynamic BH3 profiling and showed that RX-5902

increased apoptotic priming and BCL-2 dependence in AML cells. Therefore, we reasoned that simultaneous targeting DDX5 and BCL-2 may improve the therapeutic efficacy in AML. Indeed, concurrent treatment using RX-5902 and Venetoclax, a BCL-2 inhibitor, synergistically induced apoptosis in AML cells. Collectively, therapeutic targeting of DDX5 may be a novel and effective approach in AML and warrants further study.

#6249

Low Bcl-2 is a robust biomarker of sensitivity to nab-paclitaxel in Ewing sarcoma

Guillem Pascual-Pasto, Claudia Resa-Pares, Angel M. Carcaboso. *Hospital Sant Joan de Déu Barcelona, Barcelona, Spain*

Nanoparticle albumin-bound paclitaxel (nab-paclitaxel) shows potent preclinical anticancer activity in pediatric solid tumors such as Ewing sarcoma, rhabdomyosarcoma and neuroblastoma, but responses in clinical trials have been modest. In this work, we aimed to discover a rational biomarker-based approach to select the right candidate patients for this treatment. We assessed the efficacy of nab-paclitaxel in 27 patient-derived xenografts (PDX), including 14 Ewing sarcomas, five rhabdomyosarcomas and several other pediatric solid tumors. Response rate (partial or complete response) was remarkable in rhabdomyosarcomas (four of five) and Ewing sarcomas (four of 14). We addressed several predictive factors of response to nab-paclitaxel such as the expression of the secreted protein acidic and rich in cysteine (SPARC), chromosomal stability of cancer cells and expression of antiapoptotic members of the B-cell lymphoma-2 (Bcl-2) family of proteins such as Bcl-2, Bcl-xL, Bcl-W and Mcl-1. Protein (immunoblotting) and gene expression of SPARC correlated positively, while immunoblotting and immunohistochemistry expression of Bcl-2 correlated negatively with the efficacy of nab-paclitaxel in Ewing sarcoma PDX. The negative correlation of Bcl-2 immunoblotting signal and activity was especially robust ($r = 0.8352$; $P = 0.0007$; Pearson correlation). Consequently, we evaluated pharmacological strategies to inhibit Bcl-2 during nab-paclitaxel treatment. We observed that the Bcl-2 inhibitor venetoclax improved the activity of nab-paclitaxel in highly resistant Bcl-2-expressing Ewing sarcoma PDX. Overall, our results suggest that low Bcl-2 expression could be used to select patients with Ewing sarcoma sensitive to

nab-paclitaxel, and Bcl-2 inhibitors could improve the activity of this drug in Bcl-2-expressing Ewing sarcoma.

High expression level of GSK3β in basal triple negative breast cancer: Effects of the HDAC inhibitor, vorinostat

Beverly D. Lyn-Cook, Fatemeh Nouri Emamzaden, Beverly Word, George Hammons. *FDA-NCTR (National Center for Toxicological Research), Little Rock, AR*

High expression levels of glycogen synthases kinase 3 beta (GSK3β) have been correlated with poor prognosis in triple negative breast cancer (TNBC) patients. GSK3β is a multifaceted kinase and is a key regulator of a number of cellular processes. It is known to function as a positive regulator of epithelial-mesenchymal transition (EMT). Usually, cells that undergo EMT are known to acquire stem cell properties and these cells have properties that are known to be resistant to chemotherapies. Inhibition of GSK3β has been shown to decrease markers of EMT and reduce cancer stem cells. High levels of GSK3β were found in the basal-2 subtype of triple negative breast cancer cells, HCC1806. Histone deacetylases (HDACs) are expressed at high levels in some cancers, including TNBC. In this study, vorinostat, a histone deacetylase inhibitor, was shown to down regulate GSK3 expression in HCC1806 cells at both the gene and protein level using qPCR and western blots. Furthermore, cancer stem cells (CSC) cell markers CD44/CD24 using flow cytometry and immunostaining were significantly decreased. Previous studies published from our laboratory have shown vorinostat's ability to decrease TNBC cells invasion compacity, as well as cell growth. This study suggests that targeting GSK3β may be a potential therapeutic target for certain subtypes of TNBC. Triple negative breast cancer remains one of the most aggressive breast cancers, often having a high mortality rate in younger women.

#6252

HDAC inhibition increases Ewing sarcoma sensitivity to chemotherapy

Kaitlyn H. Smith, Chloe Sholler, Divya Gandra, Kimberly McKinney, Karl Dykema, Abhinav Nagulapally, Erin Trovillion. *Atrium Health, Charlotte, NC*

Purpose: The survival rate of those with Ewing sarcoma (ES) has seen very little improvement over the past several decades and remains dismal for those with recurrent or metastatic disease. Current treatment for Ewing sarcoma includes a combination of cytotoxic chemotherapeutic agents and local control with radiation and/or surgery. The purpose of this study is to identify currently available targeted agents which may be combined with chemotherapy for use in Ewing sarcoma to improve patient outcomes.
Methods: Novel targeted approaches for the treatment of ES were identified using RNA sequencing performed on ES patient tumors with bioinformatic analysis of gene expression. HDAC inhibitors were tested on patient cell lines at escalating doses and cell viability was assessed with CellTiter-Glo 2.0 and analyzed with GraphPad Prism to determine the IC50. Cells were treated with Panobinostat for 12 and 24 hours and RNA sequencing was performed. Cell cycle analysis was performed using Incucyte® Cell Cycle Lentivirus Reagent and analyzed using an Incucyte® S3. At 24- and 48-hours western blot analysis was performed to evaluate the effect on cell cycle and apoptosis. Combination studies with standard chemotherapy were performed and viability was assessed with CellTiter-Glo 2.0. At 24 hours of treatment with a combination of doxorubicin and HDAC inhibition western blot analysis was performed to evaluate changes in DNA damage and repair.
Results: RNA analysis identified HDAC2 as a potential therapeutic target. The pan-HDAC inhibitors, Panobinostat and Belinostat, and the HDAC1/2 inhibitor, Romidepsin, were cytotoxic to all Ewing sarcoma cell lines tested with clinically relevant IC50s. Mechanistically, pathways involved in cell cycle progression and DNA repair were repressed by Panobinostat as shown by RNA sequencing and western blotting (Cyclin D1, pRb, CHK1). Additionally, cell cycle analysis has shown a G1 arrest in response to HDAC inhibition. HDAC inhibitors significantly decrease cell viability when combined with standard chemotherapy (upfront and relapse therapy) compared to that of chemotherapy alone. When combined with doxorubicin, CHK1 and CHK2 were significantly decreased and pH2AX was significantly increased indicating an accumulation of DNA damage.
Conclusion: This work highlights that combining HDAC inhibitors with standard of care chemotherapy may be an effective treatment and improve outcomes for Ewing sarcoma patients. Future studies of HDAC inhibitors

combined with chemotherapy drugs will aim to determine efficacy in xenograft models.

#6253

SP-3164, a novel molecular glue degrader with activity in preclinical models of multiple myeloma

Aundrietta D. Duncan[1], Daniela Y. Santiesteban[2], Nadeem Q. Mirza[2], Steve Horrigan[2], Sheila DeWitt[2], Vincent Jacques[2], P. Leif Bergsagel[3]. *[1]Salarius Pharmaceuticals, Inc, Houston, TX,[2]Salarius Pharmaceuticals, Houston, TX,[3]Mayo Clinic, Phoenix, AZ*

Multiple myeloma (MM) makes up approximately 10% of all hematologic malignancies, with increasing incidence worldwide. Though treatment options for newly diagnosed patients have evolved in recent years, they are not curative, and relapse is common with 2,500-3,000 relapsed or refractory (R/R) MM US patients seeking novel treatments, annually. Cereblon (CRBN)-binding Ikaros and Aiolos (I/A) protein degraders (i.e., lenalidomide (LEN) and pomalidomide (POM)) have had great success in treating MM. However, due to the unstable chiral nature of the CRBN-binding moiety, common to these molecules, many exist as racemic mixtures (1:1 mixture of interconverting (*R*)- and (*S*)-enantiomers). A growing body of evidence suggests that the (*S*)- enantiomer is the active anticancer species, while the (*R*)-enantiomer is inactive and potentially results in undesired activity. The ability to stabilize the active (*S*)-enantiomer represents a potential strategy to improve therapeutic outcomes. We are developing SP-3164, the deuterium-stabilized (*S*)-enantiomer of avadomide (AVA), an I/A-degrading molecular glue which has been studied in over 400 patients, demonstrating safety and activity in hematologic diseases. Our *in vitro* data demonstrate that SP-3164 more potently and rapidly degrades the cancer-promoting transcription factors, I/A, compared to LEN, POM, and AVA, while the stabilized (*R*)-enantiomer, SP-3165, neither binds CRBN nor degrades I/A. In preliminary *in vivo* studies, SP-3164 elicited significant tumor growth inhibition (TGI). Here, we investigate the activity of SP-3164 in MM, compared to established treatment regimens.

SP-3164's potential to degrade Aiolos in MM.1S cells was compared to SP-3165, AVA, and POM. SP-3164 rapidly and robustly degraded Aiolos in a

time- and dose-dependent manner, more potently than AVA and POM, while SP-3165 demonstrated minimal Aiolos degradation. To investigate the effect of SP-3164 on cell survival, we treated NCI-H929 cells with SP-3164 (0.1 μM, 1 μM, and 10 μM) and SP-3165 (1 μM) and assessed apoptosis by flow cytometry. SP-3164 induced dose-dependent early and late apoptosis after 72 hours, while SP-3165 showed no induction of apoptosis. SP-3164's *in vivo* activity was assessed and compared to SP-3165, LEN, and POM in an NCI-H929 mouse xenograft model. SP-3164 showed significant TGI as a single agent while SP-3165 seemed to support tumor growth. LEN and POM demonstrated minimal TGI. When combined with dexamethasone (DEX), SP-3164 had improved TGI compared to the combination of POM+DEX.
These preclinical data demonstrate that SP-3164 is a potent CRBN-binding molecular glue with the ability to rapidly degrade cancer-promoting transcription factors and induce apoptosis *in vitro*. *In vivo*, SP-3164 has superior single agent and combination activity compared to approved molecular glues. These data support the continued development as a novel therapy in MM.

The discovery and preclinical characterization of the SAM-competitive PRMT5 inhibitor UCT-000445

Martina S. J. McDermott[1], Neil A. O'Brien[1], Brendan O'Boyle[2], Michael Bartberger[2], Oliver C. Losón[2], Kevin Chau[1], Ella Schwab[1], Jenny Hong[1], Jiaying Zhou[1], Chuhong Hu[1], Tong Luo[1], Raul Ayala[1], John Glasby[1], Brian M. Stoltz[3], Dennis J. Slamon[1]. *[1]UCLA, Los Angeles, CA,[2]1200 Pharma, Culver City, CA,[3]California Institute of Technology, Pasadena, CA*

Protein arginine methyltransferase 5 (PRMT5) is a methyltransferase enzyme that symmetrically dimethylates arginine residues of histones, transcription elongation factors, translation regulators, and transcription factors like p53. It also regulates the activity of MAPK and PI3K signaling through methylation and activation of various receptor tyrosine kinases. As such, it has epigenetic effects that may be therapeutic in oncology. Successful clinical development of PRMT5 inhibitors will depend on upon utilizing this unique inhibitor modality and identifying those cancers with sensitivity to PRMT5 inhibition. By evaluating the potency and efficacy of

several SAM-competitive, substrate-competitive, and MTA-cooperative PRMT5 inhibitors using a large (n>500), diverse panel of human cancer cell lines, we determined that the SAM-competitive inhibitor modality offers the best therapeutic potential thanks to its larger therapeutic window *in vitro*. This screening approach also identified several solid tumor histologies that were extremely sensitive to PRMT5 inhibition. Using our proprietary chemistry and by screening through the panel of human cancer cell lines, we identified UCT-000445, a SAM-competitive PRMT5 inhibitor with high selectivity over PRMT9 and good pharmacokinetic properties. Moreover, efficacy UCT-000445 is achieved regardless of *MTAP* gene status in histologies outside of hematological malignancies and including colon. UCT-000445 potently inhibits tumor growth in multiple human xenograft models of cancers, including but not limited to colon and lung cancers. The responses observed are durable upon cessation of treatment. Marked combined efficacy was also observed with standard of care treatment in these cancer types. UCT-000445 was well tolerated in vivo and using a CD-1 nude mouse model we found that while reticulocyte proliferation (a surrogate marker for bone marrow cytopenias) is abrogated by continuous treatment with UCT-000445, the use of intermittent dosing schedules overcomes this effect, while yielding equivalent efficacy. Our data with UCT-000445 indicate that SAM-competitive PRMT5 inhibitors may represent a novel and compelling therapeutic strategy for the treatment of multiple solid tumors.

Anti-proliferative effect of two copper complexes against medulloblastoma cells

Hope Korshie Fiadjoe[1], Christoffer Lambring[1], Umesh T. Sankpal[1], Duaa Alajroush[2], Alvin A. Holder[2], Riyaz Basha[1]. *[1]Microbiology, Immunology and genetics, University of North Texas Health Science Ctr., Fort Worth, TX,[2]Old Dominion University, Norfolk, VA*

Background and Purpose: Copper is a crucial structural component for many significant enzymes, as well as a key catalytic co-factor in redox processes. The flexible Cu(I/II) redox behavior facilitates the formation of copper complexes that are more potent and less toxic. The anticancer activity of several agents can be enhanced by forming copper complexes.

The purpose of this study is to evaluate the anti-proliferative effects of two copper (II) complexes, copper-tolfenamic acid (Cu-TA) and copper thiosemicarbazone (Cu-acetylethTSC or CuTSC) against medulloblastoma (MB). MB is a cancer of the cerebellum which is associated with frequent relapse and drug resistance with the current treatments. It necessitates the development of alternative strategies. The anti-cancer activity of Cu-TA was evaluated in laboratory testing in some cancer models, but it has not been studied in MB. CuTSC against colorectal cancer, leukemia and breast cancer has been studied but it has not in MB.
Methods: TA and TSC were complexed with Cu and Cu-TA and CuTSC complexes were characterized through colorimetric/mass spectrometric analyses. Cancer cells and cardiomyocytes were cultured using standard protocols and cell viability was measured using Cell Titer-Glo kit (Promega). Protein expression was determined by Western blot analysis.
Experiments/Results: CuTA and CuTSC complexes showed proper characterization and stability during the testing period. Cardiomyocytes (H9C2) and human cancer cell lines representing breast, Ewing sarcoma and MB were screened for anti-proliferative activity of these two Cu complexes. While, cell viability was inhibited in all cancer cell lines, MB cell lines (DAOY and D283) showed higher efficacy while H9C2 cell viability was not affected. To understand the underlying mechanism of action, the effect of Cu-TA was assessed on the expression of c-PARP, Specificity protein 1 (Sp1) and an antiapoptotic protein, survivin. Western blot results revealed a clear decrease in the expression of both Sp1 and survivin and upregulation of c-PARP.
Discussion/Conclusion: Both Cu-TA and CuTSC treatments result in a dose-time dependent anti-proliferative activity against cancer cells but not affecting non-malignant cardiomyocyte cells. Cu-TA can inhibit Sp1 and survivin and increase PARP cleavage suggesting the effect on Sp1-regulated oncogenes and an induction of apoptotic pathways. The studies to establish crossing of Blood Brain Barrier and further understand the underling mechanisms of these two Cu complexes in single and combination treatment alongside chemotherapeutic agents are currently under investigation.

Inhibition of class IIa HDACs potentiates MYC inhibitor-driven cytotoxicity by inducing MYC depletion and oxidative stress in non-small cell lung cancer

Jina Park, Ying-Yu Chen, Jennie Cao, Michelle Vaz, Ray-Whay C. Yen, Stephen B. Baylin, Michael J. Topper. *Johns Hopkins, Baltimore, MD*

Lung cancer is the most common cause of cancer mortality worldwide and non-small cell lung cancer (NSCLC) accounts for approximately 85% of all lung cancers. Dysregulation and/or overexpression of MYC are widely implicated in NSCLC, which suggests that MYC may be a promising therapeutic target for the treatment of NSCLC. Recently, two direct MYC inhibiting agents with improved *in vivo* efficacy and tolerability, MYCi975 and Omomyc, have been developed. To define new drug strategies that could potentiate the therapeutic effects of MYC inhibitors, transcriptome datasets from MYCi975 and Omomyc studies were reanalyzed. These data revealed the induction of two class IIa histone deacetylases (HDACs), HDAC5 and HDAC9, upon MYC inhibition. Importantly, class IIa HDACs are involved in cancer proliferation, aggressiveness, and prognosis. In addition, novel agents that selectively inhibit class IIa HDACs have demonstrated promising anti-tumor efficacy; thus, suggesting potential therapeutic benefits from dual targeting of MYC and class IIa HDACs. We assessed the treatment efficacy of MYCi plus class IIa HDACi across 18 NSCLC cell lines, 10 of which demonstrated substantial reduction of cell viability upon combination treatment. Querying of driver mutation spectra associated with differential drug response in our cell line panel defined that EGFR mutant cell lines exhibited resistance, while STK11 or Ras mutant cell lines were sensitive to our drug paradigm. Gene set enrichment analysis comparing the transcriptomes of sensitive versus resistant cell lines revealed that MYC Targets, Oxidative Phosphorylation, and Reactive Oxygen Species (ROS) pathways were activated in combination treatment responsive cell lines. RNA sequencing on treated cell lines identified large-scale transcriptional shifts facilitated by combination treatment, including suppression of MYC, cell cycle, and mitochondrial pathways. Furthermore, G1/S arrest and elevated mitochondrial ROS levels in combination drug-treated cells were confirmed using flow cytometry. Concordant with the role of MYC as a key cell cycle regulator, MYC protein levels were decreased in the combination treatment group as compared to the vehicle or

mono-treatment groups. Importantly, both MYC overexpression and ROS scavenger treatment partially rescued the reduction of cell viability by combination treatment, suggesting both MYC depletion and ROS elevation as contributors to therapeutic efficacy driven by combination treatment. Expanding these studies to *in vivo* models, we discern that combination MYC and class IIa HDAC inhibition significantly reduced tumor burden in a patient-derived xenograft model of human NSCLC. In summary, we define here a novel drug paradigm combining MYC and class IIa HDAC inhibitors, which potentiates anti-tumor efficacy in NSCLC via MYC depletion and oxidative stress.

Developing HDAC inhibitors as immunomodulators

Sean Colligan, Li Shen, Christopher Rupert, Jonathan Bard, Roberto Pili.
University at Buffalo, Buffalo, NY

Immune checkpoint inhibitors (ICIs) are standard of care for several solid tumor types, including renal cell carcinoma (RCC). However, the clinical success of these therapies is dampened by the fact that the majority of patients demonstrate either inherent resistance to treatment or develop secondary resistance following an initial response. One key mechanism of tumor-driven ICI resistance is the generation and recruitment of suppressive immune cell types, including regulatory T cells (Tregs) and myeloid-derived suppressor cells (MDSCs), which coordinate to suppress anti-tumor T cell responses. Thus, there is a critical need for the development of novel combination strategies aimed at mitigating the presence and function of suppressive immune cells to improve the efficacy of ICIs in the clinic. Our laboratory has previously demonstrated that histone deacetylase inhibition (HDACi) is associated with a decrease in both the number and function of tumor-infiltrating Tregs and MDSCs in the RENCA tumor model. Thus, the overall goal of these studies both preclinically and clinically is to investigate the impact of the immunomodulatory effects of HDACi in combination with ICI therapy, with the overall hypothesis that HDACi will improve the efficacy of anti-PD1 therapy in RCC. Our pre-clinical data support this hypothesis by demonstrating increased tumor control and survival in RENCA tumor-bearing mice when treated with a combination of anti-PD1 and HDACi compared to single agent therapy. These increases

were also associated with an increase in the activation state of anti-tumor immune cells, as demonstrated by increased surface expression of MHC Class II molecules on macrophages and a decrease in phenotypically defined monocytic MDSCs. ATACseq and RNAseq data generated from combination-treated animals also outline a gene expression signature associated with both myeloid and T cell activation. Interestingly, our clinical studies also afforded us the opportunity to investigate potential biomarkers associated with responder status, which will allow us to better predict patient outcomes and administer therapies accordingly. Accumulating evidence from two independent clinical trials run by our group suggests that high levels of suppressive $CD11b^{+}HLA\text{-}DR^{lo}$ MDSCs at baseline in the peripheral blood is associated with lack of clinical response to the combination of HDACi and ICI. Overall, these data support the rationale for the combination of ICI and HDACi in the clinic, and provide a potentially useful biomarker through which we can predict the success of combination therapy.

The discovery and preclinical characterization of the potent covalent $KRAS^{G12C}$ inhibitor UCT-001024

Tristin E. Rose[1], Brendan M. O'Boyle[1], Justin A. Hilf[l], Emma L. Baker-Tripp[1], Zhengao Feng[1], Kevin Yang[1], Michael D. Bartberger[1], Oliver C. Losón[1], Neil A. O'Brien[2], Martina S. J. McDermott[2], Naeimeh Kamranpour[2], Weiping Jia[2], Tong Luo[2], Raul Ayala[2], John Glasby[2], Brian M. Stoltz[3], Dennis J. Slamon[2]. *[1]1200 Pharma, Culver City, CA,[2]UCLA, Los Angeles, CA,[3]California Institute of Technology, Pasadena, CA*

Small molecule inhibitors of $KRAS^{G12C}$ have garnered substantial interest as a targeted therapy for lung, colon and pancreatic cancers bearing this mutation. Data from multiple clinical programs have shown strong efficacy in lung tumors but diminished and differential efficacy for other tumor sites including lung-derived brain metastases. We undertook a series of *in vitro* and *in vivo* studies to evaluate clinically staged $KRAS^{G12C}$ inhibitors in an effort to elucidate pharmacological factors underlying these clinical differences and identified potency, permeability/efflux, and clearance as impediments to efficacy, particularly in the context of brain metastases.

Adagrasib is reportedly efficacious in patients with brain metastases. Our preclinical experimentation suggests that distinguished potency and pharmacokinetics are critical to therapeutic benefit, particularly in the context of brain metastases. Using both structure- and ligand-based design approaches, we identified a development candidate UCT-001024, which is a covalent $KRAS^{G12C}$ inhibitor that demonstrates superior target-engagement kinetics and cellular potency *in vitro*. UCT-001024 also demonstrates improved plasma and whole brain unbound clearance, and *in vivo* potency in ectopic xenograft models and a brain-tropic NSCLC metastasis model relative to adagrasib. Additionally, UCT-001024 shows a favorable DDI profile and ion channel safety in an *in vitro* iPSC-derived cardiomyocyte cardiac proarrhythmia assay.

#6259

Novel inhibitors of StAR related lipid transfer protein 5 inhibitors target plasma membrane lipid raft growth signaling

Shoja Hajira, Chetna Sharon, Daniel RodriguezAgudo, Rio Boothelllo, Glenn Kellogg, Gregorio Gil, William Pandak, Bhaumik B. Patel. *Virginia Commonwealth University, Richmond, VA*

Background: Treatment of colorectal cancer (CRC) presents a major challenge due to chemotherapeutic resistance and recurrence, which are attributed to the presence of cancer stem cells (CSCs). Cholesterol metabolism is a critical regulator of CSCs. Lipid Rafts are cholesterol-rich microdomains in the plasma membrane (PM) that anchor various growth receptors tyrosine kinases (RTKs). STARD5 is a novel protein that helps transport cholesterol from the endoplasmic reticulum to the PM. We have identified specific small molecule inhibitors of the STARD5 which disrupt the lipid rafts, resulting in the inhibition of growth signaling pathways.
Methods and Results: In-silico modeling studies using STARD5 crystal structure revealed 8 putative inhibitors (SD5i (A-H)). In vitro binding studies to determine secondary structural changes using circular dichroism spectroscopy revealed SD5iA and SD5iB as excellent STARD5 ligands. Both SD5iA and SD5iB caused a potent inhibition (IC_{50} 0.3 -18 μM) of CSC-enriched 3D spheroids in 9 CRC cell lines representative of 3 consensus molecular subtypes. However, SD5iA but not SD5iB showed toxicity towards normal murine intestinal organoids at effective doses

against CRC CSCs. Also, SD5iB enhanced cytotoxicity by oxaliplatin and panitumumab against CRC CSCs in HT-29 spheroids. Hence, SD5iB was advanced into in vivo studies. SD5iB caused no discernible toxicity in doses as high as 100 mg/kg in NCr nude mice at gross, serum chemistry, organ viability, or intestinal stem cell level (organoid formation). Subsequently, we generated s.c. xenograft using dual CSC marker sorted HT-29 cells and enriched them further with chemotherapy (5-fluorouracil and oxaliplatin weekly x 3) treatment followed by randomization to vehicle or SD5iB (100mg/kg i.p. 3/wk x 3 wks.). We observed xenograft growth inhibition and LGR5 expression in SD5iB-treated animals compared to vehicle controls. Mechanistically, we observed a decrease in free accessible PM cholesterol by SD5i measured by fluorescently tagged cholesterol-binding bacterial protein fALOD4 in HT-29 cells. Moreover, lipid raft staining (cholera toxin B staining) was significantly reduced in SD5iB-treated HT-29 cells compared to vehicle control using immunofluorescence. Further, lipid raft isolation was done by sucrose gradient ultracentrifugation to study the changes in the phosphorylation of RTKs SD5iB treatment in HT-29 spheroids resulted in decreased phosphorylation of EGFR, IGF1Rβ, and FGFR1 in isolated lipid rafts. Consequently, we observed a robust inhibition of ERK1/2 activation following SD5iB treatment compared to vehicle control.
Conclusion: SD5i shows anti-CSC activity by targeting lipid-raft-driven growth factor signaling. Hence, STARD5 inhibitors represent a novel class of targeted therapy that will enhance the efficacy of FDA-approved therapies in CRC.

Lysine-specific histone demethylase 1A (KDM1A/LSD1) inhibition attenuates DNA double-strand break repair and augments efficacy of temozolomide in glioblastoma

Salvador Alejo[1], Bridgitte Palacios[1], Prabhakar Pitta Venkata[1], He Yi[1], Wenjing Li[2], Jessica Johnson[1], Sridharan Jayamohan[1], Weixing Zhao[2], Siyuan Zheng[3], Takayoshi Suzuki[4], Rajeshwar R. Tekmal[1], Andrew Brenner[3], Ratna K. Vadlamudi[1], Gangadhara R. Sareddy[1]. *[1]Obstetrics & Gynecology, UT Health Science Center at San Antonio, San Antonio,*

TX,[2]Biochemistry & Structural Biology, UT Health Science Center at San Antonio, San Antonio, TX,[3]UT Health Science Center at San Antonio, San Antonio, TX,[4]The Institute of Scientific and Industrial Research, Osaka University, Osaka, Japan

Background: Glioblastoma (GBM) patients face a dismal prognosis, with median survival of ~15 months and 5-year survival rate of 6.8%. Standard of care includes surgical resection, external beam radiation therapy, and adjuvant chemotherapy with temozolomide (TMZ). Unfortunately, all GBM patients succumb to their disease. Glioma stem cells (GSCs), a GBM subpopulation, possess enhanced DNA repair that contributes to chemoradiotherapy resistance. The epigenetic modifier lysine-specific histone demethylase 1A (KDM1A/LSD1) is overexpressed in GBM and emerging studies show KDM1A is implicated in DNA damage response. This study aims to determine the significance of KDM1A to promote DNA repair in GSCs. We hypothesize KDM1A inhibition augments therapeutic efficacy of TMZ via attenuation of DNA repair pathways.
Methods: Patient-derived GSCs were obtained via IRB-approved protocol from patient samples at UT Health San Antonio. KDM1A knockdown and knockout cells were generated by transduction of validated KDM1A-specific shRNA or gRNA, respectively. Brain bioavailability of KDM1A inhibitor NCD38 was established using LS-MS/MS. Effect of combination KDM1A knockdown or inhibition with TMZ was studied using cell viability, neurosphere, and self-renewal assays. Mechanistic studies were conducted using CUT&Tag-seq, RNA-seq, immunofluorescence, comet, Western blotting, RT-qPCR, homologous recombination (HR), and non-homologous end-joining (NHEJ) reporter assays. *In vivo* efficacy of KDM1A knockdown or inhibitor alongside TMZ was determined using orthotopic murine GBM models.
Results: GBM patient data sets showed KDM1A is elevated in recurrent GBM versus primary tumors. KDM1A knockdown, knockout, or pharmacological inhibition increased efficacy of TMZ in reducing cell viability and self-renewal of GSCs. Pharmacokinetic studies demonstrated KDM1A inhibitor NCD38 is readily brain penetrable. CUT&Tag-seq studies showed KDM1A is enriched at the promoters of DNA repair genes. RNA-seq studies confirmed that KDM1A inhibition reduced expression of DNA repair-related genes. RT-qPCR and Western blotting validated

downregulation of DNA double-strand break repair genes. Knockdown, knockout, or inhibition of KDM1A attenuated HR and NHEJ-mediated DNA repair capacity. Immunofluorescence and comet assay demonstrated increased TMZ-mediated DNA damage in NCD38-treated GSCs. Importantly, KDM1A knockdown or inhibition enhanced efficacy of TMZ and significantly improved survival of mice bearing orthotopic GBM tumors.
Conclusions: Our results provide compelling evidence KDM1A is essential for DNA repair in GSCs and KDM1A inhibition sensitizes GBM to TMZ via attenuation of DNA repair pathways. These findings suggest combination therapy of KDM1A inhibitor NCD38 with TMZ is a potential novel therapeutic strategy to improve GBM outcomes.

#6264
NUV-868, a novel BD2-selective BET inhibitor, in combination with enzalutamide or olaparib, inhibits growth of solid tumor xenografts
Hitisha Patel, Jennifer Hertzog, Laura Heller, Spandana Vootukuri, Yan Zhang, Chris Miller, Gary Hattersley. *Nuvation Bio, Inc., New York, NY*

The bromodomain and extraterminal domain (BET) family of proteins play a vital role in gene transcription, making it an attractive therapeutic target for cancer. BET inhibitors can also combine with many anticancer agents to enhance activity. The bromodomains of the BET protein, BD1 and BD2, have unique functions and inhibiting either domain can result in differential responses. To date, non-selective BET inhibitors have failed during early clinical development due to significant on-target toxicity and limited benefit; however, selectively targeting specific bromodomains may result in a more favorable benefit/risk profile. NUV-868 is a novel and highly selective BD2 inhibitor of the BET protein family with ~1500-fold selectivity for BRD4-BD2 relative to BRD4-BD1. Herein, we describe NUV-868 and its activity in multiple in vitro and in vivo solid tumor models. Target engagement, selectivity of bromodomain inhibition, and regulation of BET-mediated gene expression were examined. Additionally, the antitumor activity of NUV-868 in combination with enzalutamide or olaparib was studied in tumor xenograft models of prostate, breast, and pancreatic cancer. NUV-868 demonstrated high selectivity for BD2 and regulated expression of several BET target genes. NUV-868 in combination

with enzalutamide inhibited growth of several prostate cancer cell line- and patient-derived xenografts. NUV-868 in combination with olaparib inhibited tumor growth in models of breast, ovarian and pancreatic cancer. Our preclinical data demonstrate that NUV-868, a BD2-selective BET inhibitor, inhibits growth of tumor xenografts in combination with enzalutamide or olaparib and provides rationale for examination of these combinations in the clinic. An ongoing, phase 1 clinical study (NCT05252390) is evaluating NUV-868 as a monotherapy and in combination with olaparib or enzalutamide in patients with advanced solid tumors.

#6266

Group 3 medulloblastoma transcriptional networks are selectively sensitive to EP300 and CBP bromodomain inhibition

Noha Ahmed Mohammed Ahmed Shendy. *St. Jude Children's Research Hospital, Memphis, TN*

EP300/CBP are paralogous, multidomain histone acetyltransferases (HATs) that regulate gene expression by establishing enhancer and promoter marks on histone proteins. While EP300 and CBP proteins bind and regulate genes broadly across the genome, they also function to promote the expression of tumor-selective oncogenes such as the transcription factor *c-MYC*. This activity makes these proteins attractive targets for preclinical therapeutic development. EP300/CBP proteins contain highly homologous domains, including catalytic HAT domains and bromodomains (BRDs) that mediate physical binding of EP300/CBP to acetylated proteins. Importantly, however, the relative contribution of these distinct domains to tumor cell proliferation remains unresolved. To identify the relative contribution of the EP300/CBP BRD and HAT domains, we used a chemical strategy. We performed a cell viability-based high-throughput screen of the potent EP300/CBP BRD- or HAT-specific inhibitor, CCS1477 or A-485 on 454 barcoded cancer cell lines representing 31 distinct cancer types. These data revealed that the proliferation of most tumor cell lines regardless of the type of cancer were equally affected by targeting either domain of EP300/CBP. Intriguingly, Group 3 medulloblastoma (G3MB) cell lines were the most sensitive to EP300/CBP BRD inhibition, compared to HAT inhibition. Since G3MB cells are highly sensitive to BRD4 inhibition, we conducted a

bromoscan analysis of the phase 1 compound CCS1477, which revealed high selectivity for EP300/CBP (K_d~4-5nM), with limited off-target effects on BRD4 (K_d~250nM) or other bromodomain-containing proteins. To validate that the effects on G3MB were primarily due to inhibition of EP300/CBP, we performed biotinylated CCS1477 pulldown assays in G3MB neurosphere cultures using *in vitro* relevant dosing of CCS1477, which demonstrated selective pulldown of EP300 and CBP, but not BRD4. Further, crystallographic studies of the EP300, CBP and BRD4 bromodomains in complex with CCS1477 demonstrated that the selectivity for the EP300/CBP BRD was critically dependent on interactions between the difluorophenyl group of CCS1477 and amino acid side chains in the BRD of EP300/CBP. In contrast, the analogous sidechains of BRD4 were unable to coordinate efficient binding of CCS1477. Mechanistically, treatment of MB cells with CCS1477, but not A-485 or the BRD4 inhibitor JQ1, caused rapid early loss of mRNA expression of specific G3MB dependency networks including the driver oncogene c-*MYC*. These studies identify a selective role for the EP300/CBP bromodomain in maintaining genetic dependency networks in G3MB cells and provide new chemical approaches to disrupting malignant transcription in Group 3 medulloblastoma.

#6267

A novel and potent EZH1/2 dual inhibitor, HM97662 demonstrates antitumor activity in T-cell lymphoma

Jooyun Byun, Seung Hyun Jung, Yu-Yon Kim, Miyoung Lee, Gunwoo Lee, Heesun Moon, Eun Young Lee, Junghwa Park, Seon Yeong Han, Young Gil Ahn, Young Hoon Kim, Kwee Hyun Suh. *Hanmi Pharmaceutical Co., Ltd., Seoul, Korea, Republic of*

Chromatin remodeling is a crucial process for transcriptional regulation, of which dysregulation is often observed in various human cancers. The enhancer of zeste homology 2 (EZH2) and its homolog EZH1 are catalytic subunits of polycomb repressive complex 2 (PRC2), which trimethylate histone H3 at lysine 27 (H3K27me3) to repress transcription of its target genes.

Although methlytransferase activity of PRC2 is mainly contributed by EZH2, EZH1 also conducts a compensatory role to maintain tri-methylation

of H3K27. EZH1 also directly binds to chromatin and modulates its condensation. Recent studies have suggested that EZH1 as well as EZH2 played a critical role in T-cell lymphoma such as ATL/L and PTCL, which had high innate EZH1 and increased EZH2 expression upon acquisition of their malignancy. Consequently, dual inhibition of EZH1/2 might induce higher expression of downstream tumor suppressor genes than blocking EZH2 alone, expecting greater activity as an anti-cancer therapy.
Herein, we presented a novel and potent EZH1/2 dual inhibitor, HM97662, which simultaneously inhibited the methyltransferase activity of both EZH1 and EZH2 with 2.1 and 16 nM of IC_{50}, respectively. Surface plasmon resonance (SPR) assay verified that HM97662 had great binding affinity on EZH1-EED-SUZ12 complex as well as EZH2-EED-SUZ12 complex than competitors. HM97662 also showed broad and strong antiproliferative activity against various T-cell lymphoma cell lines. Representatively in HH cells, HM97662 not only suppressed global tri-methylation of H3K27, but also dose-dependently increased protein expression levels that modulate cell cycle or cancer cell apoptosis. HM97662 exhibited increment of CDKN1A (p21) proteins involved in cell cycle arrest and induced protein levels of cleaved caspase-3 as well as PARP. Additionally, resulting induction of apoptosis by HM97662 in HH cells was confirmed by TUNEL staining. Mechanistically, HM97662 increased mRNA expression of several target genes inducing cell cycle arrest and apoptosis in gene panel assay performed in HH cells. Two cell cycle repressor, CDKN2A (p16) and CDKN1C (p57), and a pro-apoptotic marker, BTG-2, were dose-dependently increased by HM97662. We further conducted chromatin accessibility assay and identified that the chromatin structures of them were loosened and highly transcribed after the treatment of HM97662.
Based our *in vitro* pharmacology data, we evaluated an antitumor activity of HM97662 in EZH1/2 co-expressed HuT-102 T-cell lymphoma cell mouse xenograft model, and daily oral dosing of HM97662 showed potent tumor growth inhibition.
In conclusion, the present studies demonstrated that HM97662 has promising prospective for the treatment of patients with T-cell lymphoma. Given that the necessity of new treatment options on T-cell lymphoma, it is urgent to assess the effectiveness of HM97662 in further clinical trials.

#6268

TT125-802 is a potent and highly selective CBP/p300 bromodomain inhibitor for the treatment of castration resistant prostate cancer and haematological malignancies

Sara Laudato, Dorothea Gruber, Thomas Bohnacker, Martin Schwill, Charles-Henry Fabritius, Raquel Herrador, Katrin Westritschnig, Thushara Pattupara, Vikram Ayinampudi, Stefanie Flückiger-Mangual. *TOLREMO Therapeutics AG, Muttenz, Switzerland*

The paralogous lysine acetyltransferases CREB-binding protein (CBP) and p300 are key epigenetic regulators involved in diverse signaling pathways in cancer. The bromodomain (BRD) of CBP/p300 serves as an acetyl-lysine "reader" that allows CBP/p300 to bind chromatin at acetylated histone and non-histone proteins leading to the regulation of gene transcription. Indeed, CBP/p300 are critical co-activators of nuclear receptors, including the androgen receptor (AR) in castration resistant prostate cancer (CRPC). Thus, inhibition of CBP and p300 is an emerging therapeutic strategy to block the transactivation activity of the AR in CRPC. In addition, inhibition of the CBP/p300 BRD has been described as a potential therapeutic strategy to treat multiple myeloma (MM) through transcriptional suppression of interferon regulatory factor 4 (IRF4) and concomitant repression of its target genes MYC and MYB.

TT125-802 is a highly selective and potent, oral small molecule inhibitor of the BRD of CBP/p300. In a BROMOscan assay against a panel of 40 BRD-containing proteins, TT125-802 revealed the unique selectivity to the BRD of CBP/p300 with a minimal off-target binding to all other BRDs, including BET proteins.TT125-802 shows selective anti-proliferative activity in AR-dependent prostate cancer cell lines (22Rv-1, C4-2, and LNCaP) and inhibits AR target gene expression (KLK2, KLK3, TMPRSS2, and MYC) in a dose-dependent manner (IC50 of 2 to 33 nM). AR-negative prostate cancer cell lines (DU-145 and PC-3) are insensitive to TT125-802 in vitro, pointing to an AR-selective mode of action. In an *in vivo* model of CRPC, TT125-802 inhibited tumor growth when administered orally to human C4-2 xenograft-bearing mice. Daily dosing of TT125-802 was well tolerated with stable bodyweights and platelet counts. In addition, preclinical studies in CRPC patient-derived xenograft (PDX)-bearing mice showed that the combination treatment of TT125-802 and enzalutamide had a synergistic effect on tumor growth inhibition compared to single agent treatments.

TT125-802 reduced mRNA expression of the AR-target genes in tumor samples and decreased plasma PSA levels compared to enzalutamide alone, and the combination reduced levels even further. In a preclinical model of MM (OPM2), TT125-802 had a dose-dependent effect on tumor growth, inducing tumor regressions at the highest dose. Target genes such as MYC, MYB, and IRF4 were potently downregulated in tumors. We conclude that TT125-802 is a novel, highly selective inhibitor of the BRD of CBP/P300. It has therapeutic potential as monotherapy in prostate cancer and multiple myeloma and in combination with next-generation AR inhibitors for patients with lethal prostate cancer. A FIH study of TT125-802 in cancer patients is on track to start in 2023.

JBI-778, a novel brain-penetrant small molecule PRMT5 inhibitor for treatment of cancer

Dhanalakshmi Sivanandhan[1], Chandru Gajendran[1], Naveen Sadhu M[2], Zainuddin Mohammed[1], Ramachandraiah Gosu[3], Divsha Sher[4], Shahar Mansur[4], Dinorah Friedmann-Morvinski[4], Sridharan Rajagopal[2], Luca Rastelli[5]. *[1]Discovery Biology, Jubilant Therapeutics Inc, Bedminster, NJ,[2]Discovery Chemistry, Jubilant Therapeutics Inc, Bedminster, NJ,[3]Protein Chemistry, Jubilant Therapeutics Inc, Bedminster, NJ,[4]Sagol School of Neuroscience, Department of Biochemistry and Molecular Biology, Tel Aviv University, Tel Aviv, Israel,[5]Chief Scientific Officer, Jubilant Therapeutics Inc, Bedminster, NJ*

Introduction: Protein arginine methyltransferases (PRMTs) transfer a methyl group from the cofactor S-adenosyl-L-methionine (SAM) to the arginine of a substrate protein [(1,2)]. PRMT5 is a type II protein arginine methyltransferase that catalyzes the symmetrical dimethylation. PRMT5 drives transcriptional suppression of cell cycle control and tumor suppressor genes by hypermethylating promoter histones H3R8 and H4R3. Recently, dysregulation of the splicing machinery has been identified to be one of the therapeutic vulnerabilities for PRMT5 inhibition in multiple cancers. Therefore, inhibitors selectively targeting PRMT5 could be of high clinical value in cancers with defects in spliceosome machinery. In this regard, we

are developing a series of novel substrate competitive PRMT5 inhibitors to target brain cancer and solid tumors with brain metastasis.
Methods: Structure based drug design was used to identify novel PRMT5 inhibitors. To assess *in vitro* potency, flash plate assay was used. Cell based activity was assessed by measuring the symmetrical dimethylation of SmD3, intron retention and long-term cell proliferation assays. Tumor growth inhibition was measured in orthotopic glioblastoma models in mice.
Results: Our lead PRMT5 inhibitor JBI-778 had a strong in vitro potency against PRMT5 where the EC_{50} was ~5 nM and a similar cellular potency (< 10 nM) in inhibiting symmetric dimethylation of arginine. JBI-778 showed a strong anti-proliferative activity in select Neuroblastoma, Medulloblastoma, NSCLC, and glioma cell lines where the IC_{50}s ranged from 27 to 700 nM. Of note, NSCLC cell lines with mutation in the spliceosome protein RBM10 appeared to be more sensitive to JBI-778 treatment, which is consistent with enhanced retention of introns that are reported to be PRMT5 substrates including ATM, POLD and PNISR. JBI-778 showed an excellent oral bioavailability with a very high and sustained brain exposure in rodents. In U87-MG human GBM orthotopic model, oral administration of the JBI-778 resulted in strong and dose dependent efficacy with complete (~95 %) tumor growth inhibition and regression in few mice and translated into significant survival advantage. In 005 mouse GBM orthotopic model that mimics human GBM, JBI-778 showed a strong tumor growth inhibition and significantly extended survival (40 in control vs 58 days in 778 treated, $p<0.05$). IND-enabling GLP toxicology studies conducted in rodent and non-rodent species did not detect anemia or thrombocytopenia even at higher than efficacious concentrations.
Conclusion: PRMT5 inhibitor JBI-778 is able to penetrate the brain in all animal species tested and it is highly efficacious in orthotopic glioma models. Its differentiated mechanism makes it a potential option for the treatment of gliomas and brain metastasis with a focus on patients with spliceosome mutations. IND application for JBI-778 has been approved by FDA and a FIH trial is being planned.

#6270
Combination therapy with selective SMARCA2 (BRM) degraders for treatment of SMARCA4 (BRG1)-deficient cancers

Michael Hulse, Margot Elkins, Jessica Burtell, Komali Vykuntam, Philip Pitis, Liang Lu, Kris Vaddi, Andrew Combs, Koichi Ito, Peggy Scherle.
Prelude Therapeutics, Wilmington, DE

SMARCA2 (BRM) and SMARCA4 (BRG1) are mutually exclusive core catalytic subunits of the SWI/SNF complexes and use their ATPase domain to regulate the composition of nucleosomes. Between 4-5% of Non-Small Cell Lung Cancer (NSCLC) patients harbor SMARCA4 damaging mutations or SMARCA4 homo-deletions, resulting in loss of SMARCA4 protein expression. These SMARCA4-deleted cancer cells are predicted to be highly dependent on the paralog gene SMARCA2 for their survival. Therefore, targeting SMARCA2 in SMARCA4-deleted cancers using selective SMARCA2 degraders induces synthetic lethality while sparing SMARCA4 wild type normal cells. Although the treatment of lung cancer has improved considerably in recent years with the development of immune checkpoint inhibitors (ICIs) and specific $KRAS^{G12C}$ covalent inhibitors, $KRAS^{G12C}$ mutations significantly co-occur in 15-17% of SMARCA4-deleted NSCLC patients and have also been shown to correlate with a worse clinical outcome. The co-occurrence of $KRAS^{G12C}$/SMARCA4-deletion mutations in NSCLC led us to investigate whether combining our selective SMARCA2 degraders with $KRAS^{G12C}$ or other MAPK pathway inhibitors would demonstrate synergistic effects. To test this hypothesis, we treated SMARCA4 damaging/low expression $KRAS^{G12C}$ mutant cell lines with our SMARCA2 degraders and several $KRAS^{G12C}$ inhibitors, in addition to SHP2 and MEK inhibitors. Robust synergy was observed with these combinations, suggesting that targeting SMARCA2 together with agents that inhibit distinct nodes of the MAPK pathway in patients with SMARCA4-deleted cancer may be a promising therapeutic strategy. To further understand the mechanisms underpinning the synergy between our SMARCA2 degraders and $KRAS^{G12C}$/MAPK pathway inhibitors, we conducted RNA-seq and found unique transcriptional signatures in the synergistic combinations relative to those of either agent alone. We are currently testing if this *in vitro* synergy with our SMARCA2 degraders extends to *in vivo* combination efficacy in CDX and PDX models. Furthermore, early data suggested that SMARCA4 deletion may indicate poor outcomes of ICIs in lung cancer patients. Interestingly, our

SMARCA2 degraders promote the antigen presentation pathway and induce pro-inflammatory cytokine expression in SMARCA4-deleted cancer cells. We are currently investigating combinations of our SMARCA2 degraders with ICIs using syngeneic mouse models and human ex-vivo approaches. In summary, our preclinical data suggest that potent and selective SMARCA2 targeted degraders may potentially improve patient outcomes when combined with therapeutic agents targeting the RAS/MAPK pathway and/or ICIs in SMARCA4-deleted cancers. The combination of SMARCA2 degraders with standard of care agents warrants further investigation as a potential novel, effective, and highly targeted combination approach.

Discovery of BR1733 for the treatment of SWI/SNF deficient or highly vascularized solid tumor

Xinghao Wang, Shichao Ma, Min (Bella) Xie, Lele Wang, Yajun Wang, Song Zhang, Sheng Chen, Lynette Zhang, Yongqi Zhou, Mengxi Zhao, Dandan Li, Guobin Li, Xiao Fan, Hailong Zhang. *Blueray Biopharma, Shanghai, Shanghai, China*

Polycomb repressive complex 2 (PRC2) catalyze the writing of H3K27me3 epigenetic marker and suppresses the expression of genes including tumor suppressors. Activation mutation of EZH2, the catalytic subunit of the PRC2 complex, drives the progression of tumors such as DLBCL. The embryonic ectoderm development (EED) protein acts as the scaffolding and H3K27me3-binding subunit of PRC2 and is essential for its activity. We have developed potent, selective, and orally bioavailable EED inhibitor BR1733. BR1733 blocks the interaction between EED and H3K27me3, and inhibits catalytic activity of PRC2. BR1733 showed superior PK profile across species and exhibited tumor growth inhibition against several B cell lymphoma CDX models. Indication expansion studies demonstrated that BR1733 could inhibit solid tumors with SWI/SNF loss-of-function mutation only when both CDKN2A and TET1 are expressed. BR1733 also inhibited tumor angiogenesis and showed tumor growth inhibition in several CDX models of highly vascularized solid tumors such as HCC and RCC. BR1733 is currently in Phase I clinical trials.

#6272

AZ-PRMT5i-1: A potent MTAP-selective PRMT5 inhibitor with pharmacodynamic and monotherapy anti-tumor activity in MTAP-deleted tumours

James T. Lynch[1], Shaun Moore[1], Ivan Del Barco Barrantes[1], Lauren Bradshaw[1], Chris Chambers[1], Ted Hong[2], Sophie Cooke[1], Jelena Urosevic[1], Mercedes Vazquez-Chantada[3], James M. Smith[4], Anna Cronin[5], Benedicte Recolin[5], Sonja Gill[5], Susan Critchlow[1], Ho Man Chan[6], Emma Dean[7]. *[1]Bioscience, Oncology R&D, AstraZeneca, Cambridge, United Kingdom,[2]Early Data Science, Oncology R&D, AstraZeneca, Boston, MA,[3]Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom,[4]Chemistry, Oncology R&D, AstraZeneca, Cambridge, United Kingdom,[5]Clinical Pharmacology and Safety Sciences, Oncology R&D, AstraZeneca, Cambridge, United Kingdom,[6]Bioscience, Oncology R&D, AstraZeneca, Boston, MA,[7]Projects, Oncology R&D, AstraZeneca, Cambridge, United Kingdom*

Background: PRMT5 is an epigenetic enzyme that catalyzes symmetric dimethylation of arginine substrates (SDMA), regulating multiple cell processes. The PRMT5-MTAP collateral vulnerability describes the accumulation of the metabolite methylthioadenosine (MTA) in tumor cells (as a result of the deletion of the *MTAP* gene), which acts as a natural endogenous partial inhibitor of PRMT5. This provides an opportunity to selectively inhibit PRMT5 in *MTAP* deleted tumors, which occurs in ~15% of all cancers. First generation PRMT5 inhibitors, which cannot discriminate between MTAP-proficient normal cells and MTAP-deficient tumor cells, have a narrow therapeutic index which may limit clinical efficacy due to on-target toxicity. MTAP-selective PRMT5 inhibitors spare MTAP-proficient normal cells, improving therapeutic index and clinical efficacy. We have developed a novel MTAP-selective PRMT5 inhibitor, AZ-PRMT5i-1, that selectively targets MTAP-deficient tumors and spares MTAP-proficient tissue.
Methods: In vitro activity of AZ-PRMT5i-1 was profiled using six MTAP isogenic cell lines, as well as in a panel of 300 cancer cell lines. In vivo efficacy was assessed using three MTAP deleted models and hematological toxicity was addressed using a 3D human bone marrow model.

Results: Using a *MTAP* CRISPR KO isogenic pair we demonstrate potent inhibition of SDMA in MTAP-null tumors with a 54-fold margin over the MTAP wildtype (WT) counterpart. MTAP differential activity was maintained in proliferation assays across a number of MTAP isogenic cell lines and in a panel of 300 cancer cell lines. AZ-PRMT5i-1 demonstrates strong dose dependent efficacy across *MTAP* deleted xenograft and PDX models of gastric and lung origin, where greater than 80% of tumor growth inhibition was detected, with no apparent toxicity. In addition, corresponding dose-dependent inhibition of SDMA is observed in the treated tumors. In an *in vitro* 28-day 3D human bone marrow model, AZ-PRMT5i-1 has reduced toxicity in erythroid and megakaryocyte cell lineages, compared to a first generation PRMT5 inhibitor.
Conclusion: Overall, these studies demonstrate that AZ-PRMT5i-1 is a potent PRMT5 inhibitor demonstrating MTAP selectivity and anti-tumor activity in *in vitro* and *in vivo* pre-clinical models.

#6273

CTS3157, a novel MTA-cooperative PRMT5 inhibitor for targeting *MTAP*-deleted human tumors

Long Wang[1], Yilin Liu[1], Hui Shi[1], Yuanyuan Liu[1], Qiugeng Ouyang[1], Jiannan Guo[1], Yiqin Wang[2], Youzhen Wang[1], Guoliang Xu[2], Yuan Mi[1], Haiping Wu[1]. *[1]CytosinLab Therapeutics Co., Ltd., Shanghai, China,[2]Shanghai Institute of Biochemistry and Cell Biology, Center for Excellence in Molecular Cell Science, Chinese Academy of Sciences, Shanghai, China*

MTAP deletion is common in about 15% of all human cancers and coincides with the deletion of tumor suppressor locus containing *CDKN2A/B*. Methylthioadenosine (MTA), the substrate of MTAP, accumulates as a result of *MTAP* deletion. Increased levels of MTA result in partial inhibition of the PRMT5 enzyme by competing with S-adenosylmethionine (SAM, the methyl donor for PRMT5 substrate) due to structural similarity. Cancer cell lines with *MTAP*-deletion exhibit profound sensitivity to PRMT5 inhibition, suggesting *MTAP*^{null}-selective PRMT5 inhibitors have the potential to treat patients with MTAP deficiency (Kryukov *et al*., 2016). We identified CTS3157 as an orally bioavailable small molecule MTA-cooperative PRMT5 inhibitor that binds to PRMT5-MTA complex and

inhibits PRMT5 enzymatic activity. Cell-based assays revealed that CTS3157 demonstrated potent PRMT5 inhibition as evidenced by suppression of symmetric dimethylarginine (SDMA) and cell growth inhibitory activity for *MTAP*-deleted cell lines over isogenic *MTAP*^{WT} cell lines. Moreover, CTS3157 series compounds exhibited strong cell growth inhibition in a diverse panel of *MTAP*^{null} human tumor cell lines across several lineages. *In vivo*, CTS3157 demonstrated potent antitumor response after once-daily oral administration in *MTAP*-deleted xenograft models. The anti-tumor activity is correlated with PRMT5 modulation as measured by reduced SDMA levels. At molecular level, PRMT5 inhibition by CTS3157 resulted in massive RNA splicing defects and differentially expressed genes involving key cellular activities in *MTAP*^{null} cells. In summary, *MTAP*^{null}-selective PRMT5 inhibitor CTS3157 showed strong and durable antitumor responses *in vitro* and *in vivo* in *MTAP*-deleted tumors across diverse lineages. CTS3157 is an effective and promising therapeutics against *MTAP*-deleted tumors.

Preclinical characterization of the BET inhibitor, INCB057643, in combination with ruxolitinib for treatment of myeloproliferative neoplasms (MPN)

Michelle Pusey[1], Gaurang Trivedi[1], Bob Collins[1], Nina Zolotarjova[1], Pat Feldman[1], Monica Bomber[2], Jacob Ellis[2], Kristy Stengel[3], Cynthia Timmers[1], Hamza Celik[1], Matt Stubbs[1], Jeff Jackson[1], Scott Hiebert[2], Susan Wee[1], Sunkyu Kim[1]. *[1]Incyte Research Institute, Wilmington, DE,[2]Vanderbilt University, Nashville, TN,[3]Albert Einstein College of Medicine, Bronx, NY*

Patients with MPNs share common characteristics including overproduction of myeloid cells and chronic inflammation. In MPNs, bromodomain and extra-terminal (BET) proteins can bind to acetylated chromatin to regulate the activity of transcription factors such as NF-kB, leading to overproduction of inflammatory cytokines. Dysregulation of transcriptional gene expression can drive disease defining characteristics, therefore, targeting BET proteins could be an attractive therapeutic approach. In preclinical models, BET inhibitors decreased inflammatory cytokine

production and restored hematopoietic cell differentiation. Combination of BET inhibitors with the JAK1/2 inhibitor, ruxolitinib, resulted in further reduction in cytokine production and bone marrow fibrosis (Kleppe M. *Cancer Cell* 2018). Here, we investigate a novel, orally bioavailable BET inhibitor, INCB057643, for the treatment of MPN in combination with ruxolitinib. INCB057643 is a potent and selective inhibitor of the BET family. In binding assays, INCB057643 selectively inhibited both BRD4 bromodomains, BD1 and BD2, with IC_{50} values of 39 nM and 6 nM, respectively. INCB057643 comparably inhibited both NF-kB reporter activity and *MYC* protein levels. Nascent transcript analysis on the JAK2 V617F-mutant cell line SET2 showed decreased transcription of genes linked to inflammation, alone and in combination with ruxolitinib. These data suggest that INCB057643 and ruxolitinib can be used in combination to effectively suppress the pathogenic gene program driving chronic inflammation. Functionally, INCB057643 inhibited proliferation of SET2 cells at nanomolar concentrations. In a SET2 xenograft model, combination of INCB057643 and ruxolitinib potently inhibited tumor growth. Similarly, in the MPLW515L-driven MPN mouse model, INCB057643 in combination with ruxolitinib resulted in a greater reduction in spleen volume, compared to that achieved with single agent treatment. Meso scale discovery assays on MPN-patient-derived $CD34^+$ cells and whole blood using INCB057643 showed inhibition of NF-kB-mediated production of cytokines such as IL-8. In addition, flow cytometry-based analysis on MPN-patient-derived $CD34^+$ cells showed that INCB057643 in combination with ruxolitinib decreased pathogenic megakaryopoiesis, and increased terminal erythroid differentiation. Our data demonstrate that the combination of the BET inhibitor, INCB057643, with ruxolitinib can restore normal hematopoietic differentiation, reduce inflammatory gene expression, and inhibit pathogenic cell differentiation in preclinical models of MPN. INCB057643 is currently being evaluated in clinical studies as monotherapy and in combination with ruxolitinib in patients with MPN.
Acknowledgments: Michelle Pusey and Gaurang Trivedi contributed equally to this study.

DW91170: A novel potent EZH1/2 dual inhibitor for lymphoma treatment

Doc-Gyun Jeong, Woon Heo, DongHyuk Shin, Yeonkyung Oh, Sangho Lee, Seongsu Jeong, Whuijung Park, Jiyoung Woo, Chanseok Jeon, Subin Kim, Jaekyung Lim, Yun-Ha Hwang. *Dong Wha Pharm, Yongin, Korea, Republic of*

EZH2(Enhancer of zeste homolog2) is a catalytic subunit of PRC2 (polycomb repressive complex 2) for chromatin remodeling through methyl transfer activity. Previous studies have reported correlation between EZH2 and cancer progression with overexpression and mutations in various cancers. EZH1, homolog of EZH2, also has been known to role in development and progression of cancers by complementarily replacing EZH2. In recent researches, EZH1/2 dual inhibition showed global epigenetic modification on histone methylation and acetylation. Also, cancers associated with change in epigenetic factors such as mutations in subunit of SWI/SNF responded on EZH1/2 dual inhibition. Therefore, EZH1/2 dual inhibition is expected to be an effective strategy for cancer treatment. Herein, we present a novel potent EZH1/2 dual inhibitor, DW91170, as a promising candidate for treatment of lymphoma with improved anti-cancer activity. DW91170 selectively inhibited EZH1 and EZH2 enzyme activity. DW91170 brought about histone modification by reducing tri-methylation and enhancing acetylation of H3K27, which increased expression of target genes and cell cycle arrest was confirmed by treatment of DW91170. DW91170 showed effective tumor growth inhibition in two types of EZH2 hot spot mutation models. In Pfeiffer (A677 mutation) and WSU-DLCL2 (Y641 mutation) CDX models, DW91170 showed improved tumor regression activity with no significant abnormal signs such as weight loss. In order to verify the potential of DW91170 in R/R-lymphoma patients, the anti-cancer effect was evaluated in Rituximab-resistant cell line and R/R-DLBCL patient-derived PDX model. As a result, DW91170 efficiently inhibited Rituximab-resistant cell proliferation and suppressed tumor growth in R/R-DLBCL PDX model more significantly compared to other EZH inhibitors. Moreover, DW91170 has a good absorption profile that works in a physiological condition. Taken together, we demonstrated that DW91170, a dual epigenetic regulator of EZH1 and EZH2, showed great anti-tumor activities in various lymphoma cell lines and animal models such as CDX and PDX. We are currently

trying to expand indication into solid tumor to find a targetable population in clinical trials.

SKL27969, an oral selective PRMT5 inhibitor, sensitizes the effect of DNA-damaging agents in preclinical models of multiple solid tumors

Mijin Moon[1], Yongje Shin[1], Soyoung Ki[1], Jungtae Na[1], Ho Yeon Lee[1], Ilkyoo Koh[1], Beomjin Hong[1], Jiyeon Yun[1], Janice Laramy[2], Vijaykumar Vashi[2], Sook-Kyung Park[1]. *[1]SK Biopharmaceuticals Co., Ltd., Seongnam-si, Korea, Republic of,[2]SK Life Science, Inc., Paramus, NJ*

Background: Protein arginine methyltransferase 5 (PRMT5) is overexpressed in various human malignancies and induces epigenetic and post-translational changes, which have a significant impact on cell growth, proliferation, apoptosis, and DNA damage repair. SKL27969 is a potent and selective brain-penetrating PRMT5 inhibitor demonstrating antitumor activity in the preclinical models of glioblastoma (GBM) and non-small cell lung cancer (NSCLC) and triple-negative breast cancer (TNBC) brain metastasis models. In this study, we evaluated the antitumor activity of SKL27969 alone or in combination with DNA-damaging agents in various cancer models.

Methods: Cell cycle analysis, apoptosis, proliferation, and invasion assays were conducted to determine *in vitro* profiles of SKL27969. *In vivo* efficacy of SKL27969 was evaluated in human cancer cell line-derived xenograft (CDX) or patient-derived xenograft (PDX) models. Immunohistochemistry and RNA-sequencing analysis in tumor samples from animal models were conducted to confirm the *in vivo* mechanism of action (MoA). *In vitro* synergistic effects of SKL27969 with combination partner drugs were analyzed using Combenefit software.

Results: SKL27969 exhibits strong anti-proliferative effect by inducing cell cycle arrest and apoptosis and also inhibits invasion of cancer cells. An evaluation of SKL27969 in a panel of over 100 cancer cell lines revealed a broad spectrum of anti-proliferative activity in various cancer types, and an especially more sensitive response in cell lines harboring genetic alterations in the mitotic DNA damage checkpoint, DNA repair, or RNA processing pathways. Administration of SKL27969 demonstrated significant tumor growth inhibition, with a decrease in tumor symmetric dimethylarginine

(SDMA) in NSCLC and TNBC subcutaneous xenograft models. Transcriptome and immunohistochemical analysis of SKL27969-treated tumors revealed that the cell cycle checkpoint pathways and DNA damage repair genes were downregulated, supporting the rationale for combination treatment with DNA-damaging agents such as chemotherapeutic agents. Robust antitumor effects were observed after treatment with SKL27969 in combination with paclitaxel or gemcitabine in NSCLC PDX or pancreatic cancer CDX models. Further *ex vivo* studies to confirm the *in vivo* MoA of this synergism, and *in vivo* combination studies of SKL27969 with standard chemotherapeutic agents in other solid cancer CDX models, are ongoing. **Conclusion:** This is the first preclinical study that suggests the therapeutic potential of SKL27969 in combination with currently approved DNA-damaging agents, and supports further clinical investigation of SKL27969's role in improving the therapeutic benefit of standard therapies.

#6277

Selective and orally bioavailable SMARCA2 targeted degraders induce synthetic lethality in SMARCA4- deficient solid tumor

Koichi Ito, Artem Shvartsbart, Joseph Rager, Anjana Agarwal, Michael Hulse, Komali Vykuntam, Min Wang, Justin Kurian, Miles Cowart, Joy Cote, Monisha Sivakumar, Jack Carter, Jessica Burtell, Alex Grego, Andrew Moore, Neha Bhagwat, Stefan Ruepp, Tom Emme, Liang Lu, Philip Pitis, Corey Basch, Klare Bersch, Song Mei, Raul Leal, John Rose, Danielle Roth, Ganfeng Cao, Kris Vaddi, Sandy Geeganage, Bruce Ruggeri, Andrew Combs, Peggy Scherle. *Prelude Therapeutics, Wilmington, DE*

Targeted protein degradation (TPD) is an emerging therapeutic modality with the potential to target previously undruggable targets. However, it has been more challenging to identify orally bioavailable TPD molecules due to the physicochemical properties of the large molecules and narrow structure-activity relationship (SAR) compared to conventional small molecule inhibitors. In the present study, we identified orally active TPD molecules that selectively and potently degrade SMARCA2 protein and induce synthetic lethality in SMARCA4-deficient cancer cells. SMARCA2 (BRM) and SMARCA4 (BRG1) are the two mutually exclusive catalytic core subunits of SWI/SNF complexes that play an important role in controlling gene expression by remodeling chromatin. The complexes are mutated in

more than 20% of human cancers and subsets of solid tumors lose expression of SMARCA4 protein due to damaging mutations or gene deletion. The SMARCA4-deficient cancer cells are highly dependent on the paralog gene SMARCA2 for their survival and thus SMARCA2 has been suggested as an attractive therapeutic target for patients with SMARCA4-deficient cancers. We have recently identified SMARCA2 selective degraders that demonstrate oral bioavailability in mice with favorable pharmacokinetic properties, and acceptable DMPK and safety profiles in rodent studies. These SMARCA2 degraders show 50 to 300-fold DC_{50} selectivity for SMARCA2 over SMARCA4 in our cellular assays. When pre-treated with a proteasome inhibitor or neddylation inhibitor, the degradation of SMARCA2 was rescued, confirming that the degradation is mediated by the ubiquitin-proteasome-dependent pathway. These TPD molecules inhibit only SMARCA4-deficient cancer cell proliferation (NCI-H838, NCI-H1693, HT1080 SMARCA4 KO) with IC_{50} values ranging from 3-10 nM, but not SMARCA4 WT cells (Calu-6, NCI-H520, HT1080 WT). Oral administration of our SMARCA2 degraders resulted in significant tumor growth inhibition of SMARCA4-deficient lung cancer xenografts at well tolerated doses. The treated tumor tissues show robust SMARCA2 protein reduction for more than 72h post dosing, consistent with the SMARCA2 degradation kinetics-based pharmacodynamic prediction model. In summary, our orally bioavailable SMARCA2 degraders induce synthetic lethality in SMARCA4-deficient cancers *in vitro* and *in vivo*. Efforts to further evaluate these compounds in additional models and in combination with other agents are ongoing.

Combination therapeutic strategy with type I PRMT inhibition in cancer treatment

Hui Shi, Xingnian Fu, Yilin Liu, Qiugeng Ouyang, Meng Wang, Jiaxin Huang, Long Wang, Youzhen Wang, Yuan Mi, Haiping Wu. *Cytosinlab Therapeutics Co., Ltd., Shanghai, China*

Type I protein arginine methyltransferases (PRMTs) are highly expressed and associated in various tumors. Targeting PRMTs as an epigenetic modulation could be valuable for treating cancer when combined with other therapies. We identified a series of orally bioavailable small molecule type I

PRMT inhibitors with demonstrated single and combination anti-tumor efficacy in a variety of scenarios or models. Firstly, mutations of RNA splicing factors (SFs) commonly occur in hematologic malignancies and a variety of solid tumors, resulting in vulnerability to further disruption of the spliceosome. Inhibiting symmetric or asymmetric dimethylation of arginine could alter the RNA-binding specificity of the SFs and lead to the preferential killing of SF-mutant leukemias over wild-type counterparts (Fong *et al*., 2019). Therefore, targeting type I protein arginine methyltransferases (PRMTs) and PRMT5 concomitantly could minimize the compensatory effects and synergistically enhance antitumor activity. We validated the synergistic effects and mechanisms of combined treatment with a type I PRMT inhibitor and a PRMT5 inhibitor (JNJ-64619178, GSK3326595/EPZ015938 or an in-house PRMT5i) using cell-based assays and *in vivo* studies. Secondly, Methionine Adenosyltransferase 2A (MAT2A) inhibition decreases formation of S-adenosylmethionine (SAM), the cofactor of PRMTs, could in turn sensitize cancer cells to type I PRMT inhibition. *In vitro* and *in vivo* studies revealed that inhibitors of type I PRMT and MAT2A (AG-270) dosing combination indeed exhibited stronger anti-cancer activity than mono-treatment. Thirdly, the arginine methylation of receptor tyrosine kinases (RTKs) mediated by type I PRMT could increase the therapeutic sensitivity to RTK inhibitors like FLT3i. PRMT1 overexpression may contribute to AML stem/progenitor cells survival possibly through FLT3-ITD methylation, which may lead to enhanced activation of downstream signaling for cell survival and impact the regulation of self-renewal genes in leukemic initiating cells (LIC) (He *et al*, 2018). Hence, the combination treatment of FLT3 and type I PRMT inhibitors may provide a broader therapeutic benefit on *FLT3* mutated and/or overexpressed Acute Myeloid Leukemia (AML). *In vitro*, strong combination synergy was observed with a remarkable induction of cell death. *In vivo*, the combination of type I PRMT inhibitor with different FLT3 inhibitors (Gilteritinib, Midostaurin, or CTS2016) led to deeper antitumor responses in a variety of *FLT3-ITD* AML models. Taken together, these findings support the co-administration of type I PRMT inhibitor with various therapies including epigenetic reprogramming, cancer metabolism modulation, or targeted therapies for receptor tyrosine kinases, which could benefit cancer patients as a promising therapeutic strategy.

#6279

CTS2190, a next-generation epigenetic inhibitor for targeting type I PRMT deregulated human tumors

Hui Shi[1], Xingnian Fu[1], Qiugeng Ouyang[1], Jiaxin Huang[1], Yiqin Wang[2], Youzhen Wang[1], Guoliang Xu[2], Yuan Mi[1], Haiping Wu[1]. *[1]CytosinLab Therapeutics, Shanghai, China,[2]Shanghai Institute of Biochemistry and Cell Biology, Center for Excellence in Molecular Cell Science, Chinese Academy of Sciences, Shanghai, China*

Methylation of arginine residues by protein arginine methyltransferases (PRMTs) is involved in the regulation of fundamental cellular processes. Type I PRMTs are frequently overexpressed in a variety of human cancers and associated with poor prognosis. Knockout (KO) of *Prmt1* in mice results in decreased asymmetric dimethylarginine (ADMA) on cellular proteins, together with increased monomethylarginine (MMA) and symmetric dimethylarginine (SDMA) (Dhar *et al*., 2013). A structure-based drug discovery effort led to the identification of CTS2190 that showed single-digit nanomolar enzymatic inhibitory activity on type I PRMTs. Here, we report the development and preclinical characterization of CTS2190, a potent, orally bioavailable small molecule type I PRMT inhibitor. CTS2190 demonstrated strong cellular proliferation inhibitory activity in a large, diverse panel of human hematological and solid tumor cell lines across several lineages. *In vivo*, oral CTS2190 administration once daily resulted in tumor regression in a variety of xenograft (both CDX and PDX) models across different lineages with good tolerance. The anti-tumor activity was dose-dependent and correlated with the inhibition of type I PRMT activity as measured by decrease in ADMA and increase in MMA. In summary, CTS2190 is a promising type I PRMT inhibitor and clinical trial is underway to explore the proof-of-concept anti-tumor benefit for patients.

#6281

OTX-015 inhibits proliferation and migration in *ARID1A*-mutated bladder cancer

Ryan M. Kemper[1], Manfred Meng[1], Jeffrey S. Damrauer[2], William Y. Kim[2], Daniel J. Crona[1]. *[1]Pharmacotherapy and Experimental Therapeutics,*

UNC Eshelman School of Pharmacy, Chapel Hill, NC,[2]Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Background: ARID1A mutations (*ARID1A*^{mut}) occur in up to 30% of metastatic bladder cancers (mBC) and have been associated with poorer response to standard treatments and shorter overall survival. We previously identified bromodomain and extraterminal (BET) protein inhibition as a potential treatment paradigm for mBC, with particular potency of BET inhibitors (BETi) in cells lines containing *ARID1A* inactivating mutations (*ARID1A*^{mut}). BETi prevents BET protein bromodomains from interacting with acetylated histone lysine tails and promoting transcription of multiple oncogenes. Our previous data shows that treatment with the pan-BETi OTX-015 reduces *ARID1B* expression, and significantly reduces both gene and protein expression of *RAD51*/RAD51 in *ARID1A*^{mut} cells compared to *ARID1A* wild type (*ARID1A*^{WT}), suggesting impaired DNA damage repair function. Here we evaluate the phenotypic effects of BETi on proliferation and migration in preclinical models of BC.
Methods: To evaluate OTX-015-induced changes to gene expression, 5637 (*ARID1A*^{WT}) and HT1197 (*ARID1A*^{mut}) cells were treated with 1 μM OTX-015 for 48-h. RNA was extracted and sent to Novogene for bulk RNA-seq. Differential expression was quantified using DESeq2, and gene enrichment was analyzed using GSEA. 5637 and HT1197 cells were treated with 1 or 5 μM OTX-015 for 48-h, and colony forming potential was assessed by crystal violet staining after 10 days. Cells were treated with the same treatment schema as above, and a wound-healing assay evaluated wound closure over 48-h. Differences in the percent area of wells covered with colonies and relative wound closure were assessed by FIJI v.2.9.1.
Results: BET inhibition of *ARID1A*^{mut} HT1197 cells lead to a significant decrease in the pathway enrichment for G2/M checkpoint (NES=-2.78, q<0.0001) and E2F target (NES-2.61, q<0.0001) genes. Conversely, BET inhibition of *ARID1A*^{WT} 5637 cells, lead to more muted response (G2/M: NES=-1.31; q=0.08, and E2F: NES=-1.53; q=0.02). After 1 μM OTX-015, cell cycle pathway targets were significantly impacted in *ARID1A*^{mut} HT1197 cells (P=0.0002), but not in *ARID1A*^{WT} 5637 cells (P=0.47). Results from our *in vitro* phenotypic data confirmed that OTX-015 significantly reduced proliferation and migration in HT1197 cells. After 1

μM OTX-015, 5637 colonies covered only 2% less area than 0.1% DMSO treated control colonies (n=3, *P*=0.99), and wounds were fully healed at 48-h (n=3, *P*=0.99). Conversely, HT1197 treated cells covered 96% less area (n=3, *P*<0.0001), and maintained a 38% larger wound size at 48-h (n=3, *P*=0.008), when compared to 0.1% DMSO treated colonies.
Conclusions: These preliminary data highlight how OTX-015 potently inhibits proliferation and migration in *ARID1A*^{mut} cells. These data will be confirmed in isogenic cell lines harboring inactivating *ARID1A* mutations, and support future mechanistic exploration (e.g., BETi-mediated cell cycle dysregulation) in *ARID1A*^{mut} bladder cancer.

EP102: Pharmacological inhibition of METTL3 arrests tumor progression and prolongs survival in CDX and PDX models of AML
Graeme Fraser, Catherine Sorlet, Nicolas Parmentier, Elodie Brunel, Anne-France Hartiel, Killian Oukoloff, Guillaume Dutheuil. *EPICS Therapeutics, Gosselies, Belgium*

METTL3 is the RNA methyltransferase predominantly responsible for the addition of N-6-methyladenosine (m6A), the most abundant modification to mRNA. The prevalence of m6A and the activity and expression of METTL3 have been linked to the appearance and progression of acute myeloid leukemia (AML)1. EPICS has discovered and optimized a small molecule inhibitor of METTL3 ("M3i"). M3i was shown to inhibit the enzymatic activity of METTL3 (IC50 = 2 nM, SPA assay) and inhibit the presence of intracellular m6A in a cell-based assay (IC50 = 8 nM, Calu6). The anti-proliferative effects of METTL3 was demonstrated in a spheroid model (NCIH-560, IC50 = 100 nM) as well as cell viability assays in various AML (Kasumi-1, IC50 = 30 nM; LEXF 41283, IC50 = 46 nM; MV-4-11, IC50 = 248 nM) and solid tumor (Calu6, IC50= 6 nM; Caov3, IC50 = 27 nM) cell lines. In vivo efficacy was evaluated in a disseminated xenograft model using established systemic MV-4-11-Luc-mCh-Puro2 in female NSG mice where M3i (30 mg/kg, i.p., QDx31 days) significantly ($p<0.01$, relative to vehicle control) inhibited cancer progression as measured by in-life imaging in addition to flow cytometry of hCD45+ cells in bone marrow, blood and spleen; M3i had minimal effects on hematopoiesis in this model with no significant changes in RBCs, WBCs

and neutrophils, but an increase in platelets (measured by IDEXX). In an orthotopic, patient-derived xenograft model of AML (LEXF 41283, intratibial implantation, female NSG mice), M3i (30 mg/kg, i.p., QDx91 days) significantly prolonged survival ($p<0.01$, relative to vehicle control) with a commensurate absence of hCD45+ cells following compound treatment. These results confirm that the pharmacological inhibition of METTL3 is a viable strategy for the treatment of AML and support the additional exploration of the role of METTL3 inhibitors in alternate blood cancers as well as solid tumors.

Evaluating the potency of a first-in-class covalent antagonist of the H3K9me3 reader protein MPP8 in bladder cancer

Stephany Gonzalez Tineo[1], Ryan M. Kemper[1], Surya K. Tripathi[1], Peter H. Buttery[2], William Y. Kim[3], Lindsey I. James[2], Daniel J. Crona[1].
[1]Pharmacotherapy and Experimental Thrapeutics, UNC Eshelman School of Pharmacy, Chapel Hill, NC,[2]Chemical Biology and Medicinal Chemistry, UNC Eshelman School of Pharmacy, Chapel Hill, NC,[3]Division of Oncology, Department of Medicine, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Background: Bladder cancer (BC) is a common and deadly disease, and despite recent treatment advances, metastatic BC (mBC) remains incurable. Mutations in genes that encode epigenetic/chromatin modifier proteins are common in mBC, with >90% of tumors harboring at least one inactivating mutation. The epigenetic reader protein MPP8 recognizes the histone-3-lysine-9-trimethyl (H3K9me3) region of target gene promoters, and recruits transcription factors associated with cell proliferation and metastasis. UNC7713 was developed as a covalent antagonist to disrupt MPP8 binding to H3K9me3. Here, we explored whether UNC7713 potently inhibits cell proliferation, migration, and viability in preclinical models of BC.
Methods: 5637 cells were treated with ascending concentrations of UNC7713 (0.1 nM-100 μM), negative control compound UNC7716, or 0.1% DMSO negative control. Cell viability was measured using CellTiter-Glo™ after 48 h and 96h incubations. IC_{50} values were calculated using a four-parameter non-linear regression model in GraphPad. Cells were

stained with Annexin V and propidium iodide (PI) to evaluate apoptosis versus necrosis signaling by flow cytometry after 48 h incubation of UNC7713. Flow cytometry experiments were performed on a Thermo Attune NxT, and data were analyzed using FlowJo. 5637 cells were grown in a monolayer, treated with UNC7713 (25 nM-100 nM), and then subjected to a wound healing assay to evaluate cell migration after 48 h. To evaluate effects on cell proliferation, 5637 cells were treated with four doses of UNC7713 (25 nM-100 nM), and colony formation was evaluated after 10 days using crystal violet and analyzed by Fiji. For wound healing, images were captured by an Olympus IX83 inverted microscope and analyzed by Fiji.
Results: UNC7713 achieved submicromolar potency for reduction of cell viability in 5637 cells and was nearly 200x more potent than UNC7716 at 48 h (IC_{50}: 0.28 μM vs. 56.03 μM). Potency was also maintained at 96 h (0.18 μM). Concentrations of UNC7713 as low as 75 nM caused over 2.5x greater apoptotic signaling than 20 μM UNC7716 after 48 h (18.5% vs. 7.3% Annexin V and PI positive cells). Next, cells treated with UNC7713 did not migrate to initiate wound closure, but instead caused cell death, increasing the size of the initial wound. Cells treated with UNC7713 at concentrations as low as 50 nM caused dramatic wound expansion compared to 0.1% DMSO and 20 μM UNC7716 (70% wound expansion for UNC7713 vs. 100% wound closure for both controls). Last, after 10 days >90% fewer colonies were detected in cells treated with UNC7713 (25 nM-100 nM) when compared to 20 μM UNC7716 and 0.1% DMSO controls.
Conclusions: These preliminary data support further inquiry into the role of *MPP8* in BC. Future studies will focus on identifying molecular mechanisms that underlie UNC7713's ability to inhibit cell proliferation, migration, and viability in preclinical models of BC.

SUV420H1 as a novel target in HPV-negative head and neck squamous cell carcinoma
Arfa Moshiri[1], Hui Cheng[2], Sohyoung Kim[3], Vassiliki Saloura[1]. *[1]Thoracic and GI Malignancies Branch, National Cancer Institute, Bethesda, MD,[2]Bioinformatics and Biostatistics Collaboration Core, National Institute on Deafness and Other Communication Disorders, Bethesda,*

MD,[3]Laboratory of Receptor Biology and Gene Expression, National Cancer Institute, Bethesda, MD

Human Papilloma Virus (HPV)-negative head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer type in the world and its outcomes are mostly unchanged for the past few decades, especially for HPV-negative HNSCC. The TCGA recently revealed a plethora of genetic alterations in chromatin modifiers in HPV-negative HNSCC, including protein lysine methyltransferases which methylate lysine residues on histone tails and regulate gene expression. One of these enzymes, SUV420H1, is known to trimethylate H4K20 and is recurrently amplified in approximately 6% of HPV-negative HNSCC tumors (TCGA). It has also been found to be significantly overexpressed in multiple HNSCC cell lines compared with normal keratinocytes. This study aims to investigate whether SUV420H1 has oncogenic activity and could be a novel therapeutic target in HPV-negative HNSCC. To evaluate the effect of SUV420H1 depletion on HPV-negative HNSCC cell lines, siRNA-mediated knockdown was performed in four SUV420H1 overexpressing HPV-negative HNSCC cell lines, and MTT assays showed significantly reduced cell viability by approximately 80-90% after 12 days of siRNA treatment. Colony formation assays, cell cycle analysis and apoptosis assays are ongoing, and these assays are planned in SUV420H1 CRISPR KO cell lines. Gene Set Enrichment Analysis in 434 HPV-negative HNSCC tumors (TCGA) showed significant enrichment of immune signatures, EMT, cell cycle and apoptosis pathways. Ongoing experiments aim to investigate the effects of SUV420H1 knockdown on the global histone methylome, and to identify direct downstream targets of SUV420H1 through combined genome-wide mapping of SUV420H1 using CUT&RUN assays and RNA-seq in HPV-negative HNSCC cell lines. Syngeneic and xenograft mouse models are also planned to evaluate the effect of SUV420H1 depletion on flank tumor growth in vivo. These studies may elucidate the oncogenic effects and mechanisms of SUV420H1, and may provide evidence to support SUV420H1 as a potential novel target in the treatment of HPV-negative HNSCC tumors with SUV420H1 amplification or overexpression.

Preclinical efficacy of CDK7 inhibitor-based combinations in cellular models of advanced myeloproliferative neoplasms (MPN)

Christopher P. Mill, Warren C. Fiskus, Christine E. Birdwell, John A. Davis, Kaberi Das, Kapil N. Bhalla. *UT MD Anderson Cancer Center, Houston, TX*

Advanced MPN are characterized by driver mutations in JAK2, c-MPL or calreticulin (CALR) gene, with hyperactive JAK-STAT5/3 and NFkB signaling. Co-occurrence of mutations in chromatin/transcriptional regulators, including DNMT3A, TET2, ASXL1, EZH2, SRSF2, RUNX1 and TP53, creates the dysregulated transcriptome, which is responsible for the increased growth, survival and therapy-refractoriness in MPN blastic phase (BP). Treatment with JAK inhibitors (JAKis), e.g., ruxolitinib, venetoclax and hypomethylating agents are ineffective in improving survival in MPN-BP. CDK7 is the crucial catalytic component of the general transcript initiation factors TFIIH, which is recruited to the transcription start-sites along with RNA-pol II (RNAP2) to initiate transcription. Complexed with cyclin H, CDK7 phosphorylates CDK1, 2, 4 and 6, as well as serine 5 and 7 in the C terminal domain (CTD) of RNAP2, thus facilitating transcript initiation. CDK7 also phosphorylates CDK9, which in turn phosphorylates serine 2 of the CTD of RNAP2, and phosphorylates and inactivates the negative elongation factors, thus enabling productive mRNA transcript elongation of growth and survival promoting oncogenes. In MPN-BP, these include RUNX1, Bcl-xL, MCL1, CDK4/6, PIM1 and MYC. CRISPR-gRNA dependency-screen (DepMap) demonstrated that CDK7 is a dependency in the Advanced-AML cell lines, SET2 and HEL cells. Present studies demonstrate that treatment with ATP-competitive, covalent CDK7 inhibitors (CDK7i) SY-1365, and its clinical grade counterpart SY-5609, dose-dependently inhibits cell cycle, growth and induces lethality in SET2 and HEL as well as patient-derived (PD), CD34+ MPN-sAML cells. ChIP-Seq analysis showed that SY-1365 treatment caused log2 fold-reduction in p-Ser2-RNAP2 occupancy on the DNA of MYC, PIM1 and MCL1 genes in HEL cells. RNA-Seq analysis showed that SY1365 treatment caused negative enrichment of gene-sets of MYC and E2F targets, as well as inflammatory response, IL6-JAK-STAT3 and mTORC1 signaling. SY-1365 treatment also dose-dependently depleted protein expressions of p-Ser5 RNAP2, p-Ser2 RNAP2, c-Myc, c-Myb,

RUNX1, PU.1, MCL1 and Bcl-xL, while inducing cleavage of PARP protein. As compared to the parental JAKi-sensitive, in vitro generated JAKi-persister/resistant (P/R) SET2/RuxP cells were significantly more sensitive to SY-1365-induced apoptosis. Co-treatment with CDK7i and ruxolitinib or the BET inhibitor OTX015 was synergistically lethal in PD MPN-BP cells (n=7). In an aggressive xenograft model of HEL-GFP/Luc cells in NSG mice, compared to the vehicle control, monotherapy with SY5609 significantly reduced the MPN sAML burden and improved survival of the NSG mice without causing host toxicity. These findings demonstrate promising activity and support the rationale to further evaluate the in vivo efficacy of CDK7i-based combinations against advanced MPN.

Targeting Polycomb Repressive Complex 1 with small-molecule inhibitors as a potential therapeutic approach to combat leukemia

Miranda L. Simes[1], Yiwu Yao[1], Se Ra Park[1], Trupta Purohit[1], Hongzhi Miao[1], Xiaotian Zhang[1], Weijiang Ying[2], Felicia Gray[3], Shirish Shukla[4], Qingjie Zhao[1], Caroline Nikolaidis[5], Alyssa Winkler[1], Jolanta Grembecka[1], Tomasz Cierpicki[1]. *[1]University of Michigan, Ann Arbor, MI,[2]Penrose TherapeuTx, Plymouth, MI,[3]Schrodinger, Portland, OR,[4]The Janssen Pharmaceutical Companies of Johnson & Johnson, Spring House, PA,[5]Wayne State University School of Medicine, Detroit, MI*

Background: Polycomb repressive complex 1 (PRC1) is an epigenetic regulatory complex that monoubiquitinates lysine 119 on histone H2A, resulting in the repression of target genes. The canonical core of PRC1 responsible for its E3 ligase activity is a heterodimeric unit comprised of RING1B and BMI1. Emerging data implicates RING1B in various cancers and highlights the importance of PRC1 function in the maintenance and proliferation of leukemic stem cells. Studies demonstrate that loss of PRC1 activity through *RING1B* knockdown impairs leukemic stem cell proliferation, causes leukemic stem cell differentiation, and enhances survival in MLL-AF9 mouse models. Therefore, development of potent small molecules targeting the activity of PRC1 might offer a new approach for generating new therapeutics for leukemia.

Results: Here, we report the discovery and development of the first-in-class small-molecule inhibitors directly binding to RING1B in PRC1. We

performed an NMR-based fragment screen against RING1B-BMI1, identifying fragment hit, RB-1, with low-millimolar binding affinity. RB-1 was extensively optimized into a class of inhibitors with considerably enhanced binding affinity to the low-nanomolar range. These inhibitors have been shown to diminish the H2A ubiquitination activity of PRC1 E3 ligase cores. Structural studies revealed that our PRC1 inhibitors bind directly to the RING domain of RING1B and ultimately block the protein-protein interaction between RING1B and the nucleosome. In leukemic cell lines and primary AML samples, PRC1 inhibitor treatment elicits an anti-proliferative effect on cell growth and displays on-target action seen by the reduction of the H2A ubiquitination mark. Additionally, small-molecule inhibition of PRC1 results in the induction of cellular differentiation of leukemic cells, as well as apoptosis. Gene expression analysis in leukemic cells treated with our PRC1 inhibitors reveals upregulation of multiple genes that are repressed by PRC1, which is also supported by the displacement of PRC1 from chromatin assessed by CHIP-seq studies. Furthermore, our PRC1 inhibitors are active *in vivo* in mouse models of leukemia, demonstrating reduction of leukemia progression upon treatment. **Conclusions:** We developed first-in class inhibitors directly targeting the E3 ligase core of PRC1. Treatment with our PRC1 inhibitors in leukemic cells elicit an anti-proliferative effect, blocks ubiquitination of H2A, and results in the de-repression of many genes repressed by PRC1. Additionally, our PRC1 inhibitors elicit an anti-proliferative effect on leukemia progression *in vivo*, demonstrating the traction for developing anti-leukemia therapeutics that inhibit PRC1.

Selective CBP degradation shows superior potency and differentiated biological activity compared to small molecule inhibitors

Laura La Bonte, Darshan Sappal. *Foghorn Therapeutics, Cambridge, MA*

CREB binding protein (CBP) and E1A binding protein (p300) are paralog histone acetyltransferases involved in many cellular processes via their activity as transcription factor co-activators. Dysregulation of one or both proteins has been implicated in a variety of cancers, and functional genomic screens have exhibited a bidirectional synthetic lethal relationship between the two genes in many cancer indications. Due to the high homology

between CBP and p300, identification of selective chemical matter that specifically and directly targets CBP has proven challenging. Small molecule inhibitors (SMIs) targeting the HAT or bromodomain of CBP/p300 have been developed, however these agents are not selective for either paralog and inhibit both proteins equally, potentially limiting their clinical application. Herein, we describe the biological activity of selective, potent CBP degraders and show differentiation from SMIs.

Enhancer reprogramming by novel SMARCA2 degrading PROTACs underlies therapeutic utility in SMARCA4 mutant tumors
Sasi Kotagiri, Nicholas Blazanin, Yuanxin Xi, Jing Wang, Yonathan Lissanu. *UT MD Anderson Cancer Ctr., Houston, TX*

Lung cancer is the top cause of cancer mortality. Despite recent advances, the majority of patients with lung cancer still lack effective therapeutic options, underscoring the dire need for additional treatment approaches. Genomic studies have identified frequent mutations in subunits of the SWI/SNF chromatin remodeling complex including *SMARCA4* and *ARID1A* in non-small cell lung cancer with a frequency of up to 33% in advanced stage disease, making it the most frequently mutated complex in lung cancer. Recent reports, as well as our own data, have identified the paralogue *SMARCA2* to be synthetic lethal to *SMARCA4* suggesting SMARCA2 is a valuable therapeutic target. However, the discovery of

selective inhibitors of SMARCA2 has been challenging. To overcome this hurdle, we have utilized iterative structure-activity relationship (SAR) studies to develop novel, potent and selective SMARCA2 degrading small molecules based on proteolysis targeting chimera (PROTAC) technology. We demonstrated that YD23, our lead SMARCA2 PROTAC, potently and selectively induces degradation of SMARCA2. Mechanistically, we demonstrated that YD23 reduces chromatin accessibility only in *SMARCA4*-deficient cells with profoundly decreased chromatin accessibility at enhancer regions. Gene expression profiling and pathway analysis indicated that core cell cycle genes were downregulated by YD23 and is consistent with reduced chromatin accessibility at their regulatory regions. Furthermore, integrative analysis of RNA-seq and ATAC-seq revealed a strong correlation between gene expression and enhancer accessibility changes by YD23. In particular, we identified the mitotic regulator NEDD9 as a critical target in enhancers that are strongly reduced by YD23 in SMARCA4-deficient lung cancer cells. In conclusion, our study provides a promising chemical probe for studying the synthetic lethal interaction between SMARCA2 and SMARCA4, dissect the chromatin and epigenetic landscape alterations and lay the foundation for future preclinical and clinical development of SMARCA2 degraders as therapeutics.

#6290

Characterizing antitumor responses to EXS-74539, a novel, reversible LSD1 inhibitor with potential in small-cell lung cancer

Andrew Payne, Manisha Naik, Simon Richards, Victor Sebastian Perez, Maria Dominguez. *Exscientia, Oxford, United Kingdom*

Background: Lysine demethylase 1 (LSD1) is a potentially important target in oncology due to its role in demethylating histones and suppressing expression of genes required for cellular differentiation. In small-cell lung cancer (SCLC), high LSD1 expression is associated with suppressed differentiation pathways. Although selective LSD1 compounds are in clinical development, understanding of the molecular markers of tumor sensitivity to inhibition of LSD1 inhibition is incomplete.Methods: We report on the pharmacological characterization of EXS-74539, a potent, selective and reversible LSD1 inhibitor. We assessed EXS-74539 efficacy in in vitro and in vivo SCLC cell line models, encompassing the four

molecular subtypes of SCLC tumor cells previously proposed (Rudin et al, 2019), based on differential expression of key transcription regulators, ASCL1, NEUROD1, POU2F3 and YAP1. Results: In vitro, EXS-74539 demonstrated similar anti-proliferative activity against both neuroendocrine (NCI-H1417 and NCI-H69, ASCL1 sub-type) and non-neuroendocrine (NCI-H526: POU2F3) SCLC cell lines, with IC50 values of 28, 12 and 11 nM, respectively. In vitro exposure of these cell lines to EXS-74539 led to concentration-dependent alterations in differentiation-associated genes. However, in vivo, significant differences in antitumor growth response upon LSD1 inhibition were observed between the cell lines; NCI-H69 tumor growth was unaffected following treatment with EXS-74539 and an irreversible LSD1 inhibitor at dose regimens which were efficacious in the NCI-H1417 and NCI-H5126 models. We describe in vitro and in vivo gene expression correlations associated with LSD1 sensitivity. Conclusions: The reversible LSD1 inhibitor, EXS-74539, is a potent inhibitor of SCLC cell line proliferation and shows in vivo efficacy. Characterizing SCLC cell line sensitivity in vitro and in vivo identified gene signatures that may have use as markers of sensitivity, which we are currently characterizing and validating in human SCLC patient samples.Rudin et al., Nat Rev Cancer, 2019

Growth Factor Receptors as Therapeutic Targets

#6294

CXCR5 is a very promising drug target for the development of antibody-drug conjugates to treat patients with lymphoma

Tibor Schomber[1], Beatrix Stelte-Ludwig[1], Amy J. Johnson[2], Oliver von Ahsen[3], Christoph Schatz[4], Raquel Izumi[2], Ahmed Hamdy[2], Hans-Georg Lerchen[1]. *[1]Vincerx Pharma, Monheim, Germany,[2]Vincerx Pharma, Palo Alto, CA,[3]Nuvisan ICB, Berlin, Germany,[4]Bayer AG, Berlin, Germany*

Introduction: The chemokine receptor CXCR5 is highly expressed in tumor cells from different lymphoma types and represents a viable drug target for the development of antibody-drug conjugates (ADC) to treat patients with lymphoma.
Methods: Immunohistochemistry of human tissues of different lymphoma types were stained using antibodies against human CXCR5, CD20, CD70

and CD79b. Slides were examined by a pathologist and scored for expression. CXCR5 expression on tumor cell lines was analyzed by flow cytometry. Cell surface receptor density was analyzed by Quantibrite ™ PE-beads. Evaluation of antibody internalization was performed using the Operetta High Content Imaging System. NOD/SCID mice were transplanted subcutaneously with lymphoma patient-derived (PDX) tumor specimens and treated with 2mg/kg or 10mg/kg VIP924 CXCR5-ADC or isotype control.
Results: CXCR5 reveals very low to no expression in most tissues except for lymph nodes. Expression of CXCR5 and other B-cell targets like CD19, CD20, CD70 and CD79b was analyzed on patient-derived tumor samples. High expression of CXCR5 was found on naïve and previously treated diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), mantle cell lymphoma (MCL), and chronic lymphocytic leukemia (CLL) samples. Based on these results, we developed a CXCR5 targeted ADC with a novel, highly potent kinesin spindle protein inhibitor (KSPi) payload linked via a legumain-cleavable linker (VIP924). To compare the performance of KSPi ADCs, the same effector chemistry was attached to antibodies against other B-cell targets and tested in cytotoxicity assays in various cell lines. CXCR5-targeted ADC demonstrates significantly higher activity compared to the other ADCs tested except for the CD79b ADC with equal potency. VIP924 was then tested in vivo in different PDX tumor mouse models with different levels of CXCR5 expression. In the LY2264 and HBL-1 DLBCL models, we obtained a tumor growth inhibition of 68% and 100% respectively compared to isotype control. The median survival time for the isotype control group was 29 days and median survival time for the mice treated with 10mg/kg VIP924 could not be determined as all mice survived until the end of the study (Day 37). No effect on body weight or any adverse effects in the VIP924 treated mice were observed.
Conclusions: CXCR5 is a highly attractive target in hematological malignancies such as DLBCL, MCL, and FL due to high protein expression and almost no expression in healthy tissues. CXCR5-targeting ADC with KSPi payload showed high potency and superiority to other B-cell-targeted ADCs in vitro on a broad range of lymphoma cell lines. VIP924 with a novel legumain-cleavable linker showed activity in in vivo PDX models from lymphoma patients. Due to the high CXCR5 expression found in

relapsed DLBCL patients, VIP924 may bring promising new treatment options for previously treated patients with lymphoma.

Belzupacap sarotalocan, an investigational virus-like drug conjugate, preferentially binds cancer cell glycosaminoglycans associated with the epithelial to mesenchymal transition

Nathan R. Fons[1], Rhonda C. Kines[2], John T. Schiller[1]. *[1]National Cancer Institute, NIH, Bethesda, MD,[2]Aura Biosciences, Boston, MA*

Human papillomaviruses (HPVs) are non-enveloped, double-stranded DNA viruses that utilize modified glycosaminogycans (GAGs) such as heparan sulfate proteoglycans, within the epidermal basement membrane as initial attachment factors prior to cell entry and infection. Similarly modified GAGs are also commonly found on the surface of tumor cells, enabling HPV capsids with tumor-selective binding properties. Belzupacap sarotalocan (bel-sar, formerly AU-011), is a virus-like drug conjugate composed of an HPV virus-like particle (VLP) conjugated to a cytotoxic payload (phthalocyanine dye) which upon light activation, causes rapid immunogenic tumor necrosis of bound tumor cells in vivo and has the potential to induce long-term anti-tumor immunity. Bel-sar has been shown to bind to and kill a wide variety of tumor types in preclinical models and is entering a Phase 3 clinical trial for the treatment of early-stage choroidal melanoma. To investigate the precise GAG modifications as well as the overall genetic signature which mediates the binding specificity of bel-sar, a large, multi-tumor type binding screen of bel-sar on 124 cancer cell lines was performed in vitro, where we identified a strong relationship between drug binding and pathways involved in the epithelial to mesenchymal transition (EMT). Additionally, through dose escalation treatments, HeLa subclones were generated which fail to bind and are resistant to the cytotoxic effects of bel-sar. Gene expression profiling and biochemical characterization of these resistant HeLa cell lines demonstrated a strong reduction in the expression of GAGs and a marked down-regulation of TGF-β signaling, ultimately resulting in the induction of a mesenchymal to epithelial transition (MET). Furthermore, gene-gene correlation studies showed that a variety of GAG biosynthesis genes are associated with TGF-β signaling and EMT progression, and that these genes are important

determinates of bel-sar binding. Overall, these data suggest that the binding of bel-sar and HPV VLPs is strongly dependent on the expression and modification of GAGs that occurs during the EMT process. As many cancers, especially metastatic tumors, are thought to undergo at least partial EMT, these data provide mechanistic insights into the tumor-targeting ability of HPV VLP-conjugates such as bel-sar and suggest possible applications for such therapies across a wide variety of other tumor types.

Preclinical study of a novel anti-CLEC12A antibody-drug conjugate with a glucuronide-protected pyrrolobenzodiazepine payload

Jinwon Jung[1], Juhee Kim[1], Bora Lee[1], Jung A Kwon[1], Suyoun Lee[1], Byeongmin Yoo[1], Minji Ko[1], Ilhwan Ryu[1], Donghoon Yeom[1], Kyoungjae Lee[1], Jaehyun Eom[1], Hanbyul Lee[1], Jinhyung Ahn[1], Eunsil Sung[1], Weonkyoo You[1], Sang Hoon Lee[1], Myeong Joo Kim[2], Keon Woo Kwon[2], Hyun Joo Bae[2], Yun-Hee Park[2], Ho Young Song[2], Chul-Woong Chung[2].
[1]ABL Bio, Inc., Sungnam-si, Korea, Republic of,[2]LegoChem Bioscience, Inc., Daejeon, Korea, Republic of

C-type lectin domain family 12 member A (CLEC12A, CLL-1) is a single-pass transmembrane protein of 265 amino acids that is found on monocytes and AML blasts. We have created and characterized antibody-drug conjugates (ADCs) based on a humanized CLEC12A specific antibody to determine whether CLEC12A may be exploited as a therapeutic target for AML. The payload is a proprietary PBD prodrug with a beta-glucuronide trigger, and the linker-payload was conjugated through farnesyltransferase-mediated functionalization. The ADC demonstrated sub-nM cytotoxicity in vitro against several CLEC12A-positive cell lines including HL-60 and PL21. Leu234Ala/Leu235Ala (LALA) mutations were employed to reduce Fc gamma receptor binding and to avoid on-target toxicity. The LALA mutation-bearing ADC displayed a nearly 50-fold decrease in cytotoxicity towards CD34+ hematopoietic stem cells. Its potency was reduced but still sufficient with IC50 values of 61 pM and 15 pM against HL60 and PL21, respectively. Regardless of LALA mutation, the ADCs demonstrated potent antitumor activities with a complete regression at a dose of 0.5 mpk against a subcutaneous HL-60 SCID mouse xenograft model. When the LALA-mutated ADC was tested against a disseminated NSGA mouse model of

HL-60-luc, all treated animals survived without clinical symptoms for three weeks after treatment, whereas vehicle-treated animals exhibited morbidity 19 days after treatment or 35 days after tumor implantation. The bone marrow of ADC-treated animals appeared to have nearly fully recovered, whereas that of vehicle-treated animals showed necrosis or tumor growth. In cynomolgus monkeys, the LALA-mutated ADC had a half-life of 82 hours at a dose of 0.2 mpk, and target-mediated drug disposition appeared weak or negligible. Our preclinical studies have shown that CLEC12A targeting ADC can be used as a therapeutics for treating AML.

Rationale for the development of a differentiated Trop2 ADC

Satyajit K. Mitra[1], William Monteith[1], Mary Do[2], Greg Tuffy[3], Scott Savage[4], Jeffrey Kang[2], Mastewal Abuhay[1], Teodora Losic[2], Sanjeevani Ghone[1], William E. Haskins[1], Vasu Jammalamadaka[5], Sanjeev Satyal[6].
[1]Peak Bio Inc., Palo Alto, CA,[2]Dren Bio Inc., Foster City, CA,[3]3T Biosciences, South San Francisco, CA,[4]Neuron23 Inc., South San Francisco, CA,[5]Aarvik Therapeutics Inc., Hayward, CA,[6]Monterey Bio, New York, NY

Background: Trophoblast antigen 2 (Trop2) or Tumor-Associated Calcium Signal Transducer 2 (TACSTD2) is a transmembrane glycoprotein that is overexpressed in several solid tumor cancers. Antibody drug conjugate (ADC) targeting of Trop2 has been clinically validated. The Trop2 ADC Trodelvy® (also known as Sacituzumab govitecan/ IMMU-132) is approved for therapy of TNBC and urothelial cancer, and Datopotamab DXd (DS-1062) is currently being tested in NSCLC.
Peak Bio's Thailanstatin suite of immunomodulatory linker-toxins (L-Ts) is a set of 7 related molecules with distinct ADC features that have been extensively characterized *in vitro* and *in vivo* as Her2 ADCs and is being used as a platform to generate a pipeline of potentially differentiated ADCs (AACR; Cancer Res 2021;81(13_Suppl):Abstract nr 1832).
Results: M2.8 is a fully humanized Peak Bio antibody (Ab) that targets human Trop2 (hTrop2) with high binding affinity [K_d (M)= 8.97^{-09}]. M2.8 was optimized for binding affinity and humanization relative to its parent M2.1 [K_d (M)= 1.78^{-08}], and, both M2.1 and M2.8, display species-

specificity for the human and cynomolgus monkey Trop2 proteins. When bound to hTrop2-positive cell lines, M2.1 and M2.8 can rapidly internalize and deliver an ADC payload.
To identify the optimal release for therapeutic efficacy, we conjugated our family of L-Ts with hRS7 at a comparable drug-to-antibody ratio (DAR) of 4. Maximal tumor growth inhibition (TGI) was associated with the Trop2 ADCs that were conjugated *via* amine coupling to lysine residues using non-cleavable L-T L22, later renamed PH1.
To determine the effect of antibody on TGI efficacy, different doses, and DARs of M2.1 PH1 ADC were compared to PH1 ADCs made from other Trop2 Abs. At low dose levels, M2.1 PH1 ADCs exhibited comparable TGI with hRS7 PH1, TINA PH1, and T6-16 PH1 ADCs, but exhibited significantly greater TGI than hRS7 SN38 (IMMU-132), suggesting that payload potency, rather than epitope, was important in targeting Trop2. The results also suggested that a PH1 DAR of 4 was sufficient to obtain 90% TGI with multiple anti-Trop2 Abs.
M2.1 PH1 ADC was safely tolerated by cynomolgus monkeys at 3 and 6 mg/kg Q3W x 3 doses with mild-to-moderate changes in liver enzymes and platelets that reversed to baseline within 7-10 days of administration of each dose.
The optimized M2.8 PH1 DAR4 ADCs killed Trop2-positive cell lines with single-digit nanomolar potency, while exhibiting low off-target cytotoxicity *vs* normal human skin fibroblasts and Trop2-negative cell lines *in vitro*.
M2.8 PH1 ADC regressed all 200mm^3 sized NCI-N87 tumors and 50% of these tumors exhibited long-term regression for 5 months.
Conclusion: The target validation studies suggest that Trop2 PH1 ADCs were sufficiently differentiated in areas of preclinical efficacy and well tolerated in a toxicologically relevant host.

#6298

A novel topoisomerase I inhibitor based anti-ICAM-1 antibody drug conjugate for the treatment of hematologic malignancies and solid tumors

Oi Kwan Wong, David Jackson, Lei Shi, Qi Fei, Xiaocheng Chen, Leonard Post. *Virtuoso Therapeutics, Inc., San Mateo, CA*

Intercellular Cell Adhesion Molecule 1 (ICAM-1, CD54) is a type I transmembrane protein and a member of the immunoglobulin superfamily. ICAM-1 is involved in many key processes such as cell-cell interactions, signal transduction and leukocytes trans-endothelial migration. ICAM-1 is constitutively present at low levels on healthy tissues but highly expressed in some lymphoma, myeloma and some types of solid tumors including melanoma, non-small cell lung cancers and liver cancers. Previous attempt to target ICAM-1 with a monoclonal antibody bersanlimab (BI505, BioInvent) showed that it was well-tolerated but with limited clinical efficacy. To improve the effectiveness of targeting ICAM-1, we developed a novel ICAM-1 antibody drug conjugate (ADC). The ICAM-1 ADC is comprised of a humanized anti-ICAM-1 hIgG1 antibody conjugated to a novel topoisomerase I inhibitor through a cleavable linker at a drug-to-antibody ratio (DAR) of about 8. The antibody moiety of the ADC targets a unique epitope on ICAM-1 which is far from its ligand binding domain. Potent *in vitro* cytotoxicity of ICAM-1 ADC, with nanomolar to sub-nanomolar EC50, was observed on a panel of hematologic and solid tumor cell lines. In preclinical studies, one or two doses of ICAM-1 ADC at 5-6 mg/kg were generally sufficient to induce tumor regression in multiple cell line-derived xenograft models, including those of lung and liver cancers. In all models tested so far, the novel topoisomerase I inhibitor conjugated ICAM-1 ADC is at least as efficacious as the same ICAM-1 antibody conjugated to the benchmark topoisomerase I inhibitor linker payload deruxtecan (ICAM-1-DXd). Furthermore, in a repeat dose exploratory non-human primate safety study, the benchmark conjugate ICAM-1-DXd (DAR 8) was well-tolerated at 41 mg/kg, the highest dose tested. In conclusion, ICAM-1 is an attractive target for topoisomerase I inhibitor based ADC and warrants further investigation.

ZB131 antibody-drug conjugates induce potent antitumor activity

Samantha M. Perez[1], Brian P. Murphy[1], Danielle B. Heckert[1], Sarah Hall[1], Abby L. Colvin[1], Molly F. Owens[1], Ben R. Verfurth[1], Julien Dimastromatteo[2], Jiang He[3], Reid B. Adams[4], Yelena Kovtun[1], Lindsey T. Brinton[1], Kimberly A. Kelly[1]. *[1]ZielBio, Inc., Charlottesville, VA,[2]Department of Biomedical Engineering, University of Virginia, Charlottesville, VA,[3]Department of Radiology and Medical Imaging,*

University of Virginia, Charlottesville, VA,[4]Department of Surgery, University of Virginia, Charlottesville, VA

Antibody-drug conjugates (ADCs) have become increasingly adopted clinically, with 13 drugs FDA-approved and over 100 under clinical development. Despite this momentum and major advances in payload and linker technology, ADCs are limited by off-cancer target-mediated toxicities incurred by currently available targets. In contrast to genomic and proteomic strategies, our unique drug discovery approach accounts for a disease's native context. This led to the identification of cancer-specific plectin (CSP) as not only overexpressed in malignant tissue compared to healthy, but exclusively present on the surface of cancer cells and absent in normal or pre-malignant tissue. A Phase 0 imaging trial (Biodistribution of Novel Imaging for Resectable Pancreatic Cancer - NCT01962909) evaluating a radiolabeled CSP-targeted peptide has revealed that CSP is bioavailable and abundant, with over a million CSP molecules per cancer cell in pancreatic cancer. Previously, we generated ZB131, a humanized monoclonal antibody that targets CSP. ZB131 demonstrated potent monotherapy efficacy in pancreatic, ovarian, and bile duct preclinical cancer models, indications that have high CSP expression and are being evaluated in a first-in-human Phase 1/2 clinical trial (NCT05074472). Here, we show that CSP is an ideal target for an ADC: it is abundantly and selectively expressed in many indications, bioavailable, and its inhibition is predicted to synergize with FDA-approved payloads. ZB131 binds specifically to CSP, rapidly internalizes, displays linear pharmacokinetics in pre-clinical models, and demonstrates a strong safety profile. We describe the development of two ZB131 ADCs, ZB131-MMAE (monomethyl auristatin E) and ZB131-DXd (Deruxtecan), with drug-to-antibody ratios of 3 – 4 and 7 – 8, respectively. After binding, both ADCs are rapidly and specifically internalized by CSP-positive cells resulting in drug payload release and enhancing cancer cell death compared to ZB131 alone. Moreover, we characterize cytotoxic activity in high and low CSP cell lines to evaluate ADC activity in relation to CSP abundance. In preclinical xenograft models, ZB131-ADC enhanced tumor regression compared to controls at clinically relevant doses. Furthermore, anti-huIgG staining revealed selective target engagement by ZB131-ADC. Taken together, these

data show that ZB131-ADCs demonstrate potent antitumor activity and support their evaluation in a Phase 1 clinical trial.

Therapeutic potential of EO-3021/SYSA1801, a Claudin18.2 antibody-drug conjugate, for the treatment of CLDN18.2-expressing cancers

Mo Dan[1], Xiwu Hui[2], Yancui Wang[1], Can Yuan[2], Thomas O'Hare[3], Valerie Malyvanh Jansen[3], Shawn M. Leland[3], Yang Zhang[1], David Dornan[3], Xiaoyan Wang[1]. *[1]CSPC Zhongqi Pharmaceutical Technology (Shijiazhuang) Co., Ltd., Shijiazhuang, China,[2]CSPC Megalith Biopharmaceutical Co., Ltd., Shijiazhuang, China,[3]Elevation Oncology, Inc., New York, NY*

Background: Claudin18.2 (CLDN18.2), a tight junction protein normally expressed only on gastric mucosa, is overexpressed in gastric, pancreatic, esophageal, ovarian, lung and other solid tumors. Unlike in normal tissue, CLDN18.2 is exposed on epithelial surfaces in malignancy. There are no approved targeted therapies for CLDN18.2-expressing cancers. An antibody-drug conjugate (ADC) composed of a monoclonal antibody (mAb) targeting CLDN18.2 with a monomethyl auristatin E (MMAE) payload site-specifically conjugated via a cleavable linker at a drug-antibody ratio (DAR) of 2, EO-3021/SYSA1801, was developed to target CLDN18.2-expressing cancer cells, minimize toxicities and maximize therapeutic index.
Methods: HEK293-CLDN18.2 cells were used to evaluate CLDN18.2-dependent EO-3021 endocytosis, MMAE payload release, inhibition of proliferation and antibody dependent cellular cytotoxicity (ADCC). Cell cycle distribution and caspase-3/7 activity were measured 24 hours after treating BxPC3-CLDN18.2 pancreatic cells with EO-3021 or the unconjugated antibody, EO-3021 mAb. Inhibition of proliferation by EO-3021 was measured on cell lines ectopically expressing medium to high CLDN18.2 and on cell lines with endogenous low to medium CLDN18.2 expression. Xenograft studies evaluating tumor growth inhibition by EO-3021, EO3021 mAb, and cisplatin or gemcitabine were done in gastric (NUGC4; NUGC4-CLDN18.2), pancreatic (Patu8988S; BxPC3-CLDN18.2), and lung (NCI-H460) cancer models.
Results: EO-3021 binding to cancer cells, endocytosis, MMAE release, and inhibition of proliferation were dependent on CLDN18.2 expression. EO-3021 (EC_{50}: 172 ng/ml) and EO-3021 mAb (EC_{50}: 130 ng/ml) demonstrated similar levels of ADCC. EO-3021 but not EO-3021 mAb promoted G2/M cell cycle arrest and apoptosis and exhibited potent activity across cell lines with low, medium, and high CLDN18.2 expression (IC_{50}:

7-456 ng/mL). EO-3021 induced tumor regressions with a single dose across low, medium, and high CLDN18.2-expressing in vivo models derived from pancreatic (2-10 mg/kg), gastric (0.5-10 mg/kg), and lung cancers (4 mg/kg), respectively. In contrast, standard of care (SOC) chemotherapies and EO-3021 mAb did not induce tumor regressions across in vivo models.
Conclusions: EO-3021 demonstrated profound *in vivo* antitumor activity and outperformed SOC in gastric, pancreatic, and lung cancer models. Results from *in vitro* and *in vivo* studies highlight the promising therapeutic potential of EO-3021/SYSA1801 for patients with CLDN18.2-expressing cancers. A Phase 1 study is ongoing to evaluate the safety, tolerability, pharmacokinetics and preliminary anti-tumor activity of SYSA1801 in patients with CLDN18.2 positive advanced solid tumors (NCT05009966).

Post-translational modifications regulate sensitivity to Polatuzumab Vedotin in DLBCL

Sean R. Corcoran[1], Louis M. Staudt[2], Daniel Hodson[1]. *[1]University of Cambridge UK, Cambridge, United Kingdom,[2]Lymphoid Malignancies Branch, National Cancer Institute, NIH, Bethesda, MD*

Diffuse Large B-Cell Lymphoma (DLBCL) is an aggressive malignancy of which one-third of diagnosed patients ultimately relapse and die. New treatment paradigms for relapsed-refractory patients are needed. Most DLBCL tumors are reliant on signaling through their cell surface B-cell receptor (BCR) mediated by ITAMs on CD79A and CD79B to drive anti-apoptotic NF-kB and PI3 kinase signaling. In order to understand how surface BCR is regulated, we performed whole genome CRISPR screens in 9 DLBCL cell lines in which we sorted for high and low surface CD79B or added the CD79B targeted antibody-drug conjugate Polatuzumab-Vedotin (POLA-V). Strikingly, independent of genetic or cell of origin subtype, sgRNAs encoding the entire N-linked glycosylation pathway and specific sugar modification by addition of galactose and sialic acid were found to be enriched in high CD79B fractions and depleted in POLA-V treated samples compared to control. Further testing showed that removing sialic acid by treating with a small molecule inhibitor of sialic acid, genetic perturbation of golgi sugar transporters SLC35A1 and SLC35A2, or the a2,6

sialyltransferase ST6GAL1 resulted in more surface CD79B antibody binding with no significant change in CD79B protein abundance. The specificity of the effect of sialic acid loss on POLA antibody binding was confirmed by removing cell surface sialic acid with exogenous sialidase and observing increased binding of POLA, but not other therapeutic antibodies like Rituximab or CD19 FMC-63. Loss of SLC35A1, SLC35A2, and ST6GAL1 synergized with POLA-V but not the drug conjugate MMAE alone, showing a BCR dependent mechanism of sialic acid loss on POLA-V sensitization. In a further cell of origin subtype analysis of the germinal center B-cell (GCB) DLBCL cell lines, loss of the E3 ligase KLHL6 was found to synergize with POLA-V. Importantly, KLHL6 is heavily mutated across all germinal center derived malignancies, is more highly expressed in germinal center B-cells than other members of the B-cell lineage, and plays an unknown role in the development of autoimmune diseases. Further work will give evidence for the target of KLHL6 mediated ubiquitination and will show how this gene can drive lymphoma and autoimmune disease development in the germinal center.

Identification of OASEP1 as a biomarker and therapeutic target for oral cancer

Atsushi Takano[1], Yoshihiro Yoshitake[2], Masahiro Shinohara[2], Yataro Daigo[3]. *[1]University of Tokyo, Tokyo, Japan,[2]Kumamoto University, Kumamoto, Japan,[3]Shiga University of Medical Science, Otsu, Shiga, Japan*

This study aims to identify new biomarkers and therapeutic targets for oral cancer. Our strategies are as follows: i) Identification of overexpressed genes in oral cancers by gene expression array analysis, ii) Validation of clinicopathologic significance of their protein expression by tissue microarray, iii) Examination of their growth effect on cancer cell by siRNAs. We identified a secreted protein, OASEP1 (oral cancer-associated serum protein 1) as a candidate. Immunohistochemical staining showed that OASEP1 protein expression was observed in 120 (75.4%) of 159 oral cancers that had undergone curative surgery. High level of OASEP1 expression was associated with poor prognosis for oral cancer patients (P = 0.0054, by log-rank test). Multivariate analysis revealed that strong

OASEP1 expression was an independent prognostic factor. Suppression of OASEP1 expression by siRNA significantly inhibited the growth of *oral cancer* cell lines through apoptosis as detected by apoptosis assays and time lapse imaging. Transient OASEP1 overexpression significantly enhanced the growth of oral cancer cells. In addition, knock down of OASEP1 receptor by siRNAs also significantly inhibited the growth of oral cancer cells. Addition of OASEP1 protein significantly increased the growth of oral cancer cells in a dose dependent manner, suggesting that the interaction between OASEP1 and its receptor regulated the growth of oral cancer cells. Microarray analysis coupled with siRNAs for OASEP1 demonstrated various OASEP1-related oncogenic pathways in oral cancer cells. Our data suggest that OASEP1 is a possible prognostic biomarker and therapeutic target for *oral cancer.*

Preclinical development of a next generation antibody drug conjugate (ADC) targeting B7-H3 for treatment of solid tumors

Jian Xu[1], Qing Zong[2], Wei Wang[2], Qigang Liu[2], Sasha Stann[1], Jiaqiang Cai[2]. *[1]MediLink Therapeutics USA, INC., Cambridge, MA,[2]MediLink Therapeutics (Suzhou) Co., Ltd., Suzhou, China*

B7-H3 (CD276), an immune checkpoint member of the B7/CD28 family, is widely expressed in multiple cancers and is associated with poor prognosis. YL201 is a novel B7-H3-targeting antibody-drug conjugate (ADC) and built on MediLink's tumor microenvironment activable linker-payload platform (TMALIN platform). This ADC is comprised of an anti-B7-H3 human monoclonal antibody conjugated to a novel topoisomerase 1 inhibitor *via* a protease-cleavable linker.

The novel linker-payload and site-specific conjugation of YL201 results in a homogeneous and more hydrophilic ADC. In addition, the binding specificity, affinity and avidity of antibodies show no impact after conjugation. *In vitro*, upon binding to B7-H3, the antigen-ADC complexes are internalized to lysosomal vesicles releasing the toxic payload, whose cytotoxic features drive cell cycle arrest, apoptosis, elevation of PARP/caspase 7 expression, as well as cell death and bystander effect. In preclinical studies, YL201 is effective in causing tumor regressions in both cell line- and patient-derived xenograft (CDX and PDX) mouse models at

doses that are well tolerated. The *in vivo* pharmacokinetics in monkeys showed that YL201 is deemed as 'highly stable' in circulation. Safety evaluations demonstrated acceptable safety profile and no off-target toxicity in monkeys. These non-clinical data suggest the stability of linker in circulation but efficiently release the payload in tumors, and eventually, expanded the therapeutic window.
Taken together, preclinical data suggest that YL201 could be a promising treatment strategy for B7-H3 positive cancer patients.

#6305

Bispecific claudin 18.2 and GPRC5D antibodies with potent cell-killing activity for cancer therapeutics

Ileine Sanchez, Hayley Roth, Brad Screnci, David Tucker, Nick Molino, Trevor Barnes, Paige Murphy, Kyle Guldner, Tim Phillips, Kristen Shema, Thomas Charpentier, Alyssa Cunningham, Janae Latta, Breanna Tyrell, Meghan Pitts, Carmen Navia, Charles Azuelos, Anna Lobley, Jawhara Karam, Valerie Fiers, Daniela Reyes, Kate Slovik, Alison Snyder, Marianne Assogba, Kai-Ti Chang, Riley Payne, Kyle Doolan, Ross Chambers, Joe Rucker, Benjamin Doranz. *Integral Molecular, Philadelphia, PA*

Tumor-associated antigens with little or no expression in healthy tissue are attractive targets for anti-tumor modalities including T cell-engaging bispecific antibodies. CLDN18.2 is a transmembrane adhesion protein undetectable in most healthy adult tissues but highly expressed in gastric, pancreatic, esophageal, and lung cancers. GPRC5D is a G protein-coupled receptor that is absent from most healthy tissues except for hair follicles but expressed on multiple myeloma cells. Both CLND18.2 and GPRC5D are novel oncology targets with no clinically approved therapies against them. Using our discovery platform tailored to complex transmembrane proteins, we have developed bispecific antibodies with the ability to potently kill CLDN18.2-positive or GPRC5D-positive cells. Multipass membrane proteins are valuable therapeutic targets in oncology and other disease areas but are largely inaccessible as antibody targets due to their poor expression, membrane-dependent structure, small extracellular regions, and poor immunogenicity due to sequence conservation. We developed an antibody discovery platform (MPS) that specifically addresses each of these challenges. This platform utilizes advanced immunization techniques

including DNA, mRNA, and Lipoparticles (virus-like particles). It also employs chickens as an evolutionarily divergent host species for robust immune responses against conserved targets. Antibodies raised in chickens are directly humanized prior to isolation, reducing the need for downstream engineering. In two separate campaigns, we immunized chickens with CLDN18.2 and GPRC5D and obtained high-titer immune responses. We were successful in isolating high-affinity antibodies specific to each of these targets. Our CLDN18.2 antibodies showed specificity for their target and did not bind the closely related splice variant CLND18.1, which is highly expressed in healthy lung tissue. Additionally, the antibodies showed no binding to ~6,000 other proteins that were screened using a Membrane Proteome Array. A subset of antibodies from both discovery programs were configured as bispecific molecules using a CD3-targeting arm to bring tumor cells into close proximity with cytotoxic T cells that mediate cell killing. The panels of molecules encompassed multiple bispecific formats bearing different stoichiometries, geometries, and sizes to enable identification of lead molecules with favorable activities and safety profiles. Both CLDN18.2 and GPRC5D bispecifics showed potent T cell-mediated cytotoxicity with picomolar potency. They also showed good cytokine release and developability profiles. GPRC5D x CD3 and CLDN18.2 x CD3 bispecifics hold promise as potent and safe therapeutics for different cancer types.

Pharmacological deuteration of SCID mice using the water-isotopologue deuterium oxide (D_2O) inhibits tumor growth in bioluminescent models of human malignant melanoma and pancreatic ductal adenocarcinoma

Jana Jandova[1], Jean-Philippe Galons[2], David L. Dettman[3], Georg T. Wondrak[1]. *[1]Pharmacology and Toxicology, R Ken Coit College of Pharmacy and UA Cancer Center, The University of Arizona, Tucson, AZ,[2]Department of Medical Imaging, The University of Arizona, Tucson, AZ,[3]Department of Geosciences, The University of Arizona, Tucson, AZ*

Since its initial discovery as a natural isotopologue of dihydrogen oxide (^1H_2O), extensive research has focused on the biophysical, biochemical,

and pharmacological effects of deuterated water [^2H_2O (D_2O, also referred to as 'heavy water')]. Here, using diverse panels of cultured human malignant melanoma and pancreatic ductal adenocarcinoma (PDAC) cells we have profiled (*i*) D_2O-induced phenotypic anti-proliferative and apoptogenic effects, (*ii*) redox- and proteotoxicity-directed stress response gene expression, and (*iii*) phosphoprotein-signaling related to endoplasmic reticulum (ER) and MAP-kinase stress response pathways. Differential RT-qPCR array analysis revealed early modulation of stress response gene expression elicited by D_2O (90%; ≤6 h) confirmed by independent RT-qPCR analysis. Immunoblot-analysis revealed rapid (≤ 6 h) onset of D_2O-induced MAP-kinase signaling (p-JNK) together with ER stress response upregulation (p-eIF2α, ATF4, XBP1s, DDIT3/CHOP) attributable to deuteration-induced alteration of hydrogen bonding triggering proteotoxic stress. Next, we tested the chemotherapeutic efficacy of D_2O-based drinking water supplementation in bioluminescent murine models of malignancy (A375-luc melanoma and BxPC-3-luc orthotopic PDAC xenografts in SCID mice). Time course of systemic deuteration (30% D_2O in drinking water fed continuously for up to 21 days) was established using time-resolved whole-body proton magnetic resonance imaging (MRI) and isotope-ratio mass spectrometry (IR-MS)-based plasma (D/H)-analysis. In both models, D_2O supplementation significantly suppressed tumor growth and metastasis with downregulated expression of PCNA/Ki67 while increasing tumor levels of DDIT3/CHOP, HO-1, and p-eIF2α. Taken together, these data demonstrate for the first time that pharmacological induction of systemic deuteration by oral administration of D_2O, associated with induction of cellular ER stress, reduces tumor burden and metastasis in murine models of human malignant melanoma and PDAC.

A novel pegylated bispecific antibody-drug conjugate (P-BsADCpb-adc) targeting cancers co-expressing PD-L1 and CD47

Shumin Liu, Weidong Lyu, Shuqiang Yin, Yang Lei, Qiudong Zhuo, Liling Zheng, Bin Sun, Shuangyu Tan, Lidong Jiang, Teng Zhang, Bo Gao, Rui Xu, Dechang Huang, Yong Li, Zibin Wu, David Wu, Yvonne (Yu) Wen.
Shenzhen Enduring Biotech, Ltd., Shenzhen, China

ADCs have demonstrated improved efficacy and target selectivity comparing to the non-specific small molecule cytotoxicity drugs in cancer treatment. Yet, in solid tumor therapies, effort for further improvement of efficacy and safety has been hindered by the poor tumor penetration of conventional IgG based ADC, low internalization efficiency, undesired efflux of ADC from tumor cells, narrow therapeutic window due to the on-target/off tumor and Fc induced toxicity, etc. To address those issues, we previously reported that the compound JY201, a Polyethylene Glycol (PEG)-based bispecific ADC (P-BsADC) targeting two epitopes of Her2, demonstrated advantages in tumor penetration, internalization efficiency, lysosome trafficking, no Fc related toxicity, and better efficacy in tumor inhibition than transtuzumab deruxtecan (Ds-8201). In this study, we reveal another novel pegylated P-BsADC (JY207) formed by site-specific conjugation of a bispecific single chain fusion protein targeting PD-L1 and CD47 with PEG-MMAE (a pegylated cytotoxic payload MMAE). As expected, the compound JY207 retains all the advantages that JY201 possesses. Furthermore, JY207 does not bind to human red blood cells, but preferentially binds to CD47/PD-L1 double positive tumor cells, thus reduces the possibility of on-target toxicities. In vitro cytotoxicity studies showed that JY207 has strong potencies in CD47/PD-L1 double positive tumor cells, while showing almost no killing effect to CD47 or PD-L1 single positive tumor cells. In CDX models and a PDX model of transplanted tumor tissues from lung cancer patients, the compound demonstrated excellent tumor inhibition at low doses. In an in vitro plasma stability test, JY207 displays high stability in cynomolgus monkey and human serums. Preliminary repeated-dosing toxicological study has found the maximum tolerated dose of JY207 in CD47/PD-L1 double transgenic mice is 50mg/kg. In vivo pharmacokinetics and toxicological studies of JY207 are being conducted in cynomolgus monkeys and are expected to show desirable results. All those findings in this study warrant JY207 as a promising candidate for the clinical development for patients with CD47/PD-L1 double positive cancers.

#6308

Preclinical development of ABBV-319: a CD19-targeting glucocorticoid receptor modulator (GRM) agonist antibody-drug conjugate (ADC) for the treatment of B-cell malignancies

Chewei Anderson Chang[1], Ethan Emberley[1], Aloma L. D'Souza[1], Weilong Zhao[1], Cormac Cosgrove[2], Axel Hernandez Jr[3], Anatol Oleksijew[2], Paul Ellis[2], Luis Rodriguez[2], Gail Bukofzer[2], David Peetz[2], Wissam Assaily[1], Raghuveer Singh Mali[1], Wei Liu[1], Danqing Xu[1], Gregory K. Potts[2], Shaun McLoughlin[2], Kimberley McCarthy[3], Zhaomei Zhang[1], Jos Campbell[1], Isabella Sturdevant[1], Gloria Zhang[1], Tyler Curran[1], Jon D. Williams[2], Erwin Boghaert[2], Milan Bruncko[2], Christopher C. Marvin[2], Adrian Hobson[3], Michael Mcpherson[3], Tamar Uziel[2], Marybeth Pysz[1], Xi Zhao[1], Alex Bankovich[1], Kevin J. Freise[2], Susan Morgan-Lappe[2], James W. Purcell[1]. *[1]AbbVie Bay Area, South San Francisco, CA,[2]AbbVie Inc., North Chicago, IL,[3]AbbVie Bioresearch Center, Worcester, MA*

Introduction: Glucocorticoids are key components of standard-of-care treatment regimens (*e.g.*, R-CHOP, Hyper-CVAD) for several B-cell malignancies. However, prolonged systemic glucocorticoid treatment results in glucocorticoid-associated adverse events and acquired resistance that limit its therapeutic potential. ABBV-319 is a novel CD19-targeting ADC engineered to reduce glucocorticoid-associated toxicity observed with systemic glucocorticoids while possessing three distinct mechanisms of action (MoA) to increase efficacy: 1) antibody-mediated delivery of GRM to activate glucocorticoid receptor (GR) induced cell death in cancer cells, 2) inhibition of CD19 signaling, and 3) enhanced Fc-mediated cancer cell killing via afucosylation of the antibody backbone.
Results: We identified a GRM agonist that is 15 and 150 times more potent at driving GR transcriptional activation and cell death compared to clinical glucocorticoids dexamethasone and prednisolone, respectively. The conjugation of GRM agonist as the payload on ABBV-319 enables potent GRM-driven anti-cancer activity against malignant B-cell lines *in vitro* as well as in cell-line and patient derived xenograft (CDX and PDX) models *in vivo*. Remarkably, a single-dose of ABBV-319 induced sustained tumor regression and enhanced anti-tumor activity compared to repeat dosing of systemic glucocorticoids (*e.g.,* prednisolone) at its maximum tolerated dose in mice. The CD19 monoclonal antibody (mAb) also reduced proliferation of a subset of B-cell malignant cell lines through inhibition of the PI3K/AKT pathway. Moreover, afucosylation of the CD19 mAb in ABBV-319 enhanced Fc-mediated antibody-dependent cellular cytotoxicity

(ADCC), and this activity was maintained after conjugation with GRM payloads. ABBV-319 bound similarly to both V158 (high-affinity) and F158 (low-affinity) FcγRIIIa allotypes and mediated potent ADCC in co-culture assays with human peripheral blood mononuclear cells (PBMCs). Notably, ABBV-319 displayed superior efficacy compared to afucosylated CD19 mAb in human CD34+ hematopoietic stem cell-engrafted NSG-Tg(Hu-IL15) mice, demonstrating that the three MoA (GR-driven cell death, CD19 signaling inhibition, and ADCC) collectively contribute to anti-tumor activity *in vivo*. ABBV-319 also displayed on-target depletion of normal human B-cells but did not affect peripheral NK cell counts in mice. Furthermore, CITE-seq profiling revealed that ABBV-319 treatment of human PBMCs activated GRM-induced signature genes restricted to B-cells, demonstrating the specificity of CD19-mediated delivery of GRM. Conclusion: ABBV-319 has potent anti-tumor activity from three distinct MoA and exhibits safety improvements compared to systemic glucocorticoids, supporting its recent progression into Phase I clinical trial.

Anti-tumor efficacy of SI-B001, a novel EGFR×HER3 bispecific antibody, against EGFR-driven epithelial tumors alone or in combination with paclitaxel and carboplatin

Blair Renshaw[1], Jahan Salar Khalili[1], Sa Xiao[2], Yi Zhu[2]. *[1]SystImmune Inc., Redmond, WA,[2]Sichuan Baili Pharmaceutical Co., Ltd., Chengdu, China*

EGFR is a member of the human epidermal growth factor receptor (ErbB) family with tyrosine kinase activity. Evidence indicates that EGFR is involved in the pathogenesis and progression of human carcinoma of different types. HER3 is a unique pseudokinase receptor of the ErbB family and known to mediate resistance to EGFR-targeting therapies. Therefore, we created SI-B001, an EGFR×HER3 bispecific antibody, which can bind EGFR×EGFR homodimers and EGFR×HER3 heterodimer to block their downstream pathways. We performed non-clinical studies to investigate *in vitro* and *in vivo* anti-tumor effects.
In vitro, the inhibition of tumor cell growth by SI-B001 was stronger than cetuximab and duligotuzumab in FaDu (mRNA expression levels of $EGFR^{high}/HER3^{high}/NRG1^{medium}$). Importantly, testing with the cell line Oka-c-1 (mRNA expression levels of $EGFR^{high}/HER3^{high}/NRG1^{low}$),

showed that NRG1 supplementation did not change the potency of cetuximab. However, SI-B001 showed much stronger potency than cetuximab and duligotuzumab under conditions of NRG1 supplementation. This result indicates that the functionality of the bi-specific SI-B001 is competitive against a HER3 natural ligand and capable to act against cancer with HER3 ligand mediated resistance to cetuximab.
In vivo, single agent SI-B001 exhibited superior anti-tumor activity to cetuximab in the FaDu xenograft model. Meanwhile, SI-B001 in combination with paclitaxel and carboplatin led to a significant synergistic antitumor effect, which was stronger than the combination of cetuximab + paclitaxel + carboplatin. Compared to chemotherapy alone in this model, which could result in weight loss and treatment related mortality, no serious weight loss or deaths occurred in the single agent SI-B001 and the combination of SI-B001 with chemotherapy.
These results suggest that SI-B001 alone and in combination with chemotherapy can exhibit favorable safety and robust anti-tumor activity. Currently, 6 phase II clinical trials of SI-B001, either alone or in combination with chemotherapy, have been conducted in different epithelial carcinomas. These studies have shown a potential break-through activity in NSCLC and HNSCC with a very good safety profile.

Phylogenetic conservation of primate Trop-2 underscores favorable pharmacokinetics and lack of toxicity of the cancer-selective Hu2G10 anti-Trop-2

Saverio Alberti[1], Martina Ceci[2], Ludovica Pantalone[2], Marco Trerotola[2], Emanuela Guerra[2]. *[1]University of Messina, Messina, Italy,[2]University of Chieti-Pescara, Chieti, Italy*

Trop-2 is a transmembrane signal transducer that activates growth-signaling networks that converge on Akt, ERK, Cyclin D1, NFkB (1). We discovered that Trop-2 cleavage by ADAM10 is an activator switch of cancer growth and metastatic diffusion (2) and exposes novel target epitopes that are inaccessible in the unprocessed wtTrop-2. The Hu2G10 mAb selectively binds these epitopes with an affinity that is ≈10,000-fold higher than for the unprocessed molecule. To validate a reliable model for Hu2G10 binding *in vivo,* we explored Trop-2 phylogenetic conservation in primates. *Pan*

troglodites (chimpanzee), *Papio anubis* (baboon), *Macaca mulatta/fascicularis* (Rhesus/Cynomolgous), *Callithrix jaccus* (marmoset) *TROP2/TACSTD2* sequences were compared. The only difference between *Pan troglodytes* and human Trop-2 is one additional leucine in the Pan leader peptide, making the mature Trop-2 identical to that in man. The *Macaca mulatta/fascicularis* Trop-2 sequences are 97% identical, 100% similar to the human sequence. Three-dimensional modeling revealed polymorphic residues usage versus activation-driven structural rearrangement of Trop-2. COS-7 and HEK-293 cells transfected with individual primate Trop-2 showed efficient recognition by Hu2G10 in all tested species. Immunohistochemistry analysis of normal Macaca tissues showed Trop-2 expression patterns essentially corresponding to the human ones. IV injected Hu2G10 at doses of 5 to 10 mg/kg was well tolerated by Cynomolgous monkeys. No neurological, respiratory, digestive and urinary adverse effects were observed, and no body-weight loss occurred during the 28-day observation. No alterations of blood monocyte, neutrophil and basophil counts nor significant changes in biochemical parameters were detected. A pharmacokinetic (PK), study was carried out. Serum concentration of Hu2G10 was determined using anti-idiotypic antibody-based ELISA assays. At the higher dosing of 10 mg/kg Hu2G10 serum values reached a peak 2-hour after the injection (13281±4686 ng/ml). The concentration of Hu2G10 then diminished gradually, and reached baseline levels on day 21. The serum concentration peak of 5 mg/kg Hu2G10 was 5759±1729 ng/ml, and reached baseline levels on day 14. Thus, Hu2G10 is stable in plasma, and is detectable in the circulation up to three weeks after the infusion ($t_{1/2}$=6.5 days). Taken together, these findings validate primate models as reliable for assessing Hu2G10 *in vivo* toxicity and PK. The lack of toxicity and favorable PK parameters candidate the cancer specific Hu2G10 as first-in-class anti-Trop-2 mAb. ABBV-400: An ADC delivering a novel topoisomerase 1 inhibitor to c-Met-positive solid tumors

Regina M. Reilly[1], Cheng Ji[1], Ryan P. Matuszak[1], Mark G. Anderson[1], Lora Tucker[1], Nadezda Klunder[1], Adelyn L. Zelaya Lazo[1], Erwin R. Boghaert[1], Marybeth A. Pysz[2], Aloma D'Souza[2], Laura Kreckler[3], Milan Bruncko[4],

Brittney J. Mills[5], Matthew Ravn[6], George Doherty[1], Kevin J. Freise[7], Andrew C. Phillips[1]. *[1]Oncology Discovery Research, AbbVie Inc., North Chicago, IL,[2]Oncology Discovery Research, AbbVie Inc., South San Francisco, CA,[3]Global Preclinical Safety, AbbVie Inc., North Chicago, IL,[4]Drug Discovery Science & Technology, AbbVie Inc., North Chicago, IL,[5]Drug Product Development, AbbVie Inc., North Chicago, IL,[6]Process Research & Development, AbbVie Inc., North Chicago, IL,[7]Oncology Early Development, AbbVie Inc., North Chicago, IL*

Antibody-drug conjugate (ADC) technology is founded on the premise that antigen-mediated payload delivery selectively targets tumor cells and spares normal tissue. While approval of several ADCs has proven this to be a successful therapeutic approach, there remain opportunities to generate optimized ADCs with tailored selection of antigen matched with payload highly active in the target indication. To this end, ABBV-400 has been developed as an ADC that targets c-Met and topoisomerase-1 (Top1), both of which are overexpressed in solid tumors. The antibody is directed to the cell surface tyrosine kinase receptor, c-Met, a key driver of tumor cell growth and development of resistance to EGFR-targeted and other targeted therapeutics. Supporting this, Teliso-V, a c-Met-targeted ADC with MMAE payload, has been granted Breakthrough Therapy Designation in non-small cell lung cancer (NSCLC). To extend activity of a c-Met-targeted ADC to patients with tumors expressing lower c-Met levels and to indications, such as colorectal cancer (CRC), where MMAE-based ADCs have not been effective, a novel topoisomerase-1 inhibitor linker-drug was developed. Screening over 400 linker-drugs identified a unique, potent Top1 inhibitor with a cleavable valine-alanine linker and stable bromoacetamide attachment designed to minimize systemic payload release. Preclinically ABBV-400 exhibits favorable pharmacokinetics, anti-proliferative activity in vitro, and compelling efficacy in NSCLC, gastroesophageal, and CRC xenograft models. Furthermore, ABBV-400 is well tolerated by cynomolgus monkeys with bone marrow and gastrointestinal tract toxicities common to other Top1 inhibitors. This pairing of a novel linker-drug and an antibody with demonstrated clinical activity provides an exciting opportunity to treat patients with c-Met expression in indications sensitive to Top1 inhibition.

ABBV-400 has progressed through dose escalation, and dose expansion is currently ongoing in a Phase 1 FIH clinical study (NCT05029882).
All authors were employees of AbbVie during this research. The design, study conduct, and financial support for this research were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the publication

Targeting HSPG is more efficient than using soluble heparin for interfering with cancer cell adhesion and migration

Lorenzo Depau, Elisabetta Mandarini, Jlenia Brunetti, Marta Zanchi, Chiara Falciani, Luisa Bracci. *University of Siena, Siena, Italy*

Given the relevance of heparan sulfate proteoglycans (HSPG) and of heparin binding ligands in the regulation of cancer cell adhesion, migration and invasiveness, drugs that may interfere with HSPG functions have been studied for decades for their possible use in oncology. In this view heparin analogues have been tested for their effectiveness not only in cancer associated thromboembolism but also for their potential effects on cancer growth and metastasis. Despite a number of promising preclinical results and clinical hypothesis, many different clinical trials on the use of heparin analogues in different cancers reported no significant benefits in tumor progression and overall survival, indicating that using heparin as a soluble decoy for the many HSPG ligands does not appear to be the best possible approach (1,2). Taking advantage of the tetra-branched peptide NT4, which is a specific ligand of HSPG sulfated glycosaminoglycan (GAG) chains (3, 4), we tested the effectiveness of targeting cell membrane HSPG, as a potential alternative approach for interfering with HSPG functions in cancer cell invasiveness. We had demonstrated that NT4 can either inhibit or increase oriented migration in respectively PANC-1 pancreas adenocarcinoma and TE671 rhabdomyosarcoma human cancer cells, indicating a crucial but diverse role of HSPGs in oriented cell migration in different cancer cells.NT4 and heparin were here compared for their effect on adhesion and migration of different cancer cell lines on extracellular matrix (ECM) supports, as well as for their effect on proliferation and in vitro invasiveness of the same cell lines. We found that inhibition of cancer cells adhesion to ECM proteins by NT4 varies in different cancer cell lines,

ranging from 90% inhibition to as low as 20%, whereas heparin has no effect. Analogous results were obtained when testing cancer cell migration. NT4 inhibited migration and in vitro invasiveness of different human cancer cell lines, with the sole exception of TE671 cells. Heparin did not modify cell migration in any of the tested cancer cell lines. NT4 had no effect on cell proliferation, whereas, notably, heparin resulted to stimulate cell proliferation in some cancer cell lines. Differently from using heparin as an unspecific soluble decoy, targeting HSPG with well-defined ligands can result in an efficient tumor-specific treatment. Nevertheless, as for most cancer cellular targets, a detailed definition of cellular mechanisms and a related personalized approach is mandatory.

IND-enabling studies for GrB-Fc-IT4: *in vivo* efficacy, pharmacokinetics, schedule optimization and maximum tolerated dose

Ana Alvarez-Cienfuegos, Lawrence H. Cheung, Khalid A. Mohamedali, Mihai Gagea, Michael G. Rosenblum. *UT MD Anderson Cancer Center, Houston, TX*

Fn14 (fibroblast growth factor-inducible 14) is the only known receptor of TWEAK (tumor necrosis factor-related weak inducer of apoptosis). The binding of TWEAK to Fn14 activates several intracellular signal transduction cascades that lead to cell death, proliferation, migration, or survival depending on the cellular contexts. Several studies have shown that Fn14 is upregulated in many solid tumors when compared with healthy tissues. The activation of TWEAK/Fn14 signaling increases the proliferation, invasion, and migration of tumor cells. Moreover, angiogenesis, pro-inflammatory cytokine expression, and epithelial-mesenchymal transitions are promoted upon TWEAK/Fn14 activation. Therefore, Fn14 is considered a potential therapeutic target, and attempts to generate targeted therapeutics have achieved limited success in pre-clinical and clinical trials. We generated a completely human fusion protein, GrB-Fc-IT4, consisting of the IT4 scFv antibody targeting the Fn14 receptor and the serine protease granzyme B (GrB) as the cytotoxic payload.

Comprehensive mechanism of action studies showed that GrB-Fc-IT4 effectively induced cell death *in vitro* against a broad selection of tumor types with high specificity. The intracellular pathway included rapid, irreversible activation of the caspase cascade and independent mitochondrial depolarization leading to intense apoptotic cellular damage. Pharmacokinetic studies in mice showed that GrB-Fc-IT4 cleared bi-exponentially from plasma with a rapid initial clearance ($t_{½}\alpha$ = 0.36 hours) followed by a prolonged terminal-phase plasma half-life ($t_{1/2}\beta$ = 35 hours), similar to that of IgGs. Based on our PK study, we compared the *in vivo* antitumor efficacy of GrB-Fc-IT4 against A549 (NSCLC) tumors, using two different dosing schedules (QODx5 vs QWx5). Tumor efficacy showed a clear dose and schedule dependence. Mice bearing A549 tumors treated with 32 mg/kg/dose (QOWx5) exhibited complete tumor growth inhibition (7/10 tumors regressed) with 3/10 tumors showing no growth up to 50 days after the last dose. Thus, GrB-Fc-IT4 displays impressive *in vitro* and *in vivo* cytotoxic effects. Even though GrB-Fc-IT4 cross-reacts with the murine Fn14 antigen, maximum tolerated dose studies in mice have confirmed that GrB-Fc-IT4 is a safe product, as mice treated with the drug up to 500 mg/kg showed no evidence of toxicity (changes in respiration, rough hair coat, unusual behavior or hunched posture). Taking in consideration these results we estimate that the therapeutic index for this class of drug is higher than four. Our data suggest that GrB-Fc-IT4 is a novel antitumor agent with a unique mechanism of action compared to all other therapeutic agents. The exceptionally safe and effective profile of this drug makes it an ideal candidate for advancing to clinical trials. Research conducted, in part, by the Clayton Foundation for Research.

Novel granzyme B-based fusion constructs targeting FRα on liquid and solid tumors

Ana Alvarez-Cienfuegos[1], Lawrence H. Cheung[1], Khalid A. Mohamedali[1], Natalia Baran[1], Marina Konopleva[2], Michael G. Rosenblum[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Albert Einstein College of Medicine, Bronx, NY*

Folate receptor α (FRα) has been an attractive therapeutic target for many decades because it is highly overexpressed on several solid tumors and demonstrates low or restricted distribution on healthy tissues. Additionally, high expression of FRα has been associated with tumor progression and thus poor prognosis of cancer patients. Therefore, utilizing FRα to effectively locate tumor cells for targeted therapy using antibody drug conjugates, small molecule drug conjugates, radioimmunoconjugates or chimeric antigen receptor T cells, has been extensively investigated. Although some of the mentioned targeted therapies have shown promising preclinical results, their clinical utility has been limited due to associated toxicities in healthy tissues. We generated two new fusion constructs targeting FRα and containing active human granzyme B (GrB) as the cytotoxic payload. We used as binding domains two different scFvs targeting the FRα from antibodies previously used in clinical trials. These human scFvs (mov003 and mov018) were fused to the human serine protease GrB through an engineered human IgG heavy-chain fragment (designated as Fc) which contains a dimerization domain for longer half-life. The cytotoxicity of the constructs against a panel of cell lines expressing various levels of FRα showed a specific cytotoxic effect with an IC_{50} in the low nanomolar range (5-100 nM), particularly exhibiting very low IC_{50} values against breast and ovarian cell lines. FRα negative cells demonstrated IC_{50} levels in the micromolar range. Immunofluorescence studies demonstrated that the fusion constructs targeting FRα are efficiently internalized and effectively delivered the active serine protease to the cytosol. *In vitro* stability assays over 96 hours showed that both constructs are highly stable in mouse serum. Additionally, recent publications suggested that FRα is significantly associated with acute myeloid leukemia (AML) and might serve as a therapeutic target. We assessed the cytotoxic efficacy of GrB-based constructs on a panel of FRα+ AML cell lines and have found that these cell lines were very sensitive (IC_{50} in the low nanomolar range). Furthermore, evaluation of GrB fusion efficacy in two AML cell lines resistant to Bcl-2 inhibitor Venetoclax showed IC_{50}s to be similar or lower than their parental cell lines. These results, therefore, demonstrate no cross-resistance to GrB. The safe and effective profile of these drugs together with their unique mechanism of action makes them ideal candidates for advancing pre-clinical development and may offer a

potential new strategy for treatment of solid tumors and particularly Venetoclax relapsed AML patients, ineligible for intensive chemotherapy. *In vivo* efficacy studies to compare the two constructs are warranted and will help to identify the optimal therapeutic for further clinical consideration. Research conducted, in part, by the Clayton Foundation for Research.

#6315

Human granzyme B fusions targeting VEGFR on tumor cells and activated vasculature

Khalid A. Mohamedali, Lawrence H. Cheung, Ana Alvarez-Cienfuegos, Walter N. Hittelman, Michael G. Rosenblum. *UT MD Anderson Cancer Center, Houston, TX*

$VEGF_{121}$ is a naturally-occurring splice variant that binds to VEGF receptors R-1 and R-2, which are over-expressed on the endothelium of tumor vasculature but not normal vasculature, as well as several tumor cells. While anti-VEGF therapy is a key therapeutic in several cancer treatment regimens, none of the current therapeutics (bevacizumab, VEGF-trap, tyrosine kinase inhibitors) are directly cytotoxic against tumor cells. The serine protease Granzyme B (GrB) is a key effector in immune-mediated cell killing by inducing apoptosis through both caspase-dependent and -independent mechanisms. We previously reported the development and characterization of a fusion protein composed of GrB and $VEGF_{121}$ (GrB/$VEGF_{121}$). Here, we report on GrB-Fc-$VEGF_{121}$, a fusion protein that incorporates a human IgG heavy chain Fc fragment for dimerization which increases the molecular weight and improves *in vivo* circulation and targeting potential. GrB-Fc-$VEGF_{121}$ was expressed in HEK-293E cells under serum-free conditions and purified from the conditioned medium with a final yield of approximately 40 mg/L. The enzymatic activity of GrB in GrB-Fc-$VEGF_{121}$ was comparable to that of commercially available human GrB. *In vitro* studies of GrB-Fc-$VEGF_{121}$ showed cytotoxicity in the nanomolar range against tumor and endothelial cell lines expressing high levels of VEGFR-1 or VEGFR-2. Receptor-negative cells demonstrated IC_{50} levels in the high micromolar range. Immunofluorescence and confocal microscopy demonstrated that GrB-Fc-$VEGF_{121}$ readily

internalized into VEGFR-2+ tumor cells and endothelial cells within 2 hours of treatment while untargeted GrB did not internalize, suggesting internalization was receptor-mediated. Treatment of VEGFR-2+ endothelial and tumor cells at the IC_{50} dose resulted in >50% cell death via apoptosis and/or necrosis within 48 h. *Ex vivo* serum stability of GrB-Fc-$VEGF_{121}$ indicated a gradual protein loss of GrB-Fc-$VEGF_{121}$, with an overall stability of about 50% over 96 hours. No toxicity was observed in BALB/c mice treated with a total 475 mg/kg given IP every other day over 5 doses, indicating that the maximum tolerated dose of GrB-Fc-$VEGF_{121}$ exceeds this dose level. *In vivo* efficacy studies in an OVCAR8 tumor xenograft model with GrB-Fc-$VEGF_{121}$ (100 mg/kg over 5 doses) resulted in significant growth inhibition of established tumors compared to vehicle controls. We observed a significant decrease in the number of CD31+ blood vessels and Ki-67+ proliferating tumor cells in treated tumors compared to controls. Thus, GrB-Fc-$VEGF_{121}$ has significant anti-tumor effects *in vivo* with virtually no toxicity against normal tissues at doses 4-5 times higher than therapeutic levels. This tumor- and vascular-targeting agent appears to have significant potential as a new class of targeted therapeutic agents with a unique mechanism of action. Research conducted, in part, by the Clayton Foundation for Research.

#6316

In vitro and in vivo studies of human granzyme B fusion constructs targeting mesothelin

Khalid A. Mohamedali[1], Lawrence H. Cheung[1], Louis R. DePalatis[2], Claire Thuning-Roberson[2], Michael G. Rosenblum[1]. *[1]Experimental Therapeutics, M.D. Anderson Cancer Center, Houston, TX,[2]H2Biologics, Inc, Shrewsbury, MA*

Mesothelin is highly expressed on tumor cells and promotes tumor growth and drug resistance. Pancreatic, ovarian, mesothelioma, and lung cancers highly express mesothelin and are cancers of unmet needs with ≤16% relative 5-year survival using standard of care. When delivered to tumor cells by immune effector cells, granzyme B (GrB) is a highly cytotoxic serine protease which induces apoptosis through both caspase-dependent and -independent mechanisms. We developed a fusion protein (GrB-Fc-

SD1) composed of human GrB and containing SD1, a novel human single-domain antibody that uniquely targets Region III of the glycoprotein, mesothelin. The SD1 and GrB domains are connected by a human IgG heavy chain fragment which enables dimerization. Thus, the increase in total construct molecular weight leads to an increased *in vivo* circulation time and anti-tumor efficacy. GrB-Fc-SD1 was transiently expressed in HEK-293E cells under serum-free conditions and purified to homogeneity to a final yield of approximately 5 mg/L. Anti-GrB western blot analysis confirmed the expression of GrB-Fc-SD1 exclusively as a dimer. Comparison of GrB-Fc-SD1 with its expected molecular weight suggests significant glycosylation when produced in HEK-293E cells. The enzymatic activity of granzyme B in GrB-Fc-SD1 was comparable to that of commercially available human granzyme B. *In vitro* cytotoxicity against a limited panel of lung, pancreatic and ovarian cancer cell lines expressing surface mesothelin indicate cytotoxicity in the nanomolar range, while cytotoxicity against mesothelin-negative cells was at micromolar levels. GrB-Fc-SD1 bound specifically to mesothelin extra-cellular domain compared to a non-specific control, as determined by ELISA. Biacore analysis confirmed binding with a dissociation constant between 10^{-7} to 10^{-8} M. These data warrant continued investigation of the protein as a therapeutic candidate. Accordingly, *ex vivo* serum stability studies are underway. In addition, screening of an expanded panel of tumor cell lines for *in vitro* cytotoxicity is currently in progress and will be reported. *In vivo* efficacy studies against nude mice bearing Capan-2 xenograft models are currently underway and will also be reported. Research supported by H2Biologics. Research conducted, in part, by the Clayton Foundation for Research.

#6317

Targeting cell-surface CEA with a novel human fusion construct delivers the serine protease granzyme B to solid tumor cells

Khalid A. Mohamedali, Ana Alvarez-Cienfuegos, Lawrence H. Cheung, Walter N. Hittelman, Michael G. Rosenblum. *UT MD Anderson Cancer Center, Houston, TX*

Cancer treatment has improved in the past decades due to advances in targeted therapies and surgical techniques. Immunotherapy, for example,

has greatly improved outcomes for people with several types of cancer that typically have a poor prognosis. However, the response rate depends on the type of cancer being treated, with an average response rate between 20 to 50%. Thus, novel approaches to overcome such therapeutic challenges are warranted. Emerging therapies include fusion proteins and immunoconjugates that deliver a cytotoxic payload to the tumor cell with more specificity and potentially less avenues for resistance than exerted by the antibody or toxin alone. Carcinoembryonic antigen (CEA) is a cell surface protein normally found at low levels in adult tissues but over-expressed in a high percentage of solid tumors including colon and rectum, lung, prostate, ovary, thyroid, or liver. Thus, oncologic therapies against CEA may promote anti-tumor activity while sparing off-target toxicity to unaffected normal tissue. Our newly developed construct, designated GrB-Fc-huMFE, is a completely human fusion protein that contains the single-chain variable fragment huMFE antibody recognizing a juxta-membrane epitope of CEA remaining after proteolytic cleavage of CEA from the cell surface. The construct rapidly internalized into target cells resulting in granzyme B (GrB)-mediated mitochondrial depolarization and irreversible activation of both apoptotic and necrotic cascade mechanisms of cell death. *In vitro* cytotoxicity of GrB-Fc-huMFE against an initial subset of CEA+ tumor cell lines demonstrated cytotoxicity in the nanomolar range, compared to micromolar IC_{50} cytotoxicity against CEA-negative cell lines. Significantly, GrB-Fc-huMFE cytotoxicity *in vitro* was unaffected by exogenously-added CEA extracellular domain at doses up to 1000 µg/ml, suggesting that the construct is not competitively absorbed by soluble CEA proteolytically released by tumors and present in the circulation of patients. An *in vivo* efficacy study against established CEA+ (A-549) tumors in nude mice resulted in significant growth inhibition compared to vehicle controls (1200 mm^3 vs <40 mm^3). Complete tumor regression was observed in 7/10 tumors in mice treated (IP) with doses of 100 mg/kg of GrB-Fc-huMFE in a Q3Dx5 dose administration schedule. Mouse weight was unaffected in both treated and control groups for the duration of the study, suggesting no apparent toxicity of the construct. Pharmacokinetic, stability and *in vitro* tests against a broader panel of tumor cell lines are ongoing and will be reported. Altogether, GrB-Fc-huMFE appears to have significant potential in targeting a large category of CEA-expressing solid tumors and is a promising candidate for further pre-clinical and eventual clinical

development. Research conducted, in part, by the Clayton Foundation for Research.

#6318

Preclinical characterization of ARX305, a next-generation anti-CD70 antibody drug conjugate for the treatment of CD70-expressing cancers

Lillian Skidmore[1], Jingjing Zhu[2], David Mills[1], Ting Jin[2], Suqin Li[2], Keith Tatsukawa[1], Nick A. Knudsen[1], Liying Gong[2], Jay Nelson[1], Kari Cox[1], Amha G. Hewet[1], Jianing Wang[1], Tim Buss[1], Feng Tian[1], Gang Xia[2], Shawn Zhang[1]. *[1]Ambrx Biopharma Inc., La Jolla, CA,[2]NovoCodex Biopharmaceuticals, Inc., Shaoxing, China*

CD70 has emerged as an attractive tumor target with its over-expression in multiple solid and hematological cancers, yet tightly controlled and limited expression in normal cells. In the last decade, multiple anti-CD70 antibody drug conjugates (ADCs) have been developed, but most, if not all, of these ADC programs have been discontinued. Using an expanded genetic code to create Engineered Precision Biologics (EPBs), Ambrx has developed ARX305, a CD70-targeted next-generation antibody drug conjugate (ADC) to potentially overcome the challenges associated with earlier ADCs and treat patients with cancers over-expressing CD70. ARX305 is comprised of a proprietary, high-affinity, humanized anti-CD70 antibody stably and site-specifically conjugated to AS269, a potent microtubule inhibitor. After binding to CD70 expressed on target tumor cells, ARX305 internalizes and releases the cytotoxic payload pAF-AS269 which inhibits cellular proliferation. In vitro testing across a panel of solid and liquid tumor cell lines showed ARX305 elicited highly potent and specific cell killing across multiple tumor types with medium to high CD70 expression levels. In multiple in vivo CD70-expressing xenograft or disseminated models, ARX305 induced significant tumor growth inhibition or regression whereas unconjugated antibody exhibited poor activity. ARX305 utilizes stable oxime conjugation chemistry, a non-cleavable PEG linker, and a membrane-impermeable payload to minimize premature payload release in circulation and associated off-target toxicity. These properties of ARX305 result in high serum stability, with rodent pharmacokinetic studies confirming a similar exposure profile of ARX305 compared to unconjugated antibody and a long serum half-life. Repeat dose toxicokinetic studies in cynomolgus

monkeys demonstrated ARX305 was tolerated at exposures well above therapeutic exposures in mouse pharmacology studies, indicating a wide therapeutic index. In summary, the highly potent anti-tumor activity in multiple tumor types and wide therapeutic index of ARX305 support clinical evaluation of this next generation anti-CD70 ADC. ARX305 is currently in a Phase 1 dose escalation study in China, and the IND in the United States is open.

Mechanism of anti-EGFR antibody endostatin fusion protein action on inhibition of vasculogenic mimicry and tumor cell motility in triple negative breast cancer

Ankita Sankar[1], Hava Gil Henn[2], Hyun Mi Cho[1], Dania Nassar[2], Sundaram Ramakrishnan[1], Yu Zhang[1], Christian Elledge[1], Seung Uon Shin[1], Joseph Rosenblatt[1]. *[1]University of Miami Miller School of Medicine, Miami, FL,[2]Bar Ilan University, Azrieli Faculty of Medicine, Tzfat, Israel*

Triple Negative Breast Cancer (TNBC) is an aggressive subtype of breast cancer with high metastatic potential and increased morbidity and mortality. Although expression of and signaling by the epidermal growth factor receptor (EGFR) is commonly seen in TNBC, anti-EGFR antibodies such as Cetuximab have had limited therapeutic efficacy, used alone or in combination with chemotherapy.

Primary TNBC tumor growth and metastases require supporting vasculature, which develops through a combination of endothelial angiogenesis and vasculogenic mimicry (VM). VM is frequently seen in TNBC and is associated with aggressive metastatic behavior. We previously developed αEGFR-E-P125A, an antibody-endostatin fusion protein, linking an anti-EGFR antibody to a mutated version of the anti-angiogenic protein endostatin (E-P125A). αEGFR-E-P125A delivers a dimeric E-P125A payload which inhibits TNBC angiogenesis and VM *in vitro* and *in vivo*, and markedly decreases metastasis in multiple TNBC xenograft models. To study changes in the transcriptome following induction of VM and inhibition of VM with αEGFR-E-P125A, RNA-seq was conducted on MDA-MB-231-4175 TNBC cells grown in a 2D monolayer and compared to TNBC cells undergoing VM when plated in matrigel. A second comparison was made between TNBC cells undergoing VM and TNBC

cells in which VM was inhibited by treatment with αEGFR-E-P125A. Differential gene expression analysis and gene set enrichment analysis (GSEA), were used to define pathways which were inversely regulated during the induction of VM on matrigel and inhibition of VM with αEGFR-E-P125A.
Gene set enrichment analysis demonstrated that αEGFR-E-P125A treatment significantly downregulated genes in the JAK-STAT and angiogenesis signaling pathways. Phospho-array analysis demonstrated decreased EGFR phosphorylation at Y1069 in addition to decreased phosphorylation of FAK Y397 and STAT3 Y705 sites downstream of α5β1 integrin. Since inhibition of EGFR signaling alone did not inhibit VM, and endostatin is a known ligand of α5β1 integrin, we focused on effects of αEGFR-E-P125A on inhibition of α5β1 integrin/FAK signaling pathway. Independent siRNA knockdowns of α5 integrin and FAK in MDA-MB-231-4175 cells confirmed that downregulation of α5 integrin/FAK signaling inhibited VM *in vitro*.
αEGFR-E-P125A additionally prevented EGF-induced EGFR phosphorylation and fibronectin-induced FAK phosphorylation by α5β1 integrin. Treatment of TNBC cells with αEGFR-E-P125A reduced total α5 integrin protein levels and decreased co-localization of EGFR and α5β1 integrin receptors. These results indicate that αEGFR-E-P125A suppressed both EGFR and α5β1 integrin signaling. Simultaneous inhibition of EGFR and α5β1integrin signaling by αEGFR-E-P125A fusion is a promising approach to inhibition of TNBC growth and metastases.

CUSP06/AMT-707, a new CDH6-targeting antibody-drug conjugate, demonstrates potent antitumor activity in preclinical models

Wei Lu[1], Jing Shi[2], Shu-Hui Liu[2], Nicole Covino[1], Xun Meng[2], Eric D. Slosberg[1]. *[1]OnCusp Therapeutics, Inc., New York, NY,[2]Multitude Therapeutics Inc., Shanghai, China*

Cadherin-6 (CDH6), also known as K-cadherin, is a type II classic cadherin molecule that plays an important role in the embryonic development of the kidney, but has very limited expression in adult tissues. It is overexpressed in several human malignancies, primarily in ovarian, renal, but also (to a lesser degree) gastric, thyroid, cholangiocarcinoma and other tumor types.

The characteristics of limited expression in normal tissues, high expression in tumor tissues, and rapid internalization upon antibody binding makes CDH6 a well-suited Antibody-drug Conjugate (ADC) target. We developed a novel CDH6-targeting ADC, CUSP06, consisting of a proprietary humanized antibody selective for CDH6, a protease cleavable linker, and an exatecan payload, with a drug-to-antibody ratio (DAR) of 8. CUSP06 selectively bound to cell surface CDH6 and was efficiently internalized into CDH6 positive ovarian and renal cancer cells. CUSP06 exhibited strong antiproliferative activity against several CDH6 positive cancer cell lines *in vitro*. Furthermore, compared to a DXd-based ADC, a exatecan-based ADC demonstrated improved bystander effect. Treatment with CUSP06 resulted in tumor regression in several CDH6 positive cell line derived xenograft (CDX) models, including PA-1, OVCAR3, and 786-O. In addition, CUSP06 demonstrated potent antitumor activity with tumor regression observed in two CDH6 low and high expressing patient derived xenograft (PDX) models. The preclinical activity of CUSP06 against CDH6-expressing tumors provide compelling support for the clinical development of CUSP06 in CDH6-expressing human cancers. CUSP06 is currently in IND-enabling studies. CUSP06 showed an expected toxicity profile consistent with it's exatecan payload in the ongoing pilot toxicology studies. We plan to initiate a Phase 1 first-in-human clinical trial in the 2nd half of 2023.

#6321

HMPL-453, a highly selective inhibitor of fibroblast growth factor receptors 1, 2, and 3, displays potent activity in FGFR-altered tumor models

Jia Hu, Jun Ni, Longxian Jiao, Jinghong Zhou, Shiming Fan, Renxiang Tang, Wei Zhang, Xuelei Ge, Qihang Zhang, Juntao Yu, Ying Yu, Dongxia Shi, Min Cheng, Weifang Xue, Sumei Xia, Zeyu Zhong, Jian Wang, Yang Sai, Weiguo Qing, Guangxiu Dai, Yongxin Ren, Michael Shi, Weiguo Su.
HUTCHMED Limited, Shanghai, China

Background: Fibroblast growth factors (FGFs) and their receptors (FGFRs) regulate numerous cellular processes. Dysregulation of FGFR signaling due to receptor fusion, mutation or amplification is observed across multiple cancer types, making activated FGFRs an important therapeutic target.

Herein, we present the preclinical characterization of HMPL-453, a highly potent and selective inhibitor of FGFR1, 2, and 3, discovered and being currently developed in phase II clinical trial (NCT04353375) by HUTCHMED.
Methods: Kinase activity was measured by Transcreener™ Fluorescence Polarization assay or Z'-LYTE kinase assay. *In vitro* anti-proliferation activity was measured by CellTiter-Glo luminescent or CCK-8 assay. The effect of HMPL-453 on FGFR signaling pathway was detected by western blot. Multiple tumor models with FGFR alteration were applied in Nu/Nu nude mice to determine anti-tumor efficacy of 453 as a single agent. A model in immune-competent BALB/c mice inoculated with the constructed NIH/3T3 cells carrying FGFR2-AHCYL1 fusion was chosen to investigate the combination effect of HMPL-453 with anti-PD-1 antibody.
Results: HMPL-453 potently inhibited the tyrosine kinase activities of recombinant FGFR 1, 2, and 3 *in vitro* (IC_{50} values of 6, 4, and 6 nM, respectively) with weaker activity against FGFR4 (IC_{50} = 425 nM). HMPL-453 selectively inhibited proliferation of tumor cell lines with dysregulated FGFR signaling (GI_{50}s: 3~105 nM) compared with cell lines lacking FGFR aberrations (GI_{50}s > 1.5 μM). HMPL-453 demonstrated strong inhibition of phosphorylation of FGFR and downstream protein in tumor cell lines harboring FGFR2 fusion. Oral administration of HMPL-453 could induce time- and dose-dependent inhibition of phosphorylation of FGFR and resulted in remarkable and dose-dependent anti-tumor activity in multiple FGFR-altered tumor models. HMPL-453 at the dose of 50 mg/kg/day could induce tumor regression in most tumor models tested. Moreover, HMPL-453 significantly improved anti-tumor activity of anti-PD-1 antibody in a FGFR2 fusion model by priming the immune environment.
Conclusion: HMPL-453 is a highly potent and selective inhibitor of FGFR 1, 2, and 3 with strong activity against FGFR-deregulated tumors in preclinical models, supporting continued investigation in patients with FGFR alterations (such as fusion and mutation) either as a single agent or in combination with PD-1 blockade.

A novel EGFR x MUC1 bispecific antibody-drug conjugate, BSA01, targets MUC1 transmembrane cleavage products and improves tumor selectivity

Yifu Zhang, Chenzhang Shang, Anqi Wang, Jia Zhang, Yuji Liu, Hao Li, Xiaopeng Li, Gao An, Li Hui, Frank An, Yi Yang. *Biocytogen Pharmaceuticals (Beijing) Co., Ltd, Beijing, China*

Epidermal growth factor receptor (EGFR) and mucin 1 (MUC1) are tumor-associated antigens that are highly co-expressed in esophageal squamous cell carcinomas, non-small cell lung cancers (NSCLC), and triple negative breast cancers, among others. MUC1, a glycoprotein essential for the formation of the epithelial mucous barrier, is hypoglycosylated and dimerizes with EGFR, a potent oncoprotein, in transformed cells. Dual-targeting of both tumor-associated antigens (TAAs) represents a promising therapeutic strategy to treat common malignancies. We generated a fully human anti-EGFR/MUC1 bispecific antibody-drug conjugate (BSA01) from RenLite® humanized, common light chain mice. BSA01 is conjugated with Monomethyl auristatin E (MMAE). BSA01 targets the extracellular domain of MUC1-C (C-terminal domain of MUC1), which is the membrane-bound MUC1 cleavage product that remains after MUC1 is cleaved, providing more access to the tumor antigen *in situ*. In addition, we generated affinity and internalization optimized binders targeting EGFR that increases the tumor selectivity, to avoid potential skin toxicity due to ubiquitous basal EGFR expression. Internalization assays demonstrate that the anti-EGFR/MUC1 bispecific antibody used to generate BSA01 was endocytosed in tumor cells co-expressing EGFR/MUC1 more efficiently than mono- or bivalent antibodies targeting EGFR or MUC1 alone. When conjugated with payload, BSA01 also exhibited strong anti-tumor efficacy *in vitro* against gastric, NSCLC and pancreatic cancer cell lines. Moreover, BSA01 showed similar activity *in vivo*, effectively inhibiting tumor growth in multiple cell-derived xenograft and patient-derived xenograft models. These results suggest that BSA01 has great clinical potential for treating tumors co-expressing EGFR and MUC1.

#6326

Discovery & preclinical evaluation of BPB-101: A novel triple functional bi-specific antibody targeting GARP-TGFβ complex/SLC, free TGF-β and PD-L1

Wenxin Xu, Jieying Xu, Deyu Xu, Hongjie Cheng, Li Zhang, Huan Zheng, Siyuan Ye, Mengshi Jiang, Jiabing Wang, Lieming Ding. *Betta Pharmaceuticals Co.,Ltd, Hangzhou, China*

Background: Recent studies on tumor microenvironment (TME) have been conferred considerable attention, especially the transforming growth factor-β (TGF-β) signal axis and the PD-L1/PD-1 signal axis. TGF-β is a crucial enforcer in promoting tumor cells angiogenesis, plasticity, fibrosis, and in regulating immune homeostasis and tolerance. The TGF-β signaling controls innate and adaptive immunity in TME by inhibiting the activity of natural killer (NK) cells and effector T cells, while promoting the expansion of regulatory T cells (Tregs). Many studies have revealed that free TGF-β mainly released from glycoprotein A repetitions predominant (GARP)-TGFβ complex at the surface of activated Tregs, B, NK, and tumor cells. Existing antibodies or fusion proteins targeting TGF-β cannot simultaneously block the TGF-β releasing and naturalized free TGF-β in TME, thus limiting the anti-tumor effect. Herein, we designed a bi-specific antibody named as BPB-101 with triple functions: specifically target GARP-TGFβ complex and/or small latent complex (SLC), free TGF-β, and PD-L1. BPB-101 can stop tumor expansion and recruitment, and may enhance the immune effector cells to eliminate the tumor.

Methods: An anti-GARP mAb was discovered using a hybridoma platform and selected for binding with GARP-TGFβ complex/SLC and free TGF-β. An anti-PD-L1 nAb was screened out by VHH library and optimized in tumor-bearing mice. After humanizing, these two antibodies were successfully assembled to form a unique bi-specific antibody, BPB-101. The binding affinity of BPB-101 to GARP-TGFβ complex/SLC, free TGF-β and PD-L1 was determined by ELISA, FACS and SPR/BLI. Report gene assay was utilized to detect the blocking activity of BPB-101. The TGF-β secretion from activated Tregs was also analyzed. Finally, the anti-tumor efficacy of BPB-101 was assessed with a transgenic mouse model (B6-hLRRC32). To address the biosafety risks, the nonclinical safety profile was also evaluated in cynomolgus monkeys.

Results and Conclusion: BPB-101 is a high-affinity antibody aims to reverse immunosuppressive TME by triple-targeting functions. The blocking ability of TGF-β in not only latent form but also free form makes our BPB-101 distinct from M7824, any other existing anti-TGF-β mAbs and anti-GARP mAbs. In a MC38-hPD-L1 tumor-bearing B6-hLRRC32 model, BPB-101 showed significant tumor growth inhibition of 93 % at the dose of 5 mg/kg ($p<0.001$), showing superior efficacy to monoclonal antibody alone or in combination with anti-PD-L1 nAb. In addition, BPB-101 showed durable responsiveness and a splendid safety profile with manageable adverse events. These striking results support the clinical development potential of our trifunctional agent as a monotherapy and in combination with other immunotherapies.

#6327

Intratumoral administration of ultra high-concentration nitric oxide (UNO) is more efficacious than anti-PD1 therapy in 4T1 tumor-bearing mice

Yana Epshtein[1], Matan Goldshtein[1], Selena Chaisson[2], Jedidiah Monson[2], Matt Johnson[2], Amir Avniel[3], Steve Lisi[4], Hila Confino[1]. *[1]Beyond Cancer, Rehovot, Israel,[2]Beyond Cancer, Atlanta, GA,[3]Beyond Air, Ltd., Rehovot, Israel,[4]Beyond Air, Inc., Garden City, NY*

Background: For the majority of metastatic triple-negative breast cancer (mTNBC) patients, chemotherapy is the standard first-line treatment, however, outcomes in this population are poor. A monoclonal antibody against the immune checkpoint inhibitor anti-programmed death 1 (PD-1) also has antitumor activity in patients with mTNBC. Previously, we reported that delivering ultra-high concentrations of nitric oxide (UNO) to mouse colon tumors stimulated innate and adaptive immune responses leading to the rejection of secondarily-induced tumors. Moreover, adding an anti-PD-1 antibody to UNO treatment resulted in primary tumor regression in 53% of the mice, the rejection of a distant tumors in all mice, and prolonged survival compared to control and anti-PD-1 arms. In this *in vivo* study, we investigated the ability of UNO to improve the efficacy of anti-PD-1 antibody treatment in the aggressive mouse breast cancer model, 4T1. Methods: We tested two treatment protocols: 4T1 mice tumors were treated with either a single dose of UNO and anti-PD-1 or a repeated dose of UNO

and anti-PD-1. In the single dose design, 4T1 tumors were treated with a single administration of UNO combined with Anti-PD1 administration starting one day after UNO treatment (n=9-10 mice per group). In the repeated dosing design, 4T1 tumors were treated with UNO twice combined with Anti-PD-1 administration starting on the first UNO treatment day (n=8 mice per group). • UNO treatment regimen: 50,000 ppm, 10 minutes, flow rate ~0.2 liters per minute • Anti-PD1 treatment regimen: 10 mg/kg antibody was administered every 3 days for a total of 5 treatments.
Results (UNO Single Dose): The primary tumors of 4T1 tumor-bearing mice were 13.2% smaller in the combined single-dose UNO group compared to anti-PD-1 alone 15 days post-UNO treatment.
Results (UNO Repeated Dosing): The primary tumors of 4T1 tumor-bearing mice were 25.2% smaller in the combined repeated dose UNO group compared to the anti-PD-1 alone group 16 days after the first UNO treatment.
Conclusion: Treating 4T1 tumors with single and repeated doses of UNO improved outcomes compared to anti-PD-1 alone. This suggests that local short-term treatment with UNO can serve as a treatment option for cancer patients with tumors that are not amenable to immune checkpoint inhibitor treatment.

#6328

An off-the-shelf Twin BiTE combination therapy controls heterogenous glioblastoma and shapes immune response

Filippo Rossignoli, Paulo Borges, Rebecca Lumia, Khalid Shah. *Harvard Medical School/Brigham and Women's Hospital, Boston, MA*

Glioblastoma (GBM) is the most common primary brain tumor in adults, characterized by a median survival of 12-14 months with less than 10% of patients surviving at least 2 years from diagnosis. The discovery of tumor-associated antigens (TAAs) has permitted development of a new array of therapeutic strategies that selectively target GBM and spare normal cells of the CNS. In this study we used an alternative off-the-shelf approach to activate the immune system and direct it against the tumor, taking into account antigen heterogeneity and TME immune suppression without the need of engineering the patient’s immune cells. We generated TAA-targeting Bispecific T-cell Engagers (BiTEs) and engineered adult stem

cells to secrete twin BiTEs (T-BiTE-SC). The approach was tested in combination with in naïve T cells on established and primary patient-derived cell lines expressing various levels of the target antigens. Moreover, to further support the therapeutic action of T cells, and combat immune-suppressive microenvironment and exhaustion, we combined our T-BiTE SC with an immune-stimulating cytokine. We show the efficacy of the individual BiTEs against different primary and established tumor cell lines. Moreover, the T-BiTE-SC, significantly controlled the growth of a tumor expressing heterogeneous levels of the targeted antigens. The immune stimulation reduced T cell exhaustion and consolidated a Th1 phenotype. Altogether our study demonstrated the feasibility and efficacy of an off-the-shelf immunotherapy, based on BiTEs simultaneously targeting tumor heterogeneity without the need for direct engineering of the immune cells.

Preclinical study of CD19 detection methods using monoclonal antibodies post tafasitamab treatment

Kristina M. Ilieva[1], Markus Eberl[1], Jan Jaehrling[1], Carmen Ginzel[1], Britta Voland[1], Michaela Zankl[1], Andrea Polzer[1], Derek Blair[1], Rainer Boxhammer[1], Liang-Chuan Wang[2], Diana Alvarez Arias[2], Christina Heitmüller[1]. *[1]MorphoSys AG, Munich, Germany,[2]Incyte Corporation, Wilmington, DE*

Introduction Tafasitamab (TAFA), an Fc-enhanced antibody immunotherapy against CD19 received accelerated/conditional approval in relapsed or refractory diffuse large B cell lymphoma (R/R DLBCL) in combination with lenalidomide. Several other CD19 targeting therapies including CAR Ts are now available for R/R DLBCL treatment warranting evaluation of potential therapeutic sequencing strategies. In this context, CD19 expression status may be assessed on patient samples post TAFA treatment. However, methods for detecting CD19 using monoclonal antibodies (mAbs) following TAFA treatment are not standardized which may lead to data misinterpretations including confusion of CD19 epitope masking with CD19 loss or downregulation.
Aim This study evaluated various CD19 detection methods following TAFA treatment using comprehensive panels of available flow cytometry

(FC) and immunohistochemistry (IHC) anti-CD19 mAbs, routinely used in laboratory practice.
Methods FC and IHC competition assays were used on TAFA pre-treated CD19+ cell lines to differentiate non-competing from competing mAbs, the latter resulting in epitope masking by TAFA. Bound TAFA was removed from CD19+ cells using an acidic dissociation protocol. Antibody affinities for CD19 were determined using Surface Plasmon Resonance (SPR) or Bio-Layer Interferometry (BLI).
Results All but one of the 8 mAbs tested in FC competed with TAFA and their affinities for CD19 were shown to be lower than that of TAFA. The non-competing clone OTI3B10, reported to recognize a linear epitope of CD19 (1), bound to only one of three tested CD19+ cell lines, which rendered it unsuitable for reliable FC detection of CD19. In contrast, several clones could detect CD19 on TAFA pre-treated samples using IHC. To circumvent TAFA masking in FC, we successfully unmasked CD19 via acidic dissociation and similar CD19 levels on TAFA pre-treated as on untreated cells could be subsequently detected by a competing CD19 antibody (HIB19).
Conclusion Our study provides an overview of commonly used mAb tools for CD19 detection post TAFA treatment, some of which may be used in routine clinical practice. Our findings reveal that CD19 expression post TAFA could be detected by IHC but lack of TAFA non-competing anti-CD19 antibodies for FC poses a risk of mistaking CD19 masking by TAFA with CD19 loss or downregulation. Prior acidic dissociation is critical in the staining protocol to avoid data misinterpretations.

Countering antidrug antibodies to programmed cell death-1 blockade in mouse *Pten*-null prostate cancer

Marco A. De Velasco[1], Yurie Kura[1], Noriko Sako[1], Naomi Ando[1], Kazutoshi Fujita[1], Mitsuhisa Nishimoto[1], Kazuko Sakai[1], Kazuhiro Yoshimura[1], Masahiro Nozawa[1], Scott A. Hammond[2], Simon J. Dovedi[3], Barry R. Davies[3], Kazuto Nishio[1], Hirotsugu Uemura[1]. *[1]Kindai University School of Medicine, Osaka-Sayama, Japan,[2]AstraZeneca, Gaithersburg, MD,[3]AstraZeneca, Cambridge, United Kingdom*

Therapeutic biologics have the potential to elicit immune responses that results in the development anti-drug antibodies (ADAs). ADAs that develop after immune checkpoint blockade (ICB) limit their therapeutic efficacy and increase the risk of adverse events. Mitigating ADAs would improve the efficacy of antibody-based therapeutics and identifying reliable biomarkers would allow for rational, evidence-based criteria for tailoring treatments. However, detecting ADAs is challenging and data regarding their biology and means to counter this phenomenon are limited. Here, we examined the development of ADAs to anti-programmed cell death-1 (PD-L1) monoclonal antibodies in a mouse model *Pten/Trp53*-null (DKO) prostate cancer and countered their negative effect with systemic administration of a JAK1/2 inhibitor. Like human prostate cancer, adding PD-L1 ICB to androgen deprivation therapy has failed to produce a therapeutic effect in DKO cancer model. Our analysis showed that tumor-bearing DKO mice have increased levels of peripheral dendritic cells (pDC) of which >80% exhibited high levels of PD-L1. Given this finding, we developed a system to monitor the development of ADAs against two murine anti-PD-L1 (aPD-L1) monoclonal antibodies clone 80 and 10F9.G2. Pharmacodynamic studies showed that a single-dose administration of the blocking antibodies effectively neutralized PD-L1 in pDC that lasted for four days. Chronic (twice/week) dosing of the aPD-L1 antibodies strongly neutralized PD-L1 in pDCs, but the efficacy waned after 22 days. Using crossover approach, consisting of clone 10F9.G2 dosing for two weeks followed by clone 80, extended PD-L1 blockade in pDCs to 36 days, but did not improve antitumor activity. Blocking STAT3 signaling with the JAK1/2 inhibitor AZD1480 restored PD-L1 blockade in pDCs and was associated with improved reduction of tumor burden. Further analysis showed improved neutralization of PD-L1 in cancer cells and tumor infiltrating immune cells in mice treated with AZD1480. These effects were associated with greater T and NK cell reactivity in tumors. Our study shows that the presence of ADAs is associated with lack of antitumor responses to ant-PD-L1 blockade in a preclinical model of prostate cancer and provides additional data that will improve our understanding of ADAs against immune checkpoint inhibitors. This study also offers an approach to monitor ADA development and a platform to investigate novel approaches to target ADAs.

#6331

The anti-tumor activity of HSP-90 therapeutic cancer vaccine (AST-021p) combine with TLR2/3 agonist in a MMTV-neu transgenic model

JinHo Kang[1], Jee Hyun Choi[1], Min Ji Seo[2], Eunjung Jung[3], Byung cheol Ahn[3], Jinback Lim[1], Hyo-Hyun Park[1], Hyunwon Shin[2], Eunkyo Joung[2], Hun Jung[2], Kyong Hwa Park[4]. *[1]Aston Research Institute, Hanam, Korea, Republic of,[2]Aston Sci. Inc., Seoul, Korea, Republic of,[3]R&D Center, CHA Vaccine Institute, Seoul, Korea, Republic of,[4]Department of Internal Medicine, Korea University College of Medicine, Korea, Korea, Republic of*

Background: AST-021p, which is derived from HLA class II binding epitopes of human HSP90 protein, is an investigational therapeutic cancer vaccine for the malignant neoplasms. AST-021p is designed to demonstrate the immunologic efficacy by activating antigen-specific CD4+ Th1 cell in humans. Due to their ability to link the innate with the adaptive immune response, Toll-like receptor (TLR) agonists are highly promising as adjuvants in vaccines against life-threatening and complex diseases such as cancer, AIDS and malaria. In this study, AST-021p was investigated to evaluate the immunogenicity and tumor growth inhibitory effect under the condition of combining with various immune adjuvants derived from TLR agonists, using in-vivo model.

Methods: Three different agonists of TLR (TLR-4, TLR-2/3, TLR-7/8) were assigned to investigate the immunogenicity in each group (4 FVB/N mice/group, total 4 groups). AST-021p was intradermally injected 3 times with different TLR-agonists and the immunogenicity was assessed from mouse splenocyte by HSP90-specific IFN-γ ELISpot method. We also examined the efficacy of AST-021p and selected TLR-agonist in MMTV/neu Tg mice (4 mice/group, conducted twice and A total 8 mice was assigned to each group). The combination of AST-021p and TLR-2/3 agonist (AST-021p plus TLR-2/3 agonist) was injected 3 times every 10 days to mice followed by inoculated mouse mammary cancer cell line. The tumor volume change and immunogenicity were evaluated.

Results: The most effective TLR-agonist as a potent immune adjuvant was a TLR-2/3 agonist (L-pampoTM, supplied by CHA Vaccine Institute). AST-021p (100 μg) plus TLR-2/3 agonist significantly improved immunogenicity by increasing HSP-90 epitope-specific T cells up to 130±10 per $1x10^5$ spleen cell of FVB/N mice (P<0.001). AST-021p plus

TLR-2/3 agonist also showed higher tumor growth inhibitory effect (170±108 mm^3) on post-implantation 35^{th} day by suppressing mouse mammary cancer cell line ($5x10^5$)-derived tumor growth, compared with a TLR-2/3 agonist alone (1031±450 mm^3).
Conclusions: Combination regimen of AST-021p and TLR-2/3 agonist (as immune adjuvant) demonstrated significant immunogenicity and tumor prevention effect in in-vivo study. These data supported the clinical study of AST-021p combined with TLR-2/3 agonist as active immune adjuvant in certain tumor types, and phase 1/2 clinical program would be expected to be initiated.

#6332

A humanized anti-cd40 antibody with anti-tumor pharmacological activity and cynomolgus monkey safety

Zhenyu Li, Lili Zhao, Guimin Zhang, Bin Li, Zhong Liu, Guangyan Li, Zhongsong Zhu. *National Engineering Laboratory of High Level Expression In Mammalian Cells, Lunan Pharmaceutical Group Co. Ltd., Linyi, China*

LNF1901 is a humanized CD40 agonistic antibody. LNF1901 can bind to CD40 protein of human(EC50=23.6ng/mL) and monkey(EC50=23.5ng/mL), but cannot bind to CD40 protein of rat and mouse. LNF1901 had strong activation effect on DC cells(EC50=0.04ug/mL) and had strong ADCC and CDC effects. AT a dose of 20mg/kg, the TGI_{TW} of LNF1901 was 59.9% in Female NPG mice were inoculated with Raji/CIK/DC subcutaneous transplanted tumor model. Following intravenous infusion of LNF1901 at doses of 6, 30, or 150 mg/kg to cynomolgus monkeys weekly for 4 weeks, the highest non-severely toxic dose (HNSTD) was considered to be 150 mg/kg.LNF1901 had demonstrated manageable safety and promising antitumor activity in vivo and in vitro tests.

Repurposing NSAIDs for chemo-immunotherapy: mechanisms beyond COX inhibition

Ogacheko D. Okoko[1], Md Y. Gazi[2], Xin Wang[2], Caitlin Brandle[2], Mercy Kehinde-Ige[2], Gary A. Piazza[3], Huidong Shi[2], Gang Zhou[2]. *[1]Molecular Medicine, Augusta University, Augusta, GA,[2]Georgia Cancer Center, Augusta University, Augusta, GA,[3]Department of Drug Discovery and Development, Auburn University, Auburn, AL*

It has been well-established that some nonsteroidal anti-inflammatory drugs (NSAIDs) have antitumor activities. The beneficial effects of these NSAIDs are mainly attributed to their ability to inhibit the production and activity of cyclooxygenases (COX1 and COX2) and prostaglandin (PGE2), which are known to promote tumor progression, angiogenesis, metastasis and immunosuppression. We recently reported that administration of indomethacin, a prototypical NSAID, can enhance the antitumor efficacy of adoptive T cell therapy in animal models. However, currently adoptive T cell therapy as a treatment option is only suitable for selected patients with certain types of cancer. Here, we set out to explore the utility of indomethacin in a chemo-immunotherapy setting that is readily applicable to a wide range of cancers. Cyclophosphamide (CTX) is a widely used antineoplastic chemotherapeutic agent with immunostimulatory activities when used at low-medium doses. We show that indomethacin had no impact on tumor growth but can significantly enhance the antitumor effect of CTX in multiple mouse tumor models. The beneficial effect of indomethacin was diminished in immunodeficient mice or CD8 T cell-depleted wild-type mice, indicating the requirement for the host immunity. Furthermore, the CTX and indomethacin regimen can sensitize tumors to anti-PD1 immunotherapy. scRNAseq analysis of tumor samples revealed the impact of indomethacin on the tumor microenvironment. Our data also indicate that the immunopotentiating effect of indomethacin can be independent of PGE2 inhibition, and involves the TRAIL-DR5 axis in promoting tumor regression. Other potential mechanisms, including modulation of chronic interferon signaling in tumor cells, have also been investigated. Altogether, our study sheds light on the multiple mechanisms underlying indomethacin's beneficial effects, and highlights the potential of NSAID administration as a readily applicable and cost-effective approach to augment the efficacy of chemo-immunotherapy.

#6334

VBI-002, a CD47xICAM-1 bispecific antibody for the treatment of hepatocellular carcinoma, melanoma and non-small cell lung cancers

Oi Kwan Wong, Xinhua Wang, Leonard Post, Xiaocheng Chen. *Virtuoso Therapeutics, Inc., San Mateo, CA*

Intercellular Cell Adhesion Molecule 1 (ICAM-1, CD54) is a type I transmembrane protein and a member of the immunoglobulin superfamily. ICAM-1 is involved in many key processes such as cell-cell interactions, signal transduction and leukocytes trans-endothelial migration. ICAM-1 is constitutively present at low levels on healthy tissues but highly expressed in some hematological cancers and solid tumors, making it an attractive tumor target.

VBI-002 is a novel human IgG1 based CD47xICAM-1 bispecific antibody with excellent safety profile and potent single agent activities in xenograft models of lymphoma, multiple myeloma and some solid tumors (Cancer Res 2022;82(12_Suppl):Abstract nr 3430). The bispecific design allows VBI-002 to selectively block CD47/SIRPα binding in tumor cells with high ICAM-1 expression. In contrast to the benchmark CD47 monoclonal antibody, VBI-002 exhibits minimal red blood cell binding and does not cause hemagglutination. In non-human primate (NHP) safety study, four weekly doses of 60 mg/kg VBI-002 were well-tolerated with only mild and reversible reduction in hemoglobin and platelets.

Here we further investigate the anti-tumor activities of VBI-002 in solid tumors. Gene expression analysis suggested that ICAM-1 is highly expressed in non-small cell lung cancers (NSCLC), melanoma and a subset of hepatocellular carcinoma. Flow cytometry studies confirmed the frequent co-expression of ICAM-1 and CD47 in these tumors. VBI-002 has potent ICAM-1 dependent SIRPα blocking, antibody-dependent cellular phagocytosis and antibody-dependent cellular cytotoxicity activities against cell lines of NSCLC, hepatocellular carcinoma, and melanoma. Furthermore, *in vivo* efficacy studies demonstrated that VBI-002 has potent single agent activities in cell line derived xenograft (CDX) models of NSCLC, hepatocellular carcinoma, and melanoma. Weekly dose of 20 mg/kg VBI-002 is sufficient to stop tumor growth or drive tumor regression in most models. Notably, VBI-002 is highly effective against NSCLC CDX models carrying Kras mutation and it synergizes with paclitaxel to provide additional anti-tumor activity. In conclusion, VBI-002 is a versatile novel

CD47xICAM-1 bispecific antibody with potent single agent activity in various solid tumors and combined well with standard of care chemotherapies for added activity. Thus, VBI-002 warrants clinical evaluations as a single agent and in combination with standard of care chemotherapies.

#6335

Developing anti-IL-22 therapeutics for inflammation and cancer

Christina Wheeler[1], Jian Chen[1], Cathy Chang[1], Gerhard Frey[1], Haizhen Liu[1], Jing Wang[1], Kathryn Woodard[1], Solmarie Joyner[1], Wei Zhou[1], William J. Boyle[2], Jay M. Short[2]. *[1]R&D, BioAtla, Inc., San Diego, CA,[2]BioAtla, Inc., San Diego, CA*

Chronic inflammation facilitates the development of cancer, age-related, inflammatory autoimmune and other diseases. Proinflammatory cytokines play a central role in this pathogenic process by driving activation of NF-ƙB, STAT3 and other signaling cascades. IL-22 is an inflammatory cytokine involved in the pathology of autoimmune diseases such as psoriasis, atopic dermatitis, and ulcerative colitis. IL-22 has also been shown to promote epithelial cell proliferation, stemness and tumorigenesis in cancer. Recent studies demonstrated that neutralization of IL-22 reduced dysplasia and tumor development in preclinical models. To date, there has not been a clear application for anti-IL-22 therapy for autoimmune diseases and cancer, likely due to identifying the right disease indication and to their low potency and low efficacy. Thus, there remains an opportunity to explore the potential of more potent anti-IL-22 therapeutics. Using BioAtla's proprietary antibody discovery and engineering platforms, we have generated humanized anti-IL-22 antibodies with high affinities to human, cynomolgus and mouse IL-22. *In vitro* data demonstrated that our anti-IL-22 antibodies inhibited IL-22-induced p-STAT3, CXCL-1 and IL-10 activities. In addition, our antibodies showed a 10-fold increased binding activity to human IL-22 compared to Fezakinumab, which was previously developed by Pfizer for the treatment of autoimmune diseases. BioAtla's high affinity anti-IL-22 antibodies were shown to be more potent relative to Fezakinumab using multiple *in vitro* assays. To test the functions of our antibodies *in vivo*, we also established mouse models to determine anti-IL22 efficacy. More specifically, to study whether targeting IL-22 in an

inflammation-induced tumor microenvironment reduces tumor occurrence, we developed an inflammation-driven sporadic colitis-associated colorectal cancer mouse model for ongoing cancer studies that will be discussed. In addition, we evaluated our anti-IL22 antibodies in an imiquimod-induced psoriasiform skin inflammation mouse model. The mice treated with potent anti-IL-22 antibodies had significantly reduced skin lesions, including erythema, scales, and skin thickness compared to isotype antibody-treated mice. Q-PCR analysis of the mouse skin demonstrated that treatment with our anti-IL-22 antibody led to significantly decreased RNA levels of the imiquimod-induced inflammatory marker CXCL3. Thus, the enhanced anti-IL-22 therapy is a promising strategy for targeting anti-inflammation in autoimmune diseases, such as psoriasis and atopic dermatitis, and inflammatory cancers, including colorectal cancer. In conclusion, the development of a potent, species cross reactive anti-IL-22 antibody using BioAtla's antibody discovery and engineering platforms addresses the challenges of anti-IL-22 therapeutics and allows for translational studies in relevant animal efficacy and safety models.

Heterodimeric Fc-fused IL12 shows potent antitumor activity and low toxicity

Yang Huang[1], Wenting Liu[2], Dayan Zhang[2], Pengfei Zhou[2], Weiming Zhou[2], Xiaoli Zeng[2], Qun Zhao[2], Liangwei Li[3], Guodong Shen[4], Liansheng Cheng[2]. *[1]Georgetown Lombardi Comprehensive Cancer Ctr., Atlanta, GA,[2]Hefei Hankemab Biotechnology Co., LTD, Hefei, China,[3]Georgia State University, Atlanta, GA,[4]The First Affiliated Hospital of University of Science and Technology of China, Hefei, China*

Background: Interleukin-12 (IL12) is a heterodimeric pro-inflammatory cytokine (70 kDa) composed of two different polypeptide chains: an α-chain (p35 subunit) and a β-chain (p40 subunit). IL12 could induce the proliferation and cytotoxicity of T and NK cell and production of interferon-γ (IFN-γ), promote the differentiation of T helper 1 (TH1) cells and regulate innate resistance and adaptive immunity. However, the clinical efficacy of IL12 has been hindered for its high dose-related toxicities and short serum half-life. Here we have developed a heterodimeric Fc-fused

IL12, HK054-V, with reduced potency to improve tolerability and prolong half-life.
Methods: We assessed the binding, bioactivity, anti-tumor efficacy and safety of HK054-V. The binding ability of IL12-Fc lead variants to activated PBMCs was analyzed by flow cytometry. The bioactivity of HK054-V was determined by assessing the activated T-cell proliferation and IFN-γ production in human PBMCs, and STAT-4 phosphorylation in a reporter gene assay. A murine surrogate, mHK054-V, was engineered to mimic HK054-V to evaluate the antitumor efficacy in MC38 and CT26 syngeneic tumor mouse models. Cytokine release assay was conducted by incubating HK054-V with peripheral blood mononuclear cells (PBMCs) from healthy donors. The safety profiles and pharmacokinetic (PK) behavior of HK054-V were characterized in non-tumor-bearing Balb/c mice.
Results: HK054-V is a heterodimeric Fc-fused IL12, which was designed with reduced potency. HK054-V was observed to stimulate the proliferation of activated T cells and NK cells and induce production of IFN-γ in a dose-dependent manner. HK054-V could activate pSTAT4 signal in luciferase reporter gene assay and showed up to 100-fold reduction of potency compared to wild-type IL12-Fc. Human IL12 is inactive in mice, so in vivo anti-tumor activity was assessed by a murine surrogate, mHK054-V. mHK054-V demonstrated anti-tumor efficacy in syngeneic mouse models and was better tolerated than WT mIL12-Fc. Furthermore, mHK054-V has improved PK and therapeutic index in mice.
Conclusion: These data demonstrate that HK054-V, a heterodimeric Fc-fused IL12 with reduced potency, retain strong anti-tumor efficacy with a favorable tolerability profile, which may provide a practical alternative to the systemic administration of IL12 for antitumor therapy.

#6337

Tri-specific CD3 x HER2 x HER2 antibodies in 1:2 format recognizing two different epitopes on HER2 demonstrate selective activity on human cancer cells with high HER2 expression

Jie Zhang, Xiaoqing Wang, Zhenhao Zhou. *Chimagen Biosciences, Shanghai, China*

Human epidermal growth factor receptor 2 (HER2) is a membrane tyrosine kinase that was found to be amplified and overexpressed in various human cancers including breast cancer. Monoclonal antibodies targeting HER2 such as trastuzumab and pertuzumab provide good therapeutic benefits in patients with high HER2 expression tumors, however, not all patients respond to the treatment, and many suffer recurrence. There is still a large unmet need for targeted therapies to treat HER2 high expression tumors. T cell engaging antibodies that direct T cells to kill cancer cells by simultaneously binding to CD3 on T cells and tumor-associated antigens (TAA) on cancer cells have emerged as a promising new approach. Such therapeutics are potent, but safe use of them depends on selectivity of the TAA engaged. Though HER2 is highly overexpressed in ~ 20% of breast cancer, expression of HER2 is not restricted to cancer cells and present at low level in normal tissues. The capability of selectively targeting cancer cells over HER2 low expressing normal tissues is critical to the safety of CD3 x HER2 antibodies. It is noteworthy to mention that unlike antibody-drug conjugate (ADC) therapeutics, CD3 x HER2 antibodies might not be a good approach to target HER2 low/neg expression tumors due to the difference in mechanism of action.

CMG6A19 is a 150 kD IgG-like tri-specific CD3 x HER2 x HER2 T cell-engaging antibody generated on Chimagen's TRIAD platform. It is capable of simultaneously recognizing and binding to two different epitopes on HER2 proteins. Multiple human cell lines with different levels of HER2 expression were used as targets in the antibody-mediated hPBMC killing assays in vitro and in vivo, among which SK-BR-3, KPL-4 and BT474 have high HER2 expression as seen in HER2 positive cancers, HT55 and JIMT1 have medium level of HER2 expression, and PC3 and MCF7 have HER2 expression level that is close to in normal tissues. Conventional 1:1 IgG-like CD3 x HER2 bispecific antibodies were used as control. Results showed that CMG6A19 demonstrated higher tumor inhibition effect compared to control antibodies in SK-BR-3/KPL-4/BT474 models, meanwhile remarkably weaker effect in PC3/MCF7 models suggesting better safety in HER2 low expressing tissues. This selectivity of reactivity towards HER2 high expressing cells is likely due to the unique orientation of the antibody which allows better T cell activation when antigen abundance is high. Preliminary preclinical study in cynomolgus monkeys

suggested that the antibody was well tolerated in monkeys at the dosage of 20 mpk and had a half-life that is comparable to conventional antibodies. CD3 x HER2 x HER2 tri-specific antibodies selectively showed potent anti-tumor activity on HER2 high expressing cells and good safety on HER2 low expressing cells. Current findings warrant further development in human.

#6338

Development of a novel MSLN×4-1BB bispecific antibody

Liangwei Li[1], Dayan Zhang[2], Guodong Shen[3], Wenting Liu[2], Xiaoli Zeng[2], Lingling Wu[2], Qun Zhao[2], Weiming Zhou[2], Yang Huang[1], Liansheng Cheng[2]. *[1]Georgia State University, Atlanta, GA,[2]Hefei Hankemab Biotechnology Co., LTD, Hefei, China,[3]The First Affiliated Hospital of University of Science and Technology of China, Hefei, China*

Background: 4-1BB (CD137) is not only expressed on the surface of activated T cells and NK cells, but also a marker for Treg cells. Mesothelin (MSLN) is a ~71 kDa cell surface glycoprotein that is rarely expressed in normal tissues but overexpressed in many types of tumors. The fastest progress of MSLN-targeted therapy is in clinical phase II currently, including antibodies, ADCs, immunotoxins, vaccines and CAR-T. Here, we developed a bispecific antibody (bsAb) targeting both MSLN and 4-1BB with an intact Fc fragment from human IgG1. It can simultaneously exert the cytotoxic effect of CD8+T cells and and NK cells on tumor cells expressing MSLN to achieve better antitumor efficacy.
Methods: Firstly, two bsAbs with IgG-scFv format were constructed with IgG1 and IgG4, named as HK013-G1 and HK013-G4 respectively. Secondly, we evaluated the binding activities of two candidates to tumor cells with different MSLN expression levels and their effects on 4-1BB+ cell activation mediated by MSLN-crosslinking. Subsequently, the cell-killing abilities of NK and cytotoxic T cells induced by bsAbs were quantified. Finally, we compared the ability of bsAbs to inhibit tumor growth in vivo and their effects on intratumoral CD8+T cells and Tregs. The capacity of bsAb candidates to induce liver toxicity was investigated simultaneously in these immunocompetent mice. Moreover, to further confirm the safety of HK013-G1, the risk of cytokine release storm (CRS) and activation of 4-1BB signal mediated by Fc receptors (FcRs), which are

responsible for the potential side effects of 4-1BB mAbs were also evaluated.
Results: HK013-G1 is able to bind different MSLN-expressing cancer cells and bridge MSLN+ cells and 4-1BB+ cells. In luciferase reporter assay, the bsAb-induced 4-1BB activation is dependent on expression level of MSLN. While incubated with CD8+T cells, HK013-G1 increased IFN-γ production only in the presence of MSLN+ cells. Furthermore, HK013-G1 could exert its affects via both NK cell and activated PBMC. In MC38-hMSLN tumor models, HK013-G1 showed a more significant growth inhibition effect than HK013-G4, and did not show detectable liver damage. In addition, HK013-G1 could enhance the antitumor effect of anti-PD-1 in CT26-hMSLN tumor models. Also, HK013-G1 was shown no stronger ability to inducing CRS and activating 4-1BB signal in the presence of FcRs than HK013-G4 and parent anti-4-1BB mAb in vitro.
Conclusions: HK013-G1, a MSLN×4-1BB bsAb with human IgG1 Fc fragment prevents tumor development by killing tumor cells directly via effector functions mediated by NK and cytotoxic T cells. These results show that this bsAb has the potential to develop into a new clinical therapy for cancer types with high-level MSLN expression.

#6339

BCA101, a novel tumor-targeted bifunctional fusion antibody simultaneously inhibiting EGFR and TGF-β signaling with potential for durable tumor growth inhibition

Srinivas Reddy Boreddy[1], Reshmi Nair[1], Prashant Kumar Pandey[2], Anshu Kuriakose[2], Arindam Banerjee[1], Chaitali Dey[2], Madhukara A R[1], Bhadravathi Marigowda Shivakumar[1], Hanumant Kulkarni[2], Milind Sagar[2], Prashantha Kumar M. V[2], Shiv Ram Krishn[2], Jaya Bhatnagar[1], Moni Abhram Kuriakose[3], Ram Bhupal Reddy[3], Amritha Suresh[3], Praveen Reddy Moole[4], Usha Bughani[1], Seng-Lai Tan[1], Pradip Nair[1], Rachel Salazar[1]. *[1]Bicara Therapeutics Inc., Boston, MA,[2]Discovery Biology, Syngene International Ltd, Bengaluru, India,[3]Integrated Head and Neck Oncology Program, MSCTR, Mazumdar Shaw Medical Foundation, Bengaluru, India,[4]Biocon Biologics Limited, Bengaluru, India*

Introduction: The suboptimal clinical efficacy EGFR-targeting therapeutics is attributed to both tumor intrinsic and tumor microenvironment (TME) derived acquired (extrinsic) resistance mechanisms. Intrinsic factors include activation of other receptor tyrosine kinases and key extrinsic resistance mechanism include the enhanced secretion of immunosuppressive factors such as IL-10 and TGF-β1. Here, we describe a first-in-class bifunctional monoclonal antibody fusion designed to simultaneously target EGFR and sequester TGF-β in the TME.
Experimental Procedures: Functional activity of BCA101 was evaluated in multiple in vitro assays such as ELISA, inhibition of proliferation, antibody-dependent cellular toxicity, SMAD-reporter assay. Neutralization of TGF-β by BCA101 was demonstrated by epithelial-to-mesenchymal transition and tumor cell/immune cell co-culture assays. BCA101 tumor targeting was evaluated in a whole animal imaging study and efficacy studies were performed in nude xenograft models while combination studies with immune checkpoint inhibitors were performed in B16-EGFR syngeneic models.
Results: BCA101 is an anti-EGFR IgG1 monoclonal antibody linked to an extracellular domain of human TGF-βRII. The TGF-β "trap" fused to light chain in BCA101 did not sterically interfere with its ability to bind EGFR, inhibit cell proliferation, or mediate antibody-dependent cellular cytotoxicity *in vitro.* BCA101 increased production of proinflammatory cytokines and key markers associated with T and NK cell activation, while suppressing VEGF secretion. Additionally, BCA101 inhibited differentiation of naïve $CD4^+$ T cells to inducible T-regulatory (iTreg) cells when compared to cetuximab. *In vivo*, biodistribution studies showed that BCA101 localized to tumor tissues in xenograft mouse models, with comparable kinetics as cetuximab. TGF-β in tumors was neutralized to about 90% in animals dosed with 10 mg/kg of BCA101 compared to 54% in animals dosed with equimolar TGF-βRII-Fc. BCA101 had longer tumor tissue retention compared to cetuximab, further confirming improved tumor localization. In patient-derived xenograft mouse models of head and neck squamous cell carcinoma, BCA101 showed durable response post dose cessation as compared to cetuximab. In FaDu xenografts, BCA101 displayed early and durable response to cetuximab/cetuximab plus TGF-βRII-Fc combination. The combination of BCA101 and anti-PD1 antibody improved tumor inhibition in both B16-hEGFR expressing syngeneic

mouse and in humanized HuNOG-EXL mice bearing human PC-3 xenograft models.
Conclusion: These results support clinical development of BCA101, either as a monotherapy or in combination with immune checkpoint therapy.

Preclinical development of a monoclonal antibody targeting CD24 as cancer immunotherapy
Wenzhi Tian, Song Li, Dianze Chen, Dandan Liu, Huiqin Guo, Chunmei Yang, Li Zhang, Wei Zhang, Xiaoping Tu, Liang Peng, Gui Zhao, Ruliang Zhang, Fan Zhang, Frank X. Gan. *ImmuneOnco Biopharmaceuticals (Shanghai) Inc., Shanghai, China*

CD24 is a novel immune checkpoint that suppresses activation of macrophages, natural killer (NK) cells, T cells and B cells by binding to inhibitory receptor Siglec-10. CD24 is highly expressed on cancers of genitourinary (GU) and gastrointestinal (GI) systems, breast, and lung. High expression of CD24 is also known to be associated with poor prognosis for many types of cancers including breast, lung, GU and GI systems, bone, skin and brain. Mouse models of breast and lung cancer in literature revealed that CD24 attenuation in vivo leads to tumor inhibition and prolonged survival. To address the limited (~25%) overall response rate (ORR) of approved PD-1 / PD-L1 antibodies for solid tumors, we developed IMM47, an IgG1 antibody that differentially targets phagocytosis and cytotoxicity onto CD24-expressing cancer cells. At doses between 3 mg/kg to 10mg/kg, IMM47 significantly reduced tumor volume in a MC38 mouse model of colon cancer. Mice treated with 10mg/kg IMM47 produced tumor-specific immune response that prevented growth of re-inoculation of colon cancer cells. Further mechanism of action studies showed that IMM47 selectively and differentially increased M1 spleen macrophages quantity to 7-10 folds higher in that induced by PBS control. In contrast, IMM47 only increased M2 spleen macrophages to less than 1.5 folds higher than induced by PBS control. Expression of MHC II in M1 macrophages was also increased in IMM47-treated mice, suggesting significant activation and antigen presentation by macrophages. Our data has also confirmed that IMM47 specifically binds to and induces ADCC (antibody-dependent cellular cytotoxicity) ,ADCP (antibody-dependent

cellular phagocytosis), and CDC (complement-dependent cytotoxicity) against a variety of cancer cells. Taken together, our data show that targeting CD24 on tumor cells using our IMM47 antibody may serve as potent immunotherapy for multiple cancer indications.

#6341

Preclinical development of a monoclonal antibody targeting CD70 as cancer immunotherapy

Wenzhi Tian, Song Li, Dianze Chen, Dandan Liu, Huiqin Guo, Chunmei Yang, Li Zhang, Wei Zhang, Xiaoping Tu, Liang Peng, Gui Zhao, Ruliang Zhang, Fan Zhang, Frank X. Gan. *ImmuneOnco Biopharmaceuticals (Shanghai) Inc., Shanghai, China*

CD70 is a novel immune checkpoint highly expressed on cancers of kidney, blood and lymphoid tissues, mesothelium and gastrointestinal system. High expression of CD70 is a prognostic marker for poor survival in patients with ovarian carcinoma, pancreatic cancer and mesothelioma, etc. Several CD70 antibodies are under early stages of clinical trials for oncology indications. We have developed IMM40H, a humanized IgG1 antibody that differentially induces phagocytosis and cytotoxicity in CD70-expressing cancer cells. Results of in vitro study have demonstrated that, in comparison with cusatuzumab, IMM40H possesses better CD70 binding (kD= 3.22E-11M) and functional inhibition ability, as well as more potent activities of ADCC (antibody-dependent cellular cytotoxicity, EC50 = 0.5 -2.0ng/ml) and CDC (complement-dependent cytotoxicity, EC50 = 170 ng/mL) against certain cancer cells. IMM40H also induces strong ADCP (antibody-dependent cellular phagocytosis) activity (EC50 = 0.02nM). At doses between 0.3 mg/kg to 10mg/kg, IMM40H significantly reduced tumor volume in mouse models of multiple myeloma, lymphoma and kidney cancer. Notably, in a U266 multiple myeloma model, IMM40H, at the dose of 0.3 mg/kg, completely inhibited tumor growth in a way that therapeutic effects appeared significantly earlier than that of cusatuzumab at a higher dose of 1 mg/kg. Therapeutic effects of IMM40H at the dose of 3 mg/kg also appeared earlier than that of bortezomib at the dose of 0.5 mg/kg. Interestingly, combination of IMM40H and IMM01 (a SIRPα-IgG1 Fc fusion protein targeting CD47) generated significant therapeutic synergy in models of A498 kidney cancer and Raji lymphoma. Importantly, maximum

tolerated dose of IMM40H exceeds 100 mg/kg (IV, single dose) in cynomolgus monkeys and no significant adverse reaction was observed at a dose range of 3 to 30 mg/kg (IV, QW, 5 times) in monkeys. Taken together, our data show that targeting CD70 on tumor cells using IMM40H antibody may serve as a potent immunotherapy for multiple cancer indications. IND of IMM40H has been approved in China and US. This antibody is now in a phase 1 study in patients with advanced malignancies expressing CD70.

#6342

Preclinical safety & pharmacokinetics of AFVT-2101, a tetravalent FRα x CD16A bispecific innate cell engager for the treatment of solid tumors

Wendy Luo[1], Eric J. Gaukel[1], Janice A. Lansita[2], Stephen M. Laczko[1], Peter Sandy[3], Daniel J. O'Shannessy[4], Sudhir Penugonda[1], Bhavik Manocha[1], Daniel E. Patterson[1], Izabela Kozłowska[5], Séverine Sarlang[5], Stefan Knackmuss[5], Daniela Penston[5], Uwe Reusch[5], Zoë Johnson[3].
[1]Roivant Sciences, Inc., New York, NY,[2]ToxAlliance, Kennett Square, PA,[3]Affivant Sciences GmbH, Basel, Switzerland,[4]TMDx Consulting LLC, Schwenksville, PA,[5]Affimed GmbH, Heidelberg, Germany

AFVT-2101 is a novel bispecific innate immune cell engager in development to treat solid tumors. It is comprised of bivalent folate receptor alpha (FRα) and CD16A (FcγRIIIA) binding domains with a silenced IgG1 Fc region. AFVT-2101 is engineered to exert potent and selective immune-mediated antitumor activity with minimal off-tumor toxicity by promoting NK cell and macrophage engagement of FRα-positive tumors.
A comprehensive package of IND-enabling studies is currently in progress to support the preclinical safety profile of AFVT-2101. In agreement with target sequence homology, binding affinity of AFVT-2101 against human and cynomolgus monkey FRα and CD16A is highly similar, confirming non-human primate (NHP, specifically cynomolgus monkey) as the only pharmacologically relevant preclinical safety model. The toxicology program includes tissue cross-reactivity assessment against a panel of human and cynomolgus cryosections, single- and repeat-dose range finding (DRF) non-GLP studies and a 4-week IND-enabling GLP study with 4-week recovery period in NHPs.

In a single-dose study AFVT-2101 demonstrated non-linear pharmacokinetics when administered as a 2-h IV infusion to male NHPs where the mean C_{max} (85.1 and 1620 µg/mL) and AUC_{168hr} (3,430 and 97,000 µg.h/mL) at 3 and 30 mg/kg, respectively, increased supra-proportionally with respect to dose, consistent with target-mediated drug disposition. Half-life was 103-155 h across doses.
A DRF study was conducted to characterize toxicity, identify target organs, determine toxicokinetics (TK), immunogenicity (anti-drug antibodies, ADA), and to inform the dose selection of the subsequent 4-week study. AFVT-2101 was administered once-weekly to female NHPs via 2-h IV infusion for a total of 4 doses. Mean C_{max} (1120, 3320, 7190 µg/mL) and AUC_{168hr} (83,600, 209,000, 592,000 µg.h/mL) at 30, 75, and 150 mg/kg, respectively, increased in a generally dose-proportional manner with a trend for modest accumulation (<2-fold) upon repeated administration with a half-life of 80-230 h. Exposure did not appear to be impacted by any treatment-emergent ADA. AFVT-2101 was well-tolerated with no test article-related adverse effects on clinical observations, bodyweight, clinical chemistry, hematology, coagulation, anatomic pathology, or immunotoxicity parameters. The no observed adverse effect level (NOAEL) was determined to be 150 mg/kg under the conditions of the study.
The safety profile is being further evaluated in an ongoing pivotal 4-week GLP study incorporating standard toxicology endpoints, safety pharmacology (CNS, CV, and respiratory), gross and anatomic pathology, as well as cytokine, immunophenotyping, receptor occupancy, TK, and ADA analyses.
In conclusion, AFVT-2101 is well-tolerated in NHPs with a pharmacokinetic and safety profile consistent with its intended clinical application.

#6343

7E1, a novel blocking antibody targeting human anti-Müllerian-hormone-receptor II (AMHRII), elicits potent anti-tumor activity *in vivo*

Yongfei Yang[1], Huilin Li[1], Hao Li[1], Yue Yan[1], Jianhui Li[1], Qingcong Lin[1], Huijun Yin[2], Xiangshan Zhou[2], Miao Zhang[2], Kunbao Wu[2], Leqiao Sun[2],

Shan Zhong[2]. *[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]China Resources Biopharmaceutical, Beijing, China*

Anti-Müllerian hormone (AMH), is a TGF-β family autocrine hormone and cognate ligand for the type II AMH receptor (AMHR2). AMH signaling through AMHR2 plays an important role in fetal sexual development by inducing Müllerian duct regression in males. AMHR2 is aberrantly expressed in various human malignancies, including colon, testis, gastric, and ovarian cancers. Functionally, AMH has complex effects on cell cycle regulation; at physiological concentrations it promotes survival and chemoresistance of cell lines, whereas at supraphysiological concentrations it inhibits tumor cell viability. Like other TGF-β family members, binding of its target receptor effects changes in gene expression through activation of intracellular SMAD, NF-κB, and Akt signaling. We developed a fully human anti-AMHR2 monoclonal antibody, 7E1, from RenMab™ mice, which contain the full human immunoglobulin variable domain. 7E1 was found to contain a distinct binding epitope associated with efficient inhibition of AMH binding and signaling. 7E1 also displayed a better ADCC effect than the reference AMHR2 antibody. The *in vivo* half-life of 7E1 in AMHR2- and FcRn-humanized mice exceeded the reference antibody as well and is in a desirable range from a development perspective. To evaluate the safety and efficacy of 7E1 *in vivo*, we established syngeneic murine tumor models in AMHR2-humanized mice. We found that 7E1 monotherapy significantly inhibited tumor growth in a dose-dependent manner. Moreover, 7E1 was well tolerated in mice, and no adverse effects were observed even at extremely high doses (e.g. 100 mg/kg). Taken together, these data demonstrate that 7E1 is a novel anti-human AMHR2 blocking antibody with desirable pharmacokinetic and pharmacodynamic properties. 7E1 may potentially find broad application for a range of cancer indications in which AMH signaling is implicated.

Recombinant Immunotoxin exhibited targeted killing of Trop2 overexpressing tumour cells lines

Dennis Makafui Dogbey, Sizalobuhle Masuku, Stefan Barth. *Integrative Biomedical Sciences, University of Cape Town, Rondebosch, South Africa*

Introduction: The high prevalence of cervical cancer remains a global challenge particularly in developing countries where its therapy is principally by chemoradiation marked by severe toxicities. Antibody-based therapy targeting specific overexpressed surface antigen has proven as a promising strategy. Tumor-associated calcium signal transducer 2 (Trop2), also known as epithelial glycoprotein-1 antigen, is a membrane protein found in epithelial tissues involved in cellular signalling, migration, proliferation, and differentiation in normal cells. Its overexpression is validated in several tumor types including basal, squamous and adenocarcinomas of the cervix, breast, colon, and gastrointestinal tracts. Due to its differential overexpression, Trop2 is a viable therapeutic marker whereby a recombinant immunotoxin composed of a single chain variable antibody fragment (scFv) armed with Pseudomonas exotoxin A (Anti-Trop2-ETA) may be delivered for targeted killing of such tumors.
Methods: Plasmids encoding Anti-Trop2-ETA were designed in silico by fusion of anti-Trop2 single chain variable fragment (scFv) antibody to the N-terminus of Pseudomonas exotoxin A and then cloned into an pMT backbone. Expression was performed in BL21 E. Coli cells under osmotic stress and then Anti-Trop2-ETA was purified by IMAC via an N-terminus encoded polyhistidine tag. Purified fractions were structurally characterized by SDS PAGE gel and immunoblotting to confirm the presence of the Anti-Trop2-ETA protein to be used for treatment of tumor cell lines. Trop2 expression cervical cancer and breast tumor cell lines were confirmed, and cells were treated with Anti-Trop2-ETA.
Results: Dose dependent killing by Anti-Trop2-ETA was observed in the Trop2 expressing tumor cell lines. IC50 values were significantly lower for Trop2 expressing cells as compared to control cells lacking Trop2 expression.
Conclusion: Here, we demonstrated antigen specific killing of Trop2 overexpressing tumor cells in vitro. Targeted deployment of recombinant immunotoxin to specifically engage and kill Trop2 positive cells is a potential approach for cancer therapeutics. As such, the ability of the rIT to specifically target and kill Trop2 expressing tumors is an important initial finding towards the possibility of antigen-dependent elimination of Trop2 expressing cancer cells. Ongoing evaluations are aimed at antigen dependent biological activity as well as pharmacokinetics of the rIT in tumor bearing in vivo models.

#6345

Non-clinical pharmacology of HX009, a novel FIC PD1xCD47 BsAb

Faming Zhang, Hang Ke, Feiyu Peng, Cen Chen, Lei Zhang, Henry Qixiang Li. *Hanx Bio, Hangzhou, China*

Immune checkpoint inhibitors (ICIs) have been widely tested as cancer therapeutics but with respective limitations such as marginal activity and/or poor safety profiles. It is possible that some of these limitations could be overcome by specially engineered molecules, *e.g*. bi-functional agents. Here we report a novel rationally designed bi-specific antibody (BsAb) targeting both PD1 and CD47, HX009, in order to improve both efficacy and safety over the two respective single-targeting ICIs. HX009 features IgG4 and 2x2 symmetric format, but with specifically weakened CD47 binding affinity. We performed a comprehensive preclinical pharmacology characterization of HX009 to test our hypothesis by confirming its candidacy as a novel first-in-class biologic for cancer therapy. The affinity constant (KD) of the HX009 binding to PD1 was determined to $3.96x10^{-11}$ M, while $5.06x10^{-9}$ M for binding to CD47, significantly reduced affinity as compared to the binding to PD1 and the binding between native SIRPα and CD47. HX009 has little binding to red blood cell (RBC) and platelets so to minimize hematological toxicity that usually associated with CD47 targeting. The antibody injectable formulation caused little cytokine release from PBMC (CRS or cytokine storm). HX009 cross-species binds to cynomolgus monkey PD1 and CD47 receptors, with the similar affinity as with the counterparts of human, but not to those of rodents. Cynomolgus monkey was thus chosen to investigate non-clinical pharmacokinetic (PK) and toxicology profiles of HX009. The intravenous (IV) infusion PK study revealed that HX009 is largely distributed within vasculature, with terminal half-life ($T_{1/2}$) around 50hr and dose proportional exposure. Repeat dosing caused no accumulation. The production of antidrug antibody (ADA) were observed in the dosed animals, as expected for administration into different species, which impacted PK parameters of repeated dosing. The IV single dose toxicology study revealed the maximal tolerated dose (MTD) of 150mg/kg with 14-day observation, while the maximum non-severely toxic dose (HNSTD) was determined to be 15 mg/kg in the repeated dose study after once weekly dose for 4 consecutive weeks (5 times total). The main

drug related toxicities observed seemed to be related to CD47 targeting as expected. Strong antitumor activity was also confirmed in in several preclinical cancer models, including humanized syngeneic models. In summary, the desired PK and safety profiles of HX009, along with anti-tumor activity, supporting further clinical development. Currently, HX009 is under clinical investigation (ClinicalTrials.gov Identifier: NCT05189093).

#6346

Discovery of HX011, a novel OX40 mAb, for potential cancer immunotherapy

Hang Ke, Faming Zhang, Jialin Li, Feiyu Peng, Cen Chen, Henry Qixiang Li. *Hanx Bio, Hangzhou, China*

OX40, tumor necrosis factor receptor superfamily member 4, is an immune co-stimulatory receptor, together with its ligand OX40L, forming OX40-OX40L trimer-trimer complex between the surface of T-cells (OX40) and APCs/NKs (OX40L). OX40 expresses constitutively on T_{reg} as well as on conventional T_{eff}, particularly within TME. OX40/OX40L interactions directly triggers conventional T cell activation via NF-*k*B1 pathway and inhibits bcl-x and survivin to prevent apoptosis; and it also downregulates FoxP3/CTLA4, thus T_{reg} function. OX40 agonistic antibodies have also been shown to activate tumor immunity and increase anti-tumor activity in preclinical models. Here we report that we identified/constructed a novel OX40-agonistic humanized IgG1 monoclonal antibody (mAb), HX011, with high affinity through hybridoma technology. HX011 was subsequently confirmed of the similar binding properties and functions as the original mouse mAb clone, 9C12: 1) binding to human OX40 (EC_{50} ~0.012 nM; 2) similar function binding in the reporter assay (EC_{50} ~6.6 nM); but 3) has little blockade of the OX40L binding to OX40. In another word, HX011 is similar to BMS-986178 for the first two assays, but contrastingly different for the third assay. Non-competing with OX40L may actually maximize T-cell activation, a potential advantage over a competing antibody. *In vivo* pharmacology modeling of HX011 in the humanized syngeneic CRC model, MC38, where syngeneic C57BL/6 mouse mice were knocked in with huOX40 (“HuGEMM-OX40”), demonstrated strong anti-tumor

activity (TGI ~100% at 1 mg/kg, twice weekly). HX011 is being further investigated as a potential new immunotherapy for the treatment of cancers.

Preliminary results of an exploratory phase I clinical trial of anchored canine interleukin-12 (cANK-101) in dogs with advanced oral malignant melanoma

Matheus Moreno Passos Barbosa[1], Angel J. Lopez[1], Rachel Uyehara[1], Rebecca L. Kamerer[1], Michael Schmidt[2], Sailaja Battula[2], Howard L. Kaufman[2], Timothy M. Fan[1]. *[1]Veterinary Clinical Medicine, University of Illinois Urbana-Champaign, Urbana, IL,[2]Ankyra Therapeutics, Boston, MA*

Background*:* Malignant melanoma is the most common form of oral cancer in canines with a median survival of 3 months for dogs with stage III or IV disease. Currently, there are limited effective systemic treatment options for these patients with advanced disease. We have developed an anchored immunotherapy approach in which canine interleukin-12 is stably linked to aluminum hydroxide (cANK-101). The anchored IL-12 forms a stable, functional depot of IL-12 and is expected to increase therapeutic responses with limited systemic toxicity. We report the preliminary results of an exploratory Phase I study of cANK-101 in dogs with advanced melanoma.

Methods*:* The clinical study was approved by the University of Illinois IACUC, conducted at the College of Veterinary Medicine, and all pet owners provided written informed consent. The primary objective of the trial was to determine the safety and tolerability of cANK-101 in dogs with advanced melanoma. A standard 3+3 dose-escalation design was used with three dose levels (1, 3, and 10 µg/kg) cANK-101 given by intratumoral injection every three weeks for 4 cycles. In the absence of overt clinical progression, dogs were allowed to receive a second course of four cycles. Dogs were monitored for adverse events via VCOG-CTCAE and clinical responses were measured using RECISTv1.1. Serum was collected for pharmacokinetic (PK) and immunogenicity analyses. In addition, serial tumor biopsy and lymph node cytology were performed. Serum cytokines were assayed via ELISA while immunophenotyping of PBMC and lymph node aspirates were assessed by flow cytometry. Tumor-infiltrating lymphocyte (TIL) analysis was performed by immunohistochemistry (IHC)

and gene expression profiling (Nanostring). Descriptive statistics were used for analyses.
Results*:* As of November 16, 2022, 8 dogs have been enrolled and all dogs remain on treatment. Thirteen adverse events have been reported in 6 dogs, all being grade 1. However, only two are considered related to the study drug (tumor site inflammation and pain). Treatment was associated with increases in serum IFNγ and IL-10, as well as increases in peripheral $CD4^+$ T and $CD21^+$ T cells. Additional data on PK analyses, anti-drug antibody levels, gene expression, and clinical responses will be presented.
Conclusions*:* Thus far, cANK-101 appears to be safe and tolerable in dogs with advanced melanoma. Data from this trial will help inform human clinical trials and may represent a new therapeutic option for dogs with advanced melanoma and perhaps other solid tumors. Our experience further suggests that companion animal trials could serve as relevant translational models for early immuno-oncology drug development.

ABN202 (αEGFR-interferon-β mutein), a potent antibody-cytokine fusion protein for the treatment of EGFR-positive non-small cell lung cancer

Heegeon Park[1], Saehyung Lee[1], Hayeon Park[1], Sunghyun Hong[1], Jaemun Kim[1], Sungyoul Hong[2], Ji-hyun Park[3], Young Kee Shin[3], Jun Young Choi[1], Na Young Kim[1]. *[1]ABION INC., Seoul, Korea, Republic of,[2]College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of,[3]Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of*

ABN202 is an antibody-cytokine fusion protein consisting of interferon-β mutein (ABN102) molecularly fused to a anti-EGFR monoclonal antibody that recognizes the EGFR expressed on various types of cancer cells. In previous studies, we developed ABN102, a bio-better version of recombinant human interferon-β with hyperglycosylation via site-directed mutagenesis to improve stability, productivity, and pharmacokinetics properties. An addition of glycosylation at the N25 residue of ABN102 is expected to reduce the peripheral toxicity of ABN202, as it can shield the IFNAR2 binding interface. In this study, the binding ability and biological

activity of ABN202 was evaluated *in vitro* models. ABN202 downregulates the EGFR protein expression and reduces EGFR phosphorylation by degrading target proteins via internalization in the EGFR-positive NSCLC cell line. In addition, we also determined the direct and indirect anti-cancer activity of ABN202 *in preclinical models*. Taken together, we suggest that ABN202 has potent anti-cancer activities, via direct cytotoxicity in EGFR-positive tumors and indirectly activating immune cells through Type I IFN signaling. we conclude ABN202 is a promising drug candidate for patients with EGFR-positive NSCLC.

Monoclonal antibody against BST2 isoform: potential tool for diagnostic and cancer therapy

Laura C. Bover[1], Ahmed Muhsin[2], Long T. Vien[3], Felipe Amaya Manzanares[3], Zhuang Wu[3], Janis D. Johnson[3], Diego Castro Reyes[1], Myrthala Moreno-Smith[3], Estefania Labanca[4], Irene Sorin[5], Silvia Saucedo[5], Silvina Gazzaniga[6], Alicia I. Bravo[5]. *[1]Genomics Medicine/ Immunology, UT MD Anderson Cancer Center, Houston, TX,[2]Center for Epigenetics & Disease Prevention - Institute of Biosciences and Technology, Texas A&M, Houston, TX,[3]Immunology, UT MD Anderson Cancer Center, Houston, TX,[4]Department of Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[5]Servicio de Patologia, Hospital HIGA Eva Peron, San Martin - Provincia de Buenos Aires, Argentina,[6]Química Biológica, Facultad de Ciencias Exactas y Naturales - Universidad de Buenos Aires, Buenos Aires, Argentina*

BST2, a raft-associated type II transmembrane protein, functions as a restriction factor and inhibits HIV release by cross-linking virions onto infected cell surfaces. It also engages ILT7, a specific inhibitory receptor on plasmacytoid dendritic cells, which are associated with poor prognosis when infiltrate patients' breast tumors. Two groups have identified BST2 isoforms of different lengths, generated by post-transcriptional modification. Based on these findings and our work on protein interaction of ILT7-BST2, we hypothesized that the expression of BST2 isoforms differed in normal and cancer tissues. To demonstrate that, we generated and characterized anti-long BST2 isoform monoclonal antibodies (mAbs).

Results were compared with our previously developed mAb anti-BST2 full length molecule, 26F8, that recognizes a common epitope to all BST2 isoforms. By comparing the amino acid sequences of different isoforms of BST2, we identified a region of 24 residues on the extracellular domain of BST2, restricted to its long isoform. We then generated mAbs by hybridoma technology, immunizing BALB/c mice with the 24 mers peptide-KLH conjugated. Screening and positive selection of several clones were performed following our lab SOP. One of the mAbs, LA5, was selected based on positive ELISA against the immunogen and FACS staining of recombinant HEK293 cells expressing full-length BST2 protein. Pharmacokinetic determined using OCTET platform, revealed a KD of $4.61+/- 0.074 \times 10^{-9}$ M for LA5. Epitope mapping of LA5 on BST2 overlapping peptides, confirmed specific recognition of full-length BST2 protein and the peptide used as immunogen. LA5 heavy and light chains were sequenced and analysis was performed by IgBlast and IMGTV. Binding of LA5 and 26F8 to the myeloma cell lines MM1 (B-lymphoblast) and U266 (B-lymphocyte) by flow cytometry, indicated 97-100% positive cells with both mAbs, with higher MFI values observed for clone 26F8: 5.8 and 1.8-fold-increase in MM1 and U266 cells respectively. IHC on formalin-fixed paraffin embedded tissues of human ductal breast carcinoma, revealed that LA5 staining was able to identify infiltrating carcinoma cells but not the normal surrounding acinar cells. In contrast, 26F8 staining did not discriminate between BST2+ malignant and surrounding normal acinar cells. Currently, we are analyzing a panel of >105 breast cancer tissue samples of different molecular classifications. Initial data revealed a high-level of expression of BST2 (by 26F8) on the epithelial area of the tumors, lower in the TME (tumor microenvironment-infiltrating immune cells) and almost negative expression in the surrounding fibroblasts rich stroma. Evaluation of IHC staining by LA5 is being processed and yet to be established. These IHC findings indicate a potential diagnostic value of LA5 to distinct between tumor and normal cells in patients' specimens. Treatment prospects may arise during the process.

Reversal of dysfunctional CIK cells after the exposure to resistant cholangiocarcinoma cells through chemical perturbation of resistant

gene signature

Adisak Wongkajornsilp, Khin Su Su Htwe, Porncheera Chusorn, Sunisa Duangsa-ard, Kanda Kasetsinsombat, Nathawadee Sawatpiboon.
Pharmacology, Mahidol University Faculty of Medicine, Bangkok, Thailand

Clinical trials on cholangiocarcinoma revealed differential sensitivity to cytolytic action of allogeneic cytokine-induced killer (CIK) cells. Different metastatic foci in the same individual could also display different sensitivity. The differential sensitivity of separate lines of cultured cholangiocarcinoma cells could be demonstrated based on the evaluation of GR50. Allogeneic CIK cell or $CD3^+CD56^+$ subset was co-cultured with nine cell lines at E:T ratio of 20:1 for 48 h. The tumor cells were categorized into 2 groups based on the obtained GR50. This resulted in 4 sensitive cell lines and 5 resistant cell lines. The cholangiocarcinoma cell-exposed CIK cell and $CD3^+CD56^+$ subset displayed defective anti-tumor cytotoxicity upon subsequent experiment. RNAseq analysis revealed 261 genes upregulated in sensitive cell lines and 665 genes upregulated in resistant cell lines. The top 50 resistant genes were evaluated for their linked signal transduction and protein interaction network. Based on the interaction network, a list of chemicals that could interrupt the stipulated network were selected. They were assayed for their synergistic activity with dysfunctional CIK cell or $CD3^+CD56^+$ subset for cytolysis of resistant tumor cells.

#6352

Combination treatment with recombinant murine IL-12 and anti-PD-1 antibody enhanced anti-tumor efficacy through the activation of cytotoxic T cell response

Yeng-Jey Yang[1], Pei-Yi Tsou[1], Shiuh-Dih Chou[1], Meng-Na Lee[1], San-Chi Chen[2]. *[1]Libo Pharma Corporation, Taipei, Taiwan,[2]Department of Oncology, Taipei Veterans General Hospital, Taipei, Taiwan*

Introduction:Immune checkpoint inhibitors (ICIs) are widely used in cancer therapy. Among them, anti-PD-1 antibodies are the most used and have been approved by FDA for the treatment of many types of cancer (1). In our previous studies, combination of anti-PD-1 antibody with IL-12

demonstrated significant synergistic effect on tumor growth inhibition. The elevation of IFN-γ mRNA expression suggested the potential roles of CD8 T cells and NK cells in this process. In this study, we used two syngeneic mice tumor models to investigate the mechanisms of synergistic effect by the combination of IL-12 and anti-PD-1 antibody.
Methods: We used syngeneic mice tumor models with mice cancer cell lines CT-26 and MC-38. The mice inoculated with tumor cells and were treated until tumors grew to 100 mm^3. The mice were divided into three groups to receive the treatment, including rmIL-12 alone, anti-PD1-antibody alone, and the combination of rmIL-12 and anti-PD1-antibody (BIW x 3 weeks). At the end of the study, the mice were sacrificed and tumor resection and splenectomy were performed. The tumor infiltrating lymphocyte subpopulations within the tumor microenvironment were analyzed by flow cytometry and gene expression profile by RNA Seq.
Results: The combination of rmIL-12 and anti-PD-1 antibody significantly inhibited tumor growth compared to the treatment with rmIL-12 and anti-PD-1 antibody alone. The combination group demonstrated more $CD8^+$ T cell in the tumor microenvironment via flow cytometry. In addition, RNA Seq showed the combination group increased $CD8^+$ T cells, NK cells, and Th1 populations. The levels of cytotoxicity related genes (IFN-γ, Granzyme B, Perforin) were also higher in combination group.
Conclusion: Combination of rmIL-12 and anti-PD-1 antibody increased immune cells infiltration in the tumor microenvironment and enhanced anti-tumor response suggesting the potential of this combination for cancer treatment.

Combination of poly-γ-glutamic acid with anti PD-L1 blockade leads to improved anti-tumor activity in murine models

Jae-Pyung Jang, Jae Chul Choi, Kyung-Soo Hahm, Do Young Lee, Young-Chul Park. *BL Corporation, Gyeonggi-do, Korea, Republic of*

Immune checkpoint inhibitors(ICIs) have been shown to be key role in cancer therapy. Especially, antibodies targeting programmed cell death ligand1(PD-L1) promoted T cells to activate immune response against cancer cells. However, the current ICIs still have insignificant to motivate effective antitumor immunity by blocking PD-1/PD-L1 pathway and the regulatory network of PD-L1 by cytokines in the tumor microenvironment remains to be uncovered. Previously, we have reported the anti-cancer effects of combination treatment with a natural product, poly-γ-glutamic acid(γ-PGA), and PD-1 blockade. Now, we showed that combination therapy with anti PD-L1 and γ-PGA overcome the limits of ICIs and enhance anticancer effect in murine melanoma(B16F10). In vivo efficacy studies were performed by intraperitoneal injection of antibody targeting PD-L1 and oral administration of γ-PGA in C57BL/6 model transplanted with B16F10 melanoma cell. Systemic changes in immunophenotype were measured by tumor volume size and survival rate. The splenocytes were isolated from mice and the populations of myeloid-driven suppressor cells(MDSCs) and CD4/CD8 T cells were analyzed by FACS. Combination therapy with γ-PGA and anti PD-L1 blockade showed dramatically more suppressive tumor growth and enhanced long-term survival rate than other monotherapic treatment. In addition, γ-PGA was shown to play a role in the immune modulation of tumor microenvironment by activation of T cells and inhibition of MDSCs so as to prevent tumors from immune escape. Therefore, we suggest that γ-PGA can promote ICI-mediated antitumor responses by the transformation of "cold tumors" into “hot tumors”

A new tumor-bearing humanized mouse model to evaluate the efficacy of bispecific T cell engager and monoclonal checkpoint antibodies

Li-Chin Yao[1], Danying Cai[1], Destanie Rose[1], Guoxiang Yang[1], Mingshan Cheng[1], Michael A. Brehm[2], Dale L. Greiner[2], Leonard D. Shultz[3], James G. Keck[1]. *[1]The Jackson Laboratory-West, Sacramento, CA,[2]University of Massachusetts Medical School, Worcester, MA,[3]The Jackson Laboratory, Bar Harbor, ME*

T cell-based immunotherapies such as bispecific T- cell engagers (BiTE) and checkpoint inhibitors (CIs) have been developed rapidly for cancer treatment, but each has their own limitations in the clinic. Combination

therapies are an emerging approach in ongoing clinical trials to enhance the drug efficacy of monotherapy. Here we described a new preclinical animal model using immunodeficient NSG™-SGM3-IL15 mice engrafted with human CD34+ hematopoietic stem cells (HSC) to evaluate the combination treatment of EGFRXCD3 BiTE and two CIs (anti-PD-1 pembrolizumab and anti-PD-L1 avelumab). NSG™-SGM3-IL15 mice, which were created by crossing NSG™-SGM3 with NSG™-IL15, develop a more complete humane immune system after HSC engraftment. Humanized NSG™-IL15 mice have a higher peripheral NK cell frequency, and NK cells are functional with ADCC activity when compared to NSG™ (Aryee et al., 2022 FASEB). Here we show that humanized NSG™-SGM3-IL15 mice show improved human CD33+ myeloid progenitor cells and near physiological levels of NK cells and Tregs in peripheral blood when compared to humanized NSG™-SGM3. Triple negative breast cancer MDA-MB-453 cell line is PD-L1 positive, expresses low levels of EGFR and has a low baseline tumor immune cell infiltration in xenograft using humanized NSG™ mice. Previously we have shown BiTE efficacy on this tumor model. Here tumor-bearing humanized NSG™-SGM3-IL15 mice from two donors were used to evaluate the efficacy and immune responses from the BiTE treatment in combination with CIs. For donor 0348, monotherapy BiTE and avelumab didn't result in significant tumor growth reduction when compared to PBS control whereas the combination treatment significantly reduced tumor growth. BiTE treatment alone resulted in a significant increase in CD3+ T cell infiltration into tumor and higher frequency of CD69+ CD4 T and CD8 T cells. PD-1 expression on the tumor infiltrating lymphocytes and PD-L1 expression on tumor cells increased significantly. BiTE and avelumab combination treatment further increased human CD45+ and CD3+ T cell infiltrations with activated T cell phenotypes in tumor. For the second donor 0313, BiTE alone or in combination with the CIs didn't show anti-tumor growth activity. Flow cytometry analysis showed that the immune response to BiTE treatment was less pronounced in this donor, especially there were little change in lymphocyte infiltration and CD4+ T cell population in tumor. In this study, we demonstrated donor-dependent response to combination treatment of BiTE and avelumab and found that the responding donor showed an increase in T cell infiltration and activation in tumor after the treatment. The data suggested beneficial effects from inhibition of PD-1/PD-L1 axis

when used in combination with an immunotherapy targeting tumor antigen. The potential involvement of NK cells in this combination therapy remained to be examined.

Generation of a mutant SIRPa fusion protein with highly-improved affinity and favorable safety profile

Yingying Hu, Yayuan Fu, Lei Liu, Wenjing Li, Liting Xue, Zhiyong Yu, Yun Zhang, Meijuan Gao, Yixin Tan, Fudong Wang, Yadan Wu, Jie Li, Zhenzhen Li, Feng Zhou, Wenqing Yang, Zhuoxiao Cao, Renhong Tang.
Jiangsu Simcere Pharmaceuticals Co. Ltd, Nanjing, China

Background/Purpose: CD47 has been validated to be expressed on various tumor types including acute myeloid leukemia, myelodysplastic syndrome and other hematologic or solid tumors. As primary 'don't eat me' signal, high expression of CD47 on tumor cells interacts with SIRPα negatively regulating the phagocytosis level. However, poor safety profile as well as insufficient combinatory effect remain to be the issues limiting the clinical outcomes of CD47-targeting molecules. Herein, we used rational design strategies to generate SCR9168 with potent affinity improvement, and maintained favorable safety profiles in different animal species, including cynomolgus monkeys.
Procedures: Mutagenesis was introduced to the residues critical for CD47/SIRPα binding interface. Affinity was measured by SPR analysis. *In vitro* activities were determined by biochemical- or cell-based binding, blocking and antibody-dependent cellular phagocytosis (ADCP) assays. The efficacy *in vivo* was assessed with the OE19 xenograft model. Pharmacokinetics (PK) and safety were monitored in both mice and cynomolgus monkeys.
Results: The affinity of SCR9168 achieves 178 pM for human CD47 which is nearly 50-fold increase in comparison with wild-type SIRPα. Enhanced affinity has also been confirmed in binding to OE19 or DLD1 cell lines, as well as in blocking human SIRPα binding to Raji cells. SCR9168 remains strong binding potency to monkey, mouse or rat CD47 which allows the PK and safety assessment using these animal species. The combined effects of

SCR9168 and multiple therapeutic antibodies targeting tumor-associated antigens (TAAs) have been evaluated with ADCP assays using human monocyte-derived macrophages. SCR9168 markedly increases the ratio of phagocytic cells combining with antibodies, such as cetuximab. However, due to the inert function of Fc fragment, no phagocytosis of red blood cells or platelets was caused after the incubation *in vitro*. In addition, SCR9168 treatment in combination with trastuzumab leads to significantly improved suppression of tumor growth in a dose-dependent manner. Moreover, administration of two doses at day 1 and day 11 in cynomolgus monkeys results in no toxicity events related to SCR9168 based on the data from hematological analysis.
Conclusion: SCR9168 demonstrates the best-in-class potential among SIRPα mutein molecules. It elicits improved and dose-dependent efficacy in phagocytosis or tumor suppression combining with therapeutic antibodies, such as trastuzumab or cetuximab. Favorable safety profile with no phagocytosis of RBC or platelets *in vitro* as well as no hematological toxicity observation in cynomolgus monkeys allows broader dose range exploration in early clinical phase. SCR9168 is currently in development stage and IND enabling will be expected in the end of 2023.

CLEC-1 inhibitory myeloid checkpoint blockade enhances antitumor responses and tumor phagocytosis by macrophages

Vanessa Gauttier[1], Irène Baccelli[1], Marion Drouin[1], Isabelle Girault[1], Sabrina Pengam[1], Emmanuelle Wilhelm[1], Javier Saenz[2], Julien Taurelle[1], Emmanuel Mérieau[2], Bérangère Evrard[2], Caroline Mary[1], Géraldine Teppaz[1], Ariane Desselle[1], Virginie Thépénier[1], Nicolas Poirier[1], Elise Chiffoleau[2]. *[1]OSE Immunotherapeutics, Nantes, France,[2]Nantes Université, CHU Nantes, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, F-44000 Nantes, France, Nantes, France*

Myeloid cells represent the most abundant immune component of the tumor microenvironment, where they often assume immunosuppressive roles. Therefore, developing therapeutic strategies reinvigorating immunosuppressive myeloid cell subsets is of raising interest in oncology. We have identified CLEC-1, a member of the C-type lectin receptor (CLR)

family as being expressed by myeloid cells, especially by conventional type one dendritic cells (cDC1), and by tumor-associated macrophages (TAM). However, the role of CLEC-1 in myeloid function and its mechanism of action remained to be fully elucidated. Here, we investigated the effect of CLEC-1 blockade, either by genetic deletion or by antibody targeting, on myeloid function and anti-tumor response. First, we observed that CLEC-1 genetic deletion significantly increases the survival of syngeneic tumor-bearing mice in the Hepa1.6 orthotopic model of hepatocarcinoma, as well as in the AK-7 orthotopic model of mesothelioma. Moreover, the synergy with chemotherapy treatment (cyclophosphamide, gemcitabine) in the MC38 model of colon adenocarcinoma in *Clec1a* deficient animals significantly enhanced complete responses. Eventually, cured mice developed a robust memory antitumor immune response against the tumor. Next, we generated anti-human CLEC-1 monoclonal antibodies (mAbs) as well as CLEC-1 humanized mice. We found that CLEC-1 targeting through mAb treatment was able to prolong mouse survival as efficiently as by CLEC-1 genetic deletion in MC38 and Hepa1.6 models. CLEC-1 blockade by genetic deletion or by different mAbs treatment profoundly impacted the tumor microenvironment: we observed an increase in the frequency of invigorated dendritic cells (DCs) and macrophages, activated and memory T cells, while frequencies of immunosuppressive myeloid cells and PD1-expressing T cells largely decreased. Mechanistically, the *in vivo* phagocytosis of tumor cells (Hepa1.6 and MCA101) by macrophages was enhanced in CLEC-1 deficient animals compared to WT animals. Altogether, our results demonstrate that CLEC-1 acts as a novel immune checkpoint in myeloid cells and highlight its high potential as a target for innovative immunotherapy in oncology.

Structural insights into Siglec-15 reveal glycosylation dependency for interaction with T cells through integrin CD11b

Maria Pia Lenza[1], Leire Egia-Mendikute[1], Asier Antoñana-Vildosola[1], Cátia O. Soares[2], Francisco Corzana[3], Iker Oyenarte[1], Filipa Marcelo[2], Jesús Jiménez-Barbero[1], June Ereño-Orbea[1], Asis Palazon[1]. *[1]CIC bioGUNE, Derio, Spain,[2]Universidade NOVA de Lisboa, Lisbon, Portugal,[3]Universidad de La Rioja, Logroño, Spain*

Sialic acid-binding Ig-like lectin 15 (Siglec-15) is emerging as an immune modulator and target for cancer immunotherapy. However, limited knowledge regarding the mechanism of action, structure and binding partners on T cells restrains the development of drug candidates that unleash its full therapeutic potential. Here, we solve the crystal structure of Siglec-15 and delineate its binding epitope by co-crystallization with an anti-Siglec-15 blocking antibody. Saturation transfer-difference (STD) nuclear magnetic resonance (NMR) spectroscopy assisted with molecular dynamic simulations revealed the binding mode of Siglec-15 to the cancer-associated sialyl-Tn (sTn) glycoform. Binding of Siglec-15 to T cells, which lack sTn expression, depends on the presence of sialic acid. We identified the leukocyte integrin CD11b as a binding partner of Siglec-15 on human T cells. Collectively, these data provide an integrative understanding of the structural features of Siglec-15 and underscore glycosylation as an additional layer of control of T cell responses.

#6361

A preclinical model of acquired anti-PD-1 resistance is responsive to SEA-TGT, an effector-function enhanced anti-TIGIT monoclonal antibody

David R. Gruber, Weiping Zeng, Bob Thurman, Brian P. O'Connor, Shyra J. Gardai, Alyson J. Smith. *Seagen, Bothell, WA*

Immune checkpoint inhibitors, including monoclonal antibodies targeting the PD-1/PD-L1 axis, induce robust antitumor immunity in a subset of patients with various cancers. Despite continued success of these therapies, some patients experience limited efficacy owing to clinically complex and unresolved mechanisms of primary and acquired immunotherapy resistance. To begin to understand the mechanisms of acquired resistance to anti-PD-1 blockade, we developed a syngeneic murine CT26 colorectal tumor model that is resistant to anti-PD-1 therapy. To achieve this, CT26 tumors were subjected to successive rounds of increasing levels of anti-PD-1 therapy. When tumors grew out, they were cultured in vitro and then re-implanted and re-treated for three rounds until PD-1 resistance was achieved. To characterize the underlying drivers of acquired resistance across the generation of the model, wild type and anti-PD-1 resistant tumors and cultured cell lines were evaluated by flow cytometric immunophenotyping

and RNA-sequencing analysis. To assess how observed changes in the tumor microenvironment impact response to various therapeutics, the resistant tumors were treated with anti-PD-1 therapy or SEA-TGT, a nonfucosylated anti-TIGIT mAb with enhanced Fc-function that drives activity through multiple modes of action. As expected, treatment with anti-PD-1 monotherapy was ineffective, however, treatment with SEA-TGT demonstrated potent anti-tumor activity. These data are consistent with responsiveness to anti-TIGIT agents in other in vivo models of PD-1 resistance and/or PD-1 refractory response, indicating that the factors driving resistance to anti-PD-1 therapy can be different than those driving response to other known checkpoint molecules such as TIGIT. Thus, investigational agents such as SEA-TGT may have the potential to be efficacious in tumors that are primary or secondarily resistant to anti-PD-1 therapy. We have initiated a phase 1 study (NCT04254107) evaluating the safety, tolerability, and activity of SEA-TGT monotherapy and in combination with anti-PD-1 therapy in patients with advanced malignancies.

#6362

Overcoming resistance to immunotherapy due to loss of antigen presentation

Brian C. Miller[1], Yacine Choutri[2], Rose Al Abosy[3], Amy Huang[4], Emily K. Cox[1], Matthew P. Zimmerman[1], Wan Lin Chong[1], Katherine J. Vietor[1], Jenna Collier[4], Sarah A. Weiss[4], Debattama Sen[5], W. Nicholas Haining[6], Arlene H. Sharpe[4]. *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]University of Toronto, Toronto, ON, Canada,[3]Boston Medical Center, Boston, MA,[4]Harvard Medical School, Boston, MA,[5]Massachusetts General Hospital, Boston, MA,[6]Arsenal Biosciences, San Francisco, CA*

Resistance to immune checkpoint inhibitors represents a major therapeutic challenge, as only 40% of patients with melanoma (and less with other tumor types) have a long-term response to anti-PD-1 therapy. Resistance can arise because of somatic mutations in cancer cells that allow evasion of T cell-mediated killing. One commonly acquired resistance mutation in melanoma, loss of beta-2 microglobulin (B2m), prevents T cell killing by hiding cancer cells from CD8+ T cell recognition. To understand the failed

immune response against resistant tumors, we used single-cell RNA-seq to characterize tumor-infiltrating immune cells in antigen presentation-deficient human melanoma biopsies and CRISPR-modified mouse melanoma tumors. Our data demonstrate an increase in immunosuppressive M2-like macrophages and absence of CD8+ T cells in B2m-null tumors. To overcome this resistance, we treated tumor-bearing mice with CD40 agonist antibody, which promotes differentiation of macrophages towards a pro-inflammatory phenotype and increases dendritic cell priming of CD8+ T cells. Treatment with CD40 agonist reduced tumor growth and improved tumor clearance in B2m-null melanoma and colorectal cancer models. To determine how CD40 agonist treatment works, we depleted different immune populations from the tumor microenvironment. We hypothesized that by depleting M2 macrophages, CD40 agonist treatment would remove an immunosuppressive brake to allow natural killer (NK) cells to kill tumor cells lacking MHC expression. To our surprise, NK cells were not required for the efficacy of CD40 agonist. Instead CD8+ T cells were required, even though the CD8+ T cells cannot directly recognize the tumor cells. scRNA-seq identified a transcriptionally unique state of CD8+ T cells that is recruited to the tumor microenvironment after CD40 agonist treatment. These CD8+ T cells produce IFNγ, which is required for the efficacy of CD40 agonist treatment. These data demonstrate that CD8+ T cells, a key mediator of anti-tumor immunity, can still be recruited to control tumors deficient in antigen presentation. More broadly, they suggest that strategies to activate CD8+ T cells may be effective even in the context of acquired resistance to checkpoint inhibitor therapy.

#6363

Short-term exposure of cancer cells to ultra-high concentrations nitric oxide induces PDL-1 upregulation

Yana Epshtein[1], Matan Goldshtein[1], Selena Chaisson[2], Jedidiah Monson[2], Matt Johnson[2], Amir Avniel[3], Steve Lisi[4], Hila Confino[1]. *[1]Beyond Cancer, Rehovot, Israel,[2]Beyond Cancer, Atlanta, GA,[3]Beyond Air, Ltd., Rehovot, Israel,[4]Beyond Air Inc, Garden City, NY*

Background: We have previously shown that treating mouse colon carcinoma (CT26) tumor-bearing mice with ultra-high concentrations of nitric oxide (UNO) upregulates innate and adaptive immune cells both

locally and systemically. As immune-checkpoint molecules, such as the PD-L1 receptor PD-1, are expressed on immune cells, our group assessed the potential synergy of UNO and an anti-PD-1 antibody for treating tumors *in vivo*. Indeed, primary tumors regressed in 53% of the CT26 tumor-bearing mice treated with UNO and anti-PD-1. Moreover, these mice were primary and distant tumor-free and survived 100 days post-treatment. In the current study, we assessed PD-L1 expression levels on cancer cells *in vitro* following short-term exposure to UNO.
Methods: CT26 cells were exposed to 25,000 - 100,000 ppm NO for 10 - 60 seconds. The percentage of PD-L1-expressing cells was assessed by flow cytometry analysis.
Results: 1. Exposing CT26 cells to 100,000 ppm NO for 10 seconds upregulated PD-L1 expression. 85.1% of cells, which are still viable or at early apoptosis, expressed PD-L1 compared to 71% of untreated cells ($p<0.0001$). Exposure of CT26 cells to 25,000 ppm or 50,000 ppm NO for 10 seconds did not change the level of PD-L1 expression significantly. 2. Exposure to 100,000 ppm NO for 30 seconds further increased the percentage of cells expressing PD-L1 to 96.7% ($p<0.0001$ compared to untreated cells). For this duration, lower concentrations of NO also increased PD-L1-expression in viable early apoptotic CT26 cells to 82.8% - 92.3% when treated with 25,000 ppm or 50,000 ppm NO, respectively. 3. Finally, a 60 second exposure of CT26 cells to 25,000 ppm, 50,000 ppm, or 100,000 ppm NO resulted in the highest percentage of PD-L1 expressing cells. Approximately 95% of all viable or early apoptotic CT26 cells express PD-L1 under all NO conditions. This finding is significant compared to 71% of cells in the control arm that express PD-L1 ($p<0.0001$).
Conclusion: Short-term exposure (10 - 60 seconds) to UNO upregulates PD-L1 expression on cancer cells in an NO concentration-dependent and exposure-dependent process. A 10-second exposure to 100,000 ppm NO is sufficient to significantly induce PDL-1 expression. Therefore, NO therapy can potentially be combined with anti-PD-L1 antibody treatment to improve therapeutic outcomes.

#6365
TRIM21 is a novel endogenous partner of the inhibitory myeloid checkpoint CLEC-1 involved in tumor antigen cross-presentation

Irene Baccelli[1], Vanessa Gauttier[1], Marion Drouin[1], Caroline Mary[1], Isabelle Girault[1], Emmanuelle Wilhelm[1], Sabrina Pengam[1], Géraldine Teppaz[1], Julien Taurelle[1], Ariane Desselle[1], Virginie Thepenier[1], Nicolas Poirier[1], Elise Chiffoleau[2]. *[1]OSE Immunotherapeutics, Nantes, France,[2]Nantes Université, CHU Nantes, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France*

Myeloid cells represent the most abundant immune component of the tumor microenvironment, where they often assume immunosuppressive roles. Therefore, understanding the mechanisms regulating the immunosuppressive activity of myeloid cells is of major interest in oncology. We have identified CLEC-1, a member of the C-type lectin receptor (CLR) family, as a myeloid cell-driven brake for anti-tumor T cell response in different murine models, including mesothelioma, hepatocellular and colorectal carcinomas. However, the molecular mechanism underlying the immunomodulatory role of CLEC-1 remained to be fully elucidated. Here, using both murine and human cells, we identified and characterized a novel endogenous ligand for CLEC-1, shedding new light on CLEC-1 driven inhibitory myeloid checkpoint activity. First, using single cell RNA sequencing, we confirmed that CLEC-1 is expressed by human myeloid cells, especially by conventional type-one dendritic cells and by tumor-associated macrophages. Using an Fc-fusion human CLEC-1 protein (huCLEC-1) as a bait for potential endogenous ligands, we observed both in human and murine cells that huCLEC-1 binds specifically to stressed or dying cells following programmed necrosis, for instance after X-ray or chemotherapy treatments. CLEC-1 interaction with its ligand expressed by necrotic cells was able to activate the NFAT promoter in a CLEC-1-CD3zeta NFAT reporter cell line *in vitro*; furthermore, CLEC-1 ligand targeting *via* Fc-CLEC-1 treatment *in vivo* extended the overall survival of chemotherapy-treated mc38-colorectal cancer bearing mice, altogether demonstrating the functional relevance of CLEC-1 interaction with its ligand. Immunoprecipitation of proteins bound to huCLEC-1 subsequently enabled the identification of TRIM21, an intra-cellular Fc receptor and E3 ubiquitin ligase as a novel interaction partner for CLEC-1. Direct interaction between recombinant TRIM21 and CLEC-1 human proteins was subsequently confirmed by ELISA and Biacore affinity

analysis. TRIM21 was indeed detected at the cell surface of necrotic cells following genotoxic treatments *in vitro* in several human cancer cell lines and, interestingly, high TRIM21 expression was predictive of worse overall survival in patients with hepatocellular carcinoma, pancreatic cancer, or glioma. Mechanistically, we demonstrated that CLEC-1 genetic deletion in mice enhances the capacity of dendritic cells to cross-present tumor antigens, a process known to be regulated by TRIM21 through its E3 ubiquitin ligase activity. Antagonist anti-CLEC-1 or anti-TRIM21 antibodies are therefore being evaluated to further confirm the involvement of the newly identified CLEC-1 interaction with TRIM21 in the regulation of CLEC-1's function as an inhibitory myeloid checkpoint. Altogether our data highlight the CLEC-1/TRIM21 axis as a new target for cancer immunotherapy.

NB002, a novel therapeutic antibody targeting unique epitope on TIM-3 presenting potent antitumor activity

Yu Zhang[1], Jinyu Dong[1], Binbin Wang[1], Jie Ni[1], Dong Wang[1], Liegang Shao[1], Meiguang Xiong[1], Ting Wang[1], Florencia McAllister[2], Xin Dong[1].
[1]NeoLogics Bioscience Co. Ltd., Suzhou, China,[2]Clinical Cancer Prevention, The University of Texas MD Anderson Cancer Center, Houston, TX

Antibody-based Immune checkpoint inhibitor (ICI) therapies targeting cytotoxic T lymphocyte antigen-4 (CTLA-4) or programmed death receptor-1 (PD-1) have significantly improved clinical outcomes in cancer treatment. Nonetheless, a large portion of the population has limited benefit from these ICI treatments due to lack of efficacy, resistance and intolerance. T-cell immunoglobulin and mucin domain containing-3 (TIM-3) has been proposed as a target for cancer immunotherapy. It is an inhibitory receptor modulating immune tolerance, and its expression has been broadly reported to be closely correlated to T cell exhaustion and pessimistic prognosis. Besides negatively modulating T cell status, TIM-3 is also expressed on natural killer (NK) cells, dendritic cells (DCs), macrophages and regulates immune responses bridging innate immunity and adaptive immunity. NB002 is a novel humanized Fc-engineered IgG1κ antibody, developed via NeologicsBio's integrated target validation & antibody screening Tier-A

platform. It has been characterized in a serial of function and efficacy studies and completed IND-enabling preclinical development. NB002 binds to human TIM3 with high affinity in the low nanomolar range and antagonize the TIM-3 pathway effectively in reporter cell and primary cell assays. NB002 increased the secretion of IFN-γ by activated PBMC cells and enhanced activation and killing activity of NK cells. Moreover, it exhibited a distinctive activity of restoring myeloid cells and enhancing antigen presentation and processing during anti-tumor immune responses, and superior efficacy in multiple humanized mouse models of cancer as monotherapy regimen. Importantly, X-ray crystallography demonstrated that NB002 recognized a unique epitope on TIM-3 and was confirmed by epitope binning assay and structural alignment. These data could potentially explain novel features of NB002, restoring both acquired and innate immunity which could lead cold tumor to hot tumor.In summary, these data showed that NB002 is a potent anti-TIM-3 antibody with pre-clinical properties. A phase 1 study is planned and patients with advanced metastatic solid tumors will be recruited.

BSI-507, a first-in-class bispecific antibody targeting PD1 and PVRIG for cancer immunotherapy

Zeyu Peng[1], Xiaodong F. Liu[2], Hongyan Li[1], Wenwen Dai[1], Jinyu Liu[1], Xiaoyao Hao[1], Shukai Xia[1], Qun Lv[1], Hugh M. Davis[2], Mingjiu Chen[1], Mark Z. Ma[1]. *[1]Biosion, Inc., Nanjing, China,[2]Biosion USA, Inc., Newark, DE*

Introduction: Despite the success of anti-PD1/PDL1 therapies, only a small fraction of patients benefit from these checkpoint inhibitors (CPIs). Novel approaches to improve outcomes for patients who are resistant to current CPIs are needed. PVRIG is expressed on $CD4^+$ and $CD8^+$ T cells, NKT and NK cells. PVRIG binds with high affinity with its ligand PVRL2, which is expressed on tumor cells and some myeloid cells. The PVRIG-PVRL2 axis exerts an inhibitory effect on the cytotoxic activity of lymphocytes. Bispecific antibodies that exhibit dual blockade of PD1 and PVRIG provide a promising strategy to enhance anti-tumor immune response.

Methods: An anti-PD1 mAb was identified from PD1 KO mice immunized with PD1-ECD-Fc and screened by our proprietary H^3 (High-throughput, High-content and High-efficiency) platform. An anti-PVRIG mAb was identified from rats immunized with recombinant PVRIG-ECD-Fc and screened by the H^3 platform. Both anti-PD1 and anti-PVRIG antibodies were humanized, and the anti-PD1 scFv was fused to the N-terminus of the heavy chain of the anti-PD1 antibody via a flexible linker. The binding activities and affinities were evaluated by ELISA, FACS and SPR, and the ligand blocking activities were measured by ELISA and FACS. Cell-based reporter assays were used to evaluate the functions of the anti-PD1 and anti-PVRIG mAbs alone and the bispecific antibody. In addition, the activity of the bispecific antibody to reverse PD1 and PVRIG mediated suppression of CMV $pp65_{495\text{-}503}$ antigen specific $CD8^+$ T-cell cytotoxicity was evaluated.
Results: BSI-507, an anti-PD1xanti-PVRIG bispecific antibody demonstrated comparable activity to the parental anti-PD1 antibody regarding PD1 binding and PD1/PDL1 blocking. It also exhibited comparable activity to the parental anti-PVRIG antibody in PVRIG binding and PVRIG/PVRL2 blocking. Based on cell-based reporter assays, BSI-507 was able to reverse either PD1 or PVRIG mediated T-cell suppression and exhibited comparable potency to the parental antibodies. BSI-507 was also able to show enhanced reversal of both PD1 and PVRIG mediated T-cell suppression, much better than anti-PD1 or anti-PVRIG alone. In addition, BSI-507 showed the ability to reverse PD1 and PVRIG mediated suppression of CMV $pp65_{495\text{-}503}$ antigen specific $CD8^+$ T-cell cytotoxicity, stronger than either the anti-PD1 or anti-PVRIG monoclonal antibody.
Summary: BSI-507 is a first-in-class anti-PD1xanti-PVRIG bispecific antibody for dual blockade of PD-1 and PVRIG pathways to enhance reversal of T cell inhibition. BSI-507 demonstrates favorable biophysical and functional characteristics, supporting the initiation of development activities including manufacturing and IND-enabling studies.

Preclinical pharmacology and safety studies of ZG005: an anti-PD-1/TIGIT bispecific mAb in a phase I clinical trial for advanced tumors

Bing Zhu[1], Tongcheng Dai[1], Ruifeng Liu[1], Alfonso Suarez[2], Tyler Liban[2], Bin Zhang[1], Margaret Karow[2], Jackie Sheng[2], Zelin Sheng[1], Binhua Lv[1].

[1]Suzhou Zelgen Biopharmaceuticals Co., Ltd., Shanghai, China,[2]Gensun Biopharma, Inc., Newbury Park, CA

ZG005 is a humanized anti-PD-1/TIGIT bispecific antibody that effectively blocks the binding between PD-1 and TIGIT, on immune cells, with their specific ligands PD-L1 and PVR, on tumors. As a dual blockade of PD-1/TIGIT immune checkpoints, ZG005 exhibits sustained occupancy to both targets and inhibits their pathways specifically and simultaneously, leading to synergistic effects and boosting the ability of the immune system in killing tumor cells. With high binding affinities, ZG005 elicits the activation of T cells and NK cells resulting in increased release of cytokines and the depletion of Tregs, independent of ADCC activities. ZG005 utilizes the IgG4 isotype to avoid the potential negative impact of effector function and target-crosslinking that has been reported for anti-TIGIT therapeutics using IgG1 isotype. *In vivo* animal studies indicate that ZG005 has potent and dose-dependent anti-tumor efficacies in syngeneic models using CT26 and MC38 colon tumors in humanized PD-1/TIGIT dKIs mice. In these models, the whole blood and TIL analyses confirmed increases in $CD8^+$ and NK cells but reduction of Treg cell levels after ZG005 treatments. The combination of ZG005 with chemotherapeutic-reagents, cisplatin and donafenib, enhanced their anti-tumor efficacies. Toxicity and safety pharmacology studies with weekly repeat doses for four weeks in cynomolgus monkeys, indicate that ZG005 is well tolerated. Over the dose range 20-180 mg/kg, there were no obvious toxic or adverse effects, and the HNSTD and NOAEL values were 180 mg/kg and 60 mg/kg, respectively. PK/TK analyses indicate a prolonged ZG005 receptor occupancy over 80%, consistent with *in vitro* binding results that are attribute to the S228P mutation in the IgG4 hinge region to prevent Fab exchange and enhance stability. The IND application of ZG005 has been approved by both FDA and NMPA, and the molecule is currently in phase I clinical trials for advanced solid tumors at escalated dosing of 0.3~20 mg/kg, Q3W, via *i.v.* administration.

#6369

Modulation of tumor microenvironment with TIM-3 blockade improves survival in diffuse midline glioma models

Iker Ausejo-Mauleon[1], Sara Labiano[1], Virginia Laspidea[1], Daniel de la Nava[1], Oren Becher[2], Mariella G Filbin[3], Fernando Pastor[4], Marta M Alonso[1]. *[1]Department of Pediatrics, Clinica Universidad de Navarra, Pamplona, Spain,[2]Jack Martin Fund Division of Pediatric Hematology-oncology, Mount Sinai, New York, NY,[3]Department of Pediatric Oncology, Dana-Farber Boston Children's Cancer and Blood Disorders Center, Boston, MA,[4]Molecular Therapeutics Program, Center for Applied Medical Research, Pamplona, Spain*

Purpose of Study: Diffuse midline glioma (DMG) is an aggressive brain tumor and the leading cause of pediatric death caused by cancer. Despite great strides in the understanding of this disease, survival is still dismal. One of the objectives of our lab is to modulate the tumor microenvironment (TME) towards a proinflammatory phenotype to render these tumors amenable to immunotherapy. TIM-3 is a member of the TIM family of immunoregulatory proteins expressed on multiple immune cell types, including T-cells, NK, myeloid populations, and microglia, regulating adaptive and innate immunity. Therefore, the aim of this project is to study the antitumor effect of the anti-TIM-3 monoclonal antibody and its effect on the DMG tumor microenvironment. Experimental Procedures: TIM-3 expression in DMG patients was analyzed using total mRNA sequencing data and single-cell RNAseq data. To perform all the experiments, DIPG murine cell lines were used (NP53 and XFM). For in vivo experiments, cells were injected into the pons of mice using a screw-guided system. The antibody was administered intracranially (25μg) with the same system and two times intraperitoneally (10mg/kg) 3, 7, and 11 days after the cell implantation respectively. Tumor immune populations, chemokines, and cytokines were analyzed by flow cytometry.
Results: In silico assessment of TIM-3 expression in DMG mRNA and single-cell datasets showed a robust expression of this gene mainly in microglia and macrophages uncovering this molecule as a potential target in DMGs. In vivo studies showed that TIM-3 blockade with an antibody significantly increased the overall survival of two DMG immunocompetent orthotopic models, led to long-term survivors (50%), and showed immune memory. TIM-3 inhibition resulted in significant increase in the number and proliferative state of microglia, NK, and CD8+ cells and higher levels of IFNγ, GrzB and TNFα corresponding to NK and T-cell activate phenotypes.

Interestingly, there was a decrease in the Treg population, which caused an increase in the pro-inflammatory CD8/Treg ratio. Chemokine studies demonstrated an augmentation of CCL5, CCL2 chemotactic chemokines, and CXCL10, IL-1β and IFN-γ pro-inflammatory cytokines in the tumor microenvironment of treated mice. Additionally, DCs, CD4+, and CD8+ cells were increased in treated draining lymph nodes and of functional significance, expressed higher amounts of pro-inflammatory cytokines than in control mice. Interestingly, the depletion NK, CD4 and CD8 immune populations did not completely abrogate the treatment efficacy. However, microglia and macrophages depletion with an anti-CSF1R resulted in a total loss of efficacy indicating a critical role of these populations in the effect of TIM-3 blockade.
Conclusions: These data uncover TIM-3 as a potential target for the treatment of DMG and its role as an immune regulator of the DMG tumor microenvironment.

Cell-based luminescent reporter bioassays for immunotherapies targeting macrophage effector functions
Jonathan Mitchell, Julia Gilden, Jim Hartnett, Pete Stecha, Gopal B. Krishnan, Frank Fan, Mei Cong, Jamison Grailer. *Promega, Madison, WI*

Macrophages play a key role in the elimination of cancer via phagocytosis and presentation of tumor antigens to T cells. Antibody-dependent cellular phagocytosis (ADCP), mediated by macrophages and other myeloid cells, is an important mechanism-of-action (MoA) for antibody-based cancer immunotherapies. Therapeutic strategies that enhance ADCP and other macrophage effector functions can augment direct tumor destruction and enable anti-tumor immunity. ADCP is initiated by binding of antibody Fc domains to Fc gamma receptors (FcgRs), and FcgR crosslinking results in signal transduction that drives inflammatory cytokine production and phagocytosis. Simultaneously, macrophage effector functions are regulated by immune checkpoints. Blockade of these immune checkpoints (e.g., SIRPa, ILT4), or agonists of activation pathways (e.g., TLR receptors) can enhance macrophage effector functions. Current assays to measure macrophage function are tedious, low throughput, and highly variable. Here, we present a suite of cell-based luminescent reporter bioassays to

measure macrophage effector functions: 1) A monocytic cell background was used to measure ADCP via endogenous expression of multiple FcgRs and integration of a FcgR-activation dependent luminescent reporter. 2) Direct detection of cellular phagocytosis can be measured using the HiBiT split luciferase system. 3) Modulation of macrophage-expressed immune checkpoints can be determined using cell-based reporter bioassays for SIRPa/CD47 and ILT4/HLA-G. 4) Activation of TLRs 1, 2, 4, 5 and 6 can be measured using a TLR reporter bioassay. These bioassays are robust, easy-to-use, and are pre-qualified according to ICH guidelines. Together, these novel reporter bioassays provide a robust, high-throughput toolbox to facilitate discovery and development of immunotherapies targeting macrophage effector functions.

Identification of a *lymphocyte activation gene-3*-binding peptides using phage displayed-peptide libraries for cancer immunotherapy

Seok-Min Lee, Byungheon Lee. *Kyungpook National Univ. School of Med, Daegu, Korea, Republic of*

Treatment with immune checkpoint blockades against CTLA-4, PD-1, and PD-L1 is currently giving improved results to many cancer patients. Nevertheless, a significant proportion of cancer patients treated with immune checkpoint blockades are still largely unsatisfied with the benefits of these drugs. One of the reasons is that cancer cells also use other immune checkpoints such as lymphocyte activation gene-3 (LAG-3), T cell immunoreceptor with Ig and ITIM domains, and T-cell immunoglobulin and mucin-domain containing-3. In this study, we screened phage displayed-peptide libraries for peptides that selectively bind to LAG-3. After five rounds of screening, we selected a candidate peptide and named it LAG3Pep. LAG3Pep preferentially bound to human LAG-3-transfected HEK 293T cells over mock-transfected cells and phorbol myristate acetate/ionomycin/chloroquine-stimulated Jurkat T cells over unstimulated cells. LAG3Pep also bound to splenocytes isolated from tumor-bearing mice, suggesting the reactivity across human and mouse LAG-3. Pull-down assay of human recombinant LAG-3 protein using biotin-labeled LAG3Pep yielded a protein band of LAG-3. LAG3Pep showed a high-affinity binding to the LAG-3 protein in SPR assays. Pre-treatment of a LAG-3-blocking

antibody competed the binding of LAG3Pep to stimulated Jurkat T cells. LAG3Pep inhibited the binding of the LAG-3 protein to THP-1 cells expressing HLA-DR, a well-known LAG-3 ligand. In addition, treatment of T-cells with LAG3Pep in combination with a PD-L1-blocking antibody recovered the secretion of IL-2 by T-cells which was suppressed by FGL-1, another ligand of LAG-3, secreted from HepG2 tumor cells in co-culture. Intravenous administration of LAG3Pep in combination with a PD-L1-blocking peptide showed an anti-tumor growth activity in the MC38 syngeneic mouse colon tumor model. These results show that LAG3Pep acts as LAG-3 blockade and, in combination with a PD-L1-blockade, could be a promising tool for cancer immunotherapy.

#6372

In situ detection of various activated immune checkpoints via next-generation proximity ligation assays in tumor tissue

Desirée Edén, Ka I Au Ieong, Naomi Cook, Doroteya Raykova, Agata Zieba Wicher. *Navinci Diagnostics AB, Uppsala, Sweden*

Immune checkpoints (ICs), which are inhibitory signaling pathways that can down-modulate the immune responses of T cells, are pivotal in peripheral tissues and for maintaining immune self-tolerance. Among the many molecularly defined IC proteins, some of the most studied ones are CTLA-4 and its binding partners important for early T-cell co-inhibition, along with the PD-1/PD-L1 axis proteins that carry out late co-inhibitory signals. Notably, in addition to antigen presenting and other immune cells, many tumors also express CTLA-4 and PD-L1, which facilitate tumor evasion from the immune system. The inhibition of these IC proteins has revolutionized the field of cancer therapy, but its efficiency has been limited to a poorly defined subset of patients. Patient outcomes are likely to have a stronger correlation to high levels of PD-1/PD-L1 interaction and other hallmarks of pathway activation, such as PD-1 phosphorylation and recruitment of SHP-2, than to the overexpression of a single IC protein alone. To improve the predictive value of tissue staining, we created an immuno-oncology line of ultrasensitive kits based on proximity ligation, which detect the activation of multiple ICs. Naveni™ PD1/PD-L1 is a tool for direct visualization of the interaction between PD-1 and PD-L1, and has been verified in various FFPE tumor tissues. Naveni™ pY PD1 sensitively

detects PD1 phosphorylation, which is the first step in the PD-1/PD-L1 inhibitory pathway activation. To study the subsequent recruitment of SHP-2 to the activated PD-1 receptor, which is crucial in immune cells but dispensable when the pathway is activated between two tumor cells, one can use the upcoming Naveni™ PD1/SHP-2 kit. Furthermore, we are developing assays to observe the competing interactions of CTLA-4 and CD28 with their binding partners CD80 and CD86, the interplay of which is pivotal for the initiation of early co-inhibition. All kits can be used on consecutive tissue sections to obtain a comprehensive picture of tumor IC pathway activation, which may not always correspond to CTLA-4, PD-1 or PD-L1 overexpression. While these kits have a chromogenic readout applicable to brightfield microscopy, we also have preliminary data on a PD-1/PD-L1 assay with a fluorescent readout thanks to which it can also be multiplexed. The multiplex feature generates an immune profile which may help improve immunotherapeutic strategies. The Naveni™ assays can be applied in basic research to elucidate the interplay of IC axes and downstream molecules, in pre-clinical and clinical research to compare stainings with the existing IHC assays and evaluate the potential prognostic value of interaction detection, and in pharma, aiding the development of new drugs or bispecific antibodies.

#6373

P-selectin glycoprotein ligand-1 modulates the functions of human T cells and macrophages in vitro

Jun Guan[1], Sundee Dees[2], Tony Chadderton[3], Alejandro Amador Arjona[1].
[1]Applied Technology Group, Incyte Research Institute, Wilmington, DE,[2]Biotherapeutics Research Group, Incyte Research Institute, Wilmington, DE,[3]Pharmacology Group, Incyte Research Institute, Wilmington, DE

P-selectin glycoprotein ligand-1 (PSGL-1) is a type I transmembrane protein expressed on the surface of most hematopoietic cells. PSGL-1 can engage multiple ligands (e.g., selectins, VISTA, Siglec-5, versican, CCL19, and CCL21). Apart from being a key adhesion molecule involved in immune cell trafficking, PSGL-1 has been shown to function as a negative immune checkpoint receptor in both T cells and macrophages. PSGL-1 is highly expressed in tumor-infiltrating T cells (TILs) and in tumor-associated macrophages (TAMs) in the tumor microenvironment (TME). PSGL-1 signaling in TILs induces development of T-cell exhaustion and, in TAMs, it promotes immunosuppressive activity of macrophages. In the TME, PSGL-1 is also highly expressed on the surface of myeloid-derived suppressor cells, regulatory T cells, and some types of cancer cells. We hypothesized that PSGL-1 may also act as a ligand to modulate the effector functions of human T cells and macrophages in the TME. In the present study, flow cytometry analysis showed that monocytes and granulocytes had a higher PSGL-1 expression than $CD4^+$ and $CD8^+$ T cells isolated from normal human blood cells. To mimic the cell-expressing PSGL-1, a recombinant human PSGL-1-Fc protein (rhPSGL-1-Fc, R&D Systems) was coated onto 96-well plates overnight. Human peripheral blood mononuclear cells (PBMCs), purified human $CD4^+$ T cells, or $CD8^+$ T cells were cultured in the PSGL-1-coated plates for 3 days in the presence of anti-CD3 antibody. In some experiments, a commercial tool PSGL-1 monoclonal antibody (mAb) with the ability to block PSGL-1/P-selectin interaction was added into the culture system. Cytokine secretion in the culture supernatants was measured using Meso Scale Discovery assays. Similar experiments were also conducted with commercially supplied human M1 and M2 macrophages. The results demonstrated that plate-bound rhPSGL-1-Fc dose-dependently inhibited IFN-γ, IL-2, and TNF-α cytokine production in

human PBMCs, $CD4^+$ T cells, and in $CD8^+$ T cells following T-cell receptor stimulation. The tool PSGL-1 mAb was able to partially rescue the suppression of cytokine production. Plate-bound rhPSGL-1-Fc also inhibited TNF-α secretion from human M1 macrophage, and the PSGL-1 mAb significantly enhanced TNF-α production in both human M1 and M2 macrophages treated with plate-bound PSGL-1-Fc. Together, these data indicate that PSGL-1 expressed on immune cells in TME may act as both an inhibitory ligand and receptor to impact on T-cell and macrophage function.

The role of myeloid cell-expressed PVRL2 in high-grade serous ovarian cancer

Kosuke Murakami, Hirofumi Ando, Michele Doucet, William Huang, Sudipto Ganguly. *The Bloomberg~Kimmel Institute for Cancer Immunotherapy, Johns Hopkins University, Baltimore, MD*

Ovarian cancer (OC) is the fifth leading cause of cancer death in women in the United States. Standard of care (surgical resection and platinum-based chemotherapy) has limited survival benefit for patients with advanced disease. Since 3 of every 4 patients are diagnosed with stage III-IV disease, novel therapeutic approaches are needed to improve survival. In trials with PD1/PD-L1 blockers, patients with OC had modest responses, highlighting an unmet need for effective immunotherapies. Our group has shown the PVRL2-PVRIG node in the DNAM-1 axis suppresses CD8 T cell effector function in syngeneic tumors as well as patient-derived ovarian tumors. This study aims to determine the requirement of tumor- vs myeloid cell-derived PVRL2 for driving immune suppression in OC.Taqman qPCR was conducted for PVRL2, PVR and PD-L1 mRNA expressions of classically activated (M1), and alternatively activated (M2) macrophages from wild-type and $PVRL2^{-/-}$ mice. In our syngeneic OC model, ID8-Vegf-Defb29 (50,000 cells/ovary) were surgically implanted in the ovarian bursa and

monitored for disease progression. These studies were performed in (1) PVRL2$^{-/-}$ mice vs. wild type mice and (2) PVRL2$^{-/-}$ -> Wild-type vs. wild-type -> wild-type bone marrow chimeras. PVRL2$^{-/-}$ ID8-Vegf-Defb29 clones were generated by CRISPR-Cas9, validated for absence of off-target edits by whole exome sequencing and implanted in wild-type and PVRL2$^{-/-}$ mice. Multiplex immunofluorescence (mIF) of PanCK/CD8-CD68-PVRL2/PVR was performed on archived HGSOC tissue from patients treated at Johns Hopkins Hospital. CITE-seq was performed on viable TILs from 6 treatment-naïve and 4 neoadjuvant chemotherapy-treated patients.PVR transcripts were elevated in PVRL2$^{-/-}$ M1 (3.77-fold, p=0.04) and M2 (2.61-fold, p=0.003) macrophages compared to wild type. The expression of PD-L1 was increased in M2 macrophages of PVRL2-/- mice compared to wild-type mice (Mean ratio: 2.28, p=0.04). PVRL2$^{-/-}$ mice and PVRL2 bone marrow chimeras had significantly improved survival compared to their respective control cohorts. Tumors derived from PVRL2$^{-/-}$ ID8-Vegf-Defb29 clones grew slowly in PVRL2$^{-/-}$ mice compared to wild-type mice. PVRL2 and PVR were highly expressed in human HGSOC, and the prognosis was worse for patients with high PVRL2 expression. In mIF, PVRL2 was expressed not only on tumor cells but also on CD68-positive cells. In CITE-seq, PVRL2 and PVR were strongly expressed in macrophage and dendritic cell clusters.The enhanced expression of PVR and PD-L1 in PVRL2$^{-/-}$ M1 and M2 macrophages suggests compensatory activation of co-inhibitory signaling pathways. PVRL2 deficiency selectively in hematopoietically-reconstituted immune cells (primarily myeloid cells) and not in tumor cells conferred a significant survival benefit in our syngeneic OC model. Taken together, blockade of the PVRL2-PVRIG axis in conjunction with PD-1/L1 inhibition may be an effective modality in OC.

Transcriptomic signatures in melanoma lymph node metastasis that relate to immune oncology treatment

Matias A. Bustos[1], Shodai Mizuno[2], Suyeon Ryu[3], Dave S. B. Hoon[4].
[1]Providence Saint John's Health Center, Santa Monica, CA,[2]Translational Molecular Medicine, Providence Saint John's Health Center, Santa Monica, CA,[3]Genome Sequencing Center, Providence Saint John's Health Center,

Santa Monica, CA,[4]Translational Molecular Medicine and Genome Sequencing Center, Providence Saint John's Health Center, Santa Monica, CA

Background: Frequently, patients with primary cutaneous melanoma develop regional lymph node metastasis (LNM). The outcomes in melanoma patients with LNM can be poor, depending on clinicopathological features including the size and the number of the LNM. Newer immunotherapies including immune checkpoint inhibitors (ICI) have significantly improved outcomes in metastatic melanoma patients, and when tumors respond to ICI the durable responses are noteworthy. The aim of the current study is to identify transcriptomics changes in immune-related genes in LNM that correlate to outcomes in melanoma patients receiving adjuvant ICI therapy.
Methods: The analysis were performed in formalin-fixed paraffin-embedded (FFPE) sections from LNM positive (LNM(+); n=17) and LNM negative (LNM(-); n=8) of patients who received surgery at SJHC. For each tissue, a single section was processed and analyzed for 2,002 genes using the direct (mRNA extraction-free) transcriptomic assay of the HTG EdgeSeq AutoImmune Panel (HTG-AI). The HTG-AI transcriptomic normalized data were compared between both groups. For verification of gene signatures, publicly available RNA-seq datasets were obtained from patients with clinical outcomes receiving anti-PD-1. All biostatistical analysis were performed using HTG Reveal and/or GraphPad Prism software.
Results: Comparisons between melanoma LNM(+) and LNM(-) samples showed 229 DEGs (Log2fold-change <-2; >2 FDR<0.01), with 213 genes upregulated and 16 downregulated. Pathway analyses using Reactome indicated that the DEGs in LNM(+) were associated with cytokine, interferon (IFN), and chemokine signaling, as well as signaling by receptor tyrosine kinases (FDR<0.0001). The chemokines *CXCL8*, *CXCL2*, and *CXCL10* were significantly upregulated in LNM(+) (p<0.001). LNM(+) showed significantly higher levels of IFN signaling mediators (*STAT1*, *STAT2*, *IFI6*, *IFI30, IFI44*) compared to LNM(-) specimens (p<0.001). Also, LNM(+) showed a significant increase in *CD276* (B7-H3) levels (p<0.001). Then, we correlated the mRNA levels of IFN signaling (*STAT1*, *STAT2*, *IFI6*, *IFI30*, and *IFI44*) obtained from samples before anti-PD-1

therapy (Nivolumab or Pembrolizumab) to overall survival (OS). Of clinical importance, patients with elevated levels of the IFN signaling genes showed better OS for patients receiving adjuvant anti-PD-1 (HR=0.6, CI=0.42-0.86, Log-rank test, p=0.0044).
Conclusions: We identified a distinctive transcriptomic profile in LNM(+). Several genes were upregulated and associated with specific pathways. Using publicly available data, we demonstrated that *STAT1*, *STAT2*, *IFI6*, *IFI30*, and *IFI44* gene signature correlated with improved OS for patients receiving adjuvant ICI treatment. The *STAT1*, *STAT2*, *IFI6*, *IFI30*, and *IFI44* genes may represent new biomarkers to assess in biopsies of patients that will receive adjuvant or neoadjuvant ICI therapies.

Discovery and preclinical characterization of dual antagonist antibodies targeting both LILRB1 and LILRB2 that enhance innate and adaptive anti-cancer immune responses
Meghan Zuck, Myriam Bouchlaka, Huyen Dinh, Kevin Green, Francisco Zapata, Ramya Chandrasekaran, Tatyana Pisarenko, Lauren Loh, Gajendra S. Naika, Meilyn Sylvestre, Jacob Heit, Raymond Fox, Darbie Whitman, Tom Graddis, Kamal D. Puri, Peter Probst. *OncoResponse, Inc., Seattle, WA*

Background: One cause for the failure of checkpoint inhibitors is the immunosuppressive nature of the tumor microenvironment. LILRB1 (ILT2) and LILRB2 (ILT4) are ITIM-containing inhibitory receptors that recognize HLA Class 1 and nonclassical ligands (e.g., HLA-A, HLA-G, etc.). LILRB1 is expressed on myeloid cells and subsets of B, NK, and T cells, while LILRB2 expression is mostly restricted to myeloid cells. Interaction of LILRB1 and LILRB2 receptors with HLA ligands promotes an inhibitory milieu that prevents T cells from attacking cancer cells. The distinct pattern of expression and function of these lymphoid and myeloid checkpoints suggests complementary targeting approaches for cancer immunotherapy. Dual blockade of LILRB1 and LILRB2 receptors by a single antibody that restores both innate and adaptive immune responses is a promising strategy to enhance efficacy of checkpoint inhibitors.
Methods: Dual LILRB1 and LILRB2 targeting antibodies were cloned from B cells derived from rabbits immunized with human LILRB2 recombinant protein, and subsequently humanized. Antibodies were evaluated for

binding to human LILRB1 and LILRB2 proteins. Dual targeting antibodies were evaluated in a panel of functional and phenotypic assays. Selected antibodies were further tested for efficacy in a humanized NSG-SGM3 tumor model.
Results: Dual antibodies were selected based on binding to recombinant human LILRB1 and LILRB2 protein, as well as blocking of HLA-G binding. These antibodies demonstrated binding to cells expressing LILRB1 and LILRB2, with no appreciable binding to other family members. Lead antibodies demonstrated activity in functional cell-based assays modeling LILRB1- or LILRB2-mediated immunosuppression. Dual antibodies also enhanced IFN-γ production by LPS-stimulated human PBMC. Selected clones restored T-cell function from M2c macrophage-mediated suppression in coculture with $CD8^+$ T cell, and enhanced the tumoricidal activity of NK cells. Importantly, the lead antibody demonstrated in vivo efficacy with significant tumor growth inhibition and tumor regression in an SK-MEL-5 tumor model in humanized NSG-SGM3 mice.
Conclusions: We have identified dual antagonist antibodies targeting both LILRB1 and LILRB2 antibodies that restore both innate and adaptive immune responses. Additionally, dual antibodies restored $CD8^+$ T cell activation from macrophage-mediated suppression and enhanced NK cell cytotoxic activity. These data provide a strong rationale for further development of dual antibodies as an anti-cancer immunotherapy.

A translatable tumor-killing platform with robust sensitivity towards immune checkpoint inhibitor targeted therapeutics

Marie Carkill, Kaitlin Mitchell, Lauren Kelsey, Jezrom Self-Fordham, Nunan Robert, Louise Brackenbury. *Charles River Laboratories, Inc., Bristol, United Kingdom*

The cancer treatment landscape has transformed following the clinical success of early immune checkpoint inhibitors (ICI) which demonstrate the remarkable power of harnessing the immune system to treat a variety of metastatic cancers. Despite the success of Pembrolizumab, Nivolumab and Atezolizumab, the programmed cell death protein-1 (PD1)-programmed death ligand-1/2 (PD-L1/L2) pathway remains a tractable target for many drug discovery programs, particularly for bi-specific or combinational

therapies. The PD1 - PD-L1/L2 pathway is important in protecting the host from uncontrolled immune responses, but can be hijacked by tumors, rendering them resistant to immune attack. Antibodies which antagonize this pathway potentiate T-cell mediated tumor destruction yet do not show efficacy in all patients or guarantee long-term protection, in part due to tumor-associated ICI-resistance mechanisms. There is a distinct need to develop novel ICI therapeutics and robust, complex co-culture platforms to better predict clinical efficacy. Here we outline a series of translationally relevant co-culture assays using Pembrolizumab as a benchmark therapeutic alongside other ICI. PD-1 expression levels are known to be low on resting T cells, as indeed are many checkpoint receptors, and so to enhance the therapeutic window, CD3+T cells from healthy human donors were polyclonally stimulated before addition to SK-OV-3 target cell cultures. The SK-OV-3 tumor line was stably transduced with NucLight Red (NLR) to allow co-localization of the caspase 3/7 signal to tumor cells. Autologous, mature monocyte-derived dendritic cells (moDC), expressing high levels of PD-L1/PD-L2 were added into tri-cultures in a 2D tumor killing assay. Tumor killing kinetics were quantified via live cell imaging using an Incucyte S3. Although Pembrolizumab enhanced immune-mediated direct (pre-stimulated) T cell killing, the therapeutic window increased in the presence of autologous moDC. Using a modified 3D (tumor spheroid) format over a longer time course, Pembrolizumab was also shown to enhance PBMC-mediated killing and the ability of moDC to enhance this effect further was determined. In recent years, the development and implementation of combinatorial approaches has resulted in significant improvements in patient responsiveness and disease outcomes for various cancers. Here, we describe a suite of tumor killing assays which can be adapted to multiple tumor or therapeutic targets, with a focus on immune involvement. ICI are shown to work robustly and efficacy tracks expression of the relevant checkpoint receptors, making this a powerful format in which to test combination therapies or novel ICI.

An *in vitro* human CD8 T cell exhaustion model for the functional screening of immune checkpoint inhibitors

Roberto Carrio[1], Margot Cucchetti[2], Mikielia Devonish[1], Louis Poisson[1], Mihaela Babiceanu[1], Andrew Kettring[1], Yingchun Liu[3], Donald Jackson[3],

Evan Gomes[1], Jeremy Baudhuin[2], Donald R. Drake[1], Valeria Fantin[4], Anthony Byers[1], Ingrid Sassoon[2]. *[1]Sanofi, Orlando, FL,[2]Sanofi, Vitry-sur-Seine, France,[3]Sanofi, Boston, MA,[4]Sanofi, San Franciso, CA*

T cell exhaustion is a state of dysfunction that frequently occurs during chronic infections and cancer due to persistent antigen stimulation and inflammation. It is defined by poor effector function, sustained expression of inhibitory receptors, and a transcriptional state distinct from that of functional effector or memory T cells. In this state, cells remain in the local environment but lack effector functions necessary to combat the tumor or infection. In the current study, we developed an *in vitro* human antigen-specific CD8 T cell exhaustion model to evaluate the ability of immune checkpoint inhibitors to restore functionality to exhausted T cells. Using the fully human, autologous MIMIC (**M**odular **IM**mune **I**n vitro **C**onstruct) effector CD8 T cell assay as a framework, we assessed the effect of antigen dose, timing, and frequency of repeated antigen stimulation with antiviral HLA Class I-restricted peptides to drive the development of Ag-specific CD8 T cells toward an exhausted state. Epitope-specific CD8 T cell responses were monitored by HLA class I-restricted pentamers and establishment of an exhausted profile was evaluated by increased expression of inhibitory co-stimulatory receptors and decreased intracellular expression of antiviral effector cytokine via flow cytometry relative to functional Ag-specific CD8 T cells from the same donor. Repeated antigen exposure led to decreased production of IFN-γ and TNF-α and increased expression of inhibitory co-stimulation markers on antigen-specific CD8 T cells. After establishment of an exhausted phenotype, treatment with various immune checkpoint inhibitor molecules restored functionality to Ag-specific CD8 T cells upon an additional antigen re-stimulation. Moreover, here using this model we characterized distinct transcriptomic signatures of functional and exhausted MIMIC CD8 T cells. Development of an in vitro human viral antigen-specific CD8 T cell exhaustion model with characteristic features of dysfunctional CD8 T cells as observed *in vivo* and the ability to restore effector function by treatment with immune checkpoint inhibitors, provides a platform to assess the effectiveness of therapeutic mono-specific or bi-specific “checkpoint blockade” antibody candidates and, in general, the potential to evaluate a myriad of immunotherapeutic approaches for cancer treatment.

#6380

Ultrasensitive detection of circulating human PD-1 and PD-L1 using Single Molecule Counting (SMC) technology

Laila Faramarzi, Wen-Rong Lie, Rick Wiese, Jared Fiske. *MilliporeSigma, St. Louis, MO*

Immune checkpoint proteins are key regulators of the immune system and potential drug targets for cancer immunotherapy. Cancer immunotherapy targeting immune checkpoint, like programmed cell death protein-1 (PD-1) and programmed cell death ligand 1 (PD-L1) inhibitors has shown treatment efficacy for a broad spectrum of human cancers. Immune checkpoint molecules PD-1 and PD-L1 are expressed on the cell surface of immune cells and tumor cells. Recent studies have also reported these immune checkpoint proteins may undergo alternative splicing or proteolytic cleavage to produce soluble checkpoint proteins. Multiple molecular forms of soluble PD-1 (sPD-1) and PD-L1 (sPD-L1) are detectable in patient sera of multiple types of cancer, and these soluble checkpoint proteins have been reported as putative liquid biopsy biomarkers in the diagnosis and prognosis of oncological disease. Though the clinical significance of circulating soluble immune checkpoint protein profiles as predictive biomarkers has yet to be fully explored and validated, we have committed to develop better and more reliable bioassays to further this research. With that, we have developed 2 Luminex-based multiplex immunoassays for simultaneous quantitation of 48 immune checkpoint proteins, including PD-1 and PD-L1, for patient sera and tumor lysate samples. Here we report the development of 2 novel Single Molecule Counting (SMC) technology-based ultrasensitive single-plex immune checkpoint immunoassays for the detection of sPD-L1 and sPD-1 in human serum and plasma samples. Comparative studies demonstrate these SMC ultrasensitive assays possesses at least 10-100-fold higher sensitivity as compared with the Luminex-based immunoassays. Using these novel ultrasensitive assays, we have validated the detection of significant increases in sPD-L1 and sPD-1 in cancer serum samples as compared with the levels in healthy controls. We have also applied these high sensitivity assays to measure human PD-L1 and PD-1 biomarkers in other sample types including urine, tumor lysates and exosomes. In conclusion, we envision that these PD-1 and PD-L1 SMC

assays may overcome a major limitation in biomarker utility and enable the ultrasensitive detection of sPD-1 and sPD-L1 in liquid biopsy and blood biomarker research.

#6381

Quantitative multiplex analysis of soluble and cellular immune checkpoint proteins in response to interferon gamma across multiple murine tumor models

Wen-Rong Lie[1], Ryan Bucktrout[2], Sanjukta Chakraborty[2], Andrea Orlando[2], Inna Serganova[2], Christine Kornmeier[1], James Hoberg[1], Roberta Zappasodi[2]. *[1]MilliporeSigma, St. Louis, MO,[2]Joan & Sanford I. Weill Medical College of Cornell University, New York, NY*

Immune checkpoint proteins are key regulators of the immune system and drug targets of cancer immunotherapy. Immune checkpoint molecules have been found on the cell surface of various tumor cells and immune cells as immune activating or inhibitory receptors and ligands. Recent studies have shown these immune checkpoint proteins can undergo alternative splicing or proteolytic cleavage leading to soluble isoforms. IFNγ is a pleiotropic and multifunctional cytokine commonly released by cytotoxic immune cells. IFNγ production can be enhanced in response to immunotherapy and further modulates the expression of immune checkpoints in the tumor microenvironment. To better understand the immune checkpoint signatures in tumors, we developed a 28-plex mouse checkpoint protein multiplex immunoassay for quantitative analysis of soluble (secreted) and cellular immune checkpoint proteins. Using this immunoassay, we tested 16 mouse cell lines of tumor (n=13) and normal tissues as control (n=3): 2 melanomas (B16F10, YUMM1.7), 3 mammary carcinoma (4T1, NT5, AT-3), 1 lung carcinoma (LLC), 1 prostate cancer (MycCaP), 1 fibrosarcoma (MCA205), 1 ovarian cancer (ID8), 1 bladder cancer (MB49), 1 glioma (CT-2A), 2 blood cancer (RAW, EL4), 1 dendritic cells (DC2.4), 1 myoblast cells (C2C12), and 1 endothelial cells (bEnd.3). We analyzed changes in immune checkpoint protein expression and secretion in these cell lines cultured in normal conditions or upon exposure to IFNγ to reflect an immune inflamed microenvironment. Cells were cultured in 96-well plate, 100 mm, or 150 mm Petri dishes, and treated with either 10 ng/ml or 100 ng/mL mouse IFNγ. Cell culture supernatants and cell lysates were harvested after 6h,

12h, or 24h incubation with IFNγ and processed for multiplex Luminex bead-based immunoassay. The soluble and cellular checkpoint proteins most substantially modulated by IFNγ treatment in these cell lines included: CD137, BTLA, HVEM, PD-L1. The tumor-specific signature of cellular and soluble checkpoint proteins and its response to IFNγ may have implications in the tumor microenvironment and in the outcome to immunotherapy.

Activation of transcription factors, p65 and NFATc1, mediated by WNT5a, induces up-regulation of novel immune checkpoint CNTN4 expression

Mi Young Cha, Bu-Nam Jeon, Hyeokgu Kang, Kyung Mi Park, Hansoo Park. *Genome & Company, Sungnam-si, Gyeonggi-do, Korea, Republic of*

We previously confirmed that contactin 4 (CNTN4) is highly expressed in the various human tumor tissues and inhibits mouse and human T cell activity by suppressing a cascade of signaling processes associated with T cell activation through binding with amyloid precursor protein (APP) of T cells. However, the molecular mechanism for the expression of CNTN4 in tumors has yet to be elucidated. So, we investigated whether oncogenic ligands regulate the expression of CNTN4 through *CNTN4* promoter (-2,000 bp ~ + 100 bp)-based reporter gene assays in HEK293 cells using oncogenic ligands. Here, we identified that WNT5a significantly increased the expression of CNTN4 in a dose-dependent manner. Furthermore, the treatment of the WNT5a ligand in the human colorectal cancer cell line SW480, which expresses CNTN4 at a low level, increased the expression of CNTN4. In addition, CNTN4 expression was decreased when the WNT5a antagonist (Box5, a WNT5a-derived N-butyloxycarbonyl hexapeptide) was treated in the human osteosarcoma cell line U2OS expressing CNTN4 endogenously. The changes in the expression of CNTN4 were observed by RT-PCR and FACS. Treatment of the WNT5a ligand or WNT5a antagonist changed the transcriptional expression of CNTN4 in each cell line and affected the cell surface expression of CNTN4. Since WNT5a ultimately increases the activity of transcription factors such as NFATc1 or p65 to increase the transcriptional expression of the target gene, we further investigated the effect of NFATc1 or p65 on the expression of CNTN4. We

found that NFATc1 or p65 binds to the promoter of CNTN4 and increases the expression of transcription. Moreover, it was recently reported that anti-PD-1-refractory melanoma exhibits elevated WNT ligand signaling activity, especially upregulated WNT7b and WNT5a in the WNT ligands. Following this background, the expression level of CNTN4 can be increased in the refractory environment to immunotherapy induced by elevated WNT signaling. Therefore, we constructed B16F10 murine melanoma cells overexpressing WNT5a (B16F10/WNT5a) to assess the anti-tumor efficacy by administering GENA-104A16, the anti-CNTN4 humanized monoclonal antibody, in the syngeneic mice model with increased expression of CNTN4 induced by WNT5a, and *in vivo* efficacy by treatment of GENA-104A16 is under assessment in the B16F10/WNT5a syngeneic mice model. Through the investigation, we expect to support the rationale and strategy for a combination therapy approach of GENA-104A16 for non-responding patients to immunotherapy.

ATG-034, an LILRB4 antagonist antibody, reinvigorates dendritic cells and prevents tumor progression

Ao Sun[1], Enlin Zheng[1], Huili Cao[1], Mengshi Cao[2], Suya Bai[2], Peng Chen[1], Linjie Tian[3], Jay Mei[1], Bo Shan[4], Bing Hou[4]. *[1]Antengene Corporation, Shanghai, China,[2]Antengene (Hangzhou) Biologics, Hangzhou, China,[3]Antengene Biotech LLC, Doylestown, PA, China,[4]Antengene Corporation, Shaoxing, China*

Background: Dendritic cells (DCs) are vital for initiating antigen-specific T cell-dependent antitumor immune responses. However, emerging evidence reveals that local DCs within the tumor microenvironment (TME) are tolerized to facilitate immune evasion. Reprogramming of DCs is recognized as a promising strategy for tumor immunotherapy. Leukocyte immunoglobulin-like receptor B4 (LILRB4) is an inhibitory receptor belonging to the LILR family which is mainly expressed on normal myeloid cells and myeloid-derived malignant cells. It is upregulated on tolerogenic DCs (tolDCs), which exhibit low expression levels of costimulatory molecules and resistance to DC maturation. Targeting LILRB4 to reprogram tolDCs has been reported to be a promising strategy for cancer

treatment. Here we report the preclinical development of an LILRB4 antagonist antibody, ATG-034.
Method: The protein-based and cell-based binding affinity of ATG-034 were measured using SPR, ELISA and FACS analysis. Fc receptor (FcR) stimulation assay was used to evaluate the ability of ATG-034 to block the interaction of LILRB4 with its ligand fibronectin. ATG-034-mediated enhancement of antigen presentation and co-stimulation ability of DCs was determined by FACS analysis for the change of surface expression of HLA-DR, HLA-ABC, CD86, and CD206. The mixed lymphocyte reaction (MLR) assay was used to assess the immunomodulatory potential of ATG-034. The *in vivo* antitumor efficacy of ATG-034 was evaluated in a radiation therapy-resistant murine Lewis lung carcinoma (LLC) syngeneic model.
Results: ATG-034 binds to LILRB4 protein with a single-digit nM affinity. It potently reversed the fibronectin-mediated inhibition of FcR-driven TNF-α cytokine production. TolDCs were reprogrammed by ATG-034 to immunogenic DCs with significant upregulation of the expression of HLA-DR, HLA-ABC, CD86 and downregulation of the expression of CD206. Furthermore, ATG-034 remarkably reinvigorated tolDCs for priming T cell activation with noticeable upregulation of the expression of CD25 and the secretion of IFN-γ, enhancing antitumor immunity. In addition, 10 mg/kg ATG-034 significantly inhibited the LLC tumor growth *in vivo* with a TGI of 40.28%, while a benchmark antibody only demonstrated a 24.43% TGI.
Conclusion: Our data show that ATG-034 reprograms tolDC, enhancing anti-tumor immunity, and demonstrates potent *in vivo* anti-tumor efficacy. Therefore, ATG-034 may be a promising strategy for the treatment of cancer.

Immune Mechanisms Mediated by Other Therapies

High dose acetaminophen with n-acetylcysteine rescue inhibits M2 polarization of tumor associated macrophages.

Alexander Neuwelt, Allyn Bryan, Won Lee, Pavani Pingali, Howard Li, Bhaumik Patel. *Veterans Affairs, Richmond, VA*

Background: High dose acetaminophen (AAP) with n-acetylcysteine (NAC) rescue is among the few treatments that has shown a signal of activity in phase I trials (21% response rate, 3/14 assessable patients) without achieving dose limiting toxicity that has not progressed to evaluation in later line studies. We have previously shown that high dose AAP selectively depletes glutathione in the liver but not the tumor, suggesting that NAC, the FDA-approved antidote for AAP toxicity and a glutathione precursor, may selectively rescue the normal liver but not the tumor from high dose AAP. While the anti-tumor effects of AAP/NAC appear to not be mediated by glutathione depletion and free radical injury, the mechanism of anti-tumor effects of AAP/NAC has not been definitively characterized.
Methods: In vitro the effects of Vehicle, AAP, or AAP/NAC was evaluated on bone marrow derived macrophages polarized to M2 and M1 phenotypes using IL-4 or IFN/LPS, respectively. Tumor cell viability was assessed with MTT assay. Effects of AAP on IL-4/STAT6 (M2) or IFN/LPS/STAT1 (M1) signaling, and downstream gene and protein expression was studied. In vivo, effects of AAP/NAC on tumor size and tumor associated macrophage polarization were characterized in orthotopic triple negative breast tumor models 4T1 and EF43.fgf4 using cytokine elisa of tumor lysate and flow cytometry.
Results: NAC reversed AAP toxicity in the normal liver but did not reverse AAP cytotoxicity against tumor cells in vitro. AAP/NAC selectively inhibited IL-4-induced STAT6 phosphorylation but not IFN/LPS-induced STAT1 phosphorylation. Downstream, AAP/NAC inhibited IL-4 induction of M2-associated genes (such as CCL24, YM1 and arginase) and proteins (arginase, PD-L2, and CD206). However, AAP/NAC did not inhibit IFN/LPS induction of M1-associated genes (IL-6, TNF, IL-12) and proteins (INOS, PD-L1, MHC I, and CD64). In vivo, AAP/NAC inhibited tumor growth in EF43.fgf4 and 4T1 triple negative breast tumors. Flow cytometry of tumor associated macrophages revealed that AAP/NAC selectively inhibited M2 but not M1 polarization. ELISA of tumor lysate demonstrated relatively stable expression of IFN gamma but markedly suppressed expression of IL-10 in the tumor immune microenvironment.
Conclusion: Our study is the first to show that at high doses AAP/NAC has profound effects on the tumor immune microenvironment that may facilitate immune-mediated inhibition of tumor growth.

#6389

Differential role of CD8 cells and CD4 cells in anti-tumor immunity triggered by tumor cell apoptosis using HSVtk/GCV system

Sho Umegaki, Hidekazu Shirota, Tomoyuki Iwasaki, Yuki Kasahara, Chikashi Ishioka. *Medical Oncology, Tohoku University Hospital, Sendai, Japan*

Immune cells can recognize tumor antigens and elicit an adaptive immune response, potentially resulting in tumor regression. Drug-induced dead tumor cells have been reported to enhance anti-tumor immunity, but results are conflicting, possibly due to the immunosuppressive effects of the cytotoxic drugs. To investigate whether apoptotic tumor cells trigger anti-tumor immunity independent of anti-cancer treatment, local immune responses were evaluated after direct induction of tumor cell apoptosis using a herpes simplex virus thymidine kinase (HSV-tk)/ganciclovir (GCV) system. The inflammatory cytokines IFNγ and IL-12β and anti-inflammatory factor PD-1 and TGFβ1 were upregulated at the tumor site after apoptosis induction. HSV-tk/GCV-induced tumor cell apoptosis resulted in suppression of tumor growth in vivo and promoted the infiltration of CD8 and CD4 T lymphocytes in tumor. To explore the role of T cells after induction of tumor cell death, GCV was administered together with anti-CD8 or anti-CD4 depleting antibodies to syngeneic HSV-tk transfected tumor-bearing mice. CD8 T cell depletion abrogated the anti-tumor efficacy of GCV, indicating that tumor regression was mainly dependent on CD8 T cells. This anti-tumor immunity was enhanced by anti-PD-1 antibody injection. On the contrary, CD4 T cell depletion further inhibited tumor growth than GCV alone, suggesting the potential role of CD4 T cells in suppressive tumor immunity. To elucidate this immunological mechanism, tumor tissues were evaluated after tumor cell apoptosis and CD4 T cell depletion. Foxp3, a regulatory T cell marker, was decreased after CD4 T cell depletion. In addition, Arg1, a marker of immunosuppressive myeloid cells, was significantly downregulated, which was expressed on tumor-associated macrophages (TAMs) and monocytic myeloid-derived suppressor cells (mMDSCs). Collectively, these findings indicate that tumor cell apoptosis accelerates CD8 T cell-dependent anti-tumor immunity and CD4 T cell-mediated Arg1 production from TAMs and mMDSCs.

#6390

N17350 is an emerging therapeutic modality that selectively kills cancer cells and stimulates anti-tumor immunity

Ravindra Gujar[1], Chang Cui[1], Lilibet Valdovinos[1], Christine Lee[1], Arezoo Arjmand[1], Nicole Grigaitis[1], Asna Khalid[1], Catherine A. Reardon[2], Kelly Q. Schoenfelt[2], Sonia Feau[1], Chris Twitty[1], Lev Becker[1]. *[1]Onchilles Pharma, Inc., San Diego, CA,[2]University of Chicago, Chicago, IL*

INTRODUCTION: Cancer is a disease driven by variable genetic mutations. Overcoming this variability while sparing normal cells has stymied broad-acting therapy development. Our innate immune system evolved to clear genetically diverse pathogens and limit host toxicity, raising the possibility that it can produce similar effects in cancer. Previous studies showed that neutrophil elastase (ELANE) - a neutrophil-derived serine protease - killed a wide range of cancer cells without harming non-cancer cells by cleaving CD95, the FAS receptor (Cui et al.,Cell, 2021). ELANE attenuated primary tumor growth and produced a CD8+T cell-mediated abscopal effect to attack metastases. Here we leveraged this ELANE-mediated pathway to produce an optimized N17350 biologic and tested its effects on tumor development, both as a monotherapy and in combination with checkpoint inhibitors. Our findings underscore the viability of N17350 as a new therapeutic modality leveraging innate immunity.

METHODS: Anti-cancer effects of N17350 were examined in vitro and in vivo and compared with standard of care (SoC) agents. For in vitro studies, cells were treated with N17350 and viability was quantified by calcein-AM and immunogenic cell death (ICD) markers. Cancer/non-cancer cells included human/murine cell lines and primary cells isolated from healthy donors and ovarian cancer patients. We further tested the ability of cancer cells to develop resistance to N17350 and FAS-L. For in vivo studies, a single dose of N17350 was delivered intratumorally into CT26 (colon) and 4T1 (metastatic breast) tumors. Effects on primary and metastatic tumor growth, immunology, and survival were assessed in comparison to SoC agents (oxaliplatin, cyclophosphamide) or in combination with a checkpoint inhibitor (anti-CTLA4).

RESULTS: N17350 killed and induced ICD markers in all cancer cell types tested without harming non-cancer cells, while SoC agents were similarly toxic to both cell types. Repeatedly killing E0771 cancer cells with N17350 did not produce resistance, which was observed with a FAS-L that targets CD95 via a distinct mechanism. A single intra-tumoral dose of N17350 produced durable effects in the 4T1 and CT26 models (CT26:75%-100% tumor-free). N17350 induced a robust innate/adaptive immune profile, abscopal effect to limit 4T1 lung metastasis, and synergized with anti-CTLA4 in cold (4T1) and hot (CT26) tumors. Finally, N17350 showed markedly improved efficacy over SoC agents in both models.
CONCLUSIONS: Taken together, our data suggest that N17350 selectively kills cancer cells, produces complete responses in a subset of mice, induces favorable innate and adaptive immunology, and combines with checkpoint inhibitors in cold and hot tumors. Its ability to escape resistance, produce abscopal effects, and outperform SoC chemotherapies warrants further studies of this unique therapeutic modality in a clinical setting.

#6391

Development of a novel strategy for cancer immunotherapy based on tumor immunogenicity improvement by HLA-drug interaction

Takeshi Susukida[1], So-ichiro Sasaki[1], Tomohiro Shirayanagi[2], Shigeki Aoki[2], Kousei Ito[2], Yoshihiro Hayakawa[1]. *[1]University of Toyama, Toyama, Japan,[2]Chiba University, Chiba, Japan*

[Purpose] Tumors with low T cell infiltrates (poor immunogenicity) display lower probability of clinical response to immune checkpoint inhibitors. To achieve higher immunotherapy efficacy, it is imperative to establish a novel strategy for improving immunogenicity. Abacavir (ABC), an anti-HIV drug, binds to the specific allele of human leukocyte antigen (HLA-B*57:01) and activate $CD8^+$ T cells by presenting altered abnormal peptides. In this study, we considered the immune interaction between ABC and HLA-B*57:01 improving immunogenicity in poorly immunogenic tumors leading to a potent anti-cancer effect.
[Methods] Mice were inoculated subcutaneously with tumor cells into the right flanks and interperitoneally treated with either ABC 5 mg or vehicle (water) for consecutive 9 days (B16F10) or 13 days (3LL) after tumor inoculation. Each tumor size was measured using vernier calipers on every

2 days. Activation, proliferation, and IFN-γ secretion of tumor infiltrating $CD8^+$ T cells were analyzed by FACS.
[Results and Discussion] ABC treatment showed significant tumor growth inhibition associated with $CD8^+$ T cell infiltration into tumor in mice inoculated with HLA-B*57:01 expressing B16F10 melanoma or Lewis lung carcinoma (3LL) cells, but neither in HLA-B*57:03 (negative allele)-expressing nor control tumors inoculated mice. Moreover, the tumor infiltrating $CD8^+$ T cell were immune-activated and proliferated, with secreting IFN-γ. In contrast, ABC-induced anti-tumor effect was abrogated in $CD8^+$ T cell-depleted mice, IFN-γ KO mice, and CXCR3-blocked mice. The combination therapy with anti-PD-1 antibody treatment induced better inhibition of tumor growth than ABC monotherapy in HLA-B*57:01 expressing B16F10 inoculated mice. These results suggested that ABC/HLA-B*57:01 interaction could improve tumor immunogenicity associated with $CD8^+$ T cell-mediated anti-tumor effect in poorly immunogenic tumors. This finding lays a foundation to develop a novel drug-induced cancer immunotherapy targeting immune resistant tumors.

Combination of pulsed electric field, immunotherapy and cisplatin significantly prolongs survival in an orthotopic breast cancer mouse model

Chiara Pastori[1], Mukta Wagh[1], Ebtesam Nafie[1], Fatima Murad[1], Mohit Trikha[2], Robert Neal[1]. *[1]Galvanize Therapeutics Inc, San Carlos, CA,[2]Apple Tree Partners, New York, NY*

Introduction: Pulsed Electric Field (PEF) therapy is a novel approach to treat cancer by providing focal tumor ablation while sparing sensitive structures within the tumor micro-environment. Previous studies have demonstrated that PEF induces immunogenic cell death by activating inflammatory signaling pathways and stimulation of antigen presenting cells withing the tumor micro-environment. PEF ablation provides a tumor focused *in situ* vaccination strategy that combines with checkpoint blockade. We hypothesized that PEF ablation should synergize with chemotherapy and anti-PD1 in a model where checkpoint inhibitors are inactive.

Experimental Design: To test this hypothesis, we utilized a highly aggressive syngeneic orthotopic triple negative breast cancer 4T1 mouse model that is non-responsive to anti-PD1 and only marginally responsive to cisplatin to determine if this combination treatment could prolong survival. Thirty-two Balb/c mice were inoculated in the mammary fat pad with 200,000 4T1 cells. Once tumors were established (5mm in diameter), animals were randomized to the following groups: (A) Sham/IgG control (n=8; needle inserted but no PEF), (B) PEF only (n=8), (C) cisplatin + anti-PD-1 (n=8) and (D) PEF + cisplatin + anti PD-1 (n=8). Tumors in groups B and D were treated once with PEF. Anti-PD1 and isotype matched control IgG was administered once per week (200μg, i.p injections) starting on the day of PEF (Group D) for four weeks. Cisplatin was administered (2mg/kg, i.v) once per week for four weeks starting on the day of PEF (d=0) for four weeks. All the mammary fat pad tumors were resected when they achieved a tumor volume of ~200 mm^3 to recapitulate post-resection metastatic relapse (See Schematic 1).
Results and Conclusions: All mice in the Sham-control IgG group needed to be euthanized by day 43 due to metastases in multiple organs including lungs, bones, liver and brain. All mice in the cisplatin + anti PD-1 group had to be euthanized by day 74. Interestingly, all groups that were treated with PEF survived much longer. On day 90, 28% of mice in the PEF alone group were alive and 43% were alive in the PEF + anti-PD1 + Cisplatin (see Figure 1). The rank-log p-value for the Kaplan-Meier survival curve was statistically significant.
In conclusion, our results demonstrate that PEF treatment in combination with anti-PD1 and Cisplatin significantly prolongs survival in a highly aggressive triple negative breast tumor mouse model that is non-responsive to immunotherapy. These findings support evaluation of PEF in cancer patients that are receiving combination of checkpoint blockade and chemotherapy.

Atovaquone promotes release of damage-associated molecular patterns from epithelial ovarian cancer cells

Mayra A. Betancourt Ponce[1], Nicha Boonpattrawong[1], Sejal Sharma[1], Jenny Gumperz[2], Manish Patankar[1], Lisa Barroilhet[1]. [1]*University of*

Wisconsin Carbone Cancer Center, Madison, WI,[2]University of Wisconsin, Madison, WI

Epithelial ovarian cancer (EOC) is the deadliest gynecologic cancer in the United States. Most patients are diagnosed with EOC at advanced stages and have limited treatment options. Developing new therapies that are effective against localized and disseminated disease is imperative. Unfortunately, clinical trials evaluating immunotherapies in EOC have not been consistently effective. Preclinical data have shown that neoadjuvant chemotherapy can help increase antigen presentation and T cell infiltration, as well as decrease immunosuppressive effectors, suggesting that combining cytotoxic chemotherapy with immunotherapies can be a powerful approach to potentiate antitumor responses in EOC. However, studies looking at the combination of immunotherapies with carboplatin and paclitaxel, which are the mainstay chemotherapies for EOC, have not improved progression-free survival rates. We propose a novel combination approach using the well-tolerated, FDA-approved, oxidative phosphorylation (OXPHOS) inhibitor atovaquone as a sensitizer to cellular immunotherapies for EOC. OXPHOS inhibition leads to oxidative stress, which in turn leads to DNA and protein damage, activation of stress response pathways, and ultimately cell death. During cell injury and death, Damage-Associated Molecular Patterns (DAMPs) can be released into the extracellular environments, activate the innate immune system, and lead to immunogenic cell death. We have previously shown that atovaquone leads to increased reactive oxygen species levels and DNA damage. Thus, we hypothesized that atovaquone treatment would lead to release of DAMPs, including HMGB1 and TFAM, from EOC cells. Following treatment with atovaquone, we collected the supernatant of EOC cell cultures at different timepoints and measured HMGB1 and TFAM concentrations via enzyme-linked immunosorbent assays (ELISAs). We observed that both HMGB1 and TFAM concentrations were elevated at 24 and 48 hours following atovaquone treatment. This suggests that atovaquone can facilitate immune detection and attack by promoting DAMPs release. When DAMPs are released into the extracellular environment, they are recognized by innate immune cells, which become activated to produce pro-inflammatory cytokines and increase antigen presentation to T cells. Given our results showing increased release of DAMPs following exposure to atovaquone,

we are developing an in vitro culture system to study immune cell responses to atovaquone-treated EOC cells. We are also monitoring transcriptomic responses of EOC cells treated with atovaquone to identify changes in expression of DAMPs and other immune-activating pathways through RNA sequencing. Our ultimate goal is to test T cell recognition and responses toward atovaquone-treated EOC cells with the intention of utilizing this chemotherapeutic agent as an adjunct to immunotherapeutic efforts for EOC.

BET inhibition alleviates T-cell dysfunction in chronic lymphocytic leukemia

Audrey L. Smith[1], Alexandria P. Eiken[1], Sydney A. Skupa[1], Christopher R. D'Angelo[2], Avyakta Kallam[2], Matthew A. Lunning[2], Gregory Bociek[2], Julie M. Vose[2], Ben Powell[3], Gideon Bollag[4], Dalia El-Gamal[1]. *[1]Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska Medical Center, Omaha, NE,[2]Division of Hematology and Oncology, University of Nebraska Medical Center, Omaha, NE,[3]Plexxikon Inc., South San Francisco, CA,[4]Opna Bio, LLC, South San Francisco, CA*

Background: The chronic lymphocytic leukemia (CLL) tumor microenvironment (TME) is laden with hyporesponsive T-cells that permit disease persistence. Yet, redundant TME immunosuppressive mechanisms and epigenetic maintenance of T-cell exhaustion limit the efficacy of T-cell targeted therapies in CLL. Bromodomain and extra-terminal (BET) proteins regulate key pathways contributing to CLL pathogenesis and TME interactions, including T-cell function and differentiation. We hypothesize that blocking BET protein function can reverse T-cell exhaustion to yield durable tumor elimination in CLL.
Methods: WT C57BL/6 mice were engrafted with Eμ-TCL1 spleen-derived lymphocytes, then treated daily with the novel pan-BET inhibitor, OPN-51107 (OPN5; 20mg/kg PO) for up to 4 weeks. Splenic gene expression was evaluated with the NanoString PanCancer iO360 panel. T-cell differentiation status, immune inhibitory receptor (IR) expression, proliferation (72 h ex vivo α-CD3/α-CD28 stimulation), and cytokine production (6 h ex vivo PMA/ionomycin stimulation) was measured via flow cytometry. CLL patient and healthy donor PBMCs were used for

validation studies and to assess T-cell transcription factor (TF) expression via flow cytometry. Evaluation of BRD4 occupancy at select T-cell TFs via ChIP qPCR is ongoing.
Results: OPN5 significantly increased cytotoxic cell signatures and reduced exhaustion-associated cell signatures in leukemic mice through inhibition of T-cell exhaustion signaling, as well as activation of Th1, natural killer cell, and IL-7 signaling pathways. Correspondingly, T-cells from OPN5-treated mice demonstrated greater ex vivo proliferative capacity and effector response to stimuli. A greater proportion of CD8+ T-cells from OPN5-treated mice were classified as naïve, and OPN5 significantly reduced KLRG1 expression on antigen-experienced CD8+ T-cells. Importantly, OPN5 curtailed IR co-expression (PD-1, PD-L1, VISTA, CD244, CD160, and LAG3) on splenic T-cells. These findings were confirmed with primary CLL cells ex vivo. OPN5 also impaired expression of terminal differentiation-associated TFs in CLL patient-derived T-cells, enriching for a TCF1+ progenitor T-cell population. While BTK inhibitors are known to similarly improve T-cell function in CLL, ibrutinib treatment was inadequate to revert CLL T-cell terminal differentiation. Future ATAC-sequencing analysis will inform how BET inhibition alleviates exhaustion-associated chromatin organization in CLL T-cells.
Conclusion: BET inhibition dismantles immunosuppressive mechanisms in the CLL TME, alleviating CLL-induced T-cell dysfunction and terminal differentiation. These findings suggest that BET inhibition may be a useful component of combination strategies for the treatment of CLL to yield lasting anti-cancer immune memory and prevent relapsed/refractory disease.

Eribulin acts as an immune adjuvant to enhance the antitumor efficacy of STING agonists in triple-negative breast cancer models

Leila Takahashi-Ruiz, Charles S. Fermaintt, Nancy Wilkinson, Peter Y. Chan, Susan L. Mooberry, April L. Risinger. *Pharmacology, UT Health Science Center at San Antonio, San Antonio, TX*

Triple-negative breast cancer (TNBC) is a heterogenous subtype of breast cancer lacking effective targeted treatment options. However, TNBC typically has a higher mutational burden and greater degree of

immunogenicity than other breast tumors, making immunotherapy a viable strategy for effective treatment. Strategies to improve the response of TNBC patients to immunotherapy include the upregulation of the cGAS-STING innate immune sensing pathway and STING agonists are in clinical development. We previously showed that eribulin, a microtubule destabilizer used in the treatment of TNBC, functions as an indirect STING agonist because it promotes the release of mitochondrial DNA into the cytoplasm. In separate studies, we demonstrated that eribulin also significantly enhances type I interferon expression induced by STING agonists through a second TBK1-dependent mechanism downstream of STING activation. Both mechanisms of eribulin-mediated activation of interferon expression occur in immune and TNBC cells and are shared with other microtubule destabilizers but not with the microtubule stabilizer paclitaxel. Our current studies demonstrate the in vivo immunological effects of the microtubule destabilizer eribulin with the STING agonist ADU-S100 that lead to a significant decrease in tumor growth in the spontaneous MMTV-PyVT mammary tumor model upon combination treatment. The immunostimulatory effects of eribulin with or without concurrent administration of a STING agonist were determined in the spleen, tumor draining lymph nodes, and tumors with distinct effects observed in the activation of innate and adaptive responses. We further demonstrate the immunological and antitumor efficacy of combinations of eribulin and ADU-S100 in the syngeneic 4T1 model that is resistant to the antimitotic effects of eribulin as a single agent. Even in the absence of direct antimitotic effects on the tumor, eribulin was sufficient to promote activation of $CD4^+CD25^-$ effector T-cells in the spleen and lymph nodes specifically in tumored animals but not untumored controls. Additionally, eribulin was able to promote a similar increase in the activation of $CD4^+$ effector T-cells even in untumored animals when administered in combination with a STING agonist. Together, these data contribute to accumulating evidence that there are important mechanistic differences between the microtubule targeted chemotherapeutics currently used in the treatment of TNBC that could inform on their more rational use in the clinic as single agents or as chemotherapeutic backbones in combination with targeted therapy, including immunotherapeutics. More specifically, our data demonstrate that eribulin can act as an immune adjuvant to promote STING

signaling and T-cell activation in multiple in vivo TNBC models in addition to its well established anti-mitotic effects to enhance antitumor efficacy.

Targeting ENPP1 to boost anti-tumor immunity during PARP inhibition
Jie Li, Charlotte Mason, Kay Hanggi, Vincent Luca, Brian Ruffell. *H. Lee Moffitt Cancer Center, Tampa, FL*

Homologous recombination (HR) deficiency confers sensitivity to poly (ADP-ribose) polymerase inhibitors (PARPi), which have been approved for use in ovarian and triple negative breast cancers (TNBC) carrying loss-of-function mutations in HR pathway genes, most commonly *BRCA1/2*. Preclinical studies in BRCA1-deficient tumor models have demonstrated that the immune compartment is required for PARPi efficacy through the ability of PARPi to cause micronuclei formation and activate cGAS in tumors cells. The production of the 2'3'-cGAMP secondary intermediate stimulates STING in neighboring tumor-infiltrating immune cells to promote an anti-tumor response. Despite this evidence of immune stimulation, PARPi does not extend overall survival in TNBC patients, suggesting that immune suppression remains a significant barrier for efficacy. Here we sought to evaluate the role of ectonucleotide pyrophosphatase/phosphodiesterase 1(ENPP1), a type II transmembrane glycoprotein that hydrolyzes extracellular 2'3'-cGAMP. We generated *Brca1*/*Pten*/*Trp53*-deficient TNBC cell lines from a genetically engineered mouse model and found that these expressed higher levels of ENPP1 than *Brca1*-proficient TNBC and non-TNBC cell lines. Knocking out *Enpp1* via CRISPR/Cas9 increased 2'3'-cGAMP production during Niraparib treatment but did not affect cellular proliferation *in vitro*. Critically, knocking out *Enpp1* significantly reduced the growth of orthotopic *Brca1*-deficient tumors, with no change in growth observed for orthotopic E0771 or PyMT models, suggesting an important role for ENPP1 in HR-deficient tumors. Therapeutic dosing of Niraparib further reduced the growth of *Enpp1* knockout tumors in a manner that was dependent upon host STING and correlated with higher $CD8^+$ T cell infiltration and effector function. These findings demonstrate that ENPP1 suppresses anti-tumor immunity in *Brca1*-deficient tumors, suggesting that blocking the enzymatic activity of

ENPP1 may provide therapeutic benefits during PARPi treatment for TNBC patients.

Hyperthermic intrathoracic chemotherapy (HITOC) improves malignant pleural mesothelioma control through a tumor specific cytotoxic immune response

Yameng Hao[1], Aspasia Gkasti[1], Louis-Emmanuel Chriqui[2], Damien Marie[2], Michel Gonzalez[2], Thorsten Krueger[2], Solange Peters[2], Paul J. Dyson[1], Etienne Meylan[3], Johanna Joyce[4], Sabrina Cavin[2], Jean Y. Perentes[2]. *[1]École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland,[2]CHUV Lausanne University Hospital, Lausanne, Switzerland,[3]Université libre de Bruxelles, Bruxelles, Belgium,[4]University of Lausanne, Lausanne, Switzerland*

Introduction: The management of malignant pleural mesothelioma (MPM) remains challenging with poor patient survival. Local therapies such as hyperthermic intrathoracic cisplatin (HITOC) have shown good tumor control in selected patients. HITOC was shown to increase MPM drug exposure while limiting systemic side effects but alternative mechanisms for HITOC are still lacking. Here, we hypothesized that HITOC induces an immune response directed against MPM which decreases cancer related mortality.

Methods: We implanted AB12-luc MPM cells in the pleural cavity of BALB/c mice. A chemotherapy perfusion circuit was downsized to administer cisplatin (80mg/m^2 equivalent dose) in the thoracic cavity at normo (37°C, ITOC) or hyperthermic (39°C, HITOC) conditions for 30 minutes. Tumor growth (visualized by bioluminescence) and mouse survival were then assessed. We determined tumor platinum content and distribution by inductively coupled plasma mass spectrometry (ICP-MS) and by laser ablation ICP-MS (LA-ICP-MS) respectively. We also questioned the impact of (H)ITOC on the MPM immune microenvironment (innate and adaptive immune cells, activity and checkpoint expression) by 16-colour flow cytometry and immunohistochemistry. Finally, tumor response to (H)ITOC was assessed in BALB/c athymic mice implanted with AB12-luc cells.

Results: MPM tumor control and mouse survival were significantly improved by HITOC compared to controls (ITOC, saline 37 and 39°C). Tumor platinum content was significantly higher in HITOC compared to ITOC but was majorly located at the surface of tumors. HITOC enhanced MPM infiltration by $CD8^+$Granzyme B^+ T-cells and decreased the levels of $MCHII^-/CD80^-$ (M2-like) macrophages compared to controls at day 7. Interestingly, immune checkpoint expression of PD1 and CTLA4 was significantly enhanced in $CD8^+$ lymphocytes in HITOC treated MPM compared to controls at day 7. Finally, the lack of T lymphocytes (BALB/c athymic mice) abrogated the impact of HITOC on MPM control and mouse survival.
Conclusion: HITOC improves MPM control through a T lymphocyte immune mediated response. The enhanced immune checkpoint (PD1/CTLA4) expression in $CD8^+$ lymphocytes opens perspectives for the combination of HITOC with immune checkpoint inhibitors.

Synergistic combination of NCX 4040 and napabucasin induces immunogenic activation via upregulation of mitochondrial oxidative stress and STAT3 inhibition in cadmium transformed and metastatic prostate cancer cells
Nishtha Pathak, Gnanasekar Munirathinam. *Biomedical Sciences, University of Illinois College of Medicine (Rockford), Rockford, IL*

Despite recent diagnostic and therapeutic advances, prostate cancer (PCa) poses a significant burden on men's health and quality of life, retaining the second highest incidence rate after lung cancer. The combinatorial therapy approach has emerged as a useful treatment option for various types of cancer to target tumor heterogeneity and overcome the limitations of existing treatment modalities. Here, we explored the combination of NCX 4040, a nitric oxide-releasing aspirin derivative and Napabucasin, a recently developed STAT3 and cancer stemness inhibitor as a potential treatment for PCa. Two cellular models were used namely BPH-Cd, a cadmium-transformed carcinogenic cell line and DU145, a brain metastatic PCa cell line. Cell viability assay indicated reduced cell viability in both cell lines in a dose-dependent manner and more so in combination as opposed to individual treatments, with an IC_{50} of 5 μM for NCX 4040 and 250 nM for

Napabucasin. Notably, treatment with catalase prevented the synergistic activity of NCX 4040 and Napabucasin in reducing the viability of these cells. This suggested that NCX 4040 and Napabucasin might be inducing oxidative stress related cellular death. In addition, the combination of NCX 4040 and Napabucasin robustly impeded the *in-vitro* tumorigenic potential in both cell lines in colony formation assay and decreased the size of spheroids with increasing doses in *in-vitro* 3D spheroid assay in BPH-Cd. Western blot analysis revealed that in addition to the downregulation of STAT3, NCX 4040 and Napabucasin treatment showed upregulation in cGAS-STING immunogenic activation pathway related markers (pSTING, cGAS, pTBK1 in DU145 and STING, TBK1 in BPH-Cd). This data demonstrated that combination drug treatment might be inducing cell death via immunogenic activation. Additional markers related to this pathway are being tested in both cellular models. Interestingly, thioredoxin (TRX)-interacting protein was highly upregulated in both cell lines following combination treatment indicating that the synergistic effects are mediated via targeting TRX-regulated cellular redox signaling. Subsequently, TRX and thioredoxin reductase 1 were also downregulated in both cell lines. Furthermore, confocal imaging analysis indicated that NCX 4040 and Napabucasin together might be causing DNA damage and mitochondrial stress as DNA release was clearly evident. Flow cytometric analysis demonstrated that the drug combination shows a synergistic effect in producing excess mitochondrial and cellular ROS, causing apoptosis and in inducing cell cycle arrest in both BPH-Cd and DU145 cells. Taken together, our study demonstrates that NCX 4040 and Napabucasin in combination could be a potential anti-PCa therapy which warrants further evaluation for its clinical application.

HMGB1 release predicts chemotherapy combinatorial efficacy with TIM-3 blockade

Alexis Onimus, Jessica Mandula, Paulo Rodriguez, Brian Ruffell.
Immunology, H. Lee Moffitt Cancer Center, Tampa, FL

We have recently shown that TIM-3 blockade promotes response to paclitaxel chemotherapy in preclinical breast cancer models through its ability to suppress uptake of HMGB1-DNA complexes by dendritic cells.

However, it remains unclear why paclitaxel is necessary for response to TIM-3 blockade. Here we demonstrate that the taxanes paclitaxel and docetaxel induce the loss of HMGB1 from breast cancer cells *in vitro* and *in vivo*. Interestingly, this does not occur through loss of cellular integrity, but rather through an active secretion process involving ADP-ribosylation of HMGB1 by PARP1. PARP1 was activated by docetaxel treatment, as measured by detection of its cleaved form in the cytoplasm, and HMGB1 release was prevented by the use of the PARP inhibitor niraparib. Both PARP1 activation and ADP-ribosylation of HMGB1 were dependent upon the activity of TLR4, a known receptor for paclitaxel, as demonstrated with CRISPR/Cas9-generated knockout cells and TLR4 inhibitors. However, TLR4 stimulation alone was insufficient to induce HMGB1 release. By understanding how taxanes promote the release of HMGB1 we may be able to develop biomarkers for the selection of patients most likely to respond to the combination of chemotherapy and immunotherapy with TIM-3 blocking antibodies.

#6402

The effects of cytotoxic chemotherapy on colorectal cancer immunogenicity

Pietro Paolo Vitiello[1], Rosaria Chilà[2], Giuseppe Rospo[3], Gaia Grasso[3], Giovanni Crisafulli[2], Alice Bartolini[4], Vito Amodio[2], Federica Di Nicolantonio[3], Giovanni Germano[3], Alberto Bardelli[1]. *[1]Università degli Studi di Torino; IFOM - AIRC Institute of Molecular Oncology ETS, Milan, Italy,[2]IFOM - AIRC Istitute of Molecular Oncology - ETS, Milan, Italy,[3]Università degli Studi di Torino, Torino, Italy,[4]Candiolo Cancer Center, Candiolo (Torino), Italy*

Introduction: Immunotherapy based on PD1/PDL1 and/or CTLA4 blocking antibodies has shown efficacy in the molecular subgroup of colorectal cancers (CRCs) characterized by deficient mismatch repair (MMRd). This feature, present in only 4-5% of metastatic CRCs, causes a significant increase of tumor mutational burden (TMB) and tumor neoantigens, ultimately leading to immune rejection. On the other hand, for the majority of MMR proficient (MMRp) CRCs, cytotoxic chemotherapy ± targeted agents still constitute the mainstay of the treatment. Interestingly, even though it is known that cytotoxic agents induce mutations, their

immunogenic potential is still not fully understood. The aim of this work is to systematically investigate the immunogenicity of chemotherapy-induced mutations in CRC.
Methods: We performed a two-step experiment: first, murine CRC models were exposed to chemotherapy agents in an immune-free context (priming phase) and then challenged in immune-deficient and -proficient contexts (editing phase). Chemotherapy agents included the commonly used cytotoxic drugs 5-fluorouracil (5FU), oxaliplatin, SN38 (the active metabolite of irinotecan), cisplatin, and temozolomide, used as single drugs or combinations, in a pulsatile schedule using weekly 'cycles' (2 days on/5 days off) in order to mimic drug exposure in clinical settings. Whole exome sequencing (WES) was performed at baseline, and after both the priming and the editing phases.
Results and discussion: WES analysis showed that cisplatin-based treatment is associated with the highest increase in TMB and predicted neoantigens when compared to 5FU-based combinations. Multiple mutational processes contribute to the accumulation of mutations upon exposure to chemotherapy, as revealed by analysis of mutational signatures. A statistically significant growth delay and increased survival was reported for tumors primed with cisplatin/temozolomide and 5FU/Oxaliplatin/SN38 (FOLFOXIRI) combinations compared to unprimed tumors in immunocompetent but not in immunodeficient mice, suggesting the active involvement of the immune system in controlling tumor growth. Sequencing data of residual (escaped) tumors at the end of the editing phase revealed a preferential loss of mutations etiologically linked to chemotherapy in the immunocompetent models, pinpointing an active immune-editing of chemotherapy-induced mutations.
Conclusions: Cisplatin/temozolomide and FOLFOXIRI treatment effectively prime murine CRC models for subsequent immune rejection. These results suggest that the anticancer effect of chemotherapy treatment may be in part mediated by the immune-editing of chemotherapy-induced mutant cancer subclones.

#6403
A self-replicating RNA precision medicine approach to overcoming resistance to endocrine therapy in ER+BC

Zelanna Goldberg[1], Christian Maine[2], Gabrielle P. Dailey[3], Christine Domingo[2], Gaelle Picarda[2], Hunter Little[2], Annie Chou[2], Jessica Sparks[2], Darina Spasova[2], Shigeki Miyake-Stoner[2], Zachary C. Hartman[3], Christopher A. Rabiola[3], Erika J. Crosby[3], Herbert K. Lyerly[3], Nathaniel Wang[4], Parinaz Aliahmad[2]. *[1]Clinical Development, Replicate Bioscience, San Diego, CA,[2]Research, Replicate Bioscience, San Diego, CA,[3]Department of Surgery, Duke University, Durham, NC,[4]Replicate Bioscience, San Diego, CA*

Drug resistance remains the major driving factor behind the clinical failure of targeted therapeutics. Current oncology precision medicine approaches rely on targeting known acquired resistance mutations, such as EGFR T790M or ALK/ROS mutations in NSCLC with 2nd and 3rd generation molecules designed to overcome or prevent resistance. These next generation targeted therapeutic approaches have increasingly long and complex drug development timelines and burdensome toxicities from off target effects (e.g. wild-type receptor targeting) or drug-drug interactions (DDI). The toxicities limit tolerability, compliance and combinability of different targeted therapeutics. RNA-based immunotherapy approaches offer an increasingly attractive alternative to next generation small molecule targeted therapeutics approaches: (1) RNA-based approaches only require a known acquired resistance sequence, (2) drug development timelines, cost and complexity can be meaningfully condensed, and (3) multiple acquired resistance mutations can be targeted with the same candidate. RBI-1000 is a candidate using a novel type of self-replicating RNA (srRNA) to generate robust immunity directed against acquired resistance mutations that develop in ER+ breast cancer (ER+ BC) in response to endocrine therapy. RBI-1000 includes on-target mutations within the estrogen receptor ligand binding domain, and bypass mutations either in the form of activating mutations in the PI3K kinase domain or amplifications of HER2/HER3. Here, we demonstrate that this srRNA encapsulated in a lipid nanoparticle primes polyfunctional CD4 and CD8 T cells leading to tumor growth inhibition and improved survival in a mouse model expressing the targeted acquired resistance mutation. Priming of T cells against acquired mutations is also confirmed in human HLA-transgenic mice. The immune cell-mediated elimination of clones expressing the acquired resistance mutations is

predicted to prolong endocrine control of ER+BC, in an analogous manner to small molecule or monoclonal antibody targeted therapies, but with a more favorable dosing and adverse event profile due to precise immunologic targeting and no DDI.

Clinical scenario of immune checkpoint inhibitor treatment in metastatic nasopharyngeal carcinoma

Cheng-Lung Hsu, Yung-Chia Kuo. *Chang Gung Memorial Hospital - Linkou branch, Taoyuan, Taiwan*

Advanced in local treatment technology and early detection methodology, distant metastasis became a critical issue in Nasopharyngeal carcinoma (NPC). Recently, cancer immunotherapy especially immune checkpoint inhibitors (ICIs) including anti-programmed death-1 (PD-1) and PD-1 ligand (PD-L1) monoclonal antibodies (Mabs) had a rapid progress in cancer patient management. We try to clarify the clinical scenario of immune-related parameters in metastatic NPC. We had check 81 metastatic tissue PD-L1 expression without ICI treatment from the tissue bank of CGMH, Linkou, during 2005~2019. Using anti-PD-L1 antibody, 22C3 Dako, tumor proportional score (TPS) was positive in 43.2% (35/81) checked tissue and combine positive score (CPS) was positive in 58.0% (47/81) tissue respectively. For overall survival (OS) combined with PD-L1 expression in metastatic tissue analysis, positive CPS but not TPS correlated with longer survival with statistical significance (TPS: >0% vs =0%, median survival, 24m vs 22.5m, p=0.615186; CPS: >0% vs =0%, median survival, 28m vs 16m, p=0.003709). Retrospectively analysis of metastatic NPC treatment of combination of chemotherapy, ICIs, and local treatment in our institute in the past 6 years, total 40 patients was enrolled with median overall survival of 34.1 months. Objective response rate by RECIST criteria for immunotherapy-based regimen was 75% (CR:40%; PR:35%) and disease control rate was 85%. According to response by RECIST criteria, median overall survival were 34.1 months vs. 16.7 months respectively for responders and non-responders. With pre-treated NLR as cutoff value of 1.6, difference of median overall survival between two groups (responder vs nonresponder) was statistically significant (p=0.021). We also found that lower median post-treatment NLR in responders than in

non-responders (1.4 vs. 3.2, p=0.013). Using rapid lymphocyte amplification protocol via IL-2 stimulation, the PBMC from most of the patient received ICIs treatment can be amplified 1~10 folds and positively correlated with total lymphocyte count. Through flowcytometry analysis, we found these amplified PBMC was lymphocyte dominant and rich in CD8+. We also found these amplified PBMC can kill the NPC EBV-positive cell line and xenograft in vitro and in vivo. These results demonstrated that combination of chemotherapy, ICIs, and local treatment will benefit metastatic NPC patients.

#6406

Radiation and STING activation limit tumor development and modulate the immune environment via distinct mechanisms

Kay Shigemori[1], Yanyan Jiang[1], Bruno Beernaert[1], Anderson J. Ryan[1], Eileen E. Parkes[2]. *[1]Oncology, University of Oxford, Oxford, United Kingdom,[2]Oncology, Centre for Immuno-Oncology, University of Oxford, Oxford, United Kingdom*

Carcinogen-induced lung cancer in A/J mice is an established model of tumor initiation and development. The impact of radiation, immune response, and STING pathway activation on tumor development in this model is not well understood. In this study, we examined the effect of radiation and the STING agonist, DMXAA (Vadimezan), on the development of urethane-induced lung cancer.A/J mice were treated with urethane (i.p.) to induce the development of lung tumors. Three days after urethane treatment, mice received 13 Gy thorax radiation treatment (RT)/ mock RT, DMXAA (20 mg/kg i.p.)/ vehicle, or a combination treatment (n = 5). Mice were euthanized after 6 hours to 7 days after treatment to assess early events in the lung with RNA-sequencing and flow cytometry, or 5 months after treatment to assess tumor growth and long-term changes to the immune microenvironment with multiplex immunofluorescence.Mice treated with urethane followed by RT had fewer lung surface tumors ($p < 0.01$) and reduced tumor area ($p = 0.0732$) compared to their mock RT controls. In parallel, mice that received urethane pre-treatment and RT had high numbers of tertiary lymphoid structures (TLSs; these contained T-cells, B-cells, MHCII+ APCs and CXCL13) compared to the mock RT control mice ($p < 0.001$). Analysis of immune cell contents of the TLS

revealed a notable increase in CD4, CD8 and regulatory T-cells in the RT condition (with urethane pretreatment). Important early events in the lung following RT of urethane pre-treated mice included a transient increase in type I and type II interferons, CD4 and CD8 T-cell infiltration ($p < 0.001$) and a strong downregulation of cell cycle events. In contrast to these findings, DMXAA treatment after urethane resulted in fewer tumors ($p < 0.05$), but larger tumors compared to the vehicle-treated group. An increase in immune cells was observed in the lung, however, without clear structures that resembled TLSs. Early events following DMXAA treatment with urethane pre-treatment included dampened levels of type I IFN and TNF-α in circulation and a decrease in T-cell infiltration into the lungs. Interestingly, RT and DMXAA combination treatment (with urethane pre-treatment) drove a synergistic anti-tumor effect, further reducing tumor numbers compared to the RT or DMXAA controls 5 months after treatment.RT and STING agonist treatment of pre-neoplastic lesions have differential impacts on tumor growth in the A/J mouse model, and work synergistically when combined. The different outcomes of RT and DMXAA on tumor growth may be driven by their distinctive mechanism of action on immune responses and capacities to form TLSs. These findings may have future implications for strategies for the early treatment of lung and other cancers, and they suggest that immune responses, including modulation of the STING pathway, may be an important aspect of early tumor development that could be targeted therapeutically.

Radionuclide-specific effects of ^{90}Y-,^{177}Lu-, or^{225}Ac-NM600 targeted radionuclide therapy on tumor immunomodulation and enhanced immunotherapy response in syngeneic murine tumors

Thanh Phuong T. Nguyen[1], Caroline P. Kerr[1], Joseph J. Grudzinski[2], Carolina A. Ferreira[3], Julia Sheehan-Klenk[1], Ohyun Kwon[3], Maria Powers[1], Paul A. Clark[1], Raghava N. Sriramaneni[1], Reinier Hernandez[3], Bryan Bednarz[3], Jamey P. Weichert[2], Zachary S. Morris[1]. *[1]Human Oncology, University of Wisconsin - Madison, Madison, WI,[2]Radiology, University of Wisconsin - Madison, Madison, WI,[3]Medical Physics, University of Wisconsin - Madison, Madison, WI*

Background: Targeted radionuclide therapy (TRT) delivers radiation treatment systemically to tumor sites via a therapeutic radionuclide-linked tumor-selective targeting vector. NM600 is an alkylphosphocholine analog selectively taken up and retained in murine and human tumor cells. We previously showed that low dose radiation delivery with ^{90}Y-NM600 improves tumor response to immune checkpoint inhibitors (ICIs). Understanding the effect of different radionuclide physical properties (emission type, linear energy transfer (LET), half-life, and tissue range) on immunomodulation of metastatic cancers may guide therapy development. Here, we evaluated the type 1 interferon (IFN1) response elicited by ^{90}Y-, ^{177}Lu-, and ^{225}Ac-NM600 in an immunologically cold syngeneic murine tumor model, B78 melanoma. We hypothesized that the unique physical properties of radionuclides will differentially impact immunomodulation by TRT.
Methods: Mice bearing B78 WT or *Tmem173* -/- CRISPR deletion B78 (STING KO) tumors were randomized to receive 1.5 Gy external beam radiation (EBRT), an equivalent tumor dose of ^{90}Y-, ^{177}Lu-, or ^{225}Ac-NM600 determined by the Monte Carlo-based RAPID platform, or no radiation on day 1. Tumors were harvested on days 4, 7, and 10 for RT-qPCR. Mice bearing two B78 WT or *Tmem173* -/- CRISPR deletion B78 (STING KO) tumors were randomized to receive 4 Gy external beam radiation therapy (EBRT), an equivalent tumor dose of ^{90}Y- or ^{177}Lu-NM600, 0.5 μCi ^{225}Ac-NM600, or no radiation +/- dual ICI (anti-CTLA4 and anti-PDL1). Mice were monitored for tumor growth and survival following these treatments.
Results: Both EBRT and TRT upregulated expression of IFN1 response-associated genes (*Ifnβ1, Mx1*) in B78 WT tumors. Only TRT induced upregulation of *Ifnβ1* and *Mx1* in STING KO B78 tumors. *Ddx58*, which encodes RIG-I, integral to an alternative IFN1 pathway, was upregulated in both B78 WT and STING KO tumors following ^{225}Ac-NM600, but not other treatments. TRT in B78 STING KO tumors had earlier expression of IFN1 response-associated genes than B78 WT, ^{225}Ac-NM600 in combination with dual ICI improved overall survival over ^{90}Y- or ^{177}Lu-NM600 + ICI and ^{225}Ac-NM600 monotherapy.
Conclusions: The distinct physical properties of TRT radiation, γ, β or α, affect the timing, magnitude, and molecular pathways leading to this IFN1

response. Understanding TRT effects on the tumor microenvironment may optimize TRT and immunotherapy.

Anti-tumor immunity evolved by novel titanium peroxide nanoparticles (TiOxNPs) as a radiosensitizer and PD-1 blockade

Yoshiko Fujita[1], Hikaru Kubota[1], Chiaki Ogino[2], Ryohei Sasaki[1]. *[1]Division of Radiation Oncology, Kobe University Graduate School of Medicine, Kobe, Japan,[2]Department of Chemical Science and Engineering, Kobe University Graduate School of Engineering, Kobe, Japan*

Abstract: Release and presentation of tumor antigens are the preconditions of cellular immune response. Radiotherapy have been reported to release endogenous tumor antigens and enhanced the adjuvanticity from dying cancer cells via endoplasmic reticulum (ER) stress, known as immunogenic cell death. We developed a novel radiotherapy using radiosensitizer (TiOxNPs) that could drive effective anti-tumor responses. The TiOxNPs were robustly radiation-induced reactive oxygen species (ROS) generation. This burst therapy could enhance to release and presentation of endogenous tumor antigens, subsequently cross-presentation of antigens by Dendritic cells (DCs) for T-cell activation in secondary lymphoid organs (SLO).
Methods: B16-F10 murine melanoma cells ($5x10^5$) were subcutaneously injected into the right flank of C57BL/6J respectively. Mice were divided into five treatment groups: 1) untreated; 2) XRT; 3) XRT+ TiOxNPs; 4) XRT+anti-PD-1Ab; and 5) XRT+ TiOxNPs +anti-PD-1Ab. B16-F10 tumors were intratumorally injected with TiOxNPs (8mg/kg) on days 10 and received 5Gy or 10Gy X-ray radiation approximately 1 hour after the injection. Anti-PD-1 antibody (200μg) intraperitoneally administered to the mice on the first day of X-ray irradiation, days 13 and 16. The tumor volume were assessed every 2-3 days after treatment. Mice were sacrificed after days 17 and isolated spleen and tumor.
Results: TiOxNPs acted as a potent radiosensitizer, which enhanced cytotoxic ROS-mediated cell death. This combination effect could not only a local treatment that directly kills cancer cells but also could enhance the adjuvanticity from dying cancer cells by DAMPs, and significantly upregulate expression of MHC class I on tumor cells. Treatment of B16-F10 melanoma tumor model with burst therapy resulted in tumor shrinkage

and extended overall survival. Burst therapy facilitated the recruitment and maturation of DCs into SLO, and improved antigen presentation to naive T cells. Infiltration into the tumor site of CTL were correlated with increasing of migration DCs into SLO.
Conclusion: A novel radiotherapy combining with TiOxNPs played an important role in release of endogenous tumor antigens and DAMPs. The upregulation of MHC class I expression on tumor cells after X-ray irradiation facilitated the recognition of the tumor cells by T cells, leading to significantly enhanced antitumor immune response compared to exisiting immunoradiotherapy. This novel nanoparticles exposed to X-ray irradiation could trigger of antigen-specific immune responses and transform a tumor into a site for activation of antitumor immune response.

Non-redundant mechanisms of immune resistance to radiotherapy converge on innate immunity

Anthony T. Nguyen[1], Tahir B. Dar[1], Jolene Viramontes[1], Satchel Stevens[1], Julie K. Jang[1], Emily Y. Ko[1], Diana J. Lu[1], Eric M. Chung[1], Samuel C. Zhang[1], Katelyn M. Atkins[1], Mitchell Kamrava[1], Howard M. Sandler[1], Jlenia Guarnerio[1], Simon Knott[2], Zachary S. Zumsteg[1], David M. Underhill[2], Stephen L. Shiao[1]. *[1]Department of Radiation Oncology, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA*

Multiple studies have demonstrated synergy between immune checkpoint blockade (ICB) and radiotherapy (RT) in preclinical murine models; however, randomized trials of RT/ICB have been inconsistent in patients with solid tumors. To better understand this discordance, we hypothesized that there are non-redundant inhibitory immune pathways that restrain the efficacy of RT beyond T-cell oriented immune checkpoints. To this end, we performed scRNA-seq and CITE-seq analysis of the EO771 syngeneic murine model of breast cancer to characterize the immune landscape following RT±ICB. We found that ICB reprograms the immune response to RT by shifting tumor-associated macrophages (TAMs) from a lipid-associated phenotype (APOE, FABP5) to an M1-like interferon-stimulated state (CXCL10, ISG15). However, ICB also promoted the late recruitment of intratumoral neutrophils, which drive resistance to RT in other contexts.

To evaluate whether neutrophils may be limiting antitumor immunity to RT/ICB, we depleted intratumoral neutrophils using two separate antibodies, anti-Ly6G and anti-Gr-1. Compared to RT/ICB alone, both neutrophil depletion strategies enhanced tumor control and prolonged survival in advanced EO771 tumors ($P<0.001$). Given that indiscriminate neutrophil depletion is not a viable therapeutic strategy, we tested alternative immune targeting approaches to alter the TAM response to RT/ICB. By scRNA-seq, we found that RT strongly upregulated several innate immune checkpoints on TAMs (e.g., SIRPα, SLAMF3/7, LRP1). Accordingly, we disrupted the SIRPα-CD47 interaction with anti-CD47 antibodies and characterized the impact on response to RT/ICB. Anti-CD47 significantly improved tumor regression and survival when combined with RT/ICB ($P<0.001$). We then used scRNA-seq and CITE-seq to understand why disruption of SIRPα-CD47 improved antitumor responses to RT/ICB. We found that anti-CD47 depleted an entire cluster of chronically inflamed TAMs, expressing pro-inflammatory markers (IL1A, NOS2) and chemokines (CCL3, CXCL1/2/3). Furthermore, anti-CD47 reduced the recruitment of intratumoral neutrophils and depleted a cluster of pathologically activated neutrophils (PMNs), termed myeloid-derived suppressor cells (PMN-MDSCs), expressing WFDC17, PTGS2, S100A8/9. Lastly, anti-CD47 enhanced the recruitment of tumor-infiltrating lymphocytes including central memory $TCF7^+$ T cells and $CD19^+$ B cells. By inference and analysis of cell-cell communication (CellChat), we found that anti-CD47 strengthened the interactions between myeloid cells and T cells compared to RT/ICB alone. Collectively, our data indicate that innate immune cells, in particular neutrophils and chronically inflamed TAMs, promote resistance to RT/ICB in the EO771 model. These data suggest that inhibition of CD47-SIRPα is a promising therapeutic strategy to overcoming immune resistance through the elimination of PMN-MDSCs.

Deciphering the role of MyD88 signaling pathway in regulating type I IFN-mediated responses to radiation therapy in solid tumors

Aanchal Preet Kaur, Terry R. Medler, Tiffany C. Blair, Alejandro F. Alice, Megan R. Ball, Alexa K. Dowdell, Brian D. Piening, Marka R. Crittenden, Michael J. Gough. *Earle A. Chiles Research Institute, Providence Cancer Institute, Portland, OR*

The balance of innate signaling through adaptor proteins such as MyD88 and TRIF is critical in directing the pattern of inflammatory responses following exposure to endogenous adjuvants. While innate stimuli can cause inflammation that supports adaptive immunity, cancer myeloid cells can be pre-polarized such that the same inflammatory signals cause myeloid cells to suppress adaptive immune responses. We aim to investigate the signals regulating type I IFN secretion by innate immune cells in tumors in order to improve type I IFN secretion, activation of innate immune cells, direct macrophage polarization and improve CD8+ T cell mediated anti-tumor immunity. To better understand the role of MyD88-mediated signaling in driving response to innate adjuvants released following RT in solid tumors, we developed MyD88 conditional knockout mouse models. MyD88 was deleted specifically in CD11c expressing dendritic cells (DC), Lck expressing T cells, or Lyz2 expressing myeloid cells that include macrophages, monocytes and granulocytes. Mice bearing pancreatic tumors (Panc02-SIY or PK5L1940) were randomized to no treatment or 16 Gy CT-guided RT and followed for treatment responses. Lyz2-Cre/MyD88$^{fl/fl}$ mice demonstrated improved responses to RT in pancreatic tumors as compared to control MyD88$^{fl/fl}$ mice, or Lck-Cre mice. The improved responses in Lyz2-Cre/MyD88$^{fl/fl}$ mice were shown to be dependent on CD8+ T cells as well as on type I IFN signaling. To analyze mechanisms of response, tumors were digested into a single cell suspension and CD45+ cells were isolated for single cell sequencing three days post-RT. Lyz2-Cre/MyD88$^{fl/fl}$ mice showed diminished Th1 and Th2-type T cells and had a higher M1/TAM ratio compared to MyD88$^{fl/fl}$ mice. Loss of MyD88 in myeloid cells resulted in increased activation of IFN-dependent transcriptional responses in multiple immune cell populations in the tumor. To model responses ex vivo, bone marrow-derived macrophages (BMDMs) were activated with lipopolysaccharide (LPS) or a synthetic cyclic dinucleotide (CDA) for analysis of cytokine secretion in either monolayer or 3D spheroid culture conditions. BMDM derived from Lyz2-Cre/MyD88$^{fl/fl}$ cultured as a monolayer showed significantly altered secretion of TNF-α, IL-10 and IL-6 on activation with LPS as compared to controls. Preliminary data obtained from 3D spheroid culture systems demonstrated that 3D interactions between cancer cells and macrophages resulted in a significant increase in BMDM co-stimulatory phenotype following activation with innate stimuli

compared to 2D cultures. These data suggest that conventional innate signaling through MyD88 in myeloid populations suppresses IFN production and adaptive immune control of irradiated tumors. 3D cultures are an effective tool to study cellular interactions ex vivo and screen novel interventions prior to in vivo translation.

Immunotherapy Strategies and Mechanisms

Concomitant anti-tumor immunity and checkpoint blockade responses are restored by depletion of CD62L expressing cells

Brianna Burke[1], Lourdes Plaza-Rojas[2], Cynthia Perez[1], Elena Kostenko[2], Anna Austin[2], Justin Boucher[2], Kushal Prajapati[1], Michael Delos Reyes[1], Christine Chung[2], Jose-Alejandro Guevara-Patino[3]. *[1]Loyola University Chicago, Maywood, IL,[2]H. Lee Moffitt Cancer Center, Tampa, FL,[3]Immunology, H. Lee Moffitt Cancer Center, Tampa, FL*

Studies have shown the importance of CD62L in leukocyte trafficking. However, the significance of CD62L-expressing cells in concomitant anti-tumor immunity has not been investigated. Using a model of post-surgical tumor immunity, we show that in vivo depletion of CD62L-expressing cells before or immediately after surgical tumor resection enabled the development of anti-tumor concomitant responses against poorly immunogenic B16 (melanoma) or MTE-Ras (head & neck cancer) tumor cells. Anti-CD62L mAb administration depleted the cellular immune components that express CD62L, including NK, NKT, Mo, Ma, B, and T cells. Within the T cell compartment, naïve T cells (CD44lo CD62Lhi), effector (CD44hi CD62Llo), memory (CD44hi CD62Lhi) and regulatory T cells (Treg, CD4 CD25 Foxp3) were also depleted, while effector CD62L-negative T cells were spared in the TDLN. Tumor immunity did not occur in the absence of a primary tumor (sham surgery group) or after CD8 depletion. Whereas anti-CTLA-4 or anti-PD-1 mAbs failed as monotherapies, their administration during CD62L depletion restored their anti-tumor properties. The unified global gene expression analysis of the TDLN shows the significant enrichment of biological processes involved in the CD8 T cell effector phase, IL-2/IL-15, TNF-α, IFN-γ, IFN-α, IL-6, responses, mitotic cell division, glycolysis, and acetylation. Also, genes

related to Treg responses were downregulated. These data point to a process in which depletion of CD62L cells in tumor-bearing hosts transforms the TDLN into a highly active immunological site in which tumor-reactive effector CD8 T cells (CD62L-negative) actively divide in the absence of Treg, accompanied by a cytokine response, glucose consumption, and acetylation of transcriptional factors and histones. These results identify an unrecognized role of CD62L-expressing cells in regulating concomitant anti-tumor immunity and restoring anti-tumor responses by checkpoint blockade inhibitors. Our study provides a new framework that could help understand how anti-tumor responses are limited.

CD25-targeted aptamer-drug conjugate (CD25-ApDC) depletes and blocks regulatory T cells selectivel

Daekyun Lee, Ju-hyung Kang, Inu Song. *Aptamer Sciences Inc., Seongnam-si, Korea, Republic of*

Background: Regulatory T cells (Tregs) have a strong immunosuppressive function, inhibit anti-tumor immunity, and promote the occurrence and development of tumors. In addition, a high infiltration of Treg cells is associated with poor survival in various types of cancer. Since CD25 is highly expressed on Treg cells, it is a potential target protein for Treg depletion.
Methods: The binding affinity(Kd) of CD25 aptamer to rhCD25 protein was calculated through bio-layer interferometry(BLI). The cell binding of Cy5-labelled CD25 aptamer was detected by flow cytometry, and the internalization was visualized by confocal microscopy. The cell internalization rate was determined using the MFI value of flow cytometry. Competitive ELISA, western blot, and qPCR were performed to investigate the effect of CD25 aptamer on CD25/IL-2 binding. In vitro cytotoxicity of prototype-ApDC was determined by CCK-8 assay. Moreover, CD25-dependent cytotoxicity of prototype-ApDC was evaluated by Karpas299(Treg-like):HuT78(Teff-like) 1:1 co-culture model using FACS analysis.
Results: CD25 aptamer binds human CD25 protein with 4.64nM affinity. CD25 aptamer showed selective binding and internalization to CD25-positive Karpas299 and had no interaction with CD25-negative Daudi. The

internalization half-time of CD25 aptamer in karpas299 was determined to 9.9 min (95% CI 8.2~12.6min). Interestingly, CD25 aptamer was identified as IL-2R antagonist by evaluating competitive ELISA and the level of phosphor-STAT5 and downstream mRNA expression of TGF-beta. The IC50 value of prototype-ApDC was 24nM to Karpas299 while >1uM to Daudi. These results show that prototype-ApDC has selective cytotoxicity against CD25-expressing cells. Furthermore, in a study of an in vitro co-culture model mimicking the Treg-rich intratumoral T cell environment, prototype-ApDC treatment induced CD25-specific depletion resulting in escalating the ratio of HuT89/Karpas299 with increasing exposure time. Conclusions: Our CD25-targeted aptamer and its drug-conjugated ApDC have demonstrated the selective blocking of IL-2R-STAT5 signaling and induction of CD25-positive cell-specific depletion, respectively. Moreover, in the co-culture system of the Treg-like and Teff-like cells, CD25-ApDC also proved its cytotoxic selectivity. Therefore, one potential strategy in cancer patients is to use CD25-ApDC with excellent tumor permeability as an anticancer agent with a mechanism of Treg cell depletion through specific targeting of CD25 overexpressed in tumor-infiltrating Treg cells.

Statins inhibit onco-dimerization of 4Ig-B7-H3

Margie Nicole Sutton[1], Sarah E. Glazer[2], Riccardo Muzzioli[1], Ping Yang[1], Seth T. Gammon[1], David Piwnica-Worms[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Oregon Health Science University, Portland, OR*

B7-H3 (*CD276*) is a member of the B7 family of immune regulators, but unlike the immune checkpoint targets that have revolutionized cancer therapy, blockade has resulted in mixed outcomes. B7-H3 has 2Ig and 4Ig isoforms, has no known direct ligand, and many of the physiological functions remain elusive. While protein expression of B7-H3 is differentially expressed on many solid tumors and correlates with poor survival, mechanisms of how B7-H3 elicits a pro-tumorigenic phenotype are still poorly understood, significantly hampering therapeutic efforts for targeting. Using a facile, recombinase-enhanced split-luciferase reporter, we visualized 4Ig-B7-H3 homodimerization in live U2OS cells by bioluminescence imaging and confirmed 4Ig-B7-H3 dimerization using a second non-invasive imaging technique: fluorescence lifetime imaging

microscopy (FLIM) where 4Ig-B7-H3 was exogenously re-expressed following knockout of *CD276* in HeLa cervical cancer cells. Homodimerization of 4Ig-B7-H3 correlated with enhanced clonogenic cell growth in HeLa, SKOv3, MDA-MB-231, and U2OS cells and tumor growth *in vivo* for several models. This phenotype was reversed following knockout of B7-H3 and rescued upon lentiviral re-expression. By RPPA and phospho-kinase array analysis, increases in PI3K/AKT signaling, Jak/Stat pathway, and modulators of HIF1α and NF-κβ pathways were observed with B7-H3 expression and homodimerization ($p<0.05$), all which are known to support increased oncogenic functions, such as increased glycolysis, increased survival and proliferation, as well as cytokine modulation and immune evasion. Next, capitalizing on our bioluminescence-based reporter of 4Ig-B7-H3 homodimerization, we performed a high-throughput small molecule screen with a 5,362 Bioactive compound library to identify modulators of 4Ig-B7-H3 dimerization. Notably, our HTS identified several HMG-CoA reductase inhibitors (statins) as significant inhibitors of B7-H3 dimerization ($p<0.01$). Treatment with 1 μM mevastatin or atorvastatin calcium inhibited clonogenic growth of HeLa cervical, SKOv3 ovarian and MDA-MB-231 breast cancer cells, which all endogenously express B7-H3. *In vivo*, treatment with 10 mg/kg of atorvastatin calcium reduced tumor growth and increased mouse survival ($p=0.035$) of SKOv3-ip tumors and produced functional cures (15-30%) of HeLa or MDA-MB-231 xenografts in nude mice in a B7-H3 tumor expression-dependent manner, proven through knockout and rescue experiments in live cells and animals. Thus, in the context of studies to dissect the tumor-intrinsic mechanism(s) of B7-H3 biochemical functions and activation, we identified a novel, dimerization-dependent oncogenic role for 4Ig-B7-H3 that increased oncogenic intracellular signaling activation and was modulated by statin treatment. This may provide a molecular mechanism for the statin-mediated immune modulation and enhanced cancer survival clinically reported for several tumor types.

Deciphering aberrant STING pathway and exploring oncolytic viruses therapy in low grade serous ovarian carcinoma

Almira Zhantuyakova[1], Dawn Cochrane[1], Gian Negri[2], Sandra E. Spencer Miko[2], Taha Azad[3], Jutta Huvila[4], Marta Llaurado Fernandez[5], Mark

Carey[5], Gregg B. Morin[2], John Bell[3], David Huntsman[6]. *[1]Molecular Oncology, BC Cancer Research Centre, Vancouver, BC, Canada,[2]Canada's Michael Smith Genome Sciences Centre, BC Cancer Research Centre, Vancouver, BC, Canada,[3]Department of Biochemistry, University of Ottawa, Ottawa, ON, Canada,[4]University of Turko, Turko, Finland,[5]Department of Obstetrics and Gynecology, University of British Columbia, Vancouver, BC, Canada,[6]Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada*

There are two serous ovarian cancer histotypes, low and high grade (LGSOC and HGSOC), which are distinct clinical and biological entities. LGSOC is a rare histotype with a relatively stable genome, while HGSC is more common and genomically unstable. Somewhat surprisingly LGSOC expresses high levels of the stimulator of the interferon genes (STING). The STING pathway recognizes cytoplasmic double-stranded DNA and mounts innate cellular immunity through interferon-beta type I production. Our objective is to investigate the aberrant STING signaling in LGSOC and test the effectiveness of oncolytic viruses against LGSOC. We used immunohistochemistry on tissue microarrays (TMAs) to assess STING protein expression in different ovarian cancer histotypes. Whole proteome analysis was applied to identify differentially expressed proteins in LGSOC and HGSOC patient samples (both n=9). Further, a semi-targeted proteomics approach was used to evaluate the expression levels of the STING pathway-related proteins in LGSOC, HGSOC, and LGSOC precursor tumors (each subtype, n=20). To evaluate the key transcription, phosphorylation, and translocation events in STING signaling, we treated LGSOC cell lines with an agonist (dsDNA90) and performed qPCR, immunoblotting, and immunofluorescence experiments, respectively. We tested the viability of the LGSOC cell lines in response to Vaccinia Virus (VV), and Vesicular Stomatitis Virus (VSV) based oncolytic vectors with or without immunostimulatory transgenes. Our results show that STING protein levels were consistently higher in LGSOC TMAs relative to other histotypes. Proteomics analysis showed that the half of the 16 most differentially expressed proteins were the effectors of STING signaling with unexpectedly lower expression in LGSOC, suggesting that despite the robust levels of STING in LGSOC tumors, the pathway is not fully active.

Attenuated STING translocation and expression of IFNB1 and other cytokines in LGSOC cell lines confirm the aberrancy in the STING pathway. Semi-targeted proteomics revealed the considerable overexpression of STIM1 in LGSOC patient tumors, which has previously been shown to sequester STING in the endoplasmic reticulum. The treatment with VV and VSV oncolytic viruses significantly reduced the proliferation of LGSOC cell lines. In summary, we find attenuated STING signaling in LGSOC, possibly due to overexpression of STIM1 preventing STING translocation. Although oncolytic viruses show promising results in LGSOC cell lines, more research is needed to determine the optimal treatment strategy, testing oncolytic viruses expressing various transgenes and combination therapies.

xWU-NK-101 as salvage therapy post immune checkpoint blockade (ICB)

Tom A. Leedom[1], Barbara Muz[1], Jaykumar Vadakekolathu[2], John J. Muth[1], Xiao-Hua Li[1], Gregory Watson[1], Kristaan Magee[1], Ryan P. Sullivan[1], Melissa Berrien-Elliott[3], Todd Fenigher[3], Sergio Rutella[2], Matthew L. Cooper[1], Ayman Kabakibi[1], Jan K. Davidson-Moncada[1]. *[1]Wugen, St Louis, MO,[2]John VanGeest Cancer Research Centre, Nottingham Trent University, Nottingham, United Kingdom,[3]Washington University, Saint Louis, MO*

ICB therapy has transformed cancer treatment; durable responses in difficult-to-treat cancers have been observed. Despite this most patients (pts) don't respond to ICB (primary resistance), and many pts who initially respond eventually relapse (acquired resistance). Primary resistance is associated with tumor cell extrinsic factors, e.g., the immunosuppressive nature of the tumor microenvironment (TME), while acquired resistance is associated with tumor intrinsic factors, e.g., downregulation of MHC1, preventing T cell recognition. Treatments to overcome ICB resistance are necessary. WU-NK-101 is a PBMC-derived, cytokine-reprogrammed, expanded, and cryopreserved off-the-shelf memory NK cell product. WU-NK-101 cells capture the memory-like NK cell biology of cytokine-induced memory-like (CIML) NK cells, exhibiting enhanced cytotoxicity, metabolic fitness/flexibility, and resistance to TME immunosuppression (Muth *et al.* EHA 2022; Rutella *et al.* ESMO 2022). Bone marrow biopsies, collected

from R/R AML pts who received CIML-NK cells (NCT01898793), were interrogated using immune gene expression (GE) profiling and spatially resolved proteomics (IO360® panel, n = 740 genes, and GeoMx® DSP; NanoString Technologies). Higher T-cell infiltration was noted post CIML-NK. CIBERSORT deconvoluted GE data inferred higher abundance of macrophages, γδT cells and activated dendritic cells on day 28 post-treatment. GE signatures showed downregulation of NFIL3 and FAM30A (log2 fold-change <1.0; $p<0.05$) post CIML-NK. TIDE algorithm modelling indicated that lower expression of NFIL3 and FAM30A correlated with high CTL infiltration and improved outcomes in many TCGA tumors (Jiang *et al.* Nat. Med. 2018). Hence, CIML-NK treatment led to modifications in the TME towards a more T-cell amenable environment. Deleting *MHC1* on NALM6 cells significantly improved WU-NK-101 killing compared to WT ($p<0.0001$), highlighting one mechanism whereby WU-NK-101 overcomes acquired ICB resistance. In transwell assays, co-incubation of tumor cells with WU-NK-101 in the lower chamber led to dose dependent killing; in the upper chamber (tumor cells alone), viability was preserved but a dose-dependent increase of MHC1/PDL1 expression was noted. Similar results were observed using cell-free conditioned media from WU-NK-101 cytotoxicity assays, suggesting that soluble factors released from WU-NK-101 augment MHC1/PDL1 expression. Treatment of tumor cells with IFNγ alone led to similar increases in MHC1/PDL1 expression. Importantly, *in vivo* experiments revealed that residual tumor cells post WU-NK-101 treatment exhibited higher levels of MHC1/PDL1. Overall, these data highlight a further mechanism through which WU-NK-101 overcomes acquired ICB resistance. In summary, WU-NK-101 has the potential to reverse primary and acquired mechanisms of ICB resistance. A Phase 1b clinical trial of WU-NK-101 as salvage therapy post-ICB is in development.

Harnessing immune responses in prostate MMRd tumors treated with immune checkpoint blockade

Marcel Arias Badia, Zenghua Fan, Yee May Lwin, PeiXi Chen, Aahir Srinath, Lawrence Fong. *UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA*

There is increasing evidence correlating tumor mutational burden with response to immunotherapy in many different types of cancer. Some tumors show high microsatellite instability (MSI-H) as a consequence of the loss of function of mismatch repair (MMR) genes, which would resolve DNA damage in normal conditions. MSH2 plays a critical role in MMR, and several studies have identified mutations in MSH2 as key drivers of MSI in tumors**.** In preclinical mouse models, MMR deficiency and high microsatellite instability have been previously shown to translate into higher sensitivity to anti-PD-1 treatment. Despite the advances led by the recent tumor-agnostic approval of checkpoint inhibitors for highly mutated tumors, response rates among MMR-deficient (MMRd) tumors in humans are variable, and the mechanisms behind such heterogeneity are still poorly understood. We successfully knocked out the MSH2 gene in the murine prostate adenocarcinoma TRAMP-C2 cell line by CRISPR gene editing. By sequential passaging, we generated a MSH2-KO subclonal population that presents MSI and MMR deficiency, validated by increased tumor mutational burden (TMB) observed by exome sequencing. In studies where we challenged immunodeficient and immunocompetent mice with MMR-proficient (MMRp) and MMRd tumors, the latter showed increase immunogenicity, which led us to interrogate and better characterize such immune responses in the context of immune checkpoint blockade by anti-PD-1.In our studies, MMRd tumor-infiltrating T cells presented significantly enhanced effector and cytotoxic profiles, which likely led to improved tumor control with or without anti-PD-1. We observed an intriguingly lower frequency of SPAS-1 (a well-known TRAMP-C2 immunodominant epitope) antigen-specific T cells in the tumor-reactive fraction of MMRd infiltrates compared to MMRp, which prompted us to interrogate tumor-infiltrate gene expression, TCR repertoire and the potential expansion of multiple antigen-reactive subsets against MMRd tumors in successful immune responses by single cell RNA sequencing and functional *ex vivo* studies. We also interrogated TCR repertoire data from patients harboring MMRd tumors to add translatability to our findings in mice.Our results constitute a relevant addition to the understanding of immune responses in MMRd tumors and the potential features that could be exploited to improve response rates in immunotherapeutic strategies targeting such malignancies.

Molecular profiles and single cell analysis identify immunogenic pancreatic ductal adenocarcinoma (iPDAC)

Wungki Park, Catherine O'Connor, Shigeaki Umeda, Roshan Sharma, Yingjie Zhu, Elias-Ramzey Karnoub, Anna Varghese, Kevin C. Soares, Alejandro Jimemez, Asli Yavas, Kenneth H. Yu, Balachandran P. Vinod, Joanne F. Chou, Danny N. Khalil, Kelsen David, Hulya Sahin Ozkan, Olca Basturk, Marinela Capanu, Tal Nawy, Michael F. Berger, Ghassan K. Abou-Alfa, Jorge S. Reis-Filho, Ronan Chaligne, Nadeem Riaz, Dana Pe'er, Christine Iacobuzio-Donahue, Eileen M. O'Reilly. *Memorial Sloan Kettering Cancer Center, New York, NY*

Most pancreatic ductal adenocarcinomas (PDAC) are lethal and resistant to immunotherapy. Thus, identifying the immunogenic subgroup (iPDAC) and therapeutic targets can save lives. Herein, we present molecular features of iPDAC. 3 cohorts (A, B, C) from 288 patients whose sequenced tumors (MSK-IMPACT) were classified by homologous recombination deficiency groups. MSI-H were excluded. Survival, tumor mutation burden, genomic instability score, and enriched pathways for each cohort are included in Table 1. Patients in A (BRCA1/2/PALB2) had longer survivals vs B/C. 61 samples were selected for bulk RNAseq analysis for A vs C. Gene Ontology was enriched for upregulated humoral, T cell, and neutrophil immunity. CIBERSORT suggested higher infiltration of gamma delta T (Tgd) cells (p=0.039) and neutrophils (p=0.012), but lower Treg (p=0.001). Multidimensional insights in cellular components of cancer, immune, stroma, and neural genes were obtained by single nuclear RNA (snRNAseq) analysis from 30 biopsies for A vs C. 10x Genomics Chromium platform for library and Scanpy for computational analysis after Cell Ranger pipelines were used. 61,868 nuclei were profiled from 18 (13 baseline and 5 matched longitudinal) samples after quality evaluation. UMAP accurately clustered cells from each patient. Long-term survivors (LTS) had heterogenous baseline immune cell infiltrates of plasma cells, neutrophils, and CD8 (+) cytotoxic T cells. In matched samples of LTS, evolution of more prominent CD8 (+) T cells, macrophage, plasma cell, and neutrophil were observed. Single nucleus T-Cell Receptor sequencing for clonal trajectory inference will be done to determine the associated single cell

molecular features contributing to iPDAC and identify novel targets for future intervention.

Table 1

Cohort (Total: N=288)	A: core HRD (BRCA1/2/PALB2)	B: non-core HRD (ATM, BARD1, BLM, CHEK2, RAD50, RAD51C, RTEL1, MUTYH)	C: others without HR-gene alterations

#6422

Combined TGFβ/PD-L1 blockade enhances systemic antitumor immunity in head and neck cancer

Magdalena Rainey, Marco Craveiro, Yvette Robbins, Cem Sievers, Clint T. Allen. *Head and Neck Section, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Head and neck squamous cell carcinoma (HNSCC) unrelated to human papillomavirus (HPV) confers poor prognosis, with half of patients experiencing disease relapse in advanced stages. Response rates to traditional immunotherapies are low and novel approaches such as the bifunctional fusion protein Bintrafusp alfa (BA) that concurrently blocks PD-L1 signaling and neutralizes TGFβ are actively under investigation. Our group showed that when HNSCC patients received neoadjuvant BA therapy, it reversed exhaustion of tumor-infiltrating lymphocytes (TILs) by promoting antigen-mediated signaling. Additionally, we observed that BA promoted recirculation of TILs into peripheral blood possibly through decreased expression of the TGF-β-driven tissue-retention marker CD103. We hypothesize that addition of TGFβ neutralization to PD-L1 blockade can enhance systemic anti-tumor immunity compared to PD-L1 blockade alone. We assessed immune responses to BA in wild-type mice bearing established mouse oral cancer (MOC)-1 tumors that were randomized into the following groups: 1) vehicle; 2) anti-PD-L1 antibody (Avelumab); 3) TGFβ neutralizing construct with a mutated PD-L1 antibody (BA-M); 4) TGFβ neutralizing construct with a functional PD-L1 antibody (BA). Additionally, since our previous data suggests that BA responsiveness depends on CD8 T cell activity, we included two extra groups 5) CD8 depleting antibody alone or 6) in combination with BA. Three days after

completing treatment, MOC-1 tumor cells were injected into the contralateral flank and engraftment and progression of secondary challenge tumors was analyzed. Primary tumor progression was significantly inhibited by BA and to a lesser extent avelumab compared to control or BA-M. Engraftment or progression of secondary challenge tumors was significantly inhibited by BA and to a lesser extent avelumab compared to control or BA-M. The growth inhibitory effects of BA were abrogated by CD8 depletion in both the primary and challenge tumors. Flow cytometry analysis of tissue collected on day 7 post-tumor challenge showed that BA-mediated clearance of the tumors was associated with a proportional increase of $CD4^+$ and $CD8^+$ TILs. We also observed that the frequency of CD103 expression among $CD4^+$ TILs was reduced both in the primary and challenge tumors. Although TGFβ neutralization alone fails to induce anti-tumor immunity, the addition of TGFβ neutralization to PD-L1 blockade provides greater control of primary tumor growth and protection from engraftment of a challenge tumor compared to PD-L1 blockade alone. Through adoptive transfer of tumor-specific T cell receptor-engineered T cells, ongoing experiments aim to determine if TGFβ-driven CD103 expression is required for T cell tumor residency and if neutralization of TGFβ in the setting of PD-L1 immune checkpoint blockade allows for recirculation of tumor-specific T cells into the periphery.

Targeting an autophagy regulator augments antitumor immunity and immunotherapy

Yi Bao, Yuanyuan Qiao, Arul Chinnaiyan. *University of Michigan, Ann Arbor, MI*

Immunotherapy has strikingly changed the landscape of cancer treatment, yet many patients fail to respond to the therapy exhibiting primary resistance. Accumulating evidence has supported that autophagy inhibition may sensitize tumor to immunotherapy. Here, we found that pharmaceutical or genetic inhibition of an autophagy regulator induces MHC class I surface expression in cancer cells. In a co-culture of OT1 $CD8^+$ T cells and ovalbumin-expressing cancer cells, inhibition of the regulator enhances $CD8^+$ T cell killing and increases functional and proliferative $CD8^+$ T cells. Concordantly, genetic depletion or inhibition of the regulator elevates MHC

class I in tumor cells, reduces tumor growth, and increases intratumoral functional $CD8^+$ T cells in syngeneic mouse models. Furthermore, we found that inhibition of the regulator sensitizes syngeneic tumors to anti-PD1 therapy. Collectively, inhibition of this autophagy regulator augments antitumor immunity and immunotherapy via inducing MHC class I surface expression in cancer cells.

Immune characteristics and anti-PD-1-induced reinvigoration capacity of tumor-infiltrating lymphocytes in ovarian clear cell carcinoma relative to high-grade serous ovarian carcinoma

Junsik Park, Yong Jae Lee, Jung Chul Kim, Jung-Yun Lee. *Yonsei University College of Medicine, Seoul, Korea, Republic of*

Recent clinical trials have demonstrated the potential efficacy of immune checkpoint inhibitors (ICIs) for ovarian clear cell carcinoma (OCCC). However, little is known about the immune characteristics of OCCC. In this study, we aimed to investigate the distinct immune characteristics of tumor-infiltrating lymphocytes (TILs) in OCCC to high-grade serous ovarian carcinoma (HGSOC). We isolated peripheral blood mononuclear cells (PBMCs) and TILs from patients with epithelial ovarian cancer. The expression of immune checkpoint receptors and T-cell transcription factors of TILs in OCCC (n=26) and HGSOC patients (n=44) were accessed using flow cytometry. TILs were *ex vivo* stimulated with anti-CD3 in the presence of anti-PD-1 and/or anti-CTLA-4, and their proliferation was assessed to predict response to ICIs. CD8 TILs and tumor-infiltrating regulatory T cells (Tregs) exhibited higher expression of immune checkpoint receptors, including PD-1, CTLA-4, and 4-1BB, compared to PBMCs. Tregs were more infiltrated in advanced/recurrent stage than early stage OCCC. However, immune characteristics of CD8 TILs and Tregs were not significantly different regardless of stage. When we compared the characteristics of TILs in OCCC (n=26) with those in HGSOC (n=44), the expression of PD-1 on CD8 TILs was significantly lower in OCCC than in HGSOC. The frequencies of $PD\text{-}1^{high}CD8$ TILs and $PD\text{-}1^+TOX^+CD8$ TILs were also lower in OCCC than HGSOC. In *ex vivo* assay (n=19), 9 cases responded to anti-PD-1 in terms of enhanced proliferation capacity of CD8 TILs. In addition, when anti-CTLA-4 was added to anti-PD-1, an additional

increase in proliferation of CD8 TILs was observed in patients who responded to anti-PD-1. Responders to anti-PD-1 had significantly lower frequencies of effector Tregs in the TILs than non-responders. Overall, CD8 TIL in OCCC was found to be less exhausted than HGSOC in terms of PD-1 and TOX expressions. Tumor-infiltrating Tregs affected on reinvigoration ability of CD8 TILs upon ICIs treatment in OCCC. This study provides the rationale and evidence for establishing the optimal strategies for ICIs treatment in patients with OCCC.

Immune checkpoint blockade (ICB) therapy has improved long-term survival for patients with advanced melanoma. However, there is critical need to identify potential biomarkers of response and actionable strategies to improve response rates. Through generation and analysis of over 200 chromatin modification maps for ICB-treated melanoma patient samples, melanoma cells and T cells, we identified significant enrichment of active enhancer states in non-responders at baseline. Enhancer mapping by bulk ChIP-Seq or single cell ATAC-Seq methods in two independent cohorts of ICB-treated melanoma samples identified an enhancer signature that predicted response to anti-PD-1 therapy. The activated non-responder enhancers marked a group of key regulators of several pathways in melanoma cells (including c-MET, TGFβ, EMT and AKT) that are known to mediate resistance to ICB therapy. In addition, several checkpoint receptors were alternatively activated by aberrant enhancers in T cells. Unbiased CRISPRi screening in melanoma cells and T cells identified novel functional enhancers, such as one upstream of c-MET, that mediate ICB response or T cell mediated killing. Finally, inhibition of enhancers and repression of these pathways using bromodomain inhibitors along with anti-PD-1 therapy significantly decreased melanoma tumor burden and increased T-cell infiltration. Epigenomic experiments identified a signature of 107 genes that could be used as pharmacodynamic marker for BET inhibitor response. Together, these findings identify enhancer upregulation as a key mechanism of adaptive resistance to ICB response, a potential enhancer-based biomarker of resistance to anti-PD-1 and enhancer blockade in combination with ICB as a potential strategy to improve responses.

Selective-HDAC inhibitor relieves the suppressive immune microenvironment in the brain to impede breast cancer brain metastasis

Shao-Ping Yang[1], Yimin Duan[2], Xiangliang Yuan[2], Lin Zhang[2], Patrick Zhang[2], Dihua Yu[2]. *[1]The University of Texas MD Anderson Cancer Center, UT Health Houston Graduate School of Biomedical Sciences, Houston, TX,[2]Molecular and Cellular Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Brain metastasis (BrM) incidence is rising due to longer survival resulted from better systemic control of cancer, counting for approximately 20% of patients with cancers. Major cancer types, including lung, breast, and skin cancers, have a high rate to develop BrM with a 1-year survival rate of less than 20% for symptomatic patients. The overall response rate for immune checkpoint inhibitors (ICI) is merely 10-30% in patients with neurological symptoms. Developing novel combinatorial therapeutic strategies based on mechanistic understanding is urgently needed to further improve the efficacy of current immunotherapies in BrM patients. We recently found that BrMs in patients frequently have severe MHC-I loss. BrM patients' scRNA-seq data from available datasets show that MHC-I expression level is negatively correlated with HDAC level in breast cancer brain metastasis. On the other hand, HDAC inhibitors (HDACi) are epigenetic modulators which have been indicated to recover MHC-I expression loss that contributes to immune invasion. HDACi has been indicated to enhance ICI efficacy in primary tumors by reprogramming the tumor microenvironment (TME). However, the immunomodulatory effect of HDACi is unclear in the unique brain immune microenvironment (BrIME), which is characterized as immunosuppressive. Here, we report that although the selective-HDACi Entinostat has a relatively poor blood-brain barrier (BBB) penetration compared to pan-HDACi Panobinostat, Entinostat induced a comparable level of histone acetylation in the brain to that of Panobinostat. Furthermore, combinatorial treatment consisting of HDACi Entinostat/Panobinostat and anti-PD1 reduced BrM outgrowth of EO771 mammary tumor cell-induced BrM in synergetic mouse model. We explored the impact of HDACi on cell surface MHC-I expression by flow cytometry. Entinostat restored MHC-I expression levels on both brain-seeking human and murine breast and lung cancer cell lines, indicating a general epigenetic regulation on MHC-I expression by inhibition of HDACs. To dissect the impact of HDACi on the BrIME, immune profiling of BrM was performed by mass cytometry (CyTOF). Notably, Entinostat induced a dramatic increment of a specific antigen-presenting cell (APC) cluster in BrM-bearing BrIME with increased ratio of M1 proinflammatory macrophages: M2 tumor-associated macrophages (TAMs) and decreased Tregs. Our results suggest that Entinostat can upregulate MHC-I for more effective antigen presentation and enhance anti-tumor immunity in BrIME.

Targeting SMARCAL1 as a therapeutic strategy to enhance cGAS/STING signaling in gastric cancer

Po-Yen Hsu[1], Yu-Ming Chuang[1], Shu-Hui LIN[2], Yu-Ting Lee[3], Yin-Chen Chen[1], Enders K.W. Ng[4], Kun-Tu YEH[2], Alfred S.L. Cheng[5], Michael W.Y. Chan[1]. *[1]Department Biomedical Sciences, National Chung Cheng Univ., Chiayi County, Taiwan,[2]Department of Surgical Pathology, Changhua Christian Hospital, Changhua, Taiwan,[3]Divsion of Hematology & Oncology, Department of Medicine, Ditmanson Medical Foundation Chiayi Christian Hospital, Chiayi County, Taiwan,[4]Deptartment of Surgery, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[5]School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Gastric cancer is one of the leading causes of cancer death in Eastern Asia. Although immunotherapy, such as immune checkpoint blockade, is an emerging therapeutic strategy against gastric cancer, only a fraction of cancer patients show a therapeutic response. Therefore, developing a novel therapeutic strategy to turn a “cold” tumor into a “hot” tumor is considered a crucial issue in cancer treatment. By methylomic analysis, we found that SMARCAL1 is one of the STAT3 targets which might be regulated by STAT3-mediated promoter methylation. Moreover, an inverse correlation between SMARCAL1 promoter methylation and expression was observed in the TCGA online database and in our cell lines experiment. Bisulfite pyrosequencing also showed a significant hypomethylation of SMARCAL1 compared to gastritis and adjacent normal in our in-house cohort (gastritis n=15; IM n=13; cancer n=58). More importantly, SMARCAL1 knockdown showed increased sensitivity of gastric cancer cell lines to DNA-damaging agents and increase the expression of cGAS and its downstream target, IFNB1. Therefore, in this study, we propose SMARCAL1 as a therapeutic target for improving the efficiency of immunotherapy by enhancing the cGAS/STING signaling pathway.

#6429

A surrogate to the anti-IL1RAP antibody nadunolimab induces tumor microenvironment changes to the metastatic lung and reduces

metastatic lesions in mouse models of metastatic cancer

Elin Jaensson Gyllenbäck, Camilla Rydberg Millrud, Petter Skoog, Caitríona Grönberg, David Liberg. *Cantargia AB, Lund, Sweden*

Interleukin-1 Receptor Accessory Protein (IL1RAP) is a coreceptor for the IL-1 receptor (IL1R1) and is required for IL-1α and IL-1β signaling. IL1RAP is expressed in the tumor microenvironment (TME); on cancer cells, stromal cells and on infiltrating immune cells in several types of cancers, including non-small cell lung cancer (NSCLC), pancreatic cancer (PDAC), triple-negative breast cancer (TNBC) and in metastatic lesions. Nadunolimab (CAN04) is a fully humanized ADCC-enhanced IgG1 antibody targeting IL1RAP and blocking both IL-1α and IL-1β signaling, currently evaluated in combination with chemotherapy in phase I/II clinical trials in NSCLC and PDAC (NCT03267316) and in TNBC (NCT05181462). Interim efficacy data are available for PDAC and NSCLC and are stronger than expected from chemotherapy alone based on historical controls; in a total of 73 PDAC patients, median iPFS is 7.2 months and median OS 12.7 months, while in a total of 30 NSCLC patients, a response rate of 53% is achieved, resulting in median PFS of 6.8 months. Microenvironmental IL1RAP-dependent IL-1 signaling contributes to tumorigenesis, tumor invasiveness and an immune-suppressive TME, partly driven by infiltration and induction of myeloid-derived suppressor cells (MDSCs). We have thus used the MDSC-rich 4T1 murine mammary tumor TNBC model to study metastatic lesions and TME modulation in 4T1 metastatic lungs upon treatment with a mouse surrogate antibody to nadunolimab. Infiltration of gMDSC/Ly6G$^+$ cells was very prominent in metastatic lungs from mice with orthotopically implanted 4T1 breast cancer cells compared to lungs from naive mice. Interestingly, infiltrating Ly6G$^+$ cells from metastatic lungs had a distinctly upregulated IL1RAP expression compared to Ly6G$^+$ cells from naïve lungs. Treatment with the nadunolimab surrogate antibody significantly reduced the number of lung metastases and induced prominent changes in the lung microenvironment where nanostring analysis showed global changes in adhesion and migration-related genes, as well as genes associated with cell activation. The effect on metastasis was not confined to the 4T1 model since a reduction of metastatic tumor cells after treatment with the mouse surrogate antibody was also observed in the murine B16-F10-luc i.v. model. Together

these data indicate that targeting IL1RAP is an effective way to modulate the TME and counteract the suppressive environment in metastatic tissue, and ultimately may reduce the potential for metastatic tumors in cancer patients.

#6430

Single-cell transcriptomic and epigenomic landscapes of innate and adaptive immune cells in metastatic melanoma treated with immunotherapy

Jiekun Yang[1], Doris Fu[1], Kyriakitsa Galani[1], Li-Lun Ho[1], Emily J. Robitschek[2], Dennie T. Frederick[3], Sandeep K. Yadav[4], Wentao Deng[4], Anand K. Singh[4], Kelly P. Burke[2], Cassia Wang[1], Tatyana Sharova[3], David Liu[2], Kunal Rai[4], Genevieve M. Boland[3], Manolis Kellis[1]. *[1]MIT, Cambridge, MA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Massachusetts General Hospital, Boston, MA,[4]University of Texas MD Anderson Cancer Center, Houston, TX*

Immune checkpoint inhibitors (ICIs) have revolutionized the care for cancer and extended survival for advanced cancer patients. While ICIs have shown astonishing clinical benefits, less than 50% of patients experience a durable response. To find better biomarkers for ICI response and understand the diverse cellular players in the tumor microenvironment (TME), we performed single-cell RNA sequencing (scRNA; 222,351 cells; 39 samples), single-nucleus transposase-accessible chromatin sequencing (scATAC; 45,478 cells; 15 samples), and bulk RNA sequencing (39 samples) on a metastatic melanoma cohort with rich phenotypic and molecular data. In ICI resistant tumors, we revealed how cell-adhesion and ribosomal activity changes in adaptive immune cells can reflect tumor-level therapeutic failure. We characterized T cell diversity in the TME and discovered an early activated state and a terminally exhausted state. Among the innate immune cells, we detected a mature dendritic cell (DC) state as a strong prognostic predictor of progression-free survival associated with ICI treatment. We studied its differentiation trajectory, transcriptome signatures, epigenome landscape and interactome with T-cells, in comparison to conventional dendritic cell types 1 and 2. We also showed that CRISPR deactivation of the enhancers induced by the mature DC state compromised DCs' antigen-presentation capabilities and their interactions with antigen-

specific T-cells. Lastly, we identified genes and functional modules associated with ICI response (e.g. cell-adhesion) and resistance (e.g. oxidative phosphorylation). Given their functional roles in strengthening immune response to cancer, the molecular and cellular mediators discovered here can help predict ICI regimen efficacy, guide therapeutic development and drug combinations, and pave the path to targeted therapies with long-term effects and new immunotherapies.

#6431

Targeting Rab7-mediated STING degradation to amplify therapeutic STING agonism in TNBC

Yuqing Zhang[1], Jessica L. Ritter[2], Tran C. Thai[1], Deborah A. Dillon[3], David A. Barbie[1], Thanh U. Barbie[4]. *[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Homology Medicines, Inc, Bedford, MA,[3]Pathology, Brigham and Women's Hospital, Boston, MA,[4]Dana-Farber Cancer Institute; Brigham and Women's Hospital, Boston, MA*

STING (Stimulator of interferon genes), encoded by *TMEM173*, is a critical regulator of the innate immune response to cytoplasmic double stranded DNA in cancer and is actively being pursued as a target for cancer immunotherapy. STING agonist analogues of 2'-3'cGAMP, the cyclic dinucleotide that directly activates STING downstream of cyclic-GAMP synthase, have entered phase 1 clinical trials for triple negative breast cancers (TNBC). Recently, we have identified tumor cell Phosphatase and tensin homolog (PTEN) inactivation as a precision-based context in which to apply STING agonists. Mechanistically, PTEN null TNBCs maintain Ras-related protein Rab-7a (Rab7) in an inactive state and therefore trafficking of STING to the lysosome is impaired and cells are rendered hypersensitive to STING agonism. Tissue microarray analysis reveals high STING expression in PTEN null TNBCs. Consistently, PTEN null TNBC cell lines were hyper-responsive to STING agonists with increased downstream production of IRF3 targets including CXCL10. In contrast, PTEN wild-type cells exhibit low STING expression and modest sensitivity to STING agonism. As such, although a significant proportion of TNBCs are PTEN null, we sought to broaden these findings to PTEN wild-type TNBCs by genetically and pharmacologically mimicking the PTEN null state by Rab7 knockout and use of a novel selective Rab7 inhibitor,

CID1067700. Indeed, using the PTEN wild-type TNBC cell line, MDA-MB-231, we found that PTEN deletion robustly increased STING protein expression. Rab7 CRISPR-Cas9 knockout or treatment of MDA-MB-231 cells with CID1067700 and the STING agonist (ADU-S100) impaired trafficking of STING for lysosomal degradation, upregulated T cell chemokines, and enhanced growth inhibition. Next, to model the potential *in vivo* implications for immune cell recruitment and function, we used a 3D microfluidic T-cell migration assay. We found that the enhanced CXCL10 levels resulting from addition of CID1067700 to MDA-MB-231 cells led to T-cell recruitment to the tumor spheroids. Taken together, our study identifies PTEN null status as a specific genomic context in TNBC that has exquisite sensitivity to STING agonist therapy and combination with Rab7 inhibition could amplify therapeutic STING agonism in PTEN wild-type TNBCs.

#6432

Glutamine antagonist prodrug JHU083 reprograms immunosuppressive tumor-associated macrophages (TAMs) to drive tumor immunity in urologic cancers

Monali Praharaj[1], Fan Shen[1], Alex J. Lee[1], Liang Zhao[1], Thomas Nirschl[1], Xiaoxu Wang[1], Debebe Theodros[1], Alok K. Singh[2], Raekwon A. Williams[1], Laura A. Sena[1], Elizabeth A. Thompson[1], Ada Tam[1], Srinivasan Yegnasubramanian[1], Edward J. Pearce[1], Robert D. Leone[1], Jesse Alt[1], Rana Rais[1], Barbara S. Slusher[1], Andrew M. Pardoll[1], Jonathan D. Powell[1], Jelani C. Zarif[1]. *[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]University of Pennsylvania, Philadelphia, PA*

Tumor metabolism is emerging as a regulator of immune mediated anti-tumor responses. Previously, we reported increased immunosuppressive tumor-associated macrophages (TAMs) infiltration with disease progression in prostate adenocarcinoma (PCa).[1] Glutamine metabolism has been implicated in metastatic castration resistant prostate cancer (mCRPC)[2]. To harness the potent anti-tumor effects of 6-Diazo-5-oxo-L-norleucine (DON), which targets glutamine utilizing enzymes and to mitigate known significant toxicities, we here use a novel pro-drug moiety, i.e., JHU083. We hypothesize that JHU083 will enhance anti-tumor immunity by

simultaneously targeting TAMs and cancer cells.Using scRNA-seq dataset from mCRPC patients, we investigated the importance of glutamine metabolism in TAMs in the tumors.[3] Enriched expression of glutamine utilizing enzymes was observed in TAMs in the metastasized tumor tissue relative to benign. We used JHU083 to treat two urological syngeneic immunogenic mouse tumor models *in vivo*; B6CaP (PCa) and MB49 (bladder cancer). JHU083 showed significant tumor regression in both models. Using *in vivo* depletion of CD4 or CD8 T cells or adoptively transferring *in-vivo* JHU083 treated TAMs in TME, we established a direct anti-tumor role of TAMs. Moreover, to characterize the effect of JHU083 on TAMs transcriptional & translational signatures and metabolite flux *in vivo*, we used scRNA-sequencing and bulk RNA sequencing at two different time points, multi-parameter flow cytometry and targeted LC-MS/MS metabolic profiling. Clustering of the transcriptional signatures at both time points using UMAP dimensionality reduction classified 6 discreet differentially expressed clusters of TAMs. It elutes to an overall induction of TNF signaling and increased proliferation in the TAM sub-clusters. Strikingly, this was observed translationally as well. Moreover, translationally in the TME at a later timepoint, an increase of glycolytic transporter and enzyme, i.e., Glut1 and Hexokinase II was also observed. The overall impact of this on the metabolome, specifically glycolytic pathway changes in the sorted TAMs, remains to be elucidated. Lastly, we assessed in-vivo the functional phagocytosis of TAMs with flow cytometry and IF microscopy. JHU083-treated TAMs showed significantly increased phagocytic activity, providing direct evidence of functional reprogramming. Conclusions: We found that JHU083 reprograms TAMs from an immunosuppressive to an inflammatory state which we show has a direct anti-tumor effect. These macrophages convert to a highly proliferative and glycolytic state, have increased TNF production which might be resulting in improved phagocytic activity against tumor cells. As urologic cancers are heavily infiltrated with immunosuppressive TAMs, JHU083 is an excellent preclinical candidate.

A novel bacterial strain, CJRB-101, induces anti-cancer effects by repolarization of M2 to CXCL9 and CXCL10 dual expressing M1 macrophages in humanized non-small cell lung cancer mice models

Arim Min[1], Chun-bong Synn[2], Seong-san Kang[3], Bo-eun Kwon[1], Junwon Yang[1], Hyunkyung Park[1], Jieun Im[1], Hyunjeong Kim[1], Sujeong Beak[4], Dong Kwon Kim[2], Jii Bum Lee[5], Hyeonseok Oh[1], Seung Min Yang[4], Yu Jin Han[4], Mi hyun Kim[4], Heekyung Han[4], Kwangmin Na[4], Young Taek Kim[4], Sungwoo Lee[3], Mi Ran Yun[6], Jae Hwan Kim[4], Youngseon Byeon[4], Young Seob Kim[4], Ji Yun Lee[5], Chang Gon Kim[5], Min Hee Hong[5], Sun Min Lim[5], Kyoung-Ho Pyo[6], Byoung Chul Cho[5]. *[1]CJ Bioscience Inc., Suwon, Korea, Republic of,[2]College of Medicine, Brain Korea 21 PLUS Project for Medical Science, Yonsei University, Seoul, Korea, Republic of,[3]JEUK Institute for Cancer Research, JEUK Co., Ltd., Gumi, Korea, Republic of,[4]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of,[6]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of*

Backgrounds: Live biotherapeutic products (LBPs) emerged as potential therapeutics to overcome the limitation of ICIs. This research shows that CJRB-101, a novel bacterial strain, can improve anti-tumor effects in synergy with pembrolizumab in non-small cell lung cancer (NSCLC).
Objectives and Methods: Tumors from NSCLC patients (anti-PD-1 refractory and resistant) were transplanted into Hu-CD34-NSG to establish humanized patient-derived xenograft (PDX) mice models. Five models (YHIM-2003, 2004, 2009, 2010 and 2014) were treated with CJRB-101 at low ($5x10^7$ CFU) or high (10^9 CFU) doses, or with pembrolizumab (10 mg/kg, i.p., Q5D) or in combination. Tumor growth inhibition (TGI) rate was measured. Tumor microenvironment (TME) was analyzed using multiplex IHC, flow cytometry and single cell RNA sequencing. *Ex-vivo* assays were performed to validate in silico findings.
Results: Tumor in PDX models was unresponsive to pembrolizumab alone, however, in combination with CJRB-101 effectively suppressed tumor growth. The synergy was highlighted in YHIM-2009 where TGI was 10-fold higher (56%) than pembrolizumab group (5%). Immune profiling revealed that macrophages may be responsible for the anti-tumor effects of CJRB-101. IHC showed significantly increased antigen presenting

specialized DCs ($CD16^+CD68^-CD11c^+$) and granzyme B^+ $CD8^+$ T cells in the tumor by CJRB-101 compared to pembrolizumab ($p<0.01$). This suggested that CJRB-101 induced infiltration of cytotoxic CD8 T cells into the tumor nest by enhancing antigen presenting machinery. Trajectory analysis showed that CJRB-101 induced repolarization of M2 to M1 macrophages, characterized by high expression of CXCL9/10. $CXCL9^+/10^+$ M1 macrophages were comparatively more abundant in the combination group (23.11%) than the pembrolizumab group (0.91%). CXCL9/CXCL10 expression in macrophages was higher in the CJRB-101 group compared to the pembrolizumab group ($p<0.0001$). The combination group (10.84%) had a higher relative abundance of $CD8^+$ T cells compared to the pembrolizumab group (1.58%) and higher IFNγ expression in $CD8^+$ T cells compared to the pembrolizumab group ($p=0.0152$), suggesting that CJRB-101 repolarized macrophages and recruited active $CD8^+$ T cells. Co-culture assays using bone marrow-derived macrophages validated that CJRB-101 drove differentiation towards $F4/80^+$ or MHC II^+ expressing M1 macrophage ($p<0.0001$) and repolarized existing M2 ($CD206^+$) to M1 ($p=0.0002$).
Conclusion: Combination treatment of CJRB-101 with anti-PD-1 showed synergistic anti-tumor effects via repolarization of M2 to M1 macrophages, leading to activation of $CD8^+$ T cells in TME. Especially, $CXCL9^+/10^+$ M1 macrophage playing a key role in TGI induced by CJRB-101 in NSCLC models. Findings from this study provided rationale for clinical investigation of CJRB-101.

A precision probiotic therapeutic promotes a more efficacious type I immune response and limits breast cancer growth in mice

Denise L. Cecil[1], Erin Rodmaker[1], Susan Strenk[2], Lauren Corulli[1], David N. Fredricks[2], Mary L. Disis[1]. *[1]University of Washington, Seattle, WA,[2]Fred Hutchinson Cancer Center, Seattle, WA*

High levels of Type I T-cells are needed to eradicate breast cancer. Few cancers induce Type I immunity except those that contain a high mutational burden. The majority of solid tumor patients develop a Type II immune response to commonly recognized tumor antigens, which are aberrantly

expressed non-mutated tumor associated proteins. We found that within the amino acid sequence of non-mutated tumor associated antigens are class II binding epitopes that preferentially elicit a T-helper 1 interferon-gamma (g) or an IL-10 T-helper-2 response. We have identified high levels of IL-10 secreting T-cells present in the peripheral blood of both humans and mice, specific for non-mutated tumor antigens, which share significant sequence homologies with bacterial organisms found in the human gut microbiome. These lymphocytes, cross-reactive for both bacterial and tumor antigens (BAC-TA), are enriched for memory T-cells. In mice, the BAC-TA cross-reactive T-cells traffic to tumors and accelerate cancer growth. We have identified a selected number of bacterial species that are most commonly associated with numerous TA homologies (bacteria^{high}) and certain species that are rarely homologous to any TA sequences (bacteria^{low}). We hypothesized that bacteria^{low} species can safely be enriched in the gut microbiome. TgMMTV-neu mice, a transgenic model of luminal B murine mammary cancer, pre-treated with vancomycin and metronidazole in the drinking water, received six weekly oral treatments of 10^9 CFU of a combination of *Lactobacillus acidophilus* and *Ruminococcus albus*, both bacteria^{low} species. Metagenomic sequencing of stool examined one week after the last treatment revealed a mean 28% increase in *R. albus* (p=0.07) and a mean 38% increase in *L. acidophilus* (p=0.08) as compared to untreated stool. The increase in these two bacteria^{low} species corresponded with ≥30% reduction of 10 bacteria^{high} species. This oral treatment regimen also inhibited the growth of a syngeneic ectopic tumor by 36% (p=0.002). Enriching the microbiome with these bacteria^{low} species also enhanced the immunogenicity of a previously reported non-efficacious whole protein vaccine. Immunization with a full-length plasmid-DNA based vaccine targeting IGFBP-2 demonstrated no IFN-g response in control mice (p=0.012). However, after mice were treated with *L. acidophilus/R. albus*, the full-length vaccine significantly induced IFN-g secretion (p=0.02). These data provide preliminary evidence that reduction of bacteria^{high} species can inhibit tumor growth and augment immune responses, providing a basis for using a precision probiotic for the treatment of cancer. Future studies will address whether modulating bacteria^{high} species in the gut reduces BAC-TA T-cells in the blood.

BCG008, a human Siglec-15 blocking antibody, displays potent anti-tumor activity in Siglec-15-humanized mice

Yongfei Yang[1], Aidong Qu[2], Fengping Yao[1], Pan Song[1], Hongyuan Liang[2], Maopeng Tian[1], Fang Yang[1], Zhaoxue Yu[1], Xu Zhou[2], Xiuling Li[2].
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Shanghai Institute of Biological Products Co., Ltd, Shanghai, China

Sialic acid-binding Ig-like lectin 15, or Siglec-15, is identified as a critical immune suppressor. Siglec-15 expression is normally limited to certain myeloid cells, but it can be upregulated in a variety of tumors and on tumor-infiltrating myeloid cells. Siglec-15 significantly inhibits antigen-specific T cell responses both *in vitro* and *in vivo*. Conversely, genetic ablation of Siglec-15 promotes anti-tumor responses. Therefore, a Siglec-15-targeting blocking antibody could represent a novel class of anti-tumor immunotherapy. BCG008, a fully human monoclonal antibody antagonist of Siglec-15, was generated from RenMab™ mice, which contain the entire human immunoglobulin variable domain. Compared to a reference Siglec-15 blocking antibody (5G12), BCG008 exhibited higher affinity for human and cynomolgus monkey Siglec-15 and targeted distinct binding epitopes. In *in vitro* studies, BCG008 significantly abrogated Siglec-15-mediated T cell suppression in a dose-dependent manner, as measured by $CD4^+$ and $CD8^+$ T cell proliferation. Subsequently, the efficacy and safety of BCG008 was evaluated in syngeneic tumor models in Siglec15-humanized mice. BCG008 monotherapy significantly inhibited tumor growth, and the effect of the tumor inhibition was potentiated when administered in combination with other immune-checkpoint inhibitors, including anti-PD-L1 antibodies. In safety evaluation, BCG008 was well-tolerated in the tumor-bearing mice; no adverse effects were observed even at high doses (e.g. 30 mg/kg). Taken together, these results demonstrate that BCG008 is a novel anti-human Siglec-15 blocking antibody with favorable efficacy and safety profiles that can provide potential benefits for future cancer immunotherapy.

#6436

1C3, a novel non-blocking anti-human TNFR2 antibody, promotes effector T cell responses and demonstrates potent anti-tumor activity

Yongfei Yang[1], Shuzhen Cao[1], Wenjiao Zhang[1], Jing Zhang[1], Zhe Shao[2], Xueyuan Jiang[1], Qingya Duan[1], Maopeng Tian[1], Sen Mei[1], Zhaoxue Yu[1].
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Dragonboat Biopharmaceutical, Shanghai, China

Regulatory T cells (Tregs) are a subset of immunosuppressive $CD4^+$ T lymphocytes which can inhibit effector T cell activity in the tumor microenvironment (TME) and promote tumor growth. Depletion of Tregs is a promising immunotherapy strategy for treatment of cancers. Tumor necrosis factor receptor-2 (TNFR2) is highly expressed on both Tregs and many kinds of tumor cells, making it a potential candidate for tumor-targeted antibody therapy. A fully human, non-blocking agonist antibody to TNFR2, 1C3, was generated from RenMab™ mice, which contain the full human immunoglobulin variable domain. 1C3 was selected from a large panel of antibody candidates after unbiased, high-throughput efficacy screening conducted in syngeneic tumor mouse models established in humanized TNFR2 mice. *In vitro*, 1C3 effectively promoted proliferation of cytotoxic T cells. Subsequently, the *in vivo* anti-tumor efficacy and safety of 1C3 was evaluated in syngeneic tumor mouse models expressing human TNFR2. The results demonstrated that 1C3 monotherapy significantly inhibited tumor growth in a dose-dependent manner. In combination with anti-human PD-1 or PD-L1 antibodies, 1C3 also greatly potentiated anti-tumor responses compared to monotherapy of each agent. Analysis of tumor-infiltrating lymphocytes (TIL) demonstrated that 1C3 treatment significantly increased the ratio of effector T cells to Tregs in the TME. Moreover, 1C3 was well tolerated in mice, and no adverse effects were observed even at high doses (e.g. 100 mg/kg). In conclusion, these data demonstrate that 1C3 is a novel anti-human TNFR2 non-blocking agonist antibody with effective anti-tumor efficacy and favorable safety. 1C3 may exert these effects by regulating Treg and effector T cell activities.

#6437

Development of therapeutic vaccines against ovarian cancer

Leslie Hesnard, Catherine Thériault, Maxime Cahuzac, Chantal Durette, Krystel Vincent, Marie-Pierre Hardy, Gabriel Ouellet Lavallée, Joël Lanoix, Pierre Thibault, Claude Perreault. *IRIC Université de Montréal, Montreal, QC, Canada*

Epithelial ovarian cancer (EOC) has a devastating impact on the health of women and has not significantly benefited from advances in immunotherapy mainly because of the lack of well-defined actionable antigen targets. It is therefore essential to discover tumor-specific antigens (TSAs) that are specific to ovarian cancer, shared by a significant proportion of patients and capable of being targeted by the immune system. Using a groundbreaking method, we have previously identified 91 aberrantly expressed TSAs (aeTSAs), 18% of which were shared by at least 80% of the TCGA cohort (The Cancer Genome Atlas). These TSAs originate from unmutated non-exonic genomic sequences and their expression results from cancer-specific epigenetic changes. In the present study, our goal was to evaluate the immunogenicity of these aeTSAs. To do so, 49/91 antigenswere selected based on their presentation by high-frequency HLA allotypes (9 alleles included) and their expression in a large proportion of EOCs patients. Using functional *in vitro* expansion of naive CD8 T cells by co-culture with TSA-pulsed dendritic cells (DC) followed by CDR3 TCR sequencing, we first assessed the ability of aeTSAs in stimulating the immune system. Notably, 98% of our antigens were able to significantly expand CD8 T cell clonotypes, indicating that their repertoires are available for vaccination. In addition, tetramer staining of CD8 T cell populations after culture with TSA-pulsed DCs revealed that 32% of our aeTSAs tested (13/40) could expand specific CD8 T cells at levels that are detectable by flow cytometry. When selecting an optimal vaccination strategy, DC vaccines are particularly attractive. Using mass spectrometry to measure the abundance of TSAs presented at the cell surface, we next compared two modalities for engineering TSA-based DC vaccines: synthetic peptide pulsing vs TSA-encoding RNA minigenes transfection. Our preliminary results show that synthetic peptide pulsing leads to higher amounts of peptides presented at the surface of the dendritic cells compared to RNA minigenes electroporation. Moreover, we show a direct correlation between the abundance of peptides detected by MS immediately after pulsing on DCs and their predicted binding affinity. This correlation is not maintained with time (24h after pulsing), suggesting that the detection of peptides 24h post-pulsing is linked to the stability of peptide-MHC complexes rather than peptide binding affinity. In conclusion, we show that aeTSAs are attractive targets for EOC immunotherapy, as most of them can

expand sizeable populations of CD8 T cells. We also reveal that direct pulsing of aeTSAs on DCs leads to better peptide presentation than RNA minigene transfection. These results are of capital importance, as optimal TSA presentation by DCs leads to stronger anti-tumor responses. We believe that our approach could have a significant impact on immunotherapy of EOC, and eventually of other cancer types.

#6438

Next-generation pan-cancer immunotherapy with patient-derived APC

Zhen Bian, Lei Shi, Yuan Liu, harry Stylli. *Georgia Institute of Technology, Atlanta, GA*

Harnessing phagocytic antigen presenting cells (APC) and tumor neoantigen-specific T cells represent the ultimate power of immunotherapy against cancer. The promises of phagocytic APCs lie in their abilities of not only initiating phagocytosis towards cancer cells (to “eat off” tumor) but also, through immunogenic antigen presentation, activating neoantigen-specific Tcells that systemically and durably eliminate cancer cells, as well as the establishment of a long-lasting cellular and hormonal immunity that prevents tumor recurrence. However, the efforts of developing APCs -based therapy have been hindered by the current lack of technology that robustly produce APCs from cancer patients, as none of the traditional methods for differentiating DC or macrophage APCs are effective for cancer patients. Through a proprietary process, we have created a unique reagent combo that enables robust differentiation of cancer patients’ peripheral monocytes (cMo) to be potent APC, termed κAPC. κAPC display a unique gene expression profile, separating from classical DC or macrophage, and profound proinflammatory phenotype with enhanced phagocytic capability and elevated immunogenic antigen presentation machinery. In both in vitro and in vivo settings, κAPC demonstrate direct uptake of tumor antigens and presentation to T cells, the latter leading to activation and large expansion of multi-targeting, polyclonal tumor-specific CD4 and CD8 T populations -termed NeoT- from circulating and tumor-infiltrating lymphocytes. Theexpanded CD8 NeoT are highly tumoricidal and once adoptively transferred in vivo, potently eliminated late-stage metastatic solid tumors, whereas CD4 NeoT contribute to immune memory and repolarize a proinflammatory TME favorable for tumor elimination.

Key words: κAPC, NeoT, NeoT adoptive cell therapy, κAPC-based cancer vaccine, combination therapies

Actin remodeling, inhibitory ligand polarization and small vesicle recruitment hinder effective anti-tumor immunity by shaping the tumor cell side of the immune synapse

Andrea Michela Biolato[1], Liza Filali[2], Céline Hoffmann[1], Felix Kleine-Borgmann[2], Elena Ockfen[1], Max Krecke[1], Michel Mittelbronn[3], Clément Thomas[1]. *[1]Department of Cancer Research (DOCR), Luxembourg Institute of Health, Luxembourg, Luxembourg,[2]Luxembourg Institute of Health, Luxembourg, Luxembourg,[3]National Center of Pathology (NCP), Laboratoire Nationale de Santé (LNS), Dudelange, Luxembourg*

Cancer immune evasion is a major obstacle to effective anticancer immunotherapies. Recently, we unveiled a mechanism crucial in cancer escape from natural killer (NK)-mediated killing. The identified process is characterized by a rapid and massive accumulation of actin filaments at the cancer cell side of the immunological synapse (IS). We termed this process “actin response” (AR) and discovered that its inhibition is sufficient to restore cancer cell susceptibility to NK-mediated killing in vitro. Importantly, the AR is conserved across a wide range of malignancies, highlighting the broad translational potential of targeting this pathway. In this study, we investigated the molecular mechanisms underlying AR-mediated cancer cell immune evasion. Cancer-NK cell conjugates were analyzed by imaging flow cytometry (IFC) to investigate the polarization of inhibitory and activating ligands to the cancer cell side of the IS relative to the AR. We found that the AR is associated with and necessary for polarization of several inhibitory ligands. For instance, HLA-A,-B,-C molecules, which act as potent inhibitors of NK cells, were 2-fold increased at the IS of cancer cells with an AR when compared to cancer cells without an AR. Using confocal microscopy, we found that such polarization of inhibitory molecules is associated with the loss of MTOC and lytic granule polarization in conjugated human primary NK cells. In addition, correlative light and electron microscopy analysis revealed the presence of small vesicles (100 nm in size) and multivesicular bodies (MVBs) in the synaptic region of cancer cells with an AR. Quantification of vesicle markers at the

IFC revealed a significant enrichment of CD63+/CD9+/CD81+ vesicles in the synaptic region of cancer cells with an AR. Interestingly, ultrastructure analysis showed that the AR is largely made of long actin-rich protrusions projecting into and altering the morphology of the synaptic cleft. Moreover, these protrusions were decorated with inhibitory molecules, such as PD-L1, and CD63. We identified a novel, highly conserved immune escape mechanism that exploits the fast remodeling of the actin cytoskeleton in cancer cells to induce the polarization of inhibitory ligands along with small tumor vesicles towards the IS. These findings suggest that actin remodeling in tumor cells at the IS actively promotes immune evasion. Further insights on the molecular and cellular mechanisms underpinning this pathway, such as the identification of selective targeting of linker proteins between the actin cytoskeleton and inhibitory ligands or small vesicles, represent a promising therapeutic strategy to improve the efficacy of anticancer immunotherapies. Nevertheless, additional research is needed in order to evaluate the translational potential of targeting the AR in a clinical setting.

Targeting TCTP reverses the multi-malignant phenotypes of immune-refractory tumor cells

Hyo-Jung Lee, Tae Woo Kim. *Korea University, Seoul, Korea, Republic of*

Cancer immunotherapy, particularly T cell-mediated therapy such as immune checkpoint blockade (ICB) and adoptive T cell transfer (ACT), has emerged as a potentially powerful approach to cancer treatment. However, immunotherapeutic resistance limits its clinical success by disrupting one or more steps of the cancer immunity cycle. In addition, multi-malignant phenotypes of immune-refractory tumor cells are also one of the major causes result poor prognosis of patients. Therefore, identifying the immune-resistance and multi-malignant factor, which not only can be targeted by clinically available medicines it can also be a prognostic marker, is needed ideally. Here, we identified TCTP as a novel factor conferring multi-malignant phenotypes of immune-refractory tumor cells. We discovered a crucial role of TCTP at the crossroads between multi-malignant tumor cells and the anti-cancer immunity system by demonstrating that $TCTP^{high}$ tumor cells enriched by immune selection pressure drive immune-refractory phenotypes. Importantly, the levels of TCTP within the tumors significantly

correlated with the clinical outcome of anti-PD-L1 therapy, which demonstrate TCTP as a prognostic marker in the case of clinical trials. Furthermore, targeting TCTP by clinical available drug enhanced the response to T cell-mediated therapy including ICB and ACT. Thus, our findings emphasize that TCTP could be a both a valid target a prognostic marker providing a framework for patient selection to apply combined therapy of T cell-mediated therapy with TCTP-targeting agents.

Role of TWEAK-Fn14 axis in driving immunosuppression in glioblastoma multiforme

Angad Beniwal[1], Ryan Eghlimi[1], Kenneth D. Alexander[2], Mylan R. Blomquist[1], Nhan Tran[1]. *[1]Mayo Clinic College of Medicine and Science, Scottsdale, AZ,[2]University of Kentucky, Lexington, KY*

Cellular heterogeneity within glioblastoma multiforme (GBM) is a key driver of resistance to standard-of-care therapeutic approaches such as DNA damage (temozolomide, TMZ), angiogenesis inhibition (Bevacizumab, BM), radiation necrosis, and surgical resection. As such, understanding and targeting heterogeneous tumor-associated populations is a critical aim of ongoing GBM research. Central nervous system (CNS) resident microglia constitute significant percentages of primary GBM samples, often up to 50% of bulk tumor. Additionally, glioblastoma-associated microglia have been implicated in intra-tumoral immunosuppression, and are thus a key barrier to successful implementation of immunotherapies that seek to enhance T-cell mediated anti-tumoral cytotoxicity. As such, insight into targetable pathways that upregulate immunosuppressive cytokines within GBM-associated microglia is necessary for overcoming immuno-therapeutic failure. Here, we identify expression of the cytokine TWEAK (TNFSF12) and its receptor Fn14 (TNFRSF12A) within the myeloid compartment of primary GBM samples via scRNA-seq. Furthermore, we demonstrate TWEAK-mediated reprogramming of GBM-associated microglia towards an immunosuppressive phenotype capable of inhibiting CD8+ T cell activation and proliferation. These findings unveil a potent, targetable axis of immunosuppression within GBM and are thus an exciting step towards enhancing efficacy of existing T-cell based anti-cancer strategies for GBM patients.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS

Cyclin-dependent Kinases and Cyclin-dependent Kinase Inhibitors

CDK1 bridges NF-kB and b-catenin signaling in response to H. pylori infection in gastric tumorigenesis

Marwah M. Al-Mathkour, Shoumin Zhu, Longlong Cao, Shayan Khalafi, Zheng Chen, Julio Poveda, Dunfa Peng, Heng Lu, Mohammed Soutto, Tianling Hu, Oliver McDonalnd, Alexander Zaika, Wael El-Rifai. *Surgery, University of Miami Miller School of Medicine, Miami, FL*

Background: Cell cycle dysregulation is a hallmark of cancer, resulting in unregulated cell proliferation and, eventually, tumor development. Cyclin-dependent kinase 1 (CDK1) is a cell cycle regulatory protein that is involved in cell cycle maintenance. CDK1 has been discovered to be substantially elevated in a several tumors and is linked to poor overall and relapse-free survival. The aim of this study is to understand the regulation role of *Helicobacter Pylori* infection and inflammation on CDK1 expression in gastric cancer.
Methods: Using TCGA data and our integrated comprehensive gene expression analysis, we found a significant overexpression of CDK1 in gastric cancer human and mouse tissues. We detected overexpression of CDK1 in human and mouse gastric glands in response to *H. pylori* infection. Our data demonstrated that *H. pylori* infection induced phosphorylation (S536) and activation of NF-kB in vitro and in vivo. Furthermore, *H. pylori* infection and TNF-α treatment increased the CDK1 mRNA and protein levels in gastric cancer cell lines. Using the ChIP assay, we detected direct biding of NF-κB on the CDK1 promoter regulating its transcription. CDK1 promoted activation of the β-catenin signaling pathway. Using the pTOP/pFOP luciferase reporter assays, as a measure of β-catenin/TCF transcription activity, we confirmed CDK1-dependent activation of β-catenin in response to *H. pylori* infection. Pharmacologic and genetic inhibition of CDK1 reversed these effects and decreased number and size of gastric tumors organoid from mouse and human.

Conclusion: Our findings demonstrate NF-kB-mediated induction of CDK1 expression in response to *H. pylori* infection with subsequent activation of tumorigenic β-catenin signaling. This novel regulatory link between infection, CDK1, and β-catenin suggests the importance of considering CDK1 inhibitors in gastric cancer.

#5973

The brain penetrant CDK4/6 Inhibitor, PRT3645, is highly effective in combination with other targeted therapies in preclinical models of NSCLC, CRC, and HER2-positive breast cancer

Yue Zou[1], Srijita Dhar[1], Kirsten Gallagher[1], Andrew Buesking[2], Sarah Pawley[2], Ryan Holmes[2], Xiaowei Wu[2], Katarina Rohlfing[2], Min Wang[2], Joseph Rager[2], Tom Emm[2], Stefan Ruepp[2], Miles Cowart[2], Jing Ni[3], Jean Zhao[3], Bruce Ruggeri[2], Andrew Combs[2], Kris Vaddi[2], Sandy Geeganage[2], Ashish Juvekar[4], Sang Hyun Lee[2], Peggy Scherle[2]. *[1]Biology, Prelude Therapeutics Inc., Wilmington, DE,[2]Prelude Therapeutics Inc., Wilmington, DE,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Modifi Bio, New Haven, CT*

Cell cycle deregulation is a hallmark of cancer and the hyperactivation and overexpression of CDKs are often drivers of cancer pathogenesis. Cyclin-dependent kinase 4 and 6 (CDK4)/(CDK6) are critical mediators of cellular transition into S phase and important for the initiation, growth, and survival of many cancers. Activated CDK4/CDK6 complexes phosphorylate Rb1, reduce their binding affinities and release Rb1-containing transcription repressor complexes from E2F transcription factors, resulting in activation of E2F controlled cell cycle genes and progression of the cell cycle. At present three CDK4/CDK6 inhibitors are approved for the treatment of ER+/HER2- breast cancer, and are being explored in other cancer indications as well. Previously we described a novel brain penetrant CDK4/CDK6 inhibitor, PRT3645, that exhibits single digit nanomolar biochemical potency against CDK4/CDK6 and >2000-fold selectivity against CDK1, CDK2 and CDK9. PRT3645 inhibits cellular phosphorylation of Rb and exhibits a protein binding-adjusted cellular IC50 of <300 nM. PRT3645 exhibits favorable in-vitro safety pharmacology and ADME properties, including increased brain penetration, and demonstrates

oral bioavailability across rodents, dog, and non-human primates. In addition to robust monotherapy activity observed in preclinical models of ER+/HER2- breast cancer, we explored the activity of PRT3645 in other tumor types as well as in combination with other targeted therapies. In NSCLC, PRT3645 treatment resulted in significant inhibition of cell lines that harbor activation of the RAS/MEK/ERK pathway in proliferation assays and demonstrated comparable high synergy scores when combined with clinically approved covalent KRAS G12C inhibitors. In-vivo, oral PRT3645 was well tolerated and induced anti-tumor efficacy in two KRAS G12C mutant xenograft models that harbor the CDKN2A (p16) deletion. Anti-tumor efficacy was further improved when PRT3645 was combined with KRAS/MEK inhibitors in xenograft models and the combination therapy was well tolerated. In addition, we explored combinations of PRT3645 with a brain penetrant receptor tyrosine kinase inhibitor (TKI), an approved treatment for patients with advanced HER2+ breast cancer, including patients with brain metastases. In a HER2+ orthotopic human breast cancer brain metastasis model, PRT3645 was highly efficacious in combination with HER2 kinase inhibition and enhanced median survival significantly. In summary, PRT3645 demonstrates an excellent balance of potency, selectivity, PK parameters across species and brain penetrance. In preclinical studies, PRT3645 was highly efficacious when combined with KRAS/MEK inhibitors, and with a brain penetrant HER2 receptor TKI, both in-vitro and in-vivo. PRT3645 has advanced into Phase 1 clinical trials (*NCT05538572*).

#5974

Synergistic activity of the CDK4/6 antagonist narazaciclib (ON123300) with irreversible BTK inhibition in ibrutinib-resistant mantle cell lymphoma

Nuria Profitos-Peleja[1], Marcelo L. Ribeiro[1], Adar Makovski Silverstein[2], Stephen Cosenza[2], Gaël Roué[1]. *[1]Lymphoma Translational lab, Josep Carreras Leukaemia Research Institute, Badalona, Spain,[2]Onconova Therapeutics, Newtown, PA*

Bruton tyrosine kinase inhibitors (BTKi) have transformed the therapeutic landscape of B-cell lymphoma including the aggressive mantle cell lymphoma (MCL) subtype, although primary and acquired resistance is

frequently observed. Interestingly, preliminary results have suggested that the second-generation, orally bioavailable and clinical-stage CDK4/6 inhibitor, ON123300 (narazaciclib), may be effective in preclinical models of BTKi-resistant MCL. We compared the efficacy and safety of ON123300 vs the approved CDK inhibitors palbociclib, abemaciclib or ribociclib, in association with various BTKi, in a panel of 10 MCL cell lines with distinct sensitivity to the first-in-class BTKi, ibrutinib, or the second generation acalabrutinib. We evaluated the effects of these combinations by CellTiter-Glo proliferation assay, FACS-mediated analysis of cell cycle and apoptosis, RT-PCR and western blot. Efficacy and safety of ON123300 in vivo was evaluated in a chicken embryo chorioallantoic membrane (CAM) xenograft model of MCL. We observed that ON123300 exhibited a significant antitumor activity in MCL cell lines independently of their sensitivity to ibrutinib, with IC50 at 72h ranging from 0.7 to 7.1μM (mean: 3.61±2.1μM), while it achieved a 32% tumor growth inhibition, with no detectable toxicity, in the CAM-MCL model. In vitro, ON123300 demonstrated a superior activity than palbociclib and ribociclib, and a similar effect that abemaciclib. Interestingly, ON123300 exhibited an antitumor activity comparable to ibrutinib but was more effective than acalabrutinib. ON123300 single agent treatment repressed several positive regulators of the G2/M cell cycle phase and triggered the accumulation of the CDK inhibitors p21, p16, and phospho-p27, with the consequent loss of phospho-Histone H3 and phospho-CDK2. Accordingly, ON123300 treatment evoked a 20-35% increase in G1 cell cycle fraction at 24h, which preceded the ignition of mitochondrial apoptosis. When combined with ibrutinib, rather than with acalabrutinib, ON123300 exhibited a significant antitumor activity with synergistic combination indexes in both BTK-sensitive and BTK-resistant cell lines. This phenomenon was associated with a slight but constant (+10-15%) augmentation of G1 blockade, histone H3/CDK2 dephosphorylation and p27/p16 accumulation in cells exposed to ibrutinib-ON123300 combination, with no detectable potentiation of apoptosis. In conclusion, ON123300 is safe and effective as single agent in preclinical models of MCL, including BTKi-resistant cases. Due to its complete distinct MoA from BTKi involving the direct modulation of cell cycle, ON123300, but not abemaciclib or palbociclib, can achieve significant synergistic activity in combination with ibrutinib, and in lower extent with acalabrutinib, especially in BTKi-resistant MCL cases.

#5975

Discovery of mechanisms that modulate the hippo pathway and CDK6 expression in CDK4/6 inhibitor resistant breast cancer cells

Chung-Jen Yu[1], Yong-Ji Zhuang[1], Ting-Yi Lin[1], Ta-Chung Chao[2], Chun-Yu Liu[2], Ling-Ming Tseng[2], Jiun-I Lai[1]. *[1]National Yang-Ming Chiao Tung University, taipei, Taiwan,[2]Taipei Veterans General Hospital, taipei, Taiwan*

Hormone positive (HR+) breast cancer is the most common subtype in this population. The current standard of care in advanced HR+ breast cancer includes endocrine therapy (tamoxifen, aromatase inhibitors, etc) and CDK4/6 inhibitors. CDK4/6 inhibitors significantly prolong survival and is now the general accepted choice of drug in first line. Despite the enormous clinical benefit, there remains a substantial portion of patients who ultimately develop resistance against CDK4/6 inhibitors. Many mechanisms have been proposed for CDK4/6 inhibitor resistant, including upregulation of CDK4, CDK6, Cyclin E, and others. Recently studies have linked the hippo pathway to CDK6 upregulation and resulting in CDK4/6 inhibitor resistance. We have set up a kinase library screen for kinase inhibitors that downregulate CDK6 amplification and further assess for reversal of resistance. We discovered staurosporine and the PI3K inhibitor PIK-75 as small molecules that potently downregulate CDK6 expression in breast cancer cells. We further confirmed that these compounds reverse the resistance towards CDK4/6 inhibitors in CDK6 amplification cells. By kinase profiling combined with a small hairpin RNA (shRNA) screen, we discovered the mechanisms that resulted in CDK6 downregulation and modulation of the hippo pathway to reverse the CDK4/6 inhibitor resistance. Our discovery has implications for therapeutic development in this group of patients posing a huge unmet need.

#5977

Evaluation of the potential combination regimens for q901, a clinical stage selective cdk7 inhibitor, as a DNA damage repair inhibitor

Donghoon Yu[1], Yeejin Jeon[1], YoonJi Lee[1], Seung-Joo Lee[1], Jaeseung Kim[1], Hyerim Jung[2], Tae-Kyung Kim[2], Kiyean Nam[1]. *[1]Qurient Co. Ltd., Seongnam-si, Korea, Republic of,[2]Department of Life Sciences, Pohang University of Science and Technology, Pohang, Korea, Republic of*

Background; Q901 is an extremely selective CDK7 inhibitor with potent single agent activity in the multiple in vivo tumor models including small cell lung cancer, cholangiocarcinoma, colon cancer, pancreatic cancer, hormone receptor positive breast cancer, castrate-resistant prostate cancer, and ovarian cancer. Q901 is currently in Phase 1/2 clinical trial for patients with selected advanced solid tumors (ClinicalTrials.gov: NCT05394103). In the preclinical models, Q901 treatment induces DNA damage response (DDR) impairment markers, particularly ones involved in the double-strand break repair mechanisms. This opens up broad range of possibilities for new combination regimen that could benefit from the accumulated DNA damages caused by Q901 treatment.
Methods: Various combinations have been tested to evaluate potential clinical regimens in multiple solid tumor models. Two different BRCA wild-type ovarian cancer A2780 and OVCAR3 models, an estrogen receptor positive MCF7 breast cancer model, or a syngeneic RENCA mouse renal cancer model was tested with Q901 in combination with poly ADP-ribose polymerase (PARP) inhibitor, selective estrogen receptor degrader (SERD), an estrogen receptor (ER) PROTAC degrader, or an anti-PD-1 antibody, respectively.
Results: In the A2780 model, the PARPi alone group showed 15% TGI (tumor growth inhibition), but significant tumor regression (104% TGI) was observed in the Q901 and PARPi combination. In the OVCAR3 model, the Q901 and PARPi combination group showed 105% TGI, whereas the PARPi alone group showed 38% TGI. In the MCF7 model, SERD alone showed 64% TGI and Q901 combination with SERD showed 94% TGI. Remarkable tumor regression (111% TGI) was observed in the MCF7 model combining ER PROTAC and Q901, whereas ER PROTAC alone group showed 55% TGI. In the RENCA model, the anti-PD-1 antibody alone group showed 13.2% TGI and the combination of Q901 and anti-PD-1 antibody showed 66% TGI. In summary, these preclinical model studies demonstrated significant additive/synergistic effects of the Q901 combination on tumor growth inhibition.
Conclusion: The non-clinical data demonstrate that Q901 not only has a potential as a single agent,but can also be used in combination with other therapeutic strategies to develop next-generation cancer therapeutics to potentially address unmet medical needs.

Cyclin dependent kinase 9 inhibitor AZD4573 induces cell death through DNA damage accumulation in breast cancer cells *in vitro*

Minyoung Lee[1], So Hyeon Kim[1], Sujin Ham[1], Hae Min Hwang[1], Youlim Noh[1], Yu-Jin Kim[1], Ahrum Min[1], Jinyong Kim[2], Dae-Won Lee[2], Kyung-Hun Lee[2], Seock-Ah Im[2]. *[1]Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of,[2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of*

Background: Cyclin dependent kinase 9 (CDK9) regulates progression of RNA polymerase II through phosphorylation. Inhibition of CDK9 induces transcription-replication conflicts (T-R conflicts), leading to replication stress. AZD4573, a highly selective CDK9 inhibitor, showed anti-tumor effects in acute myeloid leukemia *in vitro* and *in vivo*. Recently it is being evaluated in phase 2 clinical trial (NCT04630756). However, the anti-tumor effect of AZD4573 is unknown in breast cancer. Thus, we investigated the anti-tumor effect of AZD4573 in breast cancer cells and explored the underlying mechanism.

Methods: To evaluate the antitumor effect *in vitro*, MTT assays were preformed using increasing concentration of AZD4573 (doses range : 0-100 nM). The IC_{50} values were calculated using Sigma Plot software. Cell cycle analysis was performed using flow cytometry analysis. The expression of signal transduction molecules was determined using quantitative PCR, western blotting, and immunofluorescence. Apoptotic cell death was verified by annexin-V assay. DNA strand breaks and repair efficacy were evaluated through alkaline comet assay. siRNA knock-down system was used to confirm the action mechanism.

Results: SK-BR-3, HCC70, HCC1937 and ZR-75-1 were sensitive to AZD4573 with IC_{50} ranging from 9.16-25.81 nM, whereas T47D and HCC1428 were less-sensitive (IC_{50} >100 nM), as assessed by MTT assay. After treatment of AZD4573, sensitive and less-sensitive cells showed increased T-R conflicts in 10 minutes. T-R conflicts were maintained in SK-BR-3, HCC70, HCC1937 and ZR-75-1 for 3 hours, but T-R conflicts disappeared immediately in T47D and HCC1428 cells. Moreover, expression of γ-H2AX, cleaved PARP and cleaved caspase-3 was increased, indicating the induction of apoptosis in sensitive cells. Contrary to these results, γ-H2AX induction and apoptosis were not observed in T47D and

HCC1428 cells. siRNA knock-down of CDK9 in HCC1937 resulted in an increase of T-R conflicts, γ-H2AX, with induction of PARP cleavage and caspase-3 cleavage.
Conclusion: AZD4573 induced T-R conflicts and subsequent DNA damage. Accumulation of DNA damage caused caspase-3-dependent apoptotic cell death in sensitive breast cancer cells. However, less-sensitive breast cancer cells resolved T-R conflicts immediately and maintained genomic stability. These data suggest that AZD4573 induced significant anti-tumor effects by apoptotic cell death through accumulation of DNA damage, following T-R conflicts.

TY-0540, a highly potent CDK2/4/6 inhibitor, attenuates acquired resistance against CDK4/6 inhibition

Meihua Li[1], Chengshan Niu[2], Mingtao Chen[2], Kaige Ji[2], Hui Xu[1], Shengli Dong[1], Yan Zhang[2], Qinguo Meng[2], Yuge Dou[2], Yijun Wang[1], Rui Wu[1], Yian Tu[1], Chao Zhou[1], Apeng Liang[1], Huan Wang[3], Rongzhen Ni[3], Aishen Gong[3], Hui Su[3], Mingyu Jiang[3], Feng Xing[3], Shaoqing Chen[3], Xiugui Chen[3], Jun Li[1], Yusheng Wu[1]. *[1]TYK Medicines, Inc., Huzhou, China,[2]TYK Medicines, Inc., Zhengzhou, China,[3]TYK Medicines, Inc., Shanghai, China*

The introduction of cyclin-dependent kinase (CDK) 4 and 6 dual inhibitors significantly improves the progression-free survival of patients with ER+/HER2- advanced or metastatic breast cancer. A large cohort of patients, however, eventually relapse to CDK4/6 therapy. To further empower the CDK therapy, simultaneous targeting of CDK2, CDK4, and CDK6 has been proposed as a new strategy based on the finding that abnormal activation of CDK2/CyclinE1 due to CCNE1 gene amplification is determined the key resistant mechanism to CDK4/6 inhibition. Here we present preclinical data of TY-0540, a novel CDK2/4/6 inhibitor for the treatment of breast cancer that is resistant to CDK4/6 inhibition. TY-0540 demonstrates high selectivity against CDK2, CDK4, and CDK6 compared to that of CDK1, CDK7, and CDK9 in a CDK panel screening. *In vitro* cell proliferation data shows that tumor cell lines OVCAR3 and HCC1806, both bearing CCNE1 amplification, are highly sensitive to TY-0540 treatment. To test the effectiveness of the clinical candidate compound on CDK4/6i resistance models, two Palbociclib resistant cell populations (T47D-R,

HCC1428-R) were in-house generated via gradient exposure of the cells to Palbociclib. As expected, TY-0540 potently inhibits T47D-R and HCC1428-R cell proliferation whereas Palbociclib only confers mild interruption to cell proliferation. TY-0540 abolishes Rb phosphorylation at all its three phosphorylation sites and down-regulates E2F1, FOXM1, and c-Myc expression levels in the model cell line OVCAR3. Meanwhile, cell cycle analysis suggests the occurrence of strong G1 arrest at 24 hours after TY-0540 treatment. Consistent with the *in vitro* results, TY-0540 treatment confers extraordinary in vivo efficacy with a spectrum of tumor CDX mouse models and PDX models in mice. To examine the *in vivo* effectiveness of TY-0540 over resistance models to CDK4/6 inhibition, we developed Palbociclib-resistant MCF7 tumor model (Palbociclib-R-MCF7) through a combination of *in vitro* and *in vivo* evolution of the cells under the selection pressure of Palbociclib. In agreement with its mode of action, TY-0540 is able to suppress Palbociclib-R-MCF7 tumor growth and maintain tumor size at stable disease status. Taken together, we have identified a potent CDK2/4/6 inhibitor which may grant new therapeutic opportunities for cancer patients who relapse or refractory to CDK4/6 signaling blockage therapy. #Meihua Li and Chengshan Niu contributed equally to this work. *Jun Li, Meihua Li and Chengshan Niu are the correspondent authors.

Identification of CDK15 activating cyclins by a recombinant co-expression approach

Daniel Mueller, Constance Ketterer, Diane Kraemer, Carolin Heidemann-Dinger, Lena Pilgermayer, Thomas Weber, Andreas Gericke, Frank Totzke, Michael H. G. Kubbutat. *Reaction Biology Europe GmbH, Freiburg im Breisgau, Germany*

Cyclin dependent kinases (CDK) form a family of 20 different CDKs with an additional 6 CDK-like proteins. Members of this family have been shown to be involved in the regulation of many critical cellular processes, including the regulation of cell cycle progression, gene transcription and neuronal function. Deregulated CDK activity has been observed frequently in human cancer and other diseases. Enzymatic kinase activity of CDKs has been found to depend on the formation of complexes with regulatory

proteins of the Cyclin family and requires in some cases the presence of additional complex partners, like MAT1 for CDK7/Cyclin H. To date, at least 15 different Cyclins have been described. For some CDKs it has been shown that they can also be activated by binding to proteins distinct from classical Cyclins. However, even while the 20 canonical CDKs share significant structural homology, they regulate very different functions of cell growth and development, partially due to their inherent substrate specificity but also regulated by their respective Cyclin partners. During the past 30 years several CDKs have been subject to extensive study resulting in a multitude of publications. This includes specifically CDK1, CDK2 and CDK4/6 and to a lesser extend CDK7 and CDK9. Other CDKs have been studied much less extensively and consequently the accumulated knowledge about their biological function and regulation is very limited. CDK15 (also known as PFTK2 or ALS2CR7) is one of these understudied members of the CDK family, with less than 20 publications in PubMed and the search term "CDK15" in contrast to more than 8600 hits for "CDK2". Its biological function is largely obscure even while evidence was presented that CDK15 is involved in the regulation of breast and colorectal cancer. Comparable to all other members of the CDK family, recombinantly overexpressed purified CDK15 does not exhibit detectable in-vitro activity and to date no Cyclin or other activating complex partner for CDK15 has been published. Since CDK inhibitors have been in the focus of interest at least since the approval of the first candidate (Palbociclib) for the treatment of ER+/HER+ breast cancer, testing the selectivity of other drug candidates within the complete group of CDKs is critically important to avoid unwanted off-target effects and toxicity. In order to enable in-vitro activity studies with CDK15 we evaluated different CDK15 constructs in combination with a comprehensive panel of different Cyclins using the baculo virus expression system. CDK15 and the respective Cyclins were co-expressed in insect cells, purified by affinity chromatography and tested for in-vitro activity using a panel of generic, broad-spectrum protein kinase substrates. We will present data on the identification of CDK15 activating Cyclins and the biochemical characterization of the in-vitro kinase activity of such CDK15/Cyclin complexes including a panel of kinase inhibitors.

#5981

TY-2699a is a highly potent CDK7 inhibitor to abolish dysfunctional tumor cell cycle for clinical development

Shengli Dong[1], Apeng Liang[1], Jian Zhu[1], Huan Wang[2], Meihua Li[1], Kai Wang[1], Rongzhen Ni[2], Haoyun Li[1], Yundi Cao[1], Linglin Xiao[1], Hongqiang Li[1], Yian Tu[1], Chao Zhou[1], Aishen Gong[2], Shuyi Xu[1], Hui Su[2], Chengshan Niu[3], Mingyu Jiang[2], Feng Xing[2], Xiugui Chen[2], Shaoqing Chen[2], Jun Li[1], Yusheng Wu[1]. *[1]TYK Medicines, Inc., Huzhou, China,[2]TYK Medicines, Inc., Shanghai, China,[3]TYK Medicines, Inc., Zhengzhou, China*

Cell cycle dysregulation is a hallmark of cancer and represents tremendous opportunities for clinical blockage in cancer therapy. Currently, trilaciclib, palbociclib, ribociclib, and abemaciclib that bear dual specificities against CDK4 and CDK6 have been approved for clinical usage, and more CDK4/6 targeted agents are actively under clinical evaluations, among which, TY-302, a novel CDK4/6 inhibitor being developed by TYK Medicines, is under Phase II trial (NCT04433494). To further drive the potential of pharmacological regulation of cancer cell cycle, here we report a novel CDK7 kinase inhibitor TY-2699a towards clinical investigation in 2023. CDK7 is a kinase at the core of transcription and also functions in regulating cell cycle progression. CDK7 overexpression has been identified in a wide spectrum of tumor tissues including triple negative breast cancer (TNBC), ovarian carcinoma (OC), small cell lung cancer (SCLC), and pancreatic cancer, and has been correlated to poor prognosis in the diseases. These malignant pathological profiles make CDK7 a pivotal target for the development of novel cancer therapy. Several CDK7 targeted agents, such as SY-5609 and Samuraciclib (CT7001), are under development. TYK Medicines is also committed to provide novel yet safe CDK7 kinase inhibitor. Our data show that TY-2699a potently inhibits the kinase activity of CDK7 in the form of CDK7/Cyclin H/MAT1 kinase complex (IC_{50} 9.5 nM) with high selectivity compared to that with CDK1/Cyclin A2, CDK2/Cyclin E1, CDK4/Cyclin D1, and CDK6/Cyclin D1. The screening of a panel of cancer cell lines revealed strong anti-cell proliferation activities of TY-2699a compared to that of the reference compound, and the phenotypic findings are underscored by TY-2699a-dependent cell cycle disruption. Our data demonstrate that TY-2699a triggers G2 cell cycle arrest, and induces apoptosis in tested cancer cells (HCC70, and MDA-MB-

468), but not in hTERT-immortalized normal cell (RPE-hTERT). *In vivo* studies show that TY-2699a confers significant efficacies in tested CDX mouse models of HCC70 (TNBC), OVCAR3 (OC), and MV-4-11(AML) in a dose-dependent manner. To further validate the anti-tumor activity of the agent, BR5010, a TNBC PDX model was employed to assess the response to TY-2699a treatment. Our data show that the efficacy of TY-2699a at 3 mg/kg, bid × 21 days was similar to that of the reference compound CT7001 at 100 mg/kg, qd × 21 days, and the efficacy of TY-2699a at 6 mg/kg, bid × 21 days was significantly better than that of CT7001 at 100 mg/kg, qd × 21 days in BR5010 mouse model. In summary, we report that TY-2699a is a highly selective and potent CDK7 kinase inhibitor with an acceptable toxicity profile within the therapeutic window. TY-2699a is planned to be advanced for clinical evaluation in 2023. # Shengli Dong and Apeng Liang contributed equally to this work. * Jun Li, Shengli Dong and Apeng Liang are the correspondent authors.

A potent and selective CDK8 inhibitor ABM-3249 with excellent efficacies in multiple in vivo cancer models

Chen Chen, Charles Huang, Min Xu, Xiuquan Chen, Xiaobing Lv, Chen Yang, Lanjiao Zhao, YouQin Chen, Jizhi Li, Li Zhao. *ABM Therapeutics, San Diego, CA*

CDK8 is a member of the CDK family in which belongs to the serine/threonine protein kinase. It binds with cyclin C to regulate the transcription. By modulation of various gene expression programs, CDK8 associated with the mediator complex to sustain proliferation and viability of cancer cells. CDK8 has been identified as an important factor in cancer occurrence and development. It also involves in the regulation of cancer cell stress response to radiotherapy and chemotherapy, assists tumor cell invasion, metastasis and drug resistance. Therefore inhibition of CDK8 is regarded as a promising target for cancer therapy. ABM-3249 was discovered as a potent and selective CDK8 inhibitor with a novel chemical structure. It inhibited CDK8 kinase activity in biochemical assay and cellular binding assay, with IC_{50} values of 1.4 nM and 19nM respectively. ABM-3249 displayed good kinase selectivity: <50% inhibition on all other CDK family members at 1uM. Consistently, ABM-3249 reduced STAT1-

S727 phosphorylation with an IC_{50} of less than 100nM. ABM-3249 showed good ADME properties with high oral bioavailability (~90%) in rodents. In efficacy studies, ABM-3249 exhibited excellent anti-tumor activities in multiple in vivo models. In an AML MV4-11 xenograft model at 25mpk oral dosing ABM-3249 achieved complete remission in all mice within 17 days and no tumor recurrence within one month after drug withdrawal. ABM-3249 showed good efficacies as a single agent, as well as a synergetic effect with anti-PD1 combination in a murine colon cancer MC38 model. It also showed an efficacy in a murine colon cancer B16F10 metastasis model. In addition, ABM-3249 displayed a good safety margin in a preliminary tox screen in rodents.

The secretome produced by senescent gastric cancer cells can lead to different paracrine effects depending on the status of autophagy

Claudio A. Valenzuela[1], Danitza Rebolledo[1], Angel Cayo[1], Whitney Venturini[1], Raúl Segovia[1], Rodrigo Moore-Carrasco[2], Nelson Brown[1].
[1]Center for Medical Research, Medical School, Universidad de Talca, Talca, Chile,[2]Faculty of Health Sciences, Universidad de Talca, Talca, Chile

Introduction: The initial transition from a proliferative to a senescent state is accompanied by a reduction in the activity of the cyclin-cyclin-dependent kinase (CDK) complexes, which in turn could be explained by the activation of the p53-$p21^{CIP1/WAF1}$ and/or $p16^{INK4a}$-pRB signaling pathways. As overexpression of D-type cyclins is commonly observed in gastric cancer cells, the use of CDK4/6 inhibitors could represent a viable alternative for gastric cancer treatment. Nonetheless, senescent cell can synthesize and secrete a plethora of bioactive molecules (a feature known as the senescence-associated secretory phenotype, SASP) with the potential of modifying the tumor microenvironment in ways that could be therapeutically deleterious. Among processes that are upregulated in most senescent cells, autophagy has received great attention during the last years. So far, however, the role of autophagy in the modulation of SASPs has yet to be clarified. Previous work from our lab has revealed an increased autophagic flux in gastric cancer cell lines undergoing drug-induced

senescence, suggesting a regulatory role in the implementation of this modality of cellular senescence. More specifically, the secretory phenotype of senescent gastric cancer cells seems to depend on the autophagy status. Materials and Methods: In order to determine the role of autophagy in the modulation of the SASP, cellular senescence was pharmacologically triggered in gastric cancer cell lines (AGS, MKN-45) through inhibition of CDK4/6 activity (0.5-1.0 μM of Palbociclib for 48 and 96 hours), with or without the concomitant inhibition of autophagy by either genetic (knocking down ATG5) or pharmacologic (treatment with 0.5 μM of Spautin-1) approaches. The expression of factors secreted by senescent cells under different experimental conditions was analyzed from conditioned media; and the same conditioned media were used in assays aimed to assess migration, invasion, and cell proliferation of non-senescent cells.
Results and Discussion: Inhibition of autophagy in senescent cells led to a downregulation in the expression of proinflammatory molecules that were overexpressed in autophagy-proficient senescent cells (MIF, IL-8, IL1β). Unlike conditioned media derived from AGS cells, conditioned media derived from senescent MKN-45 cells that were rendered deficient in autophagy enhanced the invasive capabilities of non-senescent cells. Our results suggest that autophagy modulates the expression of SASP components and, by so doing, affects the behavior of neighboring non-senescent cells. Interestingly, these effects were also influenced by the genetic status of gastric cancer cells. This work was supported by Fondecyt ANID 11201182

CDK9 inhibition as a potential therapeutic strategy in Ewing sarcoma

Yuta Matsumura, Richard E. Heinz, Curtis A. Allred, Adam Siddiqui, Jason M. Foulks, Steven L. Warner. *Sumitomo Pharma Oncology, Inc., Lehi, UT*

Ewing sarcoma (EWS) is the second most common bone and soft tissue sarcoma in children and adolescents and accounts for approximately 2% of all childhood cancer diagnoses. EWS is a highly aggressive cancer: the overall 5-year survival rate for localized and metastatic EWS are 67 and 38%, respectively. Each year, approximately 200 children and adolescents in the United States are diagnosed with EWS. Genetically, nearly all EWS

have chromosomal translocations in which a member of the FET gene family is fused with an ETS transcription factor, with 85% of cases being EWSR1-FLI1. Cyclin-dependent kinase 9 (CDK9) is a serine/threonine protein kinase involved in transcription elongation through phosphorylation and activation of RNA polymerase II (RPB1) and increases the levels of key oncogenic genes like myeloid cell leukemia-1 (MCL-1) and c-Myc, which are reported to be involved in chemoresistance. CDK9 may be a viable target in transcriptionally addicted cancers including EWS driven by oncogenic fusion genes like EWSR1-FLI1. TP-1287 is an investigational orally delivered phosphate pro-drug of alvocidib, a potent CDK9 inhibitor. We hypothesized that alvocidib, the pharmaceutically active form of TP-1287, may show activity in EWS cells as a single agent and in combination with standard of care agents. Alvocidib demonstrated the suppression of downstream targets of CDK9 including c-Myc in EWS cell lines after 6-hr treatment. In cell viability assays using CellTiter-Glo, alvocidib resulted in IC_{50} values of 68 - 125 nM in EWS cell lines after 3-day treatment and 27 - 160 nM in EWS cells from patient derived xenograft (PDX) models, after 6-day treatment. MCL-1 amplified EWS cells were observed significantly more sensitive to alvocidib than MCL-1 diploid EWS cells in the EWS cells from PDX models ($p=0.004$). Further bioinformatic analysis to predict alvocidib sensitivity is currently underway. Alvocidib demonstrated an additive inhibitory response in combination with topotecan, phosphoramide mustard, a biologically active metabolite of cyclophosphamide, and palifosfamide, a biologically active metabolite of ifosfamide, in EWS cell lines after 3-day treatment. Alvocidib treatment showed reduction of RAD51 which is involved in DNA damage response (DDR), suggesting the activity of alvocidib on DDR may contribute to this additive response. In an *in vivo* preclinical study using the A-673 model, TP-1287 (2.5 mg/kg, QD) showed tumor growth inhibition (TGI). *In vivo* combination studies with standard of care agents using EWS xenograft models are currently ongoing. In summary, alvocidib has shown activity inhibiting the growth of EWS cells as a single agent and an additive response in combination with EWS standard of care agents in EWS cell lines. TP-1287 may be a potential therapeutic option for the current regimen in EWS. TP-1287 is being investigated for solid tumors including EWS (clinicaltrials.gov, NCT03604783).

#5985

Cyclin dependent kinase 9 (CDK9) inhibition increased efficacy of programmed cell death protein 1 (PD-1) blockade for hepatocellular carcinoma (HCC) through decreasing programmed death-ligand 1 (PD-L1) expression

Ching-Tso Chen[1], Yu-Yun Shao[2], Hung-Wei Hsu[3], Rita R. Wo[3], Han-Yu Wang[3], Ann-Lii Cheng[3], Chih-Hung Hsu[3]. *[1]Department of Oncology, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu, Taiwan,[2]National Taiwan University, Taipei City, Taiwan,[3]Department of Oncology, National Taiwan University Hospital, Taipei City, Taiwan*

Background: PD-1 blockade has been approved as treatment for advanced HCC. We previously demonstrated the efficacy of CDK9 inhibition in reducing the expression of inducible proteins and as a treatment for HCC (Shao et al. Oncology 2022). We thus examined the influence of CDK9 inhibition on the expression of PD-L1 in HCC and the potential of improving the efficacy of PD-1 blockade with the combination of CDK9 inhibitors.

Methods: We first examined the influence of specific CDK9 inhibitors, AZD4573 and atuveciclib, on interferon-γ (IFN-γ) induced PD-L1 expression of human HCC cell lines HuH7 and Hep3B. Overexpression of CDK9 and siRNA to CDK9 were used to confirm the findings. Similar experiments were repeated in the mouse HCC cell line BNL. To test the in vivo efficacy, we orthotopically implanted BNL cells in the subcapsular area of BALB/c mice, which were then treated with vehicle, CDK9 inhibitors, anti-PD-L1 antibodies, or their combination. To compare with tumor sizes, all mice were sacrificed after 14 days of treatment. To compare survival, the mice were only sacrificed if they met the criteria of animal euthanasia.

Results: Both HuH7 and Hep3B cells had minimal PD-L1 expression, which however could be induced using IFN-γ. AZD4573 and atuveciclib decreased the IFN-γ induced PD-L1 expression of HuH7 and Hep3B cells in a dose dependent manner. The flow cytometry results confirmed that membrane PD-L1 expression was also decreased by CDK9 inhibition. Overexpression of CDK9 decreased the influence of these CDK9 inhibitors on PD-L1 expression. CDK9 knockdown using siRNA reduced the IFN-γ induced PD-L1 expression. AZD4573 and atuveciclib also reduce the PD-

L1 expression in BNL cell lines. In the orthotopic animal model, the tumors of the sacrificed mice were significantly smaller in mice treated with atuveciclib and an anti-PD-L1 antibody than mice treatment with either alone. The survival of mice treated with the combination was also longer than mice treated with each therapy alone.
Conclusion: We demonstrated that CDK9 inhibition could reduce the IFN-γ induced PD-L1 expression of HCC cells. Combination of CDK9 inhibitors and anti-PD-L1 antibodies was more effective than either therapy alone.

#5987

Differential targets engaged by narazaciclib in comparison to the approved CDK4/6 inhibitors contribute to enhanced inhibition of tumor cell growth

Petros Kechagioglou[1], Camille Dupont[1], Hajime Yurugi[1], Ute Distler[1], Stefan Tenzer[1], Alexey Chernobrovkin[2], Kristina Riegel[1], Juliane Mooz[1], Mahil Lambert[3], Volker Dötsch[3], Stephen Cosenza[4], Steven M. Fruchtman[5], Krishnaraj Rajalingam[1]. *[1]University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany,[2]3Pelagobio Bioscience, Solna, Sweden,[3]Goethe University, Frankfurt, Germany,[4]Onconova Therapeutics Inc, Newtown, PA,[5]Onconova Therapeutics Inc, Newton, PA*

CDK4/6 inhibitors are clinically approved for the treatment of HR+, HER2- metastatic breast cancer by reinstating the G1/S checkpoint in tumor cells. Despite clinical benefit, safety concerns such as neutropenia and diarrhea, and disease progression, raises a critical need to identify novel therapeutic strategies. Narazaciclib (ON123300), novel CDK4/6i, designed to enhance efficacy and safety by its multi-targeted kinase inhibitor activity at low nM concentrations against CDK4/6, ARK5, CSF1R, and c-Kit. Narazaciclib is in Ph I trials; NCT04739293 and CXHL1900340; studying different administration regimens. Since several oncogenic signaling pathways are affected, we examined the efficacy of ON123300 in various breast cancer cell lines, and consolidate its mechanism of action by identifying the other targets engaged by ON123300. To identify direct and secondary targets engaged by narazaciclib and palbociclib, proteome wide Cellular Thermal Shift Assay (CETSA) was performed. To investigate narazaciclib's effect

on signaling pathways, Integrative Inferred Kinase Activity (INKA) was performed. Bioinformatics analysis explored the potential clinical effect of the identified targets. Molecular docking simulations investigated the potential interactions of narazaciclib to engage the new targets compared to other CDK4/6i. Both CETSA and INKA analysis revealed more potential targets engaged by narazaciclib compared to palbociclib in both MDA-MB-231 lysates and intact cells such as BUB1, CHEK1, AURKA, GSK3α and GSK3β. In TNBC patients with BUB1 overexpression bioinformatics analysis indicates a low survival correlation. Docking data showed a higher affinity of narazaciclib with BUB1 compared to palbociclib and abemaciclib. A stronger induction of apoptosis and senescence was detected in narazaciclib treated MMTV-PYMT cells, a murine mammary carcinoma model, compared to the other CDK4/6i, while narazaciclib enhanced CCL5 and CXCL10 mRNA levels. Reduction of PD-L1 protein levels and a promoting effect on the H2D1 and B2M mRNA levels was perceived in narazaciclib treated PYMT cells. Lastly, inhibition of autophagy, both at the early and late stages, may sensitize cancer cells to narazaciclib and induce irreversible cell proliferation inhibition, providing a novel therapeutic approach. Our data unveiled the differential targets engaged by narazaciclib in comparison to palbociblib. Narazaciclib treatment led to BUB1 protein degradation, overexpression of which is associated with poor prognosis in TNBC. Combination of narazaciclib with autophagy inhibitors sensitized several breast cancer cells to cell death. Narazaciclib treatment may promote antitumor immunity by influencing the expression of various immune modulators in the tumor cells which needs to be further validated in preclinical animal models; and ultimately in the clinic.

#5988

A non-canonical CDK9 complex mediates endocycling in polyaneuploid cancer cell (PACC) state

Cheng-fan Lee, Michael Loycano, Luke LOFTUS, Laurie Kostecka, Melvin Li, Sarah Amend, Kenneth Pienta. *Cancer Ecology Center, The Brady Urological Institute,, Johns Hopkins University School of Medicine, Baltimore, MD*

Once prostate cancer has spread from its primary site, treatment is limited to systemically administered therapy. While tumors initially respond to

these therapies, eventually, all therapies fail, and the tumor recurs. Ours and others' recent studies have shown the presence of a universal mechanism of resistance: accession of the polyaneuploid cancer cell (PACC) state. The PolyAneuploid Transition (PAT) is initiated when a cancer cell is subjected to external stress, including therapy (we have tested three classes of chemotherapy and radiation), and accesses an alternative non-mitotic cell cycle known as endocycling, resulting in a greater-than-G2 polyploidization of the aneuploid genome (polyaneuploidy). While in this pro-survival PACC state, we have shown that cells are resistant to all forms of cytotoxic therapy. Initial RNA sequencing of cells that have accessed the PACC state in response to multiple classes of chemotherapy, including docetaxel and cisplatin, demonstrate a remodeled transcriptional profile that is distinct from control cultures. We hypothesize that accession of the resistance-mediating PACC state requires transcriptional remodeling. Our data show that cells in the PACC state had increased overall transcriptional activity. The multi protein complex pTEFB (positive transcription elongation factor) is a critical driver of RNA Polymerase II function and is composed of multiple subunits, including CDK9, a cyclin regulatory subunit, and a transcription factor. CDK9 phosphorylation was significantly elevated during accession and persistence in the PACC state. Genetic inhibitionof CDK9 by siRNA led to decreased expression of cyclin A which plays a role in S phase, both in the mitoticcycle and in the PACC endocycle. Interestingly, despite increased CDK9 levels, known CDK9 pTEFb complex members cyclin T1 and BRD4 were both decreased in cells in the PACC state. We treated cancer cells induced to enter the PACC state upon exposure to cisplatin with pharmaceutical inhibitors of CDK9, Flavopiridol and Fadraciclib. Combination of CDK9 inhibition with chemotherapy showed a suppressive effect on the PACC population. Our findings therefore suggest that a non-canonical CDK9 complex could be critical role for the endocycling to access and maintain the PACC state and represents a therapeutic candidate to eliminate the resistance-mediating PACC state.

#5989

Targeting RRM2 & cell cycle for breast cancer treatment

Nahid Sultana[1], Howard L. Elford[2], Jesika S. Faridi[1]. *[1]University of the Pacific, Stockton, CA,[2]Molecules for Health Inc., Stockton, CA*

Endocrine treatment is an effective first-line therapy for targeting ER positive, HER2 negative breast cancer. But success is limited by development of acquired resistance due to long-term therapy. Cyclin D1 and cyclin dependent kinase 4/6 (CDK4/6) complex causes phosphorylation and subsequent inactivation of retinoblastoma (Rb) tumor suppressor protein which promotes progression of the cell cycle from G1 to S phase. This observation led the development of the first CDK4/6 inhibitor palbociclib (Ibrance; Pfizer) which induces cell cycle arrest at G1 phase in cancer cells. Owing to intrinsic and acquired drug resistance development, success is limited despite promising clinical outcomes. This situation necessitates the development of potential combination strategies to overcome drug resistance. Ribonucleotide reductase (RR) is a rate limiting enzyme in DNA synthesis consisting of two subunits RRM1 and RRM2. Didox inhibits ribonucleotide reductase subunit 2 (RRM2) which ultimately blocks DNA synthesis. Combination of didox with palbociclib is a potential strategy to target ER positive and ER negative/triple negative breast cancer. Previously, we have shown that didox (DDX) can significantly halt malignant breast cancer cell division in combination with the anthracycline drug doxorubicin by targeting RRM2, mutant p53 and NFkB regulatory proteins. Recently, we confirmed that didox in combination with palbociclib significantly lowers ER positive and ER negative breast cancer and their palbociclib resistant counterparts' growth compared to no treatment or palbociclib treatment. We also confirmed that ER positive MCF7 and ER negative MDA-MB-468 parental breast cancer cells IC50 of palbociclib drug is lower than their palbociclib resistant counterparts. Here, we are reporting that didox decreases cell cycle proteins alone or in combination with palbociclib in ER positive MCF7 and ER negative MDA-MB-468 parental and palbociclib resistant breast cancer cells. This finding opens a novel approach for targeting both ER positive as well as ER negative breast cancer treatment. We are also reporting that didox treatment modulates cyclin D1 (CCND1) and RRM2 expression in MCF7 and MDA-MB-468 breast cancer along with their palbociclib resistant counterparts. Additionally, we observed that didox alone or in combination with palbociclib alters the cell cycle of MCF7 and MDA-MB-468 parental and palbociclib resistant breast cancer cells. Our data presents a novel and promising approach for the treatment of ER positive and ER negative breast

cancer that involves inhibition of RRM2 and cell cycle that merits further clinical investigation in animal and human models.

Druggable CRISPR/Cas9 screen identifies Cyclin E1 (CCNE1) as a key mediator of sensitivity to CDK4/6 inhibition in non-small cell lung cancer (NSCLC)

Matthew Bott, Maria Skamagki, Nelson Salgado, Francisco Sanchez-Rivera, Scott Lowe. *Memorial Sloan Kettering Cancer Center, New York, NY*

Objective: CDK4/6 inhibition has become an important treatment option in some epithelial malignancies but its utility in the setting of NSCLC remains limited. While CDK4-based monotherapy has been generally ineffective, combinatorial regimens have shown promise. Here we sought to perform an unbiased assessment of potential combinatorial strategies in pre-clinical models of NSCLC.
Methods: We performed a CRISPR/Cas9 screen in two NSCLC cell lines (A549 and H2030) in the presence and absence of the CDK4/6 inhibitor Palbociclib and identified guide RNAs that selectively depleted in the setting of drug treatment. We subsequently performed validation and mechanistic experiments as described. CDK4 and CDK2 activity was assessed using a fluorescent reporter system.
Results: Palbociclib-sensitizing screen hits include MAPK1 (ERK2), AKT1, MAP3K2 (MEKK2), PIK3CA, MAPK14 (p38a), AKT3, PORCN, LGR4, CDK1, CDK9, and AURKB . Screen results were compared with a previously published Palbociclib sensitizing screen and shared hits were identified. Of these, CCNE1 was the highest scoring hit suggesting relevance across histologies. Interestingly, several screen hits such as ERK2, PIK3CA, VCP and ELAVL1 have reported roles in CCNE1 transcription or post-translational stabilization suggesting a central role for CCNE1 in determining drug sensitivity. Western blot analyses demonstrate that CCNE1 is rapidly upregulated following Palbociclib exposure in a panel of NSCLC cell lines and immunofluorescence shows strong post-treatment CCNE1 expression in human A549 xenografts *in vivo*. CDK2/4 fluorescent reporter assays show partial restoration of CDK2 activity within 48 hours of Palbociclib treatment. Genetic validation experiments using

dox-inducible shRNA constructs targeting CCNE1 show that CCNE1 knockdown sensitizes cells to Palbociclib treatment and enhances senescence induction. Pharmacologic and genetic co-inhibition of CDK2 improves Palbociclib efficacy yet such co-inhibition further elevates CCNE1 levels and CDK2 suppression remains incomplete based the fluorescence reporting system. Furthermore, knockdown of CCNE1 in conjunction with CDK2/4/6 inhibition shows improved growth inhibition compared to drug treatment alone. Based on this data, we hypothesize that targeting signaling pathways upstream of CCNE1 transcription or those which affect CCNE1 stabilization and turnover may be more efficacious than combined CDK inhibition.
Conclusion: CCNE1 is a critical mediator of sensitivity to CDK4/6 inhibition and Palbociclib treatment results in rapid compensatory increases in CCNE1 levels. Despite drug treatment, NSCLC cells retain CDK2 activity which is only partially inhibited by combined CDK 2/4/6 inhibition. Screen results suggest several potential approaches for co-targeting of CCNE1 to enhance drug sensitivity.

Development and characterization of a novel CDK4/6 inhibitor for the treatment of CDK4/6 dependent cancers

Neil A. O'Brien[1], Martina S. J. McDermott[1], Brendan M. O'Boyle[2], Justin A. Hilf[2], Oliver Loson[2], Kevin Chau[1], Weiping Jia[1], Naeimeh Kamranpour[1], Tong Luo[1], Raul Ayala[1], Shawnt Issakhanian[1], John A. Glaspy[1], Brian M. Stoltz[3], Dennis J. Slamon[1]. *[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]1200 Pharma, Culver City, CA,[3]Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, CA*

CDK4/6 inhibitors give clinical benefit in the treatment of metastatic ER+/HER2- breast cancer (mBC) in combination with endocrine therapy. Although this class of inhibitor has been extensively studied in several other cancer types, CDK4/6 inhibitors have not been approved as a treatment for outside of ER+/HER2- cancer. We evaluated the clinically approved CDK4/6 inhibitors, palbociclib, ribociclib and abemaciclib—in a 500+ cell line screening platform and identified several cancers outside of breast that may have subpopulations that are sensitive to CDK4/6 inhibitors. Kinome

and KiNativ analyses helped identify differences in sensitivity/selectivity that we observed between each CDK4/6 inhibitor. Comprehensive molecular profiling of the cell lines at baseline allowed us to screen for potential associations with sensitivity to these compounds. These analyses identified potential biomarkers of sensitivity in non-small cell lung carcinoma (NSCLC) and colorectal cancer (CRC) that will later be evaluated in human clinical studies. Having thoroughly studied the CDK4/6 class and discovered new opportunities for clinical development, we set out to develop a CDK4/6 inhibitor that would have the best properties of the two distinguished class members. Using our proprietary chemistry, we developed UCT-03-008, a potent CDK4/6 small molecular inhibitor with a pharmacology known to enhance therapeutic benefit in mBC. Pharmacokinetic properties of UCT-03-008 are improved over those of other CDK4/6 inhibitors. UCT-03-008 has activity in preclinical models as a monotherapy and yields *in vivo* efficacy in multiple cancer models outside of ER+/HER2- breast cancer, including CRC and NSCLC. In summary, UCT-03-008 is a CDK4/6 inhibitor with optimized pharmacological properties. Clinical development of this compound will be guided by the biomarker hypotheses developed here. We are currently enrolling patients for treatment with UCT-03-008 in a Phase 1 clinical trial of advanced solid tumors (NCT05103046).

Worldwide Research & Development, San Diego, CA,[11]Kinnate BioPharma, San Diego, CA

CDK2 is a core cell-cycle enzyme that phosphorylates a variety of substrates to drive progression through the cell cycle. CDK2 is hyperactivated in multiple cancers and is therefore an attractive therapeutic target. Here, application of a novel small molecule CDK2/4/6 inhibitor, PF-06873600, enabled in-depth interrogation of CDK2 substrate phosphorylation, cell-cycle progression, and drug adaptation in preclinical models. CDK2-specific inhibition leads to rapid loss of substrate phosphorylation, but unexpectedly, CDK2 substrate phosphorylation rebounds within several hours. Whereas CDK1 is known to compensate for loss of CDK2 in Cdk2-/- mice, here we demonstrate an early dependence on CDK4/6 activity. CDK2 inhibition reveals latent CDK4/6 activity throughout S phase that backstops the proliferative program by maintaining Rb1 hyperphosphorylation, active E2F transcription, and Cyclin A2 expression, enabling re-activation of CDK2. Our results augment our understanding of CDK plasticity and indicate that co-inhibition of CDK2 and CDK4/6 is required to suppress adaptation to CDK2 inhibitors.

Dissecting the role of CDK4 in liposarcoma

Silvia Vanni[1], Graziana Gallo[2], Valentina Fausti[3], Giacomo Miserocchi[1], Chiara Liverani[1], Chiara Spadazzi[1], Claudia Cocchi[1], Chiara Calabrese[1], Giovanni De Luca[2], Massimo Bassi[4], Manlio Gessaroli[4], Angelo Campobassi[4], Federica Pieri[5], Giorgio Ercolani[6], Davide Cavaliere[6], Lorena Gurrieri[3], Nada Riva[3], Giovanni Martinelli[7], Laura Mercatali[1], Alessandro De Vita[1]. *[1]Ostencology Unit, Biosciences Laboratory, IRCCS Istituto Romagnolo Per Lo Studio Dei Tumori (IRST) "Dino Amadori", Meldola (FC), Italy,[2]Pathology Unit, Bufalini Hospital, Cesena (FC), Italy,[3]Clinical and Experimental Oncology, Immunotherapy, Rare Cancers and Biological Resource Center, IRCCS Istituto Romagnolo Per Lo Studio Dei Tumori (IRST) "Dino Amadori", Meldola (FC), Italy,[4]Maxillofacial Surgery Unit, Bufalini Hospital, Cesena (FC), Italy,[5]Pathology Unit, Morgagni-Pierantoni Hospital, Forlì (FC), Italy,[6]General and Oncologic Surgery, Morgagni-Pierantoni Hospital, Forlì (FC), Italy,[7]Scientific Directorate,*

IRCCS Istituto Romagnolo Per Lo Studio Dei Tumori (IRST) "Dino Amadori", Meldola (FC), Italy

Background: Liposarcoma (LPS) encompass one of most common soft tissue sarcoma (STS) histological subtypes accounting for 15% of all cases. They can be divided into four entities including atypical lipomatous tumor or well-differentiated LPS (ALT/WDLPS), dedifferentiated LPS (DDLPS), myxoid LPS (MLPS) and pleomorphic LPS (PLS). Their heterogeneity is reflected in their morphology, molecular landscape, prognosis and clinical behavior. Current treatment options for localized disease include surgery, (neo)adjuvant radiotherapy and chemotherapy; for the metastatic setting chemotherapy represents the cornerstone but its role needs to be elucidated. The unavailability of predictive biomarkers makes the management of these mesenchymal diseases even more challenging. Recent evidences have shed light on the key role of cyclin-dependent kinase 4 (CDK4) in cancer cells proliferation.
Methods: This study involved 21 adult patients affected by liposarcoma (n= 5 ALT/WDLPS and n= 16 DDLPS). IHC analyses of CDK4 and MDM2 were performed on FFPE surgically resected specimens by experienced sarcoma pathologists. Moreover, a patient-derived DDLPS cell line was established and pharmacological profiling was performed. Next, standard and innovative drugs currently used for LPS management were assessed in both 2D and 3D culture systems. Finally*, in silico* analyses based on public repositories on STS were carried out including 260 sarcoma patients.
Results: IHC results highlighted an higher expression of CDK4 and MDM2 biomarkers in DDLPS compared to ALT/WDLSP. Moreover, although CDK4 and MDM2 are codified by the same genomic region, their expression did not correlate (e.g. 100% of CDK4 and 2% of MDM2 in the same patient). Therefore we hypothesized that even exhibiting a low MDM2 expression, a patient could benefit from CDK4 inhibition. Furthermore, our data showed that in DDLPS cases CDK4 expression ranged from 90% to 100% in spermatic cord, skin and abdomen while it ranged from 5% to 50% in the retroperitoneum. The above observations prompted us to hypothesize a correlation of CDK4 expression with specific anatomical sites. Moreover, pharmacological profiling showed a synergistic effect exerted by sequential treatment with palbociclib and some chemotherapeutics including trabectedin, dacarbazine, eribulin and

lenvatinib. Indeed we observed a 10% increase in cell proliferation inhibition compared to standard treatment. In addition, *in silico* analyses revealed the role of CDK4 as negative prognostic biomarker for PFS and OS in STS.
Conclusions: Our study highlighted the promising role of CDK4 in the management of LPS patients. In particular, we pointed out encouraging results of sequential treatment combining CDK4 inhibitor palbociclib and chemotherapy. Furthermore, preliminary analyses highlighted the involvement of this biomarker as a potential prognostic tool for STS.

INX-315, a potent and selective CDK2 inhibitor, demonstrates robust antitumor activity in *CCNE1*-amplified cancers

Alec G. Trub[1], John E. Bisi[1], Catherine Dietrich[2], Michael Taylor[2], Jay C. Strum[1], Shom Goel[2], Patrick J. Roberts[1]. *[1]R&D, Incyclix Bio, Durham, NC,[2]The Sir Peter MacCallum Department of Oncology, Peter MacCallum Cancer Centrer, Melbourne, Australia*

Cyclin-dependent kinases (CDK) are a family of serine/threonine kinases that heterodimerize with regulatory subunits called cyclins to drive cell cycle progression. Uncontrolled cellular proliferation is a hallmark of cancer commonly driven by dysregulated kinase activity of specific CDK family members, including cyclin-dependent kinase 2 (CDK2). Aberrant CDK2 activity most frequently occurs through amplification of CCNE1 and/or overexpression of its protein product cyclin E1, which is a canonical binding partner of CDK2. Overexpression of cyclin E1 is observed in many solid tumors including in patients with high grade serous ovarian cancer (HGSOC), gastric cancer, and ER-positive breast cancer patients whose tumors have progressed on a prior CDK4/6 inhibitor regimen. Selective inhibition of CDK2 is thus a compelling therapeutic approach to regain cell cycle control. Here, we report preclinical data supporting the development of INX-315 for patients with cancers in which proliferation is CDK2-dependent. INX-315 is a potent inhibitor of CDK2/cyclin E (0.6 nM biochemical IC50) with high selectivity over other CDK family members in both biochemical and intracellular NanoBRET assays. In CCNE1-amplified human ovarian and gastric cancer cell lines, INX-315 potently inhibited Rb phosphorylation, induced a G1 cell cycle arrest, and inhibited proliferation.

INX-315 also showed potent anti-proliferative activity in luminal breast cancer cell lines that had been cultured in CDK4/6 inhibitor (+/- anti-estrogen therapy) for prolonged periods to the point of developing drug resistance. While these cell lines did not readily respond to either CDK4/6 or CDK2 inhibition alone, combination treatment again suppressed Rb phosphorylation, accompanied by G1 arrest and a senescent-like phenotype. Lastly, in CCNE1-amplified xenograft models of ovarian and gastric carcinomas, INX-315 inhibited Rb-phosphorylation and induced tumor regression. These data demonstrate INX-315 to be a potent and selective CDK2 inhibitor that may benefit patients with CDK2/cyclin E driven cancers.

DNA Methylation Changes in Cancer

Comparative and integrative analysis of transcriptomic and epigenome wide DNA methylation changes in African American prostate cancer

Bernard Kwabi-Addo[1], Somiranjan Ghosh[2], Chad Creighton[3], Michael Ittmann[3]. *[1]Biochemistry and Molecular Biology, Howard University, Washington, DC,[2]Biology, Howard University, Washington, DC,[3]Baylor College of Medicine, Houston, TX*

African American (AA) men have the highest incidence and mortality rate from Prostate cancer (PCa) than any other racial/ethnic group. To understand this racial disparity, molecular features of different types, including gene expression, DNA methylation and other genomic alterations, must be carried out in tumor samples from these 2 populations. To date, PCa genomic studies have largely under-represented tumor samples from AA men due to lack of inclusion of significant numbers in such studies. In this study we carried out genome-wide DNA methylation analysis in 63 clinically annotated fresh-frozen PCa and 50 normal prostate tissues from AA men using the Illumina Infunium 850K Human Methylation EPIC BeadChip array. mRNA expression database from a sub-set of the AA biospecimen were used to assess correlation of transcriptome and epigenomic datasets. Using bioinformatic analysis to integrate a comprehensive set of genomic datasets we identified probesets that were significant ($p<0.01$) and differentially methylated in AA PCa compared to

normal prostate tissues and were significant ($p<0.01$) and inversely correlated with AA mRNA expression. GO analysis in this AA cohort showed significant differential methylation that were mostly hypermethylated genes with corresponding down-regulated mRNA expression for top genes associated with biological pathways in hemidesmosome assembly, mammary gland development, epidermis development, hormone biosynthetic process and cell communication. On the other hand, few significant differential top hypomethylated genes and corresponding up-regulated mRNA expression were identified in biological pathways of negative regulation of macrophage differentiation, cAMP-dependent protein kinase inhibitor activity, protein destabilization, transcription corepressor activity and fatty acid biosynthetic process. Furthermore, we identified significant and differential methylated genes in our AA PCa cohort that were associated with PCa progression when compared to the TCGA EA and AA dataset. These genes were *AMIGO*3, *IER*3, *UPB*1, *GRM*7, *TFAP*2C, *TOX*2, *PLSCR*2, *ZNF*292, *ESR*2, *MIXL*1, *BOLL* and *FGF*6. Overall, IPA of differential methylated promoter region are genes enriched for network involved in sex-steroid hormonal signals and tumor microenvironment signaling pathways. **Our integrative analysis provides new candidate genes associated with prostate cancer progression in AA men as potential targets for** improving prostate cancer treatment and addressing the racial disparity problem.

Distinct HOX gene family DNA methylation profiles in histologically normal skin dependent on dermoscopic pattern of adjacent nevi

Meghan E. Muse[1], Helmut Schaider[2], Harald Oey[2], H. Peter Soyer[2], Brock C. Christensen[1], Mitchell S. Stark[2]. *[1]Department of Epidemiology, Geisel School of Medicine at Dartmouth, Hanover, NH,[2]Frazer Institute, University of Queensland, Brisbane, Australia*

Melanoma may arise within a pre-existing nevus, but commonly forms in the skin adjacent to nevi. We have performed global DNA methylation profiling using the Illumina EPIC array (>800K loci) of 32 dermoscopically ('globular' vs 'non-globular' pattern) and histopathologically classified nevi, together with matching adjacent perilesional skin, and discovered that methylation patterns can accurately decompose the proportion of cell types

present in the tissue. In this study, we sought to assess whether there are differences in the DNA methylation profiles of histologically normal skin samples that surround nevi, independent of cellular composition. Among the 739,270 CpG loci included in the analysis, there were a total of 8,200 CpG loci identified as significantly differentially methylated ($Q < 0.05$) in 'globular skin' vs 'non-globular skin' adjusted for age, sex, and the estimated relative proportions of epithelial cells, fibroblasts, and melanocytes in each sample. After imposing a more stringent threshold (M value of ≥ 0.5) a total 816 CpG loci were found to be DM, with 696 loci identified as significantly hypermethylated, and 120 loci significantly hypomethylated ($Q < 0.05$ and $\Delta M > 0.5$) in 'globular' vs 'non-globular' skin. Mapping of the DM ($Q < 0.05$ and $|\Delta M| < 0.5$) CpG loci to their respective genes revealed that eight of the top 20 DM genes, by proportion of differentially methylated loci, were positioned in proximity to suggest regulation of members of the HOX gene family. We next assessed the differential gene expression of the eight DM HOX genes in the perilesional skin as well as the matching adjacent nevus. After adjusting for age, sex, and sample cellular composition, none of the assessed HOX genes demonstrated statistically significant ($P \leq 0.05$) differential expression in the nevi, however, 'non-globular skin' demonstrated a statistically significant ($P < 0.05$) increase in the expression of five of the eight *HOX* genes relative to 'globular skin'. Importantly, this increased gene expression corresponds to the methylation status of the DM loci. HOX genes are known to be involved in limb and axial development as well as the positioning of dermal fibroblasts. Moreover, melanocytes from different anatomic positions have distinct transcriptional profiles and the anatomical position of melanocytes plays a key role in determining whether genetic alterations will subsequently drive melanoma formation. This positioning of melanoma subtypes (cutaneous vs acral) was recently shown to be related to interaction of specific *HOX* genes with site-specific oncogenic alterations. The distinct *HOX* gene family members we have revealed, differ to those related to melanoma development and positioning, as such we propose that these may contribute to the positioning of acquired melanocytic nevi, and in combination with common somatic alterations in *BRAF*, may contribute to nevus formation.

Epigenetic regulation of BARD1 confers resistance to anti-VEGF therapy in ovarian cancer

Emine Bayraktar[1], Cristian Rodriguez-Aguayo[1], Sudhir Kumar[2], Elaine Stur[1], Lingegowda S. Mangala[1], Stephen Baylin[3], Gabriel Lopez-Berestein[1], Sunila Pradeep[2], Anil K. Sood[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Medical College of Wisconsin, Milwaukee, WI,[3]Johns Hopkins University, Baltimore, MD*

Introduction: Vascular endothelial growth factor (VEGF) is a key promoter of angiogenesis and disease progression in epithelial ovarian cancer (OC). Bevacizumab, a humanized anti-VEGF monoclonal antibody, is approved for treatment of patients with ovarian and other cancers. Despite the wide use of anti-VEGF therapy for cancer treatment, most patients develop resistant disease. Therefore, new combinations/strategies are needed to reduce adaptive resistance to anti-VEGF antibody (AVA) therapy. Our aim is to determine the potential role of epigenetic changes in AVA-adaptive resistance. We identified and characterized epigenetic changes in BARD1, a tumor suppressor, at the emergence of AVA resistance.
Methods: To define epigenetic changes during AVA therapy induced resistance, we performed series of in vitro (methylation array, RNA sequencing) and in vivo (orthotopic OC (PDX-MDA-OVCA1, immunocompetent-IG10, and immunocompromised-SKOV3) and fibrosarcoma-HT1080, an inherently VEGF resistant model) experiments. The biological effects of DNA methylation agent (5`-Azacytidine; 5`-Aza) with B20 (murine anti-VEGF antibody) treatment were subsequently tested using in vivo models.
Results: To determine whether 5`-Aza can enhance the efficacy of AVA therapy and overcome resistance to AVA in OC, we established AVA-resistant SKOV3 model. In AVA-resistant mice treated with B20 + 5`-Aza, there was a statistically significant reduction in tumor weight ($p=0.03$). Next, we performed a Human 450k methylation and mRNA arrays from xenografts of SKOV3 tumors. Based on both analyses, we demonstrated that BARD1 was one of the top candidate which was highly expressed ($p=0.02$) and less methylated ($p<0.05$) in the combination of B20 and 5`-Aza group compared to B20 alone. Our data also showed that BARD1 expression was restored in the combination therapy. The sequential treatment with 5`-Aza reverted the resistance towards the AVA therapy in

SKOV3 model. Furthermore, the combination of B20 and 5`-Aza significantly decreased tumor weight in SKOV3 ($p=0.005$), IG10 ($p<0.05$), MDA-OVCA1 ($p=0.01$), and HT1080 ($p<0.05$). BARD1 expression levels were substantially increased in combination therapy compared to the B20 alone group (>4-fold, $p=0.006$). Tumor weight and BARD1 expression were inversely correlated. To determine the biological significance of BARD1, we knockdown BARD1 using Tet-inducible shRNA system. Our data showed a significant reduction in tumor weight in the BARD1 knockdown group in SKOV3 model ($p=0.021$). RNA-sequencing of BARD1 knockdown showed an enrichment of the angiogenesis pathway. Moreover, BARD1 expression levels were decreased in hypoxic conditions both in vitro and in vivo.
Conclusion: Our findings indicate a previously unrecognized role for BARD1 in mediating resistance to AVA therapy. Use of epigenetic drugs to control the expression of tumor suppressor genes may enhance the efficacy of AVA therapy in OC.

Characterizing dynamic landscape of DNA methylation in ovarian high-grade serous carcinoma

Alexandra Lahtinen[1], Giovanni Marchi[1], Daria Afenteva[1], Susanna Holmström[1], Kaisa Huhtinen[2], Anni Virtanen[1], Johanna Hynninen[2], Antti Häkkinen[1], Sampsa Hautaniemi[1]. *[1]University of Helsinki, Helsinki, Finland,[2]University of Turku, Turku, Finland*

Dysregulated DNA methylation (DNAm) is a hallmark of all cancer types, though the precise role of these aberrations in tumor progression and treatment response remains elusive. Advances in whole-genome bisulfite sequencing (WGBS) have enabled profiling methylomes at full resolution and stimulated interest to explore dynamics of DNAm across tumor sites and cancer treatment. A major challenge in the analysis of patient data is that a surgically removed tumor sample represents a mixture of cancer cells and microenvironment, and that the insights on DNAm changes are intertwined due to mixed effects from patient epigenomic background, tissue context, and treatment pressure. By using a computational approach, these effects can be decomposed into patient background, tissue site, and treatment phase specific changes, and controlled for natural

microenvironment variation. retion, and action, as well as in several oncogenic signaling cascades. The analysis of the tissue profiles indicated that the progression of HGSC from the tissues-of-origin to the metastatic deposits is accompanied by drastic changes in DNAm profiles. Thus, when comparing ovaries and peritoneum, intra-abdominal tissues mesentery and omentum featured prominent change of promoter DNAm: loss in 10% and gain in 20% of genes. Interestingly, the genes with aberrant DNAm included ABC transporters implicated in pumping drugs across the cell membrane, as well as the members of MAPK and PI3K signaling cascades. The joint analysis of both treatment and tissue contributions suggests that the overall modest effect of NACT is further reduced in metastases, mediated via DNAm changes in genes involved in multidrug resistance.

Study of secondary epimutations in *cis* of the promoter in germline tumor suppressor genes as a cause of hereditary breast and ovarian cancer

Miguel Ruiz De La Cruz[1], Héctor Martínez Gregorio[2], Clara Estela Díaz Velásquez[2], Aldo Hugo De La Cruz Montoya[3], Fidel de la Cruz Hernández-Hernández[4], Felipe Vaca Paniagua[2]. *[1]Infectómica y Patogénesis Molecular, Centro de Investigación y de Estudios Avanzados IPN (CINVESTAV-IPN), México City, Mexico,[2]Laboratorio Nacional en Salud, Diagnóstico Molecular y Efecto Ambiental en Enfermedades Crónico-Degenerativas, FES-Iztacala UNAM, México City, Mexico,[3]Unidad de Biomedicina, Facultad de Estudios Superiores Iztacala UNAM, Tlalnepantla de Baz, Mexico,[4]Infectómica y Patogénesis Molecular, Centro de Investigación y de Estudios Avanzados IPN (CINVESTAV-IPN), México CIty, Mexico*

Cancer is a multifactorial and highly heterogeneous disease. Breast cancer (BC) is the main malignant neoplasm in women and has the highest incidence and mortality rates worldwide. About 10% of all BC cases are hereditary and its most common form is Hereditary Breast and Ovarian Cancer Syndrome (HBOC).In a study conducted by our research group in a cohort of 300 Mexican women with HBOC using a panel of 143 genes of susceptibility to different types of cancer (Quezada-Urban et al., 2018), we found that 74% of patients were negative for variants in the coding regions and only 15% of patients had at least one pathogenic variant in 18 different

genes. In several types of hereditary cancer syndromes, it has been shown that germline genetic alterations such as single nucleotide variations, and indels in *cis* of the promoter region of tumor suppressor genes modify the methylation pattern and cause epigenetic silencing and the concomitant somatic loss of heterozygosity. These events are known as secondary *cis* epimutations and represent an alternative mechanism of molecular pathogenesis in patients with hereditary cancer syndromes. In this work we are investigating in germline gDNA the methylation profile in the promoter region of 18 tumor suppressor genes in 231 patients negative for pathogenic variants and 156 matched controls by using direct bisulfite massive parallel sequencing. So far, we have extracted gDNA and treated with sodium bisulfite from all patient and control samples. From the converted gDNA, we amplified the promoter region of the 18 study genes by PCR (9,675 endpoint PCR products). We have prepared a total of 387 genomic libraries from which we perform massive sequencing and bioinformatic analysis of 229 patients, 74 controls and 2 positive controls. Currently, we have found 4 patients with promoter hypermethylation in the *RAD51C*, *POLH*, *EPCAM*, and *BRCA1* genes that can be generated by a secondary *cis* epimutation. We have found statistically significant differences in the methylation levels of the promoter regions of the *BRCA1/2, PMS2, FANCI, MLH1, PALB2, POLH, ERCC3, ATM, MSH2, BRIP1,* and *EPCAM* genes in patients compared with controls. This result suggests that low level basal methylation marks could be potential biomarkers of HBOC pathogenesis. Interestingly, our studies indicate that hypermethylation at the promoter of *MSH2, PALB2, BRIP1,* and *EPCAM* are associated with HBOC risk, and that specific hypermethylation at the CpG sites of *MSH2* and *PALB2* (cg47630224 and cg23652916, respectively), could be potential biomarkers in HBOC risk. Lastly, according to preliminary *in silico* results, the co-occurrence of site-specific hypermethylation in *MSH2* and *PALB2* is possibly due to the absence of interaction of the common transcription factor SP4 in a GC-box site. These findings expand our vision of the genetic and epigenetic mechanisms of susceptibility to this disease.

DNA methylation diagnostics for upper urinary tract urothelial carcinoma using newly developed high-performance liquid chromatography

Mao Fujimoto[1], Eri Arai[1], Takuya Kikushima[2], Naotaka Nishiyama[2], Tomofumi Nakamura[3], Yuriko Yamada[3], Hiroaki Taira[3], Takuya Yotani[3], Hiroshi Kitamura[2], Yae Kanai[1]. *[1]Keio University School of Medicine, Tokyo, Japan,[2]Graduate School of Medicine, The University of Toyama, Toyama, Japan,[3]Sekisui Medical Co., Ltd., Ryugasaki, Japan*

Backgrounds: For diagnosis of upper urinary tract urothelial carcinoma (UTUC), conventional ureteroscopic examinations are invasive, and selective urine cytology has insufficient sensitivity. We have developed a new anion-exchange column for high-performance liquid chromatography (HPLC) with electrostatic and hydrophobic properties. Both cytosine and thymine, corresponding to methylated and unmethylated cytosine after bisulfite modification, respectively, are captured by electrostatic interaction and then discriminated from each other by their hydrophobic interactions. This method is expected to be very suitable for quantification of DNA methylation levels of cancer cells in urine samples with contamination of various cell lineages.
Purpose: The aim of this study was to establish a less invasive and more accurate method for UTUC diagnosis based on DNA methylation quantification by our newly developed HPLC.
Methods: Urine samples were collected by urinary catheterization during surgery for 218 urological cancer patients. Our previous studies have identified 4 CpG sites showing differences in DNA methylation levels between non-cancerous urothelium and UTUC based on genome-wide DNA methylation analysis using tissue specimens. In the present study, DNA methylation levels of these marker CpG sites were quantified by HPLC using the urine samples.
Results: The thresholds have been set for the retention time by HPLC and the area under the chromatogram. Diagnostic criteria have been established to distinguish cases with current UTUC from non-urothelial cancer cases, bladder cancer cases and post-urothelial cancer treatment cases by combining marker CpG sites. The sensitivity and specificity were 90.9% and 87.0% respectively.
Conclusions: Since HPLC-based DNA methylation diagnostic system was able to discriminate UTUC cells from blood cells and other contaminating cells in urine samples, application of our criteria will ultimately allow non-invasive diagnosis of UTUC in the clinical setting. It may be possible to at

least partially replace highly invasive procedures such as ureteroscopy and to enable early initiation of treatment for UTUC resulting in improved prognosis.

#6005

Promoter methylation occurs at high frequencies regardless of mutation status of tumor-associated genes in oral malignancies

Masanobu Abe[1], Kazuto Hoshi[1], Toshikazu Ushijima[2]. *[1]Graduate School of Medicine and Faculty of Medicine, The University of Tokyo, Tokyo, Japan,[2]Division of Epigenomics, National Cancer Center Research Institute, Tokyo, Japan, Tokyo, Japan*

Background: Genetic and epigenetic alterations are both important in tumorigenesis. However, their association in oral carcinogenesis has not been fully investigated yet. In this study, we analyzed somatic mutations of tumor-related genes and promoter methylation of tumor-suppressor genes (TSGs) in oral malignancies/premalignancies, and analyzed their association.
Materials and Methods: 39 oral squamous cell carcinomas (OSCCs) and 2 oral epithelial dysplasias (OEDs) were obtained as fresh-frozen?. Somatic mutations of 46 tumor-related genes, 13 TSGs and 33 oncogenes, were analyzed by targeted next-generation sequencing (NGS). Promoter methylation of five TSG: (*p16/INK4A*, *CMTM3*, *EGFLAM*, *NKX2-3,* and *RBP4*) were determined by methylation-specific PCR (MSP).
Results: Somatic mutations of tumor-related genes were observed in 63.4% of 41 OSCCs/OEDs. Particularly, mutations of *p53* and *PIK3CA* were observed 39.0% and 31.7%, respectively, of the 41 OSCCs/OEDs. Promoter methylation of *p16/INK4A*, *CMTM3*, *NKX2-3*, *RBP4*, *and EGFLAM* were observed in 34.1%, 48.8%, 41.5%, 68.3%, and 36.6%, respectively, of the 41 OSCCs/OEDs. No differences in the frequency of promoter methylation of the five genes were observed between tumors with and without somatic mutations of *p53* and *PIK3CA*.
Conclusions: Promoter methylation was observed at high frequencies regardless of mutation status of *p53* and *PIK3CA* in OSCCs/OEDs. Oral tumorigenesis appears to be difficult to be explained solely by genetic events indicating involvement of epigenetic events.

RNA m6A methylation relay the oncogenic flow from DNA methylationto gene expression of ANKRD13B

JingRong Weng, JinXin Lin, YuMo Xie, GuanNan Tang, LiangLiang Bai, JinHua Chen, ZengHong Huang, ZhuoKai Zhuang, ShaoYong Peng, Heng Wang, GaoPo Xu, Yu Zhang, XiaoXia Liu, MeiJin Huang, YanXin Luo, XiaoLin Wang, Huichuan Yu. *The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Colorectal cancer (CRC) is one of the most common causes of cancer-related death in the world. More comprehensive studies of key molecular alterations in CRC progression were urgent. DNA methylation promotes tumor progression. However, the mechanism of the ANKRD13 gene methylation that drives colorectal cancer evolution remains largely unknown. This was the first study focused on the role of ANKRD13 and the hypermethylated mechanisms in colorectal cancer.
Methods: Chi-Square tests were utilized to the comparison of the baseline characteristics of patients with hypomethylation ANKRD13B and hypermethylated ANKRD13B. Kaplan-Meier analysis were used to estimate the difference of overall survival between the two groups patients. The methylation level of ANKRD13B was quantified by qMSP in colorectal cancer, normal colon epitheliums and colorectal adenoma tissues. CRISPR/dCas9-DNMT3A and CRISPR/dCas9-TET1-CD methylation editing tools were applied to enable targeted and specific CpG methylation at the CpG loci near stop codon of ANKRD13B. Transwell-migrated assay, wound scratch assay and colony formation assay were preformed to ascertain the abilities of viability, migration and invasion in the editing CRC cell lines. The methylated RNA immunoprecipitation (MeRIP) assays, chromatin immunoprecipitation (ChIP) assays and 5-AZA treatment assays were performed combined with qPCR to quantify the m6A levels of ANKRD13B mRNA following hypermethylated-editing.
Results: Here, we identified a novel oncogenic gene, ANKRD13B, encoding ankyrin repeat domain 13B. This gene was frequently hypermethylated in CpG islands surrounding the stop codon region of colorectal cancer. This hypermethylation was associated with poor clinical outcomes in patients diagnosed with colorectal cancer. Compared with normal tissue (4.2%), this type of epigenetic alteration upregulated

ANKRD13B expression in both adenoma (73.0%) and adenoma cancer tissues (83.3%) (P< 0.0001), and it also promoted colorectal cancer cell growth, invasion, and migration. Demethylation treatment can reduce the ANKRD13B expression and the growth, migration, and invasion of the cancer cell. Moreover, we found that the aberrant ANKRD13B methylated surrounding the stop codon, and it can promote RNA N6-methyladenosine methylation modification, suggesting that aberrant DNA 5mC methylation promotes ANKRD13B expression and tumor progression in an RNA m6A-dependent manner.
Conclusions: In summary, our findings illustrated that ANKRD13B is an oncogenic gene of colorectal cancer that is commonly methylated and overexpressed in colorectal cancer whose function in the pathogenesis of colorectal cancer depends on RNA m6A-dependent manner. Aberrant DNA 5mC methylation promotes ANKRD13B expression and tumor progression in an RNA m6A-dependent Manner.
Key words: ANKRD13B, DNA methylation, Epigenetic regulation, Colorectal cancer

p16 epimutation modulates the tumor microenvironment and promotes malignancy of *Apc*-mutant colon cancer

Li Yang[1], Xiaomin Chen[1], Christy Lee[2], Jiejun Shi[3], Emily B. Lawrence[1], Lanjing Zhang[4], Yumei Li[1], Nan Gao[5], Sung Yun Jung[1], Chad J. Creighton[1], Jingyi Jessica Li[2], Ya Cui[3], Sumimasa Arimura[1], Wei Li[3], Lanlan Shen[1]. *[1]Baylor College of Medicine, Houston, TX,[2]University of California, Los Angeles, CA,[3]University of California, Irvine, CA,[4]Rutgers University, Piscataway, NJ,[5]Rutgers University, Newark, NJ*

Methylation of the *p16* promoter resulting in mitotically stable gene silencing—known as p16 epimutation—is the most common epigenetic event in human colorectal cancer (CRC) and is also common in normal-appearing colonic mucosa of aging individuals. However, the functional role of *p16* epimutation in CRC carcinogenesis is not completely understood. Here, using a mouse model of engineered *p16* promoter hypermethylation, we show that *p16* epimutation cooperates with mutant *Apc* to promote colon cancer development. Mice carrying combined *Apc* mutation and *p16* epimutation display significantly shortened survival and

increased tumor growth compared to those with *Apc* mutation only. Moreover, colon tumors from these animals express increased levels of programmed death-ligand 1 (*Pdl1*). Single-cell RNA sequencing (scRNA-seq) analysis further revealed the presence of dysfunctional cytotoxic $CD8^+$ T cells together with $Foxp3^+$ Tregs and γδT17 cells, which promote an immunosuppressive tumor microenvironment (TME). Lastly, we show that a combined therapy using an inhibitor of DNA methylation and a PD-L1 immune checkpoint inhibitor is more effective for improving survival in tumor-bearing mice than anti-PD-L1 treatment alone. These findings provide a mechanistic rationale for targeted epigenetic and immunotherapy in CRC patients, with the potential to improve colon cancer treatment.

Antibody validation for clinical pharmacodynamic assay reveals cross-reactivity of commercial DNMT3B clones

Gabriel J. Benton[1], Manisha Mohandoss[1], James H. Doroshow[2], Ralph E. Parchment[1], Katherine V. Ferry-Galow[1]. *[1]Clinical Pharmacodynamic Biomarkers Program, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Cooperativity between the maintenance DNA methyltransferase, DNMT1, and *de novo* methyltransferases, DNMT3A and 3B, is essential for proper maintenance and integrity of the methylome, and deregulation of these enzymes and associated transcriptional silencing of multiple genes has been shown in many types of cancer. Two DNA methyltransferase inhibitors are currently in clinical use with several others undergoing clinical evaluation, and the pharmacodynamic response of DNMT enzymes is a crucial aspect of understanding therapeutic effects in preclinical studies and clinical trials. Vigorous fit-for-purpose validation of research-grade reagents and the application of effective quality control testing procedures to assess lot-to-lot variability (and reject unacceptable lots) are essential to assure robust and reproducible pharmacodynamic assay performance. During the antibody validation process for the DNMT3B enzyme target, two commercial monoclonal antibody clones were found to exhibit significant cross-reactivity to another cellular protein and inappropriate subcellular localization via immunohistochemistry (IHC) , including diffuse

cytoplasmic staining and significant staining in a DNMT3B knock out (KO) cell line. Two other commercial monoclonal antibody clones showed the expected nuclear expression in the HCT116 parental cell line and lack of staining in the DNMT KO cells. Further evaluation via western blot revealed that the cross-reacting antibodies detected a band of the approximate expected molecular weight (MW) of DNMT3B but of a protein that was expressed equivalently in the parental and DNMT3B KO cell line pair, whereas the two other antibody clones only detected a significant band of correct MW in the parental but not the KO cell line. These results suggest that some commercial antibody clones are binding to a protein other than DNMT3B and that they are unsuitable for use with IHC and western blot to evaluate subcellular localization and expression levels of DNMT3B protein. We presume that these non-specific antibody clones were chosen for commercial development based on target screening via Western blot that did not include evaluation of a validated DNMT3B knock out cell line, as is not uncommon for research-grade antibody clones. This data highlights the critical importance of thorough fit-for-purpose validation and quality control for crucial reagents used for pharmacodynamic biomarker studies. Funded by NCI Contract No HHSN261200800001E

An end-to-end workflow for improved methylation detection

Lydia Bonar, Kristin Butcher, Michael Bocek, Holly Corbitt, Bryan Hoglund, Cibelle Nassif, Patrick Cherry, Derek Murphy, Jean Challacombe, Esteban Toro. *Twist Bioscience, South San Francisco, CA*

Introduction: DNA methylation at CpG nucleotide sites in eukaryotes is a key epigenetic mark that can help regulate gene expression. Specific changes in CpG methylation occur in many human cancers, making them a promising biomarker for early cancer detection. However, existing assays can be costly, lack specificity to regions of interest and often provide only semi-quantitative estimates of the methylation fraction. Here, we present a targeted methylome panel to decrease costs associated with next generation sequencing (NGS), methylation controls to calibrate quantitative assays and UMIs for accurate deduplication in low-diversity samples.
Experimental Procedures: Genomic DNA (gDNA) was prepared for sequencing using the Twist Methylation Detection System consisting of

enzymatic methylation conversion and hybrid capture using the Twist Human Methylome Panel. Twist's synthetic CpG methylation level controls were spiked-in to gDNA and taken through the Twist Methylation Detection System to demonstrate their utility in calibrating methylation assays. Additionally, libraries were generated using cell free DNA (cfDNA) and either conventional or UMI-containing adapters to investigate the impact on quantitative detection and total unique coverage.
Results: Using the Twist Human Methylome Panel at 150x raw coverage achieves uniform coverage with low off-bait Picard metrics. 6.59 million CpG sites were detected using a minimum depth of 10X. Target capture with the Human Methylome Panel allows for informative CpG calling of up to 82 samples on a single Illumina Novaseq S4 flowcell, compared to 3 samples per flowcell with a tradition whole-genome bisulfite sequencing (WGBS) assay. The Twist CpG methylation specific controls are constructed of 48 unique contrived sequences that contain a total of 8 different levels of methylation, ranging from 100% to 0%. Including these controls allows for quantitation of methylation levels in the experimental samples and qualification of the enzymatic conversion process.
Conclusions: Our study leverages the Twist methylation detection portfolio to interrogate genome-wide methylation patterns for various applications. In combination, these tools can be used to design cost effective end-to-end assays.

Targeting *p16* epimutation during lung cancer progression for anticancer therapy
Xiaomin Chen[1], Emily Brisnna Lawrence[1], Leah Farmer[1], Li Yang[1], Robert Craig Perry[1], David Joel Sequeira[1], Lanjing Zhang[2], Lanlan Shen[1]. *[1]USDA Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX,[2]Department of Pathology, Princeton Medical Center, Plainsboro, NJ*

Background: Whole-genome DNA methylation profiling revealed that epimutation (gene silencing associated with alteration in DNA methylation) is common in human lung cancer, but it remains unclear whether the aberrant DNA methylation is a cause or a consequence of tumorigenesis.

Furthermore, different from genetic mutations, which are irreversible, epigenetic mutation is reversible and could be restored to normal status. The potential reversibility of epimutation presents new therapeutic opportunities for cancer treatment.
Methods and Results: We utilized an epigenetically engineered mouse cancer model in which the expression of *p16* (also known as Cyclin-dependent kinase inhibitor 2A) is silenced by accumulating DNA methylation at the promoter region ($p16^{meth}$). To investigate whether *p16* epimutation functionally contributes to the lung cancer initiation and progression, we obtained Cre recombinase inducible $K\text{-}ras^{+/LSL\text{-}G12D}$ mice from the Jackson Laboratory and crossed them with $p16^{meth}$ mice to produce $K\text{-}ras^{+/LSL\text{-}G12D}; p16^{meth/meth}$ mice (with combined *K-ras* mutation and *p16* epimutation). These mice have been maintained on the C57BL/6J background. We administered $5x10^7$ pfu of adenovirus-Cre (Ad5-CMV-Cre) to mice at 20 weeks (wk) of age through intranasal instillation to activate oncogenic *K-ras*. We monitored the lung tumor development at 6, 8, 12, and 16 wk post-infection. Remarkably, as early as 6 wk post-infection, we found substantially increased tumor numbers and sizes in the $K\text{-}ras^{+/LSL\text{-}G12D}; p16^{meth/meth}$ mice compared with the $K\text{-}ras^{+/LSL\text{-}G12D}$ mice (n=4 per group). Histopathological analyses confirmed the tumor progression to adenocarcinoma. Interestingly, the $K\text{-}ras^{+/LSL\text{-}G12D}; p16^{meth/meth}$ lung tumors exhibited distinct papillary and intraluminal growth patterns, which were not observed in mice with *K-ras* mutation alone. In addition, to investigate the therapeutic effects of reversing *p16* epimutation, we generated MEFs from these mice and compared the efficiency of *p16* reactivation by either a standard hypomethylating agent 5-Aza-2'-Deoxycytidine (DAC) or a first-in-class reversible DNMT1-selective inhibitor GSK3685032. We found that GSK3685032 induced *p16* demethylation more effectively than DAC. Treatment of GSK3685032 at 1.5μM for 6 days resulted in robust *p16* hypomethylation (58% loss) and three-fold increase in gene expression.
Conclusion: Our study validates that *p16* epimutation functionally contributes to lung cancer initiation and provides an ideal *in vivo* preclinical platform for testing epigenetic therapeutic strategies

Methylation profiling reveals the role of PRC2 in regulating DNA methylome changes in malignant peripheral nerve sheath tumors

Christopher M. Stehn, Minu Bhunia, Kyle B. Williams, Alex T. Larsson, David A. Largaespada. *University of Minnesota, Minneapolis, MN*

Neurofibromatosis type 1 (NF1) syndrome is an autosomal dominant cancer predisposition syndrome defined by germline deletion of one *NF1* allele. Somatic loss of heterozygosity in the remaining *NF1* allele in Schwann lineage cells gives rise to benign tumors known as plexiform neurofibromas. These tumors have a high risk of developing into cancerous lesions known as malignant peripheral nerve sheath tumors (MPNST) through the sequential deletion of *CDKN2A/B* followed by recurrent mutations in *SUZ12* or *EED,* constituting the inactivation of polycomb repressor complex 2 (PRC2). PRC2 is a transcriptional repressor complex involved in the silencing of several genes throughout cell development and differentiation. Loss of this complex leads to a depletion in trimethylation marks on Histone H3 Lysine 27 (H3K27me3) and the subsequent gain of acetylation marks on the same lysine residue (H3K27Ac). However, full range of epigenetic consequences of these events are currently not well characterized, especially with respect to MPNST formation and development. The Largaespada lab has developed Schwann cell lines engineered to harbor deletions in *NF1* and either *SUZ12* or *EED* and assayed the methylation status of 850,000 CpG sites using the EPIC array. The resulting methylation profiles reveal a large degree of change in promoter methylation between cell lines with and without PRC2 inactivation. These changes, however, appear to be inconsistent. To further understand this phenomenon, I have analyzed differential methylation patterns between lines with *SUZ12/EED* deletions on top of *NF1* deletion compared to those with *NF1* deletion alone. Pathway analysis of genes whose promoters are differentially methylated upon PRC2 reveals a bias towards developmental modules such as morphogenesis and neuronal differentiation, suggesting that DNA methylation is a mechanism by which PRC2 loss promotes stemness in Schwann lineage cells prior to MPNST formation. Additionally, differentially methylated regions were overlapped with functional non-coding elements in the genome to understand potential ripple effects in the epigenome. These findings underline the importance of DNA methylation in contributing to tumor formation and define unique

functions by which PRC2 specifically leverages diverse methylation states to drive malignant transformation in Schwann lineage cells.

Comparison of pre-analytical methods for DNA methylation analysis of cfDNA

Miljana Tanic[1], Oluwadunni Emiloju[2], Pawan Dhami[2], Stephan Beck[2].
[1]Institute for Oncology and Radiology of Serbia, Belgrade, Serbia,[2]UCL Cancer Institute, London, United Kingdom

Liquid biopsies in the form of cell-free circulating tumor DNA (ctDNA) isolated from blood plasma or serum have shown great promise to be used as minimally-invasive markers in cancer patients providing an insight into the composition of both primary tumor and metastases, and an opportunity to assess clonal dynamics throughout the course of disease. CtDNA carries not only tumor- specific changes in its sequence but also distinctive epigenetic marks, namely DNA methylation patterns similar to the patterns in the primary tumor. Deregulation of tissue-specific DNA methylation patterns is an early event in carcinogenesis holding great promise to be exploited for early detection of cancer. However, in contrast to mutation detection, targeted DNA methylation sequencing of cfDNA remains a challenge due to low concentration and heavy fragmentation. The limiting step in detection of any analyte is the recovery of the DNA molecules. The pre-analytical steps in the DNA methylation detection pipeline include extraction of cfDNA molecules and their conversion using sodium bisulfite. Bisulfite conversion is a harsh chemical reaction that induces further fragmentation and degradation of already scarce cfDNA. In this study we compared commercial methods for cfDNA extraction and for bisulfite conversion to evaluate the yield, degradation and procedural loss. We compared five commercial kits for cfDNA extraction from blood plasma, three column-based (Qiagen's QIAamp Circulating nucleic acids kit, Norgen's Plasma/Serum Cell-Free Circulating DNA Purification and Macherey-Nagel's NucleoSpin® Plasma XS) and two based on magnetic beads cleanup (Bioo Scientific's Next Prep magnetic Cell-Free Circulating DNA isolation kitand Applied Biosystems' Magmax Cell-Free Circulating DNA isolation kit. The kits used for bisulfite conversion were Zymo EZ DNA Methylation Lightning with column based purification and with

magnetic beads purification, Zymo EZ DNA Methylation Direct with column based purification and with magnetic bead purification, Qiagen Epitect Fast DNA Bisulfite and Diagenode Premium Bisulfite kits. Same samples were processed by each of the kits, Sample degradation was determined using Agilent Bioanalyzer dsDNA kit. Yield was evaluated by Picogreen, absolute qPCR for single-copy gene and for contamination of gDNA by a B-cell specific assay, while procedural loss was determined based on the recovery of a synthetic spike-in.

DNA methylation-based inflammation score is associated with hepatocellular carcinoma among people living with HIV

Kyeezu Kim[1], Yinan Zheng[1], Claudia Hawkins[1], Edith Okeke[2], Olufunmilayo Lesi[3], Yishu Qu[1], Lewis R. Roberts[4], Demirkan Gursel[1], Fatimah B. Abdulkareem[3], Alani Akanmu[5], Godwin Imade[2], Jian-Jun Wei[1], Masha Kocherginsky[1], Kwang-Youn Kim[1], Wasiu L. Adeyemo[3], Firas Wehbe[1], Chad J. Achenbach[1], Atiene Sagay[2], Folasade T. Ogunsola[3], Robert L. Murphy[1], Lifang Hou[1]. *[1]Northwest University, Chicago, IL,[2]University of Jos, Jos, Nigeria,[3]University of Lagos, Lagos, Nigeria,[4]Mayo Clinic, Rochester, MN,[5]Lagos University Teaching Hospital and College of Medicine, Lagos, Nigeria*

Background: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related deaths worldwide. In countries with high human immunodeficiency virus (HIV) prevalence, such as Nigeria, HIV-associated HCC causes a great health burden due to its early onset, late diagnosis, and poorer prognosis. HIV infection is involved in inflammation of the liver, which may determine an increased risk of hepatocyte neoplastic transformation. Inflammation-related DNA methylation signatures obtained in liquid biopsy, such as circulating cell-free DNA (ccfDNA) extracted from serum/plasma are promising minimally-invasive biomarkers that may inform HCC among people living with HIV.
Methods: A total of 289 Nigerian participants with information on ccfDNA and other covariates were included. Participants were classified into three groups by their HCC/HIV status: 1) HCC+/HIV+ (n=28); 2) HCC-/HIV+ (n=185); and 3) HCC+/HIV- (n=76). We constructed ccfDNA methylation

inflammation scores using 49 CpGs previously linked to circulating C-reactive protein (CRP) concentrations, and higher scores represented elevated CRP concentrations with lower methylation levels. To compare the ccfDNA methylation inflammation score across the groups, we performed multivariable logistic regression analyses adjusting for age, sex, alcohol consumption, smoking status, body mass index, study sites, and technical variables.
Results: Participants with HCC+/HIV+ presented the highest ccfDNA methylation inflammation scores (mean=-0.03, standard deviation [SD] =0.01). Participants with HCC-/HIV+ presented the lowest scores (mean=-0.05, SD=0.01). In the multivariable logistic regressions, one SD increase of inflammation score was associated with 2.5 times higher odds of having HCC among HIV-infected participants (HCC+/HIV+ vs. HCC+/HIV-; OR=2.56, 95% CI=1.39-4.73, P=0.002). No evidence was found for the association between the inflammation score and HIV status among HCC patients (HCC+/HIV+ vs. HCC+/HIV-; OR=1.00, 95% CI=0.59-1.70, P=0.991). In the secondary analysis comparing HCC+ vs. HCC- adjusting for HIV status, one SD increase of inflammation score was associated with 3.2 times higher odds of having HCC (OR=3.22, 95% CI=1.39-7.46, P=0.006).
Conclusions: We observed that ccfDNA methylation inflammation score is associated with HCC status among people with HIV. Our findings suggest that ccfDNA methylation-based inflammatory profiles may serve as a potential biomarker for early detection and risk stratification of HCC in resource-constrained countries with a high prevalence of HIV.

Cancer risk diagnosis by epimutation burden: a multicenter prospective study

Harumi Yamada[1], Masahiro Maeda[2], Seiichiro Abe[3], Taichi Shimazu[4], Takayuki Ando[5], Kazunari Murakami[6], Shinji Tanaka[7], Takao Maekita[8], Osamu Inatomi[9], Ken Sugimoto[10], Tetsuro Kawagoe[11], Nobutake Yamamichi[12], Toshikazu Ushijima[13]. *[1]Department of Epigenomics, Hoshi University, Tokyo, Japan,[2]Center for Epigenetics, Johns Hopkins School of Medicine, Baltimore, MD,[3]Division of Science and Technology for Endoscopy, National Cancer Center Hospital, Tokyo, Japan,[4]Division of*

Prevention, Center for Public Health Science, National Cancer Center, Tokyo, Japan,[5]Third Department of Internal Medicine, University of Toyama, Toyama, Japan,[6]Department of Gastroenterology, Oita University, Oita, Japan,[7]Department of General Internal Medicine, Hiroshima University Hospital, Hiroshima, Japan,[8]Second Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan,[9]Division of Digestive Endoscopy, Shiga University of Medical Science, Shiga, Japan,[10]Center for Clinical Research, Hamamatsu University Hospital, Shizuoka, Japan,[11]Department of Gastroenterology, Nippon Medical School, Tokyo, Japan,[12]Center for Epidemiology and Preventive Medicine, The University of Tokyo Hospital, Tokyo, Japan,[13]President, Hoshi University, Tokyo, Japan

Aberrant DNA methylation, induced by aging and accelerated by chronic inflammation, accumulates in normal tissue. Accumulation of DNA methylation in multiple genes, namely epimutation burden, is closely associated with cancer risk. Indeed, we demonstrated that the measurement of the methylation level of a marker gene in normal tissue is useful for cancer risk prediction of metachronous cancers, by a multicenter prospective study with gastric cancer patients (Asada, Gut, 64:388, 2015 : Maeda, Gut, 66:1721, 2017). In this study, we attempted to predict the risk of primary gastric cancer by performing a new multicenter prospective study. We recruited 1,880 healthy people, after *Helicobacter pylori* eradication, with a clinically high risk of gastric cancer. Biopsy specimens were obtained from the antrum and body, and the methylation level of *RIMS1*, which is a preselected epigenomic risk marker for this study, was measured in 1,757 participants. The participants are annually being followed-up to detect primary gastric cancer, for 5-8 years. Currently, the median follow-up is 4.05 years, and 27 people have developed primary gastric cancers (as of September 2022). The results of statistical analysis are being determined. This study will establish the clinical utility of a cancer risk diagnosis by epimutation burden in normal tissue, and is promising for application in various inflammation-associated cancers.

#6015

Methylation synthetic lethality: *CHFR* methylation and KRAS inhibition in gastric cancers

Hideyuki Takeshima[1], Takahiro Ebata[1], Yumi Furuichi[1], Satoshi Yamashita[2], Toshikazu Ushijima[1]. *[1]Department of Epigenomics, Institute for Advanced Life Sciences, Hoshi University, Tokyo, Japan,[2]Department of Life Engineering, Faculty of Engineering, Maebashi Institute of Technology, Maebashi, Japan*

Synthetic lethality is a promising therapeutic strategy, but the number of founder mutations is limited. In contrast, DNA methylation is frequently present in many types of cancers, and can be a potential target for a synthetic lethality. So far, *BRCA1* methylation with a PARP inhibitor is known as a synthetic lethality [Kawachi *et al*., Breast Cancer Res Treat, 181:323-329, 2020]. In this study, we aimed to identify a novel methylation synthetic lethal combination in gastric cancers. Founder methylation was searched for in 8,008 genes with putative promoter CpG islands (CGIs), and 137 genes which were 1) heavily methylated and 2) frequently methylated in primary gastric cancers (10 or more of 50 cases) were selected. The association analysis between DNA methylation and gene expression showed that 10 of 137 genes were completely silenced in gastric cancer cell lines with methylation of their promoter CGIs, but were expressed in those without. Among these 10 genes, we focused on *CHFR*, a known tumor-suppressor gene in gastrointestinal cancers, and genes lethal for *CHFR* methylation were screened for using the sgRNA screening database (The Cancer Dependency Map, DepMap). Comparison of gene dependencies of 17,645 genes between four cell lines with *CHFR* methylation and 12 cell lines without revealed that knockout of *KRAS* reduced cell growth specifically in cell lines with methylation. This synthetic lethality could be experimentally confirmed in two cell lines with *CHFR* methylation, AGS and 44As3, and three cell lines without, HSC41, HSC42, and MKN74. These cell lines included those not used in the screening, validating the usefulness of the combination. These results showed that gastric cancers with *CHFR* methylation were sensitive to KRAS inhibition, and that methylation synthetic lethality is a promising therapeutic strategy.

A comprehensive analysis of gut microbiome mediated epigenetic regulation of intestinal stem cells

Robert Craig Peery[1], Jiejun Shi[2], Leah Farmer[3], Li Yang[3], Emily Lawrence[3], Yumei Li[4], Wei Li[2], Lanlan Shen[5]. *[1]USDA Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX,[2]University of California Irvine, Irvine, CA,[3] USDA Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX,[4]Baylor College of Medicine, Houston, TX,[5]Pediatrics, USDA Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX*

Background: Gut microbial colonization, represents a critical time period for establishing the overall health of an individual. The intestine is a highly dynamic tissue with high turnover of intestinal epithelial cells throughout the life span of an individual making intestinal stem cells (ISCs) critical for normal gut homeostasis. Currently, there exists a lack of knowledge in how the gut microbiota regulates DNA methylation to influence the behavior of these ISCs. Aberrant DNA methylation is now documented to be critical in the disease pathogenesis of intestinal disorders such as colorectal cancer, thus understanding how the gut microbiome influences DNA methylation and ISCs is fundamental for improving human health.
Methods: We utilized the Lgr5-GFP mouse model in which endogenous GFP expression is driven by the bonafide intestinal stem cell marker Lgr5. These mice were maintained under two different housing conditions, conventional and germ free. We collected mice under the two conditions and performed dissociation of the colon and small intestine epithelial cells using EDTA dissociation. We then analyzed cell populations using flow cytometry, and collected two cell populations: the differentiated cell population (EpiCam +, GFP -) and intestinal stem cell population (EpiCam +, GFP +). To perform a genome wide comprehensive DNA methylation analysis we performed Whole Genome Bisulfite Sequencing (WGBS) which included both stem cell and differentiated cell populations of females and males at the two age groups points (postnatal day 21 (p21) and p100).
Results: There was no significant difference in CpG methylation at the global level between the two housing conditions. Next, we analyzed age matched samples from germ free and conventional mice to determine if there are differentially methylated regions (DMRs) associated with the presence of intestinal microbiota. We have identified DMRs that are

maintained in germ free stem cells from p21 to p100 compared to conventional mice, as well as DMRs in the differentiated cell population at both ages. Interestingly in our analysis several genes displayed robust hypomethylation of control mice versus germ free mice at the p100 time point in both the stem cell and differentiated cell populations. One such gene, Ifitm3, has been heavily associated with chronic inflammation in the colonic epithelium and a poor risk factor for colonic cancer (Li D et. Al, Clin Cancer Res. 2011). We validated Ifitm3 methylation and expression changes between cohorts using pyrosequencing and RT-PCR respectively. Conclusions: This comprehensive analysis has yielded top candidate genes for studying functional consequences of DNA methylation changes that have been previously linked to severe patient diseases including cancer.

Exposure-related DNA methylation and gene expression changes in mammary glands of Sprague Dawley rats treated with lorcaserin

Volodymyr P. Tryndyak[1], Rose A. Willett[1], Todd Bourcier[2], Frederick A. Beland[1], Igor P. Pogribny[1]. *[1]FDA National Center for Toxicological Research, Jefferson, AR,[2]FDA Center for Drug Evaluation and Research, Silver Spring, MD*

The development of cancer in humans is caused by irreversible modifications of the genome through genetic or epigenetic alterations resulting in the acquisition of multiple heritable abnormal cellular phenotypes. We have investigated DNA methylation and gene expression alterations in mammary glands of Sprague Dawley rats induced by treatment with the weight-loss drug lorcaserin, a drug that increased the cancer incidence in a human clinical trial (CAMELLIA-TIMI 61) and in rats. Female Sprague Dawley rats received lorcaserin by gavage 7 days/week for 12 weeks, at doses previously used in a 2-year rodent cancer bioassay (0, 30, and 100 mg/kg bw/day). DNA methylation changes were investigated in mammary glands, a target organ for lorcaserin carcinogenicity in rats, by reduced representation bisulfite sequencing. Gene expression changes were analyzed by RNA sequencing. Lorcaserin exposure resulted in dose-dependent DNA methylation alterations in the mammary glands, as evidenced by the presence of 1832 and 2352 significantly differentially methylated CpG (dmCpG) sites in the 30 and

100 mg/kg bw/day treatment groups, respectively, as compared to the control group, among which 593 sites were hypomethylated or hypermethylated in common. Similar to DNA methylation changes, lorcaserin treatment resulted in dose-dependent changes in gene expression. Pathway enrichment analysis of the dmCpG-containing genes demonstrated a strong representation of genes associated with cell morphology, cellular function and maintenance, and cellular growth and proliferation. Analysis of dmCpG sites indicated an increase in the number of hypermethylated sites compared to the number of hypomethylated sites in both 30 (1.9 fold) and 100 (2.6 fold) mg/kg bw/day treatment groups. Furthermore, while the number of hypomethylated CpG sites did not differ between treatment groups, the number of hypermethylated CpG sites in rats treated with 100 mg/kg bw/day of lorcaserin was 1.4 times greater than in rats treated with 30 mg/kg bw/day. By combining the analysis of differentially expressed genes and dmCpG sites, we identified 13 genes (11 hypermethylated and 2 hypomethylated) the expression of which was inversely correlated with DNA methylation in the mammary glands of rats treated with 100 mg/kg bw/day of lorcaserin. We also identified 41 hypermethylated and 17 hypomethylated genes containing more than two dmCpG sites. In summary, we have demonstrated that lorcaserin induces extensive DNA methylation and transcriptomic changes in mammary glands at early preneoplastic stages of lorcaserin-induced rat carcinogenesis. These findings suggest the importance of these non-genotoxic alterations in the carcinogenicity of lorcaserin.

Sequencing of 5-hydroxymethylcytosine to single base resolution

Daniel J. Evanich, V. K. Chaithanya Ponnaluri, Vaishnavi Panchapakesa, Ariel Erijman, Matthew A. Campbell, Nan Dai, Bradley W. Langhorst, Romualdas Vaisvila, Louise Williams. *New England Biolabs, Inc., Ipswich, MA*

DNA methylation is an epigenetic regulator of gene expression with important functions in development and diseases such as cancer. The modified cytosines, 5-methylcytosine (5mC) and 5-hydroxymethylcytosine (5hmC) are identified using Illumina sequencing. Libraries are generated using either NEBNext® EM-seq™, an enzyme-based workflow, or by using

sodium bisulfite conversion. These methods, however, cannot differentiate between 5mC and 5hmC. Distinguishing these modifications is important as there is increased interest in 5hmCs role in regulating gene expression. Methods currently exist to enable discrimination of 5mC and 5hmC, for example, oxBS-seq and TAB-seq. These methods still rely upon sodium bisulfite conversion and have reduced data quality due to fragmentation and loss of DNA. Here we describe an enzymatic method that enables specific detection of 5hmC. 5hmC is detected using two enzymatic steps. Firstly, 5hmCs are glucosylated, which protects them from subsequent deamination by APOBEC. In contrast, cytosines and 5mCs are deaminated resulting in their conversion to uracil and thymine, respectively. During Illumina sequencing deaminated cytosine and 5mC are read as thymine and the glucosylated 5hmC are read as cytosine. Subtractive analysis of 5hmC data from EM-seq data, which detects both 5mC and 5hmC, permits the identification of individual 5mC and 5hmC sites. 5hmC data were generated for inputs of 0.1 ng to 200 ng DNA isolated from E14 mouse embryonic stem cells and human brain. The 5hmC libraries had similar characteristics to EM-seq libraries, including expected insert sizes due to intact DNA molecules, low duplication rates and minimal GC bias. T4147 phage DNA was used as an internal control, as all cytosines are 5-hydroxymethylated, with 98-99% of cytosines identified as 5hmC. 5mC and 5hmC levels were also profiled during E14 cell differentiation for 10 days. Interestingly, 5hmC levels decreased whereas 5mC levels increased particularly during the first five days of differentiation. LC-MS/MS quantification of this same DNA mirrored the changes observed by sequencing. The ability to discriminate between 5mC and 5hmC will provide key insights into the role of these cytosine modifications in development and disease.

Characteristics and impactof DNA methylationon prognosis in hepatitis B virus-related follicular lymphoma

Jianli Ma[1], Yuwei Deng[2], Huilai Zhang[3], Xiaosan Zhang[4], Lihong Liu[5], Xianhuo Wang[3], Hongtao Song[6], Zirong Zhang[7], Caili Liu[7], Qingyuan Zhang[2], Jinming Yu[1]. *[1]Radiation Oncology, Shandong University Cancer Center, Jinan, China,[2]Medical Oncology, Harbin Medical University Cancer Hospital, Harbin, China,[3]Lymphoma, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China,[4]Medical Oncology, Henan*

Cancer Hospital, Zhengzhou, China,[5]Hematology, the Fourth Hospital of Hebei Medical University, Shijiazhuang, China,[6]Pathology, Harbin Medical University Cancer Hospital, Harbin, China,[7]Hematology, The Fourth Hospital of Hebei Medical University, Shijiazhuang, China

Hepatitis B virus (HBV) infection (surface antigen positive, HBsAg+) has been linked to the increased risk and poor prognosis for B-cell lymphoma. Here, we aimed to discover distinctive potential factors to influence the prognosis in HBV-associated follicular lymphoma (FL). Retrospective investigation from multiple clinical centers showed that patients with HBsAg+ FL were featured with a higher incidence of disease progression within 24 months (POD24, *P*=0.031), shorter progression-free survival (PFS, *P* = 0.004) and overall survival (OS, *P* = 0.039). The patients with high HBV-DNA load (>10^5 copies/mL) had worse PFS (*P* <0.001) and OS (*P* = 0.007). Methylation detection identified that POD24 in HBsAg+ FL were contributed by pro-tumoral methylated *KMT2A*, *EP300-AS1,* and *ARID1B*. The majority of MHC I class molecular retained hypermethylated status with silencing expression to promote immune escape and progression in HBsAg+ FL. Hypermethylated *TNFRSF1A* significantly contributed to prevent the POD24 of HBsAg+ FL, whereas hypermethylated *LTA* promoted progression. Regarding the unsatisfactory prognosis guidance based on FLIPI in patients with HBsAg+ FL, we proposed new scoring combined with HBV-related clinical parameters, contributed gene methylation and FLIPI to define a high-risk group with worse prognosis than FLIPI in our study (mean OS, 67.7 vs 69.8). It exhibited good performances in internal cohort and external validation cohort from other three clinical centers. Taken together, chronic HBV infection may affect methylation of the immune-related genes to promote progression in FL. The combination of clinical features and genes methylation with FLIPI could provide a better prognostic model for HBV-related FL.

Genetic and epigenetic features OF *KMT2D*, *CREBBP*, *ATM*, *TSC2* and *GNAS* in uterine leyomiosarcomas

Laura G. dos Anjos[1], Daniela Bizinelli[2], Katia C. Carvalho[3]. *[1]Obstetrics and Gynecology, University of São Paulo, Faculty of Medicine, São Paulo, Brazil,[2]International Research Center (CIPE), São Paulo, Brazil,[3]University of São Paulo, Faculty of Medicine, São Paulo, Brazil*

Background: Uterine leiomyosarcoma (LMS) comprises 60% to 70% of the uterine sarcoma (US). These tumors present high rates of recurrence and metastasis, and the patients' survival rates are very low (20% in five years). It is known that somatic mutations and modifications in the DNA methylation levels are associated with several types of neoplasms. Previously, our group identified missense and loss of function mutations in *KMT2D*, *CREBBP*, *ATM*, *TSC2*, and *GNAS,* using a genetic screening method in LMS samples. Based on these results, we decided to investigate whether a genetic and epigenetic crosstalk could help to understand the biological processes involved in the LMS origin, development, and pathogenesis. The present study aimed to evaluate the *KMT2D*, *CREBBP*, *ATM*, *TSC2* and *GNAS* gene expression profile in LMS cell line, and their methylation levels in formalin-fixed and paraffin-embedded (FFPE) patients´ samples.

Methods: We selected 15 LMS - FFPE samples obtained via surgical procedures performed between 2012 and 2019 at the Instituto do Cancer do Estado de São Paulo (ICESP). Genomic DNA was extracted using the QIAamp DNA FFPE Tissue Kit and we evaluated methylation levels using the Illumina Infinium Methylation EPIC BeadChip system 850k, including samples treated with bisulfite-treated DNA. Leiomyoma (LM) (THESCs CRL-4003) and LMS (SK-UT-1) cell lines were cultivated for gene expression analysis. Cells were growth for 24, 48, 72, and 96 hours, and the total RNA was extracted by TRIzol. High-Capacity cDNA Reverse Transcription Kit was used for cDNA synthesis and for gene expression evaluation, real-time PCR reactions were performed using TaqMan Universal PCR Master Mix and inventoried TaqMan probes.

Results: *KMT2D* and *TSC2* showed increased expression in LMS compared to LM (cut-off $\leq$ -2 and $\geq$ 2 for down and upregulation, respectively), with higher expression in 24 hours of *KMT2D* [Fold Regulation (FR): 2.77] and *TSC2* (FR: 2.58). In contrast, *CREBBP* was downregulated, with lowest

expression in 72 hours (FR: -6.57). *ATM* was upregulated at 24, 48 with higher expression in 72 hours (FR: 2.32), and *GNAS* was downregulated, with lowest expression in 96 hours (FR: -4.31). Moreover, the methylation analyzes showed an expressive hypomethylation in LMS samples, compared to myometrium, for *KMT2D* (β value: 0.45; p= 0.004); *CREBBP* (β value: 0.51 $p < 0.0001$); *ATM* (β value: 0.47 $p < 0.0001$); *TSC2* (β value: 0.53 $p < 0.0001$) and *GNAS* (β value: 0.41 $p < 0.0001$). In conclusion, our study showed that potentially pathogenic mutations may be associated with an aberrant hypomethylation profile, as well as increased expression of *KMT2D*, *TSC2*, *ATM* and loss expression of *CREBBP* and *GNAS* in LMS. The interconnection of these genetic and epigenetic events is essential for understanding the complex biology of these tumors, in addition to enabling identification of biomarkers.

The importance of DNA methylation to breast cancer cell phenotype and its role in the anticancer activity of withaferin-A

Andrew Brane, Trygve O. Tollefsbol. *University of Alabama at Birmingham, Birmingham, AL*

Breast Cancer (BC) is a widespread malignancy that affects the lives of millions of women each year. Prevention of BC through administration of epigenetically active dietary phytochemicals has received increased interest in recent years due to its relatively low cost, few side effects and potential to reduce the financial and healthcare burdens associated with BC. Many phytochemicals' anticancer functions are thought to arise from their effects on the epigenome, although the relative importance of specific genes' epigenetic states remain unclear. To elucidate this, we utilized human BC cell lines in combination with CRISPR-dCas technology tied to methylation modifiers to explore the importance of gene specific DNA methylation to cancer cell phenotype in both naïve BC cells and BC cells treated with the phytochemical Withaferin A (WA). We found that demethylation of promoters of the tumor suppressors *p21* and *p53* results in increased gene expression, while methylation of the promoter of the oncogene *CCND1* results in decreased in gene expression. Additionally, changes to biological processes were associated with tumor suppressor promoter methylation state, including increases in cell cycle arrest for a demethylated *p21*

promoter and decreases in cell viability for a demethylated *p53* promoter. We also found that downregulation of *p21* through targeting DNMT3A to its promoter was able to ablate the anticancer function of WA in both MDA-MB-231 and MCF-7 cells. Taken together, these results highlight the potential importance of DNA methylation changes for cancer cell phenotype and a possible mechanism of action for the phytochemical WA in BC prevention.

Plasma methylome landscape across the spectrum of prostate cancer progression, and differentially methylated region (DMR) based biomarkers of hormonal therapy failure in metastatic hormone-sensitive prostate cancer

Manish Kohli[1], Jodie Wong[2], Yijun Tian[3], Amir Bitaraf[3], Claire Hanson[1], Matt Larsen[1], Jennifer Lloyd[1], Julia Batten[1], Neeraj Agarwal[1], Umang Swami[1], Benjamin Maughan[1], Sumati Gupta[1], Jonathan Tward[1].
[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT,[2]Moffit Cancer Institute, Tampa, FL,[3]Moffitt Cancer Institute, Tampa, FL

Background: DNA silencing of gene expression can affect tumorigenesis, treatment outcomes and prognosis. Epigenetic silencing of tumor suppressor genes in prostate cancer detected in plasma at different stages of progression and its effect on clinical outcomes has not been determined. In a cohort study across different stages of prostate cancer (PC) progression, we performed plasma cell-free DNA (cfDNA)-based epigenomic profiling for determining the landscape of methylation and Differentially Methylated Region (DMR) classifiers and the potential impact on clinical outcomes in metastatic hormone-sensitive prostate cancer (mHSPC) state.
Methods: Plasma was collected prospectively in a longitudinal cohort study of 108 PC patients (pts) of which 24 had non-metastatic Local PC; 28 had mHSPC; 56 had mCRPC. cfDNA was used for enzymatic methylation sequencing (EM-seq) of a targeted panel of genes (N=441) implicated in prostate cancer biology. Methylation status at CpG islands of these genes were examined using Twist targeted cfDNA methylation assay. The Bismark program was used for methylation calls. Temporal trends of differentially methylated regions (DMRs) were identified in different states of progression by comparing the methylation status of target genes in

localized PC, mHSPC and mCRPC states using a False Discovery Rate (FDR-q-value) of 0.2 or less. DMRs uniquely associated with mHSPC state were identified and determination of genes with DMRs in pts experiencing early failure of androgen deprivation therapy (ADT)-based therapies was performed. Early failure was defined as progression on ADT within 12 months.
Results: We identified 304/441 genes that were differentially methylated between localized PC and advanced PC (mHSPC and mCRPC) (FDR<0.2), of which 237 genes differed between mHSPC and mCRPC ($p<0.05$) states. mHSPC pts were serially profiles before and after 3 months of ADT-based therapies. All 28 pts experienced a PSA response at 3-months and 112/237 genes showed significant change in methylation status in these serial samples taken before/after 3 months of ADT-based therapies. The median follow up of the cohort was 18 months (range 10-24). 6/28 mHSPC pts experienced early ADT failure (<12 months; median 10 months). 8/112 genes were significantly associated with early failures and included DMRs in *RB1, FOXA1, SOX11. GSC, ALDH1L1, SCGB3A1, FLT4*, and *PTPRN2.*
Conclusions. A targeted cfDNA plasma liquid-biopsy based epigenomic profiling of PC cancer related genes was able to capture significant differences in DMRs across different states of cancer progression. Candidate differentially expressed CpG methylome gene biomarkers detected in plasma also identified biomarkers associated with early ADT-based treatment failure in mHSPC.

Precancerous nature of intestinal metaplasia with accelerated DNA methylation along with altered epigenomic landscape

Chihiro Takeuchi[1], Satoshi Yamashita[2], Yu-Yu Liu[1], Hideyuki Takeshima[1], Toshikazu Ushijima[1]. *[1]Department of Epigenomics, Hoshi University, Tokyo, Japan,[2]Department of Biotechnology, Maebashi Institute of Technology, Gunma, Japan*

Objective. The presence of intestinal metaplasia (IM) is a risk factor for gastric cancer. However, it is still controversial whether IM itself is a precancerous or paracancerous lesion. Here, we aimed to explore the precancerous nature of IM in terms of epigenetic alterations.

Design. Genome-wide DNA methylation analysis was conducted by EPIC BeadArray using IM and non-IM crypts isolated by Alcian blue staining. Organoid establishment, ChIP-seq for H3K27ac, and single-cell ATAC-seq were conducted using IM mucosa. *NOS2* was induced using a Tet-on gene expression system in normal cells.
Results. IM crypts had a methylation profile unique from that of non-IM crypts, showing extensive DNA hypermethylation in promoter regions with CpG islands, including those of tumor suppressor genes. Also, the IM-specific methylation profile was carried into a fraction of gastric cancers (GC), and the frequency of the IM-type GCs was higher than the fraction of IM cells in the adjacent mucosa, indicating that IM cells have a higher chance of developing into cancer cells than non-IM cells. Moreover, the patients with IM-type GCs showed better overall survival than those without, and IM-type GCs showed good response to chemotherapy. As for the mechanism of accelerated methylation induction, IM organoids had remarkably high endogenous *NOS2* expression, and *NOS2* induction in normal cells was shown to accelerate aberrant DNA methylation by increasing DNMT activity. IM mucosa underwent dynamic enhancer reprogramming, including the regions involved in abnormal *NOS2* expression. Single-cell ATAC-seq also showed *NOS2* open chromatin in IM cells but not in gastric cells, and frequent closed chromatin of tumor-suppressor genes in IM cells. *NOS2* expression in IM-derived organoids was up-regulated by IL-17A, a cytokine secreted by extracellular bacterial infection.
Conclusions. IM cells were considered to have a strong precancerous nature with an increased chance of converting into cancer cells in terms of the specific methylation profile and the accelerated DNA methylation induction due to abnormal *NOS2* expression.

Metabolism and Metabolomics of Cancer

Cancer-selective metabolic vulnerabilities in MYC-amplified medulloblastoma
William Gwynne. *Surgery, McMaster University, Hamilton, ON, Canada*

[Background] Medulloblastoma (MB) is the most frequently diagnosed malignant pediatric brain tumor. Multiple integrated genomic analyses have been used to stratify MB into four molecular subgroups, each unique in its gene expression profile, clinical characteristics, and prognosis. *MYC*-driven group 3 MB (G3MB) tumors are poorly understood entities, defined by metastasis down the leptomeninges, disease recurrence and particularly poor survival. *There is hence an urgent need for a more thorough molecular understanding of G3MB, particularly at recurrence, in order to develop more effective therapeutic modalities that will improve the durability of remission.*
[Methods] We previously developed a therapy-adapted mouse model of G3MB disease progression from xenoengraftment through treatment-induced minimal residual disease until eventual relapse in the brain and spine compartments. Temporal transcriptomic profiling of tumor tissue at each stage revealed an enrichment of several metabolic pathways at recurrence. Here we mapped further functional insight into the G3MB metabologenomic landscape by performing a genome-wide loss-of-function CRISPR-Cas9 genetic screen in patient-derived G3MB cells, which we cross-referenced with screens performed in human neural stem cells (NSCs), the proposed cell- of-origin for G3MB.
[Results] By examining G3MB context-specific gene ontologies, we discovered differential essentiality of several metabolic processes exclusively in G3MB. In tandem, mass spectrometry-based global metabolomic profiling shows dysregulation of several metabolic pathways in in G3MB tumor cells in comparison to NSC, including the enrichment of *de novo* pyrimidine biosynthesis and depletion of salvage pyrimidine intermediates. We investigated a lead hit from our screen, DHODH (dihydroorotate dehydrogenase), which facilitates *de novo* pyrimidine biosynthesis. Our data demonstrate that genetic or pharmacological inhibition of DHODH selectively targets G3MB brain tumor initiating cell (BTIC) activity while sparing normal NSC, by disrupting hallmark MYC activity. We further show that MYC-amplified G3MB tumors harbor subgroup-specific transcriptomic signatures that delineate enrichment of *de novo* pyrimidine biosynthesis.
[Significance] Despite clear evidence favoring an altered metabolic landscape in *MYC*-driven cancers, there have been only a few reports into the role of metabolic reprogramming in *MYC*-amplified G3MB. Given the

paucity of treatment options for patients with recurrent G3MB, this study has the potential for a significant impact on the field of pediatric oncology. Translation of therapies that target unique metabolic vulnerabilities exclusive to G3MB may lead to more durable cures and radical improvements in quality of life for survivors.

#6029

Multi-omic landscape of squamous cell lung cancer

Paul Stewart[1], Ashley Lui[2], Eric Welsh[2], Dalia Ercan[2], Vanessa Rubio[2], Hayley Ackerman[2], Guohui Li[3], Bin Fang[2], Steven Eschrich[2], John Koomen[2], Elsa Flores[2], Eric Haura[2], Gina DeNicola[2]. *[1]Biostatistics and Bioinformatics, Moffitt Cancer Center, Tampa, FL,[2]Moffitt Cancer Center, Tampa, FL,[3]Zymergen, Emeryville, CA*

Patients with squamous cell lung cancer (SCC) have high unmet medical need. Knowledge of these tumors is limited, and a lack of targetable genomic drivers means patients have few treatment options. To provide a detailed analysis on the influence of genomic alterations to proteome-level changes in SCC, we previously integrated DNA copy number, somatic mutations, RNA-sequencing, and expression proteomics in a cohort of 108 SCC patients. A major finding was identification of three proteomic subtypes, two of which made up the majority (87%) of tumors: the "Inflamed" subtype was enriched for B-cell rich tertiary lymphoid structures (TLS), and the "Redox" subtype was enriched for redox pathways and NFE2L2/KEAP1 alterations but had significantly less immune infiltration. We hypothesized these proteomic subtypes would give rise to distinct metabolic signatures. Therefore, we performed untargeted metabolomics on 87 tumors from the same cohort using chromatographic separation on a HILIC column, followed by analysis on a Q Exactive HF mass spectrometer. This analysis yielded 7,344 features corresponding to 7,072 unannotated metabolites and 272 identified metabolites. Glutathione, a key redox metabolite, was anticorrelated with immune score (R = -0.44, padj = 0.004) calculated from our transcriptomic data with the ESTIMATE algorithm, and glutathione was elevated in the Redox proteomic subtype (0.58 log2 ratio, padj = 9.87E-04). Consensus clustering was next used to identify novel metabolomic subtypes of SCC. Surprisingly, none of the five metabolomic subtypes we identified corresponded to proteomic subtype or

NFE2L2/KEAP1 alteration (Fisher's Exact test p-values > 0.05). The fifth subtype had 332 metabolites (26 identified) differentially expressed (> 1.5 fold-change, padj < 0.05) with ascorbate and aldarate metabolism as the top enriched pathway (padj = 3.36E-04). Interestingly, this fifth metabolomic subtype had significantly higher DNp63-alpha (p = 2.40E-05), a primary transcript of delta-N p63 that is known to promote non-small cell lung cancer. Ongoing integrative analyses across omic types will determine how p53, p63, and p73 transcripts influence these metabolomic subtypes, how these transcripts relate to the poor immune infiltration in some SCC tumors, and if these transcripts relate to novel metabolic vulnerabilities in SCC.

KYNU upregulation is a prominent feature of NRF2-activated cancers and is associated with tumor immunosuppression and poor prognosis

Ricardo A. Leon Letelier, Ali H. Abdel Sater, Yihui Chen, Ranran Wu, Jennifer B. Dennison, Soyoung Park, Ehsan Irajizad, Hiroyuki Katayama, Jody Vykoukal, Samir Hanash, Edwin J. Ostrin, Johannes F. Fahrmann.
Clinical Cancer Prevention, The University of Texas MD Anderson Cancer Center, Houston, TX

Activation of the nuclear factor erythroid 2-related factor 2 (NRF2) pathway, either through gain-of-function mutations in the NRF2 encoding gene *NFE2L2* or through loss-of-function of its suppressor, Kelch-like ECH-associated protein 1 (*KEAP1*), is a frequent manifestation in various malignancies. NRF2 activation exerts pro-tumoral effects in part by altering cancer cell metabolism. We previously reported a novel mechanism of NRF2 tumoral immune suppression through selective upregulation of the tryptophan metabolizing enzyme kynureninase (KYNU) in lung adenocarcinoma. In the current study, we explored the Pan-Cancer relevance of NRF2-mediated KYNU upregulation. We analyzed the gene expression dataset for 9,801 tumors representing 32 cancer types in The Cancer Genome Atlas (TCGA). Elevated KYNU expression levels paralleled increased gene-based signatures of NRF2-activation and was strongly associated with an immunosuppressive tumor microenvironment, marked by high expression of gene-based signatures of Tregs as well as immune checkpoint blockade-related genes CD274 (PDL-1), PDCD1 (PD-1), and CTLA4, regardless of cancer type. Cox proportional hazard models

further revealed that increased tumoral KYNU gene expression was prognostic for poor overall survival in several cancer types, including thymoma, acute myeloid leukemia, low grade glioma, kidney renal papillary cell carcinoma, gastric adenocarcinoma, and pancreatic ductal adenocarcinoma (PDAC). Using PDAC as a model system, we confirmed that siRNA-mediated knockdown of NRF2 reduces KYNU mRNA expression, whereas activation of *NFE2L2* (the encoding gene for NRF2) through either small molecule agonists or siRNA-mediated knockdown of *KEAP1* upregulated KYNU. Metabolomic analyses of conditioned media from PDAC cell lines revealed elevated levels of KYNU-derived anthranilate, confirming KYNU as enzymatically functional. Collectively, our findings highlight the multi-cancer relevance of the NRF2-KYNU axis and of tumoral KYNU as a prognostic marker of poor overall survival associated with immunosuppression.

Exploiting metabolic vulnerabilities of ovarian cancer with upregulated succinate dehydrogenase

Lin Wang, Magdalena Bulicz, Patryk Mucha, Michael Kinter, Atul Pranay, Timothy M. Griffin, Benjamin F. Miller, Magdalena Bieniasz. *Aging and Metabolism, Oklahoma Medical Research Foundation, Oklahoma City, OK*

Ovarian cancer remains the deadliest of all gynecologic malignancies nationwide due to limited therapeutic options and chemotherapy resistance. The response to chemotherapy is substantially influenced by the high metabolic flexibility of ovarian cancer cells, which allows the cells to reprogram their metabolism and survive the treatment. Better understanding mechanisms regulating ovarian tumor metabolism could be exploited to develop new improved therapies. Our work demonstrated that the upregulation of mitochondrial enzyme succinate dehydrogenase (SDHA) is particularly prevalent (~20% of patients) in ovarian carcinoma and contributes to high energy tumor metabolism and cell survival. We observed that SDHA overexpressing ovarian cancer cells showed improved ability to survive and generate colonies in anchorage-independent conditions, which is an important feature of ovarian tumor cells surviving and spreading in peritoneal fluid (ascites). Proteomics data revealed that the SDHA overexpressing tumor cells showed reduced levels of proteins promoting

anaerobic glycolysis (LDHA and HIF1α), and increased levels of mitochondrial pyruvate carrier (MPC) proteins. In addition, our tracer-based metabolomics data revealed that the elevated SDHA stimulates glutaminolysis by increasing mitochondrial glutamine supply fueling the TCA cycle with essential metabolites. We also demonstrated that the overexpression of SDHA is associated with a significant increase of OXPHOS and ATP production rate. Further, we reasoned that the SDHA overexpressing tumor cells could be particularly vulnerable to drugs disrupting glucose and/or glutamine metabolism. We performed a drug screening and identified an anti-metabolic compound shikonin known to disrupt glucose and amino acid metabolism. In *in vitro* studies, shikonin exhibited a profound anti-tumor efficacy and selectivity towards SDHA overexpressing tumor cells superior to that observed with chemotherapy. Importantly, our *in vivo* study validated the *in vitro* observations, and showed that shikonin is highly effective in suppressing SDHA overexpressing patient-derived tumor growth. In summary, the unique metabolic state of ovarian cancer associated with SDHA amplification could be successfully targetable offering a potential new treatment strategy for ovarian cancer patients.

RA123, a new GLS1 allosteric inhibitor demonstrates *in vitro* and *in vivo* activity in multiple myeloma models

Christophe Henry[1], Dimitri Gorge-Bernat[1], Pascal Pannier[1], Isabelle Meaux[1], Jane Cheng[2], Fangxian Sun[2], Olivier Pasquier[1], Philippe Lienard[1], Erwan Jouannot[1], Thierry Gouyon[1], Geneviève Estenne-Bouhtou[1], Bailin Zhang[2], Bérangère Thiers[1], Laurent Debussche[1], David Machnik[1]. *[1]Sanofi, Vitry-sur-Seine, France,[2]Sanofi, Cambridge, MA*

The conditional essential amino acid glutamine is utilized by tumors to sustain bioenergetic requirements in a nutrient-poor microenvironment. Based on this specific tumor need, efforts have been made to target the glutamine metabolism using glutaminase inhibitors. In this study, we present in vitro and in vivo studies demonstrating activities and target engagement of a new specific GLS1 allosteric inhibitor (RA123). In vitro, RA123 was tested in imid-resistant, CD38 low RPMI8226 multiple myeloma cell line using the ATP Cell titer Glo assay over a 72h treatment

period. In vivo, RA123 was tested in mice xenografted with RPMI8226 multiple myeloma cell line. Compound was given at three different under a BID (twice a day) regimen. Tumor growth under treatment was monitored by caliper measurement for 20 days. A terminal PK/PD study on the same model was setup measuring impact of the drug on the glutamine and glutamate tumor content post 24 hours after the last administration. Over the same period, PK measurements were planned to document drug exposure in the plasma and in the tumor. Finally, in a stand-alone study, target engagement was documented using imaging modality. [18F]FSPG PET radiotracer was used to visualize and quantify impact of RA123 on tumor (RPMI8226) glutamate pool. RA123 was given at three doses under a BID regimen. Treatment was administered for 3 days, and PET signal was recorded at baseline and at end of day 3. In vitro study demonstrated that RA123 was able to induce cell killing of RPMI8226 after 72 hours of treatment. These data translated in vivo by a dose-dependent effect on cell growth. In a terminal PK/PD study, RA123 confirmed a dose-dependent impact on glutamine and glutamate tumor levels which correlated with both plasma and tumor exposure. Further confirmation of target engagement was observed with reduced PET uptake post- RA123 treatment at the three doses tested. In conclusion, this study demonstrated that RA123, a new specific GLS1 allosteric inhibitor was able to impact multiple myeloma tumor cell growth both in vitro and in vivo. This effect was associated with reduced glutamate pools and accumulation of glutamine levels within the tumor cells.

#6034

Detection of potassium channel (KCN) gene expression, often multiple and pH sensitive, in cancer genomic landscapes, as low to mid level genes of interest, suggests potassium transmembrane flow may enable proton efflux in a Goldilocks manner

Marie E. Beckner. *Kent State University, Willoughby Hills, OH*

A reversed pH gradient across cell membranes underlies multiple malignant features, including invasiveness. Extracellular low pH activates metalloproteases and intracellular high pH activates ATP citrate lyase, inactivates caspases, etc. Hydrogen ions attracted to inner membrane fixed anions are putatively displaced by potassium ion flow through membrane

channels. Altered expression of potassium channel (KCN) genes sensitive to pH in invasive brain tumors (Beckner, Proc AACR, A3039, 2022) and 2 mutated KCN genes (1 pH sensitive) in U87 glioblastoma cells (Clark MJ et al, PLOS Genet 2010, e1000832) led to this investigation. Published studies with altered expression or mutations in KCN genes qualifying them as genes of interest (GOI) were compared. Both study types included breast, lung, gastrointestinal, brain, bone marrow, liver, melanocytic malignancies, and 8 others were in either. At least 1 figure (heatmap, Venn diagram, phylogenetic tree, etc.) or table (not Supplemental) had 1 or more KCN genes in a group of GOI. Average numbers of GOI with 95% CI for 23 expression and 14 mutation studies were 38.5 ± 0.4 and 28.4 ± 0.4. No KCN GOI was further examined in the studies. Expression was according to tumor types, inhibitors, siRNAs, regulators of pathways, transcription factors, location, etc. Mutations were single nucleotide polymorphisms, insertions, deletions, fusions, etc. Tissue from surgery, organoids, xenografts, cell lines, stem cells, etc. were analyzed. Of 27 KCN GOI in expression studies, 2/3 were detected with other KCN GOI. For 12 mutated KCN genes there were no other KCN genes mutated in the same study. In expression studies, 8 (34.8%) had multiple KCN GOI, differing from mutation studies, p=0.015, Fishers Exact. In expression studies, 8 found pH sensitive KCN GOI including KCNK1 (2X), K3, K5, K6, K12, K15 (2X), and KCNJ16. In mutation studies, KCNK9 was the only one found. The most frequently mutated KCN subfamily was KCNJ, KCNJ5 (2X) and KCNJ12 (2X). All expression studies included at least 1 repeat GOI (KCN or other). APOE, RET, and RTN1 were each GOI 3 times. Additionally, 40 expressed GOI (including 6 KCN GOI) were found 2X. A small cell lung cancer study had 6 repeats (30%) in 20 GOI (ASCL1, BCL2, KCNA1, RET, SCN3A, and SOX2). KCN gene multiplicity, often pH sensitive members, among low to mid level GOI consistent with a Goldilocks' level of expression, and repeated association with cancer genes supports a pH related measured/regulated role for potassium channels in malignancy. Mainly inward (and some outward for recirculation) potassium transmembrane flows in tumor cells potentially compete with hydrogen ions attracted to inner membrane anions to promote proton efflux by displacement with subsequent reversed pH gradients that aid invasion, cell survival, etc.

Glutaminase inhibitors block metabolic switch in prostate cancer and prevents anti-androgen treatment resistance

Hirak Subhra Basu[1], Meredith Spradlin[2], Tian Weihua[1], Jose Enriquez[1], Pratip Bhattacharya[1], Livia Eberlin[3]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Department of Surgery, Baylor College of Medicine, Houston, TX,[3]Baylor College of Medicine, Houston, TX*

Background: All prostate cancers first manifest as androgen dependent tumors and most patients are initially treated with surgery or radiation. About 30% of these patients return to clinic with recurrent prostate cancer that initially responds to androgen ablation therapy (ADT). Unfortunately, almost all of them fail ADT and develop castrate resistant disease (CRPC) that responds poorly to most cancer therapies and progress to often lethal metastatic CRPC (mCRPC). There are accumulating evidence that at a certain state of progression of hormone sensitive prostate cancer (HSPC) to CRPC, prostate cancer cells adopt to androgen signaling axis targeted therapy (ASI) by switching their metabolism from glycolysis to mitochondrial oxidative phosphorylation (OXPHOS). High OXPHOS activity induces mitochondrial dysfunction, autophagy, cancer invasion, and metastasis. A mitochondrial enzyme glutaminase (GLS) produces L-glutamate from L-glutamine. L-glutamate is utilized in mitochondrial metabolism for energy production through TCA cycle. GLS inhibitors CB-839 and IACS-6274 are being clinically developed for treatment of various human malignancies. We have shown that growth of prostate cancer patient derived xenografts (PDX) is markedly inhibited by a combination treatment of a clinically used ASI enzalutamide (ENZA) followed by a GLS inhibitor. Methods: We followed the growth of one HSPC and two CRPC PDX tumors in mice and collected tumor tissues and circulating human tumor cells (CTC) from mouse blood samples at sacrifice. We used super resolution STED confocal microscopy to image mitochondria in the tissue samples and in the CTCs, desorption ionization mass spectrometry (DESI-MS) imaging of multiple metabolites in the tissue samples as well as hyperpolarized MRI (HP-MRI) of the xenografted tumors to follow the changes in cellular central carbon metabolism *in vivo*.

Results: We observed that growth of PDXs developing ENZA resistance is markedly inhibited when ENZA is followed by adding GLS inhibitors with a concomitant reduction in OXPHOS activity. In addition, the *ex vivo* and *in vivo* methods introduced to monitor tumor metabolic activities can be easily translated into clinic to monitor the metabolic status of the tumors for early detection of resistance development and as a pharmacodynamic marker for metabolic inhibitor therapy.
Conclusion: GLS inhibitors added to ASI could be effective against CRPC and mCRPC developing resistance to ASI treatment.

Functional antibodies against multi span transmembrane proteins - revisiting the Warburg effect in cancer cells

Siret Tahk[1], Kai Virumäe[1], Paule Hermet[1], Korneelia Anton[1], Maiken Abel[1], Denis Belitškin[1], Luciano Galdieri[2], Steven Garner[2], Jillian Krings[2], Kaleb Collver[2], Emily Hoehn[2], Brendan Lahm[2], Kaitlyne Powers[2], Tuuli Käämbre[3], Alastair J. King[2], Francisca Neethling[2], Anu Planken[1], Mart Ustav[1], Andres Männik[1], Mart Ustav[1]. *[1]Icosagen Cell Factory OU, Tartu maakond, Estonia,[2]Eurofins Discovery, St Charles, MO,[3]Chemical Biology Laboratory, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia*

Background: Alterations in tumor cell metabolism are one of the central processes guiding cancer progression. The increased glucose dependence of cancer cells, also known as the Warburg effect, opens the possibility to therapeutically target the glycolytic pathway and challenge the metabolic needs of tumor cells. We generated 24 monoclonal antibodies targeting the main glucose transporter on cancer cells - SLC2A1 (GLUT1). We evaluated the ability of the antibodies to affect cancer cell fitness alone and in combination with OXPHOS inhibitors to find clinically applicable therapeutics targeting tumor metabolism.
Methods: Immunization, discovery and isolation of monoclonal antibodies against SLC2A1 protein was conducted using HybriFree technology using $SLC2A1^{+}$ virus like particle (VLP)-based immunization strategy (Kivi, et al., BMC Biotechnology, 2016). Antibodies were functionally characterized by 2-deoxyglucose uptake interference assay and sensitivity to antibody

single and combination treatments were evaluated in various tumor cell lines. Metabolomics and oxygen consumption rates were examined as mechanistic endpoints for tumor cell lines and primary tumor samples.
Results: The anti-SLC2A1 antibodies specifically bind to SLC2A1 with low nanomolar EC50 values and not to other glucose transporters. Antibody clones with functional properties inhibit glucose uptake leading to reduced metabolic activity and growth inhibition in a subset of cancer cell lines. A drastic cell proliferation inhibition is moreover observed in combination of anti-SLC2A1 antibodies and OXPHOS inhibitors metformin, phenformin or IACS-010759 in 2D cultures of colon, breast and pancreatic cancer cell lines. The inhibition of metabolic activity was further confirmed in an *ex vivo* primary patient tissue samples highlighting the putative translational applicability of our antibodies.
Conclusions: This is the first study to provide highly specific antibodies bocking the function of SLC2A1 transporter and demonstrate the proof of principle for inhibiting complex muti-pass membrane transporters with antibody therapeutics. While the developed anti-SLC2A1 antibodies could be efficacious in some indications as single agents, appreciable clinical activity could be obtained by the combined use with OXPHOS inhibitors.

#6037

Identification of collateral lethal targets in cancers using integrated machine learning and flux analysis platform for personalized metabolic therapy

Abhinav Achreja[1], Jin Heon Jeon[1], Mark Slayton[1], Tao Yu[2], Olamide Animasahun[1], Minal Nenwani[1], Fulei Wuchu[1], Anjali Mittal[1], Xiongbin Lu[2], Sofia D. Merajver[1], Deepak Nagrath[1]. *[1]University of Michigan, Ann Arbor, MI,[2]Indiana University, Bloomington, IN*

Chromosomal alterations that occur frequently in cancers confer selective advantages for tumor progression by deleting tumor-suppressing genes or amplifying oncogenic drivers. However, the collateral effect of these, i.e., deletion of essential genes or upregulation of metabolic regulators, exposes cancers to biological pressures by suppressing essential metabolic pathways. Cancer cells rely on paralogous metabolic pathways to compensate for this loss of function, which in turn opens the door to exploit metabolic vulnerabilities arising as a direct consequence of chromosomal

alterations. These pathways are collateral lethal (CL) targets and offer a unique precision medicine approach for metabolic therapeutics. We have developed an integrated machine learning and systems biology platform, collateral lethal gene identification via metabolic fluxes (CLIM) to identify metabolic targets across multiple cancers. Results: In ovarian cancers with 19p13.3 deletion, a loss of Complex III subunit-encoding gene UQCR11 occurs, leading to suppressed electron transport chain (ETC) activity. CLIM predicted that MTHFD2 acts noncanonically to oxidize NADH to NAD^+ to compensate for reduced NAD^+ recycling via the ETC. We demonstrate selective death of ETC deficient ovarian cancers by targeting MTHFD2 and provide mechanistic validation of oxidative MTHFD2 flux. We observed significant shrinkage of ovarian tumors with ETC deficiency upon MTHFD2 knockdown in mouse models. In triple negative breast cancers (TNBC), we discovered a chromosomal amplification leading to reprogramming of the serine biosynthesis pathway. CLIM predicts a target in the tryptophan metabolism. Methods: Patients are stratified using machine learning to identify tumors with distinct chromosomal alterations. Multiobjective metabolic flux analysis is employed to predict CL pathways in curated genome-scale metabolic models. Validation of metabolic rewiring predicted by CLIM were examined using 3-^{2}H-glucose, 4-^{2}H-glucose and 2,3,3-^{2}H-serine to probe the one carbon metabolism. Oxidative MTHFD2 flux was quantified using innovative combinatorial tracer study with ^{2}H-formate and 4-^{2}H-glucose. We utilized gain- and loss-of-function assays in multiple cell-lines to show utility of the predicted CL targets in TNBCs with chromosomal amplifications. Conclusion: Our integrated platform successfully identifies CL gene pairs to decipher novel metabolic targets specific to chromosomal alterations across many cancer types. Importantly, targets identified by CLIM are based on quantitative flux analysis. This approach reveals functional connection between CL pairs, thereby providing a mechanistic understanding of emerging lethality. This is critical in developing therapeutic interventions that selectively target cancer cells, with minimal off-target or side effects.

KDM2B regulates Serine-Glycine-One Carbon (SGOC) metabolism by targeting the SGOC enzyme genes via a combination of direct and indirect epigenetic mechanisms

Evangelia Chavdoula[1], Vollter Anastas[1], Allesandro La Ferlita[1], Julian Aldana[1], Giuseppe Carota[2], Mariarita Spampinato[2], Sameer Parashar[1], Ilaria Cosentini[3], Burak Soysal[1], Giovanni Nigita[1], Michael Freitas[1], Philip Tsichlis[1]. *[1]The Ohio State University College of Medicine, Columbus, OH,[2]Department of Biomedical and Biotechnological Sciences, University of Catania, Catania, Italy,[3]Department of Clinical and Experimental Medicine, Bioinformatics Unit, University of Catania, Catania, Catania, Italy*

Our earlier studies had shown that overexpression of the JmjC domain histone demethylase KDM2B renders mouse embryo fibroblasts (MEFs) resistant to oxidative stress due to the role of KDM2B in the regulation of antioxidant mechanisms. Here we present evidence that the knockdown of KDM2B in basal-like breast cancer cell lines results in a decrease of Glutathione (GSH) levels, a secondary increase of intracellular ROS levels and in enhanced sensitivity to deubiquitinase inhibitors. The expression of the Glutamate-Cystine antiporter, the Glutamate-Cysteine Ligase GCLC/GCLM and the Glutathione Peroxidase GPX4, all of which regulate GSH abundance was not affected. To address the mechanism of the GSH regulation we carried out RNA-Seq, quantitative proteomics and metabolomics analyses in shKDM2B- and empty vector-transduced MDA-MB-231 cells. The results showed that the KD of KDM2B causes major shifts in metabolism and that one of the metabolic pathways whose activity depends on KDM2B is the SGOC pathway, which has a major role in GSH biosynthesis. Experiments in cultured cells confirmed the importance of KDM2B in the regulation of this pathway and they also showed that the inhibition of the pathway via the KD of KDM2B is partly responsible for the shKDM2B-induced inhibition of cell proliferation in culture and in xenograft experiments in NSG mice. More important, the transcriptomic signature of the SGOC pathway correlates with the expression of KDM2B in basal like mammary adenocarcinomas in the TCGA database. The genes encoding the majority of the enzymes in the SGOC pathway are known to be regulated by MYC and ATF4 and our data show that both MYC and ATF4 are under the regulatory control of KDM2B. ATAC-Seq and ChIP-Seq experiments in shKDM2B and control MDA-MB-231 cells also showed that KDM2B binds the promoter region of not only MYC and ATF4, but also of the genes encoding the SGOC enzymes and that it

regulates chromatin accessibility and the abundance of H3K4me3/H3K27Ac active histone marks in these promoters. Overall, our data indicate that KDM2B regulates the SGOC pathway by targeting MYC and ATF4 and by making the promoters of the genes encoding the SGOC enzymes accessible to these regulators. Overall, our data provide new evidence on SGOC regulation, and identify novel KDM2B-dependent metabolic vulnerabilities in basal like breast cancer.

ELOVL5 affects prostate cancer cell proliferation and modulates the AR pathway

Silvia D. Rodrigues[1], Caroline Ribeiro[1], Isadora Teixeira[1], Hubert Pakula[1], Giuseppe N. Fanelli[2], Fabio Socciarelli[1], Lisa Butler[3], Johannes Swinnen[4], Massimo Loda[1]. *[1]Pathology and Lab Medicine, Weill Cornell Medicine, New York, NY,[2]University of Pisa, Pisa, Italy,[3]University of Adelaide, Adelaide, Australia,[4]University of Leuven, Leuven, Belgium*

Prostate cancer (PCa) is characterized by alterations in lipid metabolism, exemplified by increased rates of *de novo* lipogenesis and elongation by fatty acid elongase enzymes known as ELOVLs (elongation of very long chain fatty acids). We have previously shown that the ELOVL family members ELOVL2, 5, and 7 are Androgen Receptor (AR)-regulated proteins; and that ELOVL5 is overexpressed in both primary and castration-resistant prostate cancer. To confirm the role of ELOVL5 activity in prostate carcinogenesis, we generated genetically engineered mouse models (GEMM) with deletion of *Elovl5*, validated by immunohistochemistry, in combination with the overexpression of c-Myc, an oncogene known to affect lipid metabolism in cancer cells. As expected, we observed alterations in the lipid profile of the murine prostate with the partial deletion of *Elovl5*, as determined by a significant reduction in levels of phosphatidylcholine (PC) and phosphatidylethanolamine (PE) with long-chain fatty acids (22 carbons) and increased levels of PE with short-chain fatty acids (14 carbons), suggesting an overall shortening on acyl chains of the most common phospholipid species. Interestingly, we also observed that the heterozygous deletion of *Elovl5* reduced the expression levels of the AR on the anterior lobe of the murine prostate, in comparison to tissue from *Elovl5* wild type mice. Preliminary data also indicates a modulation in

prostate volume when *Elovl5* is genetically deleted in comparison to tissue from wild type mice. Heterozygous *Elovl5* deletion did not affect healthy tissue.To explore biological effects, we generated a 3D organoid line derived from the prostate of mice with homozygous deletion of *Elovl5* and overexpression of c-Myc. We found that *Elovl5 knock-out* decreased organoid diameter and proliferation of c-Myc-driven cells compared to *Elovl5 WT*. This effect was potentiated when organoids were treated with Enzalutamide, suggesting that targeting *Elovl5* may sensitize prostate cells to anti-androgen therapy.Our findings suggest lipid elongation via ELOVL5 as a potential therapeutic target for PCa.

The CHST11-CP-iron axis contributes to NSCLC stemness

Li-Jie Li[1], Wei-Min Chang[2], Michael Hsiao[1]. *[1]Genomics Research Center, Academia Sinica, Taipei, Taiwan,[2]School of Oral Hygiene, College of Oral Medicine, Taipei Medical University, Taipei, Taiwan*

The emerging advances in cancer therapies have changed the landscape for the treatment, but there are limited treatments options for advanced non-small-cell lung cancer (NSCLC). Cancer stem cell-induced chemoresistance and tumor metastasis accounts for treatment failure and recurrence in NSCLC. Additionally, the up-regulated glycosaminoglycan-chondroitin sulfate (CS) biosynthesis pathway contributes to the mesenchymal state of lung cancer and related to unfavorable prognosis. Previously, we found carbohydrate sulfotransferase 11 (CHST11), a key CS biosynthetic enzyme, was associated with tumor progression and metastasis in NSCLC as well as lung fibrosis. Furthermore, ceruloplasmin (CP) acted as a downstream effector of CHST11 through interferon-γ signaling pathway stimulation and increased NSCLC metastatic features. However, the linkage between metabolic dysregulation and NSCLC stemness remains unclear. Here, we found not only overexpression of CHST11 but also CS-A treatment, the metabolite of CHST11, promoted NSCLC tumor sphere formation, the expression of cancer stemness markers, and transcriptional activities of stemness-related pathways. Iron was a necessary ion in upregulating cancer stemness properties such as tumor-initiation, metastasis and chemoresistance. We found both CHST11 and iron enhanced NSCLC tumorigenesis. Moreover, iron chelation disrupted CHST11-CP axis

induced-stemness. The combination of iron chelator with chemotherapies showed the synergistic effect on antitumor as well as anti-cancer stemness and further promoted apoptosis. Our findings implicate that the CHST11-CP-iron axis facilitates tumor progression and cancer stemness in NSCLC. A regimen that combines an iron chelator and chemotherapies targeting cancer stem cells will benefit for not only preventing NSCLC tumorigenesis but cancer recurrence.

#6041

Investigating metabolic dependencies of group 3 medulloblastoma

Derek Dang[1], Kyle S. Smith[2], Pooja Panwalkar[3], John McKolay[3], Olamide Animasahun[4], Abhinav Achreja[4], Deepak Nagrath[4], Paul A. Northcott[2], Sriram Venneti[3]. *[1]University of Michigan, Ann Arbor, MI,[2]Department of Developmental Neurobiology, St Jude Children's Research Hospital, Memphis, TN,[3]Department of Pathology, University of Michigan, Ann Arbor, MI,[4]Department of Biochemical Engineering, University of Michigan, Ann Arbor, MI*

Medulloblastomas (MB) are the most common pediatric brain malignancy. Transcriptomic, genomic, and epigenomic insights have stratified these tumors into four distinct subtypes: SHH, WNT, Group 3 and Group 4. Of the four subtypes, Group 3 tumors bear the worst prognosis. Each MB subtype is distinguished by their unique transcriptome profile and epigenetic landscape. Metabolic reprogramming is a hallmark of cancer and allows cells to actively promote the utilization of nutrients to support their uncontrolled proliferation. We identified distinct transcriptional metabolic profiles in medulloblastomas. We found that Group 3 MB show upregulation of key anabolic pathways. We then cross-referenced these data from comprehensive single-cell RNA sequencing profiles of cerebellar developmental niches. We found that Group 3 MB exhibits metabolic signature similar that of early progenitors, rhombic lip progenitors, and cerebellar ventricular zone derivatives. Finally, we identify DLAT, the E2 subunit of the pyruvate dehydrogenase complex, as a uniquely upregulated gene in Group 3 MB. Knockdown of DLAT inhibited tumor growth in-vitro and in-vivo suggesting a potential targets for future therapeutic regimens.

#6042

Targeting metabolic vulnerabilities in MET-driven lung cancer brain metastases

Kasey R. Cargill[1], Sanja Dacic[2], Riyue Bao[1], Bharathri Sivakama[1], Eric S. Goetzman[1], Steven J. Mullett[1], Stacy G. Wendell[1], Sameer Agnihotri[1], Laura P. Stabile[1], Timothy F. Burns[1]. *[1]University of Pittsburgh, Pittsburgh, PA,[2]Yale School of Medicine, New Haven, CT*

Non-small cell lung cancer (NSCLC) has the highest incidence of brain metastases (BM) with almost 40% of lung cancer patients developing BM throughout the course of their disease. The presence of BM portends an extremely poor prognosis even when extracranial disease is controlled and remains a major clinical problem. To date, there are no BM-specific targeted therapies available. MET is a receptor tyrosine kinase that, upon binding hepatocyte growth factor (HGF), mediates proliferation, epithelial-mesenchymal transition, invasion, angiogenesis and metastasis. The MET pathway has emerged as a targetable oncogenic driver of NSCLC BM; however, almost half of patients with *MET* alterations fail to respond to MET tyrosine kinase inhibitors (TKIs). Interestingly, we identified a significant enrichment of *MET* amplification in lung adenocarcinoma (LUAD) BM (16%) compared to primary LUAD (3%) or liver metastases (5%). Subsequent RNA-sequencing and Gene Set Enrichment Analysis of *MET*-amplified and non-*MET* amplified LUAD BM identified many dysregulated pathways including those involved in cellular metabolism. In contrast to previous reports in melanoma which found that oxidative phosphorylation was the dominant metabolic pathway in BM, we found that genes involved in glycolysis and glutamine catabolism were increased in the high MET expressing cell lines compared to low MET expressing cell lines. We confirmed glycolytic pathway up-regulation by evaluating the activity of hexokinase 1 and 2 (HK1, HK2), glutaminase (GLS), and lactate dehydrogenase (LDHA) in a *MET*-amplified metastatic line (H1993) compared to a *MET* wild-type NSCLC cell line (H2073) derived from the same patient. Further, bioenergetic analysis revealed that H1993 cells were more metabolically active, generated higher levels of ATP, and exhibited increased glycolysis compared to H2073 cells. The enhanced metabolic activity of H1993 cells increased their susceptibility to glucose deprivation and metabolic inhibitors, supporting that metabolic reprogramming is important for MET-driven disease. Additionally, untargeted metabolomics

of *MET* amplified compared to non-*MET* amplified cells identified alterations in numerous amino acid catabolism pathways, including glutathione biosynthesis among other novel pathways. Treatment with the MET TKI capmatinib similarly reduced glycolysis-associated gene expression, oxygen consumption, extracellular acidification, and amino acid catabolism generating a metabolic phenotype more comparable to non-*MET* amplified NSCLC. Together, our data show *MET*-amplified NSCLC BM undergo metabolic reprogramming, which can be inhibited to suppress tumor growth. Current and future experiments are exploring whether we can specifically target *MET* altered BM with glycolytic inhibitors.

#6043

Manipulation of mitochondrial metabolism, through SIRT3 agonists, in a novel immunoreactive melanoma organoids model

Azza M. El-derby[1], Nadeem Wajih[1], Jack Arbiser[2], Konstantinous Votanopoulos[3], Shay Soker[4]. *[1]Wake Forest Institute for Regenerative Medicine, Wake Forest School of Medicine, Winston-Salem, NC,[2]Department of Dermatology, Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA,[3]Department of Surgery, Wake Forest Baptist Health, Wake Forest Comprehensive Cancer Center, Wake Forest School of Medicine, Winston-Salem, NC,[4]Department of Surgery, Wake Forest Baptist Health, Wake Forest University, Wake Forest Institute for Regenerative Medicine, Wake Forest Comprehensive Cancer Center, Wake Forest School of Medicine, Winston-Salem, NC*

The interplay between tumor cell metabolism and immune cells in the tumor microenvironment has emerged as a determinant factor in cancer progression and treatment. Sirtuin 3 (SIRT3) is a mitochondrial deacetylase that modulates ROS levels and governs many enzymes that regulate mitochondrial metabolism and homeostasis. SIRT3 has a dual role in cancer; it is regarded as an oncogene and tumor suppressor gene simultaneously. It has tumor-promoting action via keeping ROS levels low and favoring cell proliferation; on the contrary, it can trigger cell death under stress conditions by modulating tumor cell glycolysis. Recent data suggest a role for SIRT3 in cancer immunology with PD-L1 levels are found to be inversely associated with SIRT3 level in cervical cancer, and CD8+ T cells from SIRT3 knockout donor mice exhibited low GVHD in

recipients. In this study, we explored the potential role of SIRT3 agonists in sensitizing the immunoreactivity of melanoma cells in a novel immunoreactive melanoma organoids model. We used the B16-F10 melanoma cell line spheroids to determine the effects of SIRT3 agonists on cellular viability, using an ATP assay. Validation of SIRT3 expression was determined via Western blot. Non-toxic amounts of SIRT3 agonists were also applied to melanoma organoids prepared from patient-derived metastatic melanoma from a lymph node. Preliminary results revealed a significant decrease in the viability of the organoids treated with R-propranolol (20μM) and Imipramine blue (0.25μM) agonists. We further investigated the effect of SIRT3 agonists R-propranolol and Imipramine blue on immunotherapy targeting PD-1, Pembrolizumab (100 nM) and Nivolumab (100 nM), and CTLA-4 inhibitor Ipilimumab (100 nM). We found a limited effect of Pembrolizumab and Nivolumab. Anti-tumor cytotoxicity was markedly increased in combination of Imipramine blue with Pembrolizumab and R-propranolol with Nivolumab. We propose that these effects are mediated through the activation of the endogenous immune cells and/or via the regulation of the PD-L1 and NKD2 ligand expression levels in the melanoma cells to become more sensitized to immune cells. Further studies will aim to validate these results in immunoreactive organoids from both mice and human patients. Our studies will shed light on the immune and metabolic axes and the use of specific agonists to develop new immune therapy treatment strategies for melanoma.

#6044

Identification and molecular characterization of cancer cells survived under glucose starvation

Elimelech Nesher[1], Bar Levi[2], Hadas Levy[2], Raichel Cohen-Harazi[2], Igor Koman[2]. *[1]Ariel University, Ari'el, Israel,[2]Molecular Biology, Ariel University, Ari'el, Israel*

Tumors are heterogeneous, consisting of different cell subpopulations to allow tumor survival in variable conditions. We observed the survival of a small percentage of HCT116 cells under glucose starvation. We hypothesized that these cells represent a previously undescribed subpopulation able to adjust their metabolism in the absence of glucose. Here we aimed to characterize the metabolic and molecular properties

allowing these cells to survive. We propagated individual clones from HCT116 cells and further analyzed a single clone descendants were able to survive glucose starvation. Biochemical and molecular analyses were performed under standard glucose conditions, under glucose starvation during adaptation period, and under glucose starvation after resumption of proliferation. Metabolic analysis by Seahorse revealed that surviving cells completely shifted their metabolism from glycolysis to oxidative phosphorylation. LC-MS metabolomics analysis revealed that during senescence-like adaptation the cells accumulate metabolites required for NAD synthesis. FAD, a co-factor involved in the TCA cycle, was not found in the dormant cells, while higher levels of carnosine, essential for ROS elimination, were observed. The metabolic shift toward enhanced oxidative phosphorylation was accompanied by increased production of ROS leading to DNA damage, reflected in an upregulation of the genes NUPR, ST6GAL1, and EGRF as observed by RNAseq. Cells that resumed proliferation were also characterized by enhanced expression of DNA damage repair genes and upregulated subunits of ATP-synthase, a key enzyme in oxidative phosphorylation. We suggest that cells predisposed to effective DNA repair have more time and capabilities to adjust their metabolism and to survive.

#6045

Role of PP2A methylation on methionine dependence of cancer

Anna Andronicos, Da-Wei Lin, Yi-Chen Su, Mari Ishak Gabra, Mei Kong, Peter Kaiser. *University of California, Irvine, Irvine, CA*

Dependence on exogenous methionine is a well-known, but poorly understood cancer-specific metabolic requirement. Although most cancer cells can convert homocysteine to methionine, they are unable to grow when methionine depleted media is supplemented with homocysteine. In contrast, non-tumorigenic cells proliferate well in homocysteine media. Previous work from our laboratory has shown that cancer cells cultured in homocysteine medium increase metabolic flux towards the transsulfuration pathway, away from S-adenosylmethionine (SAM) synthesis resulting in overall reduced methylation potential. We have shown that methionine sensing occurs independently of the mTOR pathway, which is known to link amino acid abundance and cell growth. Instead, our results suggest that

Protein Phosphatase 2A (PP2A) methylation is sensitive to changes in the SAM/SAH ratio. Reduced PP2A methylation correlates with reduced cell proliferation in homocysteine medium. Furthermore, overexpression of the PP2A demethylase Pme1 forcibly reduces PP2A methylation and induces methionine dependence in cells that normally proliferate in homocysteine medium. These findings suggest a model that links methionine metabolism to cell cycle progression via regulation of PP2A methylation. Here we use quantitative proteomics to define changes in B-subunit binding to PP2A during methionine starvation to investigate the molecular mechanism of this methionine dependence seen in cancer.

#6046

Enhanced *Acod1* expression in cancer cells promotes immune evasion

James H. Schofield[1], Joseph Longo[2], Sean Murphy[1], Ryan Sheldon[2], Mark A. Hawk[1], Emma Albano[1], Russell G. Jones[2], Xin Lu[1], Zachary T. Schafer[1]. *[1]University of Notre Dame, Notre Dame, IN,[2]Van Andel Research Institute, Grand Rapids, MI*

The monoclonal antibody αPD-1 used in immune checkpoint blockade (ICB) therapy has made a substantial impact in clinical outcomes for melanoma, lung, and breast cancer patients. Despite the success of ICB in these contexts, such strategies are not universally effective due to unresponsiveness or development of resistance by the malignant cells. Poor understanding of the molecular mechanisms leading to ICB resistance is a crucial barrier to more effective ICB. Recent studies have demonstrated that the metabolic milieu of the tumor microenvironment (TME) can modulate the anti-tumor immune response. However, the specific mechanisms by which the secretion of cancer cell metabolites into the TME impacts the efficacy of ICB in unresponsive tumors remains poorly understood. To better characterize the factors that influence ICB, we utilized a murine model (*Smad4$^{-/-}$/Pten$^{-/-}$/Trp53$^{-/-}$)* of castration-resistant prostate cancer (CRPC) that is responsive to αPD-1. Serial culture and passage of residual tumor cells following exposure to αPD-1 treatment into new recipient mice allowed us to develop an ICB-insensitive CRPC cell line. Unbiased metabolic analysis revealed that the αPD-1 resistant cells produced elevated levels of itaconate, a metabolite whose biological functions in epithelial cells remain poorly characterized. Consistent with this finding, the resistant

cells display increased expression of aconitate decarboxylase 1 (*Acod1*), the enzyme responsible for itaconate production. Additionally, we have identified established human epithelial cancer cell lines which express high levels of *ACOD1*. Interestingly, conditioned media (CM) from the *Acod1*-high cell lines, but not the *Acod1*-low lines, restricts the proliferation and activation of naïve CD8+ T cells *in vitro*. CRISPR-mediated *Acod1* reduction in the αPD-1 insensitive cells (Acod1KO) produces CM which promotes increased naïve CD8+ T proliferation and activation, suggesting a link between Acod1 abundance in cancer cells and the activity of cytotoxic T cells. Furthermore, Acod1KO tumors have increased CD8+ tumor infiltrating lymphocytes (TILs) and increased sensitivity towards αPD-1 ICB *in vivo*. Taken together, these data suggest that cancer cell intrinsic ACOD1 abundance may be predictive of ICB efficacy.

ZFTA-RELA fusion aberrantly drives glutamine metabolism in lethal pediatric ependymomas

Siva Kumar Natarajan[1], James Haggerty-Skeans[2], Joanna Lum[2], Pranav Narayanan[2], Stefan Sweha[2], Sushanth Sunil[2], Pooja Panwalkar[2], Jill Bayliss[2], Peter Sajjakulnukit[2], Derek Dang[1], Abhinav Achreja[3], Deepak Nagrath[3], Costas Lyssiotis[2], Sriram Venneti[1]. *[1]Pathology, University of Michigan Medical School, Ann Arbor, MI,[2]University of Michigan Medical School, Ann Arbor, MI,[3]Biomedical Engineering, University of Michigan Medical School, Ann Arbor, MI*

Ependymomas are fatal brain malignancies with very few treatment options. More than 70% of supratentorial (ST) ependymomas harbor fusions of the zinc-finger containing, chromatin modifier ZFTA and the transcriptional activator of NF-κB signaling, RELA. Oncogene-driven metabolic reprogramming is a fundamental hallmark of cancer that enables sustained tumor proliferation. ZFTA-RELA fusion protein is essential for tumorigenesis and our goal is to determine how it drives metabolism in ST-ependymomas. To address this, we developed an *in vitro* isogenic system by expressing the ZFTA-RELA fusion protein in immortalized mouse neural stem cells (ZFTA-RELA^{FUS}). Using this system, we show that these tumor cells selectively upregulate expression of the glutamine transporter

(SLC1A5), glutaminase (GLS), and many downstream enzymes in the glutamine metabolic pathway. Therefore, we hypothesized that the ZFTA-RELA fusion drives glutamine metabolism in ST-ependymomas. We further demonstrate that ZFTA-RELA^{FUS} tumor cells utilize glutamine to maintain redox homeostasis and show marked cell death upon its withdrawal. Moreover, JHU-083, a specific pharmacologic inhibitor of glutaminase, killed ZFTA-RELA^{FUS} tumor cells *in vitro* and *in vivo*. To summarize, our results suggest that the ZFTA-RELA fusion expressing tumor cells exhibit strong glutamine dependence, and targeting it has significant therapeutic relevance.

OGT/CDK5/ACSS2 axis regulates breast cancer brain metastatic growth
Emily Esquea, Lorela Ciraku, Giang Le Ming, Mauricio Reginato. *Drexel University College of Medicine, Philadelphia, PA*

Brain metastases (BMs) in breast cancer patients is considered an end-stage event, with no effective drug treatment and a median survival after diagnosis measured in months. Currently, there are no effective drug treatment for BM patients, thus there is an urgent need to develop novel treatment strategies. Breast cancers that metastasize to the brain must adapt to lack of lipid availability in the brain environment and are highly dependent on fatty acid synthesis for growth and survival. However, the signaling pathways that regulate precursors of fatty acid synthesis and lipid metabolism in breast cancer brain metastatic (BCBM) tumors are not known. Here, we show that BCBM cells can generate acetyl-CoA, a major metabolite feeding lipid biosynthesis, via phosphorylation of acetyl-CoA synthetase 2 (ACSS2) by the cyclin-dependent kinse-5 (CDK5) regulated by the nutrient sensor O-GlcNAc transferase (OGT). Breast cancer cells selected to metastasize to the brain contain higher levels of O-GlcNAcylation, OGT. and ACSS2-Ser267 phosphorylation compared to parental cells, and we show that human breast cancer brain metastatic patient samples contain elevated ACSS2-Ser-267 levels. Additionally, overexpression of the OGT, CDK5, or ACSS2-S267D phospho-mimetic mutant confers a growth advantage of breast cancer cells in the brain *in vivo.* Importantly, we show that ACSS2 is required for breast cancer growth

in the brain but not in the mammary fat pad. Pharmacologically targeting the CDK5 or ACSS2 with respective small molecule inhibitors reduces tumor growth in orthotopic *ex vivo* brain slice model. These results suggest a crucial role for OGT/CDK5/ACSS2 signaling axis to regulate lipid metabolism in BCBM cells and identify CDK5 and ACSS2 as novel therapeutic targets for treatment of breast cancer brain metastatic growth.

Exogenous serine promotes cancer stem cells in oral squamous cell carcinoma

Stacy Ann Jankowski, Nina C. Hardy, Maria A. Kukuruzinska. *Molecular & Translational Medicine, Boston Univ. Chobanian & Avedisian School of Medicine, Boston, MA*

Cancer development and progression is associated with metabolic reprogramming of tumor cells required to meet their proliferative, bioenergetic and survival challenges. Some metabolites, including a non-essential amino acid, serine, have been shown to play a role in tumorigenesis by promoting aggressive cell states, such as cancer stem cells (CSCs). Previous studies from our laboratory showed that the nuclear branch of the Wnt/β-catenin signaling pathway, the β-catenin/CBP/MLL1 axis, enhanced CSC states during oral squamous cell carcinoma (OSCC) evolution through H3K4 trimethylation (H3K4me3) and epigenetic remodeling of the chromatin landscape. Given that metabolism has also been shown to modulate cell plasticity via epigenomic modifications, we have aimed to decode the relationship between serine synthesis and cell identity in OSCC.

We have shown that under serine starvation conditions, OSCC cells upregulate steady-state mRNA and protein levels of serine synthesis pathway enzymes. The latter is associated with an increase in the by-product, alpha-ketoglutarate (αKG), a co-substrate for nuclear αKG-dependent dioxygenases, which demethylate histone marker H3K27me3 and de-repress differentiation-associated genes. Furthermore, increased production of αKG is associated with downregulation of the β-catenin/CBP/ML11 complex and CSC-associated H3K4me3.

In this study, we used human OSCC cell lines CAL27 and HSC3, derived from a primary tongue tumor and a metastatic site, respectively. Each cell

line was cultured in either complete medium or serine starvation medium. Serine starvation conditions led to a downregulation of H3K27me3 along with H3K4me3, promoting a switch from cancer stem cell to differentiation-enhancing chromatin landscape. The observed changes in cell plasticity were further investigated through tumorsphere formation, a surrogate assay for cancer stem cells. We found that OSCC CAL27 and HSC3 cells readily formed tumorspheres replete with stem cell markers BMI1, KRT14 and SOX2, under non-adhesive conditions when grown in complete media, supporting our findings that utilization of exogenous serine enables OSCC cells to maintain stemness. Our findings suggest that a switch from exogenous serine uptake to the endogenous serine biosynthesis promotes OSCC cell differentiation concomitant with the loss of CSC identity.

Analysis of diverse metabolic pathways using bioluminescent cell-based assays

Donna Leippe, Natasha Karassina, Mike Valley, Kayla Sylvester, Jolanta Vidugiriene. *Research and Development, Promega Corporation, Madison, WI*

Cellular energy metabolism is a complex system of many interconnected metabolic pathways that govern both cell health and function. Cancer cells are adept at quickly switching between metabolic pathways to adapt to nutrient limitations in the environment, enhancing their growth advantages while negatively impacting other cells in the tumor microenvironment such as immune cells. To facilitate metabolic characterization of cancer cells, we developed assays for detection of metabolites involved in key pathways, such as glycolysis and glutaminolysis, using a bioluminescent NADH detection technology coupled to specific dehydrogenases. We have now extended these assays to include metabolites involved in glycogen, lipid, ketone body and amino acid metabolism, as well as intermediates in the TCA cycle such as malate, isocitrate, and 2-hydroxyglutarate. A second core bioluminescent hydrogen peroxide detection system was also used to develop an assay for pyruvate. Here we describe the use of these assays to measure metabolite levels in cell lysates and cell culture media collected from cancer cell lines plated in 96- or 384-well plates and in 2D or 3D

cultures. Changes in metabolite levels were monitored in response to altered media composition and drug treatments. Levels were also compared between different cell lines. In comparative studies of glioblastoma cell lines, 2-hydroxyglutarate production was higher in cells expressing mutant isocitrate dehydrogenase. By reconfiguring the NADH detection technology to measure cellular enzyme activity rather than metabolite levels, we were able to detect activity of dehydrogenases that participate in the glycolysis pathway, the TCA cycle, and pentose phosphate pathway. Assays for cellular malate dehydrogenase, isocitrate dehydrogenase and other dehydrogenase enzymes were sensitive, requiring ≤ 400 lysed cells per assay. The expanded collection of bioluminescent assays provides a way to quickly characterize the metabolic states and behaviors of cancer cells to help identify pathways that may present therapeutic targets.

#6051

Dissecting unique metabolic vulnerabilities in triple-negative breast cancer metastasis

Divya Ramchandani[1], Liron Yoffe[1], Arshdeep Singh[1], Linda Vahdat[2], Vivek Mittal[1]. *[1]Weill Cornell Medicine, New York, NY,[2]Dartmouth Cancer Center, Lebanon, NH*

Introduction. Triple-negative breast cancer (TNBC) exhibits the worst outcome due to an aggressive clinical course, high rates of metastasis, and therapeutic resistance. Lack of effective FDA approved anti-metastatic targeted therapies has generated an unmet medical need for developing effective novel treatments. Targeting metastatic seeding and colonization remains a therapeutic challenge. Only recently, attention has been drawn to the idea that cancer cells selectively and dynamically adapt their metabolism along the changing microenvironments of the metastatic cascade. However, the precise nature of the metabolic reprograming *in vivo* is poorly understood and constitutes a major barrier in formulating a rationally designed therapeutic approach. Using a genetic lineage tracing approach, we identified a discrete subpopulation of highly metastatic SOX2/OCT4+ cells within primary tumors that exhibit enhanced invasion and metastasis, increased self-renewal, higher chromosomal instability, and marked resistance to chemotherapy. We posited that this lineage tracing

system may allow assessment of precise metabolic alterations as a function of tumor progression directly *in vivo*.
Methods and data. Transcriptomic analysis of sorted cellular fractions from progressing primary TNBC tumor identified metabolic heterogeneities between metastatic SOX2/OCT4+ and the SOX2/OCT4- counterparts. SOX2/OCT4+ metastatic cells exhibited elevated levels of mitochondrial respiration (OXPHOS) and fatty acid (FA) metabolism; a finding supported by proteomic analysis. Using a combination of CRISPR knockout of key pathway genes, seahorse metabolic flux analysis, metabolomics, and stable isotope tracing, we provide evidence for increased dependence of the metastatic SOX2/OCT4+ population on these unique metabolic adaptions. Importantly, we have identified upstream regulators of these pathways and demonstrate impact of both genetic and pharmacological inhibition of the metabolic regulatory networks on metastasis *in vivo*.
Conclusion. By identifying metabolic adaptations unique to the metastatic compartment of the primary tumor, we provide evidence for using clinical grade pharmacological inhibitors including metformin, tetrathiomolybdate and FA pathway inhibitors like TVB-2640 and BMS-303141, as an anti-metastatic approach in TNBC. This knowledge of metabolic remodeling could therefore be employed as a next-generation therapeutic approach for high-risk TNBC patients.

#6052
Metabolic consequences of casein kinase 2α inhibition in lymphoid leukemia
Diwakar Bastihalli Tukaramrao[1], Arati Sharma[2], Dhimant Desai[2], Sinisa Dovat[1]. *[1]Department of Pediatrics, Penn State College of Medicine, Hershey, PA,[2]Department of Pharmacology, Penn State College of Medicine, Hershey, PA*

Overexpression of casein kinase 2α (CK2α) is a common feature in lymphoid leukemias. Constitutively active CK2α can disable transcriptional activity of lymphoid transcription factors like IKAROS that act as metabolic gatekeeper and limit the energy supply needed for oncogenic transformation of B cells. Our studies have shown that pharmacological inhibition of CK2α can restore the transcriptional activity of IKAROS and ablate leukemia. However, the role of CK2α in glucose metabolism has not

been fully studied in B and T acute lymphoblastic leukemia (ALL). Therefore, in the present study we explored the metabolic alterations induced by the pharmacological inhibition of CK2α in B and T ALL. We studied the effect of CK2α inhibition using a specific inhibitor - CX4945 on cell proliferation, glucose utilization, lactate production, and intracellular ATP levels using established methods in human B-ALL (NALM6) cell line. Effect of CX4945 on glycolysis was studied using the Seahorse cell analyzer in human B (NALM6 and 697) and T (MOLT4 and 697) ALL cell lines. Metabolomics study was undertaken to analyze differential metabolite profiling in NALM6 cells treated with CX4945 compared to vehicle using LC-MS/MS based methods. Results showed that CX4945 induced apoptotic cell death in ALL cell lines with IC50 concentrations ranging between 4-10 μM. CX4945 treatment significantly affected the glucose consumption in NALM6 cells. Similarly, substantial decrease in intracellular ATP and lactate levels compared to vehicle was recorded. CK2α inhibition significantly decreased the glycolytic activity in B- and T-ALL cell lines. It was observed that glycolytic reserves were significantly decreased in 697 (3-fold), MOLT4 (4-fold), CEM (3-fold) cells incubated with CX4945 in comparison to vehicle. The principal component analysis from metabolomics study showed a clear separation between CX4945 and vehicle-treated NAML6 cells. Sixty-four statistically significant, differentially expressed metabolites were recorded in the study. Analyte classes included TCA cycle intermediates, nucleic acids and their precursors as well as glycolysis intermediates that were significantly affected by CK2α inhibition. In conclusion, our study shows that selective inhibition of CK2α by CX4945 caused energy deficiency and cell death in ALL cell lines. CK2 inhibition targeted the key energy dependent pathway by rendering ALL cells inefficient in utilizing glucose and operating glycolysis for generation of cellular energy. These results offer a new mechanistic understanding of CK2α inhibition mediated ablation of ALL.

#6053

Sulfation is required for prostate cancer xenograft tumor formation but is dispensable for cell viability*in vitro*

Ko-Chien Chen[1], Yonhong Liu[1], Chenchu Lin[1], Er-Yen (Nick) Yen[1], Francesca Citron[1], Xingdi Ma[1], Tan Lin[1], Philip Lorenzi[2], Florian Muller[3], Ronald DePinho[1]. *[1]UT MD Anderson Cancer Center, Houston,*

TX,[2]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Sporos Bioventures, Houston, TX

Sulfation of proteins, carbohydrates, lipids, and xenobiotics is an essential post-translational modification (PTM) process thought to play critical roles in diverse biological processes ranging from detoxification, cell signaling, and extracellular matrix architecture, to immune modulation. Sulfation is accomplished by the universal sulfate donor, PAPS (3'-Phosphoadenosine-5'-phosphosulfate), which is synthesized by bifunctional enzymes PAPSS1 and PAPSS2 (PAPS synthases). The PAPSS2 gene situates near PTEN and is frequently deleted with PTEN across cancer types. Approximately 20% of prostate cancer patients exhibit loss of PTEN, and ~50% of these cases also sustain a loss of PAPSS2. However, the loss of PAPSS2 appears to be tolerated and possibly compensated by its functionally redundant paralogue, PAPSS1, located on chromosome 4q24. The functional redundancy between PAPSS1 and PAPSS2 suggests that these two genes may be collateral lethality pair provided that sulfation is essential for cancer cell viability. Thus, we hypothesize that targeting PAPSS1 in PTEN/PAPSS2-null prostate cancer can generate cancer-specific vulnerabilities while leaving normal cells undisturbed. To assess this possibility, knockdown and knockout of PAPSS1 in cell lines of PAPSS2-null and PAPSS2-wildtype background were generated to characterize cell viability *in vitro* and tumor formation *in vivo*. PAPS and APS, an intermediary product of the sulfation pathway, are measured to verify that no alternative pathways for sulfate donors exist and that the co-extinction of PAPSS1/2 eliminates all avenues of generating sulfate donors. Combined extinction of PAPSS1/2 across multiple cancer cell lines was shown to be tolerated *in vitro*, and recurrent changes in morphology were observed. Loss of sulfation verified by the disappearance of sulfotyrosine and mass spectrometry measurements of PAPS and APS are pending. Our *In vitro results* surprisingly indicate that a major PTM, like sulfation is entirely dispensable for cancer cell viability under normal culture conditions. However, PAPSS1/2-null cell lines demonstrated a profound delay in tumor formation and prolonged survival, suggesting that sulfation may be required for stromal and innate immune modulation.

#6054

Weight specific effects of hyaluronic acid on glioblastoma's energy metabolism and bio-molecular content

Ashwin A. Bale[1], Brendan Harley[1], Rohit Bhargava[2]. *[1]Department of Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign, Urbana, IL,[2]Department of Bioengineering, University of Illinois at Urbana-Champaign, Urbana, IL*

Glioblastoma (GBM) is one of the deadliest forms of brain cancer with inter and intra tumor heterogeneity and altered cell metabolism pathways. Developing multi-dimensional *in vitro* platforms can help explore different tumor micro-environments and can thus offer therapeutic opportunities. For a molecular-level understanding, non-destructive and label-free imaging techniques combined with *in vitro* tumor models offer discovery and automation potential for targeted studies. Here, we use the Fourier Transform Infrared (FTIR) spectroscopic imaging technique to profile biomolecular behavior of U87-MG GBM cell lines in a 2D culture in varied metabolic and tumor micro-environment conditions. As a micro-environmental cue, we chose to vary different molecular weights of hyaluronic acid (HA), a key component of brain's extra-cellular matrix (ECM) and known to significantly influence cell-behavior. U87-MG cell lines were cultured for 72 hours in a DMEM supplemented with combinations of (i) glucose concentration: absent (0 mM), normal (5.5 mM) and elevated (25 mM) and (ii) molecular weights of 2 μg/ml HA: low (10 kDa)-LMW, medium (60 kDa)-MMW and high (500 kDa)-HMW. Fixed cells at different timepoints were imaged with FTIR and stained for HA-specific CD44 and RHAMM markers. Supernatant media was analyzed for metabolite expressions with LC/MS. FTIR study revealed that the Phosphate I/Amide II and Amide I/Amide II IR absorbance ratios were significantly influenced in the presence of 500 kDa HA. Visible differences in the phosphate (~1080 cm^{-1}) and lipid (~2936 cm^{-1}) intensities indicated signs of DNA breakages and changes in oxidative stress levels. Areas under the peaks representing α-helix (decrease) and β-sheet (increase) proteins revealed signs of protein denaturation in HMW HA cultures. These cultures also revealed elevated RHAMM expressions while the CD44 expression remained relatively unchanged. Metabolic profiling with LC/MS revealed an increase in metabolites like choline, histidine, and creatine, for cells cultured in the 0 mM glucose and HMW HA. Ornithine and Methionine

remained relatively unaffected by the HA weight but showed some dependence on changing glucose levels. Proline and Tyrosine majorly showed HA weight-specific variations. Overall, this preliminary study has shown the impact of glucose and HA weight-specific effects on the biomolecular content and metabolic profiles of cancer cells. Most of the altered metabolite expressions seen are known to be involved in the Arginine-biosynthesis pathway which suggests a possible alteration in the same in response to environmental glucose and weight-specific HA levels. Further studies would involve the use of multi-dimensional hydrogel-cell models to assess variations in a more bio-mimetic surrounding. Highlighting altered metabolic pathways could help present novel therapeutic targets for future.

#6055

Polyaneuploid cancer cells are metabolically active and utilize lipid droplets to survive toxic stress

Laurie Gayle Kostecka, Anne Le, Sarah Amend, Kenneth J. Pienta. *Johns Hopkins University School of Medicine, Baltimore, MD*

Over 30,000 men in the U.S. die from metastatic prostate cancer each year. Metastatic cancer remains incurable as a population of cancer cells within a tumor are resistant to all known therapies. Despite decades of research, the source of therapeutic resistance is still unknown. We have identified the polyaneuploid cancer cell (PACC) state as a chemo-resistant cell state that is associated with therapeutic resistance. Cells in the PACC state are large in size, have high genomic content, and represent the majority cell state following high dose chemotherapy *in vitro*. While the PACC state has been documented in patient samples of many cancer types, including prostate cancer where it is associated with progression, the survival mechanisms that enable the PACC state remain largely undefined. We discovered that cells in the PACC state are highly metabolically active and contain a higher number of lipid droplets (LDs) than the non-polyploid parental cells they are derived from. LDs act as central anti-lipotoxic organelles and sequestration of toxic moieties into LDs allows for lower lipotoxicity in cells and higher chances of survival and future proliferation. Higher levels of LDs are associated with increased tumor aggressiveness and chemotherapy resistance. We found that PLIN1 (an exclusive LD surface protein), and

DGAT1 (an enzyme that catalyzes the generation of TAG, which is the main component of LDs) are expressed at higher levels in the tumors of prostate cancer patients with lower disease-free survival and higher Gleason score. This indicates that aggressive prostate cancer is most likely associated with high levels of LDs. We hypothesize that cells entering the PACC state survive chemotherapeutic stress by having an elevated metabolism and sequestering toxic lipids into LDs to enhance cell survival. Metabolomic and lipidomic data demonstrate that PACCs have a highly active TCA cycle and higher overall lipids in multiple classes compared to the parental cells they are derived from. Additionally, utilizing flow cytometry and imaging, we found that LDs form in cells accessing the PACC state as early as three hours post chemotherapy treatment, suggesting a crucial role for avoiding lipotoxicity. We also observed low levels of HSL (a rate limiting enzyme in lipolysis) in the PACC state indicating that after PACCs form LDs they do not immediately break them down, another possible mechanism of avoiding lipotoxicity. We have shown this in four cancer cell lines from two tumor types (Prostate cancer: PC3, DU145, and LNCaP. Breast cancer: MDA-MB-231) with three classes of chemotherapies (cisplatin, docetaxel, etoposide), proving the observed phenotype is not specific to any one cell line, tumor type, or drug class. Our future work will focus on inhibiting lipid droplet formation *in vivo* and *in vitro* to increase cellular lipotoxicity in the PACC state to induce cancer cell death.

A nested case-control study of untargeted plasma metabolomics and lung cancer risk among never-smoking women in the prospective Shanghai Women's Health Study

Mohammad L. Rahman[1], Xiao-Ou Shu[2], Douglas Walker[3], Dean P. Jones[4], Wei Hu[1], Bu-tian Ji[1], Batel Blechter[1], Jason YY Wong[1], Qiuyin Cai[2], Gong Yang[2], Tu-Tang Gao[5], Wei Zheng[2], Nathaniel Rothman[1], Qing Lan[1].
[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[2]Division of Epidemiology, Vanderbilt University School of Medicine, Nashville, TN,[3]Division of Environmental Health, Emory University School of Public Health, Atlanta, GA,[4]Medicine, Emory

University, Atlanta, GA,[5]Epidemiology, Shanghai Cancer Institute, Shanghai, China

Background: The etiology of lung cancer among never-smokers is unclear despite 15% of cases in men and 53% in women worldwide are not smoking-related. Metabolomics provides a snapshot of dynamic biochemical activities, including those found to be driving tumor formation and progression. This study used untargeted metabolomics with network analysis to agnostically identify network modules and independent metabolites in pre-diagnostic blood samples among never-smokers to further understand the pathogenesis of lung cancer.
Methods: Within the prospective Shanghai Women's Health Study, we conducted a nested case-control study of 395 never-smoking incident lung cancer cases and 395 never-smoking controls matched on age. We performed liquid chromatography high-resolution mass spectrometry to quantify 20,348 unique metabolic features in plasma. Because metabolic features are expected to be highly correlated and more likely to be involved in biological processes as a network of intertwined features than individually, we agnostically constructed 28 network modules using a weighted correlation network analysis approach. The associations between metabolite network modules and individual metabolites with lung cancer were assessed using conditional logistic regression models, adjusting for age, body mass index, and exposure to environmental tobacco smoke. We accounted for multiple testing using a false discovery rate (FDR) < 0.20.
Results: We identified a network module of 122 metabolic features enriched in lysophosphatidylethanolamines that was associated with all lung cancer combined ($p = 0.001$, FDR = 0.028) and lung adenocarcinoma ($p = 0.002$, FDR = 0.056) and another network module of 440 metabolic features that was associated with lung adenocarcinoma ($p = 0.014$, FDR = 0.196). Metabolic features were enriched in pathways associated with cell growth and proliferation, including oxidative stress, bile acid biosynthesis, and metabolism of nucleic acids, carbohydrates, and amino acids, including 1-carbon compounds.
Conclusions: Our prospective study suggests that untargeted plasma metabolomics in pre-diagnostic samples could provide new insights into the etiology of lung cancer in never-smokers. Replication and further characterization of these associations are warranted.

Association of liver cancer and chronic liver disease with urinary glyphosate and its metabolites in Thailand

Daxesh P. Patel[1], Benjarath Pupacdi[2], Siritida Rabibhadana[2], Leila Toulabi[1], Majda Haznadar[1], Bhavik Dalal[1], Mohammed Khan[1], Joshua Stone[1], Vajarabhongsa Bhudhisawasdi[2], Nirush Lertprasertsuke[3], Anon Chotirosniramit[3], Chawalit Pairojkul[4], Chirayu U. Auewarakul[5], Thaniya Sricharunrat[6], Kannika Phornphutkul[7], Suleeporn Sangrajrang[8], Anuradha Budhu[1], Chulabhorn Mahidol[2], Xin W. Wang[1], Frank J. Gonzalez[1], Mathuros Ruchirawat[9], Christopher A. Loffredo[10], Curtis C. Harris[1], TIGER-LC Consortium. *[1]NIH-NCI, Bethesda, MD,[2]Chulabhorn Research Institute, Bangkok, Thailand,[3]Chiang Mai University, Chiang Mai, Thailand,[4]Khon Kaen University, Khon Kaen, Thailand,[5]Chulabhorn Royal Academy, Princess Srisavangavadhana College of Medicine, Bangkok, Thailand,[6]Chulabhorn Royal Academy, Chulabhorn Hospital, Bangkok, Thailand,[7]Rajavej Hospital, Chiang Mai, Thailand,[8]National Cancer Institute, Bangkok, Thailand,[9], Office of Higher Education Commission, Ministry of Education, Center of Excellence on Environmental Health and Toxicology, Bangkok, Thailand,[10]Georgetown University Medical Center, Washington, DC, MD*

Background: Glyphosate, the primary weed-killing ingredient in Roundup®, is the most widely used herbicide worldwide. The World Health Organization's International Agency for Research on Cancer (IARC) Monographs Program classified glyphosate is a probable human carcinogen (Group 2A), capable of causing human cancer under some circumstances. Methods: We analyzed urine specimens from 848 sequential patients with liver cancer and matched non-cancer controls from five different regional hospitals in Thailand. Gas chromatography electrospray ionization mass spectrometry (GC-ESI/MS) technique was used to measure glyphosate and its metabolites aminomethylphosphonic acid (AMPA) and phosphoric acid (PPA) to study their levels in hepatocellular carcinoma (HCC), intrahepatic cholangiocarcinoma (CCA), and chronic liver disease (CLD) in comparison to matched population controls.

Findings: Significantly higher levels of glyphosate were found in CLD patients compared to cancer cases and population controls, while significantly elevated levels of both AMPA and PPA were observed in HCC and CLD patients. Glyphosate and its metabolites were also detected at low to moderately high levels in convenience samples of food products and drinking water.
Interpretation: These results raise concern about the potential role of glyphosate in chronic human liver disease and cancer.

Viral genome structure correlates with patterns of somatic alteration in human papillomavirus associated head and neck squamous cell carcinoma
Jeremiah Ray Holt[1], Xiaobei Zhao[1], Hyo Young Choi[2], Paul Little[3], Angela L. Mazul[4], Benjamin Wahle[4], Vonn Walter[5], Jose P. Zevallos[6], David Neil Hayes[1]. *[1]Medicine - Hematology/Oncology, University of Tennessee Health Science Center, Memphis, TN,[2]Preventive Medicine, University of Tennessee Health Science Center, Memphis, TN,[3]Public Health Sciences Division, Biostatistics Program, Fred Hutchinson Cancer Research Center, Seattle, WA,[4]Otolaryngology—Head & Neck Surgery, Washington University School of Medicine, St. Louis, MO,[5]Public Health Sciences, Penn State College of Medicine, Hershey, PA,[6]Otolaryngology, University of Pittsburgh, Pittsburgh, PA*

Integration of viral DNA into the host genome has been implicated in human papillomavirus (HPV) associated tumorigenesis, and studies in HPV associated head and neck squamous cell carcinoma (HNSCC) attempting to classify viral integration status have reported associations among HPV status, viral load, and overall survival. However, few genomic studies have correlated HPV structure with commonly occurring somatic mutations in HNSCC. Here, we conducted hybrid-capture DNA sequencing using a panel of over 800 cancer related genomic targets, as well as probes specific for the full HPV16 and HPV18 genomes, in a novel cohort of 525 HNSCC cases. Paired reads were aligned to a human reference containing complete

viral genomes, including all high-risk HPV types, which allowed for robust identification of HPV(+) tumors and specific HPV type. Variant calling and filtering, followed by pathway analysis of significantly mutated genes, defined the catalog of somatic driver alterations in HNSCC. Viral genome structure, integration status, and viral load were determined via initial copy number analysis of HPV-specific reads, followed by identification of viral/human breakpoints and indels with variant calling algorithms. Manual review was required in some cases due to variability in read coverage and alignment to HPV genome. We identified 252 HPV(+) tumors, the majority of which were HPV16 (n=228, 90%). Analysis of HPV16(+) tumors revealed five classes with variable viral loads: pure episome (EPI, n=54), episomal rearranged (EPI-R, n=51), episomal chimeric (EPI-C, n=22), integrated (INT, n=92), and integrated deleted (INT-A, n=12). Integrated tumors had at least one integration event (INT) and a few exhibited recurrent deletions in the viral genome (INT-A). Episomal samples had either complete HPV genomes (EPI), circular genomes with one or more indels (EPI-R), or circular genomes with HPV and human DNA (EPI-C). Interestingly, PIK3CA, the most frequently mutated gene in HPV(+) HNSCC, was mutated at a higher frequency in all integrated samples compared to all episomal types (44% vs 23%, p=0.005). We also noticed more deleterious mutations in innate immunity genes (HLA-A/B, B2M, TRAF3, BIRC3) in the episomal samples (16% vs 8%), which may allow cells with intact HPV genomes to evade anti-viral immune responses. Additionally, mutations in oxidative stress response genes that lead to the constitutive activation of NRF2 (NFE2L2, CUL3, KEAP1) were more frequent in integrated samples (11% vs 4%), which could confer radiotherapy resistance and a worse prognosis. Overall, using DNA sequencing and integrative genomic analysis in the largest cohort of HPV(+) HNSCC to date, we developed a novel classification method based on viral genome structure which associates with host somatic alterations that may contribute to variable outcomes in HNSCCs.

Genomic characterization of non-small cell lung cancer (NSCLC) brain metastasis (BM) patients identifies novel alterations associated with tropisms and disease progression

Henry Walch[1], Anna Skakodub[1], Kathryn R. Tringale[1], Harish N. Vasudevan[2], Jordan Eichholz[1], Daniel W. Kelly[1], Emily Lebow[1], Nelson S. Moss[1], Kenny Kwok Hei Yu[1], Bob T. Li[1], Boris Mueller[1], Atif Khan[1], Yao Yu[1], Simon Powell[1], Jorge S. Reis-Filho[1], Brandon S. Imber[1], Pedram Razavi[1], Daniel R. Gomez[1], Nikolaus Schultz[1], Luke R. G. Pike[1].
[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]University of California San Francisco, San Francisco, CA

Intro: Half of all patients with NSCLC develop BM during their clinical course. While modern NSCLC-directed agents yield excellent systemic response, most patients require focal BM treatment. Prior reports of BM genomics have been limited by low numbers and a lack of matched specimens. Here, we report the largest cohort to date of molecularly-profiled NSCLC BM samples with comprehensive clinical follow-up.
Methods: Clinical data and outcomes for 244 patients with NSCLC and resected BM were identified. Samples were assessed using MSK-IMPACT, a custom tumor-normal next generation sequencing assay. 51 (20.9%) patients had matched primary site tissue, and 44 (18%) patients had matched tissue from another metastatic site or CSF. Genomic alterations were filtered for driver variants using OncoKB. Publicly available genomic data for NSCLC primary samples was used for comparison against the primary samples from our BM cohort.
Results: The most frequently altered genes in BM tumors were *TP53* (72%), *CDKN2A* (34%), *KRAS* (31%), *KEAP1* (26%), and *EGFR* (21%). *CDKN2A* was more frequently altered in BM samples compared to NSCLC primary lesions (34% vs 14%, $p = 0.003$). Additionally, cell cycle pathway alterations were enriched in BM (56% vs 31%, $p = 0.002$). BM samples also had a significantly higher fraction of genome altered (FGA) relative to primary samples ($p < 0.0001$). We then compared primary samples from BM patients against primary samples from metastatic NSCLC patients without BM and primary samples from non-metastatic NSCLC patients. We found an enrichment of alterations in *TP53* (68.6% vs 27.7%, $p < 0.0001$), *NKX2-1* (11.4% vs 1.7%, $p = 0.006$), *SMARCA4* (11.4% vs 2.1%, $p = 0.01$), *RB1* (11.4% vs 1.7%, $p = 0.006$), and *FOXA1* (11.4% vs 0.9%, $p = 0.001$) in the primary samples from BM patients compared to non-metastatic patients. Next, we grouped patients based on CNS progression patterns and found that *EGFR* alterations were enriched in patients with leptomeningeal

progression when compared to patients without progression (42% vs 18%, p = 0.03).
Conclusions: In our cohort of molecularly-profiled NSCLC BM, we found an enrichment of cell cycle pathway alterations and a higher FGA in BMs compared to their primary tumor controls. Additionally, several genes were enriched in the primary tissue of patients that developed BM compared to primary tissue from non-metastatic patients. *EGFR* alterations were enriched in patients who develop leptomeningeal disease (LMD). Our work herein characterizes the genomic profiles of NSCLC patients with BM and identifies specific genes enriched in the primary tissue of BM patients compared to primary tissue from both non-BM metastatic patients and non-metastatic patients. Finally, our finding that *EGFR* alterations were enriched in patients with LMD suggests specific biologic underpinnings driving patterns of CNS progression.

Patient-partnered research enables germline characterization of angiosarcoma predisposition genes

Hoyin Chu[1], Marissa Hollyer[1], Seunghun Han[2], Sabrina Y. Camp[1], Riaz Gillani[3], Eliezer Van Allen[1], Nikhil Wagle[1], Corrie A. Painter[4], Saud H. AlDubayan[1]. *[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Harvard Medical School, Boston, MA,[3]Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA,[4]Cancer Program, Broad Institute, Cambridge, MA*

Background: Angiosarcoma (ASC) represents 1-2% of soft tissue sarcomas. Due to its rarity, to date, no large-scale studies have been done to systematically identify ASC-predisposition genes and the broader landscape of pathogenic germline variants in patients with ASC remains unclear.
Methods: Through the Angiosarcoma Project, an ongoing patient-partnered research approach that allows patients living anywhere in the U.S. or Canada with angiosarcoma to participate through a website, blood and saliva samples were collected from more than 300 patients and whole-exome-sequencing was performed. Machine-learning frameworks were used to identify germline short variants (SNPs, indels) and rare germline copy number variants (CNVs). The pathogenicity of variants in 107 curated cancer-predisposition and sarcoma-related genes were evaluated according

to the ACMG guidelines. A short-variant-based gene-burden analysis was then performed using 223 unrelated ASC patients and 4557 ancestry-matched unrelated cancer-free controls.
Results: In total, 38 patients (17.04%) carried at least one pathogenic short variant, including 37 carrying germline heterozygous pathogenic variants in POT1 (9, 4.04%), BRCA2 (3, 1.35%), CHEK2 (3, 1.35%), MUTYH (3, 1.35%), BRCA1 (2, 0.90%), PRF1 (2, 0.90%), ERCC3 (1, 0.45%), TP53 (2, 0.90%), ATM (1, 0.45%), TSHR (1, 0.45%), TSC2 (1, 0.45%), SDHA (1, 0.45%), SBDS (1, 0.45%), MSH6 (1, 0.45%), MITF (1, 0.45%), MET (1, 0.45%), LZTR1 (1, 0.45%), FH (1, 0.45%), ERCC2 (1, 0.45%), XPC (1, 0.45%). In addition, one patient harbored pathogenic short variants in both BRCA1 and ERCC3. In the 8 unique CNVs detected in 10 (4.55%) patients, 6 were classified as pathogenic including 3 heterozygous duplications overlapping MSH2, LZTR1, SMARCB1, and 3 heterozygous deletions overlapping NF1, MSH2, and WRN. Two unique heterozygous duplications met VUS criteria including one overlapping ERCC2 and one overlapping SMARCB1. In a comparison between ASC patients and cancer-free controls of predominantly European ancestry, we found ASC patients tobe 40 times more likely to carry a pathogenic variant in POT1 (OR: 42.91, CI: [15.40-174.08], $q < 0.001$, $p < 0.001$), while TP53 was nominally significant (OR: 7.37, CI: [1.19 - 41.13], $p = 0.037$).
Conclusion: We confirmed prior observations of POT1 being responsible for ASC and called for attention to investigate the effect of germline CNVs in ASC. Overall, the elucidation of various germline elements associated with ASC risk highlighted the value and importance of patient-partnered research, particularly for rare cancers, and the analysis support using germline testing of patients for more precise clinical management.

Patterns of dysregulated coding and noncoding gene expression in high-grade serous ovarian carcinomas

Brett M. Reid[1], Ann Chen[1], Zhihua Chen[1], Florian A. Karreth[1], Peter Kanetsky[1], Jennifer B. Permuth[1], Ozlen Saglam[2], Jamie Teer[1], Xiaoqing Yu[1], Simon Gayther[1], Ellen Goode[3], Paul Pharoah[4], Thomas A. Sellers[5], Kate Lawrenson[4]. *[1]Moffitt Cancer Center, Tampa, FL,[2]Oregon Health and Science University, Portland, OR,[3]Mayo Clinic, Rochester, MN,[4]Cedars-Sinai, Los Angeles, CA,[5]TAS Consulting, Portland, OR*

Purpose: Identifying dysregulated gene expression in ovarian cancers has been limited by a deficit of available normal tissues. Here, we generated the largest set of high-grade serous ovarian cancer (HGSOC) tumors with normal precursor tissues for transcriptome analyses.
Methods: We performed RNA sequencing on 220 primary HGSOCs and 116 benign epithelia (micro-dissected fallopian tube, ovarian surface, and inclusion cysts), and combined samples with 428 HGSOCs from TCGA, 60 HGSOCs from a prior study, and 180 bulk ovary tissues from GTEx. Raw reads were processed with a uniform bioinformatic and quality control pipeline; combined data were batch corrected. We tested for differences in median normalized CPM expression values using the Wilcoxon rank sum test with >2-fold change and a false discovery rate <1% considered statistically significant. We also conducted weighted gene co-expression network analysis in each tissue type. The hypergeometric test was used for enrichment of differentially expressed genes (DEGs) and gene ontologies within modules.
Results: Transcriptomes comprised 27,700 expressed genes (8,202 lncRNAs) across 706 HGSOCs, 180 bulk ovary, and 88 ovarian epithelia tissues. Most (~90%) genes were expressed in all tissues; 5% each showed HGSOC- or normal tissue-specific expression and ≥50% were lncRNA. Comparing HGSOCs to ovarian epithelia and to bulk ovary identified 11,804 DEGs with 4,522 lncRNAs (DElncRNA) of which ~50% were tissue-specific. DEGs included *MUC16* and multiple GWAS/TWAS implicated susceptibility genes including *RAD51*, *BRIP1*, *BNC2*, *TIPARP-AS1*, *PRC1*, *KANSL1*, *ANKLE1*, *CHMP4C*, *ESRP2*, and *CCNE1*. The most highly expressed DElncRNA in HGSOC were upregulated *RMRP* ($P=1.4x10^{-39}$), *SNHG1* ($P=3.0x10^{-27}$), and *HAGLR* ($P=2.0x10^{-24}$) at the *HOXD* risk locus. The highest expressed DElncRNA in precursor tissues was the HGSOC-downregulated *MEG3* ($P=1.7x10^{-67}$). DEGs were enriched in HGSOC co-expression modules associated with immune response, cell motility/localization, cell cycle regulation, angiogenesis, reproductive development, transcriptional regulation, and metabolic processes. Tissue-specific DElncRNA tended toward upregulation compared to ovarian epithelia with enriched modules associated with cell cycle regulation (hub=*BUB1B;* top DElncRNA *TRPM2-AS*, $P=1.5x10^{-38}$); and toward downregulation compared to bulk ovary with enriched modules associated

with chemokine signaling/response (hub= *GADD45B*, top DElncRNA *RP11-87P3.1*, P=1.7x10^{-113}).
Conclusion: HGSOC-dysregulated lncRNA expression revealed tissue-specific differences that highlight unique biological pathways in precursor epithelia and the ovarian microenvironment that contribute to HGSOC pathogenesis. Our results provide additional evidence to support previously nominated risk genes. Integration with eQTL and GWAS are underway to further elucidate novel HGSOC susceptibility genes.

Genomic analysis of end-stage renal disease
Kosuke Ieiri[1], Nobuyuki Kakiuchi[1], Tomonori Hirano[1], Tomomi Nishimura[1], Koichi Watanabe[1], Hiroko Tanaka[2], Satoru Miyano[2], Dai Takamatsu[3], Keisuke Monji[3], Eiji Kashiwagi[3], Masaki Shiota[3], Junichi Inokuchi[3], Masatoshi Eto[3], Seishi Ogawa[1]. *[1]Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[2]Department of Integrated Analytics, M&D Data Science Center, Tokyo Medical and Dental University, Tokyo, Japan,[3]Department of Urology, Graduate School of Medical Science, Kyushu University, Fukuoka, Japan*

Background: Chronic kidney disease is frequently associated with persistent inflammation, which results in fibrosis in the stroma, a reduced number of renal tubules, the formation of multiple cystic lesions, ultimately terminating in renal failure and hemodialysis. Given the high incidence of renal cell carcinoma (RCC) in hemodialysis patients, suggesting a relationship between tissue remodeling by chronic inflammation and carcinogenesis. However, little is known about the genetic background of cancer development from remaining tubules and cystic lesions in hemodialysis patients.
Method: We enrolled 5 patients under hemodialysis who were accompanied by acquired cystic kidney disease and underwent radical nephrectomy for RCC. Surgical specimens were fixed with alcohol-based solution and paraffin-embedded, and after H&E staining, subjected to laser capture microdissection (LCM) to collect remaining tubules and cysts containing approximately 200 cells. DNA was extracted and analyzed for somatic mutations and copy number alteration by whole-exome sequencing.

Result: In total, we collected 161 LCM samples, including 118 from proximal tubules, 17 from collecting ducts, and 26 from cysts. Median variant allele frequencies of detected mutations were 0.237 in proximal tubules, 0.133 in collecting duct, and 0.381 in cysts, indicating larger clonal expansion in proximal tubules and cysts than in collecting ducts. Proximal tubules and cysts contained recurrent mutations in *FAT1* (11% and 8%, respectively), *STAG2* (5% and 8%), and *PTEN* (3% and 4%), whereas no recurrent driver mutations were identified in collecting ducts. In copy number analysis, 26% of proximal tubules, 35% of collecting ducts, and 80% of cysts had copy number alterations. Of note, samples from cysts had more copy number alterations compared to remaining tubules (on average, 2.3 vs. 1.1). Proximal tubules had recurrent copy number gains of chromosomes 3, 7, 10, 18, and 20, and loss of chromosome 22 and samples from collecting ducts showed gains of chromosome 7 and loss of chromosome 18. In cysts, gains of chromosomes 2, 3, 7, 10, 12, and 16 and loss of chromosomes 15, 16, 21, and 22 were frequently observed. Copy number profile in cysts was similar to that of papillary RCC and acquired cystic disease-associated RCC.
Conclusion: In the end-stage cystic kidney, proximal tubules and cysts showed an enrichment of driver mutations commonly found in papillary RCC and RCC with acquired cystic disease, reflecting the fact that the incidence of these two types of RCC increases as the duration of dialysis becomes longer. In addition, clear cell RCC drivers, such as *VHL* mutation and loss of chromosome 3, were not observed, possibly explaining the rare occurrence of clear cell RCC in hemodialysis patients. Since cysts had more frequent copy number alterations than remaining tubules, cysts in the end-stage kidney might be precursor lesions of RCC.

Characterizing the landscape of rare structural variant events in newly diagnosed multiple myeloma

Monika Chojnacka[1], Benjamin Diamond[1], Bachisio Ziccheddu[1], Even Rustad[2], Kylee Maclachlan[3], Marios Papadimitriou[1], Eileen Boyle[4], Patrick Blaney[4], Saad Usmani[3], Gareth Morgan[4], Ola Landgren[1], Francesco Maura[1]. *[1]Myeloma Division, Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL,[2]Institute for Cancer Research, Oslo University Hospital, Oslo, Norway,[3]Myeloma Service, Department of*

Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Myeloma Research Program, Perlmutter Cancer Center, NYU Langone, New York, NY

Background: Structural variants (SV) are known to play a critical role in the pathogenesis of multiple cancer types. Using whole genome sequencing (WGS), we recently characterized the SV landscape of 752 newly diagnosed multiple myeloma (MM) patients, identifying 68 SV hotspots and 152 recurrent copy number aberrations (CNA; Rustad et al. Blood Cancer Discovery 2020). Despite comprehensive annotation, more than half of SVs were not linked to any known MM genomic driver. The biological impact of these SV events, here defined as rare SV, occurring in 93% (702/752) of patients, is unknown.
Methods: To study the biological impact of rare SVs, we interrogated WGS (n=752) and RNAseq (n=591) in the CoMMpass trial. Recurrent SVs identified by involvement in canonical Ig translocations, recurrent CNAs, or SV hotspots were excluded. All SVs within an event must not involve a recurrent region to be defined rare. To determine SV class-specific gene relationships, breakpoint enrichment was compared against a permuted background model for each SV class and gene expression direction, up to 1 Mb. Genes were considered affected if expression was above a gene specific outlier Z-score of +/- 2. Lastly, we modeled breakpoint density to the nearest MM superenhancer up to 10 MB, and compared to permuted background rates.
Results: Of the total 8,942 SVs, 4,959 (55%) were identified as rare. 201 (34%) patients had at least 1 enriched rare SV event associated with gene expression outliers. Amongst over-expressed gene outliers, rare templated insertions and duplications were enriched within the gene body and up to 1 MB away. Rare inversions were enriched in genes 100kb and 1MB away, and rare translocations were associated with outliers 1 MB away. Amongst under-expressed gene outliers, rare complex SVs were enriched within the gene body, while deletion SVs were enriched in the gene body and up to 1 MB away. Rare duplications, translocations and templated insertions were enriched up to 1 MB of superenhancers. Rare templated insertions were significantly enriched against the background model ($p < 0.001$, Fisher Exact). Overall, 82% (104/126) of gene outliers affected by rare templated insertions were associated with superenhancers, (95 over-expressed, e.g.

IRF6 and 9 under-expressed), 54% (130/237) by rare translocations, (105 overexpressed, e.g. *FAM46A* and 25 under-expressed), and 55% (96/172) by rare duplication events, (93 overexpressed, e.g. *MAPK13*, and 7 under-expressed). In addition, among the 853 outlier genes affected by enriched rare SVs, at least 15 are involved with B-cell development, suggesting a potential driver role in myeloma pathogenesis.
Conclusion: In summary, leveraging WGS and RNA-seq of clinical samples, we demonstrate that rare SVs are frequently associated with aberrant gene expression, expanding our understanding of their potential role in heterogenous clinical response in patients diagnosed with MM.

#6068
Methylomic, transcriptomic and immune profiles of high grade serous ovarian cancer among Black and non-Hispanic White women
Hao Huang[1], Russell Keathley[1], Ping Xie[1], JianJun Wei[2], Ernst Lengyel[3], Bin Zhang[1], Daniela Matei[1]. *[1]Department of Medicine; Hematology/Oncology Division, Feinberg School of Medicine, Northwestern University, Chicago, IL,[2]Department of Pathology, Feinberg School of Medicine, Northwestern University, Chicago, IL,[3]Department of Obstetrics and Gynecology/Section of Gynecologic Oncology, University of Chicago, Chicago, IL*

Background: Ovarian cancer (OC) is the most lethal gynecological malignancy. There remains a significant difference in outcomes among black women, whose mortality/incidence ratio is 0.68 - the highest among all ethnic groups. Little is known about racially-defined biological key determinants of OC disparity. We recently characterized transcriptomic and methylomic profiles of high grade serous ovarian tumors (HGSOC) from black vs. non-Hispanic white women (NHW) to understand the observed disparity in survival.
Methods: Nucleic acids were extracted from treatment-naïve HGSOC specimens (30 black and 26 NHW) and used for DNA methylation (EPIC array) and RNA-sequencing. Differential expression was performed using EBseq; pathway enrichment was performed using Enrichr. TIMER was used to deconvolute immune cell infiltration based on RNA-seq results, and multiplex immunohistochemistry (mIHC) was used for validation. Top

differentially expressed genes (DEGs) were validated by qRT-PCR and studied functionally.
Results: 191 and 825 genes were up- and down-regulated, respectively, in HGSOC tumors from black vs. NHW women (FDR-adjusted p-value < 0.10). Significantly enriched pathways among these DEGs included multiple classes of *GPCRs - Class A, Monoamine GPCRs, and Peptide GPCRs*. Among DEGs, calmodulin like-5 gene *CALML5,* involved in GPCR signaling, was significantly downregulated in tumors from black patients (0.086 fold-change). *CALML5* downregulation in tumors from black vs. NHW women was validated by qRT-PCR. *CALML5* knockdown by using shRNA disrupted colony and tumor sphere formation ($p<0.05$). Analysis using TIMER predicted that $CD8^+$ and $CD4^+$ memory-resting T-cells were enriched in tumors from black patients. mIHC validated increased infiltration by $CD3^+CD4^+$ and $CD4^+FOXP3^+$ lymphocytes in humors from black women, as well as increased expression of PD-L1, supporting an immunosuppressive phenotype. Global, modest hypermethylation was discovered in tumors from black vs. NHW patients: 47 CpGs were hypermethylated (FDR-adjusted p-value < 0.10) and 19 regions were differentially methylated between the two groups.
Conclusions: We identified significant transcriptomic and modest methylation differences in HGSOC tumors from black and NHW patients. Pathway enrichment within GPCR-signaling was observed and an immunosuppressive phenotype was identified. Further exploration of the contribution of these differences to clinical outcomes and treatment response in black women is needed.

Genomic and transcriptomic characterization of medullary thyroid cancer

Seong Eun Lee[1], Seongyeol Park[2], Shinae Yi[1], Joonoh Lim[2], Na Rae Choi[1], JungHak Kwak[3], June-Young Koh[2], Boram Yi[2], Jaemo Koo[2], Jae Won Chang[4], Young Seok Ju[2], Bon Seok Koo[4], Jin Man Kim[5], Young Joo Park[6], Minho Shong[7], Eun Kyung Lee[8], Jae Kyung Won[9], Yea Eun Kang[7], Kyu Eun Lee[3]. *[1]Chungnam National University, College of Medicine, Daejeon, Korea, Republic of,[2]GENOME INSIGHT THECNOLOGY Inc, Daejeon, Korea, Republic of,[3]Department of Surgery, Seoul National University*

Hospital & College of Medicine, Seoul, Korea, Republic of,[4]Department of Otolaryngology-Head and Neck Surgery, Chungnam National University, College of Medicine, Daejeon, Korea, Republic of,[5]Department of Pathology, Chungnam National University, College of Medicine, Daejeon, Korea, Republic of,[6]Department of Internal Medicine, Seoul National University Hospital & College of Medicine, Seoul, Korea, Republic of,[7]Department of Internal Medicine, Chungnam National University, College of Medicine, Daejeon, Korea, Republic of,[8]Department of Internal Medicine, National Cancer Center, Goyang, Korea, Republic of,[9]Department of Pathology, Seoul National University Hospital & College of Medicine, Seoul, Korea, Republic of

Medullary thyroid carcinoma (MTC) is a rare thyroid malignancy derived from the parafollicular C cells of thyroid gland. It features relatively aggressive biologic behavior among thyroid cancers, but its genomic landscape has not yet been fully explored. Here, we conducted multi-omics data (whole genome sequencing (WGS), and bulk (bulk RNA-seq) or single nucleus RNA sequencing (snRNA-seq)) on MTC, and found genetic characteristics of MTC and a new gene signature predicting aggressiveness of tumors. WGS was performed for 35 pairs of tumor specimens and normal thyroid tissues from 30 patients. And bulk RNA-seq for 59 samples (20 normal thyroid tissues, 26 primary MTCs, 9 recurred lymph nodes, and 4 metastatic lymph nodes) and snRNA-seq for 3 primary MTCs, and 2 recurred/metastatic lymph nodes were also performed. In WGS results, we verified driver mutations, including RET, RAS, and BRAF. Four patients were classified as germline RET mutations based on familial history. Somatic RET M918T mutations were occurred in 8 patients, 9 patients were observed other RET mutations. Also, we observed other somatic mutations such as HRAS and BRAF. Seven patients occurred somatic HRAS mutations (Q61L, Q61R, G13R, A11 and G15), and somatic BRAF mutations (G469A, K601E) were observed in two patients. We found broad-level copy-number alterations in ~50% of patients, and we also found a patient who shows whole-genome duplication. The copy-number alteration was associated with aggressive phenotype in MTC. In addition, we found complex rearrangements such as microhomology-mediated break-induced replication in five patients. Interestingly, we found intra-tumoral heterogeneity of several genes related to C cell differentiation through

snRNA-seq analysis by comparing clusters of tumor cells. Using the genes, we calculated the C cell differentiation score of the samples with bulk RNA-seq by GSVA algorithm. This score was related to poor clinical characteristics such as recurrence. In conclusion, multi-omics profiling of MTC reveals that copy number alterations and C cell differentiation status are the important biomarkers for cancer aggressiveness.

Comprehensive real-world-data based molecular profiling and mapping of non-squamous NSCLC patients to immune-checkpoint-inhibitor biomarkers

Andreas Kloetgen[1], Danyi Wang[2], Anna Coenen-Stass[1], Ioannis Gounaris[3], Julia F. Hopkins[4], Giuseppe Locatelli[1], Juergen Scheuenpflug[1], Zheng Feng[2]. *[1]Merck Healthcare KGaA, Darmstadt, Germany,[2]EMD Serono Research and Development Institute, Inc., Billerica, MA,[3]EMD Serono, Feltham, United Kingdom,[4]Foundation Medicine, Inc., Cambridge, MA*

Purpose: Non-squamous non-small cell lung cancer (nsqNSCLC) patients without detectable actionable alterations in EGFR, ALK, or ROS1, have a diverse genetic background. These patients are eligible to and usually receive untargeted, first line immune checkpoint inhibitors (ICI) and/or chemotherapy with heterogeneous outcomes. To identify potential predictive biomarkers for the stratification of nsqNSCLC patients without actionable genetic alterations, a comprehensive molecular profiling of this subpopulation was performed using the Foundation Medicine genomic database.
Methods: Molecular profiles from 53,119 nsqNSCLC patients were analyzed using the FoundationInsights^{TM} web platform. After the patients with known and likely functional short variants for EGFR and fusions for ALK and ROS1 were excluded, the prevalences for commonly altered genes were determined. Pathway analysis was conducted with Metascape. Statistical significance and enrichment in PD-L1 and tumor mutation burden (TMB) biomarker overlap with altered genes was calculated using a fisher exact test against an alteration negative cohort.
Results: nsqNSCLC patients without actionable genetic alterations can be described as a heterogenous population with different genetic alterations. We found a total of 103 genes with an individual, minimal prevalence of

>1% to be the major descriptors that collectively were found in most patients of the nsqNSCLC subpopulation. These genes relate to pathways involved in cell cycle, cell proliferation, response to growth factors or chromatin organization. Out of the most frequently altered genes, we identified those that are associated with PD-L1 or TMB high status for which ICI treatment is most effective in nsqNSCLC.
Conclusions: The results supported the lack of a general association with high PD-L1 and high TMB calls for biomarker informed treatment options for nsqNSCLC patients. We reported a subpopulation of nsqNSCLC patients that can be described by certain genetic alteration, of which some were associated with ICI-related biomarkers for which patients might benefit from a future precision oncology approach utilizing combined targeted and ICI treatment.

Whole-exome RNA sequencing of metastatic synovial sarcomas reveals heterogeneous transcriptomic profile and targetable co-alterations: Cohort study from the French Sarcoma Group

Helene Vanacker[1], Mehdi Brahmi[1], Yannick Le Meitour[2], Julien Bollard[2], Valery Attignon[3], Alexandra Meurgey[4], Myriam Jean-Denis[5], Laurie Tonon[3], Shibani Pokras[6], Erika Klohe[7], Michael Nathenson[8], Kristin Blouch[9], Ioanna Eleftheriadou[10], Jean-Yves Blay[1], Franck Tirode[2], Armelle Dufresne[1]. *[1]Medical Oncology Department, UNICANCER Centre Léon Bérard, Lyon, France,[2]CITI department, Centre de Recherche contre le Cancer de Lyon (CRCL), Lyon, France,[3]Department Of Clinical Research And Innovation, UNICANCER Centre Léon Bérard, Lyon, France,[4]Bio-pathology platform, UNICANCER Centre Léon Bérard, Lyon, France,[5]Department Of Translational Research And Innovation, UNICANCER Centre Léon Bérard, Lyon, France,[6]Oncology Cell & Gene Therapy, Global Medical, GSK, Collegeville, PA,[7]Oncology Experimental Medicine Unit, GSK, Collegeville, PA,[8]Oncology Cell & Gene Therapy, GlaxoSmithKline, Collegeville, PA,[9]Oncology Clinical Development, GlaxoSmithKline, Collegeville, PA,[10]Oncology Experimental Medicine Unit, GlaxoSmithKline, Collegeville, PA*

Introduction: Synovial Sarcoma (SS) is a rare and aggressive disease that predominantly occurs in young adult. SS are characterized by a pathognomonic t(X:18) translocation leading SS18: SSX1/2/4 fusion. Small studies (n<100) described molecular background beyond this fusion in patients and the transcriptomic profile of SS remains poorly known. The aim of our study is to provide a large cohort analyzing transcriptomic and co-alterations to better understand and treat SS.
Methods: We present a clinico-biological cohort study including all adult patients with histologically confirmed diagnosis of afvanced SS from January 2000, registered in the French Sarcoma database (NETSARC+) and with available formalin-fixed paraffin embedded (FFPE) archival tumor samples and clinical data. FFPE tumor samples were analyzed by dedicated whole-exome RNA-sequencing (WERS) to assess transcriptomic, small nucleotide variation (SNV) and fusions.
Results: 122 patients (133 samples) met the study criteria, including 11 patients with paired primary-metastatic tumor samples. Clinical characteristics (age, sex, tumor grade, primary and metastasis site distribution) were consistent with expected SS population. The SS18:SSX1/2/4 fusion was found in all patient (90% by WERS and if negative, by FISH). Unsupervised analyses of transcriptomic data by principal component analyses, hierarchical sample clustering or UMAP revealed heterogeneity in gene expression. Clinical factors (age, sex, grade, tumor type, complete response to treatment, survival) did not correlate with transcriptomic profiles. Immune cell analyses confirmed a low infiltration of immune cells, notably poor in CD8+ T cells. Cancer testis antigens such as NYESO-1, MAGE-A4 were both expressed with a heterogeneous co-expression of other CTAs across samples. In the 11 primary-metastatic paired- samples, no gene pathway was found differentially expressed between primary and metastatic samples cohort with the exception of lung tissue specific genes. Comparing chemotherapy-naïve versus pre-treated samples did not identify differential expression of specific genes across samples. Single Nucleotide Variant analyses was reliable on 84% FFPE samples and revealed an overall low Tumor Mutational Burden with some samples harboring canonical oncogene pathogenic mutations of BTK, RAS, NF1, RB1 as well as in DNA repair pathway(15% spanning over ATM ATR,CHK2, BRCA1/2 PALB2 CHK2, FANCM, RAD51), PI3K pathways (PI3KCA E545K) and other poorly described in SS.

Conclusion: Investigating the largest cohort of metastatic SS by whole-exome RNA-sequencing, revealed Synovial Sarcoma, usually classified as “simple genomic sarcoma” is a translocation-related sarcoma harboring heterogeneous transcriptomic and numerous SNV co-alterations including targetable mutations.

Introduction: Structural variants (SVs) are a unique class of mutations which have certain therapeutic implications for the tumor. Certain SVs, such as chromosomal aneuploidy, whole-genome doubling (WGD), have specific therapeutic implications. The underlying cellular processes present in the tumor are reflected in mutational signatures. Here, we describe the landscape of chromosomal aneuploidy, WGD and mutational signatures in the National Cancer Institute’s Patient-Derived Models Repository (NCI PDMR) to facilitate the investigation of their roles in therapeutic responses of the preclinical models.

Method: Chromosome arm-level aneuploidy was called by scoring at the individual arm level if >90% of the arm copy number (CN) was gained/lost based on whole-exome sequencing (WES) data. Aneuploidy score was defined as number of arms with aneuploidy. WGD was determined by derived allelic specific CN, purity and ploidy from tumor/normal matched

samples and permutation test. Mutational signatures (COSMIC v3) including single base substitutions (SBS), doublet base substitutions (DBS), small insertions and deletions (ID) and CN signatures were derived using SigProfiler for specimens with somatic mutations and CNs.
Results: A large fraction (85%) of patient-derived xenograft (PDX) models (N=755) have at least one arm -level aneuploidy. Certain chromosomes and arms (7, 8, 17p and 18) are more frequently aneuploid, which might be biased due to the overrepresentation of gastrointestinal cancer in the cohort. Histology specific differences were observed in the frequency of arm level aneuploidies. For example, synovial sarcoma (SYNS) and endometrioid carcinoma (UEC) have much lower level of aneuploidy than non-small cell lung cancer (NSCLC) or clear cell renal carcinoma (ccRCC) models. 61% of PDX models (N=277) have WGD, in which certain histologies have more WGD [NSCLC: 81%, head and neck squamous cell carcinomas (HNSCC): 71%] than others. Samples having WGD have a higher degree of aneuploidy and chromosomal instability. WGD and aneuploidy remain stable along the passages in 78% PDX models. Intra-model heterogeneity of WGD was observed due to lineage difference. Mutational signatures (SBS6,15,20) indicating concurrent DNA polymerase epsilon (*POLE*) mutation and defective DNA mismatch repair were highly enriched in microsatellite instability-high models ($p<0.01$, Fisher's exact test). Among 30 PDX models where the patients had known platinum-based chemotherapy history, 40% of them had an identifiable platinum chemotherapy treatment signature (SBS31 or DBS5). Chromothripsis associated amplification signature (CN8) was enriched in models with WGD ($p<0.05$).
Conclusion: We have characterized chromosomal aneuploidy, WGD and mutational signatures in NCI PDMR models. The models with SVs can be utilized in preclinical drug studies to understand their role in therapeutic response in patients.

Distinct subtype of multiple myeloma revealed by whole genome and transcriptome sequencing

Sheehyun Kim[1], Hyundong Yoon[2], Youngil Koh[1], Sung-Soo Yoon[1]. *[1]Seoul National University Hospital, Seoul, Korea, Republic of,[2]Seoul National University Cancer Research Institute, Seoul, Korea, Republic of*

Background: Advanced sequencing technologies have contributed to identifying genomic and transcriptomic features of various types of tumors. Despite several sequencing data from multiple myeloma (MM) being generated, understanding various properties of MM remained insufficient.
Methods: The patients confirmed with MM by bone marrow examination were analyzed in the study. Myeloma cells were enriched from the bone marrow aspirates of the patients using CD138. Whole genome sequencing (WGS) and whole transcriptome sequencing (WTS) were performed for isolated myeloma cells. Mutational signatures were analyzed using somatic mutations detected by WGS.
Results: A total of 37 MM patients (median age 67) were enrolled in this study. WGS revealed somatic mutations of an average of 8872 single nucleotide variants (SNVs) and 934 insertions and deletions (Indels) from the patients, respectively. By the analysis of structural variants, 7 chromothripsis and 4 chromoplexy patients were identified. Mutational signature analysis showed that single base substitution (SBS) 9 signature largely varied between patients. SBS9 signature high patients were mostly diagnosed with non-IgG/non-IgA heavy chain and lambda light chain type myeloma. Notably, IgD myeloma patients were solely detected in the SBS9 signature high group compared to the low group ($p = 0.001$). Gene expression patterns obtained from WTS were well-divided into SBS9 signature high and low groups, and analysis of differentially expressed genes (DEG) between SBS9 signature high and low groups implied IgD myeloma features including high expression of *IGHD*. As a validation test, we tried mutational signature analysis on whole exome sequencing (WES) data of 784 MM patients from the MMRF database. Of the 38 patients with more than 500 exonic mutations, only the SBS9 signature high group had IgD myeloma candidates, whereas the SBS9 signature low group had no IgD myeloma candidate ($p = 0.014$).
Conclusions: DNA and RNA sequencing of myeloma patients could classify specific subtypes of disease categories. Further study for SBS 9 signature high and IgD myeloma is needed to discover the underlying mechanism of distinct features and to find out their clinical implication.

Germline and somatic genomic profiling of urothelial carcinoma

Bing-Jian Feng[1], Wendy Kohlmann[2], David A. Nix[2], Aaron Atkinson[2], Kenneth M. Boucher[2], Courtney Carroll[1], Jill Kolesar[3], Eric A. Singer[4], Stephen B. Edge[5], Kamal Sahu[2], Alejandro Sanchez[2], Mikaela Larson[2], Michelle L. Churchman[6], Laura Graham[7], John D. Carpten[8], Yousef Zakharia[9], Lindsey Byrne[10], Rohit K. Jain[11], Kenneth G. Nepple[9], Ahmad Shabsigh[10], Jad Chahoud[12], Sumati Gupta[2]. *[1]University of Utah, Salt Lake City, UT,[2]Huntsman Cancer Institute, Salt Lake City, UT,[3]University of Kentucky, Lexington, KY,[4]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[5]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[6]M2Gen, Tampa, FL,[7]University of Colorado, Aurora, CO,[8]University of Southern California, Los Angeles, CA,[9]University of Iowa, Iowa City, IA,[10]Ohio State University Comprehensive Cancer Center, Columbus, OH,[11]Moffitt Cancer Center, Tampa, FL,[12]Moffit Cancer Center, Tampa, FL*

Urothelial carcinoma (UC) presents most frequently as bladder cancer and is the most common cancer of the urinary system in the United States. UC relapse and progression are common and impose a significant negative impact on the lives of patients and healthcare resources. To elucidate the biological mechanisms of UC and find novel biomarkers, we analyzed the clinical and genomic data in the Oncology Research Information Exchange Network (ORIEN). We conducted gene-based and gene-set based association tests on rare germline variants comparing the exome sequencing of 336 UC patients and genome sequencing of 366 healthy controls (42 unrelated individuals from the Centre d'Etudes du Polymorphisme Humain [CEPH] families and 324 from the University of Utah Heritage 1000 [H1K] Projects). The analysis of loss-of-function (LoF) variants revealed that the forkhead box (FOX) J2 gene set was significantly associated with UC at the genome-wide level (Bonferroni-corrected p-value=0.01). Genes in this gene set contain a motif that matches the FOXJ2 transcription factor binding site. Firth-penalized Cox proportional hazard regression on overall survival identified LoF variants in genes down-regulated in naive CD8 T cells to be associated with worse prognosis (Bonferroni-corrected p-value=0.032, hazard ratio=28.2, and 95% confidence interval 6.66 to 119.0). In exome sequencing of tumor tissues, we searched for driver genes and pathways by testing for higher variant allelic fractions than the genome average. The tests yielded eleven genes with genome-wide significance (**Table 1**). By

gene set analysis using the MSigDB Hallmark database, significant pathways included the P53 pathway ($p<2x10^{-16}$), Wnt beta-catenin signaling ($p<2x10^{-16}$), E2F targets ($p=8x10^{-13}$), PI3K/AKT/mTOR signaling ($4x10^{-7}$), and apoptosis ($p=9x10^{-7}$). These results reveal the germline predisposition variants and somatic oncogenic drivers in UC and suggest immune evasion as a contributing factor for poor clinical outcomes in UC patients.

Table 1: Genes with high allelic fractions

Gene	**P-value**	**Number of Variants**
TP53	$<2x10^{-16}$	203
RB1	$2.42x10^{-16}$	67
ELF3	$2.06x10^{-7}$	38
TSC1	$4.05x10^{-7}$	32
KMT2D	$7.59x10^{-7}$	91
ZFP36L1	$8.80x10^{-7}$	33
CDKN1A	$2.47x10^{-6}$	40
FGFR3	$1.11x10^{-5}$	37
ARID1A	$1.28x10^{-5}$	62
SMARCA4	$1.53x10^{-5}$	17
PIK3CA	$2.00x10^{-5}$	53

Background: The genomic landscape of cancer is complex and includes mutations and copy number alterations (CNAs) that affect several cancer related pathways and drive tumor evolution. Non-muscle-invasive bladder cancers (NMIBC) are largely orphan for integrative genomic studies. Large studies are needed to delineate the genomic complexity and heterogeneity of NMIBC.

Methods: A total of 438 patients with NMIBC were analyzed, 296 of which were part of the UROMOL cohort (PMID: 27321955). The median follow-up was 5 years. The progression rate was 13% (n= 56). Whole exome sequencing (WES) was performed on DNA from tumor (~150x) and matched germline samples to call somatic mutations. Additionally, shallow whole genome sequencing (sWGS; ~2x) was performed on DNA from 362 of the tumors to quantify CNAs. RNA-sequencing was available for 414 of

the samples, and tumors were classified according to the UROMOL2021 transcriptomic classes. We identified significantly mutated genes by mutsigCV and significantly amplified or deleted regions by GISTIC2.
Results: The median tumor mutation burden (TMB) was 3.7/Mb. TMB was not associated with progression (p=0.28). A total of 61 genes were significantly mutated in the cohort, the most frequent being *FGFR3* (61%), *KDM6A* (44%) and *KMT2D* (38%). Mutations in *EP300* and *RHOB* were significantly associated with an increased risk of progression after adjusting for grade and stage (p=0.040 and 0.044, respectively). Several mutations showed a strong transcriptomic class dependent occurrence: mutations in *RB1, TP53, ERCC2* and *ERBB2* were enriched in the aggressive class 2a, *FGFR3* and *STAG2* in class 1 and class 3, and *KMT2C* and *KMT2D* in class 3.
Genome doubling was identified in 15% of the tumors. These tumors were enriched in the aggressive classes 2a and 2b and were associated with increased risk of progression (p=0.0049). In addition, we observed several significantly altered genomic regions, the most significant being deletions in 9p21.3 (*CDKN2A & CDKN2B*, 64%), 2q37.1 (*GIGYF2 & EIF4E2*, 28%) and amplification in 11q13.3 (*CCND1*, 9%). Class 2a tumors were enriched for genomic alterations in most of the significant regions. 9p21.3 was the only region with frequent homozygous losses (22%). High-level gains were prognostic of progression, independently of ploidy, stage and grade, for several regions, including 4p16.3 (*FGFR3*, p=0.00013), 17q23.2(*TBX2*, p=0.0004) and 8p11.23(*ZNF703, p*=0.011). In addition, we observed an enrichment of uniparental disomy in 4p16.3 (*FGFR3*, 8%).
Conclusion: Here we investigated the landscape of DNA alterations in NMIBC in a large patient cohort of NMIBC samples with paired transcriptomic data and detailed clinical follow-up. We identified several novel genomic alterations; specifically, we showed that 15% of the tumors had genome doublings, and we identified a complex underlying copy number landscape of the region containing *FGFR3*.

Compartment-specific multiomic characterisation of ovarian carcinosarcoma
Robert L. Hollis, Ailsa Oswald, Lorna J. Stillie, Ian Croy, Michael Churchman, Charlie Gourley, C. Simon Herrington. *University of*

Edinburgh, Edinburgh, United Kingdom

Background: Ovarian carcinosarcoma (OCS) is the most aggressive ovarian cancer type. Risk of relapse and death is high across all patient groups, including those diagnosed at early stage. OCS is biphasic, comprising both carcinomatous and sarcomatous populations, leading to its historic consideration alongside true sarcomas. However, we now recognize that OCS in fact represent metaplastic carcinomas, with the sarcomatous component having undergone complete epithelial to mesenchymal transition (EMT) from carcinoma. Detailed understanding of shared and compartment-specific OCS biology has the potential to identify therapeutic opportunities to improve patient survival.
Methods: We recently curated the largest pathologically-confirmed OCS cohort to date. Here, we perform compartment-specific profiling of 12 cases by mRNA sequencing, whole exome sequencing, microRNA (miRNA) profiling and quantification of tumor-infiltrating lymphocytes. These data paint a detailed picture of shared and compartment-specific biology between matched carcinomatous and sarcomatous compartments.
Results: The sarcomatous compartments harbored significantly fewer infiltrating CD8+ cells (P=0.006), with a significantly lower CD8+:CD3+ cell ratio compared to the carcinomatous components (P=0.002). In 11 of 12 cases, identical *TP53* mutations were identified in both cell populations; the remaining case was *TP53* wild-type in both compartments. Paired analysis of mRNA sequencing identified 1477 significantly differentially expressed transcripts at FDR<0.01. The sarcomatous compartments demonstrated significantly higher MAPK activity, as determined by the MPAS transcriptomic score (P=0.042). Principal component analysis and unsupervised hierarchical clustering of miRNA expression grouped samples by compartment (carcinomatous versus sarcomatous), rather than by patient, suggesting global differences in the miRNA landscape. Paired analysis identified 131 significantly differentially expressed miRNAs between the two populations (FDR<0.01). Significantly enriched miRNA gene targets were identified using The MiRNA Enrichment Analysis and Annotation Tool (miEAA), identifying key EMT-associated gene targets, including *SIRT1*, *PRDM16*, *ZEB1*, *ZEB2* and TGFB signaling components, among other biological processes.

Conclusions: Carcinomatous and sarcomatous compartments of OCS demonstrate marked differences in transcriptomic profiles, immune engagement and miRNA expression patterns. Identification of shared *TP53* mutations between compartments supports the notion that OCS represent metaplastic carcinomas. Shared biological events represent opportunities for targeted interventions that may be efficacious against both cell populations, while compartment-specific biological events allude to mechanisms by which the carcinomatous population undergoes EMT to form the sarcomatous compartment.

Comprehensive multi-omic characterization of genetic changes associated with sinonasal squamous cell carcinoma progression

Alka Singh[1], Nikita Babushkin[2], Michael Korzinkin[3], Viktoria Sarkisova[3], Vasudha Mishra[1], Ari Rosenberg[1], Mark Lingen[4], Justin Bishop[5], Alex Zhavoronkov[3], Nyall London[6], Nishant Agrawal[7], Xuanyao Liu[2], Evgeny Izumchenko[1]. *[1]Medicine, Section of Hematology and Oncology, University of Chicago, Chicago, IL,[2]Medicine, Section of Section of Genetic Medicine, University of Chicago, Chicago, IL,[3]InSilico Medicine, Pak Shek Kok, Hong Kong,[4]Pathology, University of Chicago, Chicago, IL,[5]University of Texas Southwestern, Dallas, TX,[6]Otolaryngology - Head and Neck Surgery, Johns Hopkins University, Baltimore, MD,[7]Surgery, Otolaryngology-Head and Neck Surgery, University of Chicago, Chicago, IL*

Approximately 50-80% of sinonasal tract cancers are sinonasal squamous cell carcinoma (SNSCC), a rare malignancy which occur in the nasal cavity and maxillary sinus. These lesions possess a propensity for local invasion into adjacent structures including the skull base, brain, and orbit. Owing to relatively mild symptoms during early stages, which resemble benign sinonasal disease, most patients are already in clinically advanced stages when diagnosed. Therefore, despite improvements in endoscopic surgical approaches, radiotherapy and imaging techniques, the 5-year overall survival for advanced SNSCC patients remains poor (~40%).
Inverted sinonasal papilloma (IP) is a locally aggressive, benign epithelial neoplasm arising in the paranasal sinuses which has a high recurrence rate and transforms to SNSCC in 10%-25% of cases. As some IP evolve to

malignant neoplasms, it has been presumed that they represent an intermediate step in SNSCC progression. However, the current tools for detecting altered epithelial cells, such as clinical examination and histological characteristics, have limited prognostic value for predicting which IP will progress to malignancy, and the link between IP and invasive disease remains unclear.
Activating mutations in EGFR and PIK3CA genes as well as loss-of-function mutations in TP53 have been reported in a few very small cohorts of IP and SNSCC lesions, suggesting their role in IP pathogenesis and progression to invasive malignancy. Other observed alterations potentially associated with malignant transition include KRAS mutations, loss of heterozygosity (LOH) at the 9p21 locus (containing p16INK4a), mismatch repair genes deficiency, amplification of FGFR1 and SOX2 genes, as well as NFκB, COX2 and HOXA9 overexpression. While these studies provide a snapshot of molecular changes in SNSCC, genetic alterations critical to the development of SNSCC are poorly understood, and the exact mechanism underlying malignant transformation remains unknown.
In this study we have used PandaOmic, a multi-omic data analysis and visualization algorithm, to perform a first comprehensive integrative analysis of WES, mitochondrial sequencing and transcriptomic data obtained from 11 IP lesions, matched invasive SNSCC tumors and histologically normal paranasal sinus epithelium collected from the same patients. Our analysis reveals heterogeneous mutational patterns, gene expression changes and signaling pathways features associated with SNSCC pathogenesis, and provides crucial insights that may aid in the development of novel means of prevention, diagnosis, and treatment of this rare, aggressive and poorly characterized malignancy.

#6079
Comprehensive characterization of FBXW7 mutational and clinicopathological profiles in human colorectal cancers
Hanlin Chen, Hua Bao, Haimeng Tang, Xue Wu, Yang Shao. *Nanjing Geneseeq Technology Inc., Nanjing, China*

Background: FBXW7 is a critical tumor suppressor gene of human colorectal cancers (CRC). However, the comprehensive profiling of FBXW7 in CRC is largely underrepresented in current studies. Herein, we

present molecular profiling of FBXW7 in human CRC cohorts and clinical outcomes.
Methods: 7626 colorectal cancer patients were retrospectively enrolled. Comprehensive genomic profiling was performed on formalin-fixed paraffin-embedded (FFPE) or fresh tumor samples using a next-generation sequencing (NGS) panel covering 425 cancer-related genes, and matching plasma samples were sequenced to exclude germline mutations. The patients' microsatellite instability (MSI) score, tumor mutation burden (TMB), and chromosomal instability (CIN) score were measured. 3541 colorectal cancer patients in the MSK MetTropism cohort with survival data were analyzed for survival outcomes and risk factors. Survival analyses were performed using the Kaplan-Meier method. 263 patients in the TCGA COAD cohort with RNA sequencing data were analyzed for immune cell infiltration and gene set enrichment analysis (GSEA). P values in multiple comparisons were FDR (false discovery rate) adjusted. Tests with P values or FDR less than 0.05 were considered statistically significant.
Results: The cohort had a median age of 59 (20-93), with 60.45% male patients. The median TMB of the cohort was 7.78 muts/Mb (1.11-655.56). There were 1227 (16.1%, >12 muts/Mb) hypermutated and 187 (2.5%, >100 muts/Mb) ultrahypermutated tumor-carrying patients. Within the cohort, a total of 7442 (97.6%) patients had identifiable microsatellite status, of which 548 (7.4%) were MSI. The FBXW7 mutation carrying rate was 17.9% (1365). Compared to FBXW7 wild type (WT) patients, FBXW7 mutated patients had higher TMB ($P < 0.001$), higher MSI score ($P < 0.001$), and lower CIN score ($P < 0.001$). In the MSK cohort, 500 (14.1%) patients with FBXW7 mutations showed better overall survival (HR: 0.67; 95%CI: 0.55-0.80, $P < 0.001$). The most mutated sites of FBXW7 were R505C (54), R465H (47), R465C (44). Among them, R465C showed worse OS in multivariate cox analysis when compared with other FBXW7 mutations (HR: 1.6; 95%CI: 1.13-3.1, $P = 0.015$), and when compared with all other mutations (HR: 1.87; 95%CI: 0.99-2.5, $P = 0.053$). In the immune cell infiltration analysis using the TCGA COAD cohort, patients with FBXW7 mutations displayed higher M1 macrophage ($P = 0.014$), CD8+ T cell ($P = 0.008$), and regulatory T cell ($P = 0.011$) infiltration rates. In the GSEA analysis, in MSI patients, 11 hallmark gene sets are significant enriched in FBXW7 mutated patients, including interferon gamma response (FDR = 0.031), allograft rejection (FDR = 0.026), etc.

Conclusions: Comprehensive profiling of FBXW7 in colorectal patients revealed that FBXW7 mutations were associated with better OS, except the FBXW7 R465C mutation was identified as an indicator for worse OS.

#6080

Comprehensive profiling of pathogenic/likely pathogenic large genomic rearrangements in pan cancer samples

Haimeng Tang, Hua Bao, Xue Wu, Yang Shao. *Nanjing Geneseeq Technology Inc., Nanjing, China*

Background: Correlations between large genomic rearrangements (LGRs) and cancer types beyond breast or ovarian cancer have not been sufficiently profiled, likely due to the highly inefficient methods of detecting these types of mutations.
Methods: This study utilized next-generation sequencing (NGS) to analyze and classify the germline LGR mutation profile in 17,025 cancer patients across 22 cancer types. We characterize novel LGRs based on predicted pathogenicity and take a closer look at genes that acquire both germline and somatic mutations within our samples. Detection method was validated using ddPCR assay of commonly investigated LGR genes.
Results: In total, 15,659 samples from across 22 cancer types were retained for analysis after filtering. We observed that, in our cohort, the cancer type with the highest proportion of LGRs are ovarian cancer (4.7%), renal cell carcinoma (2.5%), breast cancer (2%), glioma (1.8%), and thyroid carcinoma (1.8%). Annotation of detected germline variants revealed several genes containing novel LGRs including *MSH2*, *FANCA*, and *PMS2*. We observed co-mutational events between LGR in *MSH2* and somatic mutations in *BRCA2, KTM2B, KDM5A, CHD8*, and *HNF1A*. Furthermore, our analysis shows that samples with pathogenic and likely pathogenic germline LGR mutations tended to also have higher mutational burden, chromosomal instability, and microsatellite instability ratio compared to other samples with non-LGR germline mutations.
Conclusion: In this study, we demonstrated the prevalence of LGRs beyond that of *BRCA1/2* and *RB1* in breast and ovarian cancer. Our profiles of these pathogenic/likely pathogenic alterations can potentially fuel further investigations and highlight new understanding of LGRs in multiple cancer types.

Proportion of samples with large genomic rearrangements in each cancer type

Cancer Type	Germline Non-LRG P/LP proportion (%)	Germline Non-LRG P/LP proportion (%)	
Ovarian cancer (OC)	22.4	22.4	
Breast cancer (BC)	16.2	16.2	
Prostate (PRAD)	13	13	
Endometrial	13.4	13.4	
Glioma	11.7	11.7	
Pancreatic (PC)	11.3	11.3	
Neuroendocrine (NEN)	8.5	8.5	
Sarcoma	9.5	9.5	
Colorectal cancer (CRC)	9.7	9.7	
Thyroid (THCA)	8	8	
Hepatocellular carcinoma (HPC)	9.1	9.1	
Gastrointestinal stromal tumor (GIST)	9.5	9.5	
Gastric cancer (GC)	8.2	8.2	
Renal cell carcinoma (RCC)	9.3	9.3	
Cervical cancer	10.2	10.2	
Lung cancer	8.2	8.2	
Esophageal cancer	9.2	9.2	
Bladder cancer (BLCA)	8.8	8.8	
Leukemia	3.9	3.9	
Head and neck cancers (HNC)	6.7	6.7	
Lymphoma	1.2	4.8	4.8

Melanoma	0.5	4.8	4.8
Pan-Cancer	1	9.1	9.1
P/LP: Pathogenic/Likely pathogenic			
LGR: Large genomic rearrangement

Integrative genomic analysis of primary prostate tumors and corresponding lymph node metastases
Carlos S. Moreno, Cynthia L. Winham, Emma R. Klein, Yijian Huang, David M. Schuster, Martin G. Sanda, Adeboye O. Osunkoya. *Emory University, Atlanta, GA*

Background: Prostate cancer (PCa) is a highly heterogeneous disease, and mortality is mainly due to metastases. However, the molecular underpinnings that lead to the initial steps of metastasis have not been well characterized. We have performed integrative whole exome sequencing and transcriptome analysis of primary prostate tumor foci and corresponding lymph node metastases (LNM).
Design: Primary tumor foci (PTF) and LNM from 40 patients with high-risk PCa were analyzed by RNAseq. Two or more PTF and all available LNM greater than 0.4cm were subjected to sequencing. Of these 40 patients, 17 (42.5%) had LNM and 23 (57.5%) had benign LNs. A total of 155 tissue samples (97 PTF, 39 benign LNs, and 19 LNM) were sequenced and mapped to the human transcriptome with STAR mapper after QC trimming and removal of adapter sequences using TrimGalore. Differentially expressed genes between PTF, LNM, and benign LNs were identified using DESeq2, and gene set enrichment analysis was performed using WebGestalt. WES data was analyzed using GATK pipelines including Mutect2.
Results: A median of 57 million paired-end reads were obtained per sample, with a median of 10 million total readcounts per sample across the transcriptome, and 39,021 transcripts were detected in at least 5% of

samples. Comparing PTF to LNM, 6203 transcripts were differentially expressed (p-adj < 0.01). PTF were enriched relative to LNM in gene sets associated with Wnt signaling, hormone signaling, Hippo signaling, *KRAS* signaling, and the epithelial to mesenchymal transition. Comparing PTF from metastatic patients to non-metastatic patients, 1265 transcripts were differentially expressed (p-adj < 0.01). PTF from metastatic patients were enriched in gene sets associated with cell cycle progression, oxidative phosphorylation, ER stress, fatty acid metabolism, and DNA repair. LNM gene sets were enriched in endoplasmic reticulum (ER) stress and oxidative phosphorylation. The top 500 upregulated genes in malignant tissues were significantly enriched in genes related to androgen and estrogen signaling as expected. We also identified a set of 193 genes whose expression was significantly increased in primary tumor over benign LNs and in LNM over primary tumors. This gene set was significantly enriched in genes related to oxidative phosphorylation and included oncogenes such as *PIK3CB, NCOA2*, and *SCHLAP1.* Integrative RNAseq analyses with WES will be discussed.
Conclusions: Signaling pathways associated with ER stress, oxidative phosphorylation, metabolism, and cell cycle progression are prominent in LNM of aggressive PCa. *PIK3CB, NCOA2,* and *SCHLAP1* expression are significantly increased in LNM.

Assessing difference in the tumor and immune microenvironment of BRCA1/2 mutated versus BRCA wild type high grade serous ovarian cancers

Jing Qian[1], Lynda D. Roman[2], Seeta Rajpara[1], Monica Neuman[2], Varun Khetan[2], David W. Craig[1], Joseph Carlson[3], John D. Carpten[1].
[1]Translational Genomics, Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]Department of Obstetrics and Gynecology, Keck School of Medicine, University of Southern California, Los Angeles, CA,[3]Department of Pathology, Keck School of Medicine, University of Southern California, Los Angeles, CA

Ovarian cancer (OvCa) is the deadliest gynecological malignancy in the United States. Surgery and chemotherapy are the primary treatments for

OvCa, but 80% of late-stage OvCa patients experience chemo-resistant recurrence, which necessitates the development of new treatment strategies. The genomic diversity within a tumor and the interactions among various cell types within its microenvironment are considered key factors contributing to therapeutic efficacy. Specifically, women who harbor germline BRCA1 or BRCA2 mutations are at increased risk of developing high grade serous ovarian cancer (HGSC). To understand the genomic consequences, including somatic alterations, associated with defective DNA repair, tumor DNA and RNA was isolated from fresh frozen OCT embedded sections from 15 HGSC patients with BRCA1/2 mutation and 10 without any alterations in the BRCA genes (BRCA-wt). Whole exome sequencing (WES) and total RNA-seq was performed to determine the association of homologous recombination (HR) DNA repair gene defects with tumor mutation burden (TMB), neoantigen load (NL), and immunological assessment of tumor microenvironment. TMB was calculated from mutation rates of somatic WES. Germline exome analysis was used to validate inherited BRCA mutations. To identify the somatic mutations, somatic single nucleotide variants and InDels were detected using Strelka. TP53 mutations were most common with several other genes showing only modest mutation frequency. Mutation signatures were also detected with maftools and compared to the COSMIC mutational signature database. BRCA-mutated samples displayed a unique mutational signature associated with defects in HR DNA repair pathway. We also observed heterogeneity in copy number variation profiles amongst cases, as determined by the tool Sequenza. Furthermore, gene set enrichment analysis indicated differential enrichment of P53 pathway, MAPK pathway, and PTEN pathway, in addition to numerous pathways related to immune cell signaling and immune response. RNA-seq data was analyzed with CIBERSORTx and revealed different proportions of 22 immune effector cell types that accompany tumor cells within the HGSC microenvironment. Additional analyses are underway, including measuring differences in NL in BRCA-mutated versus BRCA-wt cases. This work will represent a significant advancement in our fundamental knowledge regarding the complexities of the TME and effective immunological responses in OvCa.

Extensive epigenetic and transcriptomic donor-specific differences observed in iPSC derived allogenic NK (iNK) cells

Rohith Srivas, Snehal Nariya, Melissa Rojsza, Barry A. Morse, Ohad Manor, Rupesh Amin, Luis Borges. *Century Therapeutics, Seattle, WA*

Several autologous CAR-T cell therapies have been approved for the treatment of B cell lymphomas and leukemias and a number of trials are in progress to investigate the use of allogeneic, donor derived CAR-T and CAR-NK cell therapies for multiple tumor indications. However, sourcing cell donors, editing cells and generating large batches of clinical grade allogeneic CAR-T and CAR-NK can be challenging. To overcome these difficulties, we are developing NK and T cell-based therapies derived from induced pluripotent stem cells (iPSCs). iPSCs have the capacity to be genetically engineered, enabling precise edits that can enhance the function of cell therapies, and indefinitely expanded in culture, allowing for the production of highly uniform master cell banks. Yet, an open question of this system is the extent to which the donors' genetic background shapes the phenotype of the iPSC-derived NK and T cells. To answer this question, we measured the genome-wide landscape of chromatin accessibility and gene expression in iNK cells generated from multiple donors. Donor background was linked to significant changes in chromatin accessibility (~30% of regions tested) and expression (~15% genes). We found accessibility changes at binding sites for transcription factors regulating various aspects of NK cell function, including differentiation (GATA2, EOMES, and ETS1), activation (AP-1, T-bet), and cytokine production (STAT3, STAT5), indicating that the donor background could impact the functionality of iPSC-derived NK cells. In particular, we noted that iNK cells derived from one donor, which had decreased effector functions compared to other cell lines, showed increased accessibility at BACH2 binding sites, a key negative regulator of NK cell function. iNK cells derived from this donor also showed an increase in expression of genes linked to NK cell differentiation and cell development, and a decrease in genes involved in cell cycle, cell proliferation, and inflammatory response pathways. Taken together, these data indicate the importance of assessing the impact of donor background on iPSC derived cell therapies through a variety of functional and genomic assays.

The Osteosarcoma and Leiomyosarcoma Count Me In Projects of the Cancer Moonshot funded PE-CGS Network directly engage patient participants in genomics research

Katherine A. Janeway[1], Suzanne George[1], Corrie Painter[2], Carrie Cibulskis[2], Taylor Cusher[2], Jordan Doucette[2], Elana Anastasio[2], Benjamin Zola[2], Ashley Mathews[2], Evelina Ceca[1], Maeve Smart[1], Beena Thomas[2], Jason Hornick[3], Alanna Church[4], Lorena Lazo De La Vega[1], Jill Stopfer[1], Sidney Benich[1], Ellen Sukharevsky[1], Sarah Winnicki[2], Brendan Reardon[1], Brian Crompton[1], Priscilla Merriam[1], Adrian Marino-Enriquez[3], Diane Diehl[2], Eliezer VanAllen[1], Judy Garber[1], Gad Getz[2], Stacey Gabriel[2], Timothy Rebbeck[1], Jennifer Mack[1], Nikhil Wagle[1]. *[1]Dana-Farber Cancer Institute, Boston, MA,[2]Broad Institute, Cambridge, MA,[3]Brigham and Women's Hospital, Boston, MA,[4]Boston Children's Hospital, Boston, MA*

Osteosarcoma (OS) and Leiomyosarcoma (LMS) are sarcomas with complex genomes for which there has been limited progress in identifying new treatments and improving outcomes. Slow progress in OS and LMS is partially due to insufficient characterization of the genomic landscape. Generating large genomic datasets in OS and LMS is challenging because of the rarity of these sarcomas and recruitment barriers such as care fragmentation between institutions and specialties. The OS and LMS Project research studies aim to: 1) establish a network of engaged pediatric and adult participants with OS and LMS who will co-create a shared database of clinical, genomic, molecular, and patient reported data to enable research; 2) define the clinicogenomic landscape of OS and LMS; and 3) optimize the approach to direct patient engagement in cancer research. Count Me In, a research initiative with prior success in angiosarcoma, working with patients and advocates created websites (OSProject.org and LMSProject.org) where patients register and consent to participation. Within two months of launching, 233 patients age 6-79 from 149 Institutions have consented. Blood and saliva are collected from consented participants, tumor samples are obtained from pathology departments and medical records are requested from treating hospitals. WES and WGS of tumor and normal, and RNASeq of tumor is performed. ctDNA is obtained and sequenced. Results are shared with patient, advocacy, physician and

research communities in several ways. Individual participants receive a shared learning report describing the somatic variants identified in their tumor from paired tumor-normal WES and are offered genetic counseling and clinical germline testing. Registered participants receive updates via email and Project websites. There are regular pre-publication data releases to the genomic data commons and to cBioPortal. A physician engagement committee meets regularly to discuss clinical insights and conundrums from shared learning reports and germline testing. Patient accrual over the next 3 years is anticipated to result in sequencing of 750 tumor-normal pairs and 500 ctDNA samples.

Molecular profile by next generation sequencing in papillary thyroid carcinoma, Colombian Cohort at Fundacion Santa fe de Bogota University Hospital

Paula Rodriguez[1], Sebastián González[2], Sergio Cruz[1], Yesith Juez[3], David Becerra[4], Margarita Baldión[1], Sandra Perdomo[5], Angela Beltran[5], Jose Hakim[6], Deyanira Gonzales[7]. *[1]Pathology Department, Fundación Santa Fe de Bogotá Univ. Hosp., Bogotá, Colombia, Colombia,[2]Pathology Department, Fundación Santa Fe de Bogotá Univ. Hosp., Bogotá, Colombia,[3]Facultad de Ingeniería, Universidad de los Andes, Bogotá, Colombia, Colombia,[4]Pathology Department, Universidad Nacional de Colombia, Bogotá, Colombia, Colombia,[5]Faculty of Medicine, Universidad el Bosque, Bogotá, Colombia, Colombia,[6]Head and Neck Surgery, Fundación Santa Fe de Bogotá Univ. Hosp., Bogotá, Colombia, Colombia,[7]Endocrine Division, Fundación Santa Fe de Bogotá Univ. Hosp., Bogotá, Colombia, Colombia*

Objective/ aim: To describe the main molecular alterations in a Colombian Cohort of patients diagnosed with Papillary Thyroid Carcinoma (PTC) at Fundacion Santa Fe de Bogota University Hospital between 1993 and 2011 Methods: A total of 231 surgically intervened patients at our institution and diagnosed with PTC with available paraffin blocks were analysed. DNA and RNA extraction was performed from FFPE samples using Quick-DNA & RNA FFPE MiniPrep Kit (Zymo Research). Next Generation Sequencing analysis was performed using SOPHiA Solid Tumor Solutions Kit

(SOPHiA GENETICS, Saint Sulpice, Suiza) , which detects 42 DNA genes and 137 fusion genes with the platform MiSeq System (Illlumina, San Diego, California). Data underwent QA and QC and variants were analysed through Sophia commercial pipeline for somatic aberrations.
Results: Among 231 patients, 82% were women, average age 45 +/- 13 y-o, 97% from Colombia, with institutional pathologic diagnosis of PTC. The most frequent histological subtypes were Classic PTG (33%), Follicular Infiltrative (29%) and Tall cell (23%). Identification of clinically relevant molecular alterations was done (see table 1). The most frequent SNV mutations were BRAF-V600E (72%), TP53 (9%) and IDH1-R132H (8%). The most frequent insertions or deletions (INDELS) were found in KIT (75%). We identified 8 fusion genes (most frequent were RET-CCD6 and ETV6-NTRK3). Interestingly, we detected 3 MSI positive cases.
Conclusions: PTC molecular profile by NGS can allow us to improve molecular understanding of the disease and identify possible prognostic factors and treatment targets.

PALB2 germline mutations in a large cohort Middle Eastern breast-ovarian cancer patients

Rong Bu, Abdul K. Sira, Sandeep Kumar Parvathareddy, Kaleem Iqbal, Saud Azam, Zeeshan Qadri, Maha Al-Rasheed, Wael Haqawi, Mark Diaz, Ingrid G. Victoria, Khawla S. Al-Kuraya. *Human Cancer Genomic*

Research, King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

Background: The *PALB2* gene encoding protein is involved in the homologous recombination repair pathway and plays an important role in maintaining genomic integrity. *PALB2* heterozygous pathological variants (PV) or likely pathogenic variants (LPV) are associated with increased risk of breast and ovarian cancer. However, the prevalence and clinicopathological association of *PALB2* germline PV/LPV in Middle Eastern breast and ovarian cancers is not fully identified.
Purpose: We retrospectively screened a cohort of 918 cancer patients (791 breast cancer and 127 ovarian cancer) from Saudi Arabia using targeted capture-based next generation sequencing (NGS) method for *PALB2* germline variants regardless the family history of these patients or the presence of other hereditary cancer susceptibility genes mutations. Clinicopathological criteria were also fully analyzed.
Results: Five heterozygous PVs or LPVs were identified in six cases, accounting for 0.65% (6/918) of entire cohort. Two cases (33.3%) harbored PVs and four cases (66.7%) carried LPVs. Four PVs/LPVs (80%) were frameshift along with one novel splicing LPV (c.2835-1 C>A). One recurrent LPV (c.3425delT) was identified in two cases. All six affected carriers have breast cancer diagnosis with median age of 39.5 years (range 34-49 years). Only two cases (33%) have documented family history of cancer. Breast cancer phenotype was invasive ductal unilateral cancer in all cases with 66.7% of hormone receptor positive and 16% of triple negative tumors.
Conclusion: Germline PVs/LPVs in the *PALB2* gene were observed in low frequency of 0.65% in Saudi breast and/or ovarian cancer. Our study confirms one recurrent LPV and one novel LPV in Saudi breast cancer patients.

#6087

Mutation and co-mutation landscape of*ERBB2* alterations in advanced NSCLC

Lingzhi Hong[1], Leylah Drusbosky[2], Yinyi Wang[3], Yuanyuan Xiong[4], Rongrong Chen[4], Simon Heeke[1], Monique B. Nilsson[1], Jianjun Zhang[1], John V. Heymach[1], Xiuning Le[1]. *[1]The University of Texas MD Anderson*

Cancer Center, Houston, TX,[2]Guardant Health, Redwood City, CA,[3]Peking Union Medical College Hospital, Beijing, China,[4]Geneplus-Beijing Institute, Beijing, China

Background: *ERBB2* (*HER2*) insertions and point mutations are oncogenic drivers in non-small cell lung cancer (NSCLC) and now has approved targeted therapy for this patient population. Here, we present the landscape of *ERBB2* genetic alterations (alts) and co-mutations, and the comparison between ERBB2 and EGFR exon 20 insertions in NSCLC.
Methods: Two large retrospective cohorts were analyzed. In the Geneplus (China) cohort, 1,281 newly diagnosed NSCLC patients (pts) harboring *ERBB2* alt were analyzed based on tissue and/or ctDNA. In the Guardant360 (Guardant Health, Redwood City, USA) cohort, 1719 ctDNA profiles of newly diagnosed NSCLC samples harboring *ERBB2* alts were evaluated, with clonal alterations defined as those with ≥50% ratio of the maximum somatic variant allele fraction.
Results: In the Geneplus cohort of 1,281 pts with *ERBB2* alts, 55% were female with a median age of 58 years. *ERBB2* mutations or insertions were identified in 930 pts, *ERBB2* amplification(amp)-only in 351 pts, with mutation and co-amp at 7.5%. Most common alterations were in the tyrosine kinase domain exon 20 (85%), with Y772_A775dupYVMA to be the most frequent (57.4%), followed by G776delinsVC/LC/VV/IC (10.6%), and S310X (10.4%). *EBRR2*-mutation NSCLC were frequently having PDL1<1% (63%) and low TMB (mean 3.5). *TP53* and *EGFR* were most frequent co-mutations. *CDK12* amp was frequently co-occurring with *ERBB2* amp as both were located to Chr17q12. In the Guardant360 cohort, 54% were female with a median age of 70 years. 634 had COSMIC/OncoKB annotated oncogenic mutations. Similar to Geneplus, Y772_A775dupYVMA (39.4%), S310F (10.7%), G776delinsVC/LC/VV (9.7%) were the most common alterations. Using Y772/G776/G778 insertion as the control, a clonality cut-off of 50% had a positive prediction value of 87.5%. When this clonality cut-off was applied to all the other variants of unknown significance (VUS), 335 (19%) samples had clonal mutations with S335 (n=9), D277Y (n=6), R499W (n=4), and G222C (n=4) being most frequent. Comparison between ERBB2 Exon20 (n=370) to EGFR (ERBB1) exon20 insertions (n=323) showed a different distribution of patterns with greater heterogeneity in EGFR exon20 insertions.

Conclusion: In two large independent cohorts, Chinese and Western, *ERBB2* mutation and co-mutation patterns were similar. *ERBB2* exon 20 insertions/mutations were dominant at over 80% with Y772_A775dupYVMA being the most common driver mutation; *TP53* and *EGFR* were the most frequently co-occurred genes. *ERBB2* mutation lung cancers had low TMB and PDL1, as expected in female dominant lung adenocarcinomas, similar to EGFR exon 20 NSCLC. Clonal VUSs may represent a novel subset of mutations to functionally characterize.

#6088

Charting new cancer dependencies with patient derived organoids

James V. Neiswender[1], Lisa Brenan[1], Tate Bertea[1], Jimmy Guo[2], Ashley Anderson[1], Megan Wong[1], Zoe Posner[1], Kevin Kapner[2], Connor Hennessey[2], Sarah Wie[1], Isabella Boyle[1], Barbara De Kegel[1], Joshua Dempster[1], Yuen-Yi (Moony) Tseng[1], David Root[1], Andrew Aguirre[2], Francisca Vazquez[1]. *[1]Broad Institute, Cambridge, MA,[2]Dana Farber Cancer Institute, Boston, MA*

The number of patients benefiting from precision cancer medicine (PCM) is very limited. The Cancer Dependency Map Initiative aims to dramatically accelerate PCM by systematically identifying the landscape of cancer vulnerabilities across all tumors. Genome-wide knockout screens have been performed in over 1000 cancer cell lines, but these have been sourced from historically derived models, leaving many cancers underrepresented. Advances have been made in model derivation by growing cells in 3D formats, such as organoids or spheroids. These models present an opportunity to screen new cancer types, but come with challenges that require a new pipeline. Here, we present a set of screens using a genome wide CAS12 library in organoid tumor models representing novel subtypes of pancreatic, esophageal, and gastric cancer, along with treatment-resistant breast, ovarian, and prostate cancer organoids. We show that genome-wide screening of these models is feasible and can be achieved with quality comparable to 2D cell lines. Our work uncovered a set of novel dependencies associated with cell-ECM interactions that have not previously been identified in 2D models. Our methods provide a framework for screening future patient derived 3D culture models and discovering vulnerabilities in new tumor types.

Identification of novel YAP/TAZ pathway regulators in the triple-negative breast cancer cell line MDA-MB231 using single-cell CRISPR screening

Mareike Berlak[1], Zuzanna Makowska[1], Filippos Klironomos[1], Julia Kuehnlenz[2], Atanas Kamburov[2], Andreas Steffen[2], Martin Lange[3], Barbara Nicke[3], Ralf Lesche[1], Peter Staller[1], Charlotte Kopitz[3], Jan Naujoks[1].
[1]Functional Genomics, NUVISAN ICB GmbH, Berlin, Germany,[2]Bayer AG, Berlin, Germany,[3]NUVISAN ICB GmbH, Berlin, Germany

The Hippo signaling cascade is a major pathway that integrates a broad spectrum of mechanosensory signals at the plasma membrane and regulates response via control of cell proliferation, self-renewal, differentiation, and apoptosis. Dysregulation of this pathway has been observed across a range of cancer types and results in an altered activity of its primary downstream effectors, the oncogenic transcription factors YAP/TAZ. For example, both germline and somatic loss-of-function mutations in the tumor suppressor gene *NF2,* a component of Hippo, induce hyperactivation of YAP/TAZ, transcriptional changes and ultimately result in tumor growth. The Hippo signaling pathway is an attractive target for drug discovery efforts, however, it is highly complex and still incompletely understood. Hence it is indispensable to get a deeper insight into the Hippo - YAP/TAZ signaling axis. To this end, we performed a genome-wide CRISPR knockout screen in the triple-negative breast cancer (TNBC) cell line MDA-MB231 ($NF2^{LOF}$) expressing a YAP/TAZ reporter construct. We identified both negative and positive regulators of YAP/TAZ in breast cancer cells. In a second step, screening hits were further characterized in a focused single-cell CRISPR screen (Perturb-Seq), aiming at better understanding of the effects on YAP/TAZ activity regulation and downstream effects on gene expression. Here we present the technical details of our screening approaches and the results of perturbing known and novel regulators of YAP/TAZ on single cell level. We discuss the use of Perturb-Seq in the initial validation of hits from genome-wide screens and provide data that may serve as a basis for future drug discovery efforts, seeking for novel and effective treatments for triple-negative breast cancers and other malignancies with Hippo pathway alterations.

Targeting DNA Damage Response and Novel Pathways

#6093

IDE161, a potential first-in-class clinical candidate PARG inhibitor, selectively targets homologous-recombination-deficient and PARP inhibitor resistant breast and ovarian tumors

Monah Abed, Diana Muñoz, Vidya Seshadri, Steve Federowicz, Arjun A. Rao, Deepthi Bhupathi, Marya Liimatta, Rita Ousterhout, Firoz Jaipuri, Claire Neilan, Mark Lackner, Mike White, Zineb Mounir. *Ideaya Biosciences, South San Francisco, CA*

Poly (ADP-ribose) polymerase inhibitors (PARPi) were the first clinically approved drugs designed to exploit synthetic lethality. Despite initial responses, patients harboring homologous recombination (HR) alterations that receive PARPi develop treatment resistance, which has generated a need for additional therapies targeting homologous recombination deficient (HRD) tumors. Poly (ADP-Ribose) glycohydrolase (PARG) plays a key role in the resolution of PARP1/2-dependent DNA damage repair through hydrolysis of Poly (ADP-ribose) (PAR) chains and consequent release of DNA repair protein complexes from chromatin. In culture, the accumulation of PAR chains in the absence of a functional PARG enzyme causes delayed repair of DNA breaks resulting in increased sensitivity to alkylating agents and ionizing radiation. Notably, some HRD cell models have shown differential sensitivity to PARGi vs PARPi, suggesting that PARGi may overcome some PARPi resistance mechanisms. The ability of PARGi to exacerbate replication deficiencies nominates it as a potential therapeutic target for a broad range of cancer types with genomic instability. IDE161 is an orally bioavailable small molecule inhibitor of PARG. Biochemical and cellular assays demonstrate that IDE161 is a potent inhibitor of PAR chain hydrolysis and has anti-proliferative activity in breast and ovarian HRD cancer cell lines with both inherent and acquired PARPi resistance. IDE161 anti-proliferative effects were associated with induction of mitotic arrest and activation of the DNA damage response pathway, suggesting the position of PARG in the DNA repair cycle remains essential in the context of some PARPi resistance mechanisms. Furthermore, profiling of IDE161 across a panel of 264 molecularly

characterized cancer cell lines indicated that PARGi may show benefit beyond HRD and in indications other than ovarian and breast. Nonclinical studies in cell line and patient derived xenograft models of breast, ovarian, and gastric tumor types harboring defects in the HR pathway demonstrated anti-tumor activity in response to IDE161. Consistent with *in vitro* findings, we observed IDE161 antitumor activity in PARPi resistant xenograft models. Moreover, studies in cell lines, tumors and tissues revealed that dose and time-dependent accumulation of PAR chains serves as a robust proximal pharmacodynamic biomarker indicative of PARG target engagement. IDE161 is a novel targeted therapy that exploits the synthetic lethal relationship between PARG and genomic instability, thus leading to selective anti-proliferative effects in tumors harboring defects in the HR pathway.

#6094

Longitudinal analysis of PARP inhibitor and platinum resistance in *BRCA1/2m* breast cancer using liquid biopsy

Elizabeth Harvey-Jones[1], Maya Raghunandan[1], Luisa Robbez-Masson[1], Alaguthurai Thanussuyah[2], Roberta Liccardo[2], Arielle Yablonovitch[3], Mingyang Cai[3], Leylah Drusbosky[3], Michael Dorschner[3], Lorena Magraner Pardo[1], Rebecca Marlow[1], Asha Konde[1], Jennifer Trendell[2], John Alexander[1], Syed Haider[1], Chris Starling[1], Ioannis Roxanis[1], Jennifer Yen[3], Stephen J. Pettitt[1], Christopher J. Lord[1], Andrew N. J. Tutt[1]. *[1]Breast Cancer Now Toby Robins Research Centre, The Institute of Cancer Research, London, London, United Kingdom,[2]Breast Cancer Now Research Unit, King's College London, London, United Kingdom,[3]Guardant Health Inc., Redwood City, CA*

Background: Assessing how clinical resistance to PARP inhibitors develops has been challenging, due to the lack of coverage of potential resistance genes in sequencing panels and biopsies being subject to spatial heterogeneity. We studied the development of PARPi and/or platinum resistant disease using both tissue and a novel liquid biopsy assay, in patients treated for BRCA1/2-mutated metastatic breast cancer (BRCA1/2m mBC).

Approach: A cohort of 35 mBC patients with germline or somatic *BRCA1*/*2* mutations were identified as having developed PARPi or platinum resistant disease. Tumour biopsies were analysed by exome and transcriptome sequencing whereas ctDNA isolated from plasma sampled across the pre-treatment, response and eventual progression journey were analysed using the Guardant INFINITY platform equipped to detect mutations in >800 genes, and genome wide methylation, including promoter methylation in 398 cancer-related genes. Somatic mutations or regions of methylation that were associated with resistance were identified, including *BRCA1/2* reversion mutations. Somatic mutations with the potential to cause PARPi resistance were annotated using CRISPR screen data and other functional analyses describing genes that alter PARPi synthetic lethality.
Results: The most common resistance mechanism was BRCA1/2 reversion mutation (51%; n=8 *BRCA1*m patients*, n*=10 *BRCA2*m patients). Most reversions (77%) occurred via deletions (*BRCA1*, 70%; *BRCA2,* 79%) and exhibited microhomology use at junctions (> 80% for both *BRCA1* and *BRCA2*). In 14 patients, multiple concurrent reversion mutations were detected with VAFs ranging from 0.1-40% for *BRCA1* and 0.05-18% for *BRCA2*. Changes in VAF over time indicated that different reversions in the same patient may impart different fitness advantages in the face of treatment. Loss-of-function mutations in the 53BP1-Shieldin pathway were identified in two *BRCA1*m patients, and VUS mutations in the pathway were seen in two further patients. In some patients, reversion mutations co-occurred with either 53BP1-Shieldin pathway mutations or with replication fork stability mutations (*PAXIP1* in *BRCA2*m patients) - indicating concurrent but mechanistically distinct forms of resistance develop in the same patient. We isolated a PDX model from one patient that exhibits resistance via both BRCA1 reversion and loss of 53BP1, allowing this phenomenon to be modelled in more detail. We also detected *BRCA1* methylation in ctDNA in a patient with a somatic rearrangement in *BRCA1*.
Conclusions: Liquid biopsy profiling of PARPi-resistance breast cancer patients indicates that many patients develop multiple reversion mutations, and that alterations in the 53BP1-Shieldin pathway are present but less frequent. The co-occurrence of 53BP1-Shieldin pathway mutations and reversion mutations suggests parallel mechanisms of resistance can operate in the same patient.

#6095

A DNA damaging agent affects *BRCA2* exon 3-skipping

Jordan R. Werner[1], Hiba Siddiqui[1], Ethan Castillo[2], Mohammed Ansari[1], James D. Fackenthal[1]. *[1]Biological Sciences, Benedictine University, Lisle, IL,[2]Biology, Elmhurst University, Elmhurst, IL*

Introduction: *BRCA2* is a tumor suppressor that participates in DNA repair. Inherited pathogenic mutations in *BRCA2* are associated with a 38%-84% risk for breast cancer and a 16.5%-27% risk for ovarian cancer. *BRCA2* exon 3, which encodes a binding site for the interacting proteins EMSY and PALB2, is frequently skipped during alternative splicing events, often due to spliceogenic mutations, but also for as yet uncharacterized environmental conditions. A genomic deletion that results in complete allelic loss of exon 3 has been shown to be pathogenic, yet sequence variants that result in increased frequency of exon 3-skipping have been shown to be non-pathogenic. Thus, the allele-specific ability of *BRCA2* to contribute to DNA repair is affected by the level of exon 3-skipping. In this study we explore the effects of the topoisomerase inhibitor doxorubicin on the frequency of *BRCA2* exon 3-skipping. Isoform-specific end-point RT-PCR shows that doxorubicin increases the frequency of *BRCA2* exon 3-skipping in the breast cancer cell line MCF7 at concentrations below those required for promoting apoptosis.

Methods: MCF7 cells were treated with doxorubicin according to standard protocols. IC_{50} levels of doxorubicin were determined using a crystal violet assay. Flow cytometry was performed using standard protocols. RNA was prepared using Qiagen reagents and amplified with Invitrogen One-Step RT-PCR reagents. Isoform-specific RT-PCR primers were designed to amplify the full-length region surrounding *BRCA2* exon 3 independently from the region left by an exon-skipping event (Δ3). RT-PCR products were visualized using agarose gel electrophoresis.

Results and Conclusion: Results suggest that doxorubicin increases the level of *BRCA2* exon 3-skipping in MCF7 at concentrations below those required for promoting apoptosis. This suggests doxorubicin may compromise the DNA repair functions of *BRCA2* and other alternatively spliced mRNAs, which may contribute to the therapeutic benefits and/or toxicity of the drug.

#6096

BRCA1-BARD1 ubiquitylates histones for genome maintenance

Wenjing Li[1], Samuel R. Witus[2], Meiling Wang[1], Peter S. Brzovic[2], Rachel E. Klevit[2], Weixing Zhao[1]. *[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Department of Biochemistry, University of Washington, Seattle, WA*

Background: Breast cancer type 1 susceptibility protein (BRCA1) is a tumor suppressor gene involved in DNA double strand break repair with well-known cancer implications. BRCA1 heterodimerizes with BRCA1 associated Ring domain 1 (BARD1) to form a complex with DNA binding and ubiquitin E3 ligase function capable of interacting with proteins of diverse biological processes, most notably homology-directed DNA repair. During DNA repair, BRCA1-BARD1 directly interfaces with nucleosomes and transfers mono ubiquitin (Ub) to lysine residues on the C-terminal tail of histone H2A. Although truncation of the enzymatic BRCA1-BARD1 RING-RING domain retains H2A ubiquitylating activity, full-length BRCA1-BARD1 binds more tightly with nucleosomes and displays higher H2A-Ub activity. However, the molecular basis and biological significance for this enhanced nucleosome binding and H2A-Ub activity is uncharacterized.

Methods: Full length BRCA1-BARD1 or truncated mutants and histones were purified from E. coli. or insect cells. Nucleosomes were assembled for *in vitro* ubiquitylation reaction and binding assays. To determine the biological significance, mammalian cell lines that stably express wild type or mutant forms of BARD1 were established for cellular fractionation, foci analysis, and clonogenic survival studies alongside various DNA damage agents.

Results: Our results show multiple interaction sites exist between BRCA1-BARD1 and nucleosomes which allow high-affinity chromatin binding and promote increased histone H2A ubiquitylation activity. Multivalent BARD1-nucleosome interactions, namely those using strong binding motifs located in the intrinsically disordered region (IDR) of BARD1, and the weak “kiss” interaction mediated by the RING domains of both BRCA1 and BARD1, are essential for H2A ubiquitylation by BRCA1-BARD1. Further, we isolated two types of specific histone binding and/or ubiquitylation-defective mutants of BARD1: a BARD1-IDR mutant with

disrupted nucleosome binding withe retained H2A ubiquitylation ability, and a RING mutant that solely impairs H2A ubiquitylation. In both cases, we demonstrate that these mutants are hypersensitive to DNA damage agents, including polyADP-ribose polymerase (PARP) inhibitors, and demonstrate reduced capacity of BARD1 to associate with chromatin and foci formation owing to attenuated repair capacity.
Conclusion: Our studies provide convincing evidence BRCA1-BARD1 interacts with nucleosomes and ubiquitylates histones via its E3 ligase activity. Further, it plays a critical role in DNA damage response and repair that contributes to genome stability, which when disrupted sensitizes them to DNA damage agents. Our results open new avenues towards understanding whether and how these mutations in BRCA1-BARD1 affect its tumor suppression functions and their implications clinically, ultimately with the goal to translate these findings for the benefit of cancer patients.

Determination of *BRCA2* deletion status by copy number estimation using next generation sequencing to predict prognosis of clinically localized prostate cancer

Makoto Sumitomo[1], Takuhisa Nukaya[1], Eiji Sugihara[1], Mayu Takeda[1], Sachio Nohara[2], Shigeki Tanishima[2], Masashi Takenaka[3], Kenji Zennami[3], Kiyoshi Takahara[3], Ryoichi Shiroki[3], Hideyuki Saya[1]. *[1]Fujita Cancer Center, Fujita Health University, Toyoake, Japan,[2]Department of Bio Informatics, Communication Engineering Center, Electronic System Business Group, Mitsubishi Electric Software Corp., Tokyo, Japan,[3]Department of Urology, Fujita Health University, Toyoake, Japan*

The significance of *BRCA* alterations has been implicated in the development of metastatic castration-resistant prostate cancer (PC). On the other hand, the details of the frequency and significance of *BRCA* alterations in localized PC remain unknown. In this study, we investigated the frequency and clinical significance of *BRCA* alterations in localized PCs using an in-house next-generation sequencer (NGS) system. NGS analyses revealed that the *BRCA2* CN decreased in 17 patients (13.5%) and the *BRCA1* CN in six (4.8%). NGS-based CN values were shown to be highly correlated with droplet digital PCR-based CN values. Tissue-specific BRCA expression investigated using the Human Protein Atlas showed that

the decreased CN of BRCA2, but not BRCA1, is responsible for the decreased BRCA activity in PC. Ten of the 22 patients with decreased *BRCA2* CN were presumed to have somatic heterozygous deletion. There were no observed associations between the heterozygous deletion of *BRCA2* and various clinicopathological parameters. Furthermore, three of 10 patients developed biochemical recurrence within 3 months after surgery. Multivariate analyses revealed that the initial prostate-specific antigen levels and *BRCA2* CN were independent factors for biochemical recurrence. Our results suggest that a decrease in *BRCA2* CN may be used as a biomarker for predicting recurrence after surgery in localized PC. Early screening for somatic alterations in *BRCA2* using NGS may help to broadly predict the risk of PC progression.

Genome wide CRISPR screen reveals genetic vulnerabilities of next generation PARP1 inhibitor AZD5305

Ling Yin[1], Junjie Chen[2]. *[1]Experimental radiation oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

The first-generation PARP inhibitors (PARPi) olaparib, niraparib, talazoparib and rucaparib have been clinically approved for several cancers, like breast, ovarian and prostate, especially in BRCA-mutant tumors which are of homologous recombination repair (HRR)-deficiency. All PARPi both target PARP1 and PARP2, causing cancer cell deaths deficient in HRR. However, only inhibition of PARP1 is required for synthetic lethality in HRR-deficient cells. AZD5305 is a highly selective PARP1 inhibitor which has been used in clinical trials. In this study, we used the Toronto Knock Out Library version 3 (TKOv3), which contains 70948 gRNAs targeting 18,053 protein-coding genes to perform whole-genome CRISPR-Cas9 screens with three isogenic cell lines 293A, MCF10A, and Hela to uncover known and new high-confidence genes synthetic lethal interacted with AZD5305. MAGeCK and Drug Z were used to analyze the results and genes were ranked according to their drugZ scores. We identify that in all three cell lines, PARP1 was in the top hit in positive selection which proves the AZD5305 indeed a PARP1 inhibitor. Moreover, through a

comprehensive and comparative analysis with the screen results of first generation PARPi olaparib, we reveal known and new essential genes which are proved to be a common mechanism for synthetic lethality. We identify the gene AUNIP (Aurora Kinase A and Ninein Interacting Protein), in the top hit from AZD5305 screen but not in olaparib screen, suggesting that AUNIP may be an additional target for synthetic lethality with PARP1 loss. Taken together, this screen reveals the potential molecular genes related with PARP1 inhibitor that can be further explored targeted and combined cancer therapy.

The Fanconi Anemia pathway protein complex FANCI/FANCD2 couples the DNA damage response to R-loop regulation through SRSF1-mediated mRNA export

Anne Olazabal-Herrero[1], Fengshan Liang[2], Arijit Dutta[3], Yuxin Huang[4], Zhuobin Liang[5], Abhishek Gupta[2], Yaqun Teng[6], Li Lan[6], Xiaoyong Chen[2], Huadong Pei[1], Manoj Pillai[2], Patrick Sung[3], Gary Kupfer[1]. *[1]Oncology, Georgetown University, Washington, DC,[2]Yale University, New Haven, CT,[3]University of Texas Health Science Center at San Antonio, San Antonio, TX,[4]Department of Biochemistry and Structural Biology, University of Texas Health Science Center at San Antonio, San Antonio, TX,[5]Shenzhen Bay Laboratory, Shenzhen, China,[6]Harvard Medical School, Boston, MA*

Background: Fanconi Anemia (FA) is a rare genetic disease characterized by bone marrow failure and cancer susceptibility. FA gene mutations are also widespread somatically in non-FA cancer patients. While the FA pathway participates in DNA repair, it is also linked to R-loop metabolism and regulation. R-loops are co-transcriptional RNA:DNA hybrids that form as a result of replication-transcription collisions that are enhanced due to DNA damage, but their aberrant formation drives genomic instability and is an endogenous source of genotoxicity. However, the interplay between FA proteins, DNA repair, and R-loops remains mechanistically ill-defined. Disturbance of mRNA processing, export, and splicing has also been linked to R-loop-mediated genomic instability. The splicing factor SRSF1 participates in mRNA export through the Nuclear Export Factor 1 (NXF1).

Aberrant splicing factors expression has been linked to R-loops, cancer, and myelodysplastic syndrome (MDS), which clinically resembles FA. In the present study, we study the coupling of the DNA damage response to the prevention of pathogenic R-loops via mRNA export regulation through the FA pathway and SRSF1.
Methods: Cells: FA-D2 mutant, corrected, and ubiquitin-dead mutant; HeLa. siRNA transfections to reduce SRSF1 and FANCD2 protein levels. Cell survival assays against DNA damaging agents. In vitro immunoprecipitation and ubiquitination assays using purified SRSF1 and ID2. DART assay, S9.6 immunofluorescence, and S9.6 slot-blot to measure R loops in cells. Immunoprecipitation of mRNPs used to detect mature mRNA-bound ribonucleoproteins. RNA FISH to measure mRNA export.
Results: In this study, we provide strong evidence that the FA pathway coordinates the prevention of R-loop formation and subsequent genomic instability through its interaction with splicing factors via regulation of mRNA export. First, we demonstrate that knockdown of SRSF1, which is known to result in increased R-loops, also is associated with diminished activation of the FA pathway. Second, the central FA complex ID2 binds to SRSF1 in cells and in recombinant protein assays. Further, we demonstrate that SRSF1 activates the FA pathway by binding ID2 and stimulates its monoubiquitination in an RNA-dependent fashion. This activity is associated with co-localization in cells at transcriptional-DNA damage inducible R loops. In turn, FANCD2 monoubiquitination proves crucial for the assembly of the SRSF1-NXF1 nuclear export complex and mRNA export. Importantly, cancer-associated SRSF1 mutants fail to interact with FANCD2, leading to inefficient FANCD2 monoubiquitination, decreased mRNA export and R-loops accumulation.
Conclusion: Our findings uncover a novel mechanism of FANCD2 and SRSF1 in the prevention of R-loop formation via coupling of mRNA export to the DNA damage response, thus preventing genomic instability.

PUM3 is a novel R-loop regulator and is essential for efficient DNA damage repair

Chenyu Lin[1], Jian Ouyang[2], Robert Wine[3], Chen Qiu[3], Jason Williams[3], Traci M. T. Hall[3], Lee Zou[2], Wayne Miles[1]. *[1]The Ohio State University College of Medicine, Columbus, OH,[2]Massachusetts General Hospital*

Cancer Center, Charlestown, MA,[3]National Institute of Environmental Health Sciences, Research Triangle Park, NC

R-loops have important roles in regulating transcription and genome integrity. To identify novel proteins that function to modulate DNA damage repair, we screened a library of CRISPR-engineered RNA binding protein knock-out cells. From this analysis, we found that a poorly characterized protein, PUM3, is important DNA damage repair and that PUM3-deficient cells were very sensitive the chemotoxic agents. We show that under normal conditions, PUM3 is localized to the nucleolus and nucleus, where it binds to R-loops and modulates transcription. In this setting, PUM3 functions to suppress/resolve R-loops and that *PUM3*$^{-/-}$ cells have elevated R-loop levels. Following DNA damage, PUM3 is rapidly re-localized from the nucleolus to sites of DNA damage in the nucleus by members of the DDX/DHX family of RNA-helicases. Using small molecule inhibitors and quantitative assays, we find that PUM3 functions in homologous recombination (HR) mediated DNA repair and that *PUM3*$^{-/-}$ cells have significantly reduced HR-efficiency. PUM3 function at sites of DNA breaks are not affected by transcription or R-loops, implicating PUM3 as functioning after DNA resection during DNA repair. Analysis of TCGA patient data shows that PUM3 levels correlate with Cisplatin resistance and patient outcome. Collectively, our data shows that PUM3 is a previously unknown regulator of R-loops and DNA damage repair that has an important role in chemotherapy sensitivity in cancer patients.

Targeting BARD1 slows PDAC growth in vitro and in vivo and sensitizes cells to DNA damaging agents

Sohum Patel, Anoohya Arkala, Avinoam Nevler, Carolyn Coats, Charles J. Yeo, Aditi Jain. *Thomas Jefferson University, Philadelphia, PA*

Pancreatic ductal adenocarcinoma (PDAC) is the most prevalent malignant neoplasm of the pancreas, responsible for over 90% of pancreatic cancer cases. Despite recent therapeutic advances, the five-year overall survival rate for PDAC is only 11% and therapies remain limited. It is now known that deficiency in DNA damage repair (DDR) renders PDAC cells vulnerable to certain DNA damage agents, for example, poly (ADP-ribose)

polymerase inhibitors (PARPi). Most of the DDR genes mutated in PDAC are crucial for the proper functioning of the homologous recombination repair (HRR) pathway, and loss-of-function alterations in DDR genes sensitize cells to DNA-damaging agents. Since this treatment strategy is currently limited to 5-10% of PDAC cases with known mutations in the DDR genes, it underscores a dire need to understand new therapeutic avenues and expand the PDAC patient population that could benefit from this therapeutic approach. We have recently published that BARD1 (BRCA1- Associated- Ring- Domain- 1), an obligate binding partner of BRCA1, is upregulated in PDAC cells exposed to PARPi/platinums. We found that transient inhibition of BARD1 rendered PDAC cells extremely sensitive to olaparib (PARPi)/oxaliplatin (platinum), and enhanced DNA damage. Based on these results, we created two genetic models of BARD1 inhibition and utilized these model systems to investigate if loss of BARD1 chemo-sensitizes PDAC cells to other PARPis and DNA damage agents. Doxycycline inducible shRNA and BARD1 CRISPR KO models were created to inhibit gene expression of BARD1 in PDAC cells. We first characterized these model systems to confirm the loss of BARD1 protein and mRNA expression by western blot and qRT-PCR analyses. Using colony formation and Pico green cell survival assays, we found that inhibiting BARD1 resulted in slower growth of pancreatic cancer cells in vitro. Moreover, expression of several cell cycle genes from G2-M phase was significantly decreased ($p=0.05$). These studies were recapitulated in a mouse xenograft subcutaneous model, where BARD1 KO and WT PDAC cells were injected subcutaneously and tumor growth was analyzed over 25-30 days. Kaplan-Meier curves were calculated and plotted using Log-rank test. We found that inhibiting BARD1 significantly ($p=0.026$) delayed formation of PDAC tumors in vivo. Next, we analyzed the efficacies of various DNA damaging agents when BARD1 was inhibited. Silencing or CRISPR KO of BARD1 enhanced efficacy of mitomycin C, irinotecan, as well as other PARPis, which are currently in clinical trials (rucaparib, veliparib) in vitro and lowered their IC50s. These results indicate that targeting BARD1 has the potential to benefit patients in terms of novel or improved treatments. Our ongoing and future studies will expand on these findings to understand BARD1-mediated pathway and evaluate sensitivity of multiple DNA damage agents by screening a library of > 250 compounds.

#6103

Genomic instability delays cell death in PDAC after simultaneous double strand breaks

Selina Shiqing K. Teh[1], Eitan Halper-Stromberg[1], Laura Morsberger[1], Kirsten Bowland[1], Alexis Bennett[1], Robert B. Scharpf[2], Ying S. Zou[1], James R. Eshleman[1]. *[1]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD*

Apoptosis, the main cell death mechanism triggered by double strand breaks (DSBs), occurs as quickly as 2-3 hours, or 6-24 hours *in vivo*. However, when we transduced Cas9-expressing pancreatic cancer (PC) cell lines with multi-target sgRNAs, in which each sgRNA contains 2-16 target sites in the human genome, we found that most of the reduction in sgRNA tag counts did not occur in the first 7 days post transduction, but rather occurred between days 7 and 21. We demonstrated that CRISPR-Cas9 scission occurs over the course of days in our PC cells and peaked at days 3-5, consistent with another recent observation. Thus, we hypothesized that the mechanism of cell death was likely not due to DNA damage response pathways that were immediately and directly triggered by the multiple scission events, but rather was caused by a slower process. To test this, we treated the Cas9-expressing TS0111 PC cell line with a 14-target sgRNA and performed cytogenetic analysis on cells harvested from 0-21 days after transduction at 3-4 day intervals using a chromosome breakage assay. We observed various karyotypic abnormalities, such as formations of ring, dicentric, and tricentric chromosomes. These abnormalities accumulated over time and peaked at day 14, except for the chromatid and chromosome breaks in which the frequency was maintained through day 21, suggesting ongoing occurrence of breakage events. Analysis of breakpoints on dicentric and tricentric chromosomes showed that although breakpoints at sgRNA targeted regions predominated at early time points and decreased over time, non-targeted regions increased and peaked at day 14. A break-apart FISH assay was also implemented to confirm that these structural variants (SVs) were a direct result of CRISPR-Cas9 cuts, in which the number of cells with abnormal FISH patterns increased over time and also peaked at day 14. Additionally, we performed bioinformatics analyses on

the whole genome sequencing data of surviving colonies post treatment of multi-target sgRNAs to identify novel SVs. We found that novel SVs increased as a function of the number of sgRNA target sites, and majority of the SVs were found at non-targeted sites, consistent with ongoing genomic instability. Interestingly, we found that cells responded to the 14-cutter by becoming polyploid, manifesting as extremely large nuclei or multinucleated giant cells. XY FISH showed that polyploidy peaked at day 10 and decreased by day 21. Finally, we assayed for apoptosis, which increased on days 7 and 14 but decreased by day 21. We concluded that cytotoxicity occurred following the induction of multiple DSBs that resulted in ongoing chromosomal rearrangements and polyploidization, ultimately leading to cell death via apoptosis and possibly other mechanisms.

Prognostic and therapeutic impact of a homologous recombination repair protein TONSL in cancer stem cells

Hani Lee[1], SeokGyeong Choi[1], Sojung Ha[1], Sukjoon Yoon[2], Woo-Young Kim[1]. *[1]Sookmyung Women's University, College of Pharmacy, Yongsan Gu, Korea, Republic of,[2]Sookmyung Women's University, Department of Biological Sciences, Seoul, Korea, Republic of*

Previously, we found that an important homologous recombination repair protein ‘Tonsoku Like, DNA Repair Protein’ (TONSL) might be required for glioblastoma cancer stem cell (CSC). In this study, we further investigated the role of TONSL in CSC from several cancer cell lines from different tissues. We also analyzed the clinical data available from the public databases to find the clinical impact of TONSL. The higher expression of TONSL is associated with the worse prognosis of lung and gastric cancer. Interestingly, in breast cancer, while its higher expression is also the negative prognostic marker of the luminal A and HER2 positive cancers, that is rather the positive prognostic marker for luminal B and basal cancers. TONSL expression is higher in all 4 subtypes of breast cancer, and ovarian cancer than the corresponding normal tissues. The knockdown of TONSL in an ovarian cancer cell line, OVCAR8, results in the increase of G2/M cells and apoptotic cells in the bulk cultured population while increase also the senescence cells only in the CSC

population leading to the severe loss of CSC population. TONSL and the close binding partner in homologous recombination repair (HRR), MMS22L, both were essential for the CSC growth but the bulk cultured cells could survive without those two in a colon cancer cell line, HCT15 suggesting the importance of HRR in colon CSC. Indeed, gemcitabine treatment induced DNA breaks showed a synergistic cytotoxicity with those two HRR factors knockdown in the CSC only. These results suggest that the TONSL and MMS2L mediated HRR is essential for the CSC and while most of bulk cultured cancer cells circumvent the HRR deficit. Collectively, these data showed that the CSCs ultimately depend on the HRR process which requires TONSL and, therefore, CSC population may be more vulnerable to HRR targeting therapeutic approaches.

#6105

Unravelling the mechanistic basis of chromoplexy, a mutational process driving early cancer genome evolution

Nataliia Serbyn[1], Myrthe M. Smit[1], Vimathi S. Gummalla[2], Gregory J. Brunette[1], David S. Pellman[3]. *[1]Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Pediatric Oncology, Dana-Farber Cancer Institute / Harvard Medical School / Howard Hughes Medical Institute, Boston, MA*

Genome evolution can happen gradually or via bursts of rearrangements. Chromoplexy is an example of a process driving rapid genome evolution. This mutational signature is detected in ~18% of human cancers (PCAWG Consortium, 2020) and is frequently observed in prostate adenocarcinoma, lymphoid malignancies, and thyroid adenocarcinoma. Chromoplexy is inferred to happen as one catastrophic event that generates copy-neutral chains of translocations involving multiple chromosomes (Baca *et al*., 2013). Existing studies of chromoplexy monitor the outcome of massive cancer genome reorganization, thus early molecular events leading to catastrophic chromosome rearrangements remain elusive. In this work, we aimed to recapitulate molecular mechanisms underlying chromoplexy. For this, we set out to establish a cell line model and use fluorescence-based reporter systems to enrich for and allow isolation of cells containing signatures of chromoplexy. We additionally address whether colocalization of multiple double-strand breaks, for example in transcription hubs or

abnormal nuclear structures, might stimulate chained inter- and intra-chromosomal translocations typical for chromoplexy. If successful, this work will provide a mechanistic understanding of an important mutational process driving rapid genome evolution in cancer, congenital disease, and potentially organismal evolution.

#6106

Epigenetic-miRNA regulatory circuit confers ovarian cancer chemoresistance through RAD18-mediated DNA damage tolerance and repair signaling

Tasmin Rahman Omy[1], Chinnadurai Mani[2], Komaraiah Palle[2], Mark Reedy[3]. *[1]Texas Tech University Health Sciences Center, Lubbock, TX,[2]Cell Biology and Biochemistry, Texas Tech University Health Sciences Center, Lubbock, TX,[3]Obstetrics and Gynecology, Texas Tech University Health Sciences Center, Lubbock, TX*

Epithelial ovarian cancer (EOC) is the deadliest gynecological malignancy. This cancer typically is not detected, 70-80% of patients, until an advanced stage (stage III-IV). The standard of care OC entails complete surgical resection of all visible abdominal-pelvic tumors, followed by platinum-based chemotherapy combined with a taxane. New recommendations for patients responding to adjuvant therapy is to include a PARP inhibitor with or without bevacizumab for maintenance therapy. Despite initial responses, the majority of stage 3 & 4 more than 70% of OC patients experience recurrent disease. Frequently, individuals become resistant to these treatments. This dreadful circumstance highlights the pressing need to identify the molecular mechanisms underlying the disease's aggressive nature upon recurrence and the development of treatment resistance. Several genetic and epigenetic factors have been linked to the reprogramming of tumor cells by controlling the pattern of transcriptional and post-transcriptional gene expression. Particularly, the miRNA-mediated regulatory circuit plays a significant role in tumor progression and therapeutic responses. Our analysis of miRNA expression signature in human ovarian cancer cell line panel showed little to no expression of miR221_5p and a corresponding increase in DNA damage response and repair gene RAD18 expression. RAD18 plays a critical role in cellular DNA damage tolerance and repair activity against chemotherapeutics,

including platinum drugs. Similarly, loss of miRNA221_5p is associated with aggressive tumor cell growth, stemness, chemoresistance to platinum drugs, and poor prognosis in several cancers. Based on this information, we have hypothesized that miR221_5p regulates RAD18-mediated DNA damage tolerance and repair and may offer novel therapeutic intervention to overcome EOC chemoresistance. Our experimental data confers that miR221_5p post-transcriptionally regulates RAD18 by binding to its 3'-UTR region and restores OC cell sensitivity to platinum drugs. Mechanistically, our results demonstrate that miRNA221_5p epigenetically regulates RAD18-mediated DNA damage tolerance and homologous recombination repair and could be a novel therapeutic to overcome OC chemoresistance. Collectively, our studies identify a novel chemotherapy-induced epigenetic modulator in OC therapeutic resistance and offer novel miRNA 221-5p-mediated therapeutic intervention for the treatment of chemoresistant OC and to prevent disease recurrence.

Novel roles for AMBRA1 in regulating DNA double-strand breaks

Yuning Jiang[1], Tarek Abbas[2]. *[1]Radiation Oncology, University of Virginia, Charlottesville, VA,[2]University of Virginia, Charlottesville, VA*

AMBRA1 (Activating Molecule in Beclin-1-Regulated Autophagy) is a tumor suppressor protein whose expression is downregulated in several human malignancies. AMBRA1 was recently found to function as a substrate receptor for the cullin-4-based ubiquitin ligase ($CRL4^{AMBRA1}$) that promotes the ubiquitin-dependent proteolysis of D-type cyclins (cyclin D1, D2 and D3); this serves to guard against premature S-phase entry and replication stress, providing a potential mechanism for its tumor suppressive activity. Cyclin D1 protein, which is stabilized, along with cyclin D2 and D3, in AMBRA1-deficient cells, has been shown to promote homologous recombination (HR) repair of DNA double-strand breaks (DSBs), suggesting that AMBRA1 may be additionally involved in the repair of DSBs. Using our recently published CRISPR-Cas9-based dual fluorescent reporter assay system, we show that while the loss of AMBRA1 increased D-type cyclins and Rb hyperphosphorylation as expected, it did, surprisingly, inhibit HR-mediated repair and stimulated error-free non-homologous end-joining (NHEJ), and that both of these new activities are

independent of cyclin D1 or RB1. High-throughput sequencing of DSB repair junctions confirm these results and shows significant depletion of indels with reduction in microhomology-mediated end-joining in AMBRA1-deficient cells, suggesting that AMBRA1 plays a role in promoting resection at DSBs. In support of this hypothesis, we found that the loss of AMBRA1 reduces RAD51 recruitment to DSBs in cells exposed to ionizing radiation. Consistent with its role in promoting HR, we found that AMBRA1-deficient cells are significantly more sensitive to PARP inhibitors compared to AMBRA1-proficient cells. In summary, we show that AMBRA1 is a novel regulator of DSBs, and that its downregulation in cancer cells and tumors render cancer cells susceptible to inhibition by PARP inhibitors.

#6108

Novel functional dSTRIDE-HR assays to report on the status of homologous recombination repair in cancer cells

Kamil Solarczyk, Agnieszka Waligórska, Karolina Uznańska, Zsombor Prucsi, Olga Wójcikowska, Ewelina Matuszyk, Magdalena Bartyńska, Agata Kitlińska, Aleksandra Bober, Franek Sierpowski, Maja Białecka, Monika Jarosz, Malgorzata Szczygiel, Szymon Koman, Karolina Korpanty, Lukasz Beben, Lukasz Bandzarewicz, Przemyslaw Stachura, Magdalena Kordon-Kiszala. *intoDNA, Kraków, Poland*

Since the early days of the synthetic lethality concept in DNA Damage Response the status of homologous recombination (HR) repair in cancer cells have been the focus of attention of researchers and clinicians. While different approaches exist, such as the RAD51 immunofluorescence (IF) or HRD genomic assays, functional biomarkers that can assess HR proficiency are missing. We report here the development, optimization and validation of two complementary, HR-specific functional assays. The assays, which are based on the STRIDE platform technology, detect double-strand DNA breaks localized in close proximity to RPA or RAD51 proteins. The optimization phase of assay development was performed in U2OS cells. First, repeatability (intra-run variation) and reproducibility (inter-run variation) of the assays were measured in untreated cells. Then, a series of technical negative controls was performed which have shown that the number of false-positive readouts is below 10% of the total number of

signals. Finally, treatment of cells with compounds known to induce double-strand DNA breaks (etoposide and cisplatin) resulted in statistically significant increase in the number of detected dSTRIDE-RAD51 and dSTRIDE-RPA foci when compared to untreated controls. The assays were further validated in NCI-H661 (BRCA2 wild-type) and NCI-H169 (BRCA2 KO) cell line pair. The cells were treated with two concentrations of etoposide and the readouts from dSTRIDE, detecting the total pool of DSBs and dSTRIDE-HR assays were compared. In NCI-H661 cells, treatment with etoposide resulted in an increase in the number of double-strand breaks detected by dSTRIDE and as expected, more DSBs were formed after treatment with the higher concentration. dSTRIDE-HR assays confirmed that approximately 15% and 10% of these DSBs contain RPA and RAD51 proteins, respectively. In NCI-H169 cells etoposide produced a stronger reaction with even more DSBs detected by dSTRIDE, but importantly, no increase in the number of dSTRIDE-RAD51 foci was observed. dSTRIDE-RPA foci increased after treatment hinting that this step of HR remains unperturbed. Interestingly, the number of dSTRIDE-RAD51 foci in untreated cells was comparable between the two cell lines. In conclusion, we show here that two newly developed dSTRIDE-HR assays are well validated and can be successfully applied to report on the status of homologous recombination repair in different cell models.

Multi-site evaluation of novel BRCA1/2 reference materials including large genomic rearrangements

Dana Ruminski Lowe, Benedicta Forson, Maria Cowen, Matthew G. Butler, Yves Konigshofer, Melissa Berenger, Krystyna Nahlik, Dianren Xia, Catherine Huang, Russell Garlick, Bharathi Anekella. *LGC Clinical Diagnostics, Gaithersburg, MD*

Mutations in the tumor suppressor BRCA1 and BRCA2 genes can cause cell damage that significantly increases the risk of developing breast, ovarian, prostate, and pancreatic cancers. Large genomic rearrangements (LGRs) are defined as deletions, duplications or insertions; often involving a significant portion of an exon. Usually pathogenic, they have been reported to account for up to 27% of the BRCA1 and 5% of BRCA2 disease-causing mutations with a strong founder effect accounting for about

1/3 of all cancer diagnoses in some populations. Accurate detection of a BRCA1/2 pathogenic variants has immense impact on clinical management of disease including eligibility for PARP inhibitor therapy. However, these LGRs are frequently missed by PCR-based methods and NGS assays that do not detect partial or complete exon losses or gains. Given the difficulty in detecting LGRs, there is a need for improvement of BRCA1/2 testing algorithms including reference materials that incorporate challenging LGRs to support NGS assays that analyze for these mutations.

Biosynthetic DNA constructs bearing clinically relevant BRCA1/2 variants including deletions up to 500 bp spanning 2 exons and duplications up to 170 bp, were mixed with purified genomic DNA from the GM24385 human reference cell line at 10% and 50% variant allele frequency (VAF) to represent somatic and inherited BRCA disease states, respectively. The same variants were engineered into GM24385 cells at the desired VAF (>5%) and the cells were formalin fixed and paraffin embedded using a proprietary method to mimic preserved tumor biopsies. In both materials, VAF was measured using digital PCR. The prepared purified gDNA and FFPE materials were sent to multiple clinical laboratories and analyzed using various NGS assays to assess variant detection performance and ensure that the product was compatible with clinical testing workflows. Digital PCR confirmed the presence of all 20 BRCA1 and BRCA2 variants within a 20% range of the target VAF in the purified gDNA material and between 11-23% in FFPE. NGS results were variable but confirmed the presence of most variants. A few variants were detected at very low levels but reported as not detected by the bioinformatic software due to limit of detection.

We have successfully developed a reference material to support both BRCA1 and BRCA2 inherited and somatic genetic testing, providing laboratories and assay developers with a tool to challenge and optimize their assay's detection and quantitation of pathogenic variants by NGS. Provided as full process in FFPE format or in purified gDNA, these reference materials include 11 challenging LGRs, which are useful in evaluating the ability of different NGS platforms to detect such variants. This study has highlighted the need for reference materials that contain these challenging genomic alterations to improve genetic testing and ultimately, support PARP inhibitor treatment selection.

#6110

Multi-site evaluation of FFPE homologous recombination deficiency reference materials

Dana Ruminski Lowe, Robert M. Whiting, Matthew G. Butler, Yves Konigshofer, Catherine Huang, Indira Chivukula, Krystyna Nahlik, Dianren Xia, Russell Garlick, Bharathi Anekella. *LGC Clinical Diagnostics, Gaithersburg, MD*

Homologous recombination deficiency (HRD) arises when defects in DNA repair pathways occur, leading to genomic instability. HRD status is an emerging therapeutic biomarker; NGS assays that measure it can be used to stratify ovarian and breast cancer patients and determine eligibility for clinical trials, and PARP inhibitor- and platinum-based therapies. Seraseq FFPE HRD reference materials were developed to cover a range of genomic instability scores (GIS) to help NGS HRD assay validation and development. Here we discuss a multi-site evaluation across various platforms of our high-positive, low-positive, and negative HRD reference materials.

Tumor cell lines were characterized by sequencing and evaluated in collaboration with several IVD partners. Three breast cancer cell lines (along with their SNP-matched normal cell lines) were selected based on their GIS. Tumor cells were blended with their SNP-matched normal cells to achieve ~65% tumor content. Biosynthetic DNA containing mutations in homologous recombination repair (HRR) genes (ATM, BRIP1, RAD51C, RAD51D) were added to the high-positive and negative reference materials targeted at >5% variant allele frequency (VAF) and measured by digital PCR. Formalin fixed paraffin embedded (FFPE) blocks were made and each block was tested for yield per curl using both the Qiagen QIAamp DNA FFPE Tissue Kit and the Maxwell RSC DNA FFPE Kit for extraction and Qubit dsDNA HS kit for concentration analysis. DNA quality was assessed using an Agilent gDNA ScreenTape Assay for the TapeStation. Whole genome shotgun sequencing was performed on extracted DNA using LGC NxSeq AmpFREE Low DNA Library Kit and Roche KAPA UDI adapters and Illumina NextSeq 2000 P1 flow cell. HRD status was evaluated by external collaborators with multiple NGS and microarray assays, including the Illumina TSO500 HRD RUO assay, the SOPHiA DDM HRD Solution and the OncoScan CNV Array.

A breast cancer cell line with a GIS of ~75 was selected as the HRD high-positive reference material, a second breast cancer cell line with a GIS of ~60 was selected as HRD low-positive, and a third breast cancer cell line with a GIS of ~30 was selected as HRD negative. Representative DNA yields per 10-micron section (determined using the HRD positive FFPE curls extracted by Qiagen QIAamp method) were 165 ± 28 ng/curl. Digital PCR confirmed the presence of the 8 HRR mutations (in 4 genes) at levels >5% VAF. GIS varied for each material across assays, but HRD status was consistent, confirming the wide applicability of the new reference materials. We have developed the Seraseq HRD reference materials to meet the needs of laboratories looking to analyze HRD in cancer patient samples. These reference materials facilitate standardization and quality control in HRD testing by clinical labs for current and new PARP inhibitor treatment stratification in expanded patient populations that may include those with WT BRCA1/2 genes.

Design of a small molecule screening assay to detect DNA trapping of PARP1/2

Kasia Zientara-Rytter, Veronique T. Baron, Junguk Park, Pavel Shashkin, Henry Zhu. *BPS Bioscience, San Diego, CA*

Poly(ADP-ribose) polymerase (PARP) inhibitors are currently used in the clinic for the treatment of tumors with a defective DNA damage response (DDR). When PARP1 or PARP2 binds damaged DNA, it adds poly(ADP-ribose) chains to its own backbone and to other DDR proteins, which recruits and activates them. PARylated PARP1/2 next detaches from the DNA so that the other PARylated proteins can initiate the repair process. It has been observed that some PARP inhibitors prevent PARP1/2 from dissociating the DNA. The continuous presence of PARP at the site of damage prevents repair and blocks replication, leading to cell death. Therefore, drugs that trap PARP1/2 to the DNA tend to be significantly more cytotoxic than other PARP inhibitors, which is highly desirable. This study describes the design and optimization of novel PARPtrap assays to specifically assess the ability of a drug to trap PARP onto DNA. The assay is based on principles of fluorescence polarization and uses fluorescently labeled DNA probes that are excited by polarized light and emit light with a

degree of polarization that is proportional to the rate of molecular rotation. The free DNA probes that rotate fast have low fluorescence polarization (FP), but high FP when are bound to PARP1 or PARP2. When NAD+ is added, the PARylated enzymes detach from the probe, reducing FP levels. If a PARP inhibitor is added, the inhibitor's trapping ability increases FP in a dose-dependent manner.Proof-of-principle titration of known PARP-trapping inhibitors (Talazoparib, AZD305, Olaparib and Veliparib) was performed to validate the assay. We observed that:i)The known relative trapping efficacies of Talazoparib, Olaparib and Veliparib were similar to known relative efficacies. ii)Talazoparib, Olaparib and Veliparib had similar trapping efficacy against PARP1 and PARP2, as measured by their EC_{50}, whereas AZD305 was 1,000 times more efficient at trapping PARP1 than it was PARP2, demonstrating selectivity between PARP1 and PARP2.iii)AZD305 displayed as efficient DNA trapping activity toward PARP1 as best-in-class Talazoparib. In summary, we have designed an innovative PARPtrap assay designed for the high throughput screening of small molecule libraries to specifically identify or compare inhibitors that are capable of trapping PARP1 and/or PARP2 onto DNA.

Automated scoring to assess RAD51-mediated homologous recombination in patient-derived tumor organoids of ovarian cancers

Lucie Thorel[1], Pierre-Marie Morice[1], Nicolas Elie[2], Louis-Bastien Weiswald[1], Romane Florent[1], Florence Giffard[1], Margaux Jacobs[1], Agathe Ricou[3], Raphaël Leman[3], Guillaume Babin[4], Jean-François Lebrun[4], Sandrine Martin[4], Mélanie Briand[1], Benoit Goudergues[1], Bernard Lambert[1], Cécile Blanc-Fournier[5], Dominique Vaur[3], Benoit Plancoulaine[2], Laurent Poulain[1]. *[1]Normandy University, UNICAEN, INSERM U1086 ANTICIPE (Interdisciplinary Research Unit for Cancers Prevention and Treatment), BioTICLA lab. Gynecological Surgery, Caen, France,[5]UNICANCER, Comprehensive Cancer Center François Baclesse, Department of Pathology, Caen, France

Extensive trials of PARP inhibitors (PARPi) have shown that they improve progression-free survival in patients with various cancers, including ovarian cancers. This improvement is marked in patients carrying *BRCA* mutations, and in Homologous Recombination Deficiency (HRD) subgroups. To date, identifying patients eligible for PARPi has been a challenge for scientific and clinical teams using next-generation sequencing (NGS) analysis and the persistence of genomic scars in tumors after restoration of proficient HR or epigenetic changes is a limitation of NGS. Functional assays could be used to improve the profiling of HR status and faithfully identify HRD tumors. The Repair Capacity Test assesses the formation of RAD51 foci in proliferating cells after irradiation and can be used on fresh primary cancer tissues irradiated *ex vivo* as well as on Patient-Derived Tumor Organoids (PDTO). However, RAD51 foci scoring is often performed manually without any possibility for the standardization of techniques. By contrast, recent progress in whole slide imaging referring to scan a complete microscope slide and creating a single high-resolution digital file, could represent an opportunity for automatizing the evaluation of HR. The purpose of this translational study was to develop an automated tool for scoring RAD51-mediated homologous recombination, to use this tool on ovarian PDTO and to compare the result to the sensitivity to olaparib (PARPi), determined by direct exposure of PDTO to the drug. We show that immunofluorescence of RAD51 foci can be automatically detected and quantified in Cyclin A2 positive nuclei in all the cells of each PDTO slice thus offering a new opportunity for the routine management and standardization of HR assessment in PDTO that goes beyond the widely used manual estimation. Finally, this automated scoring will be optimized to directly assess HR on tumor slices to make the Repair Capacity Test a highly relevant functional precision oncology tool to identify patients who will benefit from PARPi.

Predictive value of HRD testing on the response to PARP inhibitors in ovarian cancer preclinical models

Giulia Dellavedova, Alessandra Decio, Laura Formenti, Luca Porcu, Carmen Ghilardi, Raffaella Giavazzi, Maria Rosa Bani. *Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milano, Italy*

Since the introduction of Poly(ADP-ribose)polymerase inhibitors (PARPi) in the clinical practice, the search of biomarkers to distinguish homologous recombination defective tumors, eligible for PARPi therapy, has become a priority.Along with testing for BRCA mutations, commercially available tests, such as MyChoice® assay (Myriad Genetics), exploit scores calculated from genomic scarring patterns. Platinum sensitivity is also considered a surrogate marker of PARPi efficacy. However, the prognostic accuracy remains a challenge because these tests can only infer homologous recombination functionality but not directly measure it. Moreover, the association between platinum and PARPi response is imperfect since not all platinum-sensitive patients benefit from PARPi and PARPi response has been observed in platinum-resistant cancers. A panel of 20 high-grade serous ovarian carcinoma patient-derived xenografts (OC-PDXs) were molecularly and pharmacologically characterized to assess predictive markers of response to PARPi therapy. Genomic DNA and total RNA were sequenced searching for BRCA1/2 alterations or sent to Myriad Genetics to obtain HRD scores. Absolute BRCA1 mRNA expression was measured by RT-qPCR. OC-PDXs growing subcutaneously or orthotopically in nude mice were treated with the PARPi olaparib or platinum to test drug sensitivity. The molecular analyses revealed that nearly 90% (17/20) of OC-PDXs are TP53 mutated, thus reflecting the clinical scenario. 50% (10/20) of OC-PDXs harbor mutations in BRCA1/2 genes, while 10% (2/20) lack BRCA1 mRNA expression. MyChoice® assay showed that 65% (13/20) of OC-PDXs score higher than 42, which is the currently used threshold to classify HRD-positive tumors. Correlation analysis confirmed that the HRD score is highly associated with the presence of mutations in BRCA1/2 genes. Preclinical testing showed that 50% of OC-PDXs are sensitive to olaparib. Notably, in 20% of cases the therapeutic response was incorrectly predicted considering either BRCA1/2 mutations or HRD score. 30% of platinum-sensitive OC-PDXs were not responsive to olaparib, confirming that platinum sensitivity not always correlate with response to PARPi. Our results show that tumor genotype and HRD score are strongly associated. Further analyses are required to improve the predictive value of currently

used tests to select patients who will benefit the most from PARPi treatment while sparing toxicities in patients that are unlikely to respond.

Race-associated base excision repair defects alter the DNA damage landscape in prostate cancer

Kaveri Goel[1], Kimiko Krieger[2], Manoj Sonavane[1], Arun Sreekumar[2], Natalie R. Gassman[1]. *[1]Pharmacology and Toxicology, University of Alabama at Birmingham, Birmingham, AL,[2]Department of Molecular and Cell Biology, Baylor College of Medicine, Houston, TX*

Prostate cancer is the most diagnosed cancer among men in the United States. African American men are diagnosed with and succumb to prostate cancer at higher rates than other demographic groups. However, the biological drivers contributing to poorer outcomes in African American men compared to European American men with prostate cancer are still poorly defined. One understudied area is DNA repair defects, which drive genomic instability in cancers. Defects in homologous recombination are often at the forefront of repair defects examined and exploited for therapeutic intervention. However, defects in other DNA repair pathways may contribute to poor disease outcomes and chemoresistance. We demonstrated that defects in the base excision repair (BER) pathway contribute to chemoresistance and alter growth in breast cancer. Others have also shown chemoresistant effects from dysregulated BER protein expression in gastric, colorectal, and ovarian cancers. Examination of the TCGA database show dysregulation of key BER protein like X-ray cross complementing protein 1 (XRCC1) and DNA polymerase β (POLβ) are common across several cancers. Therefore, we decided to explore DNA damage and repair defects in prostate cancer to explore if altered DNA repair contributes to poorer outcomes in African American men. To measure DNA repair defects in formalin-fixed paraffin-embedded (FFPE) tissues, we employed a novel assay, Repair Assisted Damage Detection (RADD), which measures DNA lesions within the tissues. RADD fluorescently tags DNA lesions for quantification and is compatible with immunohistochemistry detection of DNA repair or other proteins of interest. Using the tissue microarrays, we used RADD to discover that prostate tumors from African American patients have more uracil and

pyrimidine lesions, elevated uracil DNA glycosylase (UNG) levels, and reduced XRCC1 levels than European American tumors, which indicate defects in the BER pathway. In addition, these men had higher uracil monophosphate (UMP) and lower expression of folate cycle metabolites, suggesting that metabolic rewiring may also contribute to the dysregulation of BER. Defects in the BER pathway may offer new therapeutic opportunities for African American prostate cancer patients. These defects may be targeted by therapeutics which pressure the BER pathways. This work demonstrates that functional detection of DNA repair defects through RADD offers new insight into race-specific DNA repair defects offering new molecular targets or therapeutic strategies to reduce racial disparities in prostate cancer.

Comprehensive DNA repair landscape analysis reveals novel small cell lung cancer biology

Benjamin B. Morris[1], Barzin Nabet[2], David Shames[2], Simon Heeke[1], Carl M. Gay[1], Jing Wang[1], Jianjun Zhang[1], John V. Heymach[1], Lauren A. Byers[1]. *[1]Thoracic/Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Oncology Biomarker Development, Genentech Inc., South San Francisco, CA*

Background: Small cell lung cancer (SCLC) is the most lethal form of lung cancer. The five-year overall survival rate for SCLC patients is only ~7%, a statistic that has not improved for decades. Compared to non-small cell lung cancers, SCLCs highly express DNA repair proteins. Despite this acknowledgement, a comprehensive analysis of the DNA repair machinery within SCLC has not been completed. This study was performed to study the SCLC DNA repair landscape.
Methods: We applied a novel DNA repair analysis method to IMPOWER133 (n = 271) and MD Anderson GEMINI (n = 85) clinical SCLC datasets. This single-sample weighted expression (ssWE) method uses transcriptomic data to assess regulation of ten single-strand break repair, double-strand break repair, translesion synthesis, and damage sensing pathways within individual tumors. Importantly, this method considers all pathway effectors and applies a scaling factor to capture effector essentiality to repair completion. Unsupervised k-means clustering

was used to group samples following ssWE analysis. Chi-square tests were used to test for significant enrichment patterns between DNA repair and established SCLC transcription factor (TF) subtypes assignments. Results: Unsupervised clustering demonstrated that IMPOWER133 and GEMINI SCLCs were robustly split into three clusters as defined by their DNA repair phenotypes (DNA Damage Response (DDR) High, Intermediate, Low). We found that expression of DNA damage responsive transcription factors (E2F1, MYBL2, FOXM1) and the intra-S and G2/M checkpoint machinery significantly increased across DDR clusters (High>Intermediate>Low). Also, we found that SCLC TF subtypes showed statistically significant enrichment patterns across DDR clusters (IMPOWER133, MDACC X^2 $p<0.001$). Most notably, inflamed SCLC (SCLC-I) were significantly under-represented in the DDR High cluster. Given this, we hypothesized that DDR Low tumors exhibited a more "inflamed" phenotype. To test this hypothesis, we isolated ASCL1+ SCLC (SCLC-A) tumors, which are considered "immune cold" compared to other subtypes, stratified them by their DDR status, and analyzed expression patterns of key immune genes. Strikingly, we found that splitting treatment naïve SCLC-A tumors by their DDR status identified tumors that appeared more "inflamed" (DDR Low). DDR Low SCLC-A showed increased expression of MHC Class I and inflammatory cytokine genes. Conversely, DDR High SCLC-A tumors exhibited an immune evasive profile. Conclusions: We provide the first evidence that SCLCs exhibit a spectrum of DNA repair machinery and cell cycle checkpoint pathway expression within TF subtypes. Additionally, we find that DDR status may be a key determinant of "inflamed" biology in treatment naïve SCLC-A—the predominant form of SCLC—independent of the SCLC-I subtype. Moving forward, our results have important implications for SCLC treatment and clinical trial design.

Ablation of mitotic checkpoint kinase BUB1 sensitizes lung adenocarcinoma to different classes of chemotherapy, radiation, and chemo-radiation

Shivani Thoidingjam[1], Sushmitha Sriramulu[1], Farzan Siddiqui[1], Benjamin Movsas[1], Shirish Gadgeel[2], Shyam Nyati[1]. *[1]Department of Radiation*

Oncology, Henry Ford Health System, Detroit, MI,[2]Department of Medical Oncology, Henry Ford Health System, Detroit, MI

Lung cancer causes the most cancer associated deaths worldwide. About 80 percent patients with inoperable non-small cell lung cancer (NSCLC) develop local recurrence and about 60 percent distant metastasis. NSCLC subtype, lung adenocarcinoma (LUAD) accounts for about 40% of all lung cancers. Recently, targeted therapy with chemotherapy combination has shown to enhance the pathologic complete response rate in a subgroup of NSCLC patients, but most patients do not benefit from therapy due to development of resistance. Thus, identifying molecular drivers of primary and adaptive chemotherapy resistance that can be effectively targeted represents a critical unmet clinical need. Here we aim to evaluate BUB1 (a mitotic checkpoint kinase) as a viable molecular target for increasing the effectiveness of radiotherapy and chemotherapy in LUAD. Bioinformatic analyses were conducted to evaluate BUB1 expression across lung cancer and normal tissues. BUB1 was found to be overexpressed in LUAD compared to normal tissues and BUB1 expression also correlated with cancer stage and tumor grade. LUAD cell lines A549, H1975 and H2030 were used to study the effect of BUB1 inhibition on chemo-radiosensitization. MTT cell proliferation and clonogenic cell survival studies were conducted with pharmacological (BAY1816032) and genomic (CRISPR) BUB1 ablation in combination with Platinum (Cisplatin), Taxol (Paclitaxel) or a PARP inhibitor (Olaparib) without/with radiation. BUB1 inhibition showed cytotoxicity in LUAD cell lines at micromolar concentration and enhanced the radiation mediated cell killing at nanomolar concentration. Moreover, BUB1 inhibition sensitized LUAD cell lines to Cisplatin, Paclitaxel and Olaparib in double or triple chemotherapy combinations. Additionally, BUB1 inhibition significantly increased LUAD cell death when combined with different classes of chemotherapies with radiation (chemo-radiation). Our preliminary mechanistic studies revealed prolonged presence of γH2AX foci, an indicator of DNA double stand breaks. BLRR DNA damage reporter assay indicated that the non-homologous end joining (NHEJ) pathway was inhibited upon BUB1 ablation. Detailed mechanistic studies combining BUB1 ablation with chemo-radiation are underway to delineate signaling cascades involved in BUB1 driven chemo-radiation sensitization. Our data provides evidence

that BUB1 inhibition sensitizes lung adenocarcinoma to radiotherapy, different classes of chemotherapy and chemo-radiation through DNA-double strand break repair pathways and provides rationale for clinical trials that combine BUB1 inhibition with chemo-radiation in NSCLC.

Dose, dose rate, and linear energy transfer influence tumor immunologic and DNA damage response following alpha- and beta-emitting radionuclides

Julia Sheehan-Klenk[1], Caroline P. Kerr[1], Thanh P. T. Nguyen[1], Joseph J. Grudzinski[2], David Adam[3], Maria Powers[1], Raghava N. Sriramaneni[1], Paul A. Clark[1], Reinier Hernandez[3], Bryan Bednarz[3], Jamey P. Weichert[2], Zachary S. Morris[1]. *[1]Human Oncology, University of Wisconsin School of Medicine and Public Health, Madison, WI,[2]Radiology, University of Wisconsin School of Medicine and Public Health, Madison, WI,[3]Medical Physics, University of Wisconsin School of Medicine and Public Health, Madison, WI*

Background: The low response rate to immunotherapies in poorly immunogenic cancers highlights the potential for combination therapies that propagate an anti-tumor response in metastatic settings. Targeted radionuclide therapy (TRT) can deliver radiation to metastatic tumor sites. In preclinical studies, combining low dose TRT with immune checkpoint blockade augments the anti-tumor immune response, promoting the immune susceptibility of metastatic disease sites. Radionuclides differ in their physical properties such as emission type, linear energy transfer (LET), half-life, and tissue range. In this study, clinically relevant α- and β-emitting radionuclides (^{225}Ac, ^{90}Y, ^{177}Lu) were compared in vitro in MOC2 head and neck squamous cell carcinoma and B78 melanoma. We hypothesized that the unique physical properties of radionuclides would differentially impact the quantity and accumulation over time of double stranded DNA breaks, mirroring the timing of effects on tumor cell immune susceptibility markers.
Methods: MOC2 or B78 cells were grown in culture and treated with external beam radiation (EBRT), or culture media containing ^{90}Y, ^{177}Lu, or ^{225}Ac delivering continuous radiation at activity levels using GEANT4

Monte Carlo to deliver 12 Gy (MOC2) and 4 Gy (B78) to the cell monolayer. Cells were harvested, and cDNA was isolated for RT-qPCR one, three, and seven days after the start of irradiation. Additional cells treated in this manner were fixed and stained with DAPI/γ-H2AX antibody for confocal microscopy at the same timepoints. γ-H2AX foci/cell were quantified manually using ImageJ.
Results: γ-H2AX foci counts/cell increased significantly and accumulated over time following treatment with ^{225}Ac, but not with ^{90}Y or ^{177}Lu. EBRT, ^{90}Y, and ^{225}Ac, but not ^{177}Lu, upregulated expression of immune response associated genes (*Fas*, *Pdl1*, *Mhc1*) compared to non-irradiated controls. In cells treated with EBRT every 24h at doses mimicking the interval dose delivered by continuous exponential decay of ^{90}Y and ^{225}Ac, but not ^{177}Lu, the time course and magnitude of *Fas* and *Pdl1* expression phenocopied that of these radionuclides.
Conclusions: DNA damage accumulation and the timing of immunomodulation are modified by the dose, dose-rate, and LET of radiation emitted from a given radionuclide. Understanding the effects of radionuclide therapies on cancer cell immunogenicity could enable rational design of clinical trials that investigate the integration of TRT and immunotherapies into the clinical care of patients with metastatic cancers.

Carotenoid and tocopherol intake in relation to pancreatic cancer risk in a population-based case-control study
Bronson Dokmanovich[1], Hao fan[2], Yunpeng Yu[1], Kristin Anderson[3], Jianjun Zhang[1]. *[1]Indiana University, Indianapolis, IN,[2]Indiana University, Bloomington, IN,[3]University of Minnesota, Minneapolis, MN*

Pancreatic cancer is the third leading cause of cancer-related death in the U.S. and has a 5-year relative survival rate of only 11.5%. The etiology of pancreatic cancer is not well understood, with cigarette smoking, type 2 diabetes, and chronic pancreatitis as the only well-established risk factors. Therefore, it is critical to identify modifiable risk factors for primary

prevention. Persistent oxidative stress and resultant oxidative damage can lead to accumulated mutations in oncogenes and tumor suppressor genes and subsequent carcinogenesis of the pancreas. Carotenoids are abundant in fruits and vegetables, while tocopherols are rich in oilseeds and nuts. Both carotenoids and tocopherols have antioxidant functions. Thus, it is possible that high intake of these bioactive compounds can reduce risk of pancreatic cancer. The present study sought to investigate this question in a case-control study conducted during 1994-1998 in Minnesota. Cases (n=150), aged 20 years or older, were ascertained from all hospitals in the metropolitan area of the Twin Cities and the Mayo Clinic; from the latter, only cases residing in the Upper Midwest of the US were recruited. Controls (n=459) were randomly selected from the general population and frequency matched to cases by age (within 5 years) and sex. Intake of carotenoids and tocopherols from diet and supplements was estimated from a validated food frequency questionnaire. Odds ratios (OR) and 95% confidence intervals (95% CI) were calculated using unconditional logistic regression. As lutein and zeaxanthin are isomers that have identical chemical formulas, they are combined into a single variable in the analysis. All dietary variables were adjusted for energy intake with the residual method prior to data analysis. After adjustment for age, sex, race, education, physical activity, cigarette smoking, and alcohol consumption, intake of lutein and zeaxanthin was associated with a significantly reduced risk of pancreatic cancer [OR (95% CI) for quartile 4 (median: 4972 μg/day) vs. quartile 1 (median: 976 μg/day): 0.39 (0.19-0.79); p-trend: 0.06]. This inverse association became slightly weaker but remained statistically significant after additional adjustment for intake of energy, fat, and fiber. No significant associations were observed for intake of α-carotene, β-carotene, lycopene, β-cryptoxanthin, α-tocopherol, β-tocopherol, and δ-tocopherol, although a higher intake of all these nutrients except α-tocopherol and δ-tocopherol tended to confer a lower risk. Our study shows that there is a significant, beneficial effect of lutein and zeaxanthin intake on pancreatic cancer risk, although it may be a chance finding due to multiple comparisons. More epidemiologic studies are warranted to further elucidate the roles of carotenoids and tocopherols in the etiology and prevention of pancreatic cancer.

Processed, red, and white meat consumption and breast composition in a prospective cohort study of Chilean girls

Claire E. Kim[1], Audrey J. Gaskins[2], Camila Corvalan[3], Ana Pereira[3], John Shepherd[4], Karin B. Michels[5]. *[1]Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[2]Epidemiology, Rollins School of Public Health, Emory University, Atlanta, GA,[3]Institute of Nutrition and Food Technology, University of Chile, Santiago, Chile,[4]Epidemiology and Population Sciences in the Pacific Program, University of Hawaii Cancer Center, Honolulu, HI,[5]Epidemiology, Fielding School of Public Health, Los Angeles, CA*

Meat consumption has been associated with risk of breast cancer. However, the association between different types of meat (processed and unprocessed red, and white) intake during childhood and breast density has not been explored. This prospective study included 290 Chilean girls from the Growth and Obesity Cohort Study. Diet was assessed every 6 months with a 24-hour recall. Dual-energy X-ray absorptiometry was used to assess breast density (absolute fibroglandular volume (FGV)) and percent breast density (FGV/total breast volume, %FGV) at Tanner Breast Staging 4 (B4). Multivariable linear regression models were adjusted for total calorie intake, age at B4, sugar sweetened beverage intake, vegetable intake, TV watching after school, highest maternal education level, BMI z-score, and height. Substitution analysis was assessed using white meat in replacement of processed and unprocessed red meat. There was no association between total, processed and unprocessed red, or white meat intake and %FGV and absolute FGV. In the estimated substitution analyses, we observed a slightly lower breast density when processed or unprocessed red meat was replaced with white meat; however, effect estimates were modest and imprecise. For example, substituting 1 serving of unprocessed white meat for 1 serving of processed or unprocessed red meat was associated -4.1 cm^3 (95% CI -10.3, 2.2) and -4.5 cm^3 (95% CI -10.3, 1.3) lower absolute FGV, respectively. In this cohort of Chilean girls, there was little association between total or specific types of meat intake and breast density.

Substitution analysis of different types of meat and average breast density at Tanner stage 4

	Beta	Confidence	P

	coefficient	interval	value
Absolute FGV (cm^3)			
Substituting 1 serving of unprocessed white meat for 1 serving of unprocessed red meat	-4.1	(-10.3, 2.2)	0.21
Substituting 1 serving of unprocessed white meat for 1 serving of processed red meat	-4.5	(-10.3, 1.3)	0.13
Percentage FGV (%)			
Substituting 1 serving of unprocessed white meat for 1 serving of unprocessed red meat	-2.5	(-5.9, 0.8)	0.14
Substituting 1 serving of unprocessed white meat for 1 serving of processed red meat	-2.8	(-5.8, 0.3)	0.08

Association between dietary one-carbon metabolism-related nutrients and the risk of colorectal cancer: Findings from the Singapore Chinese Health Study

Yen Thi-Hai Pham[1], Aizhen Jin[2], Renwei Wang[1], Woon-Puay Koh[2], Jian-Min Yuan[1], Hung N. Luu[1]. *[1]UPMC Hillman Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA,[2]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore*

Background. Colorectal cancer (CRC) is a commonly diagnosed subtype of cancer with a high mortality rate. One-carbon metabolism is a set of complex pathways, responsible for providing methyl group for DNA synthesis, repair and methylation. Adequate DNA methylation maintains chromosome stability and prevents gene disruption. Diet is a major source for key substrates and co-factors (i.e., vitamin B6, choline and folate) involved in one-carbon metabolism. A majority of epidemiologic studies that have evaluated one-carbon metabolism-related nutrients in relation to CRC risk have focused on the potential role of folate only. Due to the involvement of multiple nutrients and the complexity of one-carbon metabolism pathways, a comprehensive assessment of the nutrients involved and their associations with CRC risk is needed. The purpose of the current analysis was therefore to evaluate the association between one-

carbon metabolism-related nutrients with the risk of developing CRC using the Singapore Chinese Health Study (SCHS).
Methods. The SCHS is an on-going population-based prospective cohort study that includes 61,321 Chinese men and women in Singapore who were 45-74 years of age at baseline. A 165-item semi-quantitative food frequency questionnaire was used to obtain information of dietary intake. Cox proportional hazard regression models were used to estimate the hazard ratios (HRs) and respective 95% confidence intervals (CIs) for CRC associated with one-carbon metabolism-related nutrients, including thiamine, riboflavin, niacin, vitamin B6, folate acid, vitamin B12, choline, methionine, and betaine, adjusting for potential confounders.
Results. After an average of 17.5 years of follow-up, 2,140 participants developed CRC. An inverse association between folate acid and colon cancer. The HRs and respective 95% CIs for quarters 2, 3 and 4 vs. quarter 1 (the lowest quartile) was 0.98 (0.84-1.14), 0.93 (0.79-1.10) and 0.80 (0.64-0.98) (P_{trend}=0.04). Similar pattern was observed between folate acid intake and colon cancer risk among never smokers (HR_{Q4vsQ1}=0.67, 95% CI: 0.51-0.86; P_{trend}=0.005). No association was found between other one-carbon metabolism-related nutrients and the risk of colorectal cancer
Conclusions. In a large on-going prospective cohort study of more than 61,000 Chinese Singaporeans, we found inverse associations between dietary folate acid and the risk of colon cancer. This association was more obvious among never smokers. Our findings provide critical implication for primary prevention and control of colorectal cancer.

#6450
Fatty acid intake as potential risk factor of colorectal cancer: A multicenter case control study in Iran
Monireh Sadat Seyyedsalehi[1], Paolo Boffetta[1], Kazem Zendehdel[2].
[1]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy,[2]Cancer Research Center, Cancer Institute, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of

A higher risk of colorectal cancer (CRC) has been associated with high animal fat intake, but not vegetable fat. To date, limited data provides the quantification of the effect exerted by fatty acids (FAs) on CRC overall and

by anatomical sub-sites. This study aims to look at associations between some FAs intakes [cholesterol, total fat, total saturated fatty acids (SFAs), total monounsaturated fatty acids (MUFAs), total polyunsaturated fatty acids (PUFAs), total trans fatty acids (TFAs), oleic acid, myristic acid, total ruminant (rTFAs) and industrial fatty acids (iTFAs), eliadic acid (EA), conjugated linoleic acid (CLA), and CRC risk in a large case-control study (IROPICAN) in Iran . We analyzed 865 CRC cases (434 in colon, 404 in rectum, and 27 with unknown subsite) and 3,206 controls from seven provinces of Iran. Detailed information was collected by trained interviewers using validated lifestyle and food frequency questionnaires (FFQ). The different types of total and individual FAs intake were categorized into quartiles of intake. The odds ratios (OR) and 95% confidence intervals (CI) for the association between CRC them were calculated using multivariate logistic regression models by adjusting for the potential confounders. Furthermore, analyses were stratified by age (under and over 50) and also, we repeated the analyses for CRC subsites. There was a statistically significant positive association between CRC and high intake (quartile 4) compared to the low intake (quartile) of dietary total fat (OR=1.77, 95% CI=1.32-2.38), cholesterol (OR=1.58, 95% CI=1.22-2.05), total TFAs (OR=1.31, 95% CI=1.02-1.68), TFAs (OR=1.73, 95% CI=1.12-2.68), EA(OR=2.69, 95% CI=1.46-4.93), and SM (OR=1.45, 95% CI=1.00-2.09), as well as an inverse association with high intake of dietary rTFAs (OR=0.60, 95% CI=0.39-0.93), CLAs (OR=0.34, 95% CI=0.19- 0.60). Stratified analyses by age indicated that there was a statistically significant association between CRC and total fat intake [OR =1.30, 95% CI =1.16-1.46, p=0.006 for the interaction], cholesterol intake [OR =1.22, 95% CI=1.11-1.35, p=0.019 for the interaction], and iTFA intake [OR =1.31, 95% CI=1.06-1.62, p=0.02 for the interaction] after 50 years old. The results of our study indicate that decreasing fat consumption, particularly from industrial and animal sources, may reduce the risk of CRC.

Dietary medium-chain fatty acids and risk of incident colorectal cancer in a predominantly low-income population: a report from the Southern Community Cohort Study (SCCS)

Lei Fan[1], Xiangzhu Zhu[1], Qingxia Chen[2], Xiang Huang[1], Mark D. Steinwandel[3], Martha Shrubsole[1], Qi Dai[1]. *[1]Vanderbilt University Medical*

Center, Nashville, TN,[2]Department of Biostatistics, Vanderbilt University, Nashville, TN,[3]International Epidemiology Field Station, Rockville, MD

Purpose: Previous studies have investigated medium-chain fatty acids (MCFAs) as a part of saturated fat intake and risk of colorectal cancer (CRC). However, unlike long-chain saturated fatty acids, MCFAs possess many unique properties, including inhibition of pro-carcinogenic bacteria, biofilm formation, and induction of apoptosis. Further, C12:0 has been consistently shown *in vitro* to exhibit the most potent anti-microbial properties in a dose-dependent manner compared to other MCFAs. Black Americans have the highest CRC incidence and mortality across all racial subgroups in the US. In a predominantly low-income population, we aimed to examine whether dietary intake of MCFAs is associated with a reduced risk of CRC overall and among racial subgroups.
Methods: The daily intake of total energy and individual nutrients, including MCFAs, was derived from a food frequency questionnaire. Multivariable-adjusted Cox regression was used to assess the associations between dietary intake of MCFAs and the risk of incident CRC during the 13.75-year follow up after adjustment for confounders.
Results: Among 71,599 eligible participants, 868 incident CRC cases were identified (622 Blacks, 220 Whites and 26 other racial groups). High intake of C12:0 was significantly associated with a reduced risk of CRC only in White participants in a dose-response manner (for highest VS lowest quartile: HR, 0.37; 95% CI, 0.17 to 0.80; *P* for trend =0.0068). This protective association primarily appeared in White participants at high risk of CRC, such as those aged 50 years or older, overweight or obese, ever smokers, or living in a neighborhood with greater deprivation. On the other hand, we did not find a significant association in Black participants (HR, 0.87; 95% CI, 0.59 to 1.27); *P* for trend =0.72). However, there was a marginal linear association in Black participants with the lowest deprivation index while the association disappeared among Black participants with higher deprivation index. Finally, we found from the NHANES 2005-2016, a representative sample of the US general population, that Black Americans had the lowest intake of MCFAs across all racial subgroups and, overall, intakes of MCFAs decreased with reducing poverty-income ratio. No associations were found between intakes of C6:0, C8:0, or C10:0 and the risk of incident CRC overall or within the racial group.

Conclusion: In this predominantly low-income population, increasing dietary C12:0 intake was associated with a substantially reduced risk of CRC only among White participants, but not in Black participants. This racial difference in associations may be because Black Americans consumed the lowest levels of MCFAs in all racial groups while a much higher proportion of Black participants had lactose intolerance and a lower proportion of them consumed lactose-free fermented foods.

A plasma metabolomic signature of healthy lifestyles and risk of colorectal cancer in the UK Biobank

Fangcheng Yuan, Danxia Yu, Wanqing Wen, Wei Zheng. *Division of Epidemiology, Vanderbilt University Medical Center, Nashville, TN*

Background: Lifestyle factors contribute to the etiology of colorectal cancer (CRC). We aimed to derive a metabolomic signature of adherence to healthy lifestyles and examine its association with CRC risk.
Methods: In the analysis, we included 98,898 UK Biobank participants with 168 metabolomic biomarkers measured by nuclear magnetic resonance spectroscopy from baseline plasma samples. A healthy lifestyle score (HLS) was derived from 8 lifestyle factors according to the American Cancer Society (ACS) guidelines. We applied elastic net regularized regressions to identify a metabolomic signature from 130 biomarkers. Cox proportional hazard models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for the association of metabolomic signature with CRC risk after adjusting for known confounders.
Results: During a median follow-up time of 8.2 years, 818 incident primary CRC cases were identified after participants were enrolled for more than two years. We observed a strong partial correlation between the metabolomic signature and HLS (r = 0.34), as well as waist-to-hip ratio, sedentary time, red and processed meat intake, and tobacco smoking aspects of the HLS (r = 0.14-0.33). A higher HLS was characterized by a signature of increased levels of linoleic acid, total cholines, and polyunsaturated fatty acids and decreased levels of omega-6 fatty acids, phospholipids in intermediate-density lipoprotein, and phosphatidylcholines. The metabolomic signature showed a significantly inverse association with CRC risk (HR = 0.84; 95% CI = 0.80-0.89 per

standard deviation increment). The significantly inverse associations were observed irrespective of sex, educational attainment, and CRC subsite. Stronger associations were seen among participants aged between 50 and 60 years at study enrollment, and those diagnosed with CRC at 60 years old or later.
Conclusion: We identified a metabolomic signature characterizing adherence to the ACS guidelines and showed that the signature was inversely associated with CRC risk.

#6453

Lifestyle and environmental factors in relation to colorectal cancer risk and survival by colibactin tumor mutational signature status

Claire Elizabeth Thomas[1], Peter Georgeson[2], Conghui Qu[1], Robert S. Steinfelder[1], Daniel D. Buchanan[2], Mark A. Jenkins[3], Andrea Gsur[4], Jane C. Figueiredo[5], Polly A. Newcomb[1], Peter T. Campbell[6], Christina Newton[7], Caroline Y. Um[8], Lisa Boardman[9], Victor Moreno[10], Jenny Chang-Claude[11], Michael Hoffmeister[11], Marc J. Gunter[12], Andrew T. Chan[13], Shuji Ogino[14], Ellen L. Goode[15], Brigid Lynch[16], Yohannes A. Melaku[17], Steven Gallinger[18], Sonja I. Berndt[19], Wen-Yi Huang[19], Ulrike Peters[1], Amanda I. Phipps[1]. *[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]Colorectal Oncogenomics Group, Department of Clinical Pathology, The University of Melbourne, Parkville, Australia,[3]The University of Melbourne, Parkville, Australia,[4]Center for Cancer Research, Medical University of Vienna, Vienna, Austria,[5]Cedars-Sinai Medical Center, Los Angeles, CA,[6]Department of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY,[7]Department of Population Science, American Cancer Society, Atlanta, GA,[8]Behavioral and Epidemiology Research Group, American Cancer Society, Atlanta, GA,[9]Mayo Clinic, Rochester, MN,[10]Catalan Institute of Oncology-IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain,[11]German Cancer Research Center (DKFZ), Heidelberg, Germany,[12]Nutrition and Metabolism Section, International Agency for Research on Cancer, World Health Organization, Lyon, France,[13]Division of Gastroenterology, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[14]Program in MPE Molecular Pathological Epidemiology, Harvard*

Medical School, Boston, MA,[15]Department of Health Science Research, Division of Epidemiology, Mayo Clinic, Rochester, MN,[16]Cancer Epidemiology Division, Cancer Council Victoria, Melbourne, Australia,[17]Flinders Health and Medical Research Institute, Adelaide Institute for Sleep Health, Flinders University, Adelaide, Australia,[18]Lunenfeld Tanenbaum Research Institute, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada,[19]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD

Background: The genotoxin colibactin, produced by *Escherichia coli* containing the *pks* island, is associated with a tumor single base substitution (SBS) mutational signature SBS88. It is unknown whether lifestyle and environmental factors related to gut dysbiosis impact colorectal cancer (CRC) risk and survival differently by colibactin signature status.
Methods: Utilizing the resources of the Genetic Epidemiology of Colorectal cancer Consortium and Colon Cancer Family Registry (GECCO-CCFR), a consortium including both case-control and cohort study designs, SBS88 tumor mutational signature was measured in 4308 CRC cases who were microsatellite stable (MSS) and had at least five somatic single nucleotide variants for signature decomposition. Associations of 13 lifestyle and environmental factors with CRC risk by colibactin signature status were assessed using logistic and multinomial regression; associations with CRC survival were assessed using Cox proportional hazards regression.
Results: 392 (9%) of the 4308 MSS tumors were positive for SBS88. Having a BMI ≥30 kg/m^2 (versus a BMI 18.5-24.9 kg/m^2) was strongly associated with worse CRC-specific survival among those with the SBS88 signature, but not among those with SBS88 negative CRC [further adjusted hazard ratio (HR) = 3.40 95% confidence interval (CI) 1.47, 7.84, and HR = 0.97 95% CI 0.78, 1.21, respectively, *P* for heterogeneity = 0.066]. Associations of fruit intake with CRC *risk* may be differential by SBS88 status. In minimally adjusted models, those in the highest quartile of fruit intake (versus the first quartile) had 0.53 (95% CI 0.37, 0.76) times the risk of SBS88 positive CRC, as opposed to 0.75 (95% CI 0.66, 0.85) times the risk of SBS88 negative CRC (*P* for heterogeneity = 0.047). Among cohort studies specifically, associations between CRC risk and BMI, alcohol, and

fruit intake also differed by SBS88 status (*P* for heterogeneity ranging 0.02-0.05).
Conclusions: Higher BMI may be associated with worse CRC-specific survival among those with SBS88 positive tumors. BMI, alcohol, and dietary factors may be differentially associated with CRC risk based on SBS88 status.

Metabolic obesity phenotype and risk of obesity-related cancers in the women's health initiative

Prasoona Karra[1], Maci Winn[2], Garnet Anderson[3], Benjamin Haaland[2], Aladdin H. Shadyab[4], Marian Neuhouser[3], Rebecca Seguin-Fowler[5], Cynthia A. Thomson[6], Mace Coday[7], Jean Wactawski-Wende[8], Marcia L. Stefanick[9], Xiaochen Zhang[10], Ting-Yuan David Cheng[11], Shama Karanth[11], Yangbo Sun[7], Nazmus Saquib[12], Margaret Pichado[13], Su Yon Jung[14], Fred Tabung[10], Scott A. Summers[1], William L. Holland[1], Thunder Jalili[1], Marc Gunter[15], Sheetal Hardikar[2], Mary C. Playdon[1]. *[1]Department of Nutrition and Integrative Physiology, University of Utah, Salt Lake City, UT,[2]Department of Population Health Sciences, University of Utah, Salt Lake City, UT,[3]Fred Hutchinson Cancer Research Center, Seattle, WA,[4]University of California, San Diego, CA,[5]Texas A&M University, College Station, TX,[6]The University of Arizona, Tucson, AZ,[7]University of Tennessee Health Science Center, Memphis, TN,[8]University at Buffalo, Buffalo, NY,[9]Stanford Prevention Research Center, Stanford, CA,[10]The Ohio State University, Columbus, OH,[11]University of Florida, Gainesville, FL,[12]Sulaiman AlRajhi University, Kingdom of Saudi Arabia, Saudi Arabia,[13]Yale University, Chevy Chase, MD,[14]University of California, Los Angeles, CA,[15]Nutrition and Metabolism Branch, International Agency for Research on Cancer, Lyon, France*

Introduction: Body mass index (BMI) may misclassify obesity-related cancer (ORC) risk since metabolic dysfunction can exist at any BMI. We measured the association of metabolic dysfunction, independent of BMI with risk of ORC.
Methods: Study included 60% white and 34% black Women's Health Initiative participants with available baseline cardiovascular disease

biomarkers. Metabolic obesity phenotypes were classified as normal weight with no metabolic dysfunction (NWNMD), normal weight with metabolic dysfunction (NWMD), overweight/ obese with no metabolic dysfunction (OONMD) and overweight/ obese with metabolic dysfunction (OOMD) when defined by Wildman and ATP III criteria. We performed a Cox proportional hazards regression with death as a competing risk adjusting for confounders.
Results: Defining by Wildman and ATP III criteria, 17.0%, 6.5%, 31.0%, 45.0%; and 22.2%, 2.4%, 41% and 35% were NWNMD, NWMD, OONMD and OOMD respectively. The risk of all ORC combined was elevated among NWMD (HR 1.12, 95% CI: 0.90-1.39), OONMD (HR 1.15, 95% CI: 1.00-1.32) and OOMD (HR 1.35, 95% CI: 1.18-1.54) when compared to NWNMD using Wildman criteria. Results were similar when defined by ATP III, hs-CRP and HOMA-IR. When stratified by cancer type, NWMD were at increased risk of colorectal cancer when compared to NWNMD (HR 1.70, 95% CI: 1.02-2.82). Individuals who were overweight/obese were at increased risk of cancer for all cancer types though the effect estimates were lower among OONMD phenotype.
Conclusions: NWMD and OOMD individuals are at increased risk of all ORC combined, independent of BMI status when compared to individuals with NWNMD.

Association of dietary inflammatory and insulinemic potential with risk of liver cancer and chronic liver disease mortality

Xinyuan Zhang[1], Longgang Zhao[2], Cami Christopher[3], Fred K. Tabung[4], Wei Bao[5], David O. Garcia[6], Marian L. Neuhouser[7], Aladdin H. Shadyab[8], Nazmus Saquib[9], Lesley Tinker[7], Xuehong Zhang[1]. *[1]Channing Division of Network Medicine, Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Epidemiology and Biostatistics, Arnold School of Public Health, University of South Carolina, Columbia, SC,[3]Nutrition, Harvard T. H. Chan School of Public Health, Boston, MA,[4]Internal Medicine, The Ohio State University College of Medicine, Columbus, OH,[5]Division of Life Sciences and Medicine, University of Science and Technology of China, Institute of Public Health, Hefei, China,[6]Health Promotion Sciences, Mel & Enid Zuckerman College of Public Health,*

University of Arizona, Tucson, AZ,[7]Division of Public Health Sciences, Fred Hutchinson Cancer Center, Seattle, WA,[8]Herbert Wertheim School of Public Health and Human Longevity Science, Univeristy of California, San Diego, La Jolla, CA,[9]Clinical Sciences, College of Medicine, Sulaiman AlRajhi University, Al Bukayriyah, Saudi Arabia

Background: Increasing burdens of liver cancer and chronic liver disease (CLD) urge investigation of modifiable risk factors for primary prevention. Despite strong experimental evidence showing the role of chronic insulin resistance/hyperinsulinemia and inflammation in liver cancer and CLD, whether the insulinemic and inflammatory potential of diet are independently associated with higher risk of these outcomes requires further investigation.
Methods: We conducted a prospective cohort study among 78,356 postmenopausal women in the Women's Health Initiative Observational Study. Two validated dietary indices that predict circulating C-peptide or biomarkers of inflammation, namely, the empirical dietary index for hyperinsulinemia (EDIH) and the empirical dietary inflammation pattern (EDIP), were estimated from a food frequency questionnaire. Incident cases of liver cancer and CLD mortality were ascertained via review of medical records and linkage to national registries. Multivariable hazard ratios (HRs) with 95% confidence intervals (CIs) were calculated using Cox proportional hazard models, adjusted for age, diabetes, body mass index (BMI), and other covariates.
Results: During a median 22.1 years of follow-up, we documented 176 primary liver cancer cases and 156 CLD mortality cases. The EDIH was positively associated with incident liver cancer risk ($HR_{Quartile4\ vs.\ Quartile1}$ = 1.70; 95% CI: 1.03, 2.81; p-trend = 0.03) and CLD mortality risk ($HR_{Q4\ vs.\ Q1}$ = 2.75; 95% CI: 1.54, 4.93; p-trend = 0.01) in the multivariable adjusted model, including diabetes and BMI as covariates. The EDIP was also positively associated with liver cancer ($HR_{Q4\ vs.\ Q1}$ = 1.93; 95% CI: 1.21, 3.09; p-trend <0.001) and CLD mortality risk ($HR_{Q4\ vs.\ Q1}$ = 2.09; 95% CI: 1.24, 3.52; p-trend <0.001) in the multivariable adjusted model. The estimates remained significant and robust in sensitivity analyses, after exclusion of cases in the first 2 years of follow-up or with liver disease history. There was no additive effect between the two dietary indices.

Further analyses of individual food groups and liver outcomes indicated positive associations with refined grains, processed meat, butter, and eggs, and inverse associations with coffee, poultry, green leafy vegetables, and dark yellow vegetables.
Conclusions: Dietary insulinemic and inflammatory potential were independently associated with higher risk of liver cancer and CLD mortality in US postmenopausal women. Monitoring dietary patterns to reduce chronic hyperinsulinemia and inflammation may contribute to the primary prevention of liver cancer and CLD mortality.

#6457
Blood magnesium level is associated with liver cancer risk in a prospective cohort of liver cirrhosis patients
Xinyuan Zhang[1], Longgang Zhao[2], Tao Hou[3], Michelle Lai[4], Qi Dai[5], Xuehong Zhang[1]. *[1]Channing Division of Network Medicine, Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Epidemiology and Biostatistics, Arnold School of Public Health, University of South Carolina, Columbia, SC,[3]Epidemiology, Harvard T. H. Chan School of Public Health, Boston, MA,[4]Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Boston, MA,[5]Medicine, Vanderbilt University Medical Center, Nashville, TN*

Background: Previous studies showed that higher magnesium intake was linked to a lower risk of liver cancer. However, the relationship between blood magnesium level and the risk of liver cancer has not been fully established, especially among cirrhosis patients where magnesium deficiency commonly occurred. To address this knowledge gap, we have established a prospective cohort of patients with liver cirrhosis based on real-world, electronic health record data.
Methods: In the Mass General Brigham Biobank, a biorepository of consented patients, we established a prospective cohort by identifying liver cirrhosis patients using the International Classification of Diseases 9th and 10th version codes (ICD-9: 571.2, 571.5, and 571.6; ICD-10: K70.3, K74.3-6). We excluded patients with liver cancer history or without blood magnesium assessment at the time of cirrhosis diagnosis (baseline). We identified subsequent incident liver cancer (ICD-9: 155; ICD-10: C22) and

levels of liver function biomarkers assessed at each hospital visit, including alanine transaminase (ALT), aspartate aminotransferase (AST), and alkaline phosphatase (ALP). We used Cox regression models to generate ratios (HRs) with 95% confidence intervals (CIs) for developing liver cancer according to quartiles (Qs) of baseline blood magnesium levels, adjusting for age, sex, race, smoking status, alcohol intake, physical activity, body mass index, diabetes, ALT, and hepatitis B/C infection. We used generalized estimating equation (GEE) models to estimate the associations between baseline blood magnesium levels and repeated measurements of liver function biomarkers after cirrhosis diagnosis.
Results: We included 1257 liver cirrhosis patients (median age at diagnosis 59.5 years; 36% female; 87% white) with magnesium levels measured at baseline. During a median follow-up period of 3.55 (range: 0.1-12) years from liver cirrhosis diagnosis, 106 developed liver cancer. In multivariable-adjusted Cox models, higher baseline blood magnesium (Q4: ≥2.10 mg/dL vs. Q1: <1.80 mg/dL) was associated with a lower risk of liver cancer ($HR_{Q4\ vs.\ Q1}$ = 0.57; 95% CI: 0.33, 0.99; p-trend =0.03). Results remained similar in 1-year lagged analysis. In multivariable-adjusted GEE models, higher magnesium was associated with a slower change of ALT ($coefficient_{Q4\ vs.\ Q1}$ = -7.09; 95% CI: -12.6, -1.62) and AST ($coefficient_{Q4\ vs.\ Q1}$ = -8.06; 95% CI: -13.9, -2.25).
Conclusions: In a prospective cohort of high-risk population with liver cirrhosis, higher blood magnesium was associated with a lower risk of developing liver cancer and a slower change of biomarkers suggestive of liver function. Magnesium is implicated in liver carcinogenesis and progression, therefore monitoring and maintaining blood magnesium could be important to delay the progression from cirrhosis to cancer.

Maternal and paternal alcohol exposures program higher incidence of hepatocellular carcinoma in offspring
Alison Basel, Sanat S. Bhadsavle, Kara N. Thomas, Katherine N. Zimmel, Alexis N. Roach, Matthew Gaytan, Grace Parkey, Michael C. Golding.
Texas A&M University, College Station, TX

Environmental exposures during development are known to influence adult health and disease. Specifically, early developmental exposures have been

shown to increase susceptibility to cancer in adults through epigenetic mechanisms. Alcohol is a potent environmental carcinogen and teratogen, causing a wide range of health problems across the life course of an individual. Current literature examining early life exposures solely focuses on maternal exposures despite recent efforts to recognize paternal epigenetic contributions. Thus, we investigated the influence of preconception paternal, maternal, and dual parental alcohol exposures on offspring's predisposition to develop liver disease and hepatocellular carcinoma (HCC). We hypothesized that dual-parental alcohol exposure would exacerbate the incidence of liver cancer in adult offspring.
Using an established mouse model, we exposed male and female adult C57BL/6J mice to control (0% EtOH) or alcohol (10% EtOH) preconception treatments. Next, we randomly assigned pups from each treatment to either a single injection of Diethylnitrosamine (DEN; 25mg/kg) to promote liver tumors, or saline control. Finally, we sacrificed offspring on postnatal day 182 and collected organs and blood for enzyme analysis. DEN-treated males display an increased liver-to-body weight ratio compared to saline males while also exhibiting lower body weight. The male progeny from the dual-parental treatment group exhibited a significant increase in tumor incidence and burden in DEN-treated males, exceeding those measured for the maternal and paternal treatments. Further, offspring from the dual-parental group had high levels of alanine transaminase (ALT) and aspartate transaminase (AST) compared to the other treatment groups. Oil Red-O and Sirius Red staining of liver sections revealed increased hepatic steatosis and fibrosis in DEN males compared to saline males. Again, the dual-parental exposed offspring exhibited the most aberrant phenotype. Blind scoring of H&E-stained liver sections identified increases in steatosis, fibrosis, and HCC lesions, with the highest scores emerging in DEN-treated dual-parental offspring.
These findings demonstrate that preconception paternal and gestational maternal alcohol exposures program a predisposition to adult-onset chronic diseases including alcoholic fatty liver disease, hepatic fibrosis, and HCC. These experiments not only confirm our hypothesis that dual-parental exposed offspring exhibit an exacerbated hepatic abnormality phenotype, but also highlight the importance of both maternal and paternal environmental exposures on disease risk in offspring. While the negative effects of maternal alcohol consumption have been well established, our

novel finding that paternal alcohol exposure also promotes hepatocellular carcinoma in offspring has potentially profound clinical implications.

Developed and persistent dyslipidemia is associated with increased risk of gastric cancer in a prospective study

Dan Huang, Woo-Kyoung Shin, Katherine De la Torre, Sukhong Min, Aesun Shin, Jong-Koo Lee, Hyung-Ho Kim, Daehee Kang. *Seoul National University, Seoul, Korea, Republic of*

Background: Increasing evidence suggests that metabolic disorders are a risk factor for gastric cancer. However, there is a lack of evidence on whether changes and persistence of metabolic disorders affect the subsequent gastric cancer occurrence. Therefore, this study aimed to evaluate the effects of changes or persistence in metabolic syndrome and its components' status on the incidence of gastric cancer among Korean population.
Methods: This study comprised 59,671 individuals from the Health Examinees Study who had baseline surveys from 2004 to 2012 and repeated measurements from 2012 to 2016; and were followed up until 2018. Metabolic syndrome and its components were defined according to the National Cholesterol Education Program Adult Treatment Panel III and modified based on Korean population criteria. Participants were categorized into free, developed, recovered, and persistent metabolic syndrome and its components. We estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for gastric cancer incidence using multivariable cox proportional hazard models with age as a time scale.
Results: During the mean follow-up of 9.4 years, 312 subjects were newly diagnosed with gastric cancer. Compared with the metabolic syndrome-free group, the persistent group had a higher incidence of gastric cancer (HR 1.37, 95% CI 1.02-1.84). Among individual components, the developed-high triglycerides group had the highest gastric cancer incidence (HR 1.52, 95% CI 1.12-2.05), followed by the persistent group (HR 1.40, 95% CI 1.04-1.90) compared to the free group. The low HDL-cholesterol persistent group (HR 1.45, 95% CI 1.08-1.93) showed a higher incidence than in the free group. In the subgroup analysis, we found association between high triglycerides developed and gastric cancer in men, while for women, the

associations were significant between high triglycerides and low HDL-cholesterol persistent groups and gastric cancer incidence.
Conclusions: In this prospective cohort study, we found that developed or persistent dyslipidemia, assessed as abnormal triglycerides and low HDL-cholesterol, were associated with an increased incidence of gastric cancer. These findings suggest that effective management of dyslipidemia may reduce gastric cancer risk.

Smoking initiation at young age increases risk of gastric cancer among Korean men

Hwi-Won Lee[1], Woo-Kyoung Shin[1], Dan Huang[2], Katherine De la Torre[1], Jae Jeong Yang[1], Minkyo Song[1], Aesun Shin[1], Kyoung-Mu Lee[3], Hyuk-Joon Lee[4], Jong-koo Lee[5], Daehee Kang[1]. *[1]Preventive Medicine, SNU Medicine, Seoul, Korea, Republic of,[2]SNU Medicine, Seoul, Korea, Republic of,[3]Environment Health, Korea National Open University, Seoul, Korea, Republic of,[4]Surgery, SNU Medicine, Seoul, Korea, Republic of,[5]Family Medicine, SNU Medicine, Seoul, Korea, Republic of*

Objective: Early initiation of smoking is associated with adverse health outcomes. This study aimed to investigate the association of various smoking-related factors with the risk of gastric cancer in a population with a high incidence rate of gastric cancer.
Method: From 2004 to 2013, Korean adults 40-69 years of age were enrolled in the large-scale prospective cohort, the Health Examinees-Gem study. Incident gastric cancer cases were identified until December 31, 2017, through linkage to the Korea Central Cancer Registry. Participants' information regarding socio-demographics, smoking-related factors, and other lifestyle factors was obtained via self-reported questionnaires. Cox proportional hazards models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for gastric cancer risk associated with smoking-related factors such as smoking duration, amount, pack-years, and age of smoking initiation.

Results: Among 44,207 men included in the final analysis, 565 gastric cancer cases were identified during a mean (±SD) follow-up period of 8.6 (±2.0) years. Compared to non-smokers, current smokers who smoked for more than 35 years (HR 1.44, 95% CI 1.06-1.96) or with ≥30 pack-years of smoking (HR 1.40, 95% CI 1.05-1.87) were positively associated with gastric cancer. These associations were shown to be significant with increasing smoking years (*p* trend 0.019) and pack-years (0.016) as well. Compared to non-smokers, current smokers who initiated smoking at a younger age, before or at 20 years, were at a higher risk of gastric cancer (HR 1.46, 95% CI 1.10-1.93). No significant associations were observed among former smokers. When stratified by smoking duration, increased risk of gastric cancer was observed among those who smoked for more than 25 years in the younger smoking initiation age group (≤20 years; HR 1.50, 95% CI 1.15-1.94). In terms of smoking intensity, those who smoked less than 20 cigarettes or 1 pack a day showed an increased risk of gastric cancer in the younger smoking initiation age group that began smoking before or at 20 years of age (HR 1.78, 95% CI 1.30-2.44).
Conclusion: Our findings suggest that earlier initiation of smoking is associated with a greater risk of gastric cancer. Among those who began smoking early, longer duration is an important factor, but increased gastric cancer risk was also observed among those who smoked moderate amount on a daily basis. Thus, measures to manage and control onset age of cigarette smoking among teenagers may be considered when taking actions against the health burden of gastric cancer.

#6461

Excess risk due to smoking and modifying effect of quitting on bladder cancer incidence: the multiethnic cohort

David Bogumil[1], Victoria Cortessis[1], Daniel Stram[1], Veronica W. Setiawan[1], Christopher Haiman[1], Loic Le Marchand[2], Gertraud Maskarinec[2]. *[1]Population and Public Health Sciences, USC - University of Southern California, Los Angeles, CA,[2]Epidemiology Program, UH - University of Hawaii Cancer Center, Honolulu, HI*

Background: Smoking is an established risk factor for urothelial cancer of the bladder (BC), attributed to over 50% of cases among men, however associations outside of European-descent populations are infrequently

reported. Further, absolute risk of BC by smoking history has not yet been reported. Characterizing these associations will identify value of smoking cessation across non-European ancestry populations.
Methods: We estimated the association between pack-years, years quit, and BC among 181,231 Multiethnic Cohort Study participants from five major racial/ethnic groups (African Americans [AA], European Americans [EA], Japanese Americans [JA], Latinos [LA], Native Hawaiians [NH]) 45-75 years old at enrollment (1993-1996). Smoking history was assessed by self-report at cohort entry and on a follow-up survey (2003-2008). Associations were estimated using an excess relative risk model to distinguish between variables that affect baseline risk and variables (e.g. years quit) that only affect excess risk due to smoking, while adjusting for sex, age, race/ethnicity, diabetes, body mass index, and cigarettes smoked per day. BC cases were identified through SEER cancer registries to 2017. We tested for heterogeneity of smoking variables by race/ethnicity and estimated incidence across age, race-ethnicity, pack-years, and years quit.
Results: Over a mean 19 years of follow-up, 1,914 BC cases were identified. Age-standardized incidence rates of BC were highest among EA (51/100,000) and lowest among LA (24/100,000). Never smokers were most common among JA and LA (51%) and least common in other racial/ethnic groups (39-40%). In the full study sample, 50 pack-years smoked was associated with BC (HR=3.2 95% CI 2.7, 3.6). The association was heterogeneous by race/ethnicity ($p=0.02$) and statistically significant within each racial/ethnic group ($p<0.05$), except NH ($p=0.07$). Associations were strongest among EA (HR=4.0), followed by AA (HR=3.6), JA (HR=2.7), LA (HR=2.6), and NH (HR=2.4). There was no statistically significant heterogeneity of smoking cessation ($p=0.08$) or cigarettes smoked per day ($p=0.82$) by race/ethnicity. Each year quit resulted in a less than 1% decrease in the excess relative risk from smoking ($p=0.12$). The absolute risk models showed highest incidence at age 70 among EA current smokers (176/100,000) and lowest among AA never smokers (27/100,000). At age 70, current smokers across all ethnic groups had lower risk than EA who quit at age 45.
Conclusion: Pack-years smoked is significantly associated with BC risk. EA and AA groups experience the greatest excess relative risk from smoking and NH the lowest. Reduction in excess relative risk following smoking cessation is weak, meaning the cumulative effect of pack-years

smoked on BC risk cannot easily be attenuated with quitting. This contrasts with the risk reduction seen for lung and pancreatic cancer.

#6462

Cigarette smoking reduction and lung cancer risk in the Alpha-Tocopherol, Beta-Carotene Cancer Prevention Study

Daniela S. Gutiérrez-Torres, Sungduk Kim, Paul Albert, Demetrius Albanes, Stephanie J. Weinstein, Maki Inoue-Choi, Neal D. Freedman.
Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD

Background. Cigarette smoking is a leading cancer risk factor. In addition to quitting smoking, reducing the number of cigarettes/day may decrease risk of lung cancer compared with continuing to smoke more heavily. However, few cohort studies have longitudinal assessments of cigarette use. **Methods**. We examined the association of changes in smoking status (trying to quit, not smoking at this time, and still smoking) and changes in cigarettes/day with subsequent incidence of lung cancer in 24,613 Finnish male participants of the Alpha-Tocopherol, Beta-Carotene Cancer Prevention (ATBC) Study, a cancer prevention trial of vitamin supplements that collected serial assessments of cigarette use. At baseline (1985-1988), all participants were current smokers 50-69 years old who smoked 5+ cigarettes/day. During the five-to-eight year intervention period, men were asked at 4-month intervals about changes in their smoking use since their last visit. We obtained individual estimates of the proportion of follow-up time (% of time) in each of the three smoking statuses, the transition probabilities between statuses and intercepts and slopes for the number of cigarettes/day. We then examined associations between changes in smoking and in cigarettes/day and subsequent incidence of lung cancer occurring between the end of the trial (April 30, 1993) and December 31, 2012. Using Cox regression, we modeled lung cancer risk ratios (RRs) and 95% confidence intervals (95%CI) associated with changes in smoking (% of time and number of cigarettes/day) relative to individuals who smoked 20 cigarettes/day across all the study visits. Models were additionally adjusted for age at the end of the trial, ATBC intervention group, education, and age at smoking initiation. **Results**. Overall, 3013 lung cancers were diagnosed during follow-up. The risk of lung cancer was lower among participants

who reduced their smoking intensity by 5 or 10 cigarettes/day [RR=0.80(95%CI:0.71,0.89) and RR=0.64(95%CI:0.51,0.81), respectively]. RRs were further decreased among participants who also smoked at only 50% of study visits [-5 cigarettes/day RR=0.71(95%CI:0.57, 0.90) and -10 cigarettes/day RR=0.46(95%CI:0.44, 0.74)]. Individuals with the lowest risk were those who stopped smoking early at follow-up and continued to not smoke over the intervention period. For example, an individual who began the study smoking 15 cigarettes/day, stop smoking at 4 months and remained not smoking had a RR=0.24(95%CI: 0.11, 0.50). **Conclusion**: Even in the absence of cessation, smokers may meaningfully lower their lung cancer risk by reducing the number of cigarettes they smoke per day and the proportion of time they smoke. Yet, the lowest risk was observed among smokers who quit completely.

#6463

Persistence of smoking mutational signatures in the non-small cell lung cancer genome

Colin R. Lindsay[1], Pantelis Nicola[2], Andreas Gruber[3], Kate Brown[2], Mathew Carter[2], Helen Adderley[1], Shereen Rafee[2], Anna Moss[4], Andrew Wallace[5], George Burghel[5], Helene Schlecht[5], Katie Baker[2], Sharzad Moghadam[6], Jane Rogan[6], Jamie Weaver[1], Angeliki Malliri[7], William Newman[5], Fiona Blackhall[1], David Wedge[1], Genomics England. *[1]Division of Cancer Sciences, The University of Manchester, Manchester, United Kingdom,[2]The Christie NHS Foundation Trust, Manchester, United Kingdom,[3]The University of Konstanz, Konstanz, Germany,[4]Division of Cancer Sciences, The Christie NHS Foundation Trust, Manchester, United Kingdom,[5]Manchester Centre for Genomic Medicine, Manchester, United Kingdom,[6]Manchester Cancer Research Centre Biobank, Manchester, United Kingdom,[7]Cancer Research UK Manchester Institute, Manchester, United Kingdom*

Mutational signatures offer insights into cancer etiology. Smoking tobacco is associated with three signatures involving single base substitutions (SBS4), double base substitutions (DBS2) and insertions/deletions (ID3). Combining mutational signatures with clinical data allows examination of

temporal and quantitative aspects of carcinogenic exposures. We analyzed 132 non-small cell lung carcinoma (NSCLC) whole genomes, sequenced through the 100,000 Genomes Project (Genomics England), with paired clinical data available for 130/132 (98.5%). Clinical data included smoking status, duration, pack-years (py), and duration of smoking cessation. The majority were "ever-smokers" (ex-smokers: 90/130, 69.2%; current smokers: 32/130, 24.6%) and 120/122 (98.4%) had at least one smoking signature. DBS2 was the most sensitive signature for ever-smokers (118/122, 96.7%), although SBS4 was the optimal signature for diagnosing smoking-related NSCLCs (SBS4 positive likelihood ratio 7.15). An absence of ID3 best identified true never smoker NSCLCs (ID3 negative likelihood ratio 0.08). Ever-smokers had a higher tumor mutational burden (TMB) than never smokers (median 8.25 mutations/Mb vs 1.18 mutations/Mb, $p = <0.0001$), while TMB positively correlated with smoking pack-years ($p = 0.044$). Following smoking cessation, the median length of discontinuation was 11 years before a smoking-related NSCLC was diagnosed and, in some cases, smoking signatures persisted for up to 50 years prior to NSCLC diagnosis. To complement existing epidemiological data, 40 pack years was estimated as a critical cut-off for minimizing ongoing NSCLC risk. Prolonged smoking cessation did not reduce TMB ($p = 0.055$) or SBS4 mutations ($p = 0.11$), although this did produce lower DBS2 counts ($p = 0.0067$). Further signatures observed included SBS92 (previously seen in the bladder urothelium of ever-smokers) and a novel signature hypothesized to be linked to DNA mismatch repair deficiencies. NSCLCs from two patients with prior platinum chemo-radiotherapy harbored signatures of both chemotherapy- and radiotherapy-induced damage in their recurrent biopsy sample. These results highlight the importance of paired sequencing and clinical data, revealing that smoking-induced DNA damage can have long-lived effects, and strengthening health guidance of abstinence from smoking at the earliest possibility.

Antidepressant use and lung cancer risk and mortality: A meta-analysis of observational studies

Eunkyung Lee[1], David Li[1], Yongho Park[2], Alice Rodriguez-Fuguet[2], Xiaochuan Wang[3], Wen Cai Zhang[2]. *[1]Health Sciences, University of Central Florida, Orlando, FL,[2]College of Medicine, University of Central*

Florida, Orlando, FL,[3]School of Social Work, University of Central Florida, Orlando, FL

Objectives: Recent preclinical studies suggested potential anticancer effects of antidepressant (AD) use in multiple cancers, but the effect on lung cancer in human studies remains unclear. This meta-analysis examined the effect of AD use on lung cancer incidence and mortality.

Methods: Web of Science, Medline, CINAHL, and PsycINFO databases were searched to identify eligible studies published by June 2022. We conducted a meta-analysis using a random effects model to estimate pooled risk ratio (RR) and 95% confidence interval (CI) for comparing those with AD use and non-use. Heterogeneity was examined using Cochran's Q test and inconsistency I^2 statistics. The methodological quality of selected studies was assessed using the Newcastle-Ottawa Scale for observational studies.
Results: The meta-analysis, including 11 publications involving 1913172 participants, showed that AD use significantly increased lung cancer risk by 11% (RR= 1.11; 95% CI= 1.01, 1.22; I^2= 74.3%; n= 6); however, all-cause mortality was not affected by AD use (RR= 1.05; 95% CI= 0.68, 1.58; I^2= 90.1%; n= 4) while lung cancer-specific mortality could be reduced by 32% from one study. Subgroup analysis showed that serotonin and norepinephrine reuptake inhibitors (SNRIs) were associated with an increased lung cancer risk (RR= 1.38; 95% CI= 1.07, 1.78), but selective serotonin reuptake inhibitors (RR= 1.05; 95% CI=0.91, 1.21) and tricyclic antidepressants (RR= 1.09; 95% CI=0.95, 1.26) were not. In addition, variations in the definition of AD use could be the source of heterogeneity of observed effects. The quality of selected studies was good (n= 5) to fair (n= 6).
Conclusions: Evidence suggests that AD use was associated with an elevated risk of lung cancer but not with all-cause mortality. More research is needed to precisely estimate the effect of AD use on lung cancer-specific mortality. (Funding: University of Central Florida Center for Behavioral Health Research and Training; Registration: PROSPERO; registration number: CRD42022350719)

Associations of early menopause and hormone therapy with lung health and mortality among female never and ever smokers from the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial
Tessa Flores, Xiaochun Gai, Yiliang Zhu, Kimberly Leslie, Shuguang Leng. *University of New Mexico Health Sciences Ctr., Albuquerque, NM*

Our previous study using the Lovelace Smokers cohort identified early natural menopause (i.e., age at menopause<45 yr), which is a biomarker of ovarian aging, as a risk factor for lung disease and mortality among female smokers. However, most of the associations reported in female smokers with natural menopause were not observed in those with surgical menopause, (a mixed group of subjects with bilateral oophorectomy or hysterectomy without bilateral oophorectomy). Females with bilateral oophorectomy lose ovarian estrogen and progesterone production, while females with hysterectomy, +/- unilateral oophorectomy, maintain some of this hormone production. We hypothesize that associations between early menopause, lung health and mortality will vary based on type of menopause. Among 69,071 females from the Prostate, Lung, Colorectal and Ovarian (PLCO) Cancer Screening Trial, early menopause rates were 8.7%, 44.1%, and 72.8% in never smokers versus 12.1%, 51.6%, and 78.0% in ever smokers with natural, bilateral oophorectomy, or hysterectomy without bilateral oophorectomy, respectively. We analyzed the associations of early menopause and hormone therapy with lung health (physician diagnosed emphysema and chronic bronchitis and lung cancer incidence) and mortality (all-cause and cause-specific) outcomes by smoking status and menopause types. The most consistent associations were observed for all-cause mortality: 1) Except in never smokers who received hysterectomy only, early menopause was associated with higher all-cause mortality regardless of smoking status 2) hormone therapy was associated with lower all-cause mortality in all groups and the longer the use, the more beneficial the outcome; 3) the magnitude of this association was strongest in those who underwent bilateral oophorectomy. Furthermore, in ethnic disparity analysis, all-cause mortality was affected by early menopause to a lesser degree in non-Hispanic black ever smokers and there was increased benefit from hormone therapy in non-Hispanic black never smokers. Overall, we identified further evidence supporting early menopause as a risk factor for lung health and mortality and hormone therapy as being beneficial regardless of smoking status or menopause type. Our results support the "shorter lifetime estrogen exposure in early menopause" hypothesis and the clinical importance of hormone therapy beyond withdrawal symptom coping.

#6468

Association of food groups and dietary pattern with breast cancer risk: A systematic review and meta-analysis

Jialei Fu[1], Woo-Kyoung Shin[2], Dan Huang[2], Sukhong Min[2], Li-Juan Tan[1], Hyein Jung[1], Khongorzul Ganbat[1], Jiwon Jeong[1], Seok-Jae Oh[1], Bayarmaa Nasan Ulzii[1], Daehee Kang[1], Sangah Shin[1]. *[1]Chung-Ang University, Anseong, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of*

We conducted a systematic review and meta-analysis of current evidence for the association between food groups, dietary patterns, and breast cancer risk among the Asian population. This systematic review and meta-analysis followed the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines. We performed a systematic literature search up to November 2022 in English in the PubMed, Web of Science, Embase, and Cochrane databases. Risk ratios (RRs) with 95% confidence intervals (CIs) were extracted as effect sizes. Publication bias was estimated by the funnel plot method. We collected the data from 15 cohort studies and 30 case-control studies meeting the search criteria. The meta-analysis found that fruit and vegetable consumption was associated with a 27% and 35% lower risk of breast cancer, respectively [RR = 0.73 (0.56, 0.96); RR = 0.65 (0.47, 0.90)]. By contrast, no significance was found between meat, soy food, and green tea consumption and breast cancer risk ($P > 0.05$). However, soy protein and isoflavone intake could lower breast cancer risk by 35% and 32%, respectively [RR = 0.65 (0.51, 0.83); RR = 0.68 (0.55, 0.82)]. As for dietary pattern, higher adherence to a healthy dietary pattern and healthy eating index was associated with a 38% and 62% reduction in breast cancer risk, respectively [RR = 0.62 (0.44, 0.88; RR = 0.38 (0.22, 0.67)], while high adherence to an unhealthy dietary pattern was associated with a 44% increased risk [RR = 1.44 (1.06, 1.96)]. Considering alcohol consumption, a 75% increased risk of breast cancer was found [RR= 1.75 (1.33, 2.30)]. The present meta-analysis found that high intakes of fruit, vegetable, soy protein, and soy isoflavone significantly reduced the risk of breast cancer, while high intake of alcohol had a significantly increased risk. Meat, soy food, and green tea consumption were not significantly associated with breast cancer risk. Considering dietary patterns, higher adherence to a healthy eating index and a healthy dietary pattern may reduce breast cancer risk. Conversely, adherence to unhealthy dietary patterns may increase breast cancer risk. However, further studies are needed to confirm the associations between dietary patterns and breast cancer in the Asian population. This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (No.2022R1F1A1074279). MSIT: Ministry of Science and ICT.

Associations between serum iron levels and breast cancer tumor size

Ann Von Holle[1], Rachel L. Thompson[2], Katie M. O'Brien[3], Dale P. Sandler[3], Clarice R. Weinberg[1]. *[1]Biostatistics and Computational Biology, NIH-NIEHS (National Institute of Environmental Health Sciences), Durham, NC,[2]Environmental and Planetary Health Sciences, CUNY Graduate School of Public Health & Health Policy, New York, NY,[3]Epidemiology, NIH-NIEHS (National Institute of Environmental Health Sciences), Durham, NC*

Background: Iron metabolism is disrupted in cancer cells, with well-established associations between increased iron availability and cancer growth. Excess iron can be toxic, and animal models have demonstrated that excess iron promotes tumor growth, whereas iron deficiency reduces or slows tumor growth. Few observational studies have assessed associations between serum iron levels and human tumor characteristics. The objective of this study is to estimate the associations between serum iron levels and tumor size at diagnosis in breast cancer cases from The Sister Study, a large prospective cohort based in the United States. Methods: Data are from a case-cohort sample of the Sister Study selected in 2016 to study serum iron levels. Of the 3,007 invasive or ductal carcinoma in situ cases included, we used the 2,494 incident breast cancer cases with information on tumor size and iron levels. Serum iron (mcg/dL), ferritin (mcg/dL), and percent transferrin saturation were measured in samples collected at baseline (median time from collection to diagnosis 4.6 years). Prior to modeling, we applied a natural log transformation to the largest tumor size and ferritin levels. To estimate the associations between body iron levels and tumor size, we used Spearman's rank correlation and linear regression models adjusting for body mass index and age at study entry. If there

were multiple tumor measures for one person, we selected the largest tumor size. Sensitivity analyses included: 1) restricting analyses to diagnoses more than 6 months after or less than 4 years after baseline iron measures, 2) excluding women who reported taking iron supplements, and 3) stratifying analyses by tumor subtypes.
Results: Associations between all three serum iron levels and tumor size were close to the null, indicating no evidence of an association between iron and tumor size. Spearman's rank correlations were all close to zero. Adjusted regression slopes (95% confidence interval) were -0.0005 (-0.0010, 0.0005) for serum iron, -0.0163 (-0.055, 0.022) for ferritin, and -0.0009 (-0.004, 0.0021) for percent transferrin saturation. Results from the sensitivity analyses did not substantively differ from our primary findings.
Conclusions: We did not find evidence to support the hypothesis of a positive association between breast cancer tumor size at the time of diagnosis and serum iron levels. The conflicting evidence between this study and previous research in animal models suggests that iron in the human tumor microenvironment may operate independently of circulating iron or body iron stores.

#6470

Coffee and tea consumption, coffee-related metabolites, and breast cancer risk in US Women

Andrea Romanos-Nanclares[1], Oana A. Zeleznik[1], Mingyang Song[2], Walter C. Willett[3], Rulla M. Tamimi[4], Wendy Y. Chen[5], Michelle D. Holmes[6], Jae Hee Kang[1], A. Heather Eliassen[7]. *[1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Massachusetts General Hospital and Harvard Medical School, Boston, MA,[3]Nutrition and Epidemiology, Harvard Medical School/Brigham and Women's Hospital and Harvard T.H. Chan School of Public Health, Boston, MA,[4]Department of Population Health Sciences, Weill Cornell Medicine, New York, NY,[5]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[6]Harvard Medical School/Brigham and Women's Hospital and Harvard T.H. Chan School of Public Health, Boston, MA,[7]Nutrition, Harvard Medical School/Brigham and Women's Hospital and Harvard T.H. Chan School of Public Health, Boston, MA*

Background: Coffee intake may protect against breast cancer; however, previous studies have been inconsistent and potential underlying mechanisms remain unclear. We aimed to 1) examine the association between total coffee, tea, and caffeine intake and breast cancer risk and 2) identify plasma metabolites associated with coffee intake and examine these metabolites in relation to breast cancer risk.
Methods: Data on breast cancer risk factors were collected from questionnaires administered biennially and at the time of blood collections (Nurses' Health study, NHS, distant collection: 1989-1990, recent collection: 2000-2002; NHSII, 1996-1999). We evaluated the association between total coffee (caffeinated and decaffeinated), tea consumption and caffeine intake and breast cancer risk in the full cohort using Cox regression models. Leveraging dietary and metabolomic data, we identified and validated plasma metabolites associated with coffee intake in 2,033 women from the NHSII breast cancer sub-study. We then evaluated the prospective association of all prior (PMID: 32788283) and new coffee-related metabolites with breast cancer risk in a nested case-control study using conditional logistic regression models.
Results: We documented 10,060 cases of invasive breast cancer during 3,901,211 person-years of follow-up. In pooled, multivariable-adjusted models, compared to never consumers (0 cups/d), women consuming ≥6 cups/d of total coffee were at lower risk of invasive breast cancer (HR, 0.91; 95% CI, 0.82, 1.00; P-trend<0.01). Stratified analysis showed a significant effect modification by BMI (P-interaction=0.03). Compared to never consumers, drinking ≥6 cups of coffee per day was inversely associated with risk of invasive breast cancer among lean women (HR, 0.83; 95% CI, 0.72, 0.97) but not among overweight or obese women. Moreover, a lower risk of ER-negative breast cancer was observed with total coffee ($HR_{\geq 6 \text{ cups/d vs. } 0 \text{ cups/day}}$ 0.75; 95% CI, 0.59, 0.95; P-trend=0.01) and decaffeinated coffee consumption ($HR_{\geq 4 \text{ cups/d vs. o cups/day}}$ 0.66; 95% CI, 0.45, 0.95; P-trend=0.01). Among the 31 studied metabolites, no single metabolite was associated with breast cancer risk. Associations were generally consistent between ER-positive and ER-negative breast cancer, although trigonelline seemed to be suggestively stronger for ER-negative (OR, 95% CI, 0.87, 0.75-1.01; P-value=0.061). Furthermore, 1,7-dimethyluric acid, some cholesterol esters (C18:1 CE, C18:2 CE and C20:4 CE) and trigonelline, all positively associated with coffee, were indicative of an inverse association with breast cancer risk among lean women.

Conclusions: Coffee consumption was associated with lower breast cancer risk, particularly among lean women and ER-negative breast cancer. Some metabolites that might explain some of the observed inverse associations. Nonetheless, these results merit further exploration.

#6471

Tattooing and risk of hematologic cancer: A population-based case-control study in Utah

Rachel D. McCarty[1], Britton Trabert[1], Morgan M. Millar[1], Benjamin Haaland[1], Laurie Grieshober[1], Mollie Barnard[2], Lindsay Collin[1], Jeffrey A. Gilreath[1], Paul J. Shami[1], Jennifer A. Doherty[1]. *[1]University of Utah, Salt Lake City, UT,[2]Boston University Chobanian & Avedisian School of Medicine, Boston, MA*

Background: Tattooing is increasing in popularity throughout western countries and is seen in approximately 32% of the United States. However, little is known about long-term health effects of tattooing. Some tattoo inks contain carcinogens, which can interact with solar radiation to produce potentially toxic compounds. Tattoo inks can also migrate to the lymphatic system and produce inflammatory and immune responses. In this study, we evaluated whether tattooing exposures were associated with risk of hematologic malignancies.
Methods: This population-based case-control study included 656 cases of hematologic malignancies (156 myeloid neoplasms and 500 lymphomas), ages 19-79 years, who were diagnosed between July 2019 and December 2021, and identified through the Utah Cancer Registry using rapid case ascertainment. Controls were selected from ~19,000 adult Utah residents who participated in the 2020 Utah Behavioral Risk Factor Surveillance System (BRFSS) statewide survey and frequency matched to cases in a 3:1 ratio on age, sex, race, and ethnicity. Telephone surveys collected data on number of tattoo sessions, number of large tattoos, age at first tattoo, and relevant covariates. We fit binary logistic regression models for general hematologic malignancies and multinomial logistic regression models for myeloid neoplasms and lymphomas, to calculate odds ratios (ORs) and 95% confidence intervals (CIs) for each tattoo variable, adjusted for age, sex, race, ethnicity, education level, past cancer diagnosis (yes/no), and ever smoker (yes/no).
Results: There was no strong evidence that ever having received a tattoo versus never having received a tattoo was associated with risk of overall hematologic cancers (OR=1.01, 95% CI: [0.96-1.07]), myeloid neoplasms (1.12 [0.59-2.13]), or lymphomas (1.07 [0.77-1.49]). However, having three or more large tattoos, compared with never having received a tattoo, was suggestively associated with an increased risk of overall hematologic cancers (1.33 [0.69-2.47]). The effect estimate was strongest among myeloid neoplasms (1.73 [0.54-5.50]). Compared with never having received a tattoo, receiving a first tattoo before age 20 was associated with an elevated risk of myeloid neoplasms (2.00 [0.91-4.38]), and receiving a first tattoo at age 20 or older was associated with an elevated risk of lymphoma (1.24 [0.84-1.83]), though the estimates were imprecise.
Conclusion: We observed a potential association between having several large tattoos and risk of hematologic cancers, particularly myeloid neoplasms. The risk of myeloid neoplasms appeared to be strongest among individuals receiving tattoos at young age. If confirmed, these findings could inform public health messaging about the safety of tattoos.

#6472

Self-reported knowledge of Δ9-tetrahydrocannabinol (THC) and cannabidiol (CBD) potency in cannabis products among cancer patients and survivors: Results from a survey of cannabis consumers at an NCI-designated cancer center

Michelle Goulette[1], Nicolas J. Schlienz[1], Amy Case[1], Eric Hansen[1], Rebecca L. Ashare[2], Maciej Goniewicz[1], Maansi Bansal-Travers[1], Andrew Hyland[1], Danielle M. Smith[1]. *[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]State University of New York at Buffalo, Buffalo, NY*

Background: Cannabis use may introduce risks and/or benefits to cancer patient treatment and survivorship, depending on product type, composition and nature of its use. Δ9-tetrahydrocannabinol (THC) and cannabidiol (CBD) are two primary cannabinoids that elicit therapeutic effects, but only THC has abuse potential, highlighting the importance of patient knowledge of cannabinoid potency in patient-provider interactions and provider risk-benefit assessments. This study aims to understand factors associated with

knowledge of THC or CBD potency in cannabis products among a sample of cancer patients and survivors who consumed cannabis since diagnosis.
Methods: Data were analyzed from a random sample of cancer patients and survivors using cannabis (n=343) and completed an anonymous, mixed-mode survey at Roswell Park. Survey questions asked about modes of use post-cancer diagnosis including smoking (joints/bongs/pipes/blunts), vaping (e-cigarettes/other vaping device), eating cannabis (foods/drinks), and taking orally (pills/tinctures/sublingually), and knowledge of cannabinoid potency was defined as knowing THC or CBD (mg or %) against no knowledge. Chi-square and separate multivariable logistic regression analyses for the most prevalent modes of cannabis use (smoking and eating) were examined to determine factors associated with knowledge of THC and CBD potency. Models controlled for acquisition source (informal; unlicensed seller vs formal; licensed seller), cannabis use instruction source (informal; personal vs formal; healthcare professional), current use status, and educational attainment.
Results: Prevalence of cannabis use following cancer diagnosis was 26.5% (20.9% among patients in active treatment; 29.2% among survivors). Among consumers, eating cannabis foods/drinking cannabis beverages was the most prevalent mode of delivery (58.6%), followed by smoking cannabis in joints (52.8%), vaping (30.3%), and taking oral pills, tinctures, or sublingually (29.2%). Overall, 27.2% had knowledge of THC and CBD potency of the products that they consumed. Those who smoked cannabis had the lowest rates (7.8% & 3.9%) followed by those eating cannabis foods/drinks (15.0% & 7.0%). Controlling for other factors, knowledge of THC and CBD potency showed significant associations with cannabis acquisition source, cannabis use instruction source, and current use status.
Conclusions: Overall, cancer patients and survivors who use cannabis have low levels of knowledge of THC and CBD potency. These data reinforce the need for provider awareness. Relying on patient self-report of THC and CBD potency is unlikely to provide key information that providers require to assess risks and benefits of cannabis use in relation to cancer symptom management.

#6473
Association of sun-seeking behaviors with indoor tanning habit in US females
Bojung Seo[1], Eunyoung Cho[2], Abrar A. Qureshi[2], Jiali Han[1]. *[1]Department of Epidemiology, Richard M. Fairbanks School of Public Health, Indiana University, Indianapolis, IN,[2]Department of Dermatology, Alpert Medical School of Brown University, Providence, RI*

Introduction: Frequent exposure to ultraviolet in early life has more detrimental and long-term effects on skin than in adulthood. Teenagers with strong sun-seeking behaviors are more likely to use an indoor tanning bed than those who seek less sun, probably due to addictive component of ultraviolet exposure. We aimed to examine the associations between sun exposure behaviors and average annual indoor tanning usage frequency during high school/college in US females.
Methods: In this cross-sectional study, we included a total of 76,122 US females who answered the average annual frequency of indoor tanning during high school/college from the Nurses' Health Study II, a large prospective cohort of US female nurses. We adjusted for age, daily number of cigarettes, number of alcohol drinks, strenuous sports frequency, hair color, family history of melanoma, chronic disease history, and mole numbers.
Results: In multivariable-adjusted multinomial logistic regression models, we demonstrated positive and dose response associations between sun exposure behaviors and annual times of indoor tanning bed usage. Specifically, teenagers who spent daily outdoors in a swimsuit (adjusted odds ratio [aOR], 95% confidence interval [CI] for daily vs. <1/week: 3.17, 1.63-6.15) were more likely to use indoor tanning beds. High school students and undergraduates who spent ≥5hours/week outdoors in direct sunlight during daytime also showed more usage of indoor tanning beds (aOR, 95% CI for ≥5hours vs. <1/week: 2.01, 1.06-3.79). Teenagers who had ≥10 sunburns that blistered also tended to more frequently use indoor tanning beds (aOR, 95% CI for ≥10 vs. Never: 2.32, 1.41-3.82).
Conclusions and Relevance: Teenagers who more spent outdoors in a swimsuit or in direct sunlight during daytime, or got more sunburns tended to use indoor tanning more frequently than those who did not. These findings provide evidence that teenagers with strong sun-seeking behaviors have excessive exposure to ultraviolet through indoor tanning.

Table 1. aORs (95% CIs) on the association between sun-exposure behaviors and tanning bed use habit

	None	1-2			3-11			≥12

Stress-related sick leave and subsequent cancer risk: A Swedish national register study of 516 678 cancer cases

Sai San Moon Lu[1], Jenny Hadrévi[2], Lisbeth Slunga Järvholm[2], Florentin Späth[1], Richard Palmqvist[3], Tommy Olsson[2], Sophia Harlid[1], Bethany van Guelpen[1]. *[1]Department of Radiation Sciences, Oncology Unit, Umeå University, Umeå, Sweden,[2]Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden,[3]Department of Medical Biosciences, Umeå University, Umeå, Sweden*

Background: Despite previous studies investigating psychological stress in relation to cancer risk, no consensus has been reached as to whether stress is a modifiable risk factor for cancer. This study aims to investigate whether sick leave due to psychological stress can affect the risk of developing cancer.
Method: This is a matched case-control study using Swedish nation-wide register data (study period 2005-2018). The main exposure is stress-related sick leave defined as registered sick leave due to psychological stress with the diagnosis codes of F43 (International Classification of Diseases codes: ICD) and its subclassifications and hereafter referred to as stress leave. For each primary cancer case (except non-melanoma skin cancer), up to five cancer-free controls were matched based on sex, age and county. Conditional logistic regression, conditioned on matching factors and adjusting for socioeconomic factors, was used to calculate odds ratios (ORs) with 95% confidence intervals (CIs). For subgroup analyses by specific tumor sites, Bonferroni-corrected significance level of 0.002 (alpha value divided by the number of tumor sites = 0.05/24) was also applied.
Results: The study comprised 516 678 cancer cases and 2 357 433 matched controls. Stress leave of any duration, was associated with a modestly increased risk of cancer, with the highest risk observed for 1-30 days of leave, vs no leave during follow-up (adjusted OR 1.05, 95% CI 1.02-1.09). In subgroup analyses by tumor sites, stress leave was associated with an increased risk of prostate cancer (adjusted OR for >90 days vs no stress leave 1.10, 95% CI 1.01-1.20) and cervix cancer (adjusted $OR_{>90\ days\ vs\ no\ leave}$ 1.11, 95% CI 1.05-1.17). For lung cancer, an inverse risk relationship was found (adjusted $OR_{>90\ days\ vs\ no\ leave}$ 0.88, 95% CI 0.77-0.99). For other tumor sites, associations were generally null or had wide confidence intervals. After applying a Bonferroni-corrected significance level, the association was still significant for cervical cancer. Further examination by sex, specific types of psychological stress and cancer groups based on established etiology (tobacco use, obesity, alcohol consumption and gastric hyperacidity) showed a clear exposure-response trend in men and pronounced associations for exhaustion disorder (ICD code: F43.8A) and tobacco-related cancers. In a post-hoc analysis, the association for other HPV-related cancers was similar to that for cervical cancer but not statistically significant.
Conclusion: In this register study covering the entire Swedish population, we found that stress-related sick leave was associated with modestly higher risk of cancer, particularly the risk of cervical cancer. Potential higher risk of prostate cancer and lower risk of lung cancer were observed, though these associations were not statistically significant after controlling for multiple testing.

Compatibility of chatbot-based mobile and paper-based FFQs in participants with colorectal or gastric cancer screening

Eui Yeon Lim[1], Yun Jeong Lim[2], Sang Hoon Kim[2], Woongsup Kim[3], Jung Eun Lee[1]. *[1]Food and Nutrition, College of Human Ecology, Seoul National University, Seoul, Korea, Republic of,[2]Internal Medicine, Dongguk University Ilsan Hospital, Dongguk University College of Medicine, Goyang, Korea, Republic of,[3]Information Communication Engineering, Dongguk University, Seoul, Korea, Republic of*

Background: The food frequency questionnaire (FFQ) is the most commonly used method to assess the usual diet of groups and individuals. Paper or electronic FFQ consists of frequencies and portion sizes of foods and beverages. We developed a chatbot-based mobile FFQ, by embedding the validated FFQs in KakaoTalk, Korea's most popular mobile messenger. We examined the compatibility of the paper and chatbot-based mobile FFQs in participants who underwent cancer screening endoscopy.
Method: A total of 50 men and 45 women aged 24 to 79 were recruited from Dongguk University Ilsan Hospital between April and August 2022. Participants underwent gastroscopy or colonoscopy for cancer screening. They completed both the paper and chatbot-based mobile FFQs. Log-transformed intakes of energy and nutrients were compared using the Pearson correlation coefficient. We also calculated the Cohen's Kappa coefficients and evaluated Bland-Altman plots and the percent agreement from cross-classification to assess the compatibility.
Results: The Pearson correlation coefficients of energy and energy-adjusted nutrients ranged from 0.74 (niacin) to 0.90 (vitamin A), and the median of coefficients was 0.85. Cohen's kappa coefficient ranged from 0.56 (sodium) to 0.75 (n-6 fatty acid). In the Bland-Altman plots, most data were located between the lower and upper limits of agreement. The percentages of participants classified into the same and adjacent quartiles were between 88% and 98% for energy-adjusted nutrients.
Conclusions: Our study suggests a good compatibility of paper and chatbot-based mobile FFQs. The chatbot-based mobile FFQ may provide comparable intake rankings and be used to evaluate the association between dietary intake and disease risk in longitudinal studies.

Novel Factors Associated with Cancer Mortality

Mortality in patients with monoclonal gammopathy of undetermined significance: an analysis of National Health and Nutrition Examination Survey

Mengmeng Ji[1], John Huber[1], Mei Wang[1], Yi-Hsuan Shih[1], Yao-Chi Yu[1], Lawrence Liu[2], Theodore Thomas[3], Martin W. Schoen[3], Kristen M. Sanfilippo[1], Graham A. Colditz[1], Shi-Yi Wang[4], Su-Hsin Chang[1].
[1]Washington University in St. Louis, Saint Louis, MO,[2]City of Hope Comprehensive Cancer Center, Duarte, CA,[3]St. Louis Veterans Affairs Medical Center, Saint Louis, MO,[4]Yale University, New Heaven, CT

Introduction: Monoclonal gammopathy of undetermined significance (MGUS) is an asymptomatic premalignant plasma cell disorder with an annual risk of ~1% of progression to more advanced diseases, including multiple myeloma (MM). Few studies reported mortality risk in patients with MGUS, among which the diagnosis of MGUS was typically incidental due to unrelated symptoms or laboratory abnormalities. This study aims to compare the survival of MGUS patients with the U.S. general population using a nationally representative screening-based survey.
Methods: Data were obtained from the third National Health and Nutrition Examination Survey (NHANES III) 1988-1994 and continuous NHANES 1999-2004, with follow-up all-cause mortality data through December 31, 2019. Participants were screened for MGUS by protein electrophoresis, immunofixation, and kappa and lambda free light chain assays in serum. Multivariable Cox-proportional regressions were performed, adjusting for demographic characteristics (age, gender, race/ethnicity, education, income, body mass index [BMI]), health behaviors (smoking, physical activity), baseline medical conditions (hypertension, diabetes, osteoporosis, myocardial infarction, stroke, congestive heart failure, coronary heart disease, peripheral vascular disease [PVD], arthritis, liver diseases, chronic obstructive pulmonary disease, renal diseases, cancer), and survey year. We also tested the interaction between race/ethnicity and MGUS diagnosis in the fully adjusted model. The NHANES complex sampling design was accounted for in all analyses to obtain population estimates.

Results: The prevalence of MGUS among the U.S. population aged 50 years or older was 2.5% in 1988-1994 (sample size n=6,557; population size N=56,136,480) and 2.3% in 1999-2004 (n=5,847; N=68,835,295). MGUS patients were older and more likely to have PVD (13.1% vs. 7.7%, p = 0.03). No evidence was found showing a difference in gender distribution, education, income, BMI, and other comorbidities between the two populations. In NHANES 1999-2004, MGUS was associated with an increased risk of death (Hazard ratios [HR] 1.20, 95% CI: 1.02-1.41, p = 0.03) compared to the general population. NHANES III also showed a trend toward increased risk of mortality (HR 1.15, 95% CI: 0.89-1.48, p = 0.27). No interaction between race/ethnicity and MGUS diagnosis was found. It was notable that PVD was associated with an increased risk of death (HR 1.67, 95% CI: 1.43-1.94, p < 0.001).
Conclusion: In the large cohort of NHANES participants, MGUS was associated with an increased risk of mortality. MGUS is typically viewed as a "benign" condition that has the potential to progress to cancer. These findings suggest that there may be alternate health implications to a diagnosis of MGUS. Future studies should focus on the causes of death in this population and the role of MGUS.

#6481
Systematic review of the literature: tertiary prevention in leukemia patients
Nikita Manyak, Su Yon Jung. *UCLA - University of California Los Angeles, Los Angeles, CA*

Background: After conducting a thorough search, we found a lack of published literature review about the tertiary prevention of patients with leukemias and discussion about their prognosis. We thus searched related publications in the last decade and wrote an extensive literature review on the topic.
Method: We conducted an extensive search for electronic database via MEDLINE and PubMed. Using the key terms "progression-free survival (PFS) leukemia" and restricting the search to "English language" for the last decade, we initially found 1,083 published papers on the related topic. On the basis of review, we collected necessary data and extracted some recommendations for treatment of leukemia patients.
Results: Standard treatments such as Daunorubicin, Doxorubicin, or Asparaginase for leukemias in children, adolescents, and young adults (ages 18 to 24) were associated with high rates of relapse and other complications within 5 years post-treatment. Of note, Blinatumomab and Ibrutinib-Rituximab showed higher success rates of PFS and overall survival compared to other chemotherapy treatments. Two-year disease free survival was 39.0% for patients with intensive chemotherapy while it was 54.4% for patients given the anticancer drugs. In addition, two-year overall survival was relatively worse (58.4%) in patients treated with chemotherapy compared with those with other treatments (71.3%). In comparison, radiotherapy has been used for patients who relapsed after remission and found to be more successful in the long run in preventing another relapse and leading to higher rates of overall survival. For example, patients previously experienced a 78% response rate to the treatment received cranial radiation; compared to the survival rate (11.3%) of patients who were not treated with the radiation, they experienced higher four-year survival rates (77.7%). For most pediatric leukemias, allogenic stem cell therapies have been the most effective treatment with a higher rate of remission. However, after this treatment, a majority of the patients relapsed soon after and were unable to continue fighting the disease, resulting in death. Of note, during the past 10 years, some immunotherapies have been discovered and reported more effective than traditional chemo/radiotherapies and allogenic/autologous stem cell treatments. In particular, Tisagenlecleucel, a chimeric antigen receptor (CAR) T-cell therapy, has been approved to treat pediatric leukemias when they have relapsed after initial or tertiary remission. Their 5 or 10 year survival rate after this treatment was over 50%.
Conclusion: Among the standard treatments that have been studied during a decade for leukemia in children and adolescents, CAR T-cell immunotherapy appears to be the most effective after patient relapse. More research for the immunotherapies on different populations with diverse age groups is requested on a tertiary prevention perspective.

CLDN18.2 expression is associated with clinicopathological features and prognosis of Chinese patients with digestive system cancers: a retrospective analysis
Chong XiaoYi[1], Changsong Qi[1], Jifang Gong[1], Miao Zhang[1], Mingyang Ma[1], keren Jia[1], Ting Zhou[1], Li Jian[1], Zhi Peng[1], Jun Xiao[2], Xiaohui Peng[2], Zhen Liu[1], Zonghai Li[2], Xiaotian Zhang[1], Lin Shen[1]. *[1]Peking*

University Cancer Hospital, Beijing, China,[2]CARsgen Therapeutics Co., Ltd., Shanghai, China

Importance: CLDN18.2 was a promising therapeutic target in solid tumors, whereas the clinicopathological features of Chinese CLDN18.2-positive cancer patients were rarely elucidated.
Objective: This study aimed to explore the association between CLDN18.2 expression and clinicopathological features of Chinese patients with CLDN18.2-positive digestive system cancers.
Methods: This retrospective study included digestive system cancer patients from June 2019 to April 2021 who were screened for two clinical trials of CT041 (an anti-CLDN18.2 CAR-T cell, NCT03874897, and NCT04581473), which were initiated at our center.
Results: A total of 875 digestive system cancer patients were included. CLDN18.2 expression was observed in 73.1% GC patients, 61.8% pancreatic cancer (PC) patients, 10.6% colorectal cancer (CRC) patients, and 65.6% biliary tract carcinoma (BTC) patients. In GC, CLDN18.2 expression was associated with age, sex, and Lauren phenotype (all P<0.01). CLDN18.2-positive GC patients had a higher incidence of uterine adnexa metastasis (6.4% vs. 20.8%, P<0.001), and a lower incidence of liver metastasis (22.2% vs. 35.7%, P<0.001). In PC, CLDN18.2-positive cases had a higher proportion of tumors with moderate/high differentiation (46.1% vs. 19.0%, P<0.001), compared with CLDN18.2-negative patients. Additionally, compared with CLDN18.2-negative patients, the proportion of right colon cancer was higher in CLDN18.2-positive patients (40% vs. 18.1%, P=0.028).
Conclusions: The results of this study suggested that CLDN18.2-positive tumors had unique clinicopathological features, which provided a theoretical basis for the treatment of CLDN18.2 positive tumors.

The association between food deserts, food swamps, and obesity-related cancer mortality in the United States: the new epidemic

Malcolm Bevel, Meng-Han Tsai, April Parham, Sydney Andrzejak, Samantha R. Jones, Justin X. Moore.
Medicine, Augusta University, Augusta, GA

Background: Obesity-related cancers account for 40% of all cancers in the United States (U.S.). Healthy food consumption is a modifiable factor shown to reduce obesity-related cancer mortality, but residing in geographical areas with poor access to grocery stores/farmer's markets (food deserts) or higher access to fast-food/convenience stores (food swamps) reduces healthy food access and has been severely understudied.
Methods: We conducted an ecological study utilizing 2010 - 2020 data from the U.S. Department of Agriculture Food Environment Atlas and Center for Disease Control and Prevention mortality. 3,041 U.S. counties with complete information on food environment scores and obesity-related cancer mortality data were included. Food swamp score was calculated as the ratio of fast-food and convenience stores to grocery stores and farmer's markets. Obesity-related cancer (based on the International Agency for Research on Cancer evidence between obesity and 13 types of cancer) mortality rates were categorized as high (≥71.8 per 100,000) versus low (<71.8 per 100,000) per county. We performed an age-adjusted multivariable polytomous logistic regression for the association between food desert scores, food swamp scores, and obesity-related cancer mortality rates.
Results: Counties with high obesity-related cancer mortality rates had higher percentage of NH-black population (3.30 vs 1.80), persons older than 65 years (15.7 vs 15.4), poverty rates (19.0 vs 14.4), adult obesity rates (33.0 vs 32.1), and adult diabetes rates (12.5 vs 10.7) when compared to counties with low obesity-related cancer mortality (p-value < 0.0001; Table 1). We observed 77% increased odds of having high obesity-related cancer mortality rates among U.S. counties with high food swamp scores (adjusted odds ratio [AOR] = 1.77; 95% CI: 1.43 - 2.18). A positive dose-response relationship between three levels of food desert and food swamp scores and obesity-related cancer mortality was also observed (p-value <0.0001).
Conclusions and Relevance: Policymakers, funding agencies, and community stakeholders should implement sustainable approaches at combating obesity and establishing healthier accessible food such as creating more walkable neighborhoods and community gardens.

Impact of time between last childbirth and diagnosis of early-onset breast cancer on survival in germline *BRCA1/2* carriers

Zhenzhen Zhang[1], Shangyuan Ye[1], D Gareth Evans[2], Pepper Schedin[1]. *[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR,[2]The University of Manchester, Manchester, United Kingdom*

INTRODUCTION: Young women diagnosed with breast cancer in close proximity to childbirth have increased risk of mortality compared to nulliparous women, and the postpartum period has been identified as a risk window for breast cancer metastasis. BRCA1/2 germline mutation carriers have a high risk of developing breast cancer at young age, yet it is unknown if recent childbirth is a poor prognostic risk factor for BRCA1/2 carriers. Here we assessed whether time between last childbirth and breast cancer diagnosis impacted survival among early-onset BRCA1/2 breast cancer patients. METHODS: The study population includes 903 female BRCA1/2 mutation carriers diagnosed with stage I-III breast cancer at ≤45 years of age between 1950 and 2021 in the UK. The primary outcome of this study is all-cause mortality. The primary exposures were no prior childbirth (n=224), or time between last childbirth and breast cancer diagnosis grouped as 0-<5 years (n=228), 5-<10 years (n=191), or ≥10 years since last childbirth (n=260). Cox proportional hazards regression was applied to identify factors associated with risk of 20-year mortality. RESULTS: Breast cancer diagnosed 5-<10 years after last childbirth was associated with an elevated risk for mortality [HR=1.56 (95% CI, 1.05-2.30)] compared to nulliparous cases after adjusting for patient age and tumor stage. Across groups, nulliparous women had the best prognosis, suggesting parity may increase risk of death in BRCA1/2 carriers. ER-negative cancers were the dominant tumor type across all groups: 54.8% (nulliparous), 52.6% [postpartum breast cancer (PPBC) <5], 58.4% (PPBC 5-<10), and 54.0% (≥10). ER-negative cases were more prevalent among BRCA1 carriers (77%) compared to BRCA2 carriers (24%). In stratified analyses by either ER or BRCA status, increased mortality in the PPBC 5-<10 group was significant for ER-negative cases [HR=3.12 (95% CI, 1.22-7.97)] and BRCA1 carriers [HR=2.03 (95% CI, 1.15-3.58)], compared to nulliparous groups. For ER-positive cases, 71% of cases were BRCA2 carriers, and the most significant postpartum interval among ER-positive cases was observed in the 0-<5 group [HR=2.35 (95% CI, 1.02-5.42)]. No association was observed for BRCA2 carriers with PPBC 0-<5 vs nulliparous groups [HR=1.26 (95% CI, 0.73-2.16)].CONCLUSION: Results suggest that BRCA1/2 breast cancer patients are at increased risk for all-cause mortality if diagnosed within 10 years of childbirth. For ER-positive disease, poorest prognosis occurs within 0-5 years postpartum, consistent with promotion of existing sub-clinical tumors. For BRCA2 carriers, the association between postpartum diagnosis and mortality is weak. For ER-negative disease, similar to BRCA1 carriers, poorest prognosis occurs 5-10 years postpartum, suggesting an interaction between BRCA1 and parity may result in increased tumor initiation.

Oxidative phosphorylation-associated radiomic feature and survival of women with serous ovarian cancer

Christelle Colin-Leitzinger, Jaileene Perez-Morales, Steven Eschrich, Jamie K. Teer, Sweta Sinha, Melissa J. McGettigan, Daniel K. Jeong, Olya Stringfield, Mahmoud A. Abdalah, Natarajan Raghunand, Robert J. Gillies, Jing-Yi Chern, Matthew Schabath, Lauren Cole Peres. *H. Lee Moffitt Cancer Center, Tampa, FL*

Novel biomarkers that can be utilized for clinical decision support to improve patient outcomes are critically needed for ovarian cancer. At present, there are no standard of care biomarkers to inform the first-line treatment regimen (neoadjuvant chemotherapy vs. upfront surgical debulking) best suited for each patient or which patients are at the highest risk of recurrence. To address this unmet need, we identified pre-treatment computed tomography (CT) image-based radiomic features predictive of outcomes and primary treatment response among 298 women diagnosed with serous ovarian cancer from 2008 to 2019. A decision tree analysis identified a single volumetric feature, region of interest (ROI) volume center of mass (CoM) in the X direction, as the most informative radiomic feature that stratified patients with upfront surgery into high- and low-risk groups for overall survival. The high-risk group consists of patients with higher values of the radiomic feature. In the training (N=91) and test (N=91) cohorts of women treated with upfront surgery, high-risk patients had worse survival compared to low-risk patients (HR=2.01, 95% CI=1.07, 3.77 and HR=2.23, 95% CI=1.19, 4.17, respectively). This radiomic feature was not associated with survival among women

treated with neoadjuvant chemotherapy (N=116; HR=1.23, 95% CI=0.73, 2.07). To reveal potential underlying biology of this radiomic feature, we performed RNAseq gene expression profiling on 47 formalin-fixed paraffin-embedded tumor specimens and correlated gene expression with the radiomic feature using DESeq2 from RSEM estimates. Dichotomized analysis (high- vs. low-risk) yielded 7 significant genes and continuous analysis yielded 15 significant genes (adjusted $p<0.05$), with both approaches identifying *AKT2* and *PSMC4*. Gene set enrichment analysis (GSEA) was used to identify enriched gene sets from continuous associations using the MSigDB Hallmarks pathways (adjusted $p<0.05$). GSEA identified the oxidative phosphorylation (OXPHOS) pathway as one of the gene sets most negatively associated with the predictive radiomic feature (Hallmark Normalized Enrichment Score=-2.28, adjusted $p<0.001$). We derived a PCA-based gene signature from significantly associated OXPHOS genes ($p<0.01$) resulting in a negative correlation with the radiomic feature ($R=-0.65$, $p<0.001$). Prior studies have shown that high OXPHOS ovarian tumors are associated with an increased response to conventional chemotherapy, suggesting that OXPHOS may be a key pathway for chemoresistance in ovarian cancer. In summary, we identified an OXPHOS-associated radiomic feature predictive of survival among women with serous ovarian cancer treated with upfront surgery. Further research is needed to elucidate the biologic and mechanistic underpinnings of the identified radiomic feature and to validate these findings in a larger cohort of women with ovarian cancer.

Single nucleotide polymorphisms that predict serum cholesterol as a prostate cancer prognostic factor - a Mendelian randomization study

Sebastian Boele[1], Aino Siltari[1], Paavo Raittinen[2], Johanna Schleutker[3], Kimmo Taari[4], Kirsi Talala[5], Teuvo Tammela[1], Anssi Auvinen[6], Teemu J. Murtola[1]. *[1]Faculty of medicine and health technology, Tampere University, Tampere, Finland,[2]Oriola, Helsinki, Finland,[3]Turku University, Turku, Finland,[4]Urology, Helsinki University Hospital, Helsinki, Finland,[5]Finnish Cancer Registry, Helsinki, Finland,[6]Faculty of social sciences, Tampere University, Tampere, Finland*

Introduction: Intracellular cholesterol metabolism plays an important role in prostate cancer progression and emergence of treatment resistance. However, it remains unclear whether serum cholesterol and lipoproteins are associated with prostate cancer outcomes. Studies on serum cholesterol and cancer are often confounded by lifestyle factors such as diet and obesity. A possible solution is to use instrumental variables, such as SNPs predicting serum cholesterol. According to the Mendelian randomization theory, germline SNP distribution is unaffected by confounding variables such as diet and lifestyle factors. **Objective**: To estimate whether SNPs that predict serum cholesterol and lipoproteins also predict mortality among a cohort of men with prostate cancer. **Methods**: Our study cohort consisted of 3,241 men diagnosed with prostate cancer between 1996-2015, using data collected by the Finnish Randomized Study of Screening for Prostate Cancer. Blood samples were genotyped by PRACTICAL consortium. A UCSC genome browser was utilized for selecting 85 SNPs in lipid metabolism-associated genes. Dates and causes of deaths between 1996-2015 were obtained from the Statistics Finland's statistics on causes of death. Information on serum cholesterol and lipoprotein measurements were obtained from a regional laboratory database.Scores predicting serum cholesterol, LDL, HDL and triglyceride level by SNP genotype were created using linear regression and lasso regression. Risk of prostate cancer death and overall mortality by level of the SNP risk score were evaluated with multivariable-adjusted Cox regression. Follow-up started at prostate cancer diagnosis and continued until death, emigration or common closing date of Dec 31, 2015.**Results:** SNP score predicting total cholesterol stratified prostate cancer patients both for disease-specific (HR 1.27, 95% CI 0.49-3.28 for highest tertile vs. lowest) and overall survival (HR 1.43, 95% CI 0.94-2.20, p for trend = 0.077), albeit statistical significance was not reached. Similar survival differences were observed for SNP score predicting triglyceride level, but not for scores predicting LDL or HDL.**Conclusions:** SNPs predicting serum cholesterol and triglycerides are likely prognostic factors for survival of prostate cancer patients. This suggest serum cholesterol and lipoproteins areimportant in prostate cancer progression.

Association between telomere length and overall survival in lung cancer patients: a mendelian randomization study

Ting Zhai, David C. Christiani, Zachary D. Nagel. *Harvard T.H. Chan School of Public Health, Boston, MA*

Background: An association between chronological age and poor lung cancer survival is well established, but it is unclear whether accelerated biological aging may also predispose lung cancer patients to worse survival outcomes. While telomere shortening in blood cells is a biomarker of aging, its relationship to lung cancer prognosis remains unclear due to limited sample size, confounding, and reverse causation from observational studies. As telomere length could be a precursor of worse prognosis, a causal inference method is needed to clarify the role of telomere length in predicting lung cancer outcomes.
Methods: A Mendelian Randomization study for the causal relationship between telomere length and overall survival in lung cancer was carried out. We searched the GWAS catalog for single-nucleotide polymorphisms (SNPs) associated with telomere length and collected effect estimates for the association between each SNP and telomere length from the literature. The summary data for all SNPs were acquired by analyzing their associations with overall survival of lung cancer patients in the Boston Lung Cancer Study (BLCS) and through Cox proportional hazards regression. The effect size of telomere length on overall survival was calculated and compared through several weighting methods including inverse-variance weighting (IVW) and MR-Egger.
Results: A total of 16 SNPs were identified as the genetic instruments for telomere length. 1798 lung cancer patients from BLCS provided survival data with a median follow-up of 33 months. Surprisingly, a non-significant *positive* trend was observed for the association between telomere length and overall survival across the weighting methods (IVW: HR 1.718, 95%CI 0.849 - 3.476; MR-Egger: HR 2.347, 95%CI 0.592 - 9.309). Further analysis is ongoing to incorporate more patients and genetic instruments for additional markers of biological aging in the BLCS to explore the source of heterogeneity (I^2= 98.1%) in the present study and gain more power for detecting the underlying relationship between telomere length and overall survival in lung cancer.
Conclusion: A positive trend between telomere length and risk of death in lung cancer patients is consistent with previous reports of an association between increased cancer risk and longer telomere length, but is seemingly at odds with an established link between chronological age and poor lung cancer prognosis. Since markers of biological aging are strongly correlated with chronological age, we conclude that a more robust assessment of biological age will be needed to clarify the causal relationship between telomere length and lung cancer prognosis.

Correlation of availability of primary care physicians and colorectal cancer-related mortality in the United States: Do racial disparities exist?

Udhayvir S. Grewal[1], Shiva J. Gaddam[2], Manik Aggarwal[3], Subhash C. Garikipati[4], Prabhat Kumar[5], Naomi Fei[1]. *[1]University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA,[2]Hematology and Oncology, LSU Health Sciences Center, Shreveport, LA,[3]Gastroenterology and Hematology, Mayo Clinic, Rochester, MN,[4]Carillion Clinic, Roanoke, VA,[5]Internal Medicine, Cleveland Clinic Fairview, Cleveland, OH*

Introduction: Colorectal cancer (CRC) is the second leading cause of cancer death in the United States (US). Primary care physicians (PCP) are critical towards a successful CRC screening program. However, the impact of availability of PCP on CRC-related mortality is not well studied.
Materials and Methods: We extracted data on crude incidence and mortality rates of CRC among all 50 states and District of Columbia (D.C.) from the Center for Disease Control (CDC) WONDER database for the year 2019. Data on number of actively practicing PCPs in all 50 states and D.C. for the year 2020 were obtained from Association of American Medical Colleges (AAMC) State Physician Workforce Data Report. The correlation between the ratio of number of PCPs per CRC case with age-adjusted mortality rate (AAMR) for CRC was studied by state and within White and African American (AA) populations from 2017-2019. Pearson's co-efficient was used to study correlations and T-test was used for comparing independent samples. Statistical analysis was performed using VassarStats.

Results: The median AAMR for CRC from 2017-2019 in the US was 13.2 (IQR 11,15.4) per 100,000 population. AAMR for CRC was significantly higher among AA versus White populations (t=5.79, p<0.001). The national median PCP per CRC case ratio was 2.14 (IQR 1.46, 2.82). Higher state-wide PCP per CRC case ratio correlated with lower state CRC-related mortality (r=-0.36, p=0.011). PCP per CRC case ratio was significantly lower among AA as compared to White populations (t=-15.95, p<0.0001). Higher PCP per CRC case ratio correlated with lower CRC-related mortality among both White (r=-0.64, p<0.0001) and AA (r=-0.57, p=0.0002) populations. Using Fisher r-to-z transformation, we found no significant difference between the correlation of PCP per CRC case ratio with CRC-related mortality in White versus AA populations (z=-0.51, p=0.61).
Conclusion: Results of this study suggest that greater availability of primary care physicians correlates with lower CRC-related mortality. AA have a significantly higher AAMR for CRC with a lower PCP per CRC case ratio. This may indicate a lower access to primary care among AA populations with CRC. Our results underscore the need to expand access to primary care among AA populations with the goal of minimizing disparities in CRC-related mortality.

Marital status, living arrangement, and overall survival among individuals with advanced prostate cancer in the IRONMAN cohort

Naiyu Chen[1], Colleen B. McGrath[1], Caroline I. Ericsson[1], Jane B. Vaselkiv[1], Michelle O. Sodipo[1], Emily M. Rencsok[1], Konrad H. Stopsack[2], Daniel J. George[3], Karen A. Autio[4], Dana E. Rathkopf[4], Kathryn L. Penney[5], Lorelei A. Mucci[1]. *[1]Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[2]Clinical and Translational Epidemiology Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[3]Duke Cancer Institute, Durham, NC,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA*

Background: More than 100,000 individuals in the United States are survivors of advanced prostate cancer, defined as metastatic hormone sensitive (mHSPC) or castration resistant prostate cancer (CRPC). This growing, vulnerable population could be uniquely susceptible or responsive to factors that are associated with overall survival. We investigated the associations of marital status and living arrangements with overall survival among individuals with advanced prostate cancer in the International Registry for Men with Advanced Prostate Cancer (IRONMAN).
Methods: We included 2,347 men (ages 40-96 years, median 70 years) with advanced prostate cancer recruited between 2017 and October 2022. Cox proportional hazards models estimated adjusted hazard ratios (adjusted HR) and 95% confidence intervals (CI) for the associations between marital status (married vs. not married), living arrangement (living alone vs. not living alone) and all-cause mortality, mutually adjusting for marital status and living arrangement and potential confounders (disease state [mHSPC vs. CRPC], country of enrollment, age at enrollment, race, education, employment status, smoking status, family history of prostate cancer, prostate specific antigen level at enrollment, and Gleason score). We conducted stratified analyses by disease state (mHSPC vs. CRPC), age (<70 vs. ≥70 years), and country of enrollment (North America vs. others).
Results: This study included 1524 (65%) participants with mHSPC and 809 (35%) with CRPC. 1690 (77%) were married and 338 (16%) lived alone. Over the follow-up period (maximum: 52 months, median: 6 months, IQR: 13 months), we observed 451 deaths, with 313 deaths among married individuals and 59 deaths among those who lived alone. Overall, married individuals had better survival compared to those not married (adjusted HR: 0.52; 95% CI 0.35, 0.78), while those living alone had better survival compared to those not living alone (adjusted HR: 0.48; 95% CI: 0.29, 0.80). The protective association between being married and survival is stronger among those with mHSPC (adjusted HR: 0.42; 95% CI: 0.24, 0.71) compared to those with CRPC (adjusted HR: 0.72; 95% CI: 0.35, 1.49) and stronger among those with ages 70 or older (adjusted HR: 0.43; 95% CI: 0.25, 0.74) compared to those younger than 70 (adjusted HR: 0.71; 95% CI: 0.36, 1.43).
Conclusion: Being married was associated with better survival among advanced prostate cancer survivors. While living alone was also associated with better survival, this finding should be interpreted with caution as there may be residual confounding by socioeconomic status or physical functioning.

Post-diagnosis statin use and survival among head and neck cancer patients: A cohort study in the US military health system

Jie Lin, Craig D. Shriver, kangmin Zhu. *Uniformed Services University, Bethesda, MD*

Head and neck squamous cell carcinoma (HNSCC) arises from the mucosal lining of the aerodigestive tract. Statin is a class of commonly prescribed medications used for treatment of high cholesterol. Studies have shown that statin exhibits anticancer effects, and the use of statin is associated with improved survival of common cancers, such as prostate, breast and colorectal cancers. However, few research has been conducted on statin use in relation to the survival of HNSCC. This study assessed whether statin use after HNSCC diagnosis is associated with overall survival among patients with HNSCC in the U.S. military health system (MHS). The MHS provides universal health care to its beneficiaries with no or little out-of-pocket cost, thus a study in the MHS reduces the effects of prescription drug access related to patients' insurance coverage, race and socio-economic status. This study included 1,842 adult patients (18 or older) with histologically confirmed HNSCC identified from the MilCanEpi database which contains information from the Department of Defense's Central Cancer Registry (CCR) and the Military Health System Data Repository (MDR). Patients were diagnosed between January 1, 2002 and December 31, 2014 and followed up through December 31, 2015. Statin use was extracted from the MDR pharmacy data containing prescription records from all sources. Among the 1,842 patients, 389 patients used statin after HNSCC diagnosis. Time-dependent multivariate Cox proportional hazards models were used to assess the relationship between post-diagnosis statin use and overall survival, reducing the potential effects of immortal time bias. Statistical adjustment was made for covariables including age, sex, race, Hispanic ethnicity, active-duty status, history of cardiovascular diseases, Charlson comorbidity index, baseline statin use, tumor site, tumor stage and cancer treatments. Increased post-diagnosis cumulative use of statin (per one-year of use) conferred a significant improved survival with adjusted hazard ratio (HR) of 0.70 (95% CI=0.55 to 0.90). When analysis was stratified by status of statin use prior to HNSCC diagnosis, the HRs were 0.36 (95% CI=0.19-0.69) and 0.81 (95% CI=0.59-1.11) for those who used and did not use it before the diagnosis, respectively. While the numbers of patients for each group of this stratified analysis were not large, our study suggest that prolonged duration of Statinuse may be associated with improved survival among HNSCC patients. Future research with a larger number of patients is warranted.

Temporal changes in circulating sex hormones and aromatase activity and associations with lung cancer survival in postmenopausal women

Yingya Zhao[1], Xiao-Ou Shu[1], Yu-Tang Gao[2], Mark M. Kushnir[3], Qiuyin Cai[1], Hui Cai[1], Qing Lan[4], Nathaniel Rothman[4], Wei Zheng[1], Gong Yang[1]. *[1]Vanderbilt University Medical Center, Nashville, TN,[2]Shanghai Jiaotong University School of Medicine, Shanghai, China,[3]ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT,[4]National Cancer Institute, Bethesda, MD*

Background: Exogenous sex hormone supplements had been associated with increased lung cancer mortality in a large clinical trial. No study to date has evaluated temporal trajectories of circulating sex hormones and aromatase activity and their associations with lung cancer survival.

Objective: To characterize temporal changes in prediagnostic levels of circulating sex hormones and aromatase activity and to evaluate their associations with overall survival in lung cancer patients.

Methods: Included in the analysis were 385 incident lung cancer patients identified in a large prospective cohort among postmenopausal women who had never used cigarette products nor exogenous sex hormone supplements. Concentrations of sex hormones were quantitated using LC-MS/MS assays in prediagnostic plasma samples. The product-substrate molar ratio of estrone to androstenedione was used as an index of

aromatase activity (IAA). A multivariable Cox model with restricted cubic spline functions was used to calculate hazard ratio (HR) for overall survival.
Results: Of 385 patients with lung cancer, 308 died during a median follow-up of 18.1 years. Initial analyses in all patients showed that higher levels of circulating estrone and IAA and lower levels of androstenedione and testosterone were associated with poorer overall survival after adjusting for nonclinical covariates. In analyses restricted to those with clinical data (n=281), stronger associations were found after further adjustment for tumor stage and treatment regimens. Compared with patients at the median level of IAA, adjusted HRs (95% CI) for total mortality in those at the 30^{th}, 70^{th}, 90^{th} and 95^{th} percentiles were 0.98 (0.84-1.13), 1.05 (0.94-1.16), 1.28 (1.06-1.54), and 1.64 (1.27-2.12), respectively, with *P*-overall < 0.001. A similar positive association was observed for estrone. In contrast, inverse associations were seen for androgens. For example, compared with the median level of testosterone, HRs (95% CI) for those at the 5^{th}, 10^{th}, 30^{th}, 70^{th} percentiles were 2.10 (1.43-3.09), 1.69 (1.29-2.23), 1.45 (1.19-1.76), and 0.86 (0.78-0.94), respectively, with *P*-overall = 0.001. Further, we found that circulating levels of sex hormones changed during disease progression. The closer the hormone measurement to cancer diagnosis the higher the IAA and estrone levels (*P*-overall < 0.001 for both), and the temporal change plateaued 10 years before cancer diagnosis (*P*-nonlinearity < 0.001 for both). An opposite temporal pattern was found for testosterone. Moreover, the significant association between sex hormones and lung cancer survival was only observed when sex hormones were measured within 10 years before diagnosis.
Conclusions: Findings from our study, for the first time, demonstrate temporal changes in circulating sex hormones and their associations with lung cancer survival in postmenopausal women.

Body mass index characterization of patients undergoing neoadjuvant chemotherapy for breast cancer: Correlation with survival
Sangeetha Prabhakaran[1], Vernon S. Pankratz[2], Christopher F. McNicoll[3], Jacklyn M. Nemunaitis[2], Nadja Falk[4], Jain Zhou[4]. *[1]University of New Mexico, Albuquerque, Mexico,[2]University of New Mexico/UNM Comprehensive Cancer Center, Albuquerque, NM,[3]Kaiser Permanente Anaheim and Irvine Medical Centers, Anaheim, CA,[4]University of New Mexico, Albuquerque, NM*

Background: The significance of body mass index (BMI) on treatment outcomes of neoadjuvant chemotherapy for breast cancer and impact on overall survival is not well understood. We reviewed our single institution data on BMI of patients who underwent curative intent neoadjuvant chemotherapy for breast cancer.
Methods: An IRB-approved retrospective review identified demographics (including BMI), disease presentation, response to treatment, and outcomes. ER and PR status were categorized as low positive (1-9%), positive (≥ 10%) and negative. Treatment response was noted as percent residual cellularity(complete 0%, almost complete < 10%, good 10-30%, moderate >30-80% and poor >80%) in the surgical specimen. Cox proportional hazards models were used to assess relationships with overall survival.
Results: 372 patients underwent curative-intent from 2005-2020; mean age was 51.0 years (SD=11.8); mean BMI was 28.6 (SD=6.3). Median follow-up was 4.3 years. There are significant differences in BMI among racial groups: American Indian (mean 31, SD 6.35), black (mean 30.1, SD 6.89), white (mean 28.3, SD 6.11) (p=0.001). There are significant differences in BMI between Hispanic and non-Hispanic patients: Hispanic (mean 29.6, SD 6.07), non-Hispanic (mean 27.5, SD 6.44), (p=0.001). Hormone receptor status (ER, PR, HER2 status) was not significantly associated with BMI, nor was treatment response either as complete pathologic response (p=0.52) or percent residual cellularity (p=0.98). BMI was not significantly associated in tumor shrinkage noted by changes in T stage or N stage categorizations from pre- to post-NAC. BMI was significantly associated with overall survival through interactions with ER status (p=0.01), and residual percent cellularity (p=0.02). ER- vs. ER+ risk was higher for those with low (HR, 95% CI=7.87, 2.60-23.8 at BMI=20) and moderate (HR, 95% CI=3.25, 1.68-6.33 at BMI=27.5). A five-point higher BMI was associated with a 1.6-fold higher mortality risk for those with complete percent residual cellularity (95% CI: 1.1-2.4), but this risk differential was not observed for those with good, moderate, or poor residual percent residual cellularity.

Conclusions: In our study, BMI was significantly associated with race and Hispanic ethnicity. Although there were no significant association of BMI with treatment response to neoadjuvant chemotherapy, there appears to be a significant relationship between BMI and overall patient survival, through its interactions with other prognostic factors. Future research efforts should focus on exploring reductions in BMI through modifications of diet and exercise in improving survival of breast cancer patients, particularly those with higher risk tumors.

Ethnic disparities in breast cancer survival in Guam

Grazyna Badowski[1], Rodney Teria[1], Louis Dulana[1], Cabrini Aguon[1], Lynne Wilkens[2], Yurii Shvetsov[2], Rachel Novotny[2], Rachael T. Leon Guerrero[1]. *[1]University of Guam, Mangilao, GU,[2]University of Hawai'i Cancer Center, Honolulu, HI*

Background: Breast cancer is the second leading cause of cancer-related death among women in Guam. The breast cancer mortality rate is higher in Guam than in the U.S. (27.3 vs 20.3 per 100,000 women, age-adjusted, 2013-2017 data); even though the incidence rate remains lower (86.6 vs 126.8 respectively). Guam has major ethnic disparities in breast cancer survival with CHamoru (indigenous people) and Micronesian (immigrants from other Micronesian Islands) faring much worse than other ethnic groups. The purpose of this study was to determine the survival rates of breast cancer patients in Guam and examine the effects of demographic and other mortality risk factors on breast cancer survival.
Methods: This study included 1105 women diagnosed with primary invasive breast cancer and reported to the Guam Cancer Registry from 1998-2020. Five-year and 10-year survival rates were calculated using the Kaplan-Meier method and were compared using the log-rank test across different ethnic groups: CHamoru (N = 528), Filipino (N = 336), Asian (N = 66), Micronesian (N = 51), and Caucasian (N = 71). The Cox proportional hazards regression was used to investigate the effects of age, year of diagnosis, ethnicity, breast cancer staging, and cancer treatment status on the risk of all-cause mortality.
Results: Mean age at diagnosis was 58.2 years. Significant differences in the 5-year and 10-year survival rates were found across ethnic groups. Micronesians had the lowest 5-year and 10-year survival rates (55.9% and 48.5%) followed by CHamorus (81.1% and 68.1%, respectively). All-cause mortality was higher among CHamoru (HR = 2.28, 95% CI: 1.65, 3.16) and Micronesian women (HR=5.33, 95% CI: 3.30, 8.61) compared with Filipino women after adjusting for age, year of diagnosis, staging, and cancer treatment status. All-cause mortality among White and Asian women was not statistically significantly different from that among Filipino women. Cancer staging also indicated significantly higher hazard rate for late-stage patients when compared to early-stage patients (HR = 3.62, 95% CI: 2.70, 4.85).
Conclusion: The analysis suggests significant differences in breast cancer 5-year and 10-year survival rates across different ethnic groups, with Micronesian women exhibiting the highest hazard rate among women in Guam.
Acknowledgement: This study was supported by the PIPCHE/U54 Grant (U54CA143728), a partnership between the University of Hawai'i Cancer Center and the University of Guam.

Postdiagnosis adherence to American Cancer Society cancer prevention guidelines and mortality among survivors of obesity-related cancers

Ying Wang, Christina Newton, Marjorie L. McCullough, Lauren R. Teras, Erika Rees-Punia, Caroline Um, Alpa V. Patel. *Population Science, American Cancer Society, Atlanta, GA*

Purpose: To examine the combined and individual associations of postdiagnosis body mass index (BMI), physical activity, diet quality and alcohol consumption with all-cause mortality, cardiovascular disease mortality (CVDM) and cancer-specific mortality (CSM) among survivors of obesity-related cancers.
Methods: American Cancer Society (ACS) Cancer Prevention Study-II Nutrition Cohort participants diagnosed with one of 13 invasive (but non-metastatic) obesity-related cancers between 1992 and 2003 were followed for mortality until 2018. Postdiagnosis lifestyle exposures were assessed at least one year after cancer diagnosis between 1999 and 2003. A lifestyle score ranging 0-8 was created according to adherence to the American Cancer Society (ACS) 2020 cancer prevention guidelines on BMI, physical activity, diet, and

alcohol, with a score of 8 representing optimal behaviors for cancer prevention. Associations of the overall and individual component scores with mortality were estimated using multivariable-adjusted Cox proportional hazards regression models.
Results: Among 7,945 cancer survivors, 4,862 died between 1992 and 2018. Higher ACS guideline score was associated with 6-8% lower risk of mortality per 1 point score increase (all-cause: HR: 0.94, 95% CI: 0.92-0.95; CVDM: HR:0.92, 95% CI:0.89-0.95; CSM: HR: 0.93, 95% CI 0.90-0.97) among cancer survivors. Individual scores of BMI, physical activity, and diet were inversely associated with overall mortality; however, alcohol score was positively associated with all-cause mortality, only among female survivors. Compared with participants who had low scores both before and after cancer diagnosis, those with high scores after diagnosis had lower risk of all-cause mortality, CVDM, and possibly CSM.
Conclusion: Following ACS guidelines on diet and physical activity for cancer prevention after a cancer diagnosis is associated with better survival outcomes among survivors of obesity-related cancers.

The relationship between inflammatory diet score and cancer-specific outcomes: Systematic review and meta-analysis

Eric Han[1], Eunkyung Lee[2], David Li[1], Jeanette Garcia[2], Humberto Lopez Castillo[2]. *[1]University of Central Florida, Orlando, FL,[2]Department of Health Sciences, University of Central Florida, Orlando, FL*

Cancer remains one of the most prevalent diseases in the United States and a leading cause of death. Large prospective studies have found significant correlations between dietary intake and cancer. Chronic inflammation promotes pro-cancer inflammatory environments and nutrition can influence inflammation, with the intake of certain food items increasing inflammatory biomarkers. The objective of this research was to explore the relationship between inflammatory diet score measured by the Dietary Inflammatory index and all-cause mortality, cancer-specific mortality, and cancer recurrence among cancer survivors. Web of Science, Medline, CINHAL, and PsycINFO databases were searched to collect potentially eligible sources that focus on dietary inflammation and cancer outcomes. All sources were uploaded to Covidence software and screened by two independent blinded reviewers. The quality of the sources was assessed using the Newcastle Ottawa scale and relevant data was extracted and transferred to the Comprehensive Meta Analysis software and a random effects model was used to perform meta-analysis. Of the 1444 studies imported into the Covidence software, 13 passed all the screening stages and were included in the final analysis. Eight studies reported on pre-diagnosis diet while five others reported on post-diagnosis diet. Five studies reported on colorectal cancer, four on breast cancer, two on ovarian cancer, one on endometrial cancer and one on prostate cancer. Meta-analysis of the studies found that being in the highest postdiagnosis DII score indicating pro-inflammatory diet significantly increased the risk of all-cause death among cancer survivors by 33.5% (HR = 1.335, 95% CI = 1.049, 1.698, $n = 6$). Analysis did not show a statistically significant association between DII score and cancer mortality or recurrence (HR = 1.097, 95% CI = 0.939, 1.281, $n = 6$). Analysis by cancer subtype found a significant correlation between postdiagnosis DII score and all-cause mortality among the breast cancer survivors (HR = 1.335, 95% CI = 1.041, 1.711, $n = 3$) though there were no significant associations between DII and the outcomes of interest from the other cancer types. The meta-analysis concludes that being in the highest postdiagnosis DII score group significantly increased the risk of all-cause death among cancer survivors. This suggests that risk of all-cause mortality could be reduced for cancer survivors by consuming more anti-inflammatory food components and reducing consumption of pro-inflammatory foods. These findings also warrant more research in this field to clarify the relationship between dietary inflammation as measured by the DII and cancer outcomes, particularly cancer-specific mortality.

#6496

Exposure phenotype risk scores (E-PRS) and prostate cancer aggressiveness in the Michigan Genomics Initiative (MGI)

Xinman Zhang, Lars G. Fritsche, Bhramar Mukherjee, Alison M. Mondul. *University of Michigan, Ann Arbor, MI*

Background: Exposure phenotype risk scores (E-PRS) use genetic variation as a natural experiment to examine the causal relationship between risk or protective factors and diseases. A recent review summarized 76 studies using this approach, finding that several factors (alcohol consumption, BMI, telomere length, hormones) likely cause cancer. However, this article also highlighted the need for larger studies incorporating more, newly discovered associated, variants in the E-PRS and investigating specific cancer types vs. all cancers and cancer subtypes.
Methods: We used 21 published E-PRS that were derived from summary statistics of large genome-wide association studies using PRSCS. We evaluated 15 continuous and 6 binary E-PRS for factors that are known or hypothesized to contribute to cancer risk or progression and their association with prostate cancer aggressiveness and death. Our sample included 1784 unrelated, genotyped prostate cancer patients from the Michigan Genomics Initiative (MGI). Conditional logistic regression was used to estimate these 21 E-PRS's odds ratios (OR) and their 95% confidence intervals (CI) for high- vs. low-stage, high- vs. low-grade, and aggressive (high-stage or -grade) vs. non-aggressive (low-stage and -grade) prostate cancer. Cox regression was used to evaluate the hazard ratios (HR) and their 95% CI of prostate cancer deaths by E-PRS. Lasso and Ridge regressions were used to reduce model complexity and prevent overfitting for the final E-PRS model. All multivariable models were adjusted for age, genotyping batch, recruiting study, and genetic PCs.
Results: For high- vs. low-stage prostate cancer, we detected statistically significant associations with E-PRS for type 2 diabetes (per standard deviation (SD) change OR=0.86, 95% CI=0.77-0.97) and estimated glomerular filtration rate (eGFR) (per SD change OR=1.19, 95% CI=1.00-1.41). We also observed a suggestive inverse association with sleep apnea E-PRS. We observed no statistically significant associations for high- vs. low-grade prostate cancer, but there was a possible inverse association with the diastolic blood pressure (DBP) E-PRS. We noticed no statistically significant associations when comparing aggressive vs. non-aggressive prostate cancer; however, suggestive inverse associations with E-PRS for DBP and smoking were found. For prostate cancer death, we observed a statistically significant decreased risk of death with higher BMI E-PRS (per SD HR=0.29, 95% CI: 0.09 - 0.89). We also observed a suggestive inverse association with the eGFR E-PRS. Similar results were found in Lasso and Ridge regression.
Conclusions: Several E-PRS were significant predictors of aggressive or fatal prostate cancer. In the future, we will test significant E-PRS from this analysis to determine whether they predict aggressiveness or mortality in newly recruited MGI prostate cancer cases in 2022.

Availability of healthcare providers and its association with survival outcomes in non-Hodgkin lymphoma in the United States

Shiva Jashwanth Gaddam[1], Udhayvir Singh Grewal[2], Zara Hassan[1], Poornima Ramadas[1]. *[1]Feist Weiller Cancer Center, Shreveport, LA,[2]University of Iowa, Iowa City, IA*

Background: Survival outcome in Non-Hodgkin lymphoma (NHL) is significantly better in earlier stages, compared to advanced stages. Early identification of signs and symptoms, and prompt specialist availability and referral, are crucial for diagnosis and treatment at earlier stages. Mounting physician shortages are a growing concern, and we sought to analyze their effect on NHL mortality rates.
Methods: We extracted data on the age-adjusted mortality rate (AAMR) and crude incidence rate (CIR) of NHL for all U.S. states and the District of Columbia from the Center for Disease Control (CDC) Wide-ranging Online Data for Epidemiologic Research (WONDER) database (2017-2019). Nevada was excluded due to missing information. Data on the state-wise number of primary care physicians (PCPs) was obtained from the Association of American Medical Colleges (AAMC) state physician workforce data report (2020), and of Hematology/Oncology specialists (HOs) was gathered from the National Provider Identifier (NPI) registry (2020). The number of PCPs and HOs per each NHL incidence (PCP/CIR, HO/CIR respectively) was then calculated. Correlations were analyzed using Pearson's coefficient. Statistical analysis was performed using VassarStats.
Results: Median AAMR for NHL in the US was 5.15 (IQR 4.35, 5.95) per 100, 000 population. The median number of PCP and HO per each case of NHL incidence was 4.32 (IQR 3.43, 5.21), and 0.28 (IQR 0.1, 0.37) respectively. States with fewer PCPs per each NHL incidence had higher AAMR ($r=-0.37$, $p=0.007$). States with a lower number of HOs per each NHL incidence had higher AAMR ($r=-0.41$, $p=0.003$)
Conclusions: Based on the analysis, the availability of a lower number of PCPs and HOs per each NHL incidence is associated with increased AAMR of the disease. This data may strengthen the need for intensification of focus on decreasing the soaring physician shortages in the states, in order to help decrease the overall mortality associated with NHL.

Association of lifestyle related risk factors with multiple myeloma mortality rates in the United States

Shiva Jashwanth Gaddam[1], Udhayvir Singh Grewal[2], Himaja Kumari Avvaru[3], Poornima Ramadas[1]. *[1]Feist Weiller Cancer Center, Shreveport, LA,[2]University of Iowa, Iowa City, IA,[3]LSU Health Shreveport, Shreveport, LA*

Background: The prognosis for multiple myeloma (MM) has significantly improved over the years. Lifestyle risk factor modifications have improved the quality of life in MM patients, however, their effect on the survival outcomes in these patients remains unknown.
Methods: We extracted data on age-adjusted mortality rate (AAMR) rates of MM (per 100,000 population) for all 50 U.S. states and the District of Columbia from the Center for Disease Control (CDC) WONDER database (2015-2019). Data on risk factors such as obesity, physical activity, alcohol, tobacco abuse, and nutrition were obtained from the Behavioral Risk Factor Surveillance System (BRFSS, 2021). Florida was excluded due to missing information. Correlations were analyzed using Pearson's coefficient. Statistical analysis was performed using VassarStats.
Results: Median AAMR of MM in the US was 3.2 (IQR 2.7, 3.7) per 100,000 population. States with higher age-adjusted prevalence (AAP) percentages of obesity had higher AAMR (r=0.39, p=0.004) of MM. This association was significant in non-Hispanic white (r=0.32, p=0.021), and non-Hispanic black (r=0.31, p=0.034) subgroups as well. States with a higher AAP of adherence to recommended weekly aerobic activity had lower AAMR (r=-0.37, p=0.007). We did not identify any correlation of AAMR with AAP of binge drinking (r=-0.036, p=0.803), consumption of fruits (r=0.04, p=0.75), vegetables (r=-0.133, p=0.357), and smoking history (r=0.052, p=0.72).
Conclusions: In the current analysis, a higher prevalence of obesity and lower rates of aerobic physical activity were strongly associated with increased AAMR of MM. Our results, therefore, underscore the need for emphasis on a holistic approach in the management of MM by including lifestyle-based risk factor modification, to further improve the survival outcomes in patients with MM.

Towards a combined immunohistochemistry-based subtyping of ovarian endometrioid carcinoma

Brooke Jorgensen[1], Stacey Winham[1], Julie Cunningham[2], Sebastian Armasu[1], Chen Wang[1], Hunter Atkinson[1], Bryan McCauley[1], Linda Kelemen[3], Martin Koebel[4], Ellen Goode[1]. *[1]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[2]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[3]Department of Quantitative Health Sciences, South Carolina Department of Health and Environmental Control, Columbia, SC,[4]Department of Pathology and Laboratory Medicine, University of Calgary, Calgary, AB, Canada*

Background: Ovarian endometrioid carcinoma (OEC) is an uncommon, understudied histotype that is distinguished from other histotypes by unique genomic features and high hormone receptor expression. There is growing interest in the biological relevance of subtyping using immunohistochemistry (IHC).

Methods: Women with primary invasive OEC diagnosed from 1989 to 2010 were retrospectively identified from the population-based Alberta Cancer Registry, Canada. Pathology slide review and IHC staining for Napsin A, TP53, and WT1 were used to reduce histologic misclassification, resulting in N=166 participants (low-stage N=138, high-stage N=28), excluding those who received neo-adjuvant chemotherapy. The following markers were stained and scored on tissue microarrays: TP53 (normal/abnormal), PMS2/MSH6 (mismatch repair proficient [MMRp]/deficient [MMRd]), PGR (loss/retained), and CTNNB1 (nuclear/cytoplasmic). Using a hierarchical decision tree by stage group (low/high), we categorized tumors as TP53 abnormal, MMRd, PGR loss, nuclear CTNNB1, and no specific immunohistochemical profile (NSIP). Distributions and five-year disease specific survival (DSS) was estimated for each group; hazard ratios (HRs) adjusted for age were estimated using Cox regression with NSIP as referent group.

Results: Among low-stage cases, five-year survival was as follows: 80% for TP53 abnormal (N=10, 7%), 87% for MMRd (N=15, 11%), 80% for PGR loss (N=10, 7%), 98% for nuclear CTNNB1 (N=63, 46%), and 95% for NSIP group (N=40, 29%). Overall, IHC group was associated with DSS among low stage cases (LRT p-value=0.006), and the group with nuclear CTNNB1 had a small but statistically significant DSS advantage

(HR=0.089, 95% CI 0.011-0.742, p=0.025). TP53 and PGR loss suggested shorter DSS than the referent NSIP group, but not statistically significantly so (HR=1.26 and 3.08, respectively). Among high-stage cases, five-year DSS was as follows: 57% for TP53 abnormal (N=7, 25%), 75% for MMRd (N=8, 29%), 33% for nuclear CTNNB1 (N=3, 11%), and 17% for NSIP (N=10, 36%). There were no high-stage cases in the PGR-loss group. Nuclear CTNNB1 group had a shorter DSS among high-stage cases, but this was not statistically significantly so (HR=1.16, p=0.85).
Conclusion: Pending replication in additional datasets, results suggest that OEC cases in nuclear CTNNB1 or NSIP IHC groups may have a favorable prognosis in which de-escalation of therapy can be considered. In addition, abnormal TP53 and loss of PGR may identify a high-risk subset of low-stage OEC.

PREVENTION / EARLY DETECTION / INTERCEPTION

Early Detection and Molecular Markers of Prevention

#6503

A case of stage IIA anal squamous cell carcinoma (SCC) diagnosed using a multi-cancer early detection (MCED) test

David A. Myers[1], Brenda Wood[2]. *[1]MDVIP, Metairie, LA,[2]GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc. under the terms of the Interim Measures Order of the European Commission dated 29 October 2021, Menlo Park, CA*

Although some anal cancers can be detected early via screening, current screening options have limitations. A blood-based MCED test that uses a cell-free DNA-based targeted methylation assay and machine learning classifiers to detect a cancer signal and predict the cancer signal origin (CSO) is available for cancer screening. If the MCED test detects a cancer signal, the test reports ‘cancer signal detected’ with 1 or 2 CSO prediction(s). In the Circulating Cell-free Genome Atlas (CCGA) study, the top-predicted CSO was 89% accurate overall. Despite high average CSO prediction accuracy, the biological similarity among HPV-related cancers of the anogenital tract, and head and neck (H&N), may lead to CSO misclassification. An HPV-driven anal cancer case is reported to review the

diagnostic journey following a positive test result and misclassified CSO prediction. An asymptomatic 67-year-old White, non-Hispanic female (BMI: 21.6 kg/m^2) with history of HPV-associated cervical dysplasia and resultant hysterectomy >20 years prior was screened using the MCED test. She had an anoscopy 2 years prior to using the test for hemorrhoids. 11 days after a blood sample was collected for analysis, a positive test result (CSO1=Lung; CSO2=H&N) was communicated to the patient (Day 1). Chest CT w/o contrast was normal except for a small pericardial effusion (Day 2). The patient was referred to an ENT specialist for an extensive evaluation; there was no evidence of cancer found (Day 7). Repeat chest CT with and w/o contrast and with 2mm cuts was also normal except for the small pericardial effusion (Day 21). After the initial diagnostic workup ended, the possibility of HPV-driven CSO misclassification was raised, and in the context of past medical history, HPV-driven anorectal cancer was considered. The patient underwent a flex sigmoidoscopy, which revealed a 4 cm anterior distal anorectal mass consistent with cancer (Day 60). Biopsy showed invasive moderately differentiated SCC with focal keratinization and negative for lymphovascular invasion (Day 65). PET (skull base to mid-thigh) showed a 1.8 cm focus of activity in the anorectal area and no evidence of metastatic disease (Day 71). MRI of the pelvis with and w/o contrast showed a 2.7 cm anal mass with no lymph node invasion consistent with T2N0 disease (Day 72). Consultation with a radiation oncologist diagnosed the cancer as p16+, cT2N0M0 (stage IIA) SCC of the anal canal (Day 72). She was provided chemoradiation for ~1.5 months (Day 80). The most recent scans revealed no evidence of cancer (Day 364). The MCED test detected a cancer signal for an asymptomatic individual with stage IIA anal cancer. In the CCGA study, sensitivity was 75% in stage II anal cancer. Based on this case, CSO misclassification may be considered in patients with an HPV medical history. The use of this MCED test informed aggressive cancer workup and led to early detection and treatment with curative intent.

Germline genetically predicted body mass index is associated with endometrial cancer somatic transcriptomic, immune, and mutational signatures in The Cancer Genome Atlas

George Richenberg, Victoria Gray, Carina Owen, Tom Gaunt, Caroline Relton, Emma Vincent, Siddhartha Kar. *MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom*

High body mass index (BMI) is a causal risk factor for endometrial cancer but the molecular mechanisms underlying this association remain elusive. Here we sought to characterize the tumor genomic landscape of endometrial cancers that have developed on a germline genetic background of predisposition to elevated BMI. We built a polygenic score (PGS) for adult BMI in women using effect size estimates and allele information on 242 independent (r^2<0.05) variants associated with BMI at genome-wide significance (P<5x10^{-9}) in 379,501 women of European ancestry. We performed sample and germline (blood) genotype quality control and imputation into the 1000 Genomes reference panel on data from 354 endometrial cancer cases of genetically inferred European ancestry from The Cancer Genome Atlas (TCGA). We assigned each woman in this TCGA cohort her genetically predicted life-course BMI based on the BMI PGS and found this to be modestly correlated with BMI at the point of diagnosis (r^2=0.23; P=2.1x10^{-5}). Multivariable linear (default) and quasi-Poisson (for zero-inflated counts) regression models were used to test for associations between the BMI germline PGS and endometrial cancer tumor genomic, transcriptomic, proteomic, and immune traits in TCGA. All analyses were adjusted for age, stage, microsatellite status and 10 genetic principal components. Mutational signature models were also adjusted for signature accuracy. We ranked 18,458 genes based on the association between their tumor expression and the BMI PGS and performed gene set enrichment analysis to identify associations between the BMI PGS and upregulation of genes in the IL6-JAK-STAT3 signaling (false discovery rate (FDR)=8.50x10^{-7}), inflammatory response (FDR=7.03x10^{-6}), interferon gamma response (FDR=5.49x10^{-5}) and glycolysis (FDR=3.28x10^{-4}) pathways. High BMI PGS had an inverse association with endometrial tumor EGFR (FDR=0.07) protein levels of the 131 tumor proteins profiled by reverse phase protein array. Endometrial tumors that had developed on a germline background predictive of high BMI were also associated with increased infiltration of activated mast cells (FDR=9.55x10^{-3}) in our evaluation of 22 tumor immune cell infiltrates quantified by the CIBERSORT algorithm, as well as the mitotic and aging clock-like single

base substitution (SBS) signatures 1 (FDR=0.01) and 5 (FDR=0.04). The two SBS signature associations and the activated mast cell association with the BMI PGS were substantially more pronounced in the subgroup of endometrial cancers with microsatellite instability. Thus, we combined germline and somatic data using a novel approach to identify endometrial cancer tumor molecular features associated with genetically predicted higher BMI, providing precision multi-omic portraits of endometrial cancers that develop on a background of adiposity.

ColoScape test: a molecular assay to detect early-stage colorectal cancer in plasma cell-free DNA

Hiromi Tanaka, Shuo Shen, Mauro Scimia, Larry Pastor, Jonathan Li, Andrew Y. Fu, Daniel Kim, Rui Ni, Aiguo Zhang, Michael Y. Sha.
DiaCarta Inc, Pleasanton, CA

Colorectal cancer (CRC) is the second most common cause of cancer deaths when men and women are combined in the U.S. Early detection in the precancerous stage is key to reducing the CRC morbidity and mortality rates. Thus, there is a critical need for a cost-effective, time-efficient, and convenient clinical tool for early CRC detection. We have developed a multiplex qPCR assay (ColoScape™) to detect CRC-associated genetic and epigenetic changes from liquid biopsy samples (i.e., cell-free DNA) using our proprietary QClamp® XNA technology. The QClamp® XNA technology is very unique and enables the ColoScape™ assay to selectively amplify the mutant and methylated DNA target sequences by using a synthetic DNA analog XNA (Xenonucleic Acid). This study demonstrates the analytical performance for detecting low-abundant mutated and methylated gene copies, as well as assess the clinical performance using plasma cell-free DNA samples from patients with CRC or advanced adenomas (≥1 cm) and from individuals with normal colonoscopies. The Coloscape™ test is currently designed to detect mutations in 8 genes with 61 mutations and 7 methylated markers. The test consists of two parts: (i) the detection of mutations in 8 genes (*APC*, *KRAS*, *BRAF*, *TP53*, *CTNNB1*, *NRAS*, *SMAD4*, and *PIK3CA*) and (ii) the detection of 7 methylation targeted genes. For the assay analytical performance, the ColoScape™ test shows that XNA effectively suppressed the wild-type background

amplifications and led to amplify mutation and methylation target sequences dominantly, providing a high level of analytical sensitivity and specificity. The ColoScape^{TM} test is highly reproducible with intra- and inter-assay coefficient of variation of <10% and the cross-reactivity within the assay was limited and negligible. The results for the assay analytical sensitivity indicated that each target could be detected between 0.1% and 0.5% variant allele frequency in 10 ng cfDNA. The preliminary assay clinical specificity and sensitivity were 100% (95% CI: 91.3-100%) and 86% (95% CI: 66-95%) respectively for CRC and 91% specificity (95% CI: 75%-98%) and 60% sensitivity (95% CI: 17%-93%) for advanced adenomas. In summary, the ColoScape test utilizing the XNA-based technology provides high sensitivity and high specificity to CRC and advanced adenomas with a great potential to be used as an early screening test.

Early colorectal cancer detection with a spectroscopic liquid biopsy

James M. Cameron[1], Georgios Antoniou[1], Paul M. Brennan[2], Justin J. A. Conn[1], Sharon King[3], Rose G. McHardy[1], Susan Moug[4], Jennifer Nobes[3], David S. Palmer[1], Alexandra Sala[1], Benjamin R. Smith[1], Judith Strachan[5], Craig Mowat[6], Matthew J. Baker[1]. *[1]Dxcover Ltd., Glasgow, United Kingdom,[2]Centre for Clinical Brain Sciences, University of Edinburgh, Edinburgh, United Kingdom,[3]School of Medicine, University of Dundee, Dundee, United Kingdom,[4]Royal Alexandra Hospital, Greater Glasgow and Clyde NHS and Golden Jubilee National Hospital, Glasgow, United Kingdom,[5]Department of Blood Sciences, Ninewells Hospital and Medical School, Dundee, United Kingdom,[6]Department of Gastroenterology, University of Dundee, Dundee, United Kingdom*

Background: Early detection of cancer is vital to improve patient survival, since earlier diagnosis and treatment maximizes the opportunity to combat or control disease progression. Specifically for colorectal cancer (CRC), the average 5-survival rate after diagnosis decreases from 91% in early-stage CRC, to as low as 15% for stage IV CRC. Furthermore, the rapid detection and subsequent removal of pre-cancerous adenomas - e.g., advanced adenomas (AA) - can improve survival rates of affected patients. Current

stool-based tests, such as FIT and FIT-DNA, have poor AA sensitivities of 24% and 42%, and specificities of 95% and 87%, respectively. Recent research into liquid biopsies have shown some promise, however tests based on tumor-derived biomarkers alone have limited sensitivity, especially in early-stage disease.
Methods: We initially applied the Dxcover® Cancer Liquid Biopsy for use as a multi-cancer early detection (MCED) test. The test uses Fourier transform infrared (FTIR) spectroscopy and machine learning algorithms to build a classifier of the resultant spectral profiles to detect cancer, and can be fine-tuned to maximize either sensitivity or specificity depending on the requirements of specific international healthcare systems. Additionally, we have analyzed a retrospective cohort of serum samples comprising 100 CRC, 99 advanced adenomas removed by surgical resection and 97 colonoscopy screening controls.
Results: The CRC classifier from the discovery MCED dataset reported an area under the receiver operating characteristic curve (AUROC) value of 0.91, with 74% sensitivity and 91% specificity when differentiating CRC and non-cancer, which surpasses the targets set by the Centers for Medicare & Medicaid Services (CMS) for coverage of CRC tests. When tuned for higher sensitivity, the model produced 97% sensitivity (49% specificity), and when tailored for greater specificity (97%) the sensitivity was 47%. In this study, we have progressed these findings to examine the ability of the technology to differentiate patients with CRC, AA and colonoscopy controls.
Conclusions: Cancer treatment is more effective when given earlier and this low-cost strategy can facilitate the requisite earlier diagnosis. A rapid blood test that sensitive to AA and early-stage CRC could improve patient prognosis and ultimately reduce mortality.

#6507

E3 ubiquitin-protein ligase, tetratricopeptide repeat domain 3 (TTC3), H4 clustered histone 5 (H4C5), and epithelial cell adhesion molecule (EpCAM) are novel urine-enriched liquid biopsy biomarkers to detect prostate cancer in men

Ranjan Joseph Perera[1], Marcio Moschovas Moschovas[2], Roshane Perera[2], Bongyong Lee[3], Alexandra Miller[4], Ernest K. Amankwah[1], Rudramani Pokhrel[3], Christian Pavlovich[3], Guru Sonpavde[5], Vipul Patel[2]. *[1]Johns*

Hopkins University School of Medicine, Baltimore, MD,[2]Global Robotics Institute, Advent Health, Celebration, FL,[3]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[4]Johns Hopkins All Children's Hospital, St. Petersburg, FL,[5]Cancer Instittute, Advent Health, Orlando, FL

Background: Prostate Cancer (PCa) is one of the leading causes of cancer deaths among American men; however, the estimated number of diagnoses represents a small fraction of disease-related biopsies performed yearly. Although the Prostate-Specific Antigen (PSA) test is widely used for screening, several advisory groups recommend against using PSA because of its suboptimal performance. Thus, there is an *urgent unmet* need for novel and more accurate diagnostic biomarkers for PCa detection and to differentiate aggressive cancer from its indolent form.
Methods: In our study, we used voided urine (50ml) from pre and post-prostatectomy men with PCa and urine from normal healthy men as control. We isolated RNA from exfoliated cells and debris shed into urine and performed RNA-sequencing using the Illumina Next-seq 550 platform. Advanced computational and machine-learning approaches were employed to identify candidate biomarkers in men with PCa. We examined the TCGA database to validate the PCa-specific expression of the identified RNA in tumor tissues. Two RNA markers were further tested by qPCR, and one urinary soluble protein marker was measured by immunoassays.
Results: Our study included 106 men with PCa and 88 control men. We identified and validated the presence of ≥1 RNA markers (TTC3, H4C5) and a protein marker (EpCAM) in urine as potential candidate biomarkers for PCa detection. We tested and developed these markers using qPCR for TTC3, H4C5, and ELISA assay for EpCAM with higher specificity and sensitivity (Table 1). Our results outperformed known urinary markers, PCA3 and SPDEF (Figure 1). TTC3, H4C5, and EpCAM markers diminished to low or undetectable levels in post-prostatectomy compared to pre-prostatectomy men with PCa. shRNA knockdown of TTC3 and EpCAM in androgen-sensitive and insensitive cells induced biological changes, suggesting their relevance to Prostate Cancer.
Conclusions: We report a highly accurate panel of 3 urine-based biomarkers that detect PCa consisting of EpCAM (protein) and TTC3 and H4C5

(RNA). To identify the advantage of using individual or combinatorial markers is an ongoing study in our laboratory.

Eclipse, an automated CRISPR platform for the large-scale generation of cell models

Peter Deng, Matthew Rowe, Anna King, Dana Sailor, Antinea Chair, Montse Morell, Andreia G. Sommer, Kevin Holden. *Synthego, Redwood City, CA*

Major advances in gene editing using CRISPR have improved accessibility for the creation of disease relevant *in vitro* models, allowing researchers to readily interrogate oncogenic driver mutations and elucidate novel targets to overcome challenges within cancer research such as drug resistance. Despite this, the rapid generation of disease relevant cell lines at the scale needed for successful and efficient therapeutic development remains challenging in part due to the sheer number of potential oncogenic driver mutations and cancer targets along with using traditional manual approaches. Specific challenges include: the efficient generation of gene knockouts and corresponding loss of protein; efficient knock-in of gene tags and single nucleotide variants; and controlling the zygosity of these genetic outcomes. To address these limitations, we describe the use of our automated, high throughput CRISPR editing platform, ECLIPSE, for the rapid generation of cell models such as immortalized cells and induced pluripotent stem cells. We leveraged our chemically modified synthetic sgRNAs, optimized nucleofection methods, and automated pipelines for the generation of CRISPR-edited cells at various scales to address the needs of researchers. This scale ranges from individual edited cell clones for drug target validation to the generation of hundreds of knockout cell pools in a ready-to-assay arrayed format for gene target identification in drug screening. The utilization of automated systems such as the ECLIPSE platform are critical catalysts for the rapid generation of engineered cell lines at relevant scales to address the challenges of cancer research.

Panel of CD-34, CD-105 & vimentin in immunohistochemical & histomorphometric analysis for prognostic evaluation of oral

potentially malignant lesions

Saravanan SP. *Kalinga Institute of Industrial Technology (KIIT), Bhubaneswar, India*

Introduction: The Angiogenic Theory, proposed by Folkman in 1971, is one of the most widely recognized ideas in carcinogenesis, which is a complicated and dynamic process. This emphasized the fact that tumor growth occurs at a certain density of new blood vessels during angiogenesis. However, whereas many of vascular markers are well understood in established oral malignancies, their relevance in oral premalignant lesions remains unknown.

Materials and Methods: Prospectively, 54 patients with potentially oral malignant lesions (POML) were observed for three years. These patient's paraffin blocks were subjected to immunohistochemical and histomorphometric examination with CD34 and CD105 (Endoglin), as well as qualitative analysis with Vimentin. All patients provided written informed consent to subject the blocks to immunohistochemical analysis, as well as the necessity of 3 monthly visits up to 3 years follow up to assess the malignant transformation potential. In case of clinical suspicion, a repeat biopsy was performed to rule out malignancy.

Results: With a sample size of 54, the clinical and histological parameters were evaluated using the paired 't' test, validating the underlying normality assumption. During the three-year follow-up period, 52% (n=28/54) of the total patients developed oral malignancies. The most commonly detected was Oral Squamous Cell Carcinoma with the most common site being Gingivo-Buccal Sulcus area. The microvessel
density was dramatically boosted in premalignant stage samples utilizing CD34 and CD105. In PMOL, the mean Vascular Caliber (VC) using CD 34 and CD 105 (μm^2) was 7.7 ± 1.9 μm^2 and 7.1 ± 1.4 μm^2, respectively. The mean VC - CD 34 and CD105 did not differ statistically (P-value>0.05). More than 50% of individuals with malignant transformation have shown increased vimentin expression in connective tissue of the premalignant stage samples (P-value0.001).

Conclusion: The use of CD 34 and CD105 markers to assess micro vessel density and vessel morphometry was found to be useful in predicting the malignant transformation potential of POML. The combination of these two markers, coupled with Vimentin, was proven to be a successful IHC

PANEL for predicting the malignant transformation potential of oral premalignant lesions well in advance of 1.5 ± 2.5 years. In diagnosed cancer patients, increased CD105 expression was also associated with lymph node metastases. As a result, CD34, Endoglin, and Vimentin are proposed as IHC Panel Markers to determine the prognosis of potentially malignant oral lesions.

REM-DREAMing: Low-cost digital microfluidic analysis of DNA methylation heterogeneity for enhanced, liquid biopsy-based detection of early-stage lung cancer

Yang Zhao[1], Christine M. O'Keefe[1], James G. Herman[2], Thomas R. Pisanic[1], Tza-Huei Wang[1]. *[1]Johns Hopkins University, Baltimore, MD,[2]University of Pittsburgh, Pittsburgh, PA*

We report the results of a study exploring the ability to exploit molecular heterogeneity in DNA methylation for improving the performance of liquid biopsy-based screening for early-stage (I & II) non-small cell lung cancer (NSCLC). Annual low-dose CT (LDCT) screening is currently recommended for adults aged 50 or older who are at high-risk of developing lung cancer. While this approach has resulted in improvements in survival, the false positive rate of lung nodules detection by LDCT remains over 95%, leading to unnecessary invasive follow-up procedures and further points to the need for new, complementary methods to improve diagnostics performance and reduce patient risk. DNA methylation biomarkers have demonstrated considerable potential as tumor-specific biomarkers for blood-based detection of early-stage NSCLC. Nonetheless, cell-free DNA (cfDNA) assessment techniques, such as methylation-specific PCR (MSP) or bisulfite sequencing, have limited sensitivity to assess epigenetic heterogeneity of rare epiallelic variants in a cost-effective manner. Here we reported a new platform, named REM-DREAMing (Ratiometric-Encoded Multiplex Discrimination of Rare EpiAlleles by Melt), which provides a simple, low-cost solution for multiplexed assessment of loci-specific DNA methylation heterogeneity at single molecule sensitivity. The microfluidic nanoarray contains four independent but identical 10,040 nanowell modules. Methylation biomarkers are differentiated by a ratiometric fluorescence scheme and the assessment of

individual epiallele species of each locus are achieved through digitization in the nanoarray and precise high-resolution melt (HRM) analysis. In this study, we explore the potential utility of REM-DREAMing as a complementary assay for improving LDCT screening of NSCLC by testing a cohort of 48 clinical samples (28 cancer and 20 control samples) of low-volume liquid biopsy specimens from patients with CT-scan indeterminant pulmonary nodules. A machine learning algorithm incorporating logistic regression models with leave-one-out cross validation was developed to identify a proper methylation density threshold of each biomarker in the panel. Evaluation of the receiver operation characteristic (ROC) curve yielded an area under the curve (AUC) of 0.97 (95% CI, 0.94-1) with 93% sensitivity at 95% specificity for the REM-DREAMing assay, compared with 93% sensitivity at 62% specificity achieved using a traditional, MSP-based approach. These results suggest that the assessment of intermolecular epigenetic heterogeneity can provide superior clinical performance for cfDNA methylation and noninvasive detection of early-stage NSCLC, in particular. Our results warrant further investigation in a larger sample cohort to validate its utility for improving routine screening of NSCLC in high-risk populations.

Optimizing an *in vitro* toolbox to interrogate pancreatic tumorigenesis from a patient-derived intraductal papillary mucinous neoplasm sample

Raymond M. Paranal, Julie Schlanz, Maria A. Trujillo, Nicholas J. Roberts, Laura D. Wood. *Johns Hopkins University School of Medicine, Baltimore, MD*

Pancreatic Ductal Adenocarcinoma (PDAC) is a lethal disease with a five-year survival rate of 11%. PDAC develops from pancreatic precursor lesions, including intraductal papillary mucinous neoplasm (IPMN); studying these lesions is important to understand the multi-step process of pancreatic tumorigenesis. Development of model systems and associated tools is a critical step that is 1) scientifically necessary to understand IPMN biology and 2) clinically important for improving patient outcome. To date, only one patient-derived IPMN cell line that grows in a monolayer has been reported, illustrating the challenges of growing precancerous cells in this

format. While protocols have previously been established to generate patient-derived IPMN models, the majority of these cell-based models utilize 3D organoids. To date, no study has successfully converted patient-derived IPMN organoids into 2D culture. Converting these cellular models to propagate and divide in a monolayer allows us to expand our *in vitro* toolbox to perform experimental methods that are less efficient or not practical in 3D culture. In this study, we optimized the conversion of a high-grade IPMN patient-derived organoid model into a monolayer culture. We considered conditions that could recapitulate an extracellular matrix as well as growth factors and/or inhibitors that could promote IPMN cell growth. In total, we tested 15 different conditions and were able to successfully culture the human high-grade IPMN cells in a monolayer culture for up to 5 passages (~1 month). Additionally, while human IPMN cellular models exists, genetic modification of these *in vitro* models has not been reported. Such approaches allow direct interrogation of the role of specific genes in premalignant pancreatic tumorigenesis. In this study, we report successful transduction of IPMN cells via lentivirus. By first converting the organoid into a monolayer culture, transducing them in 2D, and then converting them back into 3D culture as spheroids, we were able to successfully express EGFP into our IPMN cellular model. In summary, we optimized culture conditions to temporarily grow a patient derived 3D IPMN model in a 2D monolayer form, genetically modified this IPMN cell line model, and successfully converted it back into a 3D spheroid. These protocols have potential to be replicated in other IPMN models and can provide further insight into overall IPMN biology and pancreatic tumorigenesis.

Label-free autofluorescence imaging reveals different metabolic responses to adverse growth conditions between normal and breast cancer cells lines

Katherine Junkins[1], Angel Perez Martinez[2], Margaret Rodgers[1], Shelley A. Phelan[1], Min Xu[2]. *[1]Biology, Fairfield University, Fairfield, CT,[2]Physics & Astronomy, Hunter College and the Graduate Center of CUNY, New York, NY*

Cancer cells are metabolically distinct from normal cells, and can adapt differently to adverse growth conditions. We sought to compare normal

MCF10A and Ras-transformed MCF10AT cells under various conditions (regular growth media, doxorubicin-treatment, and glucose-deprived media) by imaging endogenous cellular FAD and NADH fluorescence and comparing it to proliferation rates (measured by MTS assay) and chromatin structure (measured by Hoescht staining).

Under normal growth conditions, MCF10AT cells displayed similar levels of FAD and higher levels of mitochondrial NADH than MCF10A cells. Elevated NADH in MCF10AT cells seems to reflect the preference for anaerobic glycolysis rather than oxidative phosphorylation (the so-called Warburg effect). Our MTS data showed that doxorubicin treatment did not significantly affect MCF10AT cell proliferation but led to a modest reduction in cell proliferation in the normal cell line. Likewise, in MCF10AT cells, doxorubicin treatment led to an increase in FAD and a decrease in NADH. Conversely, in MCF10A cells, doxorubicin led to a decrease in FAD levels and an increase in mitochondrial NADH. These results suggest that the cancer line may be switching to oxidative phosphorylation to resist doxorubicin-induced toxicity, while the normal cells reduce oxidative phosphorylation with growth inhibition.

In contrast to the doxorubicin response, glucose deprivation produced significant growth inhibition and cell death in MCF10AT cells while having a modest growth-inhibitory effect on the normal line. Interestingly, low glucose decreased FAD and mitochondrial NADH in MCF10AT cells, suggesting that both aerobic and anaerobic respiration was reduced and consistent with the marked reduction in observed cell viability. In contrast, MCF10A cells showed a slight decrease in FAD and an increase in NADH, suggesting a decrease in oxidative phosphorylation consistent with the modest growth inhibition observed.

Finally, MCF10ATs displayed higher levels of Hoechst staining than MCF10A cells, consistent with a higher proportion of condensed chromatin observed in cancer cells. In addition, we found a larger increase in Hoechst staining in MCF10AT cells in response to both doxorubicin and low glucose, as compared to MCF10A cells. This data suggests that the chromatin state of the two lines is also differentially affected by these treatments.

In conclusion, label-free measurement of autofluorescence of cellular FAD and mitochondrial NADH reveals the different metabolic and chromatin responses to adverse growth conditions between cancer and non-cancer

cells. These differences are associated with the different proliferation rates and may have important clinical implications for cancer risk stratification.

Single cell and spatial profiling reveal molecular and immune evolution from precancers to invasive lung adenocarcinomas in genetic and carcinogen-induced mouse models

Bo Zhu[1], Jian-Rong Li[2], Hong Chen[1], Pingjun Chen[1], Junya Fujimoto[1], Yanhua Tian[1], Muhammad Aminu[1], Chenyang Li[1], Lingzhi Hong[1], Alexandre Reuben[1], Edwin Roger Parra Cuentas[1], Ou Shi[1], Monique Nilsson[1], Alissa Poteete[1], Shawna Hubert[1], Khaja Khan[1], Wei Lu[1], Daniel Kraushaar[2], Xingzhi Song[1], Jianhua Zhang[1], Don Gibbons[1], Luisa Solis Soto[1], Ignacio Wistuba[1], Jia Wu[1], John Heymach[1], Chao Cheng[2], Jianjun Zhang[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Baylor College of Medicine, Houston, TX*

Introduction: An improved understanding of early lung carcinogenesis may facilitate development of novel diagnostic, screening, and prevention strategies to decrease lung cancer mortality. We have previously led a series of studies on the molecular and immune landscape of lung adenocarcinoma (LUAD) precursors. However, resected human specimens only provide molecular snapshots. Here, we sought to establish and characterize human-relevant murine lung precancer models to depict molecular evolution during early lung carcinogenesis and to provide novel insights for lung cancer interception.

Methods: We have established 3 genetically engineered mouse models (GEMMs) (K: *Kras*$^{\text{LSL-G12D/+}}$, KP: *Kras*$^{\text{LSL-G12D/+}}$/*Trp53*$^{\text{R172H/+}}$, KL: *Kras*$^{\text{LSL-G12D/+}}$/*Lkb1*$^{\text{fl/fl}}$) and 2 carcinogen-induced models (CITMs) (UWT: Urethane in wild type mice, URG: Urethane in Rag2$^{-/-}$ mice). Lung tissues were serially collected at multiple time points after induction and subjected to whole exome sequencing (WES), single cell RNA sequencing (scRNA-seq), spatial transcriptomics (Visium), and imaging mass cytometry (IMC).

Results: Pathological review of specimens from 252 mice revealed normal lung, precancers and LUAD at different timepoints mirroring the evolution of human LUAD. Overall, the tumor burden was significantly higher in GEMMs than CITMs ($p<0.05$). Tumor mutation burden progressively

increased with progression from precancers to LUADs across all models. scRNA-seq demonstrated a progressive decrease of $CD4^+$ T cell, $CD8^+$ T cell, NK cell, and B cell infiltration in all models except the B/T cell-deficient WRG model; and a progressive increase of neutrophils (in KL model) and macrophages (in K, KP, UWT and URG models) along with progression of precancers. These findings were confirmed by spatial Visium and IMC profiling. Infiltration of T cells, B cells and NK cells inside tumors was not different between GEMMs (K, KP, KL) and CITMs (UWT). However, UWT showed significantly higher density of immune cells at the peritumor regions ($P<0.05$). Compared to the immune-competent UWT model, the B/T-cell deficient URG model showed similar progression and tumor burden at early phases, but rapid progression and larger tumor burden in the later phases. URG had no mature B/T cells but significantly higher NK cell infiltration than UWT ($p<0.05$).
Conclusion: We have established 5 murine carcinogen-dependent and -independent precancer models, morphologically resembling human LUAD and its precursors. Although progressive immunosuppression along with progression of lung precancers is universal across all models, the evolution patterns and the molecular/immune features underlying immunosuppression vary in different models, particularly between CITMs and GEMMs. These models may be valuable assets for studying early lung carcinogenesis and lung cancer interception.

Liquid biopsy for lung cancer based on extracellular vesicles

Juan P. Hinestrosa[1], Harmeet Dhani[1], Jean M. Lewis[1], Gregor K. Schroeder[1], Heath I. Balcer[1], Razelle Kurzrock[2], Paul Billings[1]. *[1]Biological Dynamics, Inc., San Diego, CA,[2]Medical College of Wisconsin, Milwaukee, WI*

Background Liquid biopsy approaches for lung cancer are becoming increasingly common for diagnosis, prognosis, and management of the disease. Of the Approximately 236K new lung cancer cases that will be diagnosed in 2023, over 70% of those will be regional or distant with diminished chances of curative resection. Therefore, highly sensitive and specific approaches for early detection are key for mortality reduction. Extracellular vesicles (EVs), a new class of blood-based cell-free

biomarker, can be informative for the diagnosis of lung cancer at its earliest stages.
Methods A case-control cohort of blood plasma samples from 146 pathologically confirmed lung cancer cases (stage I = 90, II = 42, III = 14; median age = 63 yrs.) and 491 controls (median age = 58 yrs) was used in this study. EVs were isolated using a proprietary technology and the EV protein cargo was analyzed via immunoassay. A machine learning engine was employed to determine the most informative biomarkers and algorithm for differentiation between cases and controls in a detection setting.
Results Using a stratified cross-validation approach, we found a biomarker signature that yielded an AUC of 0.966 (95% CI: 0.949 - 0.979) with an overall sensitivity of 91.1% (CI: 85.4% - 94.7%) at a specificity of 91.0% (CI: 88.2% - 93.3%). By stage, the following sensitivities were obtained: stage I: 92.2%, stage II: 88.1%, stage III: 92.8%. The algorithm developed includes 13 EV-protein biomarkers using the adaptive boosted tree methodology.
Conclusions Our pilot study demonstrates utility of a blood-based approach that can detect lung cancer at early stages, when treatment can be more effective. By combining multiple EV protein signatures, it is possible to achieve high sensitivity and specificity. Independently collected cohorts including confounding conditions, such as benign lung nodules and COPD, are being evaluated for validation purposes to improve performance in clinical settings.

#6515
Pancreatic ductal adenocarcinoma (PDAC) early detection
Juan P. Hinestrosa[1], Harmeet Dhani[1], Gregor Schroeder[1], Jean M. Lewis[1], Heath I. Balcer[1], Razelle Kurzrock[2], Dove Keith[3], Rosalie Sears[4], Paul Billings[1]. *[1]Biological Dynamics, Inc., San Diego, CA,[2]Medical College of Wisconsin, Milwaukee, WI,[3]Oregon Health and Sciences University, Portland, OR,[4]Oregon Health Sciences University, Portland, OR*

Introduction Pancreatic ductal adenocarcinoma (PDAC) is the most common form of pancreatic cancer and is one of the deadliest cancer in the U.S., with a 5-year survival rate of just 11%. It is expected that ~62,000 new cases will be diagnosed in the US in 2023 and >70% of those will be at the regional or distant state, when curative resection is no longer an option.

It is imperative that tools enabling early disease detection (stages I and II) are developed to improve patient survival outcomes. Here, we report the results of a study on the utility of extracellular vesicles (EVs) for early PDAC detection.

Methods Our case-control training set was comprised of 75 pathologically confirmed PDAC cases (Stage I = 31, Stage II = 44) and 640 controls (including 11 subjects with pancreatitis) for EV biomarker and algorithm selection via machine learning. EVs from plasma were isolated using a proprietary technology, then EV-bound proteins of interest were analyzed via an immunoassay. A second independently collected cohort of 20 confirmed PDAC cases (Stage I = 10, Stage II = 10) and 27 controls (including 9 patients newly diagnosed with diabetes) was used for validation.

Results The machine learning analysis using EV-isolated proteins generated a signature that utilized 8 different biomarkers, with an AUC of 0.989 (95% CI: 0.980 - 0.998) in the training set and an AUC of 0.987 (CI: 0.964 - 1.000) in the validation set. For the validation set, the sensitivity was 95% (CI: 76.4% - 99.1%) and the specificity was 92.6% (CI: 76.6% - 97.9%), with 10 out of 10 stage I cases and 9 out of 10 stage II cases correctly classified.

Conclusions The ability to alter the future outcomes of PDAC patients will be predicated on development of a new generation of early-detection biomarkers and technologies. The use of EV protein signatures, a new class of cell-free biomarker, permits detection at high sensitivity and specificity, as demonstrated for the independently collected validation cohort. Studies aimed to assess this test for high-risk patients (family history of PDAC, known germline mutations, precursor lesions, hereditary pancreatitis, new onset diabetes will continue towards the establishment of real-world evidence.

Comparison study between a ketogenic diet and a high-fat diet on pancreatic cancer incidence in mice

Tarek Bacha[1], Natalia Cortez Penso[2], Maria Rodriguez[1], Brian Hong[1], Gerardo Mackenzie[1]. *[1]UC Davis, Davis, CA,[2]University of Turin, Turin, Italy*

Pancreatic Ductal Adenocarcinoma (PDAC) remains among the most lethal cancers. PDAC can take up to 15-20 years to develop from the occurrence of the first initiating mutational event, which opens the opportunity for intervention and prevention strategies. In particular, nutritional interventions could provide an avenue to prevent or slow down pancreatic carcinogenesis, since certain diets such as high-fat diets (HFD) have shown to promote it. On the other hand, ketogenic diets (KD), characterized by a high fat and very low carbohydrate content, have gained attention for their anti-tumor and anti-inflammatory potential. However, the role of a KD in the onset and progression of PDAC is still unknown. In this project, we investigated the impact of both a HFD and a KD on late-stage pancreatic carcinogenesis. For this purpose, we used an animal model of pancreatic cancer carrying a pancreas-specific oncogenic $KRAS^{G12D}$ mutation [*LSL-*$KRAS^{G12D}$*; P48+/Cre;* (KC mice)]. On average, KC mice develop PDAC at 12-15 months of age, so they are a valuable tool to study late-stage carcinogenesis. We hypothesized that a HFD would accelerate PDAC progression while a KD would slow it down. To test our hypothesis, 6 months-old male and female KC mice (n=18/group) were randomized and fed, either a control diet (CD), a HFD, or a KD for 6 months and then euthanized at 12-months of age to evaluate pancreatic cancer incidence and progression. At 12-months of age, HFD-fed mice had significantly higher body weight compared to the other two groups. Moreover, KD-fed mice had significantly higher levels of blood ketone bodies, with lower levels of glucose and serum insulin levels, when compared to KC mice fed a HFD. However, after 6 months on the diets, no significant differences in pancreas weight nor in PDAC incidence were observed across all diet groups. Of note, male KC mice experienced double the PDAC incidence rates (55%) than female KC mice (27%), irrespectively of the group. In addition, no significant differences among the groups were observed in RAS/RAF/ERK and PI3K/AKT/mTOR pathways, known to be associated with cancer proliferation. In summary, despite the improvement in insulin and increases in ketone bodies, consumption of a strict KD failed to improve late-stage pancreatic carcinogenesis in mice.

Time course genomic characterization reveals progressive accumulation of mutations during tumor development in a Lynch

syndrome mouse model

Yurong Song[1], Shaneen Baxter[1], Lisheng Dai[1], Chelsea Sanders[1], Holli Loomans-Kropp[2], Brandon Somerville[1], Ryan N. Baugher[1], Stephanie D. Mellott[1], Todd B. Young[1], Heidi E. Lawhorn[1], Teri M. Plona[1], Bingfang Xu[1], Lei Wei[3], Qiang Hu[3], Song Liu[3], Alan Hutson[3], Baktiar Karim[1], Simone Difilippantonio[1], Ligia Pinto[1], Matthias Kloor[4], Steven M. Lipkin[5], Shizuko Sei[6], Robert H. Shoemaker[6]. *[1]Frederick National Laboratory for Cancer Research, Frederick, MD,[2]The Ohio State University, Columbus, OH,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]University of Heidelberg, Heidelberg, Germany,[5]Weill Cornell Medicine, New York, NY,[6]Division of Cancer Prevention, Bethesda, MD*

DNA mismatch repair (MMR) genes (e.g., *MLH1, MSH2, MSH6, PMS2*, and *EPCAM*) play an important role in maintaining genomic stability during DNA replication and recombination. Deficiency in MMR resulting from mutations in these genes leads to mutations in microsatellite regions throughout the genome (microsatellite instability; MSI) and in cancer driver oncogenes or tumor suppressor genes, which accumulate over time and eventually lead to cancer formation. Monoallelic germline mutation in MMR genes causes Lynch syndrome (LS). Among LS-related cancer types, the lifetime risk for colorectal cancer (CRC) is the highest (~80%). Frameshift mutations (FSMs) in coding microsatellites produce neoantigens, which have been shown to elicit immune responses. It was thus postulated that they can serve as vaccine targets. To develop a prophylactic vaccine and prevention strategy for this high-risk population, we characterized a LS mouse model (*Msh2$^{LoxP/LoxP}$;Villin-Cre*) to determine whether these mice recapitulate the human LS oncogenic process. We found that tumor development was already notable at 7-8 months of age and median survival was 11.5 months. Histopathological analysis showed that tumors were adenoma or adenocarcinoma mixed with mucinous features. Using a targeted sequencing approach, a panel of FSMs in mononucleotide regions were identified in both tumors and histologically normal mucosa, suggesting that Msh2 deletion and FSMs were not sufficient for tumor development. In addition, *Apc, Ctnnb*, and *Trp53* mutations were also observed with low frequency in organoids derived from these tumors, indicating that other driver mutations may be required for tumor initiation

and progression, and most FSMs detected in tumors and mucosa were probably passenger mutations. To determine if fecal samples can be used to monitor the FSM load, fecal DNA from different time points was sequenced. We found that FSMs can be detected at 1month of age although the number of FSMs was relatively low compared to that from older mice, indicating that FSMs accumulate over time. MSI detection via fragment analysis confirmed that these tumors were MSI-H. Interestingly, mucosa and fecal samples from a time course study showed progressive increase in microsatellite instability, suggesting the possibility of using MSI score for disease monitoring. Our preliminary data indicates that combined fecal FSM status and MSI score can be potentially used as a biomarker to monitor the tumor development and disease progression for LS colorectal cancer.

Haploinsufficiency for BRCA2 leads to common fragile site instability in human mammary epithelial cells

Mihriban Karaayvaz, Kavya Vipparthi, Antony Caputo. *Genomic Medicine Institute, Cleveland Clinic Lerner Research Institute, Cleveland, OH*

Individuals with germline heterozygous mutations of breast cancer susceptibility genes *BRCA1* or *BRCA2* have a 50 to 80% lifetime risk of developing breast cancer, yet the mechanisms of these cancers remain largely unknown. There is growing evidence that *BRCA1* and *BRCA2* heterozygosity confer haploinsufficiency in normal human mammary epithelial cells for their multiple known functions. Haploinsufficiency for *BRCA1* leads to defects in differentiation, replication stress response, premature senescence and genomic instability in human mammary epithelial cells. Deficiencies in error-free DNA damage repair has been observed in genetically engineered cells as well as primary human mammary epithelial cells carrying *BRCA1* heterozygous mutations. There is relatively less research on understanding the role of haploinsufficiency for *BRCA2* in human mammary epithelial cells. It has been reported that haploinsufficiency for *BRCA2* leads to genomic instability via unscheduled R-loops. We previously showed that accumulation of sub-chromosomal

copy number variations (CNVs) and replication stress-induced DNA damage, together with attenuated checkpoint and apoptotic responses, constitute a haplo-insufficient phenotype in mammary epithelial cells of *BRCA2* mutation carrier patients. Common fragile sites (CFS) are found in all individuals and represent a normal component of chromosome structure. Numerous studies have shown that CFSs are prone to deletions and rearrangements in many cancers, a situation referred as CFS instability. Importantly, Fanconi Anemia/BRCA pathway has been previously reported to have a role in regulating CFS instability. In this study, we further explored a link between *BRCA2* haploinsufficiency and CFS instability. We induced replication stress with DNA polymerase inhibitor aphidicolin (APH) treatment in control and BRCA2- deficient human mammary epithelial cells. We then performed DAPI banding to map and score the cytogenic lesions in metaphase spreads cells, in the absence or presence of APH treatment. Our results demonstrated that BRCA2- deficient human mammary epithelial cells showed increased frequency of CFS regions such as FRA18B. Correspondingly, BRCA2-deficient cells exhibited a failure to activate CHK1, a central coordinator of the response to replication stress and DNA damage, in response to APH treatment, despite normal levels of total CHK1 protein. ATR/CHK1 pathway is a major regulator of CFS stability. Thus, our results provide support for *BRCA2* haploinsufficiency leading to CFS instability in human mammary epithelial cells. These studies will yield unanticipated opportunities for improved risk assessment and prevention strategies in high-risk patients.

Combination of serum human satellite RNA and miR-21 levels as a biomarker for diagnosis of pancreatic cancer

Takahiro Seimiya, Takahiro Kishikawa, Mtoyuki Otsuka, Mitsuhiro Fujishiro. *University of Tokyo, Tokyo, Japan*

Pancreatic ductal adenocarcinoma (PDAC) has a poor prognosis due to the difficulty of its diagnosis. Because human satellite II (HSATII) RNA, a satellite repeat RNA, is highly and specifically expressed in human PDAC, the serum HSATII RNA level may be a biomarker for diagnosis of PDAC. To measure the serum HSATII RNA level with high sensitivity and reproducibility, we previously developed a convenient method, tandem

repeat amplification by nuclease protection (TRAP) combined with droplet digital PCR (ddPCR). Here, we refined the original method by simultaneously measuring the serum miR-21 level to enhance the detection of PDAC. A total of 135 patients were enrolled in this study, including 65 patients with pancreatic cancer and 70 healthy controls. We developed the PDAC-Index as a combination of the HSATII RNA and miR-21 levels to discriminate PDAC from healthy controls. The PDAC-Index demonstrated good diagnostic performance (AUC: 0.92 (95% CI: 0.86-0.99); sensitivity: 0.94; specificity: 0.85) which was significantly better than HSATII RNA alone (AUC: 0.92 vs 0.82, p=0.004) . Importantly, the PDAC-index was elevated in an early-stage PDAC case that was negative for CA19-9. The PDAC-index also discriminated PDAC from chronic pancreatitis and intraductal papillary mucinous neoplasm more accurately than CA19-9. These results suggest that the PDAC-Index may be a promising biomarker for diagnosis of PDAC.

Subtype-specific molecular signatures of field cancerization in patients with sporadic breast cancer

Anjana Bhardwaj[1], Zhenlin Ju[2], Constance Albarracin[1], Celestine Trinidad[3], Preethi Gunaratne[4], Jing Wang[2], Randa El-Zein[5], Isabelle Bedrosian[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]University of Santo Tomas Hospital Benavides Cancer Institute, Manilla, Philippines,[4]University of Houston, Houston, TX,[5]Houston Methodist Research Institute, Houston, TX*

Background: We have previously shown the presence of molecular field cancerization in patients with sporadic breast cancer. Given the heterogeneity of breast cancer, we hypothesized that such field cancerization is likely to be subtype-specific.
Methods: RNA exome sequencing was performed on 360 samples obtained from 75 breast cancer patients undergoing mastectomy; 25 cases were selected from each subtype: hormone receptor (HR) positive, Her2 positive, triple negative (TN) breast cancer. Four sites were sampled from each patient: primary tumor (A), adjacent normal parenchyma within 2cm of the tumor (B), 2 separate, histologically normal sites at least 2cm away from

the tumor (C &D) or, if available, tissue from the unaffected contralateral breast (E). Normal breast tissue (N) from cancer-free controls was obtained from reduction mammoplasty. Tumor-associated genes (TAGs) were identified by comparison of primary tumor to tissue from cancer free controls. We estimated tumor content that was shared across samples B-E by applying deconvolutional analysis to the tumor associated genes, to calculate indices that ranged from 0, indicating normal, to 1, indicating tumor. Molecular field-associated genes and pathways were identified by Spearman's correlation coefficient analysis between the differential genes/pathways and ISTC.

Results: Across all subtypes, the proportion of tumor content present in the histologically normal breast tissue samples (samples B, C, D, E) obtained from cancer patients ranged from 80% in tissue adjacent to the tumor to approximately 50% in tissue obtained from the contralateral breast. We found over 600 deregulated genes to constitute the molecular field across all of the 3 major subtypes tested ($Her2^{+}$, HR, and TNBC), of which approximately 20% were shared in the molecular field of all 3 subtypes of breast cancer. Among the 664 genes noted to be part of the molecular field in TNBC, 23.8% were unique to this subtype. In contrast, only 13% of the genes that constituted the field cancerization in the Her2 and HR+ subtypes were subtype-specific. PIP3-AKT, TCR signaling, and DNA synthesis were among the top pathways specifically activated in the molecular field of the Her2+ subtype of breast cancer. The molecular field of HR+ breast cancer was uniquely characterized by upregulation in the mitotic cell cycle, G1- S transition, and RB pathway. The field of cancerization in the TNBC subtype showed an upregulation in MEK-MAPK, mTOR, and JNK-JUN-TAK1 pathways.

Conclusions: Our study suggests the presence of a breast cancer molecular field effect that extends beyond the adjacent normal breast tissue and includes the entire mammary gland. A substantial proportion of this field cancerization is subtype specific with uniquely deregulated pathways within each subtype. These findings provide new opportunities for developing subtype-specific chemoprevention strategies.

Improved detection of low frequency mutations in ovarian and endometrial cancers by utilizing a highly accurate sequencing platform

Jiannis Ragoussis[1], Nairi Pezeshkian[2], Lucy Gilbert[1]. *[1]McGill University, Quebec, QC, Canada,[2]Pacific Biosciences, Menlo Park, CA*

Ovarian and endometrial cancers come within the top-4 for incident cancers as well as deaths in North American women. Cure rates have not improved in 30 years as high-grade subtypes continue to be diagnosed in Stage III/IV. Attempts at early diagnosis have failed because high-grade cancer cells exfoliate and metastasize while the primary cancer is small and undetectable by existing tests based on imaging and blood-based tumour markers.DOvEEgene (Detecting Ovarian and Endometrial cancers Early using genomics) is a genomic uterine pap test developed by a McGill team to screen and detect these cancers while they are confined to the gynecologic organs and curable by surgery. The test identifies pathogenic somatic mutations in uterine brush samples A high sensitivity error-reducing capture technology (DOvEEgene-SureSelectHS) utilizing duplex sequencing interrogates the exons of 23 genes involved in the development of sporadic and hereditary ovarian and endometrial cancers. We apply a combination of germline gene panel testing on saliva samples with deep duplex sequencing to detect somatic mutations at <0.1% VAF, interrogation of microsatellite loci for instability and low coverage WGS for copy number analysis of uterine brush samples. Currently, DOvEEgene is the only test that can discriminate ovarian and endometrial cancers in peri- and postmenopausal women from benign gynecologic diseases common in that age group. This is important because pathogenic somatic driver mutations are also associated with increasing age and benign disease. DOvEEgene incorporates a deep machine-learning derived classifier that can discriminate the mutational signature of these cancers from benign disease aiming for a sensitivity of 70% and a specificity of 100% in a population with high background mutational burden. Here we tested the Onso system, a highly accurate sequencing technology from PacBio in order to potentially increase sensitivity while driving down sequencing costs by reducing required sequencing depth vs the current NGS standard. We sequenced 15 duplex Illumina sequencing libraries produced using the DovEE assay at PE 100bp mode and compared Onso data in non- duplex sequencing mode as well as duplex sequencing mode to the original duplex sequencing method. Here, we present this comparison and highlight the

benefits of high accuracy sequencing for the detection of very low frequency (<0.1%) somatic mutations.

#6523

A case of stage I HPV-mediated oropharyngeal squamous cell carcinoma (SCC) diagnosed using a multi-cancer early detection (MCED) test

Janet Vittone[1], Julia Feygin[2], Jason Carey[2]. *[1]Mayo Clinic, Rochester, MN,[2]GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc. under the terms of the Interim Measures Order of the European Commission dated 29 October 2021, Menlo Park, CA*

There are no routine screening tests for head and neck (H&N) cancers, which account for approximately 4% of all cancers in the US. Risk factors for oropharyngeal cancer include smoking and human papillomavirus (HPV) infection. An MCED test that uses a cell-free DNA-based targeted methylation assay and machine learning classifiers to detect a shared cancer signal and predict the cancer signal origin (CSO) is available as a complement to existing single-cancer screening tests. If a cancer signal is detected, the positive result is reported with 1 or 2 CSO prediction(s). We report here a tonsil cancer case detected using an MCED test and review the CSO-guided diagnostic journey. An asymptomatic 74-year-old White male (BMI: 29.9 kg/m^2) with history of chronic lymphocytic leukemia (CLL; Rai stage 0; 13q, CD38, and ZAP-70 negative; no treatment was needed) 17 years prior and papillary thyroid cancer (stage IVa; pT3N1bM0; thyroidectomy and radiation therapy; no recurrence) 8 years prior was screened using the MCED test. Patient had an elevated PSA level (9-10 ng/mL) and was a nonsmoker. Fifteen days after a blood sample was collected for analysis, a positive test result (CSO prediction=H&N) was communicated to the patient (Day 1). PET showed abnormal uptake in the right tonsil (Day 28). The patient was referred for an ENT consult and underwent a right lymph node biopsy (Day 54). The biopsy showed invasive moderately differentiated SCC, non-keratinizing, forming a 3x2.1x1.2 cm mass (Day 57). Patient underwent right tonsillectomy (the surgical margins were negative for invasive or in situ carcinoma) and lymph node dissection (Day 57). The cancer was diagnosed as HPV-mediated p16+, pT2, pN1, cM0 (stage I) SCC of the oropharynx (Day 57). No

chemotherapy or radiation was required due to the early stage of detection. The patient will follow-up with ENT and radiation oncology. The MCED test detected a cancer signal and predicted an accurate CSO for an asymptomatic individual with stage I HPV-mediated oropharyngeal SCC. Notably, despite a history of CLL and an elevated PSA level, the test accurately predicted CSO leading to a directed workup diagnosing asymptomatic cancer in less than 2 months, while the cancer was still at stage I. In the case-control Circulating Cell-free Genome Atlas study, the MCED test sensitivity to detect a cancer signal was 63% in stage I H&N cancer. The use of this MCED test led to detection of cancer in a patient with CLL history and treatment (surgery without complications and without chemotherapy or radiation) with curative intent.

Single-cell transcriptomic analysis reveals immune landscape in the malignant transformation of normal lung to lung adenocarcinoma in genetic murine models

Hong Chen[1], Bo Zhu[1], Junya Fujimoto[1], Yanhua Tian[1], Jian-Rong Li[2], Pingjun Chen[1], Alexandre Reuben[1], Monique B. Nilsson[1], Xiuning Le[1], Alissa Poteete[1], Shawna M. Hubert[1], Don L. Gibbons[1], Ignacio I. Wistuba[1], Jia Wu[1], Chao Cheng[2], John V. Heymach[1], Jianjun Zhang[1]. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Baylor College of Medicine, Houston, TX*

Background: Our understanding of the initiation and progression of lung precancers is rudimentary, which has impeded advance for lung cancer prevention and interception. Although human specimens are the gold standard to study human cancer biology, lung precancer specimens designated for research are often very limited. Furthermore, human specimens are not amendable for preclinical intervention studies. We sought to establish and characterize human-relevant murine lung precancer models to study evolution of lung precancers and to provide insights for lung cancer interception.

Methods: We established two mouse models, KrasG12D (a genetically engineered mouse model with KrasG12D activating mutation) and CITMs (a carcinogen urethane-induced model) in the same 129S4 background. We performed single-cell transcriptome sequencing of lung tissues collected at

5 time points after induction for each model to characterize the dynamics of immune response along with the initiation and progression of lung adenocarcinoma.
Results: A total of 82,198 immune cells were analyzed and 23 immune cell subpopulations were identified. The results demonstrated dynamic changes of immune cell compositions and cell states along with the evolution from normal lung to lung precancers, and to lung adenocarcinomas in both models. CD4+ effector T cells, CD4+ regulatory T cells, mucosal associated invariant T cells (MAIT) and macrophages progressively increased during tumor progression, in contrast to progressively decreasing naive CD4+ T cells, naive CD8+ T cells and naive B cells. In contrast to CITMs, KrasG12D model harbors a clear decrease in conventional dendritic cells (cDCs) and activated B cells, but significantly more neutrophils (Wilcoxon test, $P < 0.01$).
Conclusion: These data provide a temporal atlas of lung cancer evolution during early lung carcinogenesis and a resource for interception preclinical study. Our results revealed progressive immunosuppression along with progression of lung precancers in both genetic and carcinogen-induced models, but the immune features underlying immunosuppression may be different.

Colon cancer screening and treatment with engineered probiotics
Candice R. Gurbatri[1], Georgette Radford[2], Jongwon Im[1], Courtney Coker[1], Nicholas Arpaia[1], Susan L. Woods[2], Daniel L. Worthley[3], Tal Danino[1].
[1]Columbia University, New York, NY,[2]Adelaide Medical School, Adelaide, Australia,[3]South Australian Health and Medical Research Institute, Adelaide, Australia

Bioengineered probiotics enable new opportunities to improve colorectal cancer (CRC) screening, prevention and treatment strategies. Here, we demonstrate selective colonization of CRC tumors with the orally-delivered probiotic *E. coli Nissle 1917* (EcN) in genetically-engineered and orthotopic murine models of CRC, and human CRC patients. We subsequently engineer EcN to produce screening and therapeutic molecules, resulting in non-invasive detection of precursor CRC lesions and reduction of tumor burden through local induction of robust anti-tumor immunity.

Investigation levels of trace elements in breast cancer types using laser spectroscopic techniques

Ola Sayed Ahmed[1], hisham imam[2]. *[1]National Cancer Institute, Cairo University, Cairo, Egypt,[2]National laser Institute, Cairo University, Cairo, Egypt*

Breast cancer (BC) is the 2nd leading cause of death from cancer in women. Women have a lifetime risk of breast cancer of around 31%, which makes it the first most common malignancy in women .Diagnosing cancer and classifying its types is a complex process that relies heavily on sample analysis. Early detection of cancer diseases is one of the important and main factors in determining treatment and saving many patients before the disease worsens and reaches dangerous stages. Alterations in the levels of trace elements have been observed in breast cancer (BC) patients. However, the relationships between these alterations and the metabolic and clinical consequences of BC are unknown. The aim of the present work is to study in vitro possibilities and the effectiveness of introducing an efficient optical spectroscopic technique such as LIBS for the identification types of breast cancer, as well as determining the disease grade and severity. The ultimate goal of this work is to investigate the concentrations of several trace elements in BC patients, and their relationships with the molecular subtypes of tumors. The atomic transition of the neutral element lines of Fe, Al, Na, Ca, K, V, Co and Pb was chosen to determine the trace element levels of four breast cancer types. We found that the measured average level of trace elements can differentiate between different types of breast cancer.

Fusion genes as novel putative biomarkers for head and neck squamous cell carcinomas

Yabdiel A. Ramos Valerio[1], Hannah C. Van Wyk[2], Esther Peterson Peguero[3], Josué Pérez Santiago[1]. *[1]Cancer Biology, UPR - Comprehensive Cancer Center, San Juan, PR,[2]Epidemiology, University of Michigan School of Public Health, Ann Arbor, MI,[3]Natural Sciences, UPR - Rio Piedras, San Juan, PR*

Head and neck squamous cell carcinomas (HNSCC) are highly aggressive types of cancers with a complex molecular etiology of disease and consequently result in delayed clinical detection, poor prognosis, and limited treatment strategies. Fusion genes, a hallmark of cancer, may be targeted for early identification and treatment of HNSCC; however, studies characterizing fusion genes in HNSCC remain limited. Oral Human Papillomavirus (HPV) infection is a major cause of HNSCC and can also promote the acquisition of fusion genes due to the genomic instability induced by its integration. Here, we retrieved RNA-sequencing data from 36 HNSCC tumors (18 HPV+ and 18 HPV-, GEO Accession: GSE74956) to identify fusion genes using the STAR fusion algorithm in each sample. Statistical analyses were performed in R statistical software. A total of 10 fusion genes were identified in at least 4 of the samples regardless of HPV status. We identified 3 fusion genes that were present in at least 4 of the HPV+ tumors: PMS2P9-CCDC146, MACC1-AC005062.1, AC096711.2-RPL7AP28, and one solely present in HPV- tumors: CTSC-RAB38. The remaining 6 fusion genes were present in both HPV+ and HPV- tumors: TVP23C-CDRT4, AC009271.1-LINC01905, MIR205HG-AOPEP, SEPTIN7P2-PSPH, KRT5-KRT84, KANSL1-ARL17A. While 4 of the identified fusion genes had been previously associated with cancer, there were 6 novel identified fusion genes, in which one or both partner genes have been associated with different cancers. Additionally, the identified fusion genes may be a product of transcription read-through of neighbor genes. The fusion genes associated with HPV infection might explain biological disparities in HPV+ versus HPV- HNSCC and may be targets for the prevention and diagnosis of HNSCC. Future studies need to determine the functional impact of the identified fusion genes in HPV+ tumors.

#6528

HPV status and epigenetic profiling of saliva from a cancer-free population

Ana Paula Muterle Varela[1], Dieila Giomo De Lima[2], Laura Palmieri[2], Juliana Comerlato[1], Fernando Hayashi Sant'Anna[1], Isabel C Bandeira[1], Marina Bessel[1], Pedro Isaacsson Velho[1], Eliana M. Wendland[1], Mariana Brait[2]. *[1]Hospital Moinhos de Vento, Porto Alegre, Brazil,[2]Johns Hopkins University School of Medicine, Baltimore, MD*

Identifying environmental factors and their relationship with epigenetic alterations is essential for understanding cancer, a leading cause of death. Currently, cancer screening and early detection development efforts are ongoing and epigenetics-based tests are one of the top choices as strategies. The understanding of how these alterations behave in cancer-free (CF) populations with well annotated data is essential. We randomly selected 601 saliva specimens from two Brazilian countrywide epidemiological studies POP-Brazil and SMESH. Extracted DNAs were sodium bisulfite converted and analyzed by Quantitative Methylation-Specific PCR (QMSP). Five genes previously reported as DNA methylation prone in cancer were selected (*ITGA4*, *EDRNB*, *PAX5, p16, CCNA1*). All participants were interviewed and provided sociodemographic and sexual behavior information as well as genital (gn) and oral biological samples. Variables were categorized and Fisher's exact test was performed using SAS 9.4.Surprisingly, methylation in 3 cancer associated genes showed considerable frequencies in this CF group. DNA methylation was observed for *EDNRB* in 75/601 samples (12.5%), *PAX5* in 55/601 (9.2%), and *ITGA4* in 20/601 (3.3%). 12 samples displayed concomitant methylation on 2 of these 3 genes. *p16* and *CCNA1* methylation were only present in 1 sample each. Preliminary analyses suggest that specific genes methylation are observed with the presence of low (LR) and high-risk (HR) HPV types. *EDNRB* methylation groups with the presence of HR HPV type 16, 31, 39, 51, 58 and 59 from gn samples and LR types 6 and 42. *ITGA4* methylation and HR HPV types 16 and 59 were detected in oral samples, and types 52, 56 and 68 in gn samples, as well as LR HPV types 40 and 42. In people with early onset of smoking, *EDNRB* and *PAX5* seem to be more frequently methylated. The positivity of *PAX5* was higher in participants who smoke, use alcohol and presented a positive diagnosis of syphilis and/or HIV. *PAX5* methylation was more frequent in HR HPV 33, 58, 68 and 62 and LR type 6. Further analyses are ongoing. Our study shows methylation in cancer related genes in a CF population. The variables collected include some proven cancer risk factors and others still unknown, thus lead us to uncover directions to identify main cancer related players in a Brazilian population. The presence of cancer related alterations may indicate premalignant stages, exposure and lifestyle consequences, both at the same time or separately. In our pilot analysis, different types of HPV seem to correlate with epigenetic changes, this could bring attention to less studied HPV types and their role

in carcinogenesis. Additional analyses of the current data and larger prospective, population-based studies, assessing the use of salivary DNA methylation in cancer-free and cancer groups of subjects are needed to explore the current findings and dissect the potential of saliva as a means of tracking cancer related changes.

#6529

Early life liver proteomic signature and minerals mitigation of liver injury

Isabelle Harber, Shannon D. McClintock, Randall N. Knibbs, James Varani, Muhammad N. Aslam. *University of Michigan Medical School, Ann Arbor, MI*

Background and Aims: Previous long-term murine (12- and 18-month) studies in C57BL/6 mice have demonstrated the beneficial role of Aquamin, a red marine algae-derived multi-mineral supplement containing calcium, magnesium, and 72 additional trace elements, in inhibiting liver tumor formation in mice on high-fat, Western-style diet (HFWD). Liver tumor incidence in mice on HFWD was decreased to 12% with the addition of Aquamin supplementation compared with 48% in the HFWD mice. Similarly, in mice on the low-fat diet, tumor incidence was only 16% and Aquamin further reduced it to 4%. Recently, we assessed the safety and tolerability of Aquamin in human subjects in a 90-day interventional trial and there was no evidence of potential liver harm, measured by liver enzymes. A short-term (16-week) mouse study was carried out to investigate early protein changes in the liver that may play a role in liver tumorigenesis and how Aquamin can interfere with that signature.
Methods: Male MS-NASH mice were maintained on a HFWD for 16 weeks with and without red algae-derived minerals. A cohort of C57BL/6 mice maintained on a standard chow (low-fat diet) was used as a control. At the end of the in-life portion of the study, body weight, liver weight, liver enzyme levels and liver histology were assessed. Samples obtained from individual livers were subjected to Tandem Mass Tag labeling and quantitative proteomics mass spectrometry.
Results: As expected, no tumors were observed at 16 weeks. Mice on the HFWD demonstrated multiple protein changes associated with dysregulated fat and carbohydrate metabolism, lipotoxicity and oxidative stress. In mice

receiving Aquamin-supplementation along with the HFWD, there was reduced liver toxicity as evidenced by a decrease in levels of several cytochrome P450 enzymes and other oxidant-generating moieties. Additionally, multiple keratins, which provide cytoskeletal support were elevated. Phosphate and tensin homolog (PTEN), a tumor suppressor, was upregulated with Aquamin. There was an upregulation of several pathways implicated in tumor suppressor activity, notably *keratinization*, *hedgehog signaling in the off-state*, and *regulation of PTEN stability and activity*. *Conclusions:* The proteomic expression of the livers of HFWD mice in this short-term study explains early protein changes that may contribute to liver cancer and the potential mechanisms by which dietary minerals may mitigate such down-stream effects.

Preferential low frequency allele enrichment with lower sequencing depth requirement using KAPA HyperPETE specialized primer designs

Florence K. Crary-Dooley, Liu Xi, Ruben van der Merwe, Nitya M. Furtado, Jingchuan Li, Junyan Lin, Manuel Ochoa, Brian Godwin. *Roche Diagnostics, Pleasanton, CA*

Background: The presence of circulating tumor DNA (ctDNA) can be used for minimal residual disease (MRD) monitoring and guide adjuvant therapy decisions. However, even when present, total ctDNA could be less than 0.01% of cell free DNA (cfDNA). Sequencing such low mutation frequency can be costly due to high sequencing read depth and accuracy requirements. The ability to enrich for low-abundance variants could improve detection performance and greatly lower sequencing cost by reducing the sequencing depth required.
Purpose: The KAPA HyperPETE (Primer Extension Target Enrichment) workflow employs primer extension reactions to specifically capture and release target library molecules for sequencing, detects all major somatic variant types (SNV, InDel, CNV, MSI status, and novel fusion transcript partners) and could be leveraged to specifically target certain alleles. In this study, we assessed the variant enrichment capabilities of the KAPA HyperPETE workflow.

Methods: Variant specific primers were designed to 8 low allele frequency single nucleotide variants (SNVs) in mixed cell line samples (NA12878 and NA24143, two Epstein-Barr virus transformed B cell female cell lines, with variant allele frequency (VAF) 1%, 0.5%, and 0.1%). Variant enrichment primers were used alongside a 37kb panel in the KAPA HyperPETE workflow. Additional optimizations and a study enriching all low allele frequency SNVs* in SeraCare ctDNA Mutation Mix v2 reference samples (VAF 1%, 0.5%, and 0.125%) are planned.

Results: The preliminary results exhibited a median of 249×, 159×, and 86.5× enrichment of the targeted variants compared to the expected VAFs of 0.1%, 0.5%, and 1%, respectively. All 8 targeted variants were detected at 100K, 150K, and 550K read pairs per variant for VAF 1%, 0.5%, and 0.1%, respectively. Results from further optimizations and the study using SeraCare ctDNA samples will be shared at the AACR meeting.

Conclusion: Preferential enrichment of specific variants down to 0.1% can be achieved using the KAPA HyperPETE Workflow. Utilizing primers designed for variant enrichment, we simultaneously enriched multiple variants and demonstrated the potential to minimize required sequencing. The KAPA HyperPETE workflow can be a powerful, cost-effective tool for detecting low frequency mutations in MRD research applications.

KAPA HYPERPETE is For Research Use Only. Not for use in diagnostic procedures. KAPA HYPERPETE is a trademark of Roche.

*Except GNA11 (COSM52969) due to stretches of polybase. Seraseq ctDNA Mutation Mix v2 gene list available on SeraCare website.

Point of care test for cervical cancer screening

Samrin Farouk Idris Habbani[1], Sayeh Jalali Dowlatshahi[2], Monisha Elumalai[2], Scott Charles Bolton[2], Lucy Teberh Tecle[2], Pankti Rajesh Thakkar[2], Jacqueline C Linnes[2], Sulma I Mohammed[1]. *[1]Comparative Pathobiology, Purdue University, West Lafayette, IN,[2]Biomedical Engineering, Purdue University, West Lafayette, IN*

Cervical cancer is a lethal gynecological malignancy and the fourth most common cancer among women. Most high-grade cervical pre-cancers and cancer cases are linked to infection with high-risk human papillomaviruses

(HPV). There is an inequity between high-income countries (HICs) and low- and middle-income countries (LMICs) in cervical cancer burden; according to the World Health Organization, the estimated mortality rate of cervical cancer is 342,000 women worldwide in 2020, and 90% of these women reside in low- and middle-income nations where the human papillomavirus vaccine is unavailable and access to early detection testing are either unavailable or too expensive. This study aims to develop a simple and affordable point-of-care test based on four critical biomarkers for screening high-risk pre-cancer and invasive cervical cancer in collaboration with the biomedical engineering department. A cervical cancer swab will be used in the test. The swab will be placed on a paper-based device that looks for four protein biomarkers critical for the progression of noninvasive cervical cancer into invasive cervical cancer by combining two approaches using proteomics and lateral flow immunochromatography technology. We have validated the markers' expression in cervical cancer and precancerous tissues. The four markers were expressed in squamous cell carcinoma, glassy cell carcinoma, adenocarcinoma, clear cell carcinoma cancer tissues, and the high-grade cervical intraepithelial neoplasia. This point-of-care test will be affordable and implementable, especially in low and middle-income countries.

Autophagy & PIM1 kinase inhibition in breast cancer stem cells & bulk cancer cells attenuates breast cancer & metastasis

Kanakaraju Manupati[1], Mingang Hao[2], Michael Haas[2], Syn Kok Yeo[1], Jun-Lin Guan[1]. *[1]University of Cincinnati, Cincinnati, OH,[2]Department of Cancer Biology, University of Cincinnati, Cincinnati, OH*

Autophagy is a self-degradation process, it is essential for growth of heterogenous of breast cancer cells. Breast tumor heterogeneity majorly comprises bulk cancer cells & cancer stem cells (CSCs). Targeting either CSCs or cancer cells could lead to interconversion between these cells due to EMT/MET transitions. Therefore, it is important to identify a common

molecular targets & its mechanism of regulation in these populations for improvement of breast cancer therapy. Here, we utilized a PCR based screen & identified NUMA1 downregulation in FIP200 KO (autophagy gene) cells of three major breast cancer subtypes, FF99 (luminal), N418 (Her2+) & BF3M (basal). Further, NUMA1 KO in these cells reduced tumor formation & CSCs indicating the role of NUMA1 on regulation of CSCs. Therefore, we sorted breast CSCs, $ALDH^{+}$ and $CD29^{hi}$ $CD61^{+}$ from WT & NUMA1 KO cells, tail-vein injected nude mice depicted reduced metastatic potential with NUMA1 KO than WT CSCs. Mechanistically, NUMA1 regulation by PIM1 kinase was observed in CSCs but not in bulk cancer cells. Cell viability assays revealed that combination treatment of autophagy & PIM1 inhibitor showed higher efficacy against cancer cells of three breast cancer subtypes than individual treatments alone. Finally, the combination treatment of autophagy inhibitor, Lys05 & PIM1 inhibitor, SMI-4a reduced tumor formation & metastasis of breast cancer. Human tissue microarray results depicted high expression of NUMA1 & PIM1 in different breast cancer subtypes than non- tumor tissues. Our study demonstrated that inhibition of autophagy & PIM1 in bulk cancer cells & CSCs showed attenuation of tumor formation & metastasis, suggesting this combination treatment serves as an important therapeutic approach for treating breast cancer.

The novel therapeutic diiminoquinone exhibits anticancer effects on human prostate cancer cells in 2D and 3D in vitro models

Amani Yehya, Alissar Monzer, Kevork Wakimian, Fatima Ghamlouche, Nour Saheb, Ayman Tawil, Hala Gali-Muhtasib, Deborah Mukherji, Albert El-Hajj, Wassim G. Abou-Kheir. *American University of Beirut, Beirut, Lebanon*

Aim: To investigate the anticancer potential of the novel quinone DIQ on prostate cancer (PCa) cells in two-dimensional (2D) and three-dimensional (3D) *in vitro*.

Methods: The anti-proliferative effect of DIQ on PC3 and DU145 PCa cell lines was determined *in vitro* by using 3-(4,5 dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) and trypan blue exclusion assays. In addition, the potency of DIQ was tested on the formation and size of PCa

cell-derived prostatospheres and organoids grown in a specialized 3D-culture system. Also, 3D organoids were established from fresh tissue samples representing different stages of PCa obtained from consented patients who underwent radical prostatectomy at the American University of Beirut Medical Center (AUBMC) according to appropriate Institutional Review Board (IRB) approval guidelines. This model was used to assess DIQ
individualized tumor response on organoids growth and the effect was evaluated by quantifying the number of organoids formed (OFC) and calculating the average size (diameters).
Results: Our results showed that DIQ significantly attenuated cell proliferation and viability in PC3 and DU145 PCa cell lines. DIQ also reduced the formation ability and size of PC3 and DU145 prostatospheres and organoids at sub-toxic doses of 1 μM. Potently, DIQ displayed a significant decrease in both the count and the size of the different patient-derived organoids as compared to their respective control.
Conclusion: This study provides promising clues for the use of the novel anticancer therapeutic DIQ in targeting CSCs, findings that may have promising therapeutic implications for PCa patients.

#5793

Met confers radioresistance-associated aggressiveness through enhancing PLXDC2-mediated cancer stem cell plasticity

Fanghui Chen[1], Liwei Lang[2], Chloe Shay[1], Georgia Chen[1], Nabil Saba[1], Yong Teng[1]. *[1]Emory University, Atlanta, GA,[2]Augusta University, Augusta, GA*

The development of radioresistance in head and neck squamous cell carcinoma (HNSCC) remains a significant problem in cancer treatment, contributing to the lack of improvement in survival trends in the past decades. One of the clinical challenges is that radioresistance often promotes tumor aggressiveness. However, the underlying mechanisms and molecular determinants are largely unknown. We report here that radioresistance-associated HNSCC aggressiveness is effectively exacerbated by c-Met but can be suppressed by its genetic knockdown and pharmacological inactivation. Through unbiased RNAseq data, we further uncovered that the resulting upregulation of c-Met signaling increases the

expression of PLXDC2. a critical gene associated with the tumor microenvironment. Mechanistically, PLXDC2 is upregulated in radioresistant HNSCC cells through c-Met mediated activation of ERK1/2-ELK1 signaling cascade. Most importantly, PLXDC2 modulates cancer cell plasticity by inducing epithelial-mesenchymal transition (EMT) and the emergence of cancer stem cell (CSC) subpopulation. Additionally, depletion of PLXDC2 overcomes c-Met-mediated radioresistance by reversing the EMT progress and blunting the self-renewal capacity of CSCs. Therapeutically, a combination of the c-Met selective inhibitor SU11274 with radiation remarkably induces tumor shrinkage and constrains tumor metastasis to lymph nodes in vivo. Our study is novel in being the first to explore the role and mechanism of the c-Met-PLXDC2 axis in radioresistance-associated HNSCC aggressiveness and the first to our knowledge to evaluate how to take advantage of blocking this signaling to overcome radioresistance in preclinical mouse models of HNSCC.

Targeting CD133$^+$/CD90$^+$ liver cancer stem cells by piperlongumine: A novel strategy for liver cancer treatment

Basma A. Abdelaziz[1], Omayma M. Sadek[2], Ahmed S. Sultan[2]. *[1]Basic Sciences / Biochemistry, Pharos University in Alexandria / Alexandria University, Alexandria, Egypt,[2]Biochemistry, Alexandria University, Alexandria, Egypt*

Liver cancer is an aggressive malignant disease. It's the most common cancer worldwide and the leading cause of cancer death. Because of the atypical early symptoms of liver cancer, the majority of liver cancer patients are diagnosed with advanced-cancer stage, decreasing the chance of resection and resulting in a poor survival rate. Liver cancer stem cells (LCSCs) are a small subpopulation inside the tumor bulk, characterized by the maintenance of self-renewal and pluripotency. Thus, LCSCs are responsible for cancer initiation, metastasis, relapse, and chemoresistance. Elucidating LCSC characteristics and disclosing their regulatory mechanism might facilitate the development of prognostic, diagnostic, and therapeutic approaches to improve the clinical management of liver cancer. Piperlongumine (PL) an active biological pyridine alkaloid has anti-angiogenic, anti-diabetic, and anti-bacterial activities. The present study

aimed to isolate highly tumorigenic and aggressive subpopulation of LCSCs ($CD133^+/CD90^+$) from primary tumors and different cell lines and investigate the effect of (PL), a novel targeting therapy, on LCSCs proliferation. The isolated LCSCs were treated with different concentrations of PL and its effect was examined by cell viability, cell morphological changes, western blot, caspase-3 activity, apoptotic induction, and clonogenic formation. By using Immunocytochemistry (ICC) analysis, the localization of nuclear and cytoplasmic Aldehyde dehydrogenase (ALDH6A1) was detected. PL inhibited the viability of $CD133^+/CD90^+$LCSC-sub-popupation and caused morphological changes after 48 hours while enhancing the pre-apoptotic signals and caspase-3 activity. In addition, PL decreased the colonies' formation ability compared to control group. Furthermore, PL suppressed the protein expression levels of ALDH6A1, Notch-1, β-catenin, ERK1/2, and Cyclin-D1 in the dose and time-dependent manners. Besides, PL decreased the localization and intensity of nuclear and cytoplasmic ALDH6A1 compared to the control group, indicating that PL decreased the proliferation and stemness markers of LCSCs. Overall, Piperlongumine as a novel targeting therapy has an important role in targeting $CD133^+/CD90^+$ LCSCs sub-population proliferation.

#5795

Leukemic stem cells confer ferroptosis resistance in aggressive blood cancer

Nunki Hassan, Hangyu Yi, Lucie Gaspard-Boulinc, Jenny Wang. *School of Medical Sciences, Faculty of Medicine and Health, University of Sydney, Sydney, Australia*

Acute myeloid leukemia (AML) is an aggressive blood cancer with limited therapeutic options against leukemic stem cells (LSCs), resulting in poor clinical outcomes for decades. We have demonstrated the clinical importance of aberrant activation of RSPO3/β-catenin pathway in a subset of poor prognosis AML (*Cancer Cell,* 38:263-278, 2020) and its ability to sustain low levels of reactive oxygen species (ROS), a critical characteristic of human LSCs. This current study has extended our recent finding, and for the first time linked the pathway activation to ferroptosis resistance, a new drug resistance mechanism in cancer therapy. Our single-cell multiomics

data in patient-derived xenograft mouse models of relapsed AML showed that the pathway activation in human LSCs led to upregulation of 43 differentially expressed genes associated with iron detoxification (e.g., FTH1) and ROS sensing/detoxification (e.g., PRDX1), two key features of ferroptosis resistance. Consistent with this observation, we found that AML patient specimens with favourable outcomes, which are independent of RSPO3 pathway, were sensitive to RSL3 treatment leading to increased cell death associated with elevated levels of intracellular ROS and iron. In contrast, AML patient specimens with poor clinical outcomes, which critically depend on RSPO3 pathway activation for survival and maintenance of myeloid undifferentiated state, revealed resistance to ferroptosis inducers (e.g., RSL3). Intriguingly, we found that anti-RSPO3 antibody, a clinical-grade drug that inhibits AML LSCs by blocking the interaction of RSPO3 with its receptor, sensitizes human LSCs to RSL3 treatment, leading to reduced cell viability. Overall, this study is the first to demonstrate the role of ferroptosis resistance in human LSCs and provides an opportunity to develop precision combination therapy by concurrently targeting self-renewal and ferroptosis resistance to improve therapeutic outcomes for patients with poor-risk AML.

#5797

NTX301, a novel DNA hypomethylating agent, targets lipid metabolism in ovarian cancer

Yinu Wang, Xiaolei Situ, Horacio Cardenas, Daniela Matei, Ellie Siu, Sayedabdulrazzaq A. Alhunayan. *Northwestern University - Chicago, Chicago, IL*

Background: DNA methylation causes the silencing of tumor suppressor and differentiation-associated genes being linked to chemoresistance and stemness. Previous studies demonstrated that hypomethylating agents (HMA) re-sensitize ovarian cancer (OC) cells to chemotherapy, however, translation to the clinic has been slow. NTX 301 (PinotBio) is a novel, highly potent, and orally bioavailable HMA, in early clinical development. Methods: We assessed the anti-tumor effects of NTX301 in OC models and studied the underlying molecular mechanisms by using cell proliferation, stemness, and ferroptosis assays, RNA sequencing, and validation.

Results: OC cells (SKOV3, IC_{50}=5.089nM; OVCAR5 IC_{50}=3.664nM) were highly sensitive to NTX301 ($p<0.05$) compared to immortalized fallopian tube epithelial cells (FT-190) (IC_{50}=103.3nM). Treatment with NTX301 induced significant downregulation of the DNA methyltransferases (DNMTs) 1-3 expression in SKOV3 and OVCAR5 cells compared with decitabine ($p<0.05$). Treatment with low dose NTX301 (100nM) induced significant transcriptomic reprogramming with 15,000 differentially expressed genes (DEGs) compared to DMSO ($p<0.05$). Among the NTX301 down-regulated DEGs, Gene Ontology (GO) enrichment analysis identified pathways related to the *regulation of alcohol, cholesterol, and fatty acid biosynthetic process and* molecular functions related to *aldehyde dehydrogenase (ALDH) and oxidoreductase activity*, known features of cancer stem cells (CSCs). Indeed, treatment with low dose NTX301 (100nM) reduced the ALDH(+) cell population and expression of stemness-associated transcription factors (Oct4 and Sox2). Additionally, stearoyl-Coenzyme A desaturase 1 (SCD), a key enzyme that regulates unsaturated fatty acid homeostasis in the lipogenesis process was found among the top DEGs downregulated in response to NTX3 (fold change=9.36, *FDR*<0.05). As blockade of SCD had been shown to induce ferroptosis, oxidized lipids levels were measured by C11-BODIPY staining. NTX301 treatment increased the levels of oxidized lipids compared to DMSO and this was blunted by deferoxamine, indicating that NTX301 promoted cell death via ferroptosis. NTX301-induced ferroptosis was successfully rescued by the addition of oleic acid (200μM) into the culture medium, supporting that it was mediated through SCD depletion. *In vivo*, monotherapy with NTX301 (0.5mg/kg), significantly inhibited subcutaneous OC xenograft tumor growth ($p<0.05$). Decreased SCD levels and increased oxidized lipids were recorded in NTX301-treated xenografts.
Conclusions: NTX301 is a potent HMA active in OC models. Our findings point to a new mechanism by which epigenetic blockade disrupts lipid homeostasis and promotes cancer cell death.

Ex vivo culturing of primary AML cells facilitates the study of developmental therapeutics

Satyam Patel[1], Upendarrao Golla[2], Arati Sharma[3], David Claxton[2]. *[1]Penn State College of Medicine, Hershey, PA,[2]Department of Medicine, Penn*

State College of Medicine, Hershey, PA,[3]Department of Pharmacology, Penn State College of Medicine, Hershey, PA

Studies with acute myeloid leukemia (AML) cell lines have limited potential as they tend to acquire mutations, thus, do not represent typical leukemias found in patients. Ex vivo culturing of primary human AML patient cells is therefore of interest; however, the long-term culture of these cells has been limited by rapid differentiation and loss of clonogenicity. Previously, different growth factors and stromal cells were implicated in the short-term culturing of primary cells. Thus, we aimed to evaluate culture conditions using a cytokine cocktail, allowing long-term expansion and phenotypic maintenance of primary AML cells in vitro. Different culture conditions were constituted by combination of cytokines (SCF, FLT-3L, TPO, IL-6, IL-3, GCSF, GM-CSF) and small molecules (SR1, UM729) in serum-free StemSpan SFEM media. The ability of different growth mediums to support the expansion and clonogenicity of 6 primary AML cells (collected from blood/bone marrow) over two weeks was assessed using cell counts and colony formation assays. Additionally, cell surface markers (hCD34, hCD45, hCD123, hCD117) were assessed by flow cytometry during the culture period. All tested cultured conditions exhibited successful cell proliferation (4-6-fold expansion) and survival of primary AML cells over two weeks of culture. In addition, the growth media successfully supported 3.5-fold CD34+ stem cell expansion. Growth mediums with early-acting cytokines (SCF, FLT-3L, TPO, and IL-6) and small molecules resulted in phenotypic maintenance of cell surface markers (CD34, CD123) and secondary clonogenicity of primary AML cells over the culture period. The addition of late-acting cytokines (IL-3, GCSF, and GM-CSF) showed a higher growth rate but negatively affected the cell surface markers and clonogenicity. Secondary colony counts (day-9 culture) showed a significant positive correlation with CD34 expression levels. Thus, CD34 levels could serve as a potential surrogate marker for the clonogenicity of primary AML cells. Furthermore, we tested the engraftment ability of two primary AML cells grown in 3 of our promising culture conditions (Day 4, Day 8) in xenograft mice. Flow cytometry analysis on peripheral blood and tissues (spleen and bone marrow) from xenograft mice showed successful engraftment of primary cells cultured for 8 days. On an application note, the optimal condition from our results was

used to study the effects of ceramide nanoliposomes (CNL) in AML patient cells. Interestingly, the AML patient cells treated for two weeks with IC15 and IC30 doses of CNL led to cell cycle arrest, reduced CD34 expression, and clonogenicity relative to control cells. The CNL findings from primary cells are different from that of cell lines cultured under the same conditions. Thus, our optimal growth conditions may facilitate researchers to understand AML biology and study various therapeutics under development using primary AML cells.

SPINK1-induced tumor plasticity provides a therapeutic window for chemotherapy in hepatocellular carcinoma

Ki-Fong Man[1], Lei Zhou[1], Ying-Tung Lam[1], Jun Yu[2], Jing-Ping Yun[3], Xin-Yuan Guan[4], Ming Liu[5], Stephanie Ma[1]. *[1]School of Biomedical Sciences, The University of Hong Kong, Hong Kong, Hong Kong,[2]The Chinese University of Hong Kong, Hong Kong, Hong Kong,[3]Pathology, Sun Yat-Sen University Cancer Centre, Guangzhou, China,[4]Clinical Oncology, The University of Hong Kong, Hong Kong, Hong Kong,[5]School of Basic Medical Sciences, Guangzhou Medical University, Guangzhou, China*

Intratumor molecular heterogeneity of hepatocellular carcinoma (HCC) is partly attributed to the presence of cancer stem cells (CSCs), which we now know represents a critical root of tumor recurrence and chemotherapy resistance. CD133 is known to represent an important functional marker of liver CSCs. We have demonstrated CD133 to enrich following chemotherapy treatment, while CD133/Prom1-depletion would enhance sensitivity of HCC tumors to chemotherapy. Yet unfortunately, CD133 is not specific to HCC, but is also expressed in normal regenerating liver. Identifying critical factors expressed specifically in liver CD133+ CSCs, but not in liver normal CD133+ stem/progenitor cells may offer important therapeutic opportunities overcoming chemoresistance in HCC. RNA-seq profiling comparing sorted CD133+ and CD133- subsets of normal regenerating liver induced by DDC diet and HCC induced by either N-nitrosodiethylamine (DEN)/carbon tetrachloride (CCl_4) or hydrodynamic tail vein injection of oncogenic plasmids AKT and NRAS identified Serine Peptidase Inhibitor Kazal Type I (SPINK1) to be distinctly expressed in the

HCC CD133+ subpopulation but not in normal regenerating liver CD133+ subpopulation. SPINK1 overexpression in HCC clinical samples is correlated with a poor prognosis. Expression of SPINK1 increased during early liver progenitor development, peaked during the premature hepatocyte stage, decreased during hepatocyte maturation and increased progressively from well-differentiated to poorly differentiated HCCs. Enhanced transcriptional activity of SPINK1 was mediated by promoter binding of the epithelial cell-specific transcription factor ELF3, which like CD133, were both increased following chemotherapy treatment. SPINK1 inhibition by lentiviral-based knockdown or a specific monoclonal antibody (mAb) mitigated tumor initiation, self-renewal and chemoresistance. Mechanistically, secretory SPINK1 bound to epidermal growth factor receptor (EGFR) activating MEK/ERK signaling and consequently promoting the formation of CDK4/6-cyclin D1 complex to phosphorylate Rb and release E2F2, allowing the cells to overcome G1/S checkpoint promoting cell cycle progression as well as transcribing stemness, oncogenic dedifferentiation and chemoresistance-related genes. Collectively, our findings suggest SPINK1 to play a critical role in hepatocarcinogenesis and that SPINK1 mAb may represent a novel therapeutic option for the treatment of HCC, targeting at the CD133+ CSC tumor roots and overcoming chemoresistance.

Anti-metastatic potential of pitavastatin in triple-negative breast cancer via targeting breast cancer stem-like properties and STAT3 signaling

Dongmi Ko, Juyeon Seo, Seongjae Kim, Soeun Park, Minsu Park, Kee Dal Nam, Yong koo Kang, Sora Seock, Eunsun Jung, Yoon-Jae Kim, Jaeyoun Park, Ji Young Kim, Jae Hong Seo. *Korea University Guro Hospital, Seoul, Korea, Republic of*

Triple-negative breast cancer (TNBC) is the most deadly and aggressive phenotype, with a higher rate of metastatic recurrence. TNBC does yet have a suitable treatment option other than cytotoxic anticancer drugs. Although pitavastatin has been shown to exert anti-proliferative effects and cytotoxicity in various types of cancer cells, the precise mechanisms underlying pitavastatin’s anti-cancer effects in TNBC have not been fully

elucidated. We sought to investigate the mechanism of pitavastatin-induced apoptosis and its effects on cancer stem cell (CSC)-like characteristics in TNBC. Exposure to pitavastatin induced mitochondria-mediated apoptotic cell death in BT549 and 4T1 cells. Mitochondrial dysfunction was accompanied with a robust production of reactive oxygen species (ROS) and collapse of mitochondrial membrane potential (MMP), resulting in subsequent activation of caspase-3/-7 and PARP cleavage. Pitavastatin effectively suppressed CSC-like properties in TNBC via targeting CD44+/CD24- and CD49f+/CD24- phenotypes, as well as impediment of mammosphere formation *in vitro*. This phenomenon was accompanied with dysregulation of STAT3 survival pathway, concomitant with significant downregulation of cyclin D1, survivin and vimentin. Pitavastatin effectively targets both the proliferating TNBC tumor cells and CSCs via the dysregulation of STAT3 and suppression of CSC-like properties, markedly reducing angiogenesis and tumor growth, coinciding with decreased Ki-67 expression. It is noteworthy that pitavastatin considerably suppressed metastasis, coinciding with significant reduction of MMP-2, MMP-9 and VEGF in the circulating blood of mice. Our findings highlight that pitavastatin may be potentially effective for the treatment of metastatic TNBC.

Inhibition of muscarinic acetylcholine receptors in glioma stem cells blocks tumor progression

Sumyuktha V. Anand[1], Min K. Lee[1], Alexander G. Skorput[1], Isabella B. Fox[2], Alison L. Young[1], Brock C. Christensen[1], Allan Gulledge[1], Matthew C. Havrda[1]. *[1]Dartmouth Geisel School of Medicine, Lebanon, NH,[2]Dartmouth College, Hanover, NH*

Primary gliomas arising within the brain are the deadliest form of brain cancer and account for 78% of all malignant brain tumors. Glioma patients have a 5 percent five-year survival rate and drug-resistant tumors often recur following surgical resection and treatment with radiation and/or chemotherapy. The cancer stem cell hypothesis suggests the presence of a subset of undifferentiated cells, namely glioma stem cells (GSCs), in the heterogenous tumor mass responsible for disease progression. Understanding mechanisms responsible for maintaining GSCs and

developing strategies to deplete the GSC population could improve glioma treatment and prognosis. Some GSCs are similar to oligodendrocyte precursor cells (OPCs), which are observed in neural development and the adult brain. OPCs are prone to malignant transformation and are believed to be a cell of origin for glioma. Recent findings indicate that the well-characterized neurotransmitter acetylcholine (ACh) maintains the primitive state of normal OPCs via muscarinic ACh receptors (mAChRs) preventing maturation and cell cycle exit. We hypothesized that cholinergic signaling may also maintain the primitive state of OPC-like GSCs. We analyzed publicly available single nuclei RNASeq data of patient glioblastoma samples and observed high expression of *CHRM3*, encoding the M3 mAChR, in OPC-like cells of the proneural subtype of glioma. Studies in mouse OPC-like GSCs confirmed high levels of *CHRM3* expression and demonstrated that ACh generated voltage changes and rapid (< 1 second) increases in cytosolic calcium from internal calcium stores. Exposure to a brain permeant FDA-approved anti-muscarinic drug targeting M3mAChR suppressed proliferation, evoked calcium release, and the activation of intracellular second messengers PKC and ERK. Pharmacologic inhibition of mAChRs in established patient derived glioma grafts prevented re-initiation of tumors in subsequent host animals compared with vehicle treated tumors. These studies suggest that the cholinergic microenvironment maintains GSCs in a manner similar to normal OPCs and provides a platform for repositioning available small molecule mAChR antagonists for treatment of glioma.

The impact of tumor-treating fields on cancer stem-like cells isolated from the sub-ventricular zone of glioblastoma patients

Yamhilette Licon Munoz[1], Rachel B. Sidebottom[1], Frank J. Martinez[1], Samantha Varela[2], Christian A. Bowers[3], Sara G.M. Piccirillo[1]. *[1]Cell Biology and Physiology, University of New Mexico Health Sciences Center, Albuquerque, NM,[2]University of New Mexico School of Medicine, Albuquerque, NM,[3]University of New Mexico Hospital, Albuquerque, NM*

Treatment of glioblastoma (GBM) is challenging due to its heterogeneous nature, invasive potential and poor response to standard of care treatments. As a result, GBM inevitably recurs and only approximately 9% of patients

survive 5 years post-diagnosis. Areas of residual disease represent the source of the recurrent tumor that is fatal for GBM patients. However, targeting the residual disease is not offered as part of the standard of care because these areas are difficult to identify and, to date, they have not been characterized during disease progression. Our laboratory was the first to identify and characterize residual disease in the sub-ventricular zone (SVZ) of the lateral ventricles of GBM patients. Specifically, we found that in the majority of GBM patients the SVZ is a reservoir of tumor cells that promote therapeutic resistance and seed the recurrent tumor. Specifically, our work revealed that in 65% of the cases the SVZ contains treatment-resistant cancer stem-like cells (CSCs), thus investigating residual disease in this area may hold the key to developing a valid therapeutic target for many patients. In this study, we are examining the impact of Tumor-Treating Fields (TTFields) on treatment-resistant CSCs isolated from the SVZ of GBM patients using molecular techniques, such as single-cell transcriptomics and functional phenotyping analysis. To date, we have isolated and characterized 12 CSCs. These cells are maintained in conditions that preserve the molecular profile of the original patient tumor, thus representing *bona fide* models to study the impact of TTFields on GBM residual disease. We observed that: (i) CSCs show heterogeneous patterns of response to the alkylating agent Temozolomide (100 μM) and radiation (10 Gy), that mimic the standard of care for GBM patients, (ii) their treatment response is independent of the MGMT promoter methylation status and (iii) the proliferation of CSCs resistant to Temozolomide and radiation is significantly inhibited by TTFields when cells are exposed for 48 hours to the optimized frequency for GBM (200 kHz). Altogether, these findings point to the effectiveness of TTFields following Temozolomide and radiation and set the foundation for the single-cell transcriptomic and functional analysis to elucidate the mechanisms whereby TTFields impact the proliferation of CSCs in the SVZ of GBM patients. In the long run, the results of this work will allow the identification of SVZ-specific targets for the development of novel and more effective treatments for GBM patients.

Targeting methyl donor synthesis inhibits platinum-induced enrichment of ovarian cancer stem cells

Shu Zhang, Tara X. Metcalfe, Christiane A. Hassel, Heather M. O'Hagan, Kenneth P. Nephew. *Indiana University Bloomington, Bloomington, IN*

Ovarian cancer (OC) is one of the deadliest gynecologic cancers in US. Platinum (Pt)-based chemotherapy can reprogram cancer cells to ovarian cancer stem cells (OCSCs) and contribute to incurable recurrence. We have previously shown that Pt-containing drugs, e.g., cisplatin, enrich for OCSCs and Pt-induced alterations in DNA methylation enhanced OCSC malignant properties. CSCs have been shown to be dependent on methionine (Met) in many cancers, and in the current study, we investigated the role of Met and the interplay between methylation and Met metabolism in OCSC enrichment. In high grade serous ovarian cancer cell lines (OVCAR5, OVCAR3), cisplatin treatment (IC50, 16hr) increased ($p<0.01$) the percentage of cells that were positive for aldehyde dehydrogenase (ALDH+ cells), a known OCSCs marker. Cisplatin treatment also increased ($p<0.05$) the whole cell level of 5-methylcytosine, indicating Pt-induced methylation changes. In addition, Met metabolism was altered by cisplatin, demonstrated by decreased ($p<0.01$) level of Met derivative, S-adenosyl-methionine (SAM), and increased ($p<0.01$) expression of Met utilization enzyme, methionine adenosyltransferase 2A (MAT2A). To investigate a possible role of Met metabolism in Pt-induced enrichment of OCSCs, OVCAR5 cells were cultured in complete or Met-depleted (Met-) media, treated with cisplatin or vehicle and examined for CSC properties, including ALDH+ cells and the ability to form spheroids under low-attachment conditions. Met depletion blocked ($p<0.01$) both the Pt-induced increase of ALDH+ cells and spheroid formation. Both Met- only and Met- in combination with cisplatin activated p38, determined by increased phosphorylated p38, which may have responded to Met depletion and promoted cell cycle arrest. In addition, MAT2A expression was higher ($p<0.01$) in ALDH+ compared to ALDH- OC cells. MAT2A inhibitor FIDAS-5 combined with cisplatin blocked the Pt-induced increase in ALDH+ cells ($p<0.01$), demonstrating a requirement for Met utilization in Pt-induced OCSC enrichment. As MAT2A is a therapeutic target in cancer, MAT2A inhibition could represent a therapeutic approach for inhibiting CSC in ovarian cancer. We are further investigating the mechanism of MAT2A-mediated inhibition on Pt-induced OCSCs enrichment by examining the OC methylome and cell cycle arrest.

Ebastine targets cancer stem cell-like properties and metastasis in triple-negative breast cancer by binding focal adhesion kinase

Juyeon Seo, Minsu Park, Dongmi Ko, Seongjae Kim, Soeun Park, Kee Dal Nam, Yong Koo Kang, So Ra Seuk, Jaeyoun Park, Eunsun Jung, Yoon-Jae Kim, Ji Young Kim, Jae Hong Seo. *Korea University Guro Hospital, Seoul, Korea, Republic of*

Triple-negative breast cancer (TNBC) exhibits an aggressive behavior associated with poor prognosis due to the absence of established molecular targets. Focal adhesion kinase (FAK) is a major determinant and participates in the acquisition of migration and invasion, as well as the maintenance of breast cancer stem cell (BCSC)-like traits in TNBC. We sought to investigate the effect of ebastine, a second-generation antihistamine on apoptosis, FAK activation, BCSC subpopulations and metastasis in TNBC in vitro and in vivo. TCGA dataset analysis revealed that mRNA levels of FAK were highly expressed in TNBC compared to other breast cancer subtypes. We found that ebastine binds to the tyrosine kinase domain of FAK, which blocks phosphorylation at the Y397 and Y576/577 residues and subsequent inactivation of SRC. Ebastine-induced apoptosis was associated with attenuation of JAK2/STAT3 and MEK/ERK signaling in TNBC cells. Kinetic analysis revealed a concentration-dependent impairment of cell migration in the presence of ebastine in MDA-MB-231 and 4T1 cells *in vitro*. Ebastine targets BCSC-like cell populations as evidenced by a sharp decline in the expression of the BCSC markers ALDH1, CD44 and CD49f and suppression of mammosphere-forming capacity. Ebastine administration led to a significant reduction in the growth ebastine of BCSC-enriched 4T1 mammospheres orthotopically injected into the mammary glands of Balb/c mice. Ebastine administration significantly impeded angiogenesis and distant metastasis while reducing MMP-2/-9 levels in circulating blood in vivo. Importantly, biochemical analysis in mice serum showed that ebastine had no effect on liver and kidney function. Our findings suggest that EBA may be an effective therapeutic repositioning candidate for the simultaneous targeting of multiple survival signaling pathways for the treatment of molecularly

heterogeneous TNBC. Further investigation of ebastine as an anti-metastatic agent for the treatment of TNBC is warranted.

Kinase library screening identifies IGF-1R/PI3K/AKT axis as a crucial pathway for survival of intrahepatic cholangiocarcinoma cells with stemness characteristics

Chotirat Rattanasinchai[1], Chidchanok Chornkrathok[2], Donlaporn Sriphan[2], Panida Navasumrit[1], Mathuros Ruchirawat[1]. *[1]Environmental Toxicology Laboratory, Chulabhorn Research Institute, Bangkok, Thailand,[2]Chemical Carcinogenesis, Chulabhorn Research Institute, Bangkok, Thailand*

Intrahepatic cholangiocarcinoma (iCCA) is a subtype of biliary malignancy that arises along the peripheral bile duct epithelium. Given its limited and inefficacious treatment options, the mortality rate of iCCA remains high and thus a novel therapeutic strategy is urgently needed. The concept of cancer stem cells (CSCs) explains a subpopulation of cancer cells that possesses self-renewal and differentiation capacities. These CSCs become the culprit for cancer metastasis, cancer recurrence and chemotherapeutic resistance, making them promising targets for cancer treatment. The propose of this study is to identify the signaling pathways crucial for the survival of iCCA with stemness characteristics. Gene expression analysis on a dataset of Thai iCCA patients (n=91) showed that iCCA tumors are enriched in the Adult Stem Cell (ASC) signature which are the shared characteristics among the epithelial-derived cancer with stemness characteristics. Although iCCA cells exhibit some degree of enrichment in stem cells markers when compared with cholangiocyte cells, further upregulation of stem cell-related genes, *e.g. Nanog, Oct3/4, Sox2, and Sox9*, were found in iCCA cells grown as 3D tumorspheres. A kinase inhibitor screening library was then performed on iCCA tumorspheres. Our initial screening demonstrated that 11 out of the top 50 kinase inhibitors that effectively decrease viability of iCCA tumorspheres belongs to the insulin-like growth factor-1 receptor (IGF-1R)/phosphoinositide-3-kinase (PI3K)/protein kinase B (PKB/AKT) axis. Additionally, these inhibitors increase cell apoptosis, judged by the caspase 3/7 activity, within iCCA tumorspheres. Conversely, IGF-1 treatment which is sufficient to induce activation of IGF-1R and AKT also enhances cell viability and decrease cell

apoptosis in iCCA. Taken together, our data demonstrate that IGF-1R/PI3K/AKT axis is crucial for survival of iCCA cells with stemness characteristics and this pathway could be a potential therapeutic target in iCCA.

#5807

mTOR regulates stem cells of glioblastoma by altering the self-renewal and proliferation

Olivia Gellerson, Julie Bree, Mohan Das, George Kleinman, Chirag Gandhi, Meena Jhanwar-Uniyal. *Department of Neurosurgery New York Medical College/WMC, Valhalla, NY*

The mechanistic target of rapamycin (mTOR: aka mammalian target of rapamycin), a serine/ threonine kinase, functions by forming two multiprotein complexes termed mTORC1 and mTORC2. Glioblastoma (GBM) is a malignant and lethal brain tumor that remains incurable partly due to the existence of untreatable cancer stem cells (CSC). The pathogenesis of GBM is largely due to the loss of the tumor suppressor gene PTEN, which is implicated in the aberrant activation of the mTOR pathway. The major cause of tumor recurrence, growth, and invasion is the presence of a unique population of CSC. Resistance to conventional therapies appears to be caused by both extensive genetic abnormalities and dysregulation of the transcription landscape. Consequently, CSCs have emerged as targets of interest in new treatment paradigms. Evidence suggests that inhibition of the mTOR pathway can also be applied to target CSCs. In this study, we explored the role of the mTOR pathway in the regulation of stem cells of GBM. GBM stem cells were treated with various inhibitors of canonical PI3K/AKT/mTOR pathways such as rapamycin (mTORC1 inhibitor), PP242 (ATP binding mTORC1/2 inhibitor), LY294002 (PI3K inhibitor), and MAPK inhibitor, U0126. We previously demonstrated the presence of CSC in the peritumor area of GBM. A significant number of GBM tumors expressed stem cell marker nestin and activated mTOR (pmTORSer2448), with most tumor cells co-expressing both markers. The expression of stem cell marker NANOG was suppressed following rapamycin treatment, while U0126 induced translocation of NANOG from the nucleus to the cytoplasm. The neurospheres were disrupted following rapamycin and LY294002 treatments. Rapamycin or

PP242 treatments given with differentiating agent All-trans-retinoic acid reduced stem cell proliferation. Treatment with novel small molecule dual inhibitors of mTORC1/2 demonstrated that Torin1 and Torin2 suppressed the proliferation of GBM CSC, while XL388 was less effective. Torin1 and XL388 delay the process of self-renewal as compared to controls, whereas Torin2 halted the self-renewal of GBM CSC. Additionally, Torin2 was able to eradicate tumor cells. Torin2 effectively targeted CSCs of GBM by halting self-renewal and inhibiting cell proliferation, underscoring the use of Torin2 in the treatment of GBM.

#5808

Integrin-linked kinase regulates Wnt transcriptional activity in platinum resistant ovarian cancer stem cells

Rula Atwani, Virginie Lazar, George Earl Sandusky, Salvatore Condello.
Indiana University School of Medicine, Indianapolis, IN

Ovarian cancer (OC) is the most lethal gynecological cancer, characterized by chemo-resistance and fatal tumor recurrence after primary treatment. The metastatic progression is mediated by exfoliation of tumor cells into the peritoneal cavity, the formation of compact OC spheroids, and their implantation onto the overlying peritoneal surface. Spheroid formation is promoted by a change of cell adhesion properties, enhanced secretion of extracellular matrix (ECM) components, such as fibronectin (FN), that stiffen the tumor stroma, promote the aberrant activation of integrins, and recruit the adaptor protein integrin-linked kinase (ILK). ILK drives cytoskeletal assembly and modulates key processes, including survival, invasion, and stemness. However, the functional role of ILK in chemoresistance of ovarian cancer stem cells (OCSCs) remains incompletely understood. We tested the hypothesis that the formation of FN-integrin complexes at the cell membrane promotes survival of OCSCs and supports OC spheroid formation by activating ILK and downstream oncogenic signaling. In OCSCs compared with non-CSC, ILK, FN, and integrin β1 *m*RNA expression levels were increased ($P<0.001$) and further enriched in OC spheroids compared with monolayers ($P<0.01$). ILK blockade with the specific inhibitor cpd-22 suppressed spheroid proliferation and tumor initiating capacity in xenograft mouse model. Furthermore, key oncogenic signaling pathways, in particular decreased β-

catenin signaling essential to sustaining cancer cell stemness, were altered in OC spheroids treated with cpd-22. Of the genes examined, expression of Wnt receptor Frizzled 7 (Fzd7) was the mostly highly downregulated in OC spheroids treated with cpd-22, indicating a direct correlation between ILK activation and Wnt signaling. By using co-immunoprecipitation and proximity ligation assay, we demonstrated that ILK co-localizes with Fzd7 in OC spheroids. Mechanistically, treatment of OC spheroids with the combination of carboplatin and ILK-Fzd7 blockade decreased β-catenin signaling, inhibited phospho-Akt at Ser473 and increased levels of cleaved-caspase-3 compared to single agent alone, resulting in apoptosis. By regulating β-catenin signaling, Fzd7 expression and ILK activation are essential for OCSCs survival. Targeting Fzd7-ILK clusters may represent a new therapeutic approach to eradicate OCSC and ultimately improve patient outcomes.

Tracking cancer stem cell expression of pancreatic and ampullary cancer organoids in response to chemotherapy

Eleanor Riedl[1], Austin Stram[1], MD Shahadat Hossan[1], Ethan S. Lin[1], Luke Koeppel[1], Jamie Warner[1], Sam Lubner[1], Stephanie McGregor[2], Wei Zhang[2], Jeremy Kratz[1]. *[1]Department of Medicine, University of Wisconsin - Madison, Madison, WI,[2]Department of Pathology and Laboratory Medicine, University of Wisconsin - Madison, Madison, WI*

Background: Cancer stem cells (CSCs) have been described to confer resistance and aggressive disease biology in pancreatic ductal adenocarcinoma (PDAC) and ampullary carcinoma (AMPC). Patient derived cancer organoids (PCOs) are an important model of PDAC that maintain the molecular features of advanced disease and have been shown to predict drug response. This study aimed to determine the dynamics of CSC expression on the oligoclonal culture growth of three independent PCOs models.

Methods: PCOs were assayed using low volume 10μL microformat in 96 well design (Ibidi, Inc). PCOs were treated with physiologic FOLFIRINOX or gemcitabine + nab-paclitaxel (nab-pac) including single agent controls. Response was assayed by growth using timecourse data from 0h to 72h using high content imaging (Cytation 5). At 72h, the PCOs were stained

using four distinct CSC markers (CD44, CD133, CD117, and EpCAM). Images were aligned using thresholded root mean standard deviation of 75μm and tracked for normalized change in longest diameter. At 72h, CSC markers were tracked using % area positive from brightfield region of interest. Response was tracked by effect size Glass's Delta (GΔ) defined as the difference between the mean of media control and treatment group normalized to standard deviation of media control.
Results: PCOs maintained nuclear atypia and high nuclear-chromatin ratios consistent with matured xenografts. AMPC1 showed similar sensitivity with growth arrest by PCO Δ diameter for gem + nab-pac (mean = +2.2%, GΔ = 1.29) and FOLFIRINOX (mean = 0.0%, GΔ = 1.33). AMPC1 had CSC enrichment for CD44 after treatment with nab-pac (GΔ = 0.93), CD133 expression after treatment with gem + nab-pac (GΔ = 0.75), CD117 after treatment with nab-pac treatment (GΔ = 0.80), and EpCAM after treatment with gem + nab-pac (GΔ = 0.78). In AMPC1, interquartile analysis revealed increased CSC expression conferred reduced growth for CD133 (+72% v. 37%, $p<0.005$) and CD117 (+81% v. +25%, $p<0.005$). Normalized Δ diameter across PDAC PCOs revealed PDAC1 had reduced sensitivity to gem + nab-pac (mean = +16.0%, GΔ = 1.2) vs. PDAC2 (Mean = 2.1%, GΔ = 1.65). PDAC1 had CSC enrichment with increased % area of CD44+ after treatment with gem + nab-pac (GΔ = 1.13). In PDAC2, interquartile analysis revealed increased CSC expression conferred decreased growth rate for CD133 (+65% v. +36%, $p< 0.005$) and CD117 (+75% v. +38%, $p<0.005$).
Conclusions: PDAC and AMPC PCOs reveal oligoclonal expression of CSC markers within a population. Increased CSC expression for CD133 and CD117 within a population consistently revealed decreased growth within an organoid population. CSC expression (CD44, CD133, CD117, and EpCAM) was found to be enriched under therapeutic challenge with gem and nab-pac containing chemotherapy. This work supports the oligoclonal and dynamic nature of CSCs for pancreaticobiliary cancers in response to therapeutic challenge.

#5810
The effects of retinoid agents and retinoic acid receptor genotype on proliferation, differentiation, and stem cells in colorectal cancer

Victoria Oluwajuwon Hunsu[1], Caroline O. B. Facey[2], Bruce M. Boman[1].
[1]Department of Biological Sciences, University of Delaware, Newark, DE,[2]Center for Translational Cancer Research, Helen F Graham Cancer Center, Newark, DE

Understanding how to therapeutically target colonic stem cells (SCs) is important because SC overpopulation drives CRC growth and development. Our *goal* is to therapeutically sensitize cancer SCs (CSCs) to differentiation-inducing effects of retinoid agents against CRC. We found that ALDH specifically marks normal and malignant colonic SCs and that retinoic acid (RA) signaling mainly occurs in colonic ALDH+ SCs. That RA signaling occurs through ALDH+ SCs was derived from finding that RA receptors and RA signaling components are selectively expressed in ALDH+ SCs. Indeed, All-*trans*retinoic acid (ATRA) is a highly effective treatment for leukemia (APL) which has a *RARA* translocation. We conjecture that response of solid tumors to RA agents depends on RA pathway genotype. Our bioinformatics analysis shows mutations often occur in RA receptors in human CRCs. Therefore, we *hypothesize* that the ability of RA agents and RA metabolism blocking agents to induce differentiation of CSCs depends on RA pathway genotype.
Methods: The ability of RA agents (ATRA, 13-*cis* retinoic acid, 9-*cis* retinoic acid) and RA metabolism blocking agents (Liarozole, Talarozole) to inhibit proliferation and induce differentiation of CRC cells was evaluated. Nanostring Profiling was used to measure effects of agents on mRNA expression of various markers.
Results: Our results show that RA pathway genotype affects the response of RA agents in CRC cell lines. HCT116 and SW480 cells, which have RA receptor mutations, displayed resistance to ATRA. In contrast, HT29 cells that have wild-type RA receptors are sensitive to ATRA. All three cell lines however showed similar responses to the CYP26A1 inhibitor Liarozole. This finding indicates that regardless of RA receptor mutations, inhibition of ATRA metabolism will increase intracellular RA levels. Nanostring profiling analysis shows ATRA treatment of HT29 cells increases expression of *RARA*,*CYP26A1* (ATRA metabolizing enzyme), & *KRT20* (differentiation marker), and decreases expression of CSC markers *LGR5* & *ALDH1A1*. Moreover, ATRA treatment of both CRC cell lines decreases

ALDH+ cell population size. These findings show upregulated RA signaling can increase differentiation and decrease CSC numbers in CRC. **Discussion** Our findings indicate that colon SCs are regulated by RA signaling mechanisms and dysregulation of RA signaling contributes to the SC overpopulation that drives CRC growth. Thus, therapeutically sensitizing CSCs to differentiation-inducing effects of RA agents should provide insight into design of new SC-targeted therapies for CRC.

Epigenetic regulation of chromosomal instability in triple-negative breast cancer

Yang Bai[1], Albert Agustinus[2], Cem Meydan[1], Dylan R. McNally[1], Shira Yomtoubian[1], Liron Yoffe[1], Ari M. Melnick[1], Samuel Bakhoum[2], Vivek Mittal[1]. *[1]Weill Cornell Medicine, New York, NY,[2]Memorial Sloan Kettering, New York, NY*

Metastasis is the leading cause of cancer-related death among women with breast cancer. Chromosomal instability (CIN) has emerged as a hallmark of triple-negative breast cancer (TNBC) as it has recently been shown to promote metastasis. However, the underlying molecular mechanisms by which CIN drives metastasis are not completely understood. We have identified a discrete population of highly metastatic SOX2/OCT4+ cells expressing elevated levels of epigenetic regulator EZH2 associated with increased CIN in both human and mouse TNBC. EZH2 histone methyl transferase (HMT) is the catalytic subunit of the Polycomb repressive complex 2 (PRC2), represses target genes through trimethylation of Histone 3 at lysine 27 (H3K27me3). Importantly, genetic and pharmacologic inhibition of EZH2 lead to reduction of CIN and impaired metastasis. These findings led to the hypothesis that EZH2-mediated CIN constitutes a novel mechanism of metastasis regulation. To directly demonstrate epigenetic regulation of CIN, we used genome wide-Cleavage Under Targets and Release Using Nuclease (CUT&RUN) in parallel with RNA-seq. Gene set enrichment of EZH2-repressed target genes directly implicated the spindle formation pathway network. The central core of this network comprised of tankyrase (TNKS), a multifunctional poly (ADP-ribose) polymerase (PARP) previously implicated in DNA repair, telomere function and centrosome maturation. ChIP-PCR confirmed that EZH2 directly binds to

the TNKS promoter, and CRISPR knockout of TNKS abrogated the ability of EZH2 inhibition in suppressing CIN, consistent with pharmacological inhibition of TNKS. More specifically, dysregulation of TNKS by EZH2 in OCT4/SOX2+ cells lead to increased numbers of centrosomes and multipolar mitosis. To directly demonstrate the role of aberrant H3K27me3 in regulating chromosomal segregation during mitosis, we used dCas9-EZH2 or dCas9-EZH2 catalytically dead mutant together with chromosome-specific CRISPR guides to ectopically enhance H3K27 trimethylation at the pericentromeric region of specific chromosomes. Ectopic deposition of EZH2 at pericentromeric regions lead to increased CIN.
Conceptually, our work provides an unappreciated link between epigenetic regulation and CIN which have been hitherto studied in isolation. From a clinical perspective, demonstrating epigenetic regulation of CIN has opened the possibility for the development of first CIN suppressive therapeutic strategies targeting TNBC metastasis.

Cell Adhesion and Cell Signaling in Cancer and Drug Resistance

Nucleus positioning and composition dictate the invasion performance of E-cadherin mutant cells
Joana Figueiredo[1], Joana Pereira[1], Rui M. Ferreira[1], Luísa Carvalho[1], Margarida Gonçalves[1], Soraia Melo[1], Patrícia Carneiro[1], Parry Guilford[2], Eurico Morais-de-Sá[1], Raquel Seruca[1]. *[1]Institute for Research and Innovation in Health (i3S), University of Porto, Porto, Portugal,[2]Department of Biochemistry, University of Otago, Otago, New Zealand*

Introduction: Cell invasion is a critical step for tumor progression and dissemination into neighboring and distant tissues, which constitute the foremost cause of cancer mortality. Loss of the cell-cell adhesion molecule E-cadherin occurs in 70% of carcinomas and is widely described as an initiating event in the invasion process. Recently, data has emerged demonstrating that this milestone phenomenon is accompanied by an abnormal affair between cancer cells and the extracellular matrix (ECM). In fact, cancer cells display increased plasticity and a remarkable ability to

overcome the fibrous structure of the ECM. Since the nucleus is the largest and stiffest organelle in the cell, we hypothesize that it represents a major determinant of cell reshaping and spreading capacity. Our main aim is thus to dissect the mechanisms through which the nucleus supports invasion of cancer cells.
Material and Methods: To determine alterations in nuclear composition and architecture that are distinctive of cells with E-cadherin impairment, we have used cell lines and *Drosophila* strains expressing either wild-type E-cadherin or the Y755C variant identified in Hereditary Diffuse Gastric Cancer (HDGC) patients. Nuclear morphological features and migratory rates were assessed by fluorescent markers coupled with confocal microscopy and advanced bioimaging techniques. The molecular profile of nuclei envelope from E-cadherin mutant and wild-type cells was subsequently investigated by implementation of a proteomic workflow, encompassing cellular fractionation and processing through high-resolution Mass Spectrometry (LC-MS).
Results: We have shown that the Y755C E-cadherin mutation induces evident changes in nuclear morphology, and an increased migration performance of border cells in *Drosophila*. In particular, detailed quantitative measurements revealed differences in nuclear area, mean intensity, perimeter, solidity and relative position to basal surface of E-cadherin mutant cells, when compared with those expressing the wild-type protein. Further, proteomic analysis of enriched nuclear fractions disclosed that the composition of the nuclear envelope from E-cadherin mutant cells is significantly different from that of the wild-type counterparts. Differentially abundant molecules include proteins relevant for spatial and structural integrity of the nucleus.
Conclusion: Overall, this work provides evidence that cells with E-cadherin loss of function activate a specific mechanotransduction program that imposes nuclear remodeling at physical and biochemical levels, endowing cells with a pro-invasive signature.

Tensin1 tension sensor reveals novel features associated with actomyosin, focal adhesion dynamics, and mechanosensitivity

Yoon-Kwan Jang[1], Jung-Soo Suh[1], Gyuho Choi[1], Sanghyun Ahn[1], Ki Seok Han[1], EunHye Kim[1], Yerim Lee[1], Xiaoqi Hu[1], Eunbae Hwang[2], Tae-Jin

Kim[2]. [1]*Department of Integrated Biological Science, Pusan National University, Pusan, Korea, Republic of,*[2]*Department of Biological Sciences, Pusan National University, Pusan, Korea, Republic of*

Cellular responses to mechanical stimuli play an imperative role in the regulation of physiological and pathological functions. Unlike other integrin-mediated adhesion proteins, the force transmission mechanism of tensin1 is not well understood. In this study, we describe the development and visualization of a tensin1 tension sensor. A signal from this sensor indicates that tensin1 is under greater tension at peripheral adhesions than at central adhesions, and that it is controlled by actomyosin in fibroblasts. In a bidirectional manner, tension in tensin1 is regulated by focal adhesion kinase (FAK) activity. Our findings demonstrate that tensin1 is capable of sensing the extracellular matrix through alterations in the tension it receives from the extracellular matrix. Furthermore, tensin1 depletion increases the tension of talin1, but the absence of talin1 decreases the tension applied to tensin1. These results indicate that tensin1 is complementary and dependent on the tension received by talin1. Overall, our data, together with the prognosis following tensin1 expression in colorectal and urothelial cancer, elucidate the tension-receiving function of tensin1 and highlight the necessity of tensin1-mediated mechanotransduction studies.

LKB1 overcomes RAS pathway-mediated loss of epithelial integrity

Topi A. Tervonen[1], Shishir M. Pant[1], Johanna Englund[1], Juha Klefström[2]. [1]*University of Helsinki, Helsinki, Finland,*[2]*University of Helsinki and Finnish Cancer Institute and FICAN South Helsinki University Hospital, Helsinki, Finland*

Oncogenic RAS pathway disassembles cell-cell and cell-basement membrane junctions, thus promoting epithelial cell motility and invasion. To find tumor proteomic changes responsible for the disrupting effects of RAS on epithelial integrity, we explored cBioportal cell line proteomics data across all cancer types for correlations between oncogenic KRAS or HRAS mutations and possible regulators of epithelial integrity. We found inverse correlation between these RAS mutations and tumor suppressor LKB1 protein levels in a cohort where LKB1 was not inactivated by a

mutation. Furthermore, LKB1 protein levels were also positively correlated with NF2 protein (a negative regulator of RAS) in human breast tumors and inversely correlated with c-RAF (RAS effector) activating phosphorylation at serine 338 in breast cancer cell lines. We sought to functionally clarify the relationship between RAS pathway and LKB1, finding that an ectopic constitutive or inducible expression of $HRAS^{V12}$ downregulates LKB1 protein in mammary epithelial MCF10A cells and HMEC-hTERT cells. Furthermore, RAS-mutant MCF10A cells regained LKB1 protein levels upon treatment with MEK/ERK inhibitors. We establish that the RAS-mediated downregulation of LKB1 protein occurs through proteasomal activity. LKB1 reconstituted MCF10A-$HRAS^{V12}$ (RAS-LKB1) cells displayed restored desmoplakin, γ-catenin and E-cadherin pericellular immunostaining pattern in monolayer cultures, suggesting restoration of desmosomes and adherence junctions. We also cultured RAS-LKB1 cells in 3D egg-white and observe restoration of E-cadherin, γ-catenin, α6-integrin, and laminin-332, indicating a rescue of epithelial integrity in 3D context. Our findings suggest that LKB1 rescues mutant RAS-mediated disruption of cell-cell and cell-basement membrane junctions and general epithelial integrity. Our current aim is to define how LKB1 suppresses RAS mediated disruption of breast epithelial integrity, that is expected to shed new light into early stages of tumor invasion and uncover novel therapeutic opportunities via restoration of LKB1.

Cadherin complexes recruit PIWIL2 to suppress pro-tumorigenic transformation

Alyssa Risner[1], Joyce Nair-Menon[1], Vamsi Gangaraju[2], Antonis Kourtidis[1].
[1]Regenerative Medicine, The Medical University of South Carolina (MUSC), Charleston, SC,[2]Biochemistry and Molecular Biology, The Medical University of South Carolina (MUSC), Charleston, SC

Recent studies have shown that genomic instability, oncogene expression, and high mutation rates in more than 50% of tumors can be attributed to increased transposon activity. Transposons, also called transposable elements (TEs), are parasitic mobile DNA elements that make up 45% of the human genome and can cause DNA damage and gene mutations. The reasons for increased TE activity in somatic tumors are currently unknown.

TE RNA transcripts are targeted for degradation by PIWI ribonucleases, which are members of the Argonaute superfamily of proteins, through regulation of small RNAs called piRNAs (PIWI-interacting RNAs). Although the function of the PIWI-piRNA pathway has been extensively studied in the germline, there is little understanding about the presence or functionality of the pathway in somatic tissues. We have evidence of a novel interaction of the adherens junctions of well-differentiated epithelial cells with PIWIL2 (PIWI-like RNA-Mediated Gene Silencing 2), a key catalytic component of the PIWI-piRNA complex. Through immunofluorescence staining, confocal microscopy, and co-immunoprecipitation studies, we found co-localization and association of PIWIL2, as well as of other key members of the PIWI complex, such as PIWIL4 and TDRD1, with E-cadherin and p120 catenin at adherens junctions of well-differentiated breast and colon epithelial cells, whereas this association is lost in cancer cells and patient tissues. Adherens junction disruption results in mis-localization of PIWIL2, PIWIL4, and TDRD1 from the adherens junctions and their accumulation either to the cytoplasm or to the nucleus. E-cadherin depletion particularly results in increased expression of the LINE1 transposon, which is the most abundant transposon in human cells, and in increased levels of γ-H2AX, an indicator of DNA damage. Our working hypothesis is that cadherin junctions of well-differentiated epithelial cells recruit and regulate the PIWIL2 complex to suppress transposon activity. Since both loss of junctional integrity and increased transposon activity are universal events in cancer, this study has the potential to deepen our understanding of the role of the PIWI-transposon pathway in somatic tumorigenesis.

Src inhibitor suppresses rab11 mediated collective cell migration in colon cancer cells

Yi-Wen Lu, Xiang-Ling Hou, Hui Min Koo, Wei-Ting Chao. *Tunghai University, Taichung, Taiwan*

Collective cell migration has been demonstrated the importance in cancer metastasis. Instead of single cell migration, collective cell migration requires E-cadherin for the cohort cell migration. Rab11 the recycling vesicle protein plays the key role in E-cadherin dynamics and mediates

collective cell migration. In this study, Src was hypothesized to regulate Rab11 mediated collective cell migration. Our results demonstrated Src inhibitor Dasatinib has less toxicity in HT-29 colon cancer cells, instead, the cell morphology was turned aggregated. The immunofluorescence image also showed E-cadherin polarity was lost after Dasatinib treatment and increased the potential of cell-cell contact inhibition. In transwell assay, Rab11 was found colocalized with E-cadherin in collective migrated cells. Dasatinib treatment can suppress collective cell migration and decrease the interaction of Rab11 and E-cadherin. This study demonstrated the important role of Src in Rab11 mediated collective cell migration through E-cadherin dynamics in colon cancer.

#5820

Chloroquine inhibited Rab11 mediated E-cadherin transport in collective colon cell migration in Dasatinib resistant cells

Xiang-Ling Hou, Hui Min Koo, Chia-Wen Lin, Chien-Chi Huang, Yu-Chi Tseng, Kai-Yu Tseng, Wei-Ting Chao. *Tunghai University, Taichung City, Taiwan*

In has been demonstrated epithelial mesenchymal transition (EMT) is related to E-cadherin expression level. Recently, studies have been demonstrated the collective cancer cell migration which expresses high E-cadherin is a powerful mechanism of metastasis. Therefore, the role of E-cadherin in cancer metastasis is still not clear. Endocytosis was shown to regulate E-cadherin turnover on the membrane and the function of lysosome is also associated with cell vesicle trafficking. The past studies indicated Src can regulate vesicle trafficking. In this study, HT29 colon cancer cells were treated with Src inhibitor, Dasatinib (DST), to investigate the role of lysosome in regulating E-cadherin dynamics through vesicle trafficking in collective cell migration. In the result, the recycling protein Rab11 and lysosome marker Lamp1 were found localized with E-cadherin in the cell-cell contacts, however, Dasatinib sensitive (DSTS) cells showed less colocalization of Rab11 with E-cadherin. When cells were treated with lysosome inhibitor chloroquine, Rab11 were accumulated in the cell-cell contacts and reduced collective cell migration in Dasatinib resistant (DSTR) cells. These results suggest lysosome inhibition can suppress Rab11 mediated vesicle trafficking of E-cadherin transport for collective cell

migration, and chloroquine has therapeutic potential in colon cancer treatment.

Synergism of FAK and ROS1 inhibitors in the treatment of *CDH1*-deficient cancers mediated by FAK-YAP-TRX signaling

Jiaming Gao[1], Yunying Yao[1], Zaiqi Wang[2], Baoyuan Zhang[1], Ruibao Ren[1].
[1]Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China,[2]InxMed (Shanghai) Co., Ltd, Shanghai, China, Shanghai, China

CDH1 deficiency is common in triple negative breast cancer and diffuse gastric cancer patients, both of which lack effective therapeutics. Although inhibiting ROS1 function results in synthetic lethality in *CDH1*-deficient cancers, adaptive resistance limits their potential clinical benefits. Hyperactive focal adhesion kinase (FAK) signaling contributes to adaptive drug resistance, and FAK inhibitors are partially effective against *CDH1*–deficient cancers. Thus, co-treatment with ROS1 and FAK inhibitors may provide stronger anti-cancer effects by targeting *CDH1* deficiency and potentially overcome drug resistance. Here, we evaluated the effects and mechanisms of combined treatment with FAK inhibitor IN10018 and ROS1 inhibitors. Cell-based assays and *in vivo* animal experiments revealed that FAK and ROS1 inhibitor combination treatment showed stronger anti-cancer effects than either monotherapy. ROS1 inhibitors induced FAK-YAP-TRX signaling, decreasing oxidative stress–related DNA damage, and consequently reducing its anti-cancer effects. However, the combination treatment suppressed the aberrant FAK-YAP-TRX signaling, reinforcing the cytotoxicity of ROS1 inhibitor towards cancer cells. This mechanism of action was confirmed by inhibiting the activity of FAK-YAP-TRX downstream signaling molecules and by pretreatment with oxidative stress scavengers. These findings support the co-administration of FAK and ROS1 inhibitors as a therapeutic strategy in *CDH1*-deficient triple negative breast cancer and diffuse gastric cancer patients and support further clinical testing of this combination regimen.

#5822

YAP inhibition via targeting MAP3K3-dependent lysosomal degradation pathway overcomes BRAF and CDK4/6 inhibitor resistance

Won-Ji Ryu[1], Sanghyun Park[2], Tae Yeong Kim[1], Yumi Hwang[1], Hyun Ju Han[1], Jeong Dong Lee[1], Gun Min Kim[3], Joohyuk Sohn[3], Sang Kyum Kim[1], Joon Kim[4], Min Hwan Kim[3]. *[1]Yonsei University Health System, Seoul, Korea, Republic of,[2]Department of Dermatology, Chonnam National University Medical School, Gwangju, Korea, Republic of,[3]Department of Internal Medicine, Yonsei University Health System, Seoul, Korea, Republic of,[4]Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of*

The Hippo-yes-associated protein (YAP) signaling pathway activation underlies the resistance to a wide range of molecularly targeted anti-cancer agents. However, strategies to block YAP activity in cancer by promoting YAP degradation have been largely unsuccessful despite rigorous investigations into canonical Hippo-YAP regulatory mechanisms. Here, we report a novel mechanism of YAP stability regulation by MAP3K3 independently of LATS-mediated proteasomal degradation. We observed that MAP3K3 depletion significantly reduced YAP protein levels in both normal and malignant cells, and mass spectrometry analysis revealed that MAP3K3 phosphorylates YAP at its serine 405 residue. MAP3K3-mediated serine 405 YAP phosphorylation polarizes YAP interaction with BTRC while hindering its interaction with FBXW7, collectively preventing both proteasomal degradation and the p62-mediated lysosomal degradation of YAP. We investigated the role of this mechanism in overcoming anti-cancer resistance and observed robust YAP activation in CDK4/6 inhibitor-resistant luminal breast cancer cells. Genetic and pharmacological MAP3K3 inhibition suppressed YAP-induced drug resistance. Moreover, increased MAP3K3 expression supported the pro-survival activity of YAP in BRAF inhibitor-resistant melanoma cells, and MAP3K3 depletion downregulated YAP-dependent cell cycle gene signatures. Accordingly, the combination of vemurafenib and ponatinib was effective in reducing the survival of BRAF inhibitor-resistant melanoma cells. Collectively, our study identified a novel phosphorylation-mediated YAP stability regulation mechanism and underscored MAP3K3 inhibition as a promising strategy to

overcome BRAF and CDK4/6 inhibitor resistance by directly promoting YAP degradation.

Uncovering the mechanisms of matrix metalloproteinase-3 (MMP-3) in the cisplatin resistance of ovarian cancer

Mariela Rivera-Serrano[1], Pablo E. Vivas-Mejia[2]. *[1]Biology, University of Puerto Rico Rio Piedras Campus, San Juan, PR,[2]Biochemistry, University of Puerto Rico Medical Sciences Campus, San Juan, PR*

Seventy percent of women with ovarian cancer will develop chemotherapy-resistance to cisplatin. Regardless of the advancements in technology, mortality rates for ovarian cancer have declined only slightly in the last forty years, reiterating the need to generate novel treatment options targeting cisplatin resistance. In RNA-seq and microarrays experiments we observed that Matrix-metalloproteinase-3 (MMP3) was highly abundant in cisplatin-resistant when compared to cisplatin-sensitive cells. MMP3 is a member of the matrix metalloproteinases (MMPs) family of proteolytic enzymes, involved in the degradation of proteins in the extracellular matrix (ECM). Deregulation of MMPs alters the extracellular matrix and contributes to proliferation, invasion, and metastasis of cancerous cells. A typical MMP structure consists of a pro-domain, a catalytic, and a hemopexin domain. The catalytic domain is responsible for MMPs proteolytic activity, while the hemopexin domain contributes to substrate and ligand specificity. Inhibitors targeting the catalytic domain of MMPs were unsuccessful in clinical trials due to a lack of selectivity and specificity. When we used a chemical inhibitor, we did not observe reduced cell-proliferation or invasiveness. However, MMP3-targeted small interference RNA (siRNA) was able to reduce cell proliferation and invasive capabilities in cisplatin resistant ovarian cancer cells. Additionally, MMP3-targeted siRNA significantly reduced the sensitivity of ovarian cancer cells to cisplatin treatment. Cisplatin also increased MMP3 mRNA levels in ovarian cancer mice models and human cell lines. This evidence suggests that the MMP3 levels correlate with the sensitivity of ovarian cancer cells to cisplatin treatment. We hypothesize that the hemopexin domain will bind to proteins promoting cisplatin-resistance. We validated our expression profile studies at mRNA and protein levels via western blot,

ELISA and qRT-PCR. Additionally, survival analysis using the Kaplan-Meier plotter database showed that ovarian cancer patients with low MMP3 levels live longer than patients with higher MMP3 levels. Furthermore, when we measured MMP3 activity, we observed decreased activity in cisplatin-resistant versus cisplatin-sensitive cells. Taken together, these data suggest that other domains of MMP3 (i.e., hemopexin domain) may have a function in the cisplatin resistance of ovarian cancer cells.

#5824

Human ovarian cancer cell seeding density as a mechanism of cisplatin resistance associated with expression of anti-apoptotic and autophagy proteins

Thomas W. Brown, Ujwal Punyamurtula, Wafik S. El-Deiry. *Brown University, Providence, RI*

Drug effects may vary depending on cancer cell density. We investigated discrepancies in phenotypes for high density and low-density cultured cancer cells and elucidated relevant variables that influence them. We assessed chemosensitivity as a function of tumor cell density by plating TOV-21G and OVMANA ovarian cancer cell lines in 96-well plates at various seeding densities per well and treated them with various concentrations of cisplatin. CellTiterGlo assays were performed at 72 hours of treatment to determine cisplatin dose response curves. We used ethidium homodimer fluorescence staining and imaging to quantify extent of cell death at differing cell densities of TOV-21G and OVMANA cells treated with cisplatin for 48 and 72hours in 48-well plates. We performed western blot analyses of apoptotic and autophagy proteins from TOV-21G and OVMANA cells that were seeded at high and low cell densities in 24-wellplates. TOV-21G and OVMANA cells plated at higher cell seeding densities displayed less cisplatin sensitivity than TOV-21G and OVMANA cells plated at lower seeding densities, as shown by cisplatin dose response curves. Ethidium homodimer staining of TOV-21G and OVMANA cells treated with cisplatin revealed that cells seeded at lower densities experience a greater amount of cell death that cells seeded at higher densities. Western blot analyses showed that high density TOV-21G cells may express greater amounts of BCL2 and c-FLIP and lower amounts of p62 and NOXA compared to low density cells when normalized for protein

expression. Similarly, high density OVMANA cells express greater amounts of c-FLIP andBCL2 and lower amounts of NOXA compared to low density cells when normalized for protein expression. Our experiments reveal that human ovarian cancer cells display different phenotypic changes depending on cell density, causing higher density cells to require increased cisplatin to achieve the same level of effect seen in lower density cells. Ovarian cancer cell resistance to cisplatin is associated with alterations in autophagy and anti-apoptotic protein expression at high cell seeding density. These alterations may also affect chemosensitivity *in vivo* in settings of differential tumor density, such as single circulating tumor cells compared to clumps of tumor cells, and other settings, such as metastasis.

#5825

TM4SF19 regulates oxidative stress-dependent YAP transcription in HNSCC

Eunbie Shin, Joon Kim. *KAIST, Daejeon, Korea, Republic of*

Head-and-neck squamous cell carcinoma (HNSCC), which arises from epithelial cells in mucosal surfaces of the upper aerodigestive tract, is the sixth leading cancer worldwide with 40-50% mortality rates. YAP is a transcriptional regulator that plays important roles in cancer cell proliferation and survival. HNSCC shows the highest levels of YAP gene expression among various types of human cancers. However, the molecular mechanisms explaining upregulation of YAP expression in HNSCC are poorly understood. Excessive consumption of tobacco and alcohol are classical risk factors of HNSCC. Tobacco and alcohol generates metabolites that increase reactive oxygen species (ROS) to abnormally high levels. It is not known whether YAP expression and function are interlinked with the oxidative stress response in HNSCC. Here, we aimed to elucidate the mechanism of YAP upregulation involved in the progression of HNSCC under conditions of oxidative stress. To identify candidates for YAP expression regulators in HNSCC, we analyzed whole-genome siRNA library screening data and TCGA genomics data. We performed loss-of-function and gain-of-function experiments to elucidate the molecular mechanism of TM4SF19, which is the top candidate for mediating transcriptional regulation of YAP in HNSCC. TM4SF19 is one of the transmembrane 4 L six family proteins that have topological similarities to

tetraspanins, but little is known about its biological function. We found TM4SF19 controls the expression of YAP gene by regulating GABPβ1, a subunit of the GABP transcription factor complex, which is known to bind and activate YAP gene promoter. We observed that the depletion of TM4SF19 reduced GAPBPβ1, thereby decreasing the transcriptional activity of GABP complex. Importantly, we observed that TM4SF19 was dimerized in response to oxidative stress and consequently mediates the upregulation of YAP transcription by ROS elevation. We further show that TM4SF19 knockdown significantly reduces key characteristics of malignant cells, such as active proliferation and migration. Our results suggest that TM4SF19 is not only a novel transcriptional regulator of YAP but also a strong therapeutic target to suppress the oncogenic activity of YAP, and also provide new clue to understand HNSCC tumorigenesis involving YAP and oxidative stress.

Crosstalk between Cancer Cells, Immune Cells, and Fibroblasts

#5828

Distinct immunosuppressive tumor microenvironment modulates small cell lung carcinoma neuroendocrine phenotypic plasticity and heterogeneity

Parth Anil Desai[1], Nobuyuki Takahashi[2], Yingying Cao[1], Christopher Schultz[1], Darryl Nousome[1], Desiree Tillo[1], Lakshya Chauhan[3], Mayank tandon[1], Rajesh kumar Bhardwaj[1], Delphine Lissa[1], Vinodh Rajapakse[1], Suresh kumar[1], Yang Zhang[1], Elmeskini Rajaa[1], Donna Butcher[1], Linda Scuito[1], Jingjing Gong[4], Brett Schroder[1], Andrew Warner[1], Samantha Nichols[1], Jordan Kimberly[5], Alejandro Schaffer[1], Mohit kumar Jolly[3], Stephen Hewitt[1], Anish Thomas[1]. *[1]National Institutes of Health, Rockville, MD,[2]Center Hospital, National Center for Global Health and Medicine, Tokyo, Japan,[3]IISC, Bangalore, India,[4]Nanostring, Seattle, WA,[5]University of Colorado-Anschutz Campus, Boulder, CO*

Small cell lung carcinoma (SCLC) is prototypical of cancers with exceptional chemoresistance, and metastatic capabilities fueled by remarkable heterogeneity. The cell-extrinsic factors that govern SCLC heterogeneity are poorly understood especially since non-genetic

mechanisms are thought to be major contributors to its intratumoral heterogeneity and plasticity. In order to answer the above question, we sought to inquire about the role of tumor microenvironment (TME) in SCLC heterogeneity which is challenged universally by a lack of patient-derived adequate tumor biopsies. Leveraging large tumor sampling performed at rapid autopsies done on 10 different patients who died from SCLC metastatic disease, we developed a multi-omics approach involving spatial transcriptomics (ST) (Whole transcriptomic atlas), bulk whole genome sequencing, and multiplex immunofluorescence (IF) and standard immunohistochemistry (IHC) to better characterize spatially proximate tumor (36 segments), TME (32 segments) and 4 normal segments. Genomically, SCLC characteristic alterations like TP53 (70%) and RB1 (80%) inactivation and MYC (50%)/MYCL (80%) were evident. ST profiling reveals three distinct tumor subtypes corresponding to the known high-Neuroendocrine (NE) and low-NE SCLC subtypes as well as a novel hybrid-NE state with multiple elevated cancer hallmark capabilities and morphological evidence of nesting and budding. High-NE and hybrid-NE subtypes appear to be driven by ASCL1 and the low-NE subtype resembles the SCLC- inflamed subtype. ST profiling of proximate TMEs reveals similar heterogeneity that is closely linked with SCLC-NE heterogeneity at inter-patient and intra-tumoral levels with distinct features and cellular compositions. Specifically, low-NE TME is marked by increased pro and anti-tumor features including B cells, NK cells, M1-macrophages, and evidence of more checkpoint molecules. High-NE TMEs are predominated by a distinct absence of adaptive immune cells and a strong presence of M2 macrophages. Most strikingly the hybrid-NE TME shows a significant enrichment of immunosuppressive cancer-associated fibroblasts with the absence of T and other adaptive immune cells confirmed using IHC and IF. Next, we attempt to narrow down the fibroblast growth factor receptor (FGF) axis as one of the unique TME-driven factor(s) that could groom non-NE features in SCLC fueling their plasticity and heterogeneity. Subsequently using various SCLC cell lines, we demonstrate that in-vitro modulation of FGFR in SCLC may constrain their plasticity by downregulation of NOTCH signaling, MYC, and its downstream effector REST. We describe the remarkable phenotypic heterogeneity of SCLC tumor and TME and demonstrate their interlinking as well as potential

translational avenues of leveraging the cellular crosstalk in order to constrain SCLC heterogeneity.

#5829

Differential expression of PD-L1 and PD-L2 is associated with M2 tumor-associated macrophages and tumor differentiation in non-small cell lung cancer

Ryota Sumitomo[1], Cheng-long Huang[2], Hiroshi Date[1]. *[1]Thoracic Surgery, Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[2]Thoracic Surgery, Kitano Hospital, Tazuke Kofukai Medical Research Institute, Osaka, Japan*

Objectives: To improve the treatment strategy of immune-checkpoint inhibitors for non-small cell lung cancer (NSCLC), a comprehensive analysis of programmed death-ligand (PD-L)1 and PD-L2 expression is clinically important. The expression of PD-L1 and PD-L2 on tumor cells (TCs) and tumor-infiltrating immune cells (ICs) was investigated with respect to M2 tumor-associated macrophages (TAMs), which are key components of the tumor microenvironment.
Methods: We performed immunohistochemical studies to evaluate the M2 TAM distribution by CD163 staining, PD-L1 expression on TCs and ICs by the Ventana SP263 assay, and PD-L2 expression on TCs and ICs, using the Ventana BenchMark GX system, in 175 patients with resected NSCLC.
Results: M2 TAM density revealed high levels of variation among the 175 tumor tissues (mean ± standard deviation (SD), 382.5 ± 381.9 cells per mm^2). The percentage of PD-L1-positive TCs and PD-L1-positive ICs varied greatly among the 175 tumor tissues (mean ± SD; 15.6 ± 27.0% and 9.4 ± 10.9%, respectively). In addition, the percentage of PD-L2-positive TCs and PD-L2-positive ICs also ranged widely among the 175 tumor tissues (mean ± SD, 14.6 ± 22.9% and 12.5 ± 18.4%, respectively). M2 TAM density was significantly associated with the expression of PD-L1 on TCs and ICs ($P < 0.0001$ and $P < 0.0001$, respectively). M2 TAM density was also significantly associated with the expression of PD-L2 on TCs and ICs ($P = 0.0452$ and $P = 0.0125$, respectively). The percentage of PD-L1-positive TCs was significantly correlated with the percentage of PD-L1-positive ICs ($r = 0.396$; $P < 0.0001$). In addition, the percentage of PD-L2-positive TCs also was significantly correlated with the percentage of PD-L2-positive ICs ($r = 0.488$; $P < 0.0001$). However, there was no correlation

between the percentage of PD-L1-positive TCs and the percentage of PD-L2-positive TCs (r = 0.019; P = 0.8049). Meanwhile, tumor differentiation was significantly associated with PD-L1 expression on TCs and ICs (P = 0.0002 and P < 0.0001, respectively). By contrast, tumor differentiation was inversely associated with PD-L2 expression on TCs and ICs (P = 0.0260 and P = 0.0326, respectively).
Conclusions: PD-L1 and PD-L2 expression on TCs and ICs was associated with M2 TAMs in NSCLC, although there was no correlation between PD-L1 and PD-L2 expression on TCs. The combined evaluation of PD-L1 and PD-L2 expression could be clinically important in the treatment strategy of immune-checkpoint inhibitors in patients with NSCLC. In particular, the evaluation of PD-L2 expression may be necessary for patients with PD-L1-negative NSCLC.

Germany,[5]Research Department Cell and Gene Therapy, Department of Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[6]Department of Molecular Biology and Immunology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany,[7]Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[8]Department of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Immune therapies have revolutionized the treatment of cancer, however, until now only a minority of patients derive long-term benefit. Notably, despite widely reported significant differences between the immune system of males and females, there continues to exist a knowledge gap regarding sex disparities in anti-cancer immune responses. Recent meta-analyses indicate that immune checkpoint blockade (ICB) treatment has higher efficacy in male patients compared to females, regardless of the cancer type. To investigate the mechanisms underlying these sex-specific differences we utilized the syngeneic colorectal cancer model MC38 because it mirrors the clinical situation yielding responding and non-responding mice. Therefore, we inoculated tumor cells subcutaneously (s.c.) into male and female mice, and treated them with either IgG2a control Ab or anti-PD1 Ab. When analyzing the tumor response to anti-PD1 treatment we observed significant sex-biased growth kinetics upon ICB favoring males. To asses a potential role of androgens in impacting observed sex differences to ICB response *in vivo*, we performed surgical androgen deprivation therapy (orchiectomy) in male mice, as well as sham-surgery in male and female mice as control. After a recovery period, we proceeded with s.c. cell injection and ICB treatment as previously described. Sham male mice showed a very high response rate to anti-PD1 (92%) compared to sham females (58%), but more importantly, testosterone suppression by surgical androgen deprivation therapy led to a lower response rate of castrated mice (71%). To further confirm whether the presence of testosterone was beneficial for ICB response, we implanted s.c. sham or testosterone pumps into male and female mice and proceeded as before. Males with sham pumps showed a very high response rate to anti-PD1 (90%) compared to females with sham pumps (50%), while testosterone supplementation in females led to enhanced response rate (85%). Overall, this demonstrated that regardless of biological sex,

presence of testosterone is sufficient to positively impact ICB therapy outcome. Furthermore, immunophenotyping analysis by flow cytometry showed that females supplemented with testosterone and treated with anti-PD1 had significantly increased intratumoral stem-like $CD8^+TCF1^+PD1^+$ T cells compared to sham females. Additionally, these findings also correlated with enhanced intratumoral terminal differentiated effector $CD8^+TCF1^-PD1^+$ T cells in both sham males and females supplemented with testosterone, compared to sham females. In summary, androgens can modulate anti-cancer immune responses by contributing to a more sustained anti-tumor $CD8^+$ T cell response and consequently better responses upon treatment with anti-PD1. These findings are in concordance with male cancer patients responding better to ICB and warrant therapy escalation in female patients.

CD200R signaling contributes to unfavorable tumor microenvironment through regulating production of chemokines by tumor associated macrophages

Cho-Hao Lin[1], Fatemeh Talebian[1], Yang Li[2], Jianmin Zhu[1], Bolin Zhao[2], Jin-Qing Liu[1], Sujit Basu[1], Xueling Pan[2], Xi Chen[2], Pearlly Yan[2], William E. Carson[2], Gang Xin[2], Haitao Wen[2], Ruoning Wang[2], Zihai Li[2], Qin Ma[2], Xue-Feng Bai[1]. *[1]Pathology, The Ohio State University, Columbus, OH,[2]The Ohio State University, Columbus, OH*

CD200 is overexpressed in human solid tumors such as neuroblastoma and melanoma and is considered as an immune checkpoint molecule for dampening cancer immunity. However, how CD200 affects tumor microenvironment (TME) and host immunity is incompletely understood. In the present study, we evaluated the role of the CD200-CD200R pathway in TME using loss-of-function $CD200R^{-/-}$ mice, along with two clinically relevant, CD200-positive murine tumor models: the mouse neuroblastoma NB9464D and melanoma Yummer1.7. We found that comparing with the wild type mice, $CD200R^{-/-}$ mice were significantly more potent in rejecting these $CD200^{+}$ tumors. Transcriptome analysis by single cell RNA sequencing demonstrated that tumors from $CD200R^{-/-}$ mice had more infiltration of $CD45^{+}$ immune cells, including $CD4^{+}$ and $CD8^{+}$ T cells, and NK cells but less infiltration of neutrophils. Antibody depletion experiments revealed that immune effectors including $CD8^{+}$ T cells and NK cells in combination, are crucial in inhibiting tumor growth in $CD200R^{-/-}$ mice. Mechanistically, we found that CD200R signaling differentially regulates the expression of chemokines in tumor-associated macrophages (TAMs). In the absence of CD200R, TAMs up-regulate CCL24 and CCL8 and down-regulate CXCL3, CXCL2, and CCL3 via activation of ERK and/or p38 MAP kinases. Increased expression of CCL24 in CD200R-deficient tumors resulted in increased infiltration of eosinophils, which also contributes to anti-tumor activity. Overall, we conclude that CD200R-mediated signaling, via interaction with CD200 on tumor cells, contributes to unfavorable TME primarily through chemokine-dependent recruitment of immune suppressive neutrophils and exclusion of anti-cancer immune

effectors. Our study has significant implications in developing CD200-targeted immunotherapy of solid tumors.

Integrinα5 mediates the direct heterocellular interaction between cancer cells and cancer-associated fibroblasts and promotes peritoneal metastasis of diffuse-type gastric carcinoma

Hideki Yamaguchi, Shingo Miyamoto, Yoshiko Nagano, Makoto Miyazaki, Yuko Nagamura. *Department of Cancer Cell Research, Sasaki Institute, Sasaki Foundation, Tokyo, Japan*

Diffuse-type gastric carcinoma (DGC) is an aggressive subtype of gastric cancer characterized by rapid infiltrative growth and frequent peritoneal metastasis. Peritoneal metastasis is the main cause of poor prognosis and decreased quality of life for patients with DGC. Histologically, DGC tumor lesions are associated with massive fibrotic stroma caused by the extensive proliferation of cancer-associated fibroblasts (CAFs). Peritoneally metastasized tumors of DGC are also accompanied by abundant fibrotic stroma and CAFs. CAFs are known to promote the progression of DGC by enhancing the growth, invasion, and dissemination of tumor cells. Previously, we reported that the direct heterocellular interaction between cancer cells and CAFs is necessary for the invasion and peritoneal metastasis of DGC. In this study, we aimed to identify and target the molecules that mediate such direct heterocellular interaction. Monoclonal antibodies (mAbs) against intact DGC cells were generated and subjected to high-throughput screening to obtain mAbs that block the adhesion of DGC cells to CAFs. As a result, several such inhibitory mAbs were obtained. Immunoprecipitation and mass spectrometry revealed that all mAbs recognized integrin α5 complexed with integrin β1. Blocking integrin α5 in DGC cells abrogated the adhesion of DGC cells to CAFs. Similarly, blocking fibronectin, a ligand of integrin α5β1, deposited on CAFs blocked the heterocellular adhesion. Furthermore, administration of mAbs or knockout of integrin α5 in DGC cells suppressed their invasion led by CAFs in vitro and peritoneal metastasis in a mouse xenograft model. Analysis of the public database revealed that integrin α5 and fibronectin were highly expressed in DGC. In addition, integrin α5 and fibronectin expression levels were correlated with worse overall survival in DGC

patients. Taken together, these results show that integrin α5 mediates the heterotypic cancer cell-CAF interaction during peritoneal metastasis of DGC and may thus be a promising therapeutic target.

Crosstalk between cancer-associated fibroblasts and CD8 T cells leads to improved T cell activation in head and neck cancer

Diana Graves[1], Aleksandar Obradovic[2], Henry Schares[1], Michael Korrer[3], Brian Bachmann[1], Young Kim[4], Ben Park[1], Paula Hurley[1]. *[1]Vanderbilt University, Nashville, TN,[2]Columbia University, New York City, NY,[3]Elephas Biosciences, Madison, WI,[4]Regeneron Pharmaceutical, Tarrytown, NY*

Cancer-associated fibroblasts (CAFs) have been shown to modulate immune responses in the tumor microenvironment (TME), however, the extensive heterogeneity of these cells has precluded rigorous understanding of their immunoregulatory role in the head and neck TME. To gain a better understanding of the relationship between CAFs and the immune environment in head and neck cancer, we leveraged protein activity inference tools to analyze single-cell RNA sequencing of advanced-stage head and neck squamous cell carcinoma (HNSCC) patients pre- and post-treatment with the αPD-1 therapy, nivolumab. From this analysis, we identified a novel CAF population predictive of patient response to αPD-1 therapy. Utilizing *in vitro* co-culture assays with primary human CD8 T cells, we discovered that this novel CAF population was able to elicit features associated with enhanced CD8 T cell function, namely the reduction of PD-1+TIM-3+ exhaustive phenotypes and induction of CD103+NKG2A+ tissue-resident memory phenotypes and cytotoxicity. Due to their unique ability to stimulate T cells in this manner, we termed this novel CAF population T cell-stimulating CAFs (tsCAFs). In efforts to elucidate the mechanism behind this pro-inflammatory function, we determined that tsCAFs secrete a heat-sensitive small molecule/s in order to alter CD8 T cell behavior. However, tsCAFs will only secrete this factor in the presence of activated T cells demonstrating crosstalk between T cells and CAFs in the head and neck TME. This pro-inflammatory crosstalk between CAFs and T cells represents a novel finding that further contributes to the idea of immunoregulatory pleiotropy among CAFs.

Accordingly, our findings highlight the functional importance of distinct CAF subsets in modulating the immunoregulatory milieu of human HNSCC and warrant more extensive characterization of CAF-T cell interactions in human squamous cell carcinoma.

The pro-tumoral function of cancer-associated mesothelial cells

Maeva Chauvin. *Massachusetts General Hospital / Harvard Medical School, Boston, MA*

Cancer-associated mesothelial cells have emerged as significant contributors to the tumor microenvironment, influencing tumor growth and immune evasion. Mesothelial cells are the first point of contact with ovarian cancer cells during peritoneal spread. Peritoneal mesothelial cells also play an essential role in immune surveillance. However, the mechanism by which cancer and mesothelial cells within the tumor microenvironment coordinate growth and immune evasion remains poorly understood. To study the role of mesothelial cells in the tumor microenvironment, we have recently generated novel syngeneic mouse models of high-grade serous ovarian cancer, which were derived from Fallopian tube epithelium, and bear human-relevant mutational genotypes. Analysis of one such model (CCNE1 amplified) using single-cell transcriptomics in omental metastases revealed specific expression of the anti-Mullerian hormone type II receptor (Amhr2) in cancer-associated mesothelial cells, whereas normal omental mesothelium does not express Amhr2. Co-culture of cancer cells with normal omental mesothelial cells induces AMHR2 expression along with a pro-tumorigenic cancer-associated mesothelial cell phenotype. Overexpression of AMHR2 in a human immortalized mesothelial cell line significantly modulated the expression of genes involved in immune response pathways, remodeling of extra-cellular matrix, and secretion of growth factors by RNAseq and qPCR. Furthermore, we showed that anti-Mullerian hormone (AMH) (the ligand of AMHR2), is secreted by ovarian cancer cells and further downregulates the chemoattractant cytokines secreted by CAMCs, thus promoting immunosuppression within the tumor. Finally, implantation of ovarian cancer cells in syngeneic Amhr2$^{-/-}$ hosts results in tumors that grow significantly slower than those implanted in wild-type hosts. Together these data suggest AMHR2 is a specific marker of

CAMCs, whose expression is necessary for the reprogramming of mesothelial cells into CAMCs. The AMH-AMHR2 axis mediates paracrine signaling between cancer cells and CAMCs within the tumor microenvironment to promote tumor growth and immune evasion. These results suggest that AMHR2 could be a highly specific target to enhance immunotherapies in ovarian cancer.

Targeting discoidin domain receptor 1 (DDR1) reverses glioma immune suppression by remodeling collagen fiber architecture

Syed M. Faisal, Andrea Comba, Maria L. Varela, Anna E. Argento, Emily Brumley, Molly E. J. West, Santiago Haase, Anzar A. Mujeeb, Clifford Abel, Marcus N. Barissi, Jarred E. Clewner, Brooklyn Stack, Grace A. Abbud, Maria G. Castro, Pedro R. Lowenstein. *Neurosurgery, University of Michigan Medical School, Ann Arbor, MI*

Glioblastoma (GBM) is the most aggressive and immunosuppressive form of brain tumor, and its treatment remains a large, unmet medical need. Recently, we introduced oncostreams to refer to dynamic multicellular neuropathological structures that facilitate glioma cell growth and invasion into the normal brain. Moreover, we have shown that targeting Col1α1 within gliomas eradicates oncostreams and prolongs median survival in two genetic murine models. However, the signaling that collagen utilizes to maintain the glioma tumor microenvironment is still unknown. Our RNA-seq data show that collagen receptor DDR1 is overexpressed in genetically engineered glioma mouse models (GEMMs) including NPA (NRAS/shp53/shATRX), NPD (NRAS/shp53/PDGFβ), and NPAI (NRAS/shp53/shATRX/ $IDH1^{R132H}$) compared to healthy mouse brain tissue. We discovered that pharmacological inhibition of DDR1 radio-sensitized gliomas *in vitro* and dismantled oncostreams *ex vivo,* imaged with time-lapse confocal microscopy. GEMMs of DDR1 knockdown (NRAS/shp53/shATRX/shDDR1) using the Sleeping Beauty transposase system significantly increased median survival. This suggests that gliomas employ DDR1 mediated mechanisms to promote the immunosuppressive TME and thus stimulate tumor growth. Inhibition of DDR1 within gliomas enhanced intratumoral infiltration of $CD45^+$, and $CD3^+$ immune cells at the tumor core and invasive tumor border and prolonged median survival in

GEMMs of glioma. We postulate that glioma DDR1 blocks immune-surveillance by enhancing collagen fiber alignment, which we assessed using collagen-specific second-harmonic generation microscopy. In human datasets such as CGGA and TCGA, DDR1 expression negatively correlates with PTPRC (CD45) gene expression. Furthermore, our results show that DDR1 inhibition suppresses oncostream formation, impairs glioma cell proliferation ($PCNA^+$) and remodeled the tumor microenvironment by lowering $Iba1^+$ glioma-associated microglia. We propose that DDR1 inhibition within glioma cells reprograms the TME to an immune-stimulatory state with enhanced radio-sensitivity. Targeting the DDR1 collagen receptor is a novel and highly promising avenue for GBM therapeutics.

Non-invasive quantification of fibroblast activation protein (FAP) cleaved type III collagen in serum reflects FAP activity and has biomarker potential in non-small cell lung cancer

Rasmus Sund Pedersen, Jeppe Thorlacius-Ussing, Nicholas Willumsen, Morten A. Karsdal. *Nordic Bioscience, Herlev, Denmark*

Introduction: Fibroblast activation protein (FAP) is an established cancer associated fibroblast (CAF) marker. FAP is highly expressed in the cancer stroma and is a predictor of poor survival for patients with non-small cell lung cancer (NSCLC). For this reason, it is being explored as a potential drug target. FAP has broad proteolytic activity and can directly promote multiple aspects of tumor progression. The aim of this study was to develop a tool to non-invasively measure FAP activity and validate its potential as a non-invasive biomarker in NSCLC.
Methods: An ELISA, named C3F, was developed to reflect proteolytic activity of FAP by quantifying FAP-mediated cleavage of type III collagen in serum. To confirm that C3F reflects proteolytic activity of FAP, type III collagen was assayed after incubation with and without FAP. C3F was measured in serum samples from healthy controls (n = 26) and patients with NSCLC: adenocarcinoma (AD) (n = 26) and squamous cell carcinoma (SCC) (n = 14). An ELISA quantifying matrix metalloprotease degraded type III collagen (C3M) was used for measuring the same serum samples

and compared to C3F using spearman correlation test and area under receiver operating characteristic curves (AUROCs).
Results: A C3F signal only appeared after FAP cleavage of type III collagen, supporting that C3F reflects FAP proteolytic activity. Compared to healthy controls, C3F was significantly elevated in serum from patients with SCC ($p = 0.0004$, AUROC = 0.86), but not AD ($p = 0.21$, AUROC = 0.66). C3F was also significantly elevated in SCC compared to AD ($p = 0.030$, AUROC = 0.77). In comparison, C3M was significantly elevated in serum from both SCC and AD compared to healthy controls ($p < 0.0001$, AUROC = 0.93 and $p < 0.0001$, AUROC = 0.92, respectively), but no difference was seen between SSC and AD ($p > 0.99$, AUROC = 0.56). Only a moderate correlation was seen between C3M and C3F ($r = 0.58$, $p < 0.0001$).
Conclusion: FAP activity can be non-invasively quantified in serum by assaying FAP cleaved type III collagen (C3F). C3F shows promise as a cancer biomarker in NSCLC with potential for discriminating between NSCLC subtypes. As C3F reflects FAP activity, it is potentially a more suitable (or complementary) biomarker for anti-FAP drug development and prediction of anti-FAP treatment response compared to methods that asses the presence of FAP.

Cancer-associated fibroblasts drive spheroid formation and pleural dissemination in non-small cell lung cancer
Masayoshi Ohki, Naoki Matsuda, Ken Suzawa, Tomohiro Habu, Mao Yoshikawa, Kazuma Iwata, Yin Min Thu, Kazuhiko Shien, Hiromasa Yamamoto, Shinichi Toyooka. *General Thoracic Surgery and Breast and Endocrinological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan*

Introduction: Cancer-associated fibroblasts (CAFs) play an important role in cancer progression and malignant transformation by interacting with cancer cells in the tumor microenvironment. Pleural dissemination of non-small cell lung cancer (NSCLC) is a condition in which cancer cells directly spread from the primary tumor site into the extrapulmonary thoracic cavity and colonize the pleura. However, not all free detached cancer cells can survive under anchorage-independent conditions in thoracic cavity, and

some important factors are assumed to be involved in the formation of pleural dissemination. In this study, we investigated the role of CAFs in the formation of pleural dissemination in NSCLC.
Methods: Using in vitro co-culture models, conditioned medium, and in vivo xenograft models, we investigated CAF-induced phenotypic changes in lung cancer cell: proliferative ability, invasive ability, anchorage-independent growth ability, cell adhesion to extracellular matrix, and tumorigenicity in thoracic cavity. Next, we performed RNA sequencing analysis using 3D co-culture models of cancer cells and CAFs to explore a molecule that contributes to the formation of pleural dissemination, and then verified it using in vitro and in vivo mice models of pleural dissemination.
Results: Cancer cells showed enhanced migration, anchorage-independent growth, adhesion, and invasion ability by co-culture with CAFs. In 3D co-culture model of cancer cells and CAFs, even cancer cells which did not form spheroid by themselves acquired the ability of spheroid formation surrounding the CAF core, suggesting that the interactions with CAFs promote spheroid formation. Inoculation of cancer cells together with CAFs into mouse thoracic cavity developed pleural dissemination more efficiently than inoculation of cancer cells alone. RNA sequencing analysis revealed that co-culture with CAFs upregulated the expression of Cellular Communication Network Factor 1 (CCN1), a matricellular protein, in cancer cells. We then verified that ectopically CCN1-overexpressing lung cancer cell lines increased migration and adhesion ability in vitro, and tumorigenicity in thoracic cavity in mouse pleural dissemination model.
Conclusions: CAFs promote development of pleural dissemination via driving spheroid formation and upregulating CCN1 expression in NSCLC.

Novel stroma-derived prostate cancer subtypes are associated with risk of clinical progression

Martin Rasmussen[1], Jacob Fredsøe[1], Paul V. Salachan[1], Marcus P. L. Blanke[1], Benedicte P. Ulhøi[2], Michael Borre[3], Karina D. Sørensen[1].
[1]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark,[2]Department of Pathology, Aarhus University, Aarhus, Denmark,[3]Department of Urology, Aarhus University, Aarhus, Denmark

The tumor microenvironment influences prostate cancer aggressiveness, and by focusing on how different changes to the microenvironment can affect the cancer, we aimed to identify novel stromal subtypes in localized prostate cancer (LPC), characterize these subtypes, and utilize subtypes to increase accuracy in prostate cancer risk stratification. Subtype identification was conducted using non-negative matrix factorization with consensus clustering on a stroma-specific expression signature in RNA sequencing data. A discovery cohort (127 LPC patients) and two independent validation cohorts (406 LPC & 126 LPC patients) were used for subtype identification. All three cohorts were subsequently used for subtype characterization and prognostic evaluation. Identified subtypes were characterized by evaluation of clinical characteristics, by gene set enrichment analysis, and by cell-type deconvolution analysis. Survival differences between subtypes were assessed using Kaplan-Meier and univariate Cox regression analyses with biochemical recurrence (BCR) as endpoint. Lastly, a high-risk stromal subtype was investigated for its ability to improve risk stratification for intermediate risk prostate cancer using hazard ratio changes from univariate Cox regression analysis. We identified three stromal subtypes (S1-S3) in prostate cancer. Of these, subtype S3 showed characteristics of a highly reactive stromal environment with significantly (adj. $p < 0.05$) decreased cell polarity and stroma related functions, significantly (adj. $p < 0.05$) reduced fibroblast infiltration, and a significantly (adj. $p < 0.05$) increased immune cells infiltration compared to the other subtypes. Survival analysis also revealed significant ($p < 0.05$) association of S3 with BCR in all three cohorts (HR = 3.2, 2.1, and 3.4 in cohorts 1, 2 and 3 respectively). Lastly, S3 significantly ($p < 0.05$) improved the risk prediction for patients with intermediate recurrence risk according to the clinical nomogram CAPRA-S (cohort 1, delta HR = 1.4; cohort 2, delta HR = 2.3; cohort 3, delta HR = 4.2). In conclusion, by focusing on the stromal alteration in prostate cancer, this study sheds new light on the influence of tumor microenvironment on LPC aggressiveness. A stromal subtype characterized by dysregulated stromal functions and changes in stroma and immune cells infiltration predicted adverse outcome in patients with a high prognostic ambiguity. This utilization of stromal information to improve risk assessment for clinically intermediate risk PC indicates a potential use in future evaluation of PC aggressiveness.

#5840

Normal fibroblasts, cancer-associated fibroblasts, and their senescent counterparts exert varying effects on tumorigenic potential and ABT-263 sensitivity of gastric cancer cells

Francesca R. Di Cristofano, Shengliang Zhang, Kelsey E. Huntington, Wafik S. El-Deiry. *Legorreta Cancer Center at Brown University, Providence, RI*

It has become increasingly apparent that cancer is not a tumor cell-centric disease. Elements of the tumor microenvironment (TME), including fibroblasts and senescent cells, have been shown to contribute to tumor cell proliferation, metastasis, and therapy resistance, and are therefore major contributors to disease progression. However, this has been complicated by accumulating evidence suggesting that the function of fibroblasts is heterogeneous, with normal fibroblasts (NFs) and cancer-associated fibroblasts (CAFs) both promoting or suppressing tumorigenesis and drug sensitivity within different contexts. Moreover, although senescent fibroblasts have been shown to accelerate tumor growth and contribute to therapy resistance, whether phenotypic differences exist between different senescent fibroblasts remains poorly understood. It is clear that additional work must be done to unravel the precise mechanisms by which NFs, CAFs, and their senescent counterparts interact within the tumor microenvironment to modulate tumor cell growth and sensitivity to therapy. Here, we show different NF and CAF lines exert varying effects on AGS gastric cancer cells. We found that when AGS cells are co-cultured with IMR90 lung fibroblasts, they form fewer and smaller colonies (total colony area = 5.14E3 pixels^2) than when cultured alone (total colony area = 2.57E4 pixels^2). On the other hand, colony formation ability is enhanced when AGS cells are co-cultured with GF1 primary gastric fibroblasts (total colony area = 3.56E4 pixels^2), and to a greater extent when cultured with CK4520 (total colony area = 4.59E4 pixels^2) and CK8612 (total colony area = 4.88E4 pixels^2) primary gastric CAFs. We next sought to determine whether these cells modulate AGS sensitivity to ABT-263, a BH3 mimetic that activates the intrinsic apoptotic pathway by targeting and inhibiting Bcl-2 and Bcl-xl. We treated AGS cells with ABT-263 with or without the addition of fibroblast-conditioned medium. We showed that IMR90 cells sensitize AGS cells to ABT-263, with an IC50 shift from 109 nM to 54 nM

in AGS cells treated with IMR90-conditioned medium. On the other hand, AGS cells were more resistant to ABT-263 when treated with GF1, CK4520, or CK8612-conditioned medium, with IC50s of 270 nM, 520 nM, and 540 nM, respectively. Ongoing efforts involve expanding these experiments to senescent fibroblasts and conducting cytokine profiles to begin investigating the mechanisms underlying these phenotypes. These results contribute to our understanding of tumorigenesis and drug resistance.

Exploring the role of versican in immune exclusion within triple negative breast cancer

Priyanka Hirani[1], Kimberly M. Alonge[2], Daniel J. Pennington[3], Pedro R. Cutillas[1], Thomas N. Wight[4], Oliver M. T. Pearce[1]. *[1]Cancer Research UK Barts Centre, London, United Kingdom,[2]University of Washington Medicine Diabetes Institute, Seattle, WA,[3]Blizard Institute, London, United Kingdom,[4]Benaroya Research Institute, Seattle, WA*

Immunotherapy has found limited success in solid tumors such as triple negative breast cancer (TNBC). The poor response can be attributed to the presence of the extracellular matrix (ECM) that can act biochemically or physically to interfere with cytotoxic T cell migration, leading to a limitation in tumor cell killing. Through previous work on deconstructing this matrix and outlining the spatial arrangement of proteins, we were able to identify versican as a key protein in T cell location. Versican is a chondroitin sulfate proteoglycan and has multiple functions in the ECM due to its ability to bind many ECM components. Using immunohistochemistry in this study, we analyzed the localization of CD8+ T cells within human TNBC tissues to classify them as inflamed ($tumor^{hi}$, $stroma^{hi}$), desert ($tumor^{lo}$, $stroma^{lo}$) or immune excluded ($tumor^{lo}$, $stroma^{hi}$). From the analysis of 26 tissues, nearly half were classified as immune excluded with most of the CD8+ T cells restricted to the stroma, whilst only a quarter were inflamed. When comparing this to versican accumulation we noticed that immune excluded tissues have significantly higher levels of versican in the tumor epithelium compared to inflamed tissues where versican is mostly found within the stroma. To investigate the function of versican's structure,

we carried out transwell migration assays using versican enriched protein treated with or without chondroitinase ABC and showed that the chondroitin sulfates attached to versican's peptide backbone are an important factor towards T cell trafficking with a reduction in migration following chondroitinase ABC treatment. Comparison of versican levels to chondroitin sulfate via immunohistochemistry showed a positive correlation within inflamed tissues, however no correlation was observed in immune excluded tissues. Versican isoforms expression in TNBC tissues and cell lines was examined with qRT-PCR which showed that within all tissues and cell lines the V0 and V1 isoform are the highest expressed out of the 5 isoforms. Overall, in this work, we have found that versican is differentially expressed in excluded tissues in comparison to inflamed tissues. With chondroitin sulfate shown to play a major role in immune cell trafficking, understanding how it differs between inflamed and excluded tumors can help identify potential targets to improve immunotherapy response.

Determining the tumor supportive and inhibitory capabilities of cancer associated fibroblast subpopulations in central nervous system metastasis

Thomas Simon[1], David N. Buckley[1], Gerald C. Gooden[1], Ben Y. Tew[1], Gabriel Zada[2], Bodour Salhia[3]. *[1]Department of Translational Genomics, Keck School of Medicine, USC - University of Southern California, Los Angeles, CA,[2]Department of Neurosurgery, Keck School of Medicine/USC Norris Comprehensive Cancer Center, USC - University of Southern California, Los Angeles, CA,[3]Department of Translational Genomics, Keck School of Medicine/USC Norris Comprehensive Cancer Center, USC - University of Southern California, Los Angeles, CA*

Central nervous metastases (CM) are surrounded by a complex tumor microenvironment (TME) comprised of a meshwork of extracellular matrix (ECM) proteins and an assemblage of cell types including cancer-associated fibroblasts (CAFs). We have previously shown that patient-derived CM CAFs can either support or inhibit tumor growth *in vivo*, suggesting that CM CAFs comprise a heterogenous subgroup of cells. Accordingly, we recently reported, based on literature in other cancer types, that CAFs can be categorized into four main subpopulations: 'desmoplastic', 'immune',

‘contractile’ and ‘aggressive’. The purpose of our study is to identify different CAF subpopulations in the TME of CM and determine their impact on CM growth. To do this, we performed single cell RNA sequencing (scRNA-seq) on 10 CM patient tissues and 8 patient-derived CM CAF cell lines established in our lab. ScRNA-seq analysis of tumor tissues revealed that desmoplastic, immune, contractile, and aggressive CAF subpopulations are also present in the TME of CM. In addition, scRNA-seq showed that CM CAF cell lines were mainly comprised of the desmoplastic and aggressive CAF subpopulations. These two subpopulations showed differential expression of the newly described tumor inhibitory CAF marker Immunoglobulin Superfamily Containing Leucine Rich Repeat (ISLR) and classic tumor supportive CAF marker Actin Alpha 2, Smooth Muscle (ACTA2, α-SMA), with desmoplastic CAFs showing $ISLR^{high}/\alpha\text{-}SMA^{low}$ expression while aggressive CAFs were associated with $ISLR^{low}/\alpha\text{-}SMA^{high}$ expression. Next, we used fluorescence activated cell sorting (FACS) based on the expression of ISLR on the cell surface to enrich and expand the $ISLR^{high}/\alpha\text{-}SMA^{low}$ desmoplastic CAF and the $ISLR^{low}/\alpha\text{-}SMA^{high}$ aggressive CM CAF subpopulations. Reciprocal expression of α-SMA and ISLR was confirmed by western blot and immunofluorescence after FACS. Additionally, co-culture experiments showed that $ISLR^{high}/\alpha\text{-}SMA^{low}$ CM CAFs inhibit CM cell proliferation. In summary, our data show that there are several molecularly defined subpopulations of CAFs in the TME of CM that can act to either inhibit or promote CM tumor growth *in vitro* and *in vivo*. Our results support that the desmoplastic CM CAFs characterized by $ISLR^{high}/\alpha\text{-}SMA^{low}$ can inhibit tumor growth. Overall, the present study improves our understanding of the CM TME, which ultimately will help establish new strategies to harness the cancer restraining capabilities of tumor inhibitory CAFs in order to improve outcomes for patients with CM.

miR-224 activates cancer-associated fibroblasts to promote cancer cell invasion in lung tumor microenvironment

Seonyeong Oh, Inyoung Cheon, Young-Ho Ahn. *Ewha Womans University, Seoul, Korea, Republic of*

Cancer-associated fibroblasts (CAFs) promote EMT (epithelial-mesenchymal transition), invasion, and metastasis of cancer cells in the tumor microenvironment. To identify microRNAs (miRNAs) associated with the reprogramming of normal lung fibroblasts (LFs) into CAFs, global miRNA expression was profiled in LFs and CAFs through Nanostring nCounter. miR-224 was one of the increased miRNAs in CAFs, and its expression was higher in tumors than in normal tissues in dbDEMC and TCGA_lung adenocarcinoma data. miR-224 levels were then checked by qRT-PCR in paraffine-embedded tumor samples from patients with lung adenocarcinoma. Kaplan-Meier survival analysis showed that high miR-224 expression was related to poor survival. These data show that lung cancer progression is promoted by miR-224. To discover the roles of increased miR-224 in CAFs, miR-224 was overexpressed by lentiviral infection in LFs. LF_miR-224 overexpression enhanced the expression of CAF activation markers including *Fap, S100a4,* and *Vim*. In spheroid invasion assay using co-culture of LFs and cancer cells, as an experimental model of the tumor microenvironment, LF_miR-224 promoted invasion of lung cancer cells compared with control LFs. In transwell migration assay, LF_miR-224 stimulated migration of lung cancer cells more than control LFs. Collectively, these results indicate that CAFs reprogrammed by miR-224 promote the migration and invasion of lung cancer cells.

Fibroblasts play an immunoregulatory role in lung cancer through exosome secretion and by controlling extracellular matrix composition

Giulia Bertolini, Elvira Pantano, Giuliana Pollaci, Federica Facchinetti, Ugo Pastorino, Gabriella Sozzi, Luca Roz*. Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Introduction: Cancer associated fibroblasts (CAF) are increasingly recognized as central players in the regulation of the tumor immune microenvironment. In lung cancer however little is known about specific fibroblast subpopulations or mechanisms subtending their immunoregulatory potential. We previously identified the nuclear transporter XPO1 as a master controller of lung fibroblast protumorigenic potential. Here we evaluated the potential of fibroblasts to modulate interactions between immune and cancer cells.

Material and Methods: Cultures of primary lung fibroblasts isolated from tissues resected during lung cancer surgery were characterized by multiparametric flow-cytometry and used for experiments with lung cancer cells and monocytes. Co-cultures, conditioned media and decellularized extracellular matrices deposited by fibroblasts (dECM) were employed to investigate different modes of interactions. Modulation of stemness and EMT properties were evaluated by flow cytometry and Real-Time PCR. Co-injection of dECM and lung cancer cell lines were performed in immunocompromised mice and heterotypic tumors were evaluated for their growth, local microenvironments and disseminating potential.
Results and Discussions: Using fibroblast cultures form both cancer and normal lung tissue we detected protumorigenic potential also in cultures form normal lungs, in line with presence of classical activation markers (alpha-SMA, FAP). Bioactivity of fibroblasts include the ability to induce EMT and modulate stemness potential (increase of CD133+ cancer stem cells and CD133+/CXCR4+ metastasis initiating cells). Interestingly dECM displayed similar potential compared to co-cultures. Exosomes isolated from both CAF and normal fibroblasts also showed potential to induce conversion of normal monocytes into myeloid derived suppressor cells. In co-injection experiments, dECM from pro-tumorigenic fibroblasts regulated the local immune microenvironment of ensuing tumors inducing generation of a stroma with high content of COL1A and COL6A3, reducing the infiltration from NK cells and increasing neutrophil content, thereby favoring dissemination of cancer cells to distant organs. Pharmacological inhibition of fibroblast activation through compounds targeting XPO1 activity was able to reduce these effects and counteract fibroblast protumorigenic action.
Conclusion: Fibroblasts play a regulatory role in tumor stroma and dissection of their activities could pave the way for rationale development of treatments to reverse immunosuppressive microenvironments.

Periostin secreted by cancer-associated fibroblasts promotes cancer progression and drug resistance in non-small cell lung cancer

Mao Yoshikawa, Fumiaki Takatsu, Ken Suzawa, Tomohiro Habu, Ohki Masayoshi, Kazuma Iwata, Naoki Matsuda, Yin Min Thu, Kazuhiko Shien, Hiromasa Yamamoto, Shinichi Toyooka. *Okayama University Graduate*

School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan

Background: Cancer-associated fibroblasts (CAFs) are key players in the tumor microenvironment (TME) due to their abundance in most solid tumors and active crosstalk with cancer cells, and promote the initiation of tumor formation, tumor growth, angiogenesis, metastasis, and therapeutic resistance. In this study, we sought to identify effective therapeutic targets in CAFs for non-small cell lung cancer (NSCLC).
Experimental Design: We established fibroblast cell lines from the cancerous and non-cancerous parts of surgical lung specimens from patients with NSCLC and evaluated the differences in behaviors towards NSCLC cells using in vitro co-culture models, conditioned medium, and in vivo xenograft mouse models. Next, RNA sequencing analysis was performed to investigate the differentially expressed genes between normal fibroblasts (NFs) and CAFs, and we then verified the biological activity of the identified molecule on NSCLC cells in vitro and in vivo mouse model.
Results: Cancer cells showed enhanced cell proliferation, migration, and drug resistance by co-culture with CAFs or CAF-derived conditioned medium. RNA sequencing analysis revealed that CAFs showed higher expressions of POSTN, a matricellular protein, than NFs. Single-cell RNA sequencing data of NSCLC from public database confirmed that POSTN-positive fibroblasts were highly enriched in lung tumor tissues but rarely observed in normal lung tissues, suggesting CAF-specific POSTN expression in lung cancer. Recombinant POSTN increased cell proliferation via NSCLC cells' ERK pathway activation and induced epithelial-mesenchymal transition (EMT), which improved migration in vitro. In addition, POSTN knockdown in CAFs suppressed these effects, and in vivo experiments demonstrated that the POSTN knockdown improved the sensitivity of EGFR-mutant NSCLC cells for Osimertinib treatment.
Conclusion: Our results showed that CAF-derived POSTN is involved in tumor growth, migration, EMT induction, and drug resistance in NSCLC. Targeting CAF-secreted POSTN in TME could be a potential therapeutic strategy for NSCLC.

#5847

The splanchnic mesenchyme is the main tissue origin of fibroblasts in the pancreas during homeostasis and tumorigenesis

Lu Han[1], Yongxia Wu[1], Kun Fang[2], Sean Sweeney[1], Ulyss Roesner[1], Melodie Parrish[1], Khushbu Patel[1], Tom Walter[1], Julia Piermattei[1], Anthony Trimboli[2], Julia Lefler[1], Cynthia Timmers[1], Xue-Zhong Yu[1], Victor Jin[2], Michael Zimmermann[2], Angela Mathison[2], Raul Urrutia[2], Michael Ostrowski[1], Gustavo Leone[2]. *[1]The Medical University of South Carolina (MUSC), Charleston, SC,[2]Medical College of Wisconsin, Milwaukee, WI*

In pancreatic ductal adenocarcinoma (PDAC), cancer associated fibroblasts (CAFs) play critical and complex roles in the tumor microenvironment. CAFs are also a major cell type in the desmoplastic stroma in PDAC and may account for half of the entire tumor tissue. Multiple subtypes of CAFs have been suggested, but the tissue origin(s) of CAF subtypes are unknown and genetic tools to robustly target them *in vivo* are lacking. Here we aimed to examine three potential tissue sources of CAFs: the pancreatic epithelium (through epithelium-to-mesenchyme transition), the bone marrow (through circulation), and the pancreatic mesenchyme or tissue resident fibroblasts (TRFs) in the normal pancreas (through proliferation). We utilized a genetically engineered mouse model of PDAC, where *Kras* and *p53* mutations were engineered in the pancreatic epithelium using an *Flp-Frt* system. To determine whether the pancreatic epithelium gives rise to CAFs, we permanently labeled the pancreatic epithelium with a GFP reporter and traced their cell descendants by GFP expression. Despite robust GFP labeling of the epithelium, GFP expression was rarely identified in CAFs. To determine whether the bone marrow gives rise to CAFs, we transplanted donor bone marrow carrying a ubiquitously expressed GFP reporter to GFP-negative recipient mice. We found that minimal proportion of pancreatic CAFs were tagged with GFP. Lastly, to determine whether pancreatic TRFs give rise to CAFs, we used an inducible *CreER-LoxP* system to allow for permanent Tomato labeling in TRF progenitors, the splanchnic mesenchyme, during mid-gestation. Lineage tracing in PDAC showed that the vast majority of CAFs were labeled with Tomato expression, suggesting their splanchnic origin. Furthermore, certain splanchnic gene expression signatures persisted in subsets of CAFs in both the PDAC mouse model and human patient samples. Deletion of one of the splanchnic genes, *Gata6*, in CAFs resulted in increased tumor burden in the

pancreas, suggesting a tumor-restraining role of Gata6 in CAFs. In summary, we found that the pancreatic epithelium and bone marrow contributes to a minimal proportion of CAFs in PDAC. Meanwhile, pancreatic TRFs are derived from the splanchnic mesenchyme during fetal development and they expand to contribute to the vast majority of CAFs in PDAC. Moreover, the persistence of splanchnic signature defines subtypes of CAFs, with a potential tumor-suppressing function. This study provides genetic approaches to robustly target CAFs *in vivo,* and novel insights into CAF origin, heterogeneity and function in PDAC.

Identification of mechanosensitive cancer associated fibroblasts in pancreatic cancer

Weikun Xiao[1], Chae-Young Eun[1], Weian Zhao[2], Reginald Hill[1]. *[1]Lawrence J. Ellison Institute for Transformative Medicine, Los Angeles, CA,[2]Department of Biomedical Engineering and Department of Pharmaceutical Sciences, Chao Family Comprehensive Cancer Center, Irvine, CA*

The purpose of this study is to investigate whether a subpopulation of cancer associated fibroblasts (CAFs) are responsible for mechanosensation-mediated chemoresistance in pancreatic adenocarcinoma (PDAC). PDAC is one of the most lethal types of cancer with few effective treatments. The abundant stromal cells and the stiff desmoplastic microenvironment constitute more than 90% of the primary tumor bulk. However, there are few easily tunable models to recapitulate this stiff microenvironment. To address this issue, we have developed a Matrigel-based, orthogonally tunable 3-dimensional (3D) culture system to co-culture mouse derived PDAC organoids and host-matching cancer-associated fibroblasts (CAFs). Using this biomimetic model and a mechano-sensation-dependent reporter, we have identified a unique subpopulation of CAFs responsible for mechano-sensing the fibrotic matrix and facilitating CAF-mediated chemoresistance. Moreover, these mechanosensitive CAFs (mecCAFs) respond to increased stiffness through YAP-mediated pathways. Our results also demonstrate how ECM stiffness affects chemoresistance via the hypersecretion CAF-derived exosomes. Moving forward, therapies

designed to interrupt the function of mecCAFs could be utilized to overcome matrix-mediated chemoresistance in PDAC.

SMAD3 in tumor associated fibroblasts drives enhanced fibroblast accumulation in lung adenocarcinoma through increased migration

Natalia Isabel Diaz Valdivia[1], Yago Juste Lanas[2], Alejandro Llorente[1], Rafael Ikemori[1], Alejandro Bernardo[1], Noemi Reguart[3], Jose M. Garcia Aznar[2], Jordi Alcaraz[1]. *[1]Unit of Biophysics and Bioengineering, Universitat de Barcelona, Barcelona, Spain,[2]Multiscale in Mechanical and Biological Engineering Group, University of Zaragoza, Zaragoza, Spain,[3]Medical Oncology, Hospital Clinic, Barcelona, Spain*

Lung cancer is characterized by a stiff fibrotic microenvironment rich in activated/pro-fibrotic tumor-associated fibroblasts (TAFs). We previously reported a larger accumulation of TAFs in lung adenocarcinoma (ADC) compared to lung squamous cell carcinoma (SCC), the two most frequent lung cancer subtypes. However, the underlying mechanisms remain elusive. TAF accumulation is largely contributed by the proliferation and/or migration of resident fibroblasts. Moreover, we recently showed that SMAD3 is epigenetically repressed in SCC-TAFs compared to ADC-TAFs owing to an excessive exposure to cigarette smoke particles, which elicited a compensatory increase in its closely related homolog SMAD2 in SCC-TAFs. However, it remains unknown whether the differential SMAD2/3 expression between ADC- and SCC-TAFs contributes to the larger accumulation of TAFs in ADC. To address this question, we knocked-down SMAD2 or SMAD3 in control pulmonary fibroblasts by shRNA and used them as ADC-like or SCC-like models. To assess proliferation, we examined cell number density and found that shSMAD2 (ADC-like) fibroblasts exhibited a significantly lower number density in basal conditions compared to shSMAD3 (SCC-like) fibroblasts, which was confirmed in TAFs. In the presence of TGF-β1, number density increased and attained similar values in shSMAD2 and shSMAD3 fibroblasts as well as in ADC- and SCC-TAFs. To assess fibroblast migration, we used a microfluidic device to quantify biophysical descriptors of protrusions and subsequent migration within a 3D collagen culture. Notably, both protrusions and migration descriptors were increased in basal conditions

selectively in shSMAD2 (ADC-like) fibroblasts concomitantly with Erk1/2 hyperactivation This enhanced migration was abrogated by TGF-β1 as well as by the MEK inhibitor Trametinib. In contrast, high SMAD2 fibroblasts were poorly responsive to TGF-β1 and Trametinib, exhibiting impaired migration in all conditions. Consistent results were observed in ADC-TAFs upon knocking-down SMAD3 as well as using the Transwell migration Boyden assay, thereby revealing that the enhanced migration in high SMAD3 conditions as in shSMAD2 and ADC-TAFs is caused by an intrinsic migratory priming. These results reveal that altered SMAD2/3 expression provide growth and migration advantages only in the absence of TGF-β1, although in opposing directions, since growth advantage was observed in high SMAD2 conditions (as in SCC), whereas migration advantage was found in high SMAD3 conditions (as in ADC). These findings strongly support that the larger TAF accumulation in ADC occurs at early stages (under low TGF-β1) and is driven by the enhanced migration of ADC-TAFs due to their high SMAD3 and Erk1/2 activation. Moreover, our results encourage the therapeutic use of MEK inhibitors in ADC-TAFs but not SCC-TAFs.

Development and characterization of patient-derived pancreatic fibroblasts to study CAF heterogeneity

Nidhi V. Dwivedi, Shailendra K. Gautam, Satya Rachagani, Ramakanth C. Venkata, Vipin Dalal, Maneesh Jain, Surinder K. Batra. *BMB, University of Nebraska Medical Center, OMAHA, NE*

Pancreatic ductal adenocarcinoma (PDAC) has complex tumor microenvironment (TME), characterized by phenotypically and functionally heterogenous cancer-associated fibroblasts (CAFs). Different CAF subtypes have been identified that evidently contribute to desmoplasia, immunosuppression, and therapy response variably. The lack of models to study their plasticity and heterogeneity reproducibly poses a major limitation. We, thus, describe the development and characterization of a panel of immortalized patient-derived pancreatic fibroblasts (iPDPFs), studying their impact on PDAC cell lines *in vitro* and *in vivo*.
Method: We developed six iPDPF lines using human telomerase reverse transcriptase (hTERT) from cancer-adjacent normal pancreas (9-26-NP),

chronic pancreatitis (CPP1), and PDAC CAFs (9-17-P, 10-15-P, 10-03-P, & 10-32-P). Immunoblotting, bulk-RNAseq, and qPCR were performed for their molecular characterization. Functional characterization was done *in vitro* using collagen contraction assay and co-culture studies with COLO357. The impact of iPDPFs on the tumor cell behavior *in vivo* was studied by their co-implantation with COLO357 in athymic nude mice.
Results: The iPDPFs exhibited variable expression of activation, inflammatory, and ECM markers indicative of heterogeneity across the panel. While CAFs expressed high levels of αSMA (alpha-smooth muscle actin) and fibroblast-specific protein-1 (FSP1), the expression of these markers was low in 9-26 NP & CPP-1. Also, the iPDPFs variably expressed TGFβ, PDGFRβ, VDR, COL1A, and small GTPases. High expression of inflammatory markers was observed in 9-26 NP, CPP-1, & 10-32-P suggesting their iCAF type while 9-17-P, 10-03-P, and 10-15-P were of myCAF type. These observations were recapitulated in the transcriptomic analysis. Interestingly, the marker expression changed with passage suggesting existence of plasticity in the iPDPFs. 9-17-P induced highest collagen contraction (47.9%) while 10-15-P induced the least contraction (25.89%). Co-culture of iPDPFs with COLO357 enhanced the expression of ROCK-1. *In vivo*, iPDPFs resulted in stroma-rich tumors; however, the extent of stroma and growth rate were variable across iPDPF lines and implantation sites. 9-17-P xenograft tumors exhibited the highest percent αSMA (14.5%), and FSP1 (30.7%) positive cells. Limited analysis showed that iPDPF co-implanted tumors exhibited variable vascularity and ECM composition suggesting that the heterogeneity observed *in vitro* was manifested *in vivo*.
Conclusion: Overall, the iPDPFs recapitulate pancreatic fibroblasts heterogeneity, reflecting the overlapping nature of CAF subtypes. Also, the iPDPFs are functionally variable and plastic *in vitro*. Importantly, these fibroblasts exert variable effects on the tumor cells *in vivo*. The iPDPFs can thus serve as a useful model to reproducibly study CAF heterogeneity and plasticity in PDAC.

#5851
Cancer associated fibroblast crosstalk through VEGF increases tumor cell proliferation in human pancreatic ductal adenocarcinoma

Samantha Guinn, Joseph Tandurella, Jignasha Patel, Richard Burkhart, Jacquelyn Zimmerman, Elizabeth Jaffee. *Johns Hopkins Medicine, Baltimore, MD*

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a classically heterogeneous tumor for which tumor cells comprise less than 40% of the total tumor mass. To better understand mechanisms of intercellular interactions driving tumor response or resistance to chemotherapy, it is crucial to account for the complex tumor microenvironment (TME). Cancer associated fibroblasts (CAFs) have been implicated as key drivers supporting mechanisms that both promote and restrain tumor growth. Using our model system that investigates interactions between CAFs and cancer cells, we show a novel intercellular interaction through VEGF signaling that drives proliferation.
Methods: We interrogate intracellular crosstalk in the PDAC TME using a novel 3-dimensional (3D), patient-matched coculture system of patient-derived organoids (PDO) and CAFs, obtained from patients undergoing surgical resection. Molecular characterization is performed by profiling with a 1200 analyte multiplex ELISA screen, multiparameter flow cytometry, bulk RNA sequencing of CAF and PDO cocultures, imaging mass cytometry (IMC) on patient samples, and qPCR.
Results: Secretome profiling of 7 patient-derived CAF lines demonstrated patient-specific heterogeneity in proteins such as: FGF-12, FGF3, and CD79a. Common CAF-derived signaling proteins with the potential to regulate intercellular crosstalk that were seen across all samples include CRP, IL-6R, R-Spondin and others. To better understand how factors change with intercellular interactions, we set up direct CAF-PDO cocultures over 4 days to identify global transcriptional changes using bulk RNAseq. Phenotypically, coculture drives gene expression changes in both PDO subtype (basal vs classical) and CAF subtype (prevalence of iCAFs vs myCAFs). We used these transcriptome data to identify pathways modulated by CAF-PDO crosstalk. Profiling coculture supernatant, we identified upregulation in VEGF secretion. In tandem, when we investigate cellular surface marker changes, we see upregulation of VEGFR2 on the surface of CAFs by flow cytometry. This interaction is accompanied by an increase in PDO proliferation seen in the coculture conditions. Ongoing

experiments aim to investigate the impact of this relationship spatially using matched patient tissue.
Conclusions: Interactions between cancer cells and CAFs compound the complexity of the biology of the TME and contribute to poor patient outcomes; therefore, we have put forth a model that better represents these interactions through patient matched PDO - CAF cocultures. Using this model, we demonstrate a novel interaction through VEGF that enhances tumor cell proliferation. We introduce a targeted approach to investigating the complex biology of the TME to inform the mechanisms driving cancer biology in individual patients that can also be used to develop novel therapeutic targets.

Vimentin content associated with shear wave speed in hepatocellular carcinoma: Non-invasive identification of more aggressive tumor phenotypes.

Andrea C. Cortes[1], Kiyoyuki Minamiguchi,[1], Patricia L. Da Costa Lopez[1], Simone Anfossi,[2], Williams Malea L[1], Maria S. Stenkamp[3], Rony Avritscher[1], Natalie W. Fowlkes[4]. *[1]Interventional Radiology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]SAnfossi@mdanderson.org, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Experimental Radiation Onc, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Veterinary Medicine & Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX*

Tumor stromal heterogeneity can negatively impact immune surveillance and treatment outcomes. Current cross-sectional imaging tools rely solely on tumor size and perfusion to monitor therapy and fail to characterize tumor biomechanics. Shear-wave elastography has emerged as a non-invasive technique that can quantify stromal elasticity. The goal of the present study is to characterize the molecular underpinnings associated with shear wave elastography measurements in liver cancer. To this end, rat hepatoma cell line McA-RH7777 stably expressing green fluorescent protein genes (fluc/GFP) were implanted in the left liver lobe of Buffalo rats. Three weeks after tumor implantation, adequate tumor size was verified by B-mode ultrasound. A 7-color panel was developed to assess the

percentage of vimentin, α-smooth muscle actin, IBA-1, S100A4, TGF-β, and glial fibrillary acidic protein (GFAP) in tumor sections. Shear wave elastography data was used to stratify tumor nodules as stiff or soft according to the mean value of the shear wave (3.05 versus 2,26 m/s). Our results showed two distinct tumor phenotypes. Stiffer tumors, as determined by higher shear wave speed measurements on ultrasound, were characterized by higher percentages of vimentin-positive cells, low S100A4 and IBA-1 macrophages expressing TGF-b, and intermediate expression of IBA-1 macrophages and GFAP cells. Slow shear wave speed, characteristic of softer tumors, displayed the opposite phenotype (two-factor ANOVA; $P \leq 0.001$). The most remarkable difference between stiffness phenotypes was the percentage of cells expressing vimentin, with a mean percentage in stiffer tumors of 26.54 compared with 13.68% in softer tumors ($P < 0.003$). Our results indicate that high expression of vimentin is highly correlated with increased shear wave speeds. Given the association between vimentin expression and epithelial-mesenchymal transition a marker of aggressive characteristics of tumor cells (increased migration and invasion), our findings suggest that longitudinal quantification of shear wave speed can be useful to assess functional changes in the stromal component and identify more aggressive tumor phenotypes with a higher likelihood of metastatic potential.

#5854

Suppression of phosphorylated focal adhesion kinase+ (pFAK+) fibroblasts and C-X-C chemokine receptor type 4 (CXCR4) expressing granulocytes is associated with exceptional clinical outcomes in pancreatic ductal adenocarcinoma (PDAC)

John Davelaar, Anser A. Abbas, Angela Minasyan, Omer H. M. Elmadbouh, Natalie Moshayedi, Brent Larson, Nicholas Nissen, Simon Lo, Srinivas Gaddam, Kambiz Kosari, Jun Gong, Andrew Hendifar, Stephen Pandol, Arsen Osipov. *Cedars-Sinai Medical Center, Los Angeles, CA*

Background: PDAC is an aggressive and treatment-refractory cancer due to its desmoplastic and immunosuppressive tumor microenvironment (TME). Overexpression of pFAK, a master regulator of the TME, and CXCR4, a receptor involved immunosuppression and tumor progression, are associated with poorer outcomes in PDAC. Exceptional responders, broadly

defined by extended survival and durable treatment responses, represent a rare subset in PDAC. We hypothesize that the immune and stromal signatures of exceptional responders vary significantly from non-exceptional responders, specifically exhibiting decreased p-FAK and CXCR4 expression and decreased immunosuppressive myeloid phenotypes in the TME.
Methods: We performed correlative quantitative analysis of multiplex immunohistochemistry (mIHC) employing 40 biomarkers on stage I/II PDAC, surgically resected formalin-fixed paraffin-embedded tissues from 9 non-exceptional responders and 11 exceptional responders. Exceptional responders were selected based on degree and duration of disease-free survival or overall survival more than double the historical matched medians. mIHC and image cytometry were used to distinguish and quantify total immune cell populations and colocalize biomarker expression across each distinct cell type. Cell populations and expression levels were compared using unpaired T-tests.
Results: Exceptional responders showed significantly decreased overall pFAK expression ($p=0.02$) and overall CXCR4 expression ($p=0.04$). In exceptional responders, pFAK expression and CXCR4 expression were significantly decreased in immunosuppressive $CD66b^+$ granulocytes ($p=0.01$, $p=0.03$, respectively) and in tumor associated macrophages ($p=0.01$, $p=0.006$, respectively). While not significant, exceptional responders demonstrated a marked decrease in immunosuppressive $pFAK^+$ fibroblasts ($p=0.12$) when compared to non-exceptional responders. No change was seen in the $CD8^+$ T cell infiltration between groups; however, a trend was observed towards an increased proportion of granzyme B^+ $CD3^+$ $CD8^+$ cytotoxic lymphocytes ($p=0.57$) in exceptional responders.
Conclusion: Exceptional responders selected in this preliminary study have significantly lower FAK and CXCR4 expression and markedly reduced populations of immunosuppressive FAK^+ and $CXCR4^+$ myeloid cells. Suppression of pFAK and CXCR4 in fibroblasts and granulocytes, respectively are associated with exceptional clinical outcomes. Future expanded research comparing the distinct TME and genetic signatures of exceptional responders to non-exceptional is warranted.

Spatial transcriptomics deciphers the cellular society of advanced colorectal cancer

Masahiro Hashimoto[1], Yuki Ozato[2], Yusuke Nakano[1], Tadashi Abe[1], Yuichi Hisamastu[1], Takeo Toshima[1], Yusuke Yonemura[1], Mamoru Uemura[2], Takaaki Masuda[1], Hirofumi Yamamoto[2], Masaki Mori[3], Hidetoshi Eguchi[2], Yuichiro Doki[2], Koshi Mimori[1]. *[1]Department of Surgery, Beppu Hosipital, Kyusyu University, Beppu, Japan,[2]Department of Gastroenterological Surgery, Osaka University, Graduate School of Medicine, Suita, Japan,[3]Tokai University, School of Medicine, Isehara, Japan*

Introduction: In recent years, single-cell RNA sequencing (scRNA-seq) and high-dimensional spatial transcriptomics (ST-seq) have contributed significantly to our understanding of the tumor microenvironment (TME) in many cancers. This is essential for understanding the tumor-stromal crosstalk. Thus, integrating scRNA-seq data with ST-seq data will facilitate understanding intercellular communication in TMEs.
Material and Method: We performed and combined ST-seq in CRC with public scRNA-seq. And, immunohistochemistry (IHC) (HLA-G, CD68, and SPP1) was performed on 20 CRC surgical specimens collected in our hospital. To verify this, we knocked out H2-M3 (HLA-G in humans) in mouse CRC cell lines (MC-38 cells) using the CRISPR/Cas9 system and examined H2-M3 KO tumor volume in xenograft mouse models.
Results: We identified co-localized cells with CRC cells at the invasive front and those in the center based on the spatial distribution estimated by an analytical pipeline, Cell2location. At the invasive front, CRC cells co-localized more frequently with SPP1+ macrophages than other cells. To dissect the molecular machinery and cell types inducing SPP1+ macrophages, we found ligand activity by another pipeline, NicheNet. The prominent signal to SPP1+ macrophages was mediated by several ligand-receptor pairs including HLA-G- immunoglobulin-like transcript (ILT)2/ILT4. Next, we disclosed the effect on CD8+ cells, and SPP1+ macrophages secrete IL-10 suppressing the immune activity of CD8+ T cells. And the ratio of HLA-G-positive cancer cells was predominantly higher in areas with more SPP1+ macrophages by IHC in CRC. In vivo analysis, H2-M3 KO reduced CRC tumor volume and tumor tissue from H2-M3 KO cells exhibited higher SPP1 and CD68 staining compared with wild type cells.

Conclusion: SPP1+ macrophages and cancer cells secreting high levels of HLA-G may represent targets to improve the prognosis of patients with CRC. Further analysis is currently underway with a focus on early-stage cancer in carcinoma in adenoma.

Immunotherapy and Cellular Interactions in the Tumor Microenvironment

ZEB1-driven reconstruction of the hyaluronan network establishes a pro-metastatic microenvironment in lung adenocarcinoma.

Sieun Lee[1], Jihye Park[1], Eun Ju Kim[1], Sungsoo Park[2], Jonathan M. Kurie[3], Young-Ho Ahn[1]. *[1]Ewha Womans University, Seoul, Korea, Republic of,[2]Deargen, Inc., Daejeon, Korea, Republic of,[3]University of Texas MD Anderson Cancer Center, Houston, TX*

Hyaluronan, one of the major components of the extracellular matrix (ECM), surrounds and protects neighboring cells from diverse stresses. Hyaluronan promotes epithelial-to-mesenchymal transition (EMT) and metastasis in various epithelial cancers. However, the mechanism by which the hyaluronan network built up by cancer cells regulates cancer progression and metastasis in the tumor microenvironment has not been elucidated in detail. In this study, ITIH2, a hyaluronan-binding protein that participates in building a hyaluronan network, was confirmed to be secreted from mesenchymal-like lung cancer cells when co-cultured with cancer-associated fibroblasts. ITIH2 was transcriptionally upregulated by ZEB1, an EMT-inducing transcription factor. Hyaluronic acid synthase-2 (HAS2) was also up-regulated by ZEB1, and the expression of HAS2 and ZEB1 showed a positive correlation in the TCGA database. In addition, ZEB1 controlled alternative splicing and isoform expression of CD44, a hyaluronan receptor. Interestingly, ITIH2 knockdown and 4-methylumbelliferone (4-MU), a HAS inhibitor, reduced the formation of hyaluronan cables and inhibited the migration and invasion of lung cancer cells. Likewise, when lung cancer cells were treated with “Compound S,” an ITIH2 inhibitor predicted by a deep learning-based drug-target interaction algorithm, the formation of hyaluronan cables and cell migration were suppressed. In addition, the ITIH2 inhibitor prevented the growth of metastatic tumors in an orthotopic

lung cancer mouse model. Collectively, the EMT signal controlled by ZEB1 establishes the pro-metastatic hyaluronan network in the tumor microenvironment, suggesting a novel strategy for targeting the hyaluronan network to suppress lung cancer progression and metastasis.

Tumor cell-intrinsic factors promoting fibrotic tumor microenvironment in gastric cancer

Takashi Semba[1], Yiling Tong[1], Feng Wei[1], Atsuko Yonemura[1], Tadahito Yasuda[1], Tomoyuki Uchihara[1], Huaito Wang[1], Hideo Baba[2], Takatsugu Ishimoto[1]. *[1]Gastrointestinal cancer biology, International Research Institute of Medical Sciences, Kumamoto University, Kumamoto, Japan,[2]Department of Gastroenterological Surgery, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan*

Background: Gastric cancer (GC) is one of the leading causes of death in the world. Evidence has shown over the past decade that cancer-associated fibroblasts (CAFs) play essential roles in various types of cancers, including GC, such as tumorigenesis, therapy resistance, and immunosuppression, which contribute to the progress of tumors. Although GC tumors are known to be enriched with stroma, the molecular mechanisms of how GC tumors foster the fibrotic milieu is still largely unknown. Here we analyzed a large-scale genomic and transcriptomic dataset of GC to identify GC tumor cell-intrinsic factors for developing fibroblast-rich microenvironments.
Methods: We analyzed GC patient samples with gene expression data and copy number variation profiles from the Asian Cancer Research Group (ACRG) (N = 271). The microenvironment cell populations-counter (MCP-counter) method was used for transcriptome deconvolution to estimate the population of fibroblasts and immune cells in GC tumors. Genes with q value < 0.05 and fold change > 1.5 were defined as differentially expressed genes (DEGs) and identified using the Subio Platform. The copy number amplified genes found in more than 3% of the samples were selected as amplified genes. Pathway and process enrichment analysis and protein-protein interaction analysis were performed using Metascape.
Results: We analyzed MCP-counter outputs and observed a fibroblast-enriched population with few infiltrations of anti-tumor immune cells, such as CD8 T cells and cytotoxic T cells in GC patients, suggesting the

immunosuppressive role of CAFs in the GC tumor. By analyzing 933 DEGs upregulated in fibroblast-high patients, we found 96 genes with frequent copy number amplification that were not listed on the curated stroma and extracellular matrix-related genes and thus potentially tumor cell-intrinsic genes correlated with the abundance of the stroma. Pathway and protein-interaction analyses revealed that G protein-coupled receptor (GPCR) signaling pathway was enriched in these genes, including *HTR2A*, *AGTR1*, *FZD1*, *CALCRL*, and *NBEA* with strong correlations between fibroblast score (Spearman's $r > 0.55$), implying that these signaling in GC tumor cells contribute to promoting fibroblast-enriched microenvironment. Conclusions: Bioinformatic analyses of a publicly available genomic and transcriptomic dataset revealed a fibroblast-rich and immune-excluded population in GC patients. Several GPCR signaling in tumor cells were strongly correlated with fibroblast abundance in tumors, and these signaling pathways have potential roles in promoting the stroma-rich GC microenvironment.

ABCB5 knockdown suppresses tumor-intrinsic expression of immune checkpoint regulators PD-1 and PD-L1 in hepatocellular carcinoma (HCC)

Chun Philip Yeung[1], Brian J. Wilson[2], Yuzuru Sasamoto[3], Ana Maria Waaga-Gasser[4], Svetlana Karpova[5], Qin Guo[5], Natasha Y. Frank[5], Markus H. Frank[6]. *[1]Medical Sciences, Harvard Medical School, Boston, MA,[2]Transplant Research Program, Boston Children's Hospital, Boston, MA,[3]Ophthalmology, Boston University School of Medicine, Boston, MA,[4]Medicine, Brigham and Women's Hospital, Boston, MA,[5]Genetics, Harvard Medical School, Boston, MA,[6]Dermatology, Harvard Medical School, Boston, MA*

ATP-binding cassette member B5 (ABCB5) identifies cancer-initiating cells (CICs) in multiple malignancies, including malignant melanoma, colorectal cancer, glioblastoma, and hepatocellular carcinoma (HCC). In human melanoma, ABCB5-positive CIC subpopulations have been shown to preferentially express the immune checkpoint molecules PD-1 and PD-L1, and tumor-intrinsic PD-1 receptor functions have been found to promote

tumor growth, even in mice lacking adaptive immunity. In HCC, where ABCB5 mediates CIC chemoresistance, PD-1 expression has also recently been identified. However, whether ABCB5 regulates tumor-intrinsic PD-1 expression in HCC or other malignancies is currently unknown. Here, we employed RNA interference in Hep G2 HCC cells with high endogenous ABCB5 expression to study the potential role of ABCB5 in regulating PD-1 expression, utilizing the ABCB5 shRNA target sequence GCTGGAAAGATAGCAACTGAA for ABCB5 knockdown (KD) as described previously. Endogenous ABCB5 levels in ABCB5-KD cells were successfully reduced by 92.8% compared to controls. Investigation of the effects of ABCB5-KD on tumor-intrinsic immune checkpoint molecule expression and on expression of the HCC-CIC marker GRN revealed that ABCB5-KD significantly reduced PD-1 expression by 98.0%, and PD-L1 expression by 62.8% compared to controls. Expression of GRN was also significantly reduced in ABCB5-KD cells by 78.8% compared to controls, suggesting ABCB5 KD-dependent loss of CIC phenotype. Injection of ABCB5-KD cells in NSG mice showed 32.3% reduction in tumor size at endpoint (6 weeks) compared to controls (728.7 ± 199.3mm^3 vs 1076.0 ± 450.9 mm^3, mean ± SD; $p<0.005$, repeated measures ANOVA) and 8.53% reduction in tumor weight at endpoint (0.47 ± 0.21g vs 0.51 ± 0.21g, mean ± SD). These results provide initial evidence in an HCC cell line model system that ABCB5 functionally regulates tumor-intrinsic PD-1 and PD-L1 expression. They therefore suggest that ABCB5 blockade represents a novel therapeutic strategy for targeted inhibition of pro-tumorigenic tumor-intrinsic PD-1/PD-L1 expression, with important additional implications for immune checkpoint-targeted cancer immunotherapy.

Blockade of tumor glucocorticoid production inhibits Treg function and tumor growth

Shizuka Otsuka[1], Matthew D. Taves[2], Kaitlynn M. Donahue[1], Jonathan D. Ashwell[1]. *[1]NIH-NCI, Bethesda, MD,[2]Department of Neurobiology & Behavior, Cornell University, Ithaca, NY*

Glucocorticoids (GCs) are steroid hormones with potent immunosuppressive properties. GCs are primary produced from cholesterol in the adrenals via the *de novo* synthetic pathway. In some tissues, however,

there is also a recycling pathway in which the enzyme 11β-HSD1 generates GCs from the inactive metabolites dehydrocorticosterone (rodent) or cortisone (human). Here we find that multiple tumor types produce GCs via 11β-HSD1 *in vitro* and *in vivo*. We used CRISPR/Cas9 technology to knock out *Hsd11b1* in GC-producing tumor cell lines and found that lack of 11β-HSD1 in B16 melanoma, Panc02 pancreatic adenocarcinoma, and MC38 colon carcinoma lines reduced their growth *in vivo*. Reduced tumor growth corresponded with increased expression of the activation marker CD44 and production of the effector cytokines IFNγ and TNFα by tumor-infiltrating $CD8^+$ T cells (TILs). Rather than directly suppressing effector cell function, recent findings have suggested that GCs instead act primarily by activating Treg cells, and that these Treg are responsible for inhibition of effector cell function. Consistent with this, we found that tumor-derived GCs upregulate Treg expression of miRNA-342, which downregulates the mTOR component Rictor and activates Treg activity. A role of tumor-derived GCs in enhancing Treg function was demonstrated by inoculating tumor cells into mice with Treg-specific glucocorticoid receptor deficiency ($GR^{Foxp3Cre}$ mice). Notably, growth of tumors was reduced in $GR^{Foxp3Cre}$ mice, along with increased $CD8^+$ TIL activation. Importantly, pharmacologic inhibition of 11β-HSD1 reduced WT tumor growth to the same degree as knockout of 11β-HSD1, and rendered immunotherapy-resistant tumors susceptible to inhibition with anti-PD-1 antibodies. Given that 11β-HSD1 expression is upregulated in many human tumors, these data suggest that its inhibition, which has been accomplished in a number of phase 3 clinical trials for other indications and is well-tolerated, may be beneficial in their treatment.

An angiogenic target of immune exclusion with checkpoint blockade in melanoma

Saba Tabasum[1], Dinesh Thapa[1], Anita Giobbie-Hurder[1], Jason L. Weirather[1], Xinqi Wu[1], Marco Campisi[2], Xiaoyun Li[1], Jingjing Li[1], Michael P. Manos[1], David A. Barbie[1], F. Stephen Hodi[1]. *[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Dana-Farber Cancer Institute, Boston, MA*

With the development of immune checkpoint blockade to treat a variety of malignancies, better predictive biomarkers as well as new targets to further improve anti-tumor immunity remains a need. Our understanding of the role of angiogenesis in immune regulation continues to improve, and combinations of anti-angiogenesis and immune checkpoint blockade demonstrate improved clinical efficacy, as well as mechanisms for improved immune cell trafficking. Tumor biopsies from a phase I study with 46 advanced melanoma patients treated with Ipilimumab and Bevacizumab combination (Ipi-Bev) therapy, revealed activated endothelium accompanied by lymphocyte infiltration. To discover possible targets involved in the observed clinical benefit, a serological screen was performed using human protein arrays with post-treatment plasma samples of long-term patients with clinical benefit to Ipi-Bev therapy (Wu et. al., 2017; Hodi et. al., 2014). EDIL3 (EGF Like Repeats and Discoidin Domains 3), a pro-angiogenic extracellular matrix protein, was identified. Humoral responses against EDIL3 were associated with favorable clinical outcomes including improved response rates *(p=0.003)* and overall survival *(p=0.03)* to Ipi-Bev therapy. The anti-EDIL3 response was also observed to be significantly *(p=0.03)* related to Ipi-Bev treatment when compared with patients treated with Ipilimumab alone, anti-PD1 therapy alone, or the combination of Ipilimumab and Nivolumab in a combined analysis. Transcriptome analyses of TCGA SKCM (n=469) and BMS Checkmate 064 trial (n=90) related upregulated EDIL3 expression with enrichment of EMT, TGFβ signaling in fibroblasts, and angiogenesis signatures. Interestingly, TIDE analysis demonstrated a role for EDIL3 in T cell exclusion and immunosuppressive cancer-associated fibroblasts (CAFs) as its source in the tumor microenvironment. EDIL3 was also predicted as a biomarker of non-response to immune checkpoint blockade treatment. *In vitro* studies confirmed the upregulation of EDIL3 expression and secretion by patient-derived CAFs along with its role in modulating TGFβ1 mediated EMT. Mechanistically, EDIL3 was found to interfere with leukocyte-endothelial interactions by disturbing LFA-1/ICAM1 mediated adhesion and inhibited T cell transmigration in 2-D and microfluidic 3-D coculture studies with patient-derived tumor endothelial cells. Our findings suggest that the humoral response against EDIL3 may serve as one of the underlying mechanisms involved in effectuating an excluded to an inflamed phenotype observed in responders of checkpoint blockade treatment. This

study develops EDIL3 as a potential target to enhance cytotoxic immune responses and improve the outcomes of combination immune therapy. Studies are ongoing for targeted inhibition of EDIL3 with implications for therapeutic application to promote anti-tumor immunity.

Combinatorial activity of amivantamab and pembrolizumab in head and neck squamous cell carcinoma and lung squamous cell carcinoma expressing wild-type EGFR and MET

Sun Min Lim[1], Chun-Bong Synn[1], Seong-san Kang[2], DongKwon Kim[1], Soo-Hwan Lee[2], Sujeong Baek[1], Seung Min Yang[3], Yu Jin Han[3], Mi hyun Kim[3], Heekyung Han[1], Kwangmin Na[1], Young Taek Kim[1], Sungwoo Lee[2], Mi Ran Yun[4], Jae Hwan Kim[1], Youngseon Byeon[1], Young Seob Kim[1], Jii Bum Lee[5], Ji Yun Lee[5], Chang Gon Kim[5], Min Hee Hong[5], Kyoung-Ho Pyo[4], Joshua Curtin[6], Bharvin Patel[6], Isabelle Bergiers[7]. *[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]JEUK Institute for Cancer Research, Seoul, Korea, Republic of,[3]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Seoul, Korea, Republic of,[5]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of,[6]Janssen R&D, Spring House, PA,[7]Janssen R&D, Beerse, Belgium*

Introduction: Unmet needs exist for immunotherapy targeting PD-1/PD-L1 in head and neck squamous cell carcinoma (HNSCC) and lung squamous cell carcinoma (LUSC) due to its suboptimal response. Amivantamab, a bispecific antibody targeting epidermal growth factor receptor (*EGFR*) and c-Met, has been demonstrated to induce antibody-dependent cytotoxicity and trogocytosis in tumor cells. We hypothesized that combination of amivantamab with pembrolizumab may synergistically enhance antitumor immunity. In this study, we present comprehensive immunomodulatory and synergistic antitumor efficacy of amivantamab and pembrolizumab in humanized HNSCC and LUSC mice models.
Methods: EGFR and MET-expressing tumors from a HNSCC and a LUSC patient were transplanted into Hu-CD34-NSG to establish humanized

patient-derived xenograft (PDX) models. Tumor-bearing PDXs were treated with vehicle, pembrolizumab (10mpk, Q5D, n=10), amivantamab (10mpk, BIW, n=10), or a combination of pembrolizumab and amivantamab (n=10). Analysis of immune modulatory responses within the tumor microenvironment (TME) using multiplexed IHC, flow cytometry, and single cell RNA sequencing was performed.
Results: Combination of amivantamab and pembrolizumab showed a significant reduction of tumor volume ($p<0.001$) compared to vehicle or single treatment in both models. Additionally, significantly longer survival was observed for combination treated compared to the vehicle treated groups ($p<0.0001$). Multispectral imaging of tumor indicated that granzyme B-producing $CD8^+$ T cells were significantly increased within the tumor in the combination group ($p<0.01$). Further analysis of T cell subsets suggested that central memory type $CD8^+$ T cells were increased upon combination treatment. This group also demonstrated significantly higher CEA-tetramer positive $CD8^+$ T cells in the tumor ($p<0.01$), suggesting that cytotoxic T cells recognizing tumor specific antigens enhanced antitumor immune response. Single cell RNA sequencing analysis of HNSCC showed that an $EGFR^{high}MET^{high}$ cluster was enriched in the TME after pembrolizumab treatment. This subcluster had elevated glycolysis and lactic acid pathway-related genes compared to $EGFR^{low}MET^{low}$ cluster. Lactate transporter, MCT4 (SLC16A3) and LDHA genes were dramatically increased in the $EGFR^{high}MET^{high}$ cluster. Elevated lactic acid pathway may lead to immune evasion in the tumor, dampening the activity of pembrolizumab. Interestingly, combination treatment with amivantamab could reduce $EGFR^{high}MET^{high}$ cluster, and could effectively control tumor *via* creating favorable immune TME.
Conclusion: Our study demonstrated combinatorial benefits of amivantamab and pembrolizumab by effectively remodeling TME, providing a preclinical rationale to clinically combine amivantamab and PD-1 blockade treatments.

#5866

Mavorixafor enhances apoptosis of tumor cells treated with ibrutinib or venetoclax in diffuse large B-cell lymphoma, follicular lymphoma, mantle cell lymphoma, and chronic lymphocytic leukemia

Tom Kruitwagen[1], Thalia Martins Rebelo[1], Barbara Maierhofer[2], Gerwin Heller[3], Halenya Monticelli[2], Arthur G. Taveras[4], Chi Nguyen[2]. *[1]Former Employee at X4 Pharmaceuticals (Austria) GmbH, Vienna, Austria,[2]X4 Pharmaceuticals (Austria) GmbH, Vienna, Austria,[3]Department of Medicine, Division of Oncology, Medical University of Vienna, Vienna, Austria,[4]X4 Pharmaceuticals, Inc., Boston, MA*

Despite advances in therapies for B-cell lymphoma, patients may still develop resistance and often relapse. Contributing factors may include interactions between lymphoma cells (LCs) or leukemia cells and bone marrow microenvironment (BMM). Overexpression of $CXCR4^{WT}$ and its ligand CXCL12 promote LC-BMM interactions, contributing to disease severity in lymphomas or leukemia such as diffuse large B-cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL), follicular lymphoma (FL), and mantle cell lymphoma (MCL). Mavorixafor is an investigational oral CXCR4 antagonist being evaluated in combination with the Bruton tyrosine kinase (BTK) inhibitor ibrutinib in patients with Waldenström's macroglobulinemia (WM). In preclinical models of $MYD88^{L265P}$ $CXCR4^{WT}$ WM, mavorixafor restored sensitivity of WM cells to B-cell-targeted therapies in coculture of WM cells and bone marrow stromal cells (BMSCs); however, the effects of mavorixafor on other lymphomas with $CXCR4^{WT}$ have not been evaluated. We report the effects of mavorixafor alone or in combination with B-cell─targeted therapies on LCs in an *in vitro* preclinical model and assess the role of BMM in the pathogenesis of B-cell lymphomas in an *in vitro* coculture model of LCs and BMSCs. Bioinformatic analysis of publicly available gene expression datasets GSE11318 and GSE32918 showed patients with DLBCL and $CXCR4^{hi}$ have significantly inferior survival probability compared with those with $CXCR4^{low}$ ($P<.001$ and $P<.05$, respectively). *In vitro* studies assessing effects of targeting CXCR4 with mavorixafor showed apoptosis of $CXCR4^{+}$ LCs *OCILY19* (DLBCL), *MEC1* (CLL), *MINO* (MCL), and *DOHH2* (FL) cells increased by ≈10%─60%. The apoptosis of LCs was further enhanced by ≈5%─60% when treated with mavorixafor in combination with ibrutinib or venetoclax compared to ibrutinib or venetoclax alone. Coculture of LCs with BMSCs reduced the sensitivity of LCs to apoptosis-inducing effects of ibrutinib and venetoclax. Combining mavorixafor with ibrutinib or

venetoclax restored sensitivity of LCs to apoptosis-inducing effects of the tested B-cell–targeted inhibitors. Mavorixafor also inhibited migration of LCs toward CXCL12, suggesting prevention of the homing of LCs to protective niche. Overall, our findings suggest the contribution of *CXCR4*^{WT} to pathogenicity of LCs. This is the first *in vitro* study to show that reduced sensitivity of LCs against B-cell-targeted therapies conferred by BMSCs can be overcome by inhibition of the CXCL12-CXCR4 axis with mavorixafor. Our study provides supporting evidence for further exploration of mavorixafor alone or in combination with other B-cell-targeted therapies in the treatment of lymphomas and leukemias. Further studies using additional LC lines and/or primary patient cells are warranted to support these findings.

Multimodal analysis of glioblastoma identifies the additional function of CXCL12 for modulating GBM resistance and immunosuppressive microenvironment

Chan-Chuan Liu[1], Chia-Hung Chien[2], Wen-Bin Yang[3], Jian-Ying Chuang[4], Kwang-Yu Chang[5]. *[1]National Institute of Cancer Research, National Health Research Institutes, Tainan City, Taiwan,[2]National Institute of Cancer Research; School of Medicine, National Health Research Institutes; I-Shou University, Tainan City, Taiwan,[3]TMU Research Center of Neuroscience, Taipei Medical University, Taipei City, Taiwan,[4]TMU Research Center of Neuroscience, the Ph.D. Program for Neural Regenerative Medicine, College of, Taipei Medical University, Taipei City, Taiwan,[5]National Institute of Cancer Research; Department of Oncology, National Cheng Kung University Hospit, National Health Research Institutes; National Cheng Kung University, Tainan City, Taiwan*

Glioblastoma (GBM), a WHO Grade IV glioma, is the most common and aggressive primary brain tumor. Despite the standard of care consisting of surgery removal following radio- and chemo- therapy, the prognosis of GBM patients remain dismal. The interplay between GBM cells and its microenvironment contributes to maintaining the cancer stemness, developing resistance, and forming immunosuppression. GBM-associated macrophages (GAMs) are recruited to the GBM microenvironment by

cytokines/chemokines. Conversely, GAMs may promote GBM progression. Therefore, we hypothesized that GBM cells modulated immune microenvironment via macrophage activation. We integrated the bulk RNA sequencing (seq.) of the paired primary-recurrent GBM specimens, single-cell RNA seq., and *in vitro* validation to investigate the hypothesis. The bulk RNA seq. of the paired primary-recurrent GBM specimens indicated that recurrent GBM enhanced the neuroinflammation pathway. Among the components, we found that CXCL12, also known as stromal cell-derived factor 1 was accumulated during GBM progression and up-regulated in temozolomide (TMZ)-resistant GBM cells. On the other hand, the newly CXCL12 receptor CXCR7 may act as a scavenger for CXCL12 during developing TMZ resistance in GBM. The bulk RNA sequencing seq. from primary-recurrent GBM specimens showed the decrement of CXCR7. Single-cell RNA seq. of GBM patients' specimens indicated CXCR7 dominantly expressed in GBM cells other than normal neural and immune cells. Developing TMZ resistance in GBM cell lines down-regulated CXCR7 expression. Furthermore, silencing CXCR7 attenuated TMZ cytotoxicity while combining CXCR7 agonists (Plerixafor, VUF11207, and TC14012) and TMZ enhanced TMZ cytotoxicity. Otherwise, the GBM-associated CXCL12 activated M0 macrophages into GAMs by facilitating macrophage proliferation and inducing pro-tumor factors, including interleukine (IL)-1β and its receptors, IL-6, MMP9, and immune checkpoint PD-L1. Mechanistically, GBM-associated CXCL12 upregulated PD-L1 in GAMs via NF-κB. Accordingly, by multimodal analysis, CXCL12 was identified with the additional role in regulating resistance in GBM cells and GBM microenvironment. Also, re-activating CXCR7 may overcome the resistance to TMZ and immune checkpoint blockade therapy. Combination of CXCR7 activation with current therapy and immunotherapy may be an effective strategy for improving the prognosis of primary GBM patients.

Uncovering key microenvironmental features for immunotherapy response at the subclonal level in pancreatic cancer

Er-Yen Yen, I-Lin Ho, Chieh-Yuan Li, Charles Dyke, Shan Jiang, Francesca Citron, Sergio Attanasio, Rutvi Shah, Ko-Chien Chen, Giulio Draetta, Andrea Viale. *MD Anderson Cancer Center, Houston, TX*

The lack of suitable experimental approaches to investigate and model functional heterogeneity in vivo has had a profound negative impact on our understanding of how heterogeneity affects the response to immunotherapy. To bridge this technological gap, we leverage a new platform that visualizes the spatial architecture of subclones and microenvironments. To study heterogeneous populations of cells and their clonal dynamics in vivo, we performed barcode lineage tracing with next-generation sequencing analysis. It allows a quantitative evaluation of the spatial distribution and temporal clonal dynamic in vivo with multiple pharmacological perturbations, such as immune checkpoint blockade (ICB). We found that treatment with a PD1 inhibitor, despite a limited effect on tumor volume, induced dramatic changes in tumor clonal architecture. Furthermore, we revealed that subclones from well-defined geographical domains in vivo share differential behavior upon immune checkpoint blockade (ICB). By visualizing 40 different markers with multiplexed staining technology, we further identified that the microenvironment also exhibits a high level of spatial heterogeneity. Therefore, we coupled spatial barcode sequencing with high-content imaging and revealed the differential microenvironment feature of sensitive and resistant clones. We will further explore the mechanisms of immune evasion at the subclonal level. Through isolation and deep characterization of clonal lineages endowed with a distinct ability to engage the immune response, we hope to identify new vulnerabilities to overcome resistance to ICB.

The concordant disruption of B7/CD28 immune regulators predicts the prognosis of oral carcinoma

Sih-Rou Chang. *National Yang Ming Chiao Tung University, Taipei, Taiwan*

Immune-escape is a critical factor determining the survival of malignancies including oral squamous cell carcinoma (OSCC). The immune escape of cancer cells may be driven by B7/CD28 family members and others on the tumor cells that form ligand-inhibitory receptor complexes with immune cells. Since the family members of B7/CD28 can functionally compensate, the concomitant disruption of multiple B7/CD28 family members in OSCC pathogenesis remains elusive. RNAseq performed on OSCC and paired oral mucosa retrieved the transcriptome of OSCC, and algorithms signified the

general alterations of T cell population and the increase of macrophage population in tumors relative to controls. Upregulation of CD80, CD86, PD-L1, PD-L2, CD276 and CTLA4, and downregulation of L-ICOS in OSCC relative to normal mucosa was noted. In addition, there was a high concordance in the expression profile across the dysregulated regulators. The co-upregulation of CD276 and CTLA4 was associated with the decrease of T helper and NK cell population, and the increase of Treg and myeloid dendritic cell population. Interestingly, tumors harboring higher PD-L1 and/or PD-L2 expression accompany with lower ICOS or PD1 expression exhibited worse prognosis. In combination with these immunity features in primary tumors, the survival of patients with lymph node metastasis was further worsened. In the isografic models of murine OSCC cell lines, the decrease of CD4+T population in the lymph node and increase of myeloid dendritic cell population in the spleen were induced in the host mice. Many miRNAs are involved in the modulation of immune escape for malignancies. With the treatment of inhibitors against oncogenic miRNAs which enabled the OSCC suppression, the inhibitors of miR-146a and miR-211 also resulted in the down-regulation in the protein expression of multiple B7/CD28 members. This study concludes the eminent co-disruption of B7/CD28 members in OSCC tumors, which would confound the patient survival. The efficacy of miRNA inhibitors in abrogating oncogenicity and B7/CD28 members could be a therapeutic strategy.

T-cell factor-4 variants regulate PD-L1 expression in liver cancer cells

Hironori Koga[1], Yasuko Imamura[1], Toshimitsu Tanaka[1], Hideki Iwamoto[1], Toru Nakamura[1], Atsutaka Masuda[1], Takahiko Sakaue[1], Hiroyuki Suzuki[1], Hirohisa Yano[2], Takumi Kawaguchi[1]. *[1]Kurume Univ. School of Medicine, Kurume, Japan,[2]Pathology, Kurume Univ. School of Medicine, Kurume, Japan*

Background: We previously identified 14 isoforms of T-cell factor (TCF)-4, a key transcriptional factor in the Wnt signaling pathway, from human hepatocellular carcinoma (HCC) cell lines (Exp Cell Res 2011). The TCF-4J and K pair has been characterized based on the presence (K) or absence (J) of a conserved SxxSS motif at the head of exon 9. TCF-4J-overexpressing HCC cells (J cells) exhibited high tumorigenic potential in

contrast to TCF-4K-overexpressing cells (K cells) (PLoS ONE 2012); however, resistance to anti-cancer agents was more prominent in K cells than J cells. Another analysis demonstrated that loss of exon 4 increased resistance to chemotherapeutic agents and induced epithelial-mesenchymal transition (EMT) (Liver Int 2013). EMT and the expression of programmed cell death 1-ligand 1 (PD-L1) is closely associated with each other, and our preliminary study revealed that EMT was regulated by TCF-4 variants, suggesting possible involvement of the variants in the regulation of PD-L1 expression. In general, PD-L1 is known to be upregulated by hypoxia-inducible factor-1α (HIF-1α) under hypoxic conditions. Therefore, if the TCF-4 variants regulate PD-L1 expression under normoxia, it would be a unique mechanism bridging the Wnt signaling pathway and the tumor immune microenvironment (TIME).
Aim: To assess whether or not the TCF-4 variants regulate the expression of PD-L1 in cancer cells under normoxia.
Methods: HAK-1A, a well-differentiated HCC cell line (Hepatology 1993), was used in this study. TCF-4K mutants (S269A, S272A, and S273A) were prepared with the conversion of serine (S) in the SxxSS motif to alanine (A) by site-directed mutagenesis. HAK-1A-derived stable clones overexpressing TCF-4J, K, and K-mutants (S269A, S272A, and S273A cells, respectively) were established. Empty vector-transfected mock cells (EV cells) were used as a control. Western blot analysis and real-time RT-PCR were employed to evaluate protein and mRNA expression levels, respectively.
Results: J cells and K cells expressed PD-L1 mRNA 2-fold and 4-fold of that in the EV cells, respectively. Of note, the PD-L1 expression mRNA was enhanced up to 11-fold in S269A cells, 11-fold in S272A cells, and 17-fold in S273A cells. The increased mRNA expressions were verified in protein levels.
Conclusion: PD-L1 expression was regulated by TCF-4 variants in liver cancer cells under normoxic conditions. The finding suggests that the Wnt signaling pathway fine-tunes the TIME by regulating the expression levels of PD-L1 in a HIF-1α-independent manner.

Pan-cancer myeloid cell analysis at the single cell level reveals the influence of distinct organ sites in myeloid cell phenotypes and support

targeting S100A4 to reverse immune suppression

Nourhan Abdelfattah[1], Parveen Kumar[2], Caiyi Wang[1], Jia-Shiun Leu[1], David Baskin[1], William Flynn[2], Ruli Gao[1], Kumar Pichumani[1], Omkar Ijare[1], Stephanie Wood[1], Suzanne Powell[1], David Haviland[1], Brittany Parker Kerrigan[3], Frederick Lang[3], Sujit Prabhu[3], Kristin Huntoon[3], Wen Jiang[3], Betty Kim[3], Joshy George[2], Kyuson Yun[1]. *[1]Houston Methodist Research Institute, Houston, TX,[2]The Jackson Laboratory, Farmington, CT,[3]MD Anderson, Houston, TX*

With abundant pro-tumorigenic myeloid cells and few tumoricidal tumor-infiltrating lymphocytes (<5%), GBM is representative of "immune cold" tumors. As such, many different types of immunotherapies have failed to show significant benefits for most glioma patients. Hence, a better understanding of drivers of the immune suppressive microenvironment in GBM and other immune cold tumors is urgently needed to guide future immunotherapy development and application. We recently analyzed 201,986 human glioma and immune cells from 44 tissue fragments from 18 human glioma patients, and present a comprehensive and high-resolution cellular, molecular, and spatial heterogeneity atlas of human glioma. We report an extensive spatial and molecular heterogeneity of glioma and immune cells within the same patient. In addition, we discovered that cell:cell communication between glioma:myeloid cells is considerably more robust than glioma:T-cells, indicating that myeloid cells form a communication hub *in vivo*. To gain a deeper understanding of these important immune cells, we analyzed 83,479 glioma-infiltrating myeloid cells and identified 9 molecularly distinct myeloid subtypes: 3 microglia subtypes, 3 bone marrow-derived macrophage (BMDM) subtypes, MDSCs, neutrophils, and dendritic cells. Notably, we found that five of these myeloid cell subtype gene signatures are significant predictors of glioma patient survival, independent of glioma cell mutational profiles or gene expression patterns. Leveraging our dataset, we also identified a novel immunotherapy target that is highly expressed in immune-suppressive macrophages and T cells but not in anti-tumor leukocytes: *S100A4*. We provide both *in vitro* and *in vivo* evidence that *S100a4* deletion in stromal cells is sufficient to reprogram the immune microenvironment and significantly extend the survival of two independent glioma models. To

broaden the potential impact of targeting S100A4 as a selective modulator of immune suppressive leukocytes, we compared the molecular signatures of glioma-associated myeloid cells to those from 12 other cancer types and peripheral blood myeloid cells. We found that *S100A4* expression pattern is highly consistent among all tumor types, where its expression is highest in the monocytes and MDSCs and low in most DCs and tissue-resident macrophages. Our preliminary analysis also shows that myeloid cells in gliomas are molecularly distinct from corresponding cell types in other cancers, strongly indicating the role brain microenvironment in influencing the infiltrating BMDM maturation and polarization.

Spatial immunophenotypes contribute to predict survival of triple-negative breast cancer assessed as Miller-Payne grade 4 and N0 after neoadjuvant therapy

Jianli Ma[1], Yuwei Deng[2], Dawei Chen[1], Xiaomei Li[3], Zhiyong Yu[4], Haibo Wang[5], Lei Zhong[6], Yingjie Li[7], Chengqin Wang[8], Xiaoping Zhou[2], Xiang Li[2], Qingyuan Zhang[2], Jinming Yu[1]. *[1]Radiation Oncology, Shandong University Cancer Center, Jinan, China,[2]Medical Oncology, Harbin Medical University Cancer Hospital, Harbin, China,[3]Pathology, Harbin Medical University Cancer Hospital, Harbin, China,[4]Breast Cancer Center, Shandong University Cancer Center, Jinan, China,[5]Breast Disease Center, The Affiliated Hospital of Qingdao University, Qingdao, China,[6]Breast Surgery, the Second Affiliated Hospital of Harbin Medical University, Harbin, China,[7]Pathology, the Second Affiliated Hospital of Harbin Medical University, Harbin, China,[8]Pathology, the Affiliated Hospital of Qingdao University, Qingdao, China*

Objectives Some Miller-Payne 4 and N0 patients with triple-negative breast cancer (TNBC) after neoadjuvant chemotherapy (NACT) who had better survival should avoid treatment escalation. We aimed to identify these patients based on spatial distributions of immunophenotypes at initial diagnosis.

Methods We retrospectively analyzed 272 TNBC patients with Miller-Payne grade 4/5 and N0 for tumor-infiltrating lymphocytes (TILs) in relation to clinical survival. The spatial immunophenotypes were analyzed

by multiplexed ion beam imaging by time of flight combined with proteomic. A prognostic classifier was established by the random forest algorithm.
Results The 5-year disease-free survival (DFS) was 63.8% for Miller-Payne 4 and 83.0% for Miller-Payne 5 (p=0.003), and overall survival (OS) was 71.0% and 85.5% respectively (p=0.007). High TILs were significantly associated with better DFS and OS in the Miller-Payne 4 patients (both p=0.016). Spatially, Miller-Payne 4 with good prognosis exhibited inflamed phenotype, with dominant CD8+ T cells on tumor center, few scattered CD68+ myeloid-derived cells far away from T cells, and deposit of increased lymphocyte activate molecules. Miller-Payne 4 with poor prognosis presented excluded phenotype, with few CD8+ T cells restricted to invasive margin, high density of $CD14^{+}CD68^{+}CD11c^{+}$ myeloid cells with related molecules. These spatial immunophenotypes provided a good classifier model (AUC=0.975) to identify Miller-Payne 4 patients with different prognosis. We also observed similar signatures in Miller-Payne 5.
Conclusion Spatial immunophenotypes may indicate the prognosis in TNBC assessed as Miller-Payne 4 and N0.

LDH inhibition boosts effector T cells while destabilizing regulatory T cells and improves responses to CTLA-4 blockade
Svena Verma[1], Inna Serganova[1], Lauren Dong[2], Sadna Budhu[2], Levi Mangarin[3], Roberta Zappasodi[4], Taha Merghoub[5], Jedd D. Wolchok[6].
[1]Weill Cornell Medicine, New York, NY,[2]Pharmacology, Weill Cornell Medicine, New York, NY,[3]Meyer Cancer Center, Weill Cornell Medicine, New York, NY,[4]Medicine, Weill Cornell Medicine, New York, NY,[5]Pharmacology, Meyer Cancer Center, Weill Cornell Medicine, New York, NY,[6]Meyer Cancer Center, Immunology, Weill Cornell Medicine, New York, NY

Tumor reliance on glycolysis is a hallmark of cancer and a mechanism of resistance to immunotherapy. This resistance is due to lactate-mediated immune suppression and competition for glucose between T cells and tumor cells within the tumor microenvironment. We have shown that CTLA-4 blockade is more effective in glycolysis-low tumors, or tumors

lacking functional lactate dehydrogenase A (LDH-A), primarily due to functional destabilization of regulatory T cell suppression. LDH inhibitors (LDHi) have been reported to inhibit tumor glucose uptake and slow tumor cell proliferation in pre-clinical models of cancer. However, their effect on immune cells has not been explored in depth. In addition, the optimal conditions for pharmacological inhibition of LDH in combination with immunotherapy to maximize anti-tumor immune and therapeutic responses require further investigation. At baseline, tumor cells express higher levels of *ldha* and consume more glucose than tumor-infiltrating T cells, creating a therapeutic window for tumor-specific targeting of the glycolysis pathway. In vivo, LDHi relies on the adaptive immune system and the overexpression of tumor LDH to delay B16F10 murine melanoma progression. We found that treatment with LDHi has two effects: 1) reduction of tumor cell glucose uptake and 2) increase in glucose uptake by tumor-infiltrating T cells. Thus, LDH inhibition is an effective, tumor-specific strategy to reduce tumor cell glucose uptake and increase glucose availability within the tumor microenvironment, consequently boosting tumor-infiltrating T cell glucose uptake. *In vitro,* increased glucose levels improve effector T cell killing of tumor cells while reducing regulatory T cell suppressive ability. Accordingly, inhibiting LDH in combination with CTLA-4 blockade is more effective in controlling tumor progression compared to CTLA-4 blockade alone, and that this combination promotes effector T cell infiltration and activation, while destabilizing regulatory T cell function. Additionally, we observe serum LDH and lactate levels correlate with primary tumor burden as well as tumor LDH levels. Therefore, serum LDH may serve as a biomarker for tumor burden and tumor LDH, as well as clinical response to LDHi. This study provides a comprehensive rationale for combining immune checkpoint blockade with inhibitors of glycolysis for patients with highly glycolytic cancers.

HSF1 downregulation of CCL5 reduces CD8 T cell trafficking in breast cancer

Curteisha LeeAnn Jacobs, Sakhi Shah, Wen-Cheng Lu, Richard Carpenter, Haimanti Ray, Xin Lu, Sha Cao. *Indiana University School of Medicine, Bloomington, IN*

Breast cancer is the leading cause of cancer related deaths in women. The presence of cytotoxic immune cells, specifically CD8+ T cells, in breast tumors is associated with better patient outcomes. Our goal is to understand mechanisms that regulate the infiltration of CD8+ T cells. This will in turn, improve the treatment and enhance patient overall survival. Utilizing a novel HSF1 activity gene signature, we observed that HSF1 activity was negatively associated with the presence of CD8+ T cells in breast cancer patients. Both CIBERSORT analysis of TCGA data as well as direct assessment of patient primary specimens demonstrated that patient tumors with high HSF1 activity had lower numbers of CD8+ T cells. To functionally test this relationship, HSF1 was knocked down in 4T1 breast cancer cells and grown orthotopically in BALB/c mice. Tumors with HSF1 knockdown showed lower tumor volumes and increased CD8+ T cell infiltration. We subjected the control and knockdown tumors to single- cell RNA sequencing analysis and found increased immune cell presence specifically CD8+ T cell presence in knockdown tumors. We further tested the effect of CD8+ T cells on the growth of HSF1 knockdown tumors by depleting CD8+ T cells in BALB/c mice. HSF1 knockdown tumors were significantly larger with CD8+ T cell depletion suggesting a functional role for HSF1 to inhibit CD8+ T cell infiltration and protect the tumor from immune-mediated killing. To investigate the mechanism by which HSF1 affects CD8+ T cells, we investigated whether HSF1 affects chemotactic cytokines. We found that loss of HSF1 significantly increased secretion of CCL5, a known chemoattractant for CD8+ T cells. Loss of HSF1 also increased mRNA levels of CCL5, suggesting a transcriptional effect on CCL5. To test the importance of CCL5 in the phenotype of HSF1 knockdown, a transwell migration assay was performed wherein T cells from BALB/c mice were placed in the upper chamber of a transwell chamber and the lower chamber contained conditioned medium from 4T1 cells with knockdown of HSF1 with or without knockdown of CCL5. The lower chamber was subjected to flow cytometry for CD3/CD8 to identify CD8+ T cells and we observed that loss of HSF1 increased migration of CD8+ T cells and this was ablated with additional loss of CCL5. These results suggest CCL5 is a significant mediator for the recruitment of CD8+ T cells when HSF1 is lost in cancer cells. We propose the model whereby high HSF1 activity in breast cancer cells suppresses expression and

secretion of the chemo-attractant cytokine CCL5 that ultimately leads to a decrease in CD8+ T cells in breast tumors microenvironment.

Rab37 mediates intracellular trafficking and membrane presentation of PD-1 in T cells to foster an immunosuppressive microenvironment in lung cancer

Wan-Ting Kuo[1], I-Ying Kuo[1], Shih-Ting Wu[1], Wu-Chou Su[2], Yi-Ching Wang[1]. *[1]National Cheng-Kung University, College of Medicine, Department of Pharmacology, Tainan, Taiwan,[2]National Cheng-Kung University, College of Medicine, Division of Oncology, Department of Internal Medicine, Tainan, Taiwan*

Programmed cell death protein 1 (PD-1) expressed on the surface of $CD8^+$ T cells is known as an immune checkpoint protein. High expression of PD-1 leads to T-cell dysfunction in the tumor microenvironment (TME). Our published studies show that Rab37 small GTPase-mediated vesicular trafficking of cell surface proteins and cytokines is critical in immunosuppressive TME. Here, we identify novel mechanisms of intracellular trafficking and plasma membrane presentation of PD-1 mediated by Rab37. Confocal immunofluorescence (IF) and vesicles isolation data demonstrated that PD-1 colocalized with Rab37-specific vesicles in T cells in a GTP-dependent manner. Total internal reflection fluorescence imaging, membrane fractionation, and flow cytometric analyses confirmed the dynamic trafficking and membrane presentation of PD-1 by Rab37. In addition, sucrose density gradient centrifugation and IF revealed that the level of glycosylated wild-type PD-1 in membrane compartment was more than glycosylation mutant PD-1, suggesting that glycosylation mutant PD-1 delayed in recruitment to the Rab37 vesicles and thus stalled in membrane presentation. Furthermore, T cell proliferation and activity were downregulated in *Rab37* wild-type splenocytes co-cultured with cancer cells compared to those from *Rab37* knockout mice using various T cell functional assays. Clinically, the multiplex IF-immunohistochemical assay indicated that the tumor infiltrated $Rab37^+/PD1^+/TIM\text{-}3^+/CD8^+$ exhaustion T cells were more in late staged lung cancer patients compared to those in early staged patients. Importantly, patients with $Rab37^+/PD\text{-}1^+/TIM\text{-}3^+/CD8^+$ tumor infiltrated T cells

expression profile correlated with poor overall survival. Our results provide first trafficking mode of PD-1 mediated by Rab37 small GTPase and novel evidence of the tumor promoting function of Rab37/PD-1 axis in T cells of the tumor microenvironment.

Sorafenib and Lenvatinib induce vascular responses in patient derived HCC on-Chip models

Orsola Mocellin[1], Abbie Robinson[1], Aleksandra Olczyk[1], Stephane Treillard[2], Thomas Olivier[1], Chee Ng[1], Jeroen Heijmans[3], Désiréé Goubert[1], Arthur Stok[1], Gilles van Tienderen[4], Monique Verstegen[4], Sebastian Trietsch[1], Henriëtte Lanz[1], Paul Vulto[1], Jos Joore[1], Karla S. Queiroz[3]. *[1]MIMETAS, Oegstgeest, Netherlands,[2]MIMETAS, oegstgeest, Netherlands,[3]MIMETAS, Leiden, Netherlands,[4]Erasmus MC, Rotterdam, Netherlands*

Hepatocellular carcinoma (HCC) is the most common type of liver cancer. Its incidence is increasing, and is closely related to advanced liver disease. Interactions in the HCC microenvironment between tumor cells and the associated stroma actively regulate tumor initiation, progression, metastasis, and therapy response. In the present study, we used the OrganoPlate graft to establish a co-culture system consisting of dissociated HCC tumors (HCC 1-8) and cell lines, HCC derived fibroblasts and vasculature. Cultures were prepared and validated by assessing their response to Sorafenib and Lenvatinib (72 hours). Cultures had their viability (alamar blue assay), and chemokine/cytokine levels in the supernatant (Luminex) determined. In addition, the organization of the vasculature in the tumor compartment was studied through immunostainings, confocal imaging, and subsequent morphological analyses. HCC models were characterized by a range of specific markers, tumor (albumin), endothelial (CD31 and VE-Cadherin) and stromal (aSMA) cells. CD31 immunostained cultures were imaged, and morphology changes quantified. Sorafenib and Lenvatinib induced changes in the tumor vasculature area and organization. Hereby, we present vascularized patient-derived HCC models that include relevant cellular players of the HCC microenvironment. These co-cultures are highly suitable for studying specific cell types as well as patient-specific responses. We envision that this patient derived model will evolve to

become a platform for understanding the interplay between angiogenesis, stroma and immune infiltrate in HCC.

Intratumoral lymphocyte networks harbor TCF1+ PD1+ progenitor CD8 T cells in lung cancer

Megan L. Burger[1], Giorgio Gaglia[2], Claire C. Ritch[2], Danae Rammos[2], Yang Dai[2], Grace E. Crossland[3], Sara Z. Tavana[3], Simon Warchol[4], Alex M. Jaeger[3], Santiago Naranjo[3], Shannon Coy[2], Ajit J. Nirmal[2], Robert Krueger[5], Jia-Ren Lin[2], Hanspeter Pfister[4], Peter K. Sorger[2], Tyler Jacks[3], Sandro Santagata[2]. *[1]Oregon Health and Science University, Portland, OR,[2]Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA,[3]Koch Institute, Massachusetts Institute of Technology, Cambridge, MA,[4]School of Engineering and Applied Sciences, Harvard University, Boston, MA,[5]Harvard Medical School, Boston, MA*

Cancer immunotherapies that activate cytotoxic T cell responses against tumors have been remarkably effective in some patients, but the determinants of response remain unclear. To investigate how spatial organization of T cells might influence immunotherapy response, we developed a tissue-based cyclic immunofluorescence (t-CyCIF) platform to characterize preclinical genetically engineered mouse models (GEMMs) of cancer. We optimized a 21-antibody panel delineating major myeloid and lymphoid cell subsets, that included key markers for characterizing T cell phenotypes and function. The panel was used to characterize the Kras/p53-mutant GEMM of lung adenocarcinoma, treated with anti-PD-1/anti-CTLA-4 immune checkpoint blockade (ICB) therapy or a neoantigen-targeted long-peptide vaccine. Spatial profiling by t-CyCIF identified intratumoral lymphocyte networks (“lymphonets”) as a key feature associated with a productive immune response against lung tumors. Lymphonets were predominantly composed of B cells and conventional CD4 T cells, but harbored tumor-reactive CD8 T cell populations. TCF1+ PD1+ progenitor CD8 T cells, a subset previously correlated with patient response to ICB, were almost exclusively localized to lymphonets inside tumors. Lymphonets of similar composition harboring TCF1+ PD1+ cells were also found in early-stage human lung adenocarcinomas. In response to

ICB and vaccine therapies in mice, cytotoxic CD8 T cells (Granzyme B+/Perforin+) colocalized with TCF1+ PD1+ cells in lymphonets, likely having differentiated from this progenitor pool. Notably, vaccination further induced a highly proliferative ($Ki67^{hi}$) and cytotoxic ($GranzymeB^{hi}Perforin^{hi}$) population of CD8 T cells localized outside of tumors that we posit enter tumors without passing through the intratumoral progenitor cell state. Upon becoming dysfunctional, marked by loss of Granzyme B/Perforin expression and upregulation of inhibitory receptors, CD8 T cells were excluded from lymphonets and localized predominantly to the tumor margin. Altogether, these results shed light on the spatial dynamics associated with a productive response to immunotherapies and open avenues for exploration into the function of lymphonets in supporting cytotoxic CD8 T cell responses in tumors.

Defining the cancer Immunogram using multimodal analysis to guide immunotherapy in diffuse large B cell lymphoma

Michael D. Mattie[1], Regis Perbost[2], Sarah Turcan[2], Corinne Danan[2], Frederick L. Locke[3], Sattva S. Neelapu[4], David B. Miklos[5], Caron A. Jacobson[6], Lazaros J. Lekakis[7], Yi Lin[8], Armin Ghobadi[9], Jenny J. Kim[10], Zixing Wang[11], Allen Xue[1], Simone Filosto[1], Nathalie Scholler[12], Jerome Galon[13]. *[1]Translational Medicine, Kite Pharma, a Gilead company, Santa Monica, CA,[2]Veracyte, Marseille, France,[3]Moffitt Cancer Center, Tampa, FL,[4]MD Anderson Cancer Center, Houston, TX,[5]Stanford University School of Medicine, Palo Alto, CA,[6]Dana Farber Cancer Institute, Boston, MA,[7]University of Miami Health System, Sylvester Comprehensive Cancer Center, Miami, FL,[8]Mayo Clinic, Rochester, MN,[9]Washington University School of Medicine, St. Louis, MO,[10]Clinical Development, Kite Pharma, a Gilead company, Santa Monica, CA,[11]Biostatistics, Kite Pharma, a Gilead company, Santa Monica, CA,[12]Gilead Sciences, Foster City, CA,[13]Laboratory of Integrative Cancer Immunology, INSERM, Sorbonne Universite, Universite Paris Cite, Centre de Recherche des Cordeliers, Equipe Labellisee Ligue Contre le Cancer, Paris, France*

(a) Expansion of therapeutic strategies against diffuse large B-cell lymphoma (DLBCL) offers new opportunities to fight aggressive non-

Hodgkin's lymphoma. Therapy approaches, such as R-CHOP and stem cell transplant, and CAR-T cell therapies are now available for the treatment of DLBCL. While the role of the tumor microenvironment (TME) during the therapeutic response is now recognized, the spatial organization and the communication between the diverse factors that compose the TME remains to be fully understood. In this study, we describe a new immunogram tool to help clinical researchers measure the tumor microenvironment contribution to drug efficacy or toxicity in DLBCL context.
(b) In a previous work, using a high-quality testing and innovative multimodal and integrative approach, we constructed the first Veracyte Biopharma Atlas for DLBCL lesions. Based on this knowledge and the understanding of the immune contexture of tumors, we constructed an immunogram using the scoring of clinically relevant biomarkers.Our immunogram scoring approach is composed of key features driving computational derivation of DLBCL Atlas clusters, which include immune gene signatures, immune cell phenotyping combined with spatial information, and genomic and clinical parameters.
(c) Patterns that strongly associated with CAR-T treatment response were determined. In addition, promising results have been obtained in the prediction to CAR-T toxicity related to T-regulatory cells or R-CHOP response with transcriptomic signature.
(d) Retrospective analysis of CAR-T clinical trial data and tumor biopsies highlighted the Veracyte Immunogram as a powerful tool to score the patient probability of response to CAR-T. This work provides the framework for identification of predictors of response to therapy, potential targets of interest or biomarkers that could be applied in future clinical trials.

The role of SOAT1 on $CD8^+$T cells-mediated immune response in ovarian cancer

Jiangnan He, Michelle K.Y. Siu, Runying Long, Ruiqian Zhang, Mingo M.H. Yung, Hextan Y. S. Ngan, Karen K.L. Chan. *Obstetrics and Gynecology, University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, China*

Introduction: Sterol-O acyltransferase 1 (SOAT1) functions by converting cholesterol and acyl-CoA into cholesterol ester and coA-SH. High SOAT1 expression with its mediated tumorigenesis has been shown in multiple cancers. Studies showed that SOAT1 inhibition by its inhibitors augmented the outcome of immunotherapies, in terms of the immune checkpoint blockades, cancer vaccines, and CAR-T cells, by boosting the function of T cells. However, in order to have a better understanding of the role played by SOAT1 in the tumor microenvironment of ovarian cancer (OC) and optimize strategies of combination immunotherapy, it's necessary to detect the role of SOAT1 in OC cells on T cell-mediated immune response.
Methods: *SOAT1* knockdown was manipulated by siRNAs transfection. SOAT1 was inhibited by avasimibe and OC cells were treated in different doses of avasimibe. qPCR was performed to detect gene expressions in ovarian cancer cells. T cells, isolated and activated from healthy donors, were cocultured with SOAT1-silenced and avasimibe pre-treated OC cells and their tumor-conditioned medium (TCM). Flow cytometry analysis was used to measure cytotoxic secretory molecules of human T cells, like IFN-r, TNF-a, and Granzyme B.
Results: The downregulation of intracellular cytotoxic cytokines was shown in the T cells cocultured with SOAT1-silenced and avasimibe-pretreated OC cells or treated by their TCM, thereby impairing the cytotoxic capacity of T cells, compared to the corresponding control group. qPCR results showed that several immunosuppressive cytokines, like IL-6, IL-8, TGF- were upregulated in the SOAT1-silenced or avasimibe-treated OC cells.
Conclusion:SOAT1 inhibition in ovarian tumor cells impairs $CD8^+$ T cell cytotoxic function, to some extent, via the upregulation of immunosuppressive-related cytokines.

PERIO-01: Initial safety experience and immunologic effects of a Class C TLR9 agonist using pressure- enabled drug delivery in a phase 1 trial of hepatic arterial infusion of SD-101 +/- checkpoint inhibition in metastatic uveal melanoma

Sapna P. Patel[1], Cara Haymaker[1], Rahul A. Sheth[1], Joshua D. Kuban[1], Joshua Weintraub[2], Eric Wehrenberg-Klee[3], Paula Novelli[4], Carin Gonsalves[5], Robert Adamo[5], Virgina Honaker[1], Laura Timciuc[1], Tarin Hennegan[1], Juan C. Amador Molina[1], Dzifa Duose[1], Edwin R. Parras

Cuenta[1], Anthony Lucci[1], Salyna Meas[1], Vanessa Sarli[1], Victor G. Prieto[1], Jason LaPorte[6], Ann-Marie Hulstine[6], Ashley Moody[6], Bryan Cox[6], David Geller[4], Diwakar Davar[4], Kamaneh Montazeri[3], Marlana Orloff[5], Steven C. Katz[6], Richard Carvajal[2]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Columbia University Irving Medical Center, New York, NY,[3]Massachusetts General Hospital, Boston, MA,[4]University of Pittsburgh Medical Center, Pittsburgh, PA,[5]Thomas Jefferson University, Philadelphia, PA,[6]TriSalus Life Sciences, Westminster, CO*

Immune checkpoint inhibitors (ICI) have demonstrated limited success in patients with metastatic uveal melanoma (MUM) with liver involvement due to an immunosuppressive tumor microenvironment (TME) driven in part by myeloid-derived suppressor cells (MDSCs). Toll-like receptor-9 agonists (TLR-9A) have improved ICI response rates in cutaneous melanoma, but delivery challenges have limited their application for MUM. Hepatic arterial infusion (HAI) of TLR-9A using a pressure-enabled drug delivery™ (PEDD™) device has the potential to enhance responsiveness to ICI by optimizing delivery to intrahepatic tumors and reprogramming the TME, including elimination of MDSCs.PERIO-01 is an open-label first-in-human Phase 1 trial of SD-101 given by HAI using a PEDD™ in MUM (NCT04935229). The study consists of dose-escalation cohorts of single agent SD-101 alone and with ICI. SD-101 is delivered over 2 cycles, with 3 weekly doses per cycle. Research blood, tumor and normal liver biopsies are collected serially for correlative studies. At data cutoff, a total of 20 patients were enrolled, with 13 in the single agent dose escalation cohort (2, 4, and 8 mg) and 7 patients with SD-101 (2 mg) + nivolumab. The median age was 65.5 years with an equal gender distribution. Only 2 patients were treatment-naïve and the median number of liver metastases was 5.1. The average number of SD-101 infusions was 5.2. One patient in the combination cohort experienced a serious adverse event related to treatment - asymptomatic Grade 3 increase in liver enzymes. PEDD™ resulted in high drug levels in the liver (up to 2,340 ng/ml at 8mg) with only transient exposure in the periphery (<4 hours) with one Grade 2 cytokine related syndrome adverse event. Dose-dependent increases in canonical TLR9-associated cytokines (IL-18, IFNγ, IP-10, and soluble CD25) was observed across the 2mg, 4mg, and 8mg single-agent dose levels. Concordant with

predicted mechanism of action, PEDD^{TM} HAI administered SD-101 resulted in decreases in liver monocytic MDSCs in 4 of 4 patients with available multiplex immunofluorescence data. NanoString analysis from three patients revealed increases in ISG15, IL-9, IFNα, and IL-2 transcripts and decreases in ARG1 and IDO transcripts, with increased scores for macrophages, activated CD8 T cells, Th1 cells, and Th1 activation. For patients who received 2mg SD-101 + ICI with available liquid biopsy data, 4 of 7 demonstrated decreases in circulating tumor cells and 3 of 5 showing ctDNA decreases after the first cycle.In this first-in-human experience, HAI of SD-101 via PEDD^{TM} was well tolerated and associated with encouraging immunologic activity. Evidence of biologic activity with 2 mg of SD-101 with nivolumab is encouraging and patients are currently enrolling at higher SD-101 dose levels + ICI.

Prevention of antibiotic-induced dysbiosis in human volunteers by DAV132 and preservation of responsiveness to anti-PD-1 demonstrated by transplantation of human feces into tumor-bearing mice

Meriem Messaoudene[1], Nathalie Saint-Lu[2], Frédérique Sablier-Gallis[2], Stéphanie Ferreira[2], Mayra Ponce[1], Clément Le Bescop[2], Thomas Loppinet[2], Tanguy Corbel[2], Céline Féger[1], Fabien Vitry[2], Antoine Andremont[2], Jean de Gunzburg[2], Bertrand Routy[1]. *[1]University of Montreal, Montreal, QC, Canada,[2]Da Volterra, Paris, France*

Background: Over the last decade, studies unraveled the cancer-immune dialogue in the setting of immune checkpoint inhibitors (ICI) and influenced by the gut microbiota. The first evidence of the key role of the microbiota in ICI modulation was observed during antibiotics (ATB) treatment, where altering the microbiota composition by ATB inhibited ICI responses. DAV132 (DAV) is an orally administered colon-targeted ATB adsorbent capsules designed to prevent ATB-induced dysbiosis. We investigated whether DAV co-administered with ATB could prevent ATB-related dysbiosis and ICI response.

Methods: 72 human healthy volunteers (HV) were randomized to receive either IV ceftazidime-avibactam (CZA) or Piperacillin tazobactam (PTZ) alone or in combination with oral DAV. CZA and PTZ plasmatic and fecal

pharmacodynamic levels were measured using HPLC-MS/MS. Microbiome was profiled with metagenomics at different timepoints. FMT experiments in germ-free mice were performed using fecal samples from HV from the trial, before (D1) or after 6 days (D6) of CZA or PTZ+/-DAV; subsequently mice were inoculated with MCA205 or B16 tumors and treated with anti-PD-1. Tumor infiltrating lymphocytes (TILs) were analyzed by flow cytometry.
Results: DAV did not impact plasmatic CZA or PTZ concentrations, but significantly reduced ceftazidime and piperacillin concentrations in feces compared to ATB groups alone. DAV significantly prevented the reduction in microbiota alpha-diversity at D6 and was associated with a rapid return to baseline microbiota. 50 and 43 metagenomics species were preserved in the CZA+DAV *vs* CZA, or PTZ-DAV vs PTZ such as *Faecalibacterium praunistzii, Alistipes Spp and Blautia obeum*. FMT in germ-free mice using feces collected at D1 exhibited a significant anti-PD-1 activity. This anti-tumor response was inhibited in two tumors models in mice transplanted with D6 feces from patients in the CZA or PTZ alone groups. Conversely, the anti-tumor response was maintained in mice transplanted with D6 feces from HV treated with CZA+DAV or PTZ+DAV groups. Flow cytometry on TILs demonstrated that CZA decreased $CD8^+$T cell and $CD8^+$/Treg ratio compared to CZA+DAV.
Conclusions: DAV prevented ATB-induced dysbiosis in HV treated with CZA or PTZ without influencing plasmatic concentrations. In avatar mice FMT from HV treated with CZA+DAV was able to preserve anti-PD-1 efficacy. These results provide rationale to launch clinical trials combining DAV in patients on ATB amenable to ICI.

Computational analysis of immune synapses in melanoma tumor microenvironment
Zichao Liu, Victor G. Wang, Jan Martinek, Ali Foroughi pour, Jie Zhou, Karolina Palucka, Jeffrey H. Chuang. *The Jackson Laboratory for Genomic Medicine, Farmington, CT*

High-resolution multiplexed tissue imaging such as imaging mass cytometry (IMC) has enabled quantitative cell characterization with preserved tissue architecture. However, the subcellular resolution

information has not been fully leveraged yet, as most analyses have focused on cellular or compartment level features. Here, we have developed a robust computational approach integrating cellular spatial and molecular features in multiplexed images to quantify immune synapses. Our approach enables computational detection of subcellular enrichment of T cell co-receptors at immune synapses, which are key regulators of T cell functions in the tumor microenvironment (TME). We quantified immune synapse strength between T cells and various antigen-presenting cells in tumor regions in one melanoma whole tissue immunofluorescence dataset and two independent melanoma IMC datasets covering 99 patients. We observed that sub-localizations of immune synapse-related molecules are highly correlated, e.g. CD3 with CD8. These co-localizations are cell type-specific, with differential behaviors in CD4+ or CD8+ T subtypes. Intra-tumoral T-cell-myeloid synapses are associated with improved T cell proliferation ($p = 2.8E-4$). In addition, we also observed that cytotoxic T cell - melanoma synapses in immune rich regions are stronger in immune checkpoint inhibition therapy responders than in non-responding patients ($p = 0.013$). Our approach enables computational resolution of spatial inter-cellular interactions within the TME, is applicable across imaging modalities, and facilities assessment of biological and clinical significance.

#5884

Targeting T regulatory cells to intercept progression from preinvasive to invasive lung adenocarcinoma using a novel KRAS-driven murine model

Mitchell Martin, Michael J. P. Crowley, Geoffrey Markowitz, Alain Borczuk, Chen Zhang, Liron Yoffe, Arshdeep Singh, Nasser K. Altorki, Vivek Mittal. *Cardiothoracic Surgery, Weill Cornell Medicine, Memorial Sloan Kettering Cancer Center, New York City, NY*

Non-small cell lung cancer is the leading cause of cancer-related death in the US and worldwide, with a 5-year survival of ~18-20%. Understanding of the biology of early lung cancer is necessary to intercept early steps of progression. Indeed, increased utility of low-dose CT guided lung cancer screens in populations at risk have begun to detect early premalignant disease; however, little is known about the underlying biology that drives progression of preinvasive lesions to invasive adenocarcinoma. Moreover,

there exists a lack of reliable animal models to assess interception strategies to target disease progression. We have developed and characterized a lung cancer cell-of-origin-specific KRAS-driven mouse model which accurately mirrors progression of human precursor lesions to invasive disease. Transcriptional analysis of preinvasive and invasive stages identified cellular and molecular alternations observed in human lesions, including upregulation of cell proliferation, extracellular matrix remodeling, and an increasingly complex immune microenvironment. Interrogation with immunofluorescence microscopy and Hyperion mass cytometry imaging showed marked reprogramming of the immune microenvironment including increased T cell infiltration and abundance of T regulatory cells (Tregs). Surprisingly, depletion of T cells impaired progression of preinvasive lesions, implicating the critical immunosuppressive roles of Tregs. Spatial transcriptomics (10X Genomics Visium) revealed unique spatial transcriptional changes in the progression from preinvasive to invasive stage disease, including specific ligand-receptor interactions highly expressed in Tregs. Genetic and pharmacological approaches using FoxP3-DTR-GFP mice and low dose cyclophosphamide have begun to define the functional role of Tregs in early premalignant disease.
This study demonstrates critical roles of immunosuppressive Tregs in driving progression of preinvasive to invasive lung cancer, and advocates for Treg targeting as a potent immunoprevention approach for patients at risk of developing lung cancer.

A pathway-centric approach to characterising tumour heterogeneity and cell diversity across multiple cancer types

Leiam Colbert, Benjamin Patterson, Cheng Yi Chen, Nicolas Fernandez, Jiang He. *R&D, Vizgen, Boston, MA*

Biological tissues are composed of heterogeneous populations intricately organized in 3D architectures, yet cell type composition and spatial organization remain largely unknown for most tissue types. Single-cell sequencing analysis provides a systematic and quantitative approach to identify cell types and determine their composition in tissues. However, the spatial organization of cells and cell-cell interactions that are critical for tissue function are lost when cells are dissociated from tissue. This is

especially important when working with the complex microenvironment of a tumour where such information is needed to fully understand patient prognosis. Complex diseases such as cancer can be better understood from the perspective of dysregulated pathways, rather than as a disease resulting from alterations of individual genes. Recently, spatially resolved, single-cell imaging platforms have provided a necessary solution to bridge the spatial information gap evident in previous transcriptomic methodologies. Vizgen's MERSCOPE platform, built on multiplexed error robust in situ hybridisation (MERFISH) technology, enables the direct profiling of the spatial organisation of intact tissue with subcellular resolution. Here, we present a Pan-Cancer approach to characterise various cancers in human clinical samples with MERSCOPE. Using a 500-gene panel that includes the canonical signalling pathways of cancer, cancer type-specific genes, key immune genes, proto-oncogenes, and tumour-suppressor genes we demonstrate MERSCOPE's ability to spatially profile gene expression across multiple tumour samples, including breast, colon, prostate, ovarian, lung, and skin cancer. To confirm the specificity and sensitivity of our pathway-focused gene panel, we assessed how tumour cell clusters in each dataset expressed different cancer type-specific markers. As expected, we found specific cancer types enriched in corresponding marker genes. To further evaluate how individual cell types in each tumour are dysregulated by cancer, we compared non-tumour cell clusters to similarly annotated clusters derived from single-cell RNA-sequencing data of normal tissue. Notably, the non-tumour cells in these datasets exhibit higher expression of stress and inflammation pathways, while immune cell clusters demonstrate higher immune activity and higher immune exhaustion compared to those in normal tissue. These results demonstrate the power of the MERSCOPE platform to generate individualised, accurate cell atlases from patient-derived tumours and to enable further insights into the relationship between genomic profiles, dysregulated pathways, and disease phenotype. Such network-centric approaches are critical for identifying genotypic causes of diseases, classifying disease subtypes, and identifying drug targets.

Targeting IDO1 and TDO2 is crucial for the modulation of immune effector in platinum resistant non-small cell lung cancer

Sydney Spector[1], Chunjing Wu[1], George Theodore[1], Jonathan Dan Nguyen[1], Emily Kim[1], Ashley Garcia[1], Niramol Savaraj[1], Diane Lim[1], Lynn Feun[2], Medhi Wangpaichitr[1]. *[1]Univ. of Miami/VA Medical Ctr., Miami, FL,[2]Univ. of Miami, Miami, FL*

The impact of non-small cell lung cancer (NSCLC) tumor metabolism on the immune microenvironment is not well understood in the context of platinum resistance. We have identified and characterized crucial metabolic differences between cisplatin-resistant (CR) and cisplatin-sensitive (CS) NSCLC cells in which CR cells possessed higher indoleamine 2,3-dioxygenase-1 (IDO1) activity as determined by an increase in extracellular kynurenine concentration *in vitro* and *in vivo*. Utilizing *in vitro* co-culture models (n=6), we showed that IDO-mediated kynurenine production from CR cells suppressed natural killer group 2 member D (NKG2D) on natural killer (NK) and CD8+ T cells, but enhanced immunosuppressive regulatory T cell (Treg) and myeloid-derived suppressor cells (MDSC) populations. Utilizing syngeneic (n=7) and humanized (n=5) mouse models, mice with CR tumors exhibited a more highly immunosuppressive environment that blocked the antitumor immune response. Inhibition of IDO1 by the selective IDO1 inhibitor epacadostat (200 mg/kg P.O. once a day for 15 days) attenuated tumor growth in these CR tumor-bearing mice. Interestingly, we found an induction of tryptophan 2,3-dioxygenase-2 (TDO2) enzyme in epacadostat-treated mice. To overcome this compensatory effect induced by IDO1 inhibition, mice were treated with a novel IDO1/TDO2 dual inhibitor (AT-0174; Antido Therapeutics Pty Ltd, Melbourne, Australia) at 170 mg/kg P.O. once a day for 15 days. Dual inhibitors suppressed tumor growth to a greater degree than IDO1 inhibitors in CR conditions, and significantly enhanced immune effector populations as well as suppressed immunosuppressive Tregs and MDSC population in CR tumors. In addition, increased expression of programmed death-ligand 1 (PD-L1) was observed in CR cells, we assessed the effects of combination treatment of AT-0174 + anti-PD1 antibody. This combined therapy produced a profound anti-tumor effect in CR tumors and extended survival in mice. Our data support an increase in the therapeutic efficacy of blocking both IDO1/TDO2 in treating CR lung cancer by enhancing tumor immune surveillance. Thus, inhibiting the kynurenine pathway may be a more suitable therapeutic approach in a subgroup of lung cancer patients who

failed platinum therapy and lead to improved outcomes in the treatment and management of NSCLC. Support by Dept. of Veterans.

Interactions Between the Microbiome, Cancer Cells, and Tumor Stromal Components

Distinct differences in microbial enrichment and diversity identified between gastric and gastroesophageal junction adenocarcinoma

Miseker Abate[1], Harrison Drebin[1], Shoji Shimada[1], Santosh Vardhana[2], Smita Sihag[3], Vivian E. Strong[1], Chad Vanderbilt[4]. *[1]Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Thoracic Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY*

Objective: The microbiome is associated with the pathogenesis and progression of disease in gastric cancer (GC). Eradication of *Helicobacter pylori* has reduced overall GC incidence, however, gastroesophageal cancer (GEJC) continues to increase. While there are oncologic differences between GEJC and GC, distinctions based on microbial profiles are unknown. In this study, we characterize differences in the microbial profiles of GEJC and GC.
Methods: 562 patients with microsatellite stable GC (n=303) and GEJC (n=259) who had an institutional Integrated Mutation Profiling of Actionable Cancer Targets assay on the primary tumor were included in the study. A validated microbiome bioinformatics pipeline that is generalizable across multiple next generation sequencing platforms was utilized to compare microbial enrichment and alpha diversity between GC and GEJC, defined by type 1-3 Siewert classification.
Results: Over 20 unique microbial species were enriched in GC when compared to GEJC, including *Helicobacter* and *Lymphocryptovirus* (Table 1). *Prevotella* had increased incidence in GEJC (OR:1.57,95%CI:1.02,2.41). Siewert type 2 and 3 GEJC had a significantly lower alpha diversity compared to GC. There was no significant difference in alpha diversity between GC and Siewert type 1 GEJC.

Conclusion: There are distinct differences in microbial enrichment and alpha diversity between GEJC and GC. *Helicobacter* and *Lymphocryptovirus*, the genus family for Epstein Bar Virus, were noted to have the highest odds ratios in the GC group. Our findings showing the reduced incidence of microbes in GEJC which are the current targets of GC screening, prevention, and therapy, have implications in evaluating optimal preventative and treatment strategies in GEJC.

Table 1. Microbes with enrichment in gastric cancer (GC) when compared to gastroesophageal cancer (GEJC)

Microbes	**OR (95% Confidence Interval)**	**p-value**
Helicobacter	85.40 (5.191, 1404.81)	0.002
Lymphocryptovirus	6.83 (2.31,20.17)	0.001
Pelagibacterium	6.01 (1.71, 21.06)	0.005
Gluconacetobacter	5.14 (1.70, 15.53)	0.004
Myxococcus	5.14 (1.70, 15.53)	0.004
Kribbella	4.48 (1.46, 13.74)	0.009
Celeribacter	3.46 (1.43, 8.37)	0.006
Halomonas	3.46 (1.43, 8.37)	0.006

Identification of intratumor pathogens from single-cell RNA sequencing, cellular dysfunction and immune response

Laura Bukavina[1], Mohit Sindhani[2], Henkel Valentine[1], Daniel Ranti[3], Kirtishri Mishra[4], Alexander Kutikov[1], Shilpa Gupta[5], John Sfakiano[3], Mahmoud Ghannoum[6], Mauricio Retuerto[6], Andres Correa[1], Robert Uzzo[1], Philip Abbosh[1]. *[1]Fox Chase Cancer Center, Philadelphia, PA,[2]India Institute of Technology, Delhi, India,[3]Mount Sinai, New York, NY,[4]University Hospitals Cleveland Medical Center, Cleveland, OH,[5]Cleveland Clinic, Cleveland, OH,[6]Case Western Reserve, Cleveland, OH*

Introduction: We aim to assess the transcriptomic features of the single cell level to identify intracellular pathogens in patients with high grade bladder cancer.

Methodology: CellRanger and Alevin were utilized to extract cell barcodes and unique molecular identifiers. After quality control, reads were aligned with human reference genome with Kraken2 for species level identification of bacteria. Contaminants (false positives) were removed based on higher frequencies and negative control (reference control) of 2,491 sterile cell experiments. Seuret Findmarkers, scIntegrate, and scDensity Plot were utilized to normalize the data, cluster the cells, and calculate markers in each cluster of differentially expressed genes between the two conditions. We focused our analysis on *Pseudomonas aeruginosa* due to high urogenital virulence, and immunomodulation capabilities by pattern recognition receptors and inflammasome.

Results: We identified presence of three over-represented intracellular taxa in tissue biopsies of patients with BC compared to healthy controls (after false discovery rate correction and cross validation of contaminants). Patients with history of high-grade BC demonstrated increased presence of Aeromonas (175,473 reads, 54%), Pseudomonas (75,002 reads, 26.73%), and Bacillus (15,410 reads, 5.49%) in their tissue samples, not visualized in healthy controls (counts <10). Among 8,324 cells (across 7 patients), classical CD14+ monocyte subtype was most likely to be exposed to Pseudomonas species (4150 /5069, 81.8%), followed by non-classical CD16+ monocytes (722/1040, 69.4%), and CD8+ Tcells (348/680, 51.1%).

(Figure 1A-C). Relative gene expression level between exposed and non-exposed monocytes demonstrated total 25 upregulated genes, with increased expression *GNBL21* (aka: RACK1, *log10 4.1*), *MALAT1(log10 3.7), TCEB2(log10 2.9) (increasing proliferation, migration, and reduction of cell autophagy) compared* to non-infected, and normal controls. Pseudomonas involvement of non-monocyte cells (CD8+, CD4+Th17, CD4+ naïve) was associated with disease progression (2/5 patients), as well as increased expression of *IFI6/27*(interferon alpha inducible protein 6 &27), *ITAC* (interferon inducible T cell alpha-chemoattractant). Conclusion: Altogether, our analysis depicted the distribution of intracellular bacteria not previously recognized within tumor microenvironment utilizing scRNAseq, and revealed overexpression of *RACK1* in Pseudomonas positive cells, associated with apoptosis resistance.

Microbial diversity and composition according to short-term postoperative complication status in colorectal cancer patients

Hyeree Park[1], Tung Hoang[1], Min Jung Kim[2], Ji Won Park[2], Seung-Yong Jeong[2], Aesun Shin[1]. *[1]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of*

Background: Previous studies have suggested the disturbance in the microbial composition followed by dysbiosis contribute to the onset of gastrointestinal malignancies, including colorectal cancer (CRC). However, the impact of microbiome on short-term postoperative complications after CRC surgery is not well investigated. This study aimed to investigate whether the gut microbial diversity and composition in CRC patients were associated with the occurrence of short-term postoperative complications. Methods: We linked the clinical data and preoperative sequencing data of fecal samples of 331 patients who underwent CRC surgery from 2017 to 2019 in Seoul National University Hospital. Short-term postoperative complications were defined as first complications that developed within 30 days of surgery. We used linear discriminant analysis (LDA) of effect size (LEfSe) in the Galaxy webserver to identify enriched bacteria in patients with and without complications. Then, we calculated microbial dysbiosis

index (MDI) by each patient and compared them according to the complication status. Wilcoxon rank sum test was conducted to compare the alpha diversity indices according to the complication event. Subgroup analyses according to types of complications were also performed: surgical procedure-related (SP) group and nonsurgical procedure-related (NSP) group.
Results: Overall, 84 patients (25%) developed short-term postoperative complications: SP group (n=39) and NSP group (n=45). From the LEfSe analysis, *Bacteroides uniformis* (LDA score: 3.64, p-value 0.04) and *Clostridium colicanis* (LDA score: 3.39, p-value 0.01) were enriched in patients who developed short-term complications, whereas *Roseburia faecis* (LDA score: 3.26, p-value 0.05), *Bifidobacterium bifidum* (LDA score: 2.98, p-value 0.03), *Faecalibacterium sp.* (LDA score: 3.12, p-value 0.02) and *Prevotella nigrescens* (LDA score: 2.87, p-value 0.05) were enriched in patients without complications. When compared with patients without complications, taxa related to class *Gammaproteobacteria*, genus *Clostridium*, species *Roseburia faecis*, and *Desulfovibrio D168* were abundant in the SP group. Alpha diversity indices were not significantly different according to the complication status or the type of complication. MDI from the enriched bacteria were significantly higher in patients with complications compared to those without complications (p-value<0.001), and MDI of the SP group were also significantly higher than that of patients free of complications (p-value 0.001).
Conclusion: Our study suggests a potential relationship between microbial composition and surgical outcome in CRC patients. No significant difference in alpha diversity was observed according to the occurrence or the type of complication. Further studies are needed to investigate the postoperative changes of microbial features.

#5893

Suppression of anti-tumor immunity by the *Fusobacterium nucleatum* protease fusolisin

Amjad Shhadeh[1], Liat Dassa[2], Jamal Fahoum[3], Nicole Haj[1], Reuven Wiener[3], Ofer Mandelboim[2], Gilad Bachrach[1]. *[1]Institute of Dental Sciences, The Hebrew University-Hadassah School of Dental Medicine, Jerusalem, Israel,[2]Department of Immunology and Cancer Research, Institute for Medical Research Israel Canada, Hebrew University-Hadassah*

Medical School, Jerusalem, Israel,[3]Department of Biochemistry and Molecular Biology, Institute for Medical Research Israel Canada (IMRIC), Faculty of Medicine, The Hebrew University Medical School, Jerusalem, Israel

Fusobacterium nucleatum is an oral pathogen associated with periodontal disease, preterm births and the exacerbation of colorectal, esophageal, pancreatic, and breast cancers. *F. nucleatum* was previously found to inhibit killing of cancer cells by natural killer (NK) cells and tumor infiltrating T cells by inducing the NK cells killing-suppressing receptors TIGIT and CEACAM1. In this study, we show that the incubation of *F. nucleatum* with primary human natural killer (NK) cells causes the cleavage of the activating receptors CD16, NKp44 and NKp46 by fusolisin. Fusolisin is a fusobacterial outer-membrane, auto-transporter, serine protease and to date the only functional protease found in *F. nucleatum*. We previously showed that fusolisin is essential for fusobacterial growth in culture. High expression of a functional recombinant fusolisin in *E. coli* was enabled using codon optimization and replacement of the fusolisin's signal peptide with that of the *E. coli* OmpA. Recombinant fusolisin was found to cleave the same NK-activating receptors degraded by *F. nucleatum*. Cleavage of these activating receptors by fusolisin inhibited NK cells activity including killing of tumor cells *in-vitro* and *in-vivo*. Our results provide a new bacterial protease-dependent mechanism in which tumors colonized by *F. nucleatum* are protected from NK cells attack by exploiting fusolisin proteolytic activity. Importantly, our previous and current results suggest that fusolisin might serve to target for tumor-colonized fusobacteria.

Changes in the gut microbiota associated with oncolytic virotherapy efficacy in a gastric cancer murine model

Natalie M. Melendez-Vazquez[1], Sagar Sohoni[2], Arie Van Wieren[2], Juan Fueyo[2], Candelaria Gomez-Manzano[2], Filipa Godoy-Vitorino[1].
[1]Department of Microbiology and Medical Zoology, University of Puerto Rico-Medical Sciences Campus, San Juan, PR,[2]Department of Neuro-Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Gastric cancer is the third leading cause of cancer-related mortality worldwide, and current standard-of-care treatment allows for a 5-year survival rate of 20%. Newer treatments against solid tumors include an oncolytic adenovirus armed with T-cell activator OX40L, named Delta-24-RGDOX, which expresses the positive immune checkpoint OX-40L. While studies have revealed the interaction between the gut microbiome and immunotherapy agents, it's still unknown how the gut microbiome might influence viroimmunotherapy efficacy. We hypothesized that the gut microbiota plays an important role in modulating the virus-driven anti-tumor response. To test this hypothesis, immunocompetent C57BL/6 mice were subcutaneously implanted M12Luc gastric cancer cells and were administered PBS (control) or Delta-24-RGDOX by intratumoral injections. Mice fecal pellets were collected at three different time points: (1) before tumor implantation, (2) after tumor establishment, and (3) 14 days after the first dose of the treatment. Genomic DNA was isolated with the QIAGEN DNeasy Powersoil Kit from fecal pellets of cancer-bearing mice (n=60), and the V4 region of the 16S ribosomal RNA gene (prokaryotes) was sequenced using the Illumina platform. Data was deposited in QIITA for quality assessment, followed by microbial community analysis using the taxonomic reference database SILVA and the downstream platforms QIIME2 and R with a rarefaction depth of 9,187 reads per sample. We found significant differences in the gut microbiome community structure of viroimmunotherapy-treated mice compared to controls (ANOSIM p-value=0.025). No differences in gut diversity were observed, although control animals tended to show higher richness (Kruskal-Wallis p-value>0.05). Of interest, the bacterial composition of responders to the viroimmunotherapy had a decrease in Actinobacteria and an increase of Patescibacteria. Additionally, responders had higher levels of butyrate-producer bacteria such as *Ruminococcaceae* and *Clostridium sensu stricto*. These findings suggest that butyrate producers may be important in regulating host gut homeostasis associated with the clinical efficacy of Delta-24-RGDOX, suggesting possible benefits of microbiota modulation in patient survival. *This project was sponsored by a pilot award within The University of Puerto Rico/University of Texas MD Anderson Cancer Center (MDACC) Partnership for Excellence in Cancer Research Grant (2U54CA096297-16).*

Analysis of microbiome in gastric MALT lymphoma

SeungJoo Yoo[1], Dong-Yeop Shin[2], Ja Min Byun[2], Junshik Hong[2], Hongseok Yun[2], Youngil Koh[2], Sung-Soo Yoon[2]. *[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of*

Gastric MALT (mucosa-associated lymphoid tissue) lymphoma is found at a rate of 50% or more among the types of MALT lymphoma. Majority of patients with gastric MALT lymphoma are infected with *Helicobacter pylori* and also have clinical improvement with eradication therapy. However, it is unclear how *H. pylori* cause gastric MALT lymphoma. To explore it, we prospectively collected 13 patients who are newly diagnosed with gastric MALT lymphoma with *H. pylori.* We gathered samples from normal regions and lesions during endoscopy for diagnosis. Samples of lesion were harvested again after eradication of *H. pylori*. we sequenced 10 of WES (whole exome sequencing) and 13 of WTS (whole transcriptome sequencing) with these samples. With sequencing data, we aligned the sequenced reads to human reference genome (hg19) using BWA and called the variants with Mutect2. We aligned the reads and calculated TPM (Transcripts Per Million) from WTS with STAR and RSEM. We performed DEG (Differentially Expressed Genes) and GSEA (Gene Set Enrichment Analysis) for three comparison groups which are divided into normal, lesion, and after eradication. Gene fusions were detected using STAR-Fusion and Arriba with WTS. To detect potential microbiome from the samples, we used Kraken2, a taxonomic classification tool. We found that *MUC6* was mutated from all samples and some samples have mutated *MUC3A, KMT2C*, *ZNF595*, *CDC27,* etc., and two have *BIRC3-MALT1* fusion. From DEG and GSEA analysis, G protein-coupled receptor activity was activated in the group of lesion samples and suppressed in normal samples and eradication samples. Lymphocyte activation and immune response were also activated in the cancerous lesion. Kraken2 classified the reads which were not aligned to the human reference genome as reads from microbiota including *H. pylori*. The reads of *H. pylori* were more abundant in the lesion group than the other groups. According to the result of differentially expressed species analysis between the groups of lesion and eradication, the following species were also more abundant in the lesion

group; *Veillonella dispar, Helicobacter hepaticus, Helicobacter winghamensis,* etc. We analyzed genetic alterations and differentially expressed genes and also classified non-human reads as microbiome with sequencing data from gastric MALT lymphoma. Our results suggest how H.pylori infection is related to carcinogenesis of gastric MALT lymphoma.

Identification of microbial biomarkers to predict recurrence of oral squamous cell carcinoma

Wei-Ni Lyu[1], Mei-Chun Lin[2], Pei-Jen Lou[2], Liang-Chuan Lai[1], Mong-Hsun Tsai[1]. *[1]National Taiwan University, Taipei, Taiwan,[2]National Taiwan University Hospital, Taipei, Taiwan*

Introduction: Oral cancer is a fatal cancer and the sixth most common neoplasm worldwide. Over 90% of oral cancer is oral squamous cell carcinoma (OSCC). OSCC is a global health problem because of its late diagnosis and high rate of relapse and metastasis. Currently, cumulative evidence has suggested the association between oral microbiome and oral cancer. However, the correlation between the oral microbiome and OSCC recurrence remained unclear. Therefore, we investigated the OSCC patients' oral microbiota to understand the roles of oral microbiome in the recurrence of OSCC.
Materials and Methods: To evaluate the role of the oral microbiome in the recurrence of oral cancer, we compared the oral bacterial composition of tumor samples from the OSCC patients with or without recurrence based on 16S rRNA amplicon sequencing of 54 oral swab samples. Then, the structures of the oral microbiome were analyzed to establish a prediction model for the recurrence of OSCC. To identify microbial signatures capable of distinguishing recurrence from non-recurrence, the 54 tumor samples from OSCC patients were used as a training dataset. Furthermore, 46 external tumor samples from other OSCC patients were used to validate the dataset.
Results: The oral bacterial compositions differed in OSCC patients between with and without recurrence. Compared to nonrecurrence OSCC, periodontitis-related bacteria were enriched in OSCC recurrence. Functional analysis of the oral microbiome showed several functions associated with OSCC recurrence including amino acid metabolism,

carbohydrate metabolism, lipid metabolism, glucose utilization, and drug resistance. Subsequently, we established a random forest prediction model with high accuracy (accuracy = 0.963) to discriminate OSCC recurrence from the original OSCC based on five specific microbial signatures. Moreover, the prediction model achieved an accuracy of 0.761 in another independent cohort (46 OSCC patients). On the other hand, the accuracy predicted by the current clinical-used model was 0.519 with the training dataset. Thus, our novel model could improve the prediction accuracy of OSCC recurrence.
Conclusions: In this study, we elucidated the relationship between oral bacteria and the recurrence of OSCC. Moreover, we established a novel bacteria-based prediction model for the recurrence of OSCC. Thus, the present study provided a new insight and treatment strategy for the clinical prediction of OSCC recurrence.

#5898
Gut microbiota-derived metabolism of 5-fluorouracil affects drug efficacy

Despoina Chrysostomou, Mark David, James L. Alexander, Julian R. Marchesi, James M. Kinross. *Imperial College London, London, United Kingdom*

Introduction: Fluoropyrimidines are drugs currently used as a first-line treatment for colorectal cancer (CRC)[1]. The impact of gut bacteria on 5-Fluorouracil (5FU) activity remains relatively unknown. The objective of this analysis was to delineate potential bacteria-drug interactions that modify 5FU.
Methods: Tumor and tumor-adjacent healthy tissue samples from 130 colorectal adenocarcinoma patients, 55% males and 45% females, median age of 71 years old (36-91 age range), were extracted following surgical resection of the tumor. TNM classification varied across the cohort (15% pT1, 43% pT2, 35% pT3, 4% pT4). 16s rRNA gene amplicon sequencing was performed to map the microbiome composition of tumor and paired normal mucosa. 20 bacterial from the genera whose abundance changed significantly between tumor and healthy tissue were incubated with 5FU to assess drug-bacteria interactions. Ultra-performance liquid chromatography-mass spectrometry (UPLC-MS) was employed to identify changes in drug concentration (Wilcoxon spare rank test) as well as products of bacteria-driven drug metabolism. A metabolic activity-based assay was used to assess viability of a colorectal adenocarcinoma cell line (HCA46) following co-incubation with microbe-driven drug metabolites, aiming to determine significant effects on 5FU efficacy, assessed by 2-way ANOVA.
Results: *Escherichia coli* BW25113, *Bifidobacterium longum*, *Citrobacter freundii* and *Enterococcus faecalis* significantly modify 5FU *in vitro*, allowing us to conclude that bacteria can metabolise the drug *($q < 0.001$)*. *Ruminococcus gnavus* does not have the ability to metabolise the drug as no significant change in 5FU concentration was observed. Incubation of microbe-derived drug metabolites with HCA46 resulted in significant decrease in cell viability compared to incubation with 5FU only, indicating that bacteria-5FU interactions result in increase of drug efficacy (Figure 2).
Conclusion: This is the first report of 5FU metabolism by *Escherichia coli* BW25113, *Bifidobacterium longum*, *Citrobacter freundii* and *Enterococcus faecalis in vitro*. This study provides an insight into the potential of large

and small intestinal bacteria in chemically modifying chemotherapeutic agents and therefore modulating their activity.

Tolerance to colibactin correlates with response to chemotherapeutic agents in colorectal cancer

Alberto Sogari[1], Emanuele Rovera[2], Nicole Megan Reilly[2], Simona Lamba[3], Mariangela Russo[2], Annalisa Lorenzato[1], Erika Durinikova[3], Livio Trusolino[1], Sabrina Arena[1], Manuela Donalisio[4], Federica Di Nicolantonio[1], David Lembo[4], Alberto Bardelli[5]. *[1]Department of Oncology, University of Torino - Candiolo Cancer Institute FPO-IRCCS, Candiolo, Italy,[2]University of Torino - Candiolo Cancer Institute FPO-IRCCS, Candiolo, Italy,[3]Candiolo Cancer Institute FPO-IRCCS, Candiolo, Italy,[4]Department of Clinical and Biological Sciences, University of Torino, Orbassano, Italy,[5]University of Torino; IFOM - Istituto Fondazione di Oncologia Molecolare, ETS, Candiolo, Italy*

Introduction: The bacterial genotoxin colibactin is enriched in colorectal cancer (CRC) and promotes the accumulation of mutations that drive tumorigenesis. However, systematic assessment of its impact on DNA damage response is lacking and the effect of colibactin exposure on response to other genotoxic agents (such as chemotherapy) is missing.
Materials and Methods: We implemented an *in vitro* bacteria-coculture system to assess the effect of colibactin on a representative subset of 40 molecularly and pharmacologically annotated CRC cell lines and in a panel of isogenic DDR KO cell lines we generated. We further validated our results in patient-derived organoids. Finally, we recapitulated prolonged exposure to colibactin occurring during tumorigenesis by chronically infecting sensitive cells until the emergence of a tolerant phenotype. }
Results: We found that different cell lines display specific sensitivity to colibactin's genotoxic stress: while colibactin-tolerant cells are capable to quickly and efficiently repair colibactin-induced DNA damage, sensitive cells lack this ability. Moreover, we found that homologous recombination (HR) proficiency discriminates colibactin-tolerant cells, which display

higher levels of RAD51 foci (as marker of activation of HR) compared to sensitive cells upon infection with colibactin. Screening of isogenic DDR KO cell lines revealed that genetic inactivation of the intertwined pathways of HR (through KO of *ATM*) and replication stress (RS) response (through KO of *ATRIP*) significantly sensitized cells to colibactin. In addition, we found that restoration of HR activity was sufficient to induce a colibactin-tolerant phenotype in initially sensitive cell lines. Notably, thanks to a previous effort of pharmacological characterization of CRC cell lines in our lab, we found a significant correlation between sensitivity to colibactin and irinotecan active metabolite SN38, but not oxaliplatin. We validated the same correlation in patient-derived organoids annotated for response to SN38. While colibactin, SN38 and oxaliplatin all induced RS in treated cells, we found that colibactin and SN38 showed a similar DNA damage response which involved activation of ATM. Finally, chronic re-infection of sensitive, HR-deficient CRC cells with colibactin selected a tolerant phenotype characterized by restoration of HR activity. Of translational relevance, colibactin-tolerant derivative cells acquired cross-resistance to SN38 and PARP inhibitor olaparib but not to oxaliplatin.
Conclusion: Our results shed novel insight into colibactin's genotoxic mechanism and support a model in which colibactin both promotes tumorigenesis and acts as an evolutionary bottleneck which selects HR proficient CRC cells. Furthermore, our study provides preclinical evidence on colibactin's role in promoting chemoresistance in colorectal cancer.

Microbiome and genomic profiling in rectal adenocarcinoma
David Hein, Laura Coughlin, Nicole Poulides, Andrew Koh, Nina Sanford.
University of Texas Southwestern Medical Center, Dallas, TX

Introduction: Recent studies have identified bacteria associated with colorectal cancer (CRC), with some data supporting causality in preclinical CRC models. We examined the gut microbiome composition and tumor genomic profiles in a diverse cohort of rectal cancer patients.
Methods: Twenty-two patients with newly-diagnosed, Stage II-IV rectal cancer without pathogenic germline mutations (mismatch repair genes, *MUTYH*) were included in the study. Gut microbiome profiling was performed on genomic DNA extracted from collected fecal samples (16S

rRNA sequencing, V4 region). Tumor specimens were tested for somatic and germline mutations using the Tempus xT 648-gene panel and whole transcriptome RNA sequencing, providing information on tumor mutation burden (TMB), pathogenic *KRAS* mutation status and consensus molecular subtype (CMS). We then assessed differential abundance of microbial taxa (using ANCOM-BC) between the following groups: high vs low TMB (dichotomized at median, 3.7 mut/MB), presence versus absence of pathogenic *KRAS* mutation, and CMS subtype.
Results: The median age of study subjects was 49 years (range 37-78). Racial/ethnic breakdown was as follows: 2 non-Hispanic Asian, 4 non-Hispanic Black, 5 non-Hispanic White, and 11 White Hispanic. Twelve tumors carried a pathogenic *KRAS* variant and the median TMB was 3.7 m/MB (range 0.5-8.9 m/MB). Among 20 tumors that underwent whole transcriptome RNA sequencing, 1 was categorized as CMS1, 8 CMS2, 3 CMS3, 7 CMS4, and 2 CMS undetermined. There were no statistically significant differences in gut bacteria taxa abundance by *KRAS* mutation status or among CMS subtypes. The group with greater than median TMB, however, had statistically significant enrichment of *Pepostreptococcus stomatis* (18.4 fold increase, p=0.039 after Benjamini-Hotchberg adjustment with FDR = 0.05).
Conclusions: In this pilot study, we found that CRC patients with higher TMB had an enrichment of *Peptostreptococcus stomatis*, a bacteria associated with colonic dysplasia in mouse models and enriched in CRC patients as compared to healthy controls. (PMID 28823860, 35292756) Higher TMB is a predictive biomarker for response to immunotherapy across cancer types including CRC. Since the gut microbiome is potentially modifiable, further research is needed to better elucidate the connection between microbiome and CRC carcinogenesis including specific mutation profiles, which could pave the way for microbiome-related risk reduction or therapeutic strategies in CRC.

Background: Biliary tract cancer (BTC) is an aggressive malignancy associated with a poor prognosis. Most BTC patients are diagnosed at an unresectable stage; further, the efficacy of cytotoxic chemotherapy for BTC remains unsatisfactory. Recently, there is growing evidence that gut microbial dysbiosis is related to multiple diseases, including biliary disease and cancer. However, the association between tumor and gut microbiome environments and BTC, especially extrahepatic cholangiocarcinoma (EH-CCA), remains unclear. In the present study, we compared the microbiome from the tissue and stool samples of EH-CCA patients and healthy living liver donors (controls). Methods: A total of 24 people (13 EH-CCA patients and 11 healthy controls) were included. We collected fecal and swab samples, which were obtained from the EH-CCA tissues of the patients and normal gallbladder tissues of the controls during operation. The bacterial 16S rRNA gene (V3 and V4 region) was amplified using PCR and sequenced on the Illumina MiSeq platform. The QIIME 2 pipelines were used to analyze the raw data. Results: The median age of the patients and controls were 70 (range, 58-79) and 29 (range, 19-35) years, respectively. The swab samples from EH-CCA patients showed significantly lower alpha diversity than the samples from the controls ($pShannon < 0.001$). Proteobacteria was the most commonly found phylum (53%) in the EH-CCA patients; Firmicutes (79%) and Actinobacteria (13%) were the common phyla in the controls. The genera Streptococcus (25.1%), Escherichia_Shigella (16.9%), and Enterococcus (13.9%) were found in the patient samples, whereas Blautia (12%), Limosilactobacillus (12%), and Bifidobacterium (19%) were observed in the controls. The Principal Coordinate Analysis (PCoA) plot of the weighted UniFrac distances showed that the patient and control groups formed separate clusters. Among the fecal samples, Streptococcus (12.5%), bacterioides (8.2%) is most common in patients' group, whereas Blautia (13.8%) and Faecalibacterium

(11.5%) is most common in control group at the gene levels. The PCoA plot of the fecal samples showed significant differences in microbiota composition between the EH-CCA patients and healthy controls (P=0.001 by PERMANOVA). In the beta diversity analysis of all samples (swab plus fecal), the patient-swab samples formed distinct clusters, whereas the patient-fecal, control-swab, and control-fecal samples showed overlapping clusters.Conclusions: To the best of our knowledge, this study is the first that compares the microbiome of tissues and stools from EH-CCA patients and healthy controls; the EH-CCA patients and healthy controls showed different microbiota profiles. Further studies are needed to investigate the clinical implications of microbial dysbiosis in BTC and formulate novel microbiome-based treatments for BTC.

Intra-tumor microbes identified by RNAseq associated with response to immune checkpoint blockade in metastatic melanoma

Caroline E. Wheeler[1], Samuel Coleman[2], Rebecca Hoyd[1], Afaf Osman[3], Louis Denko[1], Aik Choon Tan[2], Daniel Spakowicz[1], Ahmad Tarhini[4].
[1]Department of Medical Oncology, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Data Science, Huntsman Cancer Institute, Salt Lake City, UT,[3]Internal Medicine, Huntsman Cancer Institute, Salt Lake City, UT,[4]Department of Cutaneous Oncology, Moffitt Cancer Center, Tampa, FL

The tumor microbiome has recently been shown to play a key role in the context of oncogenesis, cancer immune phenotype, cancer progression and treatment outcomes in a variety of cancers. We investigated the possible associations between tumor microbiome and successful treatment outcomes with immune checkpoint blockade (ICB) in patients with metastatic melanoma.
We evaluated RNAseq from tumor samples, collected prior to the start of treatment with ICB, from 71 patients with metastatic melanoma. Samples were provided by eight members of the Oncology Research Information Exchange Network (ORIEN). Non-response was determined as change in treatment after less than 12 months. Patients maintaining the same treatment regimen for greater than 12 months were classified as responders.

We applied our custom tool, {exotic} (Exogenous sequences in Tumor and Immune Cells), to carefully identify non-human sequences within the RNAseq data. After filtering reads aligning to the human reference genome, reads were further filtered of common laboratory contaminants, taxa inversely correlated with input RNA quantity, and taxa frequently found in the negative controls of microbiome experiments. A differential abundance analysis was performed on the response groups at every taxonomic level utilizing DESeq2. We calculated expression signatures using {tmesig}, and related them to ICB response using {IOSig}.
We observed significantly enriched taxa (p-value < 0.05) with a high (>1.00) fold-difference in abundance between responders and non-responders found within the tumor RNAseq data, including *Fusobacterium nucleatum* and several viruses in responders, and *Delftia lacustris* and Fungi in non-responders. These microbes were associated with immune cell expression signatures, including Th17 cells and CD8+ T-cells.
We calculated the gene expression scores of 30 signatures with literature precedence for the ability to predict ICB treatment outcomes in melanoma. The receiver operator characteristic (ROC) curve of the random forest classification model for prediction of response to ICB using the combined expression signature scores resulted in an AUC of 0.8750. Combining expression signature scores with microbe relative abundances at the genus level improved the ability to predict ICB response (AUC = 0.8958). Combining tumor expression signatures with curated tumor microbiome relative abundances improves the performance of predictive models for treatment outcomes with ICB in melanoma.

Enterotoxigenic *Bacteroides fragilis*, a colon microbe, dysregulates polyamine catabolism to promote breast cancer progression

Deeptashree Nandi[1], Sheetal Parida[1], Sowjanya Thatikonda[1], Jackson Foley[1], Tracy Stewart[1], Cynthia L. Sears[2], Robert A. Casero[2], Dipali Sharma[2]. *[1]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Johns Hopkins University School of Medicine, Baltimore, MD*

Background: With more than 2.3 million cases worldwide, breast cancer persists as a major health burden and warrants a greater understanding of

the molecular triggers underlying this disease. Focusing on microbial dysbiosis, our lab discovered the pivotal role of the enterotoxigenic *Bacteroides fragilis* (ETBF) in promoting breast tumorigenesis through activation of key oncogenic pathways. A gap in knowledge exists regarding how microbes/microbial toxins modulate the oncogenic pathways in cancer cells. Polyamines are imperative for various physiological processes, including cell growth, survival, differentiation and apoptosis and are strongly associated with breast cancer. We questioned the involvement of polyamine pathway in mediating the oncogenic effects of microbial dysbiosis on breast cancer.

Methods: Human Her2 expressing spontaneous breast cancer model, MMTV.f.HuHer2 mice, were infected with ETBF and tumor incidence and progression were monitored for 18 months. We used qRT-PCR, western blotting, immunocytochemistry and immunohistochemistry to examine expression of key nodes of polyamine pathway. Various growth, migration and invasion assays were performed to assess carcinogenic properties in breast cancer cells. We employed a colorimetric-based assay to analyze enzymatic activities of key polyamine metabolic members. ROS generation was examined *via* DCFA staining.

Results: Our *in vivo* data showed that ETBF colonization in mice led to a considerable increase in the level of spermine oxidase (SMOX) in breast tumors, hinting at a correlation between ETBF and polyamine metabolism. Moreover, a marked rise in expression of γH2AX foci was observed in these tumors and in breast cancer cells, suggesting a critical role of ETBF in SMOX-related DNA damage. In agreement, we found SMOX upregulation in breast cancer cells. Our findings displayed a substantial increase in SMOX enzymatic activity in the presence of ETBF toxin, BFT, in breast tumor cells. BFT caused a marked rise in ROS generation of breast tumor cells, suggesting a plausible association of ETBF in SMOX-mediated oxidative stress. Interestingly, we noted a significant induction of ornithine decarboxylase (ODC) expression and activity in response to ETBF or BFT in breast cancer cells. Treatment of BFT-exposed breast cancer cells with SMOX inhibitors led to a sharp inhibition of neoplastic transformations, like cellular migration and γH2AX induction.

Conclusion: Our collated evidences suggest the existence of an important cross-talk between key polyamine metabolic enzymes and ETBF that aids in exacerbating breast tumorigenesis. Of importance, therapeutic inhibition

of SMOX dramatically impeded BFT-related breast tumorigenesis. Collectively, our results demonstrated the attractive potential of intervening the polyamine catabolic pathway for the management of breast cancer.

Gut microbiota signatures are associated with immunotherapy induced cognitive decline and neurotoxicity

Anik Banerjee[1], Christina Roland[2], Sarah Johnson[2], Nadim Ajami[2], Jennifer Wargo[2]. *[1]MD Anderson UTHealth Graduate School of Biomedicial Sciences, Houston, TX,[2]MD Anderson Cancer Center, Houston, TX*

Studies have demonstrated promising outcomes of combined immune checkpoint blockade (CICB) modulating tumor cytotoxicity via targeting cytotoxic T lymphocyte-associated antigen 4 (CTLA-4) and programmed cell death 1 (PD-1). The emergence of long-term patient management has been transformed among health care professionals as patient survival rates are increasing significantly. Despite promising advances, patient outcomes are heterogenic and are correlative to host intrinsic and extrinsic factors. Multiple reports have highlighted the negative effects of cancer treatments towards inducing cognitive impairment and neurotoxicity often referred to as “chemofog”. More recently, the gut microbiome has been increasingly recognized to regulate antitumor immunity and further distinct microbiome signatures can confer favorable outcomes in the context of CICB. Interestingly, specific microbes within the gut microbiome have been shown to regulate social behavior and cognition via the bidirectional communication along the gut-brain axis though changes in microbiota-derived metabolites and vagal afferent fibers. Insights into mechanisms of immunotherapy induced cognitive decline are warranted. Thus, we hypothesize CICB exacerbates cognitive impairment and neurotoxicity via the detrimental alterations to the gut microbiome. To address this, we profiled the gut microbiome, through 16S rRNA gene and metagenomic sequencing of fecal samples from patients (n=146) with advanced melanoma treated with CICB stratified based on severity of cognitive dissonance. Beta-diversity, incorporating weighted UniFrac distances by principal coordinate analysis (PCoA), revealed a cluster of samples from patients with cognitive impairment as compared to samples from those with minimal to absent cognitive decline. Further, taxonomical analysis showed

significant alterations in relative abundances of microbial candidates (e.g., *L. intestinalis*, *A. muciniphila*, *F. prausnitizii*, and *R. hominis*). These results suggests that CICB patients with cognitive impairments and neurotoxicity have altered microbiome signatures which may potentially exacerbate downstream neuroinflammatory signaling. Further studies investigating specific host-microbe pathways and profiling microbiota-derived metabolites which are implicated in these detrimental effects are essential for biomarker discovery and mechanistic insight.

The tumor microbiome associates with features of the tumor microenvironment, treatment outcomes, and histologies: A national collaboration of the exORIEN Consortium

Rebecca Hoyd[1], Caroline E. Wheeler[1], Samuel Coleman[2], Louis Denko[1], Carlos Chan[3], Yousef Zakharia[4], Rebecca Dodd[4], Cornelia M. Ulrich[5], Sheetal Hardikar[5], Jennifer Ose[5], Michelle Churchman[6], Ahmad Tarhini[7], Lary A. Robinson[8], Eric Singer[9], Alexandra P. Ikeguchi[10], Martin McCarter[11], Kyra Anderson[12], John Carpten[13], Gabriel Tinoco[14], Marium Hussain[1], Nicolas Denko[15], YunZhou Liu[15], Ning Jin[15], Youngchul Kim[8], Asgeir Masson[16], Naomi Fei[16], Martin Benej[17], McKenzie Kreamer[18], Dennis Dennis Grencewicz[15], Ahmed Hussein[15], Aik Choon Tan[19], Daniel Spakowicz[1]. *[1]Division of Medical Oncology, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Data Science, Huntsman Cancer Institute, Salt Lake City, UT,[3]Department of Surgery, University of Iowa Carver College of Medicine, Iowa City, IA,[4]Department of Internal Medicine, University of Iowa Carver College of Medicine, Iowa City, IA,[5]Huntsman Cancer Institute, Salt Lake City, UT,[6]M2GEN, Tampa, FL,[7]Departments of Cutaneous Oncology and Immunology, Moffitt Cancer Center, Tampa, FL,[8]Moffitt Cancer Center, Tampa, FL,[9]The Cancer Institute of New Jersey, New Brunswick, NJ,[10]Department of Medicine, College of Medicine University of Oklahoma Health Sciences Center, Oklahoma City, OK,[11]University of Colorado Denver School of Medicine, Aurora, CO,[12]University of Colorado Cancer Center, Aurora, CO,[13]National Human Genome Research Institute, Bethesda, MD,[14]The Ohio State University Comprehensive Cancer Center, Columbus,*

OH,[15]Comprehensive Cancer Center, The Ohio State University Wexner Medical Center, Columbus, OH,[16]University of Iowa Carver College of Medicine, Iowa City, IA,[17]The Ohio State University Wexner Medical Center, Columbus, OH,[18]Department of Radiation Oncology, The Ohio State University Wexner Medical Center, Columbus, OH,[19]Department of Data Science, Huntsman Cancer Institute, Salt Lake city, UT

A tumor microbiome has recently been established as present in many cancer types. Further study is needed to define the scope of its role in cancer tumorigenesis, progression, and treatment outcomes. The Oncology Research Information Exchange Network (ORIEN) established a collaboration among eight member institutions to study the tumor microbiome and clinical features across several cancers. We evaluated RNAseq data from n = 2,892 tumors , including colorectal adenocarcinomas, lung adeno- and squamous cell carcinomas, pancreatic adenocarcinomas, sarcomas, melanomas, and thyroid carcinomas, using the tool {exotic}. Matched cancers from the Cancer Genome Atlas were processed by the same method (n = 2,720 samples). Clinical data, including treatment information, lab values, detailed histology, and long-term follow-up, were collected and harmonized across sites. Microbe abundances (bacteria, fungi, and viruses) were associated with clinical features and human gene expression, which was deconvolved into immune cell composition using {CIBERSORT} and {TIMEx}, and aggregated into expression signatures using {tmesig} and {IOSig}. Microbes were found in all tumors and associated with treatment outcomes for all modalities tested, including radiation in colorectal cancer, chemotherapy in pancreatic cancer, and immunotherapy in melanoma. In the case of radiation treatment in colorectal cancer, the microbes also affected outcomes in preclinical model systems and were modified by altering hypoxia levels with the drug atovaquone. Virus prevalence associated with histological subtypes in lung cancer. Similar microbes in ORIEN and TCGA tumors associated with overall survival in subtypes of sarcoma (dedifferentiated liposarcoma, leiomyosarcoma, and others). Finally, microbes associated with expression-based indicators of the tumor microenvironment across cancer types. These results suggest that the tumor microbiome may have broad clinical utility as a biomarker of treatment outcomes and as a target for rational manipulation.

Specific gut microbial community is associated with specific cancer types: A strategy for cancer detection and prevention

Ekansh Mittal[1], Andrew Oliver[2], Kenza El Alaoui[2], Carolyn Haunschild[2], Julio Avelar-Barragan[2], Laura F. Mendez Luque[2], Katrine Whiteson[2], Angela G. Fleischman[2]. *[1]Westview High School, Portland, OR,[2]University of California Irvine, Irvine, CA*

Background: Cancer is the second leading cause of death in the world. Unfortunately, survival rates for cancer patients have stayed poor for many decades. Thus, there is an unmet need to identify novel strategies for early cancer detection and prevention. Recent studies suggest that the gut microbiome including bacteria may have a role in cancer initiation and progression. These bacteria play a vital role in maintaining homeostasis in the body. An imbalance in the bacterial composition may cause diseases including cancer. This evidence led us to hypothesize that the changes in the composition of the gut microbiome can be used as a biomarker for early cancer detection. To test this hypothesis, we focused on analyzing the microbial community of colorectal and blood cancers, which have poor survival rates.

Methods and Results: To analyze the association of cancer with the microbiome, we used a published microbiome dataset of leukemic and healthy individuals that were collected by sequencing stool samples (Oliver et al., 2022). We identified that specific bacteria are either abundant, such as *Faecalibacterium* (1.17 fold), or reduced, such as *Clostridium* (0.32 fold, *p* value=0.0029), in leukemia patients compared to healthy controls. We observed similar correlations by analyzing the published colorectal cancer data (Flemer et al., 2017) in which *Prevotella* increased by 3.75 fold and *Escherichia/Shigella* increased by 4.0 fold in colorectal cancer while *Blautia* is reduced compared to healthy controls. *Faecalibacterium,* which is abundant in leukemia, is reduced in colorectal cancer. Further, we found that treatment of leukemia patients normalized the abundance of these bacteria to the level of healthy patients. To improve analysis efficiency, we applied machine learning algorithms to predict the presence of cancer in patients based on the composition of bacteria, age, gender, and symptoms. Among the tested algorithms, the decision tree and Random Forest both had very high false-negative rates, with 45.5% and 40% respectively, as well as

having low sensitivities, with 50% and 60% respectively. The support Vector Machine had a suboptimal false-negative rate of 28.6% and good sensitivity of 80%. Finally, the Neural network had a good false-negative rate of 16.7% and great sensitivity of 90%. Overall, our results suggest that different cancers have an abundance of specific bacteria that can be used as biomarkers for cancer detection.
Conclusion: We demonstrate that the increased abundance of certain bacteria in the microbiome can be used as a biomarker for cancer detection. Our data set was small for this project, but the machine learning approaches can be used to further predict cancer These are clinically relevant findings as a microbiome test would be non-invasive and easily accessible that can be performed at a routine checkup.

Characterization of the lung cancer microbiome using whole genome sequencing
John McElderry, Tongwu Zhang, Jianxin Shi, Maria Teresa Landi. *NCI Div. of Cancer Epidemiology & Genetics, Rockville, MD*

Microbiome studies have been rapidly increasing over the last decade, providing valuable insights into the commensal bacterial contribution to human physiology and disease, including human cancer. Many studies have demonstrated the important roles of the microbiome in cancer progression, anti-tumor immunity, resistance to therapies, metastasis formation, and in some rare cases even cancer development through the production of genotoxins. However, relatively few studies have analyzed the lung cancer microbiome, and both its composition and role in cancer progression are largely unknown. To characterize the microbiome of tumor and matched normal lung tissues, we performed whole-genome sequencing (WGS) in 872 never smokers using the Kraken pipeline. At the phylum level, WGS analyses of tumor and normal samples showed predominantly *Proteobacteria* and *Actinobacteria* (58% and 32%, respectively). Notably, we found overall similar microbiome composition in tumor and normal lung tissue samples. At the genus level, *Cutibacterium, Klebsiella*, *Pseudomonas, Sphingomonas, Staphylococcus, and Acinetobacter* genera were among the most abundant bacteria in tumor and normal tissues, alike, and the genera *Prevotella*, *Corynebacterium*, and *Streptococcus* were more

abundant in tumor samples compared to normal lung tissue. Comparison of alpha diversity at the genus level between tumors and normal samples showed no substantial difference. We are currently investigating whether the microbiome composition varies by lung tumor anatomical location, sex, histology, study subjects' geographical location, and immune microenvironment. We will also investigate whether the tumor microbiome composition varies in relation to important genomic features, like cancer driver genes and mutational signatures. Finally, we have 16s rRNA seq data from 771 tumor and normal lung tissues from never smokers and we will compare bacterial microbiome composition and diversity based on WGS and 16s rRNA seq for the same samples. This study, based on the largest analysis of lung microbiome to date, is poised to provide important insights into the role of commensal microbiota in shaping lung tumor development and progression.

Prospective platform to define microbiome correlates of metastasis and therapy resistance in early onset and average onset gastrointestinal cancers

Melissa A. Lumish, Asha R. Saxena, Nicholas Waters, Anqi Dai, Saskia Hartner, Teng Fei, Matthew Drescher, Jonathan Bermeo, Dorina Ismailgeci, Maggie Fox, Yelena Y. Janjigian, Luis A. Diaz, Martin R. Weiser, Jonathan Peled, Marcel van den Brink, Karuna Ganesh. *Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The incidence of early onset (EO) gastrointestinal (GI) cancers prior to age 50 is rising, and the etiology is unknown. The gut microbiome may contribute to GI cancer pathogenesis, though how bacteria drive metastasis and treatment resistance is not known.
Purpose: To define the microbiome contribution to EO-GI cancers and metastasis by analyzing longitudinal samples from previously untreated patients with GI cancers.
Methods: We designed a prospective biospecimen collection platform. We selected patients with newly diagnosed, previously untreated colorectal cancer (CRC) and esophagogastric cancer (EGC). We collected stool, biopsy or surgical tissue, and peripheral blood mononuclear cells (PBMCs) at baseline prior to treatment and at each restaging scan for patients with

metastatic disease. For those with locally advanced disease, we collected samples at baseline and after each treatment phase (surgery, radiation, chemotherapy). Stool samples were analyzed using shotgun sequencing. Tissue samples were banked for further analysis. Clinical data was manually curated. Relative abundances of bacteria at the species level were compared between groups. Alpha diversity was calculated using the inverse Simpson index and compared between groups using the Wilcoxon signed-rank test. Beta diversity was analyzed using the Bray-Curtis dissimilarity matrix and compared using PERMANOVA. Multivariate association between species abundance and clinical covariates was performed using MaAsLin2 R package.
Results: We analyzed a total of 150 stool samples from 76 patients (colorectal n=53, esophagogastric n=23), including up to 6 samples from a single patient over time. Mean alpha diversity did not differ significantly by primary site or age at diagnosis in patients with CRC but was higher in stage IV compared with stage I disease (P=0.054). Beta diversity was significantly different between samples from patients with right- compared with left-sided CRC (P=0.005) but did not differ significantly by diagnosis age (<50 vs. $\geq$ 50). Among those with EGC, mean alpha diversity was not significantly different in samples from patients with esophagus or gastroesophageal junction (proximal) tumors compared with gastric (distal) tumors and did not differ significantly by age group. Beta diversity was significantly different between patients with EGC over 50 compared with those under 50 (P=0.002). When CRC baseline samples were examined, several bacterial species were associated with age <50 at diagnosis, including *Streptococcus anginosus* group (P=0.001), *Solobacterium moorei* (P=0.013), and *Firmicutes* bacterium CAG83 (P=0.016).
Conclusions/Future Directions: Microbiome composition may cluster by primary tumor site and age at diagnosis in patients with previously untreated GI cancers. Functional analysis and is ongoing and will be presented.

Bitter taste receptors link between microbiome dysbiosis and programmed cell death in oral squamous cell carcinoma
Byeong-Oh Hwang, Se-Young Park, Na-Young Song. *Yonsei University, Seoul, Korea, Republic of*

Oral squamous cell carcinoma (OSCC) is the most common type of head and neck cancers. It has been reported that the composition of the oral microbiome was shifted in OSCC patients compared to healthy subjects. In particular, *Pseudomonas aeruginosa* was enriched in the oral cavity of OSCC patients. Bitter taste receptors (taste 2 receptors, TAS2Rs), known as G protein-coupled receptors (GPCRs), can recognize quorum sensing molecules, such as N-(3-oxododecanoyl)-L-homoserine lactone (oxo-C12) secreted from *P. aeruginosa*. Based on The Cancer Genome Atlas analysis, downregulation of TAS2Rs was correlated with poor prognosis in various cancers. This prompted us to investigate the role of TAS2Rs in oral dysbiosis and cancers. Here, we found that TAS2Rs mediated both apoptosis and pyroptosis, distinct types of programmed cell death, in response to oxo-C12, in OSCC cell lines. Of note, it was blocked by knockdown of *TAS2R4, 14*, or *38*. Unexpectedly, TAS2Rs-mediated apoptosis and pyroptosis were GPCR-independent. Given our observation that the blockade of NLRP3 inflammasome attenuated oxo-C12-induced OSCC cell death, TAS2Rs seem to recruit NLRP3 inflammasome rather than G protein signaling pathway in order to mediate the programmed cell death in OSCC. Once NLRP3 is activated, caspase-8 triggered both apoptosis and pyroptosis in response to oxo-C12, supporting the role of TAS2Rs-NLRP3-caspase-8 axis. Interestingly, siRNA knockdown of *MyD88* diminished oxo-C12-induced programmed cell death, implying the possible involvement of MyD88 in the TAS2Rs-NLRP3-caspase-8 axis. Taken together, bitter taste receptors promote the programmed cell death of OSCC in response to oral dysbiosis through activation of NLRP3 inflammasome, which further supports TAS2Rs as prognostic markers in OSCC. Thus, these results will shed light on better understanding of interplay between microbiome and cancer, proposing TAS2Rs as novel therapeutic targets in oral dysbiosis-induced OSCC development.

#5913

Semi-supervised analysis of myeloid and T cell behavior in *ex vivo* ovarian tumor slices reveals changes in cell motility after treatments

Florian Laforets[1], Panoraia Kotantaki[1], Beatrice Malacrida[1], Samar Elorbany[1], Ranjit Manchanda[2], Emmanuel Donnadieu[3], Frances Balkwill[1].
[1]Cancer Research UK Barts Centre, London, United Kingdom,[2]Wolfson

Institute of Population Health, London, United Kingdom,[3]Institut Cochin, Paris, France

Cell motility is an important component of anti-tumor responses, allowing immune cells like myeloid and cytotoxic T cells to infiltrate tumors. Using *ex vivo* human and mouse high-grade serous ovarian cancer (HGSOC) tumor slices combined with time-lapse imaging, we monitored the movement of $CD8^+$ T and myeloid cells in live tumors, in real-time. To analyze the recordings and characterize immune cell movements, we developed a semi-supervised analysis, identifying four types of cell behavior: migrating, long migrating, static and wobbling. Tumor slices were maintained 24h *ex vivo*, retaining viability and cell movements. We show that *ex vivo* treatments with LPS altered $CD8^+$ T and myeloid cell behavior. *In vivo* chemotherapy reduced *ex vivo* cell movements in human and mouse tumors, and differentially affected $CD8^+$ T and myeloid cells in 60577 and HGS2 murine tumors, respectively chemo-sensitive and chemo-resistant mouse models, suggesting those cell types have different roles in the response to chemotherapy. *Ex vivo* tumor slices can extend *in vivo* mouse work to human, providing a stepping stone to translate mouse cancer studies to clinical trials.

#5914

Colorectal cancer attributes and outcomes according to *Fusobacterium nucleatum* enrichment and presence

Courtney M. Hill[1], Meredith A. J. Hullar[2], Adriana Reedy[2], Rachel Malen[2], Hamza Ammar[2], Orsalem Kahsai[2], Ningxin Ma[2], Shuji Ogino[3], Timothy Randolph[2], Polly Newcomb[2], Amanda Phipps[2]. *[1]Epidemiology, University of Washington, Seattle, WA,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]Pathology, Brigham & Women's Hospital, Harvard Medical School, Boston, MA*

Purpose: *Fusobacterium nucleatum* (*Fn*) has been associated with colorectal cancer (CRC) etiology and outcomes. However, these relationships may differ by tumor attributes. We examined whether *Fn* enrichment and presence in CRC was associated with tumor attributes and survival.

Experimental Design: We measured the abundance of *Fn* via droplet digital PCR in patient-matched CRC tumor and normal tissue samples from a subset of participants in the Puget Sound CRC Cohort (n=526). *Fn* enrichment was defined as the continuous difference in *Fn* abundance (normalized to counts of a host housekeeping gene) between patient-matched tumor and normal tissue samples. *Fn* presence in tumor was classified categorically as negative, low (*Fn* abundance >0 but <median level among those positive for *Fn*), or high (abundance ≥median). *Fn* enrichment and presence variables were examined in relation to tumor attributes (site, stage, microsatellite instability [MSI] status, CpG island methylator phenotype [CIMP] status, *BRAF* and *KRAS* mutation status), molecular subtypes, and CRC survival. Molecular subtypes were defined as: type 1 (MSI-high, CIMP-high, *BRAF*-mutated); type 2 (microsatellite stable [MSS]/MSI-low, CIMP-high, *BRAF*-mutated); type 3 (MSS/MSI-low, non-CIMP, *KRAS*-mutated); type 4 (MSS/MSI-low, non-CIMP, *BRAF*- and *KRAS*-wildtype); and type 5 (MSI-high, non-CIMP, *BRAF*- and *KRAS*-wildtype). Logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI) for associations of *Fn* enrichment and presence with tumor attributes, adjusted for age, sex, tumor site, and *Fn* abundance in normal tissue (*Fn* enrichment only). Cox regression was used to estimate hazard ratios (HR) and 95% CIs for the associations of *Fn* enrichment and presence with CRC survival, adjusted for age, sex, tumor site, tumor markers, and *Fn* abundance in normal tissue (*Fn* enrichment only).
Results: High *Fn* presence was negatively associated with left-sided colon and rectal tumors. While *Fn* enrichment was only significantly associated with CIMP-high status (OR 1.2; 95% CI 1.0, 1.4; p=.03), high *Fn* presence was positively associated with MSI (OR 4.9; 95% CI 2.8, 8.4; p<.001), CIMP-high (OR 3.2; 95% CI 1.8, 5.7; p<.001), and *BRAF*-mutated status (OR 3.3; 95% CI 1.8, 6.1; p<.001). *Fn* enrichment was associated with higher odds of type 2 tumor classification (OR 1.2 95% CI 1.0, 1.5; p=.03) and high *Fn* presence was associated with higher odds of type 1 (OR 5.8; 95% CI 2.3, 15.0; p<.001) and type 5 tumor classification (OR 3.4; 95% CI 1.1, 10.4; p=.03). Continuous *Fn* enrichment was independently associated with lower survival (HR 1.1; 95% CI 1.0, 1.1; p=.006) but high *Fn* presence was not (HR 1.0; 95% CI 0.6, 1.6; p=.99).

Conclusions: Our findings suggest that *Fn* enrichment and presence are associated with certain CRC tumor attributes and survival, but associations varied by how *Fn* status was defined.

#5915

Exploring the impact of microbiome in the response of combined radiation with immune checkpoint blockade in muscle invasive bladder cancer (MIBC)

Eva Michaud[1], Cynthia Faubert[2], Jose Joao Mansure[1], Irah King[2], Wassim Kassouf[1]. *[1]McGill University Health Centre Research Institute, Montréal, QC, Canada,[2]McGill Interdisciplinary Initiative in Infection and Immunity, Montréal, QC, Canada*

BACKGROUND : Radiation therapy is a promising bladder-sparing option for MIBC treatment. Yet, 30% of patients do not respond and of those, half will later die of metastasis. Combining radiation therapy with immunotherapy (CT) thus presents a worthy candidate to fulfill this unmet need. In preclinical models, improved antitumor responses when RT is combined with PD-1/ PD-L1 blockade have been described. Yet, there remains a flagrant lack of knowledge on the determinants of combination therapy success. In this context, the composition of the gut microbiome is critical in conditioning local and peripheral immunity. Recent metagenomic studies have shown the gut microbiome influences the efficacy of PD-1-based IT in epithelial tumors, melanoma, and lung cancer, to name a few. In addition, modification of the gut microbiome with oral gavage of immunogenic bacteria potentiates the activity of combined RT and anti-PD-L1 therapy. Furthermore, immune profiling shows enhanced systemic and antitumor immunity in responding patients with a favorable gut microbiome (such as enrichment in *Akkermansia muciniphila*, *Bifidobacterium* and *Faecalibacterium*). Therefore, we aim to document the role of patients' microbiome in polarizing anti-tumor immune responses to CT in order to eventually use its composition as a predicting factor of CT success. METHODS : Fecal material from responder (R, n=3) and non-responder (NR, n=3) MIBC patients was gavaged into 20 germ-free (GF) mice in two administrations one week apart. 3 weeks after the last gavage, tumor cells (MB49) were delivered subcutaneaously. Once tumors reached 0.1-0.15cm^3, mice were randomized into 4 groups : control; anti-PD-L1 alone;

RT alone; RT + anti-PD-L1. 7 days after the start of treatment, tumors were harvested, dissociated and frozen as cell suspensions for single cell immune profiling and TCR sequencing (10X Genomics). Stool were collected weekly for 16S sequencing. Correlation networks from sequencing data were built (TransNet and Microbiome R packages) and visualized using Cytoscape to show interactions between the tumor immune microenvironment and the gut microbiome in R and NR-receiving mice.
RESULTS : We show feasibility of the experimental design as well as robust engraftment of human FMT to germ-free mice in a bladder cancer tumor model. FMT from NR lessened the known beneficial effects of RT in the MB49 model compared to FMT from R. Transkingdom analysis of sc-RNA-seq and 16S show robust statistical interactions between immunosuppression and enrichment in microbes associated to poor outcome in immunotherapy.
SIGNIFICANCE : To our knowledge, this is the first study to use FMT as a modulator of response in the context of radiation therapy combinations in MIBC. Findings from this study have a strong predictive value that could be used to select patients who will benefit most from a personalized therapeutic approach.

#5916

Weight loss intervention triggered gut microbiota modulation can positively impact obesity associated endocrine therapy resistance

Sheetal Parida[1], Sumit Siddharth[1], Nethaji Muniraj[1], Zhenhui Liu[2], Ishan Barman[3], Michael Smith[1], Jenni Sheng[1], Vered Stearns[1], Janelle W. Coughlin[1], Dipali Sharma[1]. *[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Mechanical Engineering, Johns Hopkins University, Baltimore, MD,[3]2Department of Mechanical Engineering, Johns Hopkins University, Baltimore, MD*

Background: 41.9% of adult US population is obese and every 5-unit BMI increase is associated with 12 percent increase in breast cancer risk; it is an independent predictor of poor outcomes in breast cancer. Microbiome has emerged as a central regulator of obesity and we recently discovered that microbes can not only potentiate breast cancer growth and metastasis but also affect therapeutic response. We showed weight-loss by Diet/Exercise/Behavioral intervention (POWER-remote trial) exerts

favorable effects. Here, we examine molecular underpinnings of poor therapy response in obese state and explore the gut microbiome to mitigate the same.
Methods: We co-implanted lineage determined human White preAdipocytes (hWAT) with MCF7 breast cancer cells in the mammary glands of mice. Changes in tumor microenvironment and tumor cells were evaluated *ex situ* by RNA sequencing, flow cytometry, Raman spectroscopy, Quantitative phase microscopy, PCR, immunoblotting and functional assays. To inspect the gut microbiome, 16 obese breast cancer patients were subjected to weight loss intervention over 14 weeks. Gut microbiome was analyzed at baseline and post-intervention by microbial shotgun sequencing. Patients were divided into responders and non-responders based on % weight-loss.
Results: We found that human breast cancer cells co-implanted with hWAT formed more aggressive tumors compared to controls. RNA sequencing revealed significant upregulation of multiple oncogenic pathways along with robust innate immune response. Tumor dissociated cells from hWAT-MCF7 tumors showed extensive molecular reprogramming rendering them more proliferative, motile and stem-like along with dramatic physiological changes like increased intercellular lipid accumulation. hWAT-MCF7 cells attained resistance to multiple drugs including Tamoxifen, Fulvestrant, Letrozole and Palbociclib. Simultaneous targeting of multiple signaling pathways using pharmacological inhibitors is infeasible in clinical setting hence we explored the obesity-microbiome axis. Obese breast cancer patients underwent POWER-remote intervention and their gut microbiome analysis showed significant differential expression of many microbes. Based on abundance and metabolite profile, *F. prausnitzii* was selected as the candidate of interest. On treatment with *F. prausnitzii* growth media, acquired multi-drug resistance in hWAT-MCF7 cells could be reversed suggesting that increase in gut population of the bacterium could be helpful in sensitizing patients unresponsive to therapy.
Conclusion: Direct interaction between breast cancer cells and WAT rendered them resistant to multiple drugs. Metabolites produced by weight-loss-associated bacterium *F. prausnitzii* reversed adiposity-induced multi-drug resistance, hence, can potentially have therapeutic benefits in obese breast cancer patients.

#5917

Development of a medium-to-high throughput organoid-bacteria co-culture platform for the assessment of host pathogen interaction

Eider Valle-Encinas[1], Roshni Nair[1], Katerina Pisa[1], Mayke Doorn[1], Farzin Pourfarzad[1], Lani San Mateo[2], Nicole Desch[2], Prashanth Gokare[2], David Pocalyko[2], Sylvia F. Boj[1], Carla Verissimo[1]. *[1]Hubrecht Organoid Technology, Utrecht, Netherlands,[2]Janssen, Spring House, PA*

Pathogens such as colibactin-producing bacteria strains of the *Enterobacteriaceae* family are highly prevalent in the gut microbiota of colorectal cancer (CRC) patients. HUB patient derived Organoids, (HUB-Organoids™ or PDOs) are self-organized epithelial cell structures with near-physiological features, extensively used to model aspects of cancer initiation and progression. Studies conducted by Pleguezuelos-Manzanos et al. (2020) showed that repetitive cycles of colibactin-producing bacteria into the organoid lumen via microinjection, led to two co-occurring mutational signatures appearance, a single-base substitution signature (SBS-pks) and an indel signature (ID-pks), identified in a subset of CRC patients (~2% and 7%, respectively). These results highlight the relevance of organoids for modelling host-pathogen interactions and the application of these systems as *in vitro* platforms for investigating long-standing cause-correlation relationship between the presence of genotoxic pathogens and CRC development. The limited scalability of sophisticated co-culture strategies with pathogens such as microinjection has represented a bottleneck in the use of organoids as throughput screening tools in the development of preventive therapies. Thus, there is an unmet need to develop alternative co-culture systems compatible with the process of compound screening. An organoid-bacteria co-culture system compatible with medium-to-high throughput screening readouts has been developed. This co-culture system is currently tailored for the modeling of colibactin genotoxic effects in the gut epithelium, but theoretically could be extended as a discovery platform to identify targetable, novel and complex interactions between host and pathogen. Key words: colibactin, organoids, CRC, screening

Interrogating host-intratumoral microbial interactions in pancreatic cancer

Vidhi Chandra[1], Hajar Rajaei[1], Seyda Baydogan[1], Javier Gomez[1], Sammy Ferri-Borgogno[1], Anirban Maitra[1], Erick Riquelme[2], Ismet Sahin[3], Jared Burks[1], Michael Kim[1], Florencia McAllister[1]. *[1]University of Texas MD Anderson Cancer Center, Houston, TX,[2]Universidad Mayor, Santiago, Chile,[3]Texas Southern University, Houston, TX*

Cancer is increasingly becoming a rising cause of mortality worldwide. Microbiota, both within the gut and tumors, has emerged as a significant player influencing tumor growth and responses to therapies. The tumor niche provides a privileged microenvironment for microbial colonization. Recent evidence links microbiota and pancreatic tumorigenesis. Pancreatic ductal adenocarcinoma (PDAC), is an aggressive cancer surrounded by a highly immuno-suppressive tumor microenvironment (TME) which limits efficacy of most available therapies. We have previously reported that rare long-term survival in pancreatic cancer is associated with an intratumoral microbial signature which correlates with enhanced TME immunoactivation, suggestive of microbial mediated immune cell recruitment. A gut-to-tumor microbial crosstalk was also found in a human-to-mouse Fecal Microbiota Transplant (FMT) tumor model. While we have identified the vital role of microbiota in affecting tumor immunity, there is still a gap of knowledge about local microbial interactions within TME. Deeper understanding of the microbial mediated events that are triggered and follow PDAC development, which act to induce and support tumor growth, would provide us with potential novel targets that could be blocked to reverse PDAC immunosuppression and tumor growth. To interrogate the features of the pancreatic tumor microbial niche, we performed spatial co-detection of microbial and host targets to identify the cellular compartment which interacts with microbes inside the TME in clinical samples. We developed novel qualitative and quantitative imaging methodologies for evaluating crosstalk between the host and microbes. We also evaluated the effect of microbial burden on transcriptomic changes in host cells through multiple spatial sequencing approaches. Overall, we dissect the functional role of microbes in orchestrating TME organization and their effect on tumor signaling.

The significant role of HMGB1 in mesothelial cells in contributing to the mesothelioma development induced by asbestos

Joelle S. Suarez[1], Giovanni Gaudino[1], Tak W. Mak[2], Michele Carbone[1], Haining Yang[1]. *[1]University of Hawai'i Cancer Center, Honolulu, HI,[2]The Campbell Family Institute for Breast Cancer Research, Princess Margaret Cancer Center, University Health Network,, Toronto, ON, Canada*

Diffuse Malignant mesothelioma is a very aggressive cancer that is related to asbestos exposure. We found previously that following asbestos deposition in the pleura and in the peritoneum, mesothelial cells release HMGB1 that attract granulocytes and macrophages that, in turn, secrete HMGB1. It was unknown whether the primary source of HMGB1 that drives the inflammatory process caused by asbestos, which may ensue in mesothelioma, derives from the mesothelial cells exposed to asbestos or from the granulocytes and macrophages. To study separately the contribution of mesothelial cells and of the inflammatory cells to HMGB1 secretion that drives mesothelioma development, we used two tissue-specific HMGB1 knockout mouse models: (1) An inducible mesothelial conditional HMGB1 knockout ($HMGB1^{\Delta pMeso}$) mouse model, and (2) a constitutive myelomonocytic-lineage knock out ($HMGB1^{\Delta Mylc}$) mouse model. To investigate the role of HMGB1 in asbestos induced carcinogenesis *in vivo*, we conducted both short-term and long-term experiments in $HMGB1^{\Delta pMeso}$ mice and in $HMGB1^{\Delta Mylc}$ mice. For the Short-term experiment, we observed that one week following the completion of the 10-weekly crocidolite i.p. injections, all the mice in experimental and control groups showed inflammation with multiple granulomas around asbestos deposits in the various tissues and organs present in the abdomen, and diffuse mesothelial hyperplasia. However, the granulomas in $HMGB1^{\Delta pMeso}$ mice were significantly smaller compared to those found in the control WT mice. TNFα IHC stain was minimal to non-detectable in the granulomas and areas of mesothelial hyperplasia of $HMGB1^{\Delta pMeso}$ mice, compared to a strong TNFα staining in both $HMGB1^{\Delta Mylc}$ and WT mice. For the Long-term experiment, we observed that the incidence of mesothelioma was significantly lower in $HMGB1^{\Delta pMeso}$ mice compared with the 3 control groups including WT mice, $HMGB1^{F/F}$ mice and $Wt1ERT2^{Cre/+}$ control mice. Moreover,

HMGB1$^{\Delta pMeso}$ mice had a significantly longer mesothelioma-specific survival compared to all three controls. Histologically, the HMGB1$^{\Delta pMeso}$ mesotheliomas were smaller and grew largely over the surface rather than infiltrating the abdominal organs, compared to the mesotheliomas that developed in the three control groups.In summary, our findings underscore the role of HMGB1 in asbestos pathogenesis, including asbestos induced chronic inflammation and mesothelioma. Moreover, our findings elucidated the mechanisms responsible for asbestos induced inflammation and asbestos carcinogenesis, and the causal link between HMGB1, TNFα secretion and mesothelioma. Our results point to the HMGB1 secreted by mesothelial cells as the culprit and thus the ideal target to prevent the growth of mesothelioma upon asbestos exposure and during the early phases of mesothelioma growth.

Methods to Measure Clonal Evolution

The genetic landscape of metastatic breast cancer reflected in circulating tumor DNA

Stephanie Kavan. *Odense University Hospital, Odense, Denmark*

Tissue biopsies of breast tumors only provide a snapshot of the evolution of the disease and may miss potential therapeutic targets, especially in the metastatic setting. Plasma-derived cell-free tumor DNA constitutes a potential surrogate for tumor DNA obtained from tissue biopsies to potentially capture inter-and intra-tumoral heterogeneity present in metastatic breast cancer. We aimed to investigate to what extent variants identified in the primary tumor and metastases are reflected in plasma. We performed whole-exome sequencing on tumor DNA from primary and metastatic lesions and plasma-derived circulating tumor DNA of eight patients with metastatic breast cancer. Our results show that metastases most often follow parallel evolution, given the low levels of stem mutations detected between primary tumors and matched metastases and mutational events private to the primary tumor. Furthermore, we demonstrated that ctDNA mainly reflected old stem mutations shared between primary tumor and metastasis, and less often, genetic alterations found solely in primary tumor or metastasis. Lastly, clinically relevant variants, e.g., resistance

mutations detected in primary tumor and metastasis, were to some extent reflected in ctDNA, including affected genes *MET, MTOR, CDK6, PIK3CA,* and *GATA3*. However, mutations in MED*1, NCOR1,* and *NCOR2* were only found in tumor tissues. These findings support the importance of a metastatic deposit biopsy to guide treatment decisions. Together, our results have implications for future ctDNA studies. For monitoring tumor burden using ctDNA, our results suggest that truncal mutations are the best candidates, as they are highest in circulating levels. For confident tracking of subclonal mutations in ctDNA, liquid biopsies are not yet to substitute metastatic tissue biopsies and instead demonstrate support to the current gold standard.

#5924

Intratumor heterogeneity in thyroid cancer progression

Vincenzo Davide Pantina. *University of Palermo, Palermo, Italy*

Thyroid cancer (CT) is the most common endocrine organs malignancy and is classified into:well-differentiated carcinomas, characterized by favourable prognosis and sensitive to standardtreatments, and undifferentiated carcinomas (UTC), the most lethal and highly refractoryagainst current therapies. UTCs have invasive and highly metastatic phenotype. The metastaticcascade model described distant metastasis origin deriving from cancer cells that seed to lymphnode and then disseminate to distant organs. According to this, lymphadenectomy was definedas an elective therapy for TC patients. However, recent TC trials discredit the improvement inpatient outcome. We aim to unveil the mechanism underlying tumor promotion, primary tumorclonal selection and TC metastatic origin determining which specific subclone is able to colonizedistant organs.
Material and method:Thyroid carcinogenesis model was previously generated starting from human embryonic stemcells which underwent to a differentiation protocol. At day 22 of differentiation, thyroidprogenitor cells (TPCs) were engineered using CRISPR CAS-9 technology to introduce mutationin BRAFV600E/TP53R248Q and NRASQ61R /TP53R248Q gene in order to recapitulate, wheninjected in *vivo*, UTC. Double mutated TPCs were transduced with Barcode-mediated clonaltracking technology and subcutaneously/orthotopically injected in immunocompromisedmice.

Results:We trasduced D22 double-mutated TPCs using highly complex lentiviral barcode library to mapclonal architecture in serial subcutaneous xenograft and multiple metastatic sites.Immunohistochemistry analysis obtained from P1 and P3 engraftment revealed conservation ofanaplastic thyroid cancer histologic features. Moreover, tumor-derived cells were in vitrocharacterized showing that P3 retains high migratory, invasion capacity and high MMP-9expression level, compared to P1. Transcriptomic analysis of P3 versus P1 derived cells showalso a critical metabolic switch. Cell derived from P3 engraftment were used to generateorthotopic model using Barcode mediated-clonal tracking technology.
Conclusion:Given its impact on patient care, understanding the evolutionary history of anaplastic thyroidcarcinoma is critical in cancer treatment. Phylogenetic studies on the primary and metastatictumor should determine the emergence of one or more subclones, which have a crucial roleduring all the phases of tumor promotion, progression and metastatic onset. A phylogeneticanalysis performed via the barcode-mediated clonal tracking technology, will allow us to trackprimary tumor cellular clones selection and the arising progenity, determining their role in themetastatic cascade. NGS Analysis and RNA-Seq technology will define a specific primary tumor
vs metastatic signature. The identification of cellular clones enriched in the metastasis willprovide new prognostic markers for metastatic thyroid carcinoma.

Medical Center, Dallas, TX,[4]Division of Cardiology, Department of Internal Medicine, Utsouthwestern Medical Center, Dallas, TX,[5]Division of Hematology and Oncology, Department of Internal Medicine, Children's Research Institute, Utsouthwestern Medical Center, Dallas, TX

INTRODUCTION: Clonal hematopoiesis of indeterminate potential (CHIP) is defined by the expansion of progeny derived from hematopoietic stem cells that have acquired somatic mutations at a VAF greater than 2%. CHIP manifests in 10% of patients older than 65 and is associated with an increased risk of progression to malignancies such as the MDS or AML. Although the risk factors for developing CHIP remain incompletely defined, they include prior exposure to chemotherapy and a history of smoking. Monoclonal gammopathy of undetermined significance (MGUS) is characterized by the abnormal growth of clonal plasma cells in the bone marrow and carries a risk of 1% for progression to multiple myeloma (MM) per year. Like CHIP, it becomes more prevalent with age and is associated with smoking. Additionally, patients with MM have demonstrated an increased risk for malignancies. Thus, an examination for a correlation between CHIP and MGUS promises to reveal a link between these two pre-malignant conditions. A recent study did not demonstrate such an association, but this study was performed in a very elderly population and may not be applicable to younger patients. In this study, we aim to assess the relationship between CHIP and MGUS in a population-based cohort of MGUS patients seen at UT Southwestern Medical Center.
METHODS: To evaluate an association between CHIP and MGUS, we collected bone marrow samples from 37 patients diagnosed with MGUS. We employed a hybridization capture-based next generation sequencing assay in order to detect CHIP. We identified 24 genes known to cause CHIP in adults. We also evaluated patients risk for developing MM after having been diagnosed with CHIP.
RESULTS: The mean age was 68, (range 26-92). 22 patients were white, 8 were black and 3 Hispanic/Latino. 17 patients had IgG, 7 had IgA, 3 had IgM, 3 had biclonal gammopathy and 7 light-chain MGUS. We identified 18 mutations to validate the presence of CHIP in 10 (27%) patients, with the most frequent being DNMT3A (7 patients) and TET2 (5 patients). Other common mutations noted were PPM1D (2), GND1 (1), SF3B1 (1), ASXL1 in (1), and NRAS in (1). 3 out of the 10 patients harbored 2 mutations and 1

harbored 4 mutations. History of chemotherapy (n=6) and smoking (n=14) was taken into consideration to determine the relative risk of patients with MGUS developing CHIP. We found that those who had a prior history of smoking and chemotherapy displayed a higher risk of CHIP. CONCLUSION: There was no significant association between CHIP and MM progression. Our analysis showed 1 patient with CHIP progression and 2 without CHIP progression. Because the rates of CHIP and MGUS are positively correlated with characteristics like aging and a history of smoking, we expected to see high rates of CHIP in patients within our cohort. However, our data suggests that CHIP is frequent (27%) in MGUS patients, but larger future cohorts need to be evaluated to validate this association.

High dimensional morphology analysis reveals new insights in melanoma cell heterogeneity

Evelyn Lattmann[1], Aizhan Tastanova[1], Andreja Jovic[2], Kiran Saini[2], Tiffine Pham[2], Christian Corona[2], Jeanette Mei[2], Michael Phelan[2], Stephane C. Boutet[2], Ryan Carelli[2], Kevin B. Jacobs[2], Julie Kim[2], Manisha Ray[2], Chassidy Johnson[2], Nianzhen Li[2], Mahyar Salek[2], Maddison Masaeli[2], Mitchell P. Levesque[1]. *[1]Department of Dermatology, University Hospital Zürich, Schlieren, Switzerland,[2]Deepcell Inc., Menlo Park, CA*

Melanomas are the deadliest skin cancers, in part due to cellular plasticity and heterogeneity within the tumors. These characteristics have made a deeper understanding of melanomas challenging. Classically, melanoma cells are characterized with a limited set of protein biomarkers. Gene expression signatures and mutational analysis (e.g., BRAF and NRAS genotyping) can provide a more detailed view of heterogeneity but may not translate to readily available biomarkers for functional studies. The Deepcell platform enables multi-dimensional morphology analysis and enrichment of unlabeled single cells using artificial intelligence (AI), advanced imaging, and microfluidics, enabling high resolution profiling of population heterogeneity. Label-free multi-dimensional morphology analysis may have higher resolution than a limited set of protein biomarkers, minimizes perturbation to the transcriptome, and reduces cell handling steps. We used patient-derived cell lines and dissociated biopsy

samples to train a Deepcell AI model to identify and sort for melanoma cells based on morphology alone. The model was tested on metastatic melanoma biopsies, with identification and enrichment of melanoma cells verified by various downstream assays, including scRNASeq. In addition to melanoma populations, the AI model classified various cells of the microenvironment, such as stromal cells and immune subtypes, based on morphology only. To further characterize tumor heterogeneity, we imaged >25 patient-derived melanoma cell lines representing melanocytic, mesenchymal, and intermediate phenotypic states on the Deepcell platform. Morphology analysis of these images revealed distinct clusters of cells for each phenotype, indicating that there are morphological differences associated with each state. We developed a random forest (RF) classifier to identify the top differential morphological features between the different cell lines, thereby providing a label-free means of phenotyping melanoma samples. The morphology analysis of the cell lines uncovered significant variability in pigmentation; an RF classifier distinguished between pigmented vs non-pigmented cells with >90% accuracy. Pigmentation is a hallmark of melanoma cells, and it has been associated with the melanocytic phenotype and differential drug response in vitro. However, there is not currently a robust method to profile and study pigmentation in live cells. We further investigated this observation by correlating morphological profiles, molecular, and functional information with the level of cell pigmentation. The Deepcell platform presents a new method for sorting and characterizing cellular heterogeneity using morphology, including pigmentation status. As such, multi-dimensional morphology analysis will bolster the understanding of complex melanoma states and tumor microenvironment, particularly in patient derived biopsies.

Leveraging single cell RNA profiling to uncover intra-tumor heterogeneity across cytogenetic subgroups in acute myeloid leukemia

Bofei Wang[1], Christopher Ly[1], Fatima Zahra Jelloul[1], Enes Dasdemir[1], Guilin Tang[1], Sonali Jindal[1], Yulong Chen[1], Sreyashi Basu[1], Poonam Desai[1], Pamella Borges[1], Preethi Gunaratne[2], Natalia Baran[1], Qing Deng[1], Dapeng Hao[3], Sean Post[1], Michael Green Green[1], Marina Konopleva[1], Andy Futreal[1], Padmanee Sharma[1], Hussein A. Abbas[1]. *[1]UT MD Anderson*

Cancer Center, Houston, TX,[2]University of Houston, Houston, TX,[3]Harbin Medical University, Harbin, China

Acute Myeloid Leukemia (AML) is a heterogenous disease characterized by immature blasts at different states of differentiation resulting in marked intra-tumor heterogeneity (ITH). Compared to patients with diploid cytogenetics, deletions in chromosome 7/7q (del7/7q), 5/5q (del5/5q) or double deletion (del5/5q & del 7/7q) confer worse outcomes in AML. We conducted single cell RNA (scRNA) profiling of bone marrow mononulear cells (BMMCs) from 20 newly diagnosed adult AML patients with diploid (n=7), del5/5q (n=5), del7/7q (n=5) and double deletion (n=3) to uncover ITH within each group and reveal cellular hierarchies associated with inferred copy number variations (CNV). Diffusion map analysis revealed heterogenous gene expression pattern in AML cells of del7/7q and double deletion patients, compared to diploid and del5/5q patients. CNV-based subgrouping of AML cells revealed significant enrichment of antigen presentation and immune response pathways in cells with inferred del7/7q or double deletion compared to cells without these deletions in the same patients, suggesting a heterogenous immune state in AML cells correlating with inferred genomic copy numbers. To dissect the composition of cellular hierarchies, AML cells were then projected onto an independent healthy BMMC reference (>20,000 cells) and labeled based on transcriptional similarity to healthy hematopoietic cells. AML cells from diploid patients were enriched for GMP-like and monocyte-like cells, while cells from non-diploid patients were enriched in more primitive states (HSC-like and CMP/LMPP-like). Correlating these hierarchal groups with leukemic stem cell (LSC) hierarchies revealed shared transcriptional program in LSC-like states across HSC-like, GMP-like, CLP-like and erythroid-like cells. This suggests that LSC signatures can also be expressed across AML cells and not just primitive cells. These findings were also validated in deconvolution analysis of bulk transcriptomes from three independent newly diagnosed AML cohorts (TCGA, BEAT-AML and MDACC). Spatial deconvolution of 3 patients using whole transcriptomic GeoMx revealed that primitive cells were more likely to be proximal to bone, while more differentiated states were enriched in distal region from the bone. Our findings reveal complex hierarchies in AML cells sharing the LSC expression pattern, while more

primitive cells were likely to localize to bone regions suggesting spatial migration of AML cells at time of differentiation.

Prevalence of clonal hematopoiesis in neuroendocrine tumor patients prior to lutetium 177 dotatate therapy (Lu177): A prospective trial of 36 patients

Yael Kusne[1], Terra Lasho[2], Zaid Elsabbagh[1], Abhishek Mangaonkar[2], Rachel Eiring[2], Timothy Hobday[2], Jason Starr[2], Tanios Bekaii-Saab[1], Thorvardur Halfdanarson[2], Mrinal Patnaik[2], Mohamad Sonbol[1]. *[1]Mayo Clinic Arizona, Scottsdale, AZ,[2]Mayo Clinic Rochester, Rochester, MN*

Introduction: Clonal hematopoiesis (CH) is defined by acquisition of somatic mutations in hematopoietic stem cells with potential for expansion over time. CH is influenced by exposures to chemotherapy/radiation & has been associated with therapy related myeloid neoplasms (tMN). Peptide receptor radionuclide therapy (PRRT) is a radionuclide therapy and is FDA approved for neuroendocrine tumors (NET). PRRT has been associated with a 2-10% risk of tMN, especially with prior exposure to alkylating agents. A prior study of 13 NET patients found CH prevalence of 64%. We carried out a prospective assessment of CH in NET patients prior to PRRT.
Methods: We evaluated pre-PRRT blood samples in 37 NET patients. Genomic DNA from mononuclear cells was analyzed for CH using a custom panel targeting 229 genes to a targeted depth of >1000X.
Results: After approval by Mayo Clinic IRB, 45 patients with Stage IV NET were enrolled & CH data was available for 37. Fifty-one percent of patients were female, with a median age of 68yrs (range, 34-84yrs). Types of NET included small bowel (51%), pancreatic (29%), carcinoid (8%), paraganglioma (5%), & other (5%). The median number of therapies prior to PRRT was 1 (range, 0-4) & included somatostatin analogues (SSA)-81%, alkylating agents-30%, & prior radiation-13%. Thirty-six of 37 patients had variants identified, 5 of which were presumed germline (DDX41, CDKN2B, CHEK2, POT1, ERBB2), & 17 (45.9%) had pathogenic variants meeting the operational definition of CH (DNMT3A, TET2, PPM1D, TP53, SF3B1, ASXL1). The median number of pathogenic variants per patient was 1 (range, 0-2), & 6 patients had >1. In patients >60yrs old, 46% had pathogenic variants & 3 patients with pathogenic variants (TET2, TP53,

DNMT3A) were <60 years old. The most common pathogenic variants were in epigenetic regulators, DNMT3A (37.5%) & TET2 (16.7%) with a median VAF of 2.8% (range, 0.70-50%). Eight patients (47%) with pathogenic CH had grade 1 cytopenias at baseline, compared to 10 patients (50%) without pathogenic CH. One patient had grade 3/4 cytopenia at baseline & had a missense variant in TP53 (VAF 50%) & history of exposure to anthracyclines, alkylating agents, platinum & radiation. The patient developed MDS before receiving PRRT. Pathogenic CH variants were more common in patients with previous exposure to radiation (p=0.008) or SSA (p=0.005). Two patients had PPM1D variants, both with a history of prior radiation, one with a history of prior alkylating treatment. Conclusion: To our knowledge this is the largest prospective evaluation of CH in NET. We identified CH to be present in 46% of patients & DNMT3A mutations were most common. This establishes the clonal landscape with mutations involving epigenetic regulators, DNA damage repair, transcription & splicing factors. Prospective longitudinal evaluation will evaluate the association between CH, cytopenias and tMN.

#5929

Individual organoid level analyses reveal hidden tumor molecular heterogeneity

Shirsa Udgata, Aishwarya Sunil, Katherine A. Johnson, Cheri A. Pasch, Dustin A. Deming. *University of Wisconsin-Madison, Madison, WI*

Introduction: Tumor heterogeneity is a major cause of resistance to therapies in cancer patients occurring during disease progression or secondary to therapeutic intervention due to clonal selection. Mapping tumor heterogeneity is crucial for developing therapeutics for cancer patients. Currently there are no reliable models for identifying heterogeneity *in vitro.* Patient-derived cancer organoids (PDCOs) from tissue samples of patients capture clonal and subclonal mutations. Here we use PDCOs from colorectal cancer (CRC) patients to study molecular heterogeneity across individual organoids and how the heterogeneity changes with passages.

Methods: Fresh CRC tissues from 4 patients undergoing endoscopy were obtained following consent on an IRB-approved protocol. PDCOs were cultured using Matrigel and previously published CRC organoid media.

Following maturation, individual organoids (spikes) were separated into Matrigel domes and expanded. Parent cultures from high/low passage numbers and expanded spikes were collected for next generation sequencing (NGS). A variant allele frequency (VAF) was determined for each nonsynonymous variant and considered subclonal if the VAF was between 10%-30%. Variants were annotated pathogenic or not using ClinVar.

Results: A total of 49 spikes were collected from 4 CRC PDCO lines and compared to the parent cultures using NGS. For low passage parent cultures, a median of 4 (range 3-8) subclonal alterations were identified. At high passages the number of subclonal variants decreased (median: 2 (range 2-4)). The individual organoid spikes maintained the founder (clonal) alterations and most also contained subclonal alterations, though at a lower frequency. Of those subclonal variants in the parent cultures, 31% were found in the spikes and an additional 54% found in the spikes were not identified in the parent. In a high tumor mutation burden line (MTB111), 12/17 spikes showed subclonal alterations in $APC^{A896V,\ F1515C,\ Q1544*}$ that were not present in the parent culture. Two PDCO lines (RC46A and RC46B) obtained from distinct sites of the same tumor were generated. One contained a subclonal mutation in MYC^{N26S} in the high passage parent culture and 7/9 spikes. This mutation was not present in any RC46A samples. The high passage RC46A parent culture and 2/7 spikes showed an alteration in $ARID1A^{G1037fs}$ while it was present only in a single spike of RC46B.

Conclusion: PDCOs identified subclonal alterations at the single-organoid level and are an exciting tool to study tumor heterogeneity. The spikes presented less subclonal variants than the parent but were largely not clonal. Future implications of using heterogeneity data from single organoids in therapeutic decisions are warranted.

Single day workflow for high-quality whole genome analysis of thousands of single cells

Jay A. A. West, Jeff G. Blackinton, Kyle Hukari, Joe Dahl. *BioSkryb Genomics, Durham, NC*

DNA sequencing technology provides the capability to tell the story of every cell in a heterogenous sample. ResolveDNA® generates uniform coverage of >95% of a single genome, enabling researchers to generate single-cell genomic data of unparalleled quality. Here, we report an enhancement to the ResolveDNA® workflow that increases the rate of data collection; the ability to reliably generate complete genomic information from up to 1536 cells in parallel from a single experiment. To achieve this, we have coupled a high-throughput automated process to a low volume reaction using the latest ResolveDNA® 2.5-hour chemistry. This establishes the potential for users to go from a single cell, or low-input DNA sample, to ready to sequence libraries in a single day for >3000 samples. As with earlier ResolveDNA® workflows, these reactions generate negligible amounts of contaminating and off target DNA during the reaction. A typical single-cell reaction yields ~ 85 ng of DNA. The single cell's amplified DNA product is amenable to multiple post amplification library preparation processes. We utilized both BioSkryb ResolveDNA® and Watchmaker Library Preparation kits for Illumina sequencing. We did not identify significant differences in the performance of the two products. Libraries were assessed at a depth of ~ 2million reads and determined to be of high quality, with low rates of chimeric DNA formation and less than 1% mtDNA resulting in the reaction product. A subset of samples was probed at >200 million reads, with >85% of the genome covered at 1x. Consistent with earlier ResolveDNA® workflows, the libraries were characterized with >99% precision and >80% sensitivity. The story told from a single cell's genome drives discovery and shines a light on the questions surrounding the causes of disease and cellular function. This workflow is designed to empower researchers to probe the genomic landscape of a heterogenous tissue sample.

Characterizing tumor heterogeneity through bulk and single cell analysis of patient derived bladder cancer models

Ziyu Chen[1], Xinran Tang[1], Eliyahu Havasov[2], Andrew Mcpherson[2], Carissa Chu[2], John R. Christin[3], Michael F. Berger[2], Nikolaus D. Schultz[2], Elisa de Stanchina[2], Michael M. Shen[3], Hikmat Al-Ahmadie[2], Kwanghee Kim[2], Gopa Iyer[2], David B. Solit[2]. *[1]Weill Cornell Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Memorial Sloan Kettering Cancer*

Center, New York, NY,[3]Columbia University Irving Medical Center, New York, NY

Background: A major hurdle to the development of novel targeted therapies for bladder cancer is the lack of preclinical models that reflect the genomic and biological heterogeneity of this human disease. To address this deficiency, we generated and characterized a new collection of patient-derived organoid (PDO) and xenograft (PDX) models and then used these models to study the role of mutated kinases in bladder cancer pathogenesis and the potential clinical utility of HER2-targeted antibody-drug conjugates (ADC).
Material and Methods: To define the landscape of HER2 and FGFR3 alterations in bladder cancer patients, we leveraged data generated by The Cancer Genome Atlas and multiple cohort subsets of the first 50,000 cancer patients enrolled in the MSK-IMPACT prospectively sequencing cohort. We successfully generated 19 PDOs and 34 PDXs that genetically and phenotypically reflect the molecular heterogeneity of human bladder cancers. A subset of these models was further characterized using a multiplatform approach, including bulk and single-cell DNA and RNA sequencing; and employed to study HER2 oncogenic dependence and sensitivity to multiple anti-HER2 targeted agents.
Results: 16% and 24% of the patients in the prospective MSK bladder cancer cohort had oncogenic HER2 and FGFR3 alterations, respectively. HER2 alteration frequency varied significantly as a function of histology, while FGFR3 alteration were less common in all variant histologies as compared to UC, NOS. Analysis of 119 patients with paired primary/metastatic tumors noted HER2 and FGFR3 mutational discordance in over 35% and 10% respectively. Single-cell RNA seq and DNA seq analysis of 4 PDOs demonstrated high interpatient and intratumoral heterogeneity of HER2 expression and *ERBB2* copy number. Our bladder cancer PDX models also demonstrated greater sensitivity to the HER2-targeted ADC trastuzumab deruxtecan (T-DXd) than to the kinase inhibitor neratinib, consistent with clinical data in bladder cancer patients.
Conclusion: FGFR3 and HER2 are both commonly mutated in bladder cancer patients. We observed frequent discordance in HER2 mutational status between primary/metastatic pairs suggesting that the analysis of archival primary tumor tissue may fail to detect actionable genomic

alterations when present in a subset of bladder cancer patients. Multi-omic single-cell analysis demonstrated significant interpatient and intratumor heterogeneity of HER2 expression and *ERBB2* copy number gain. Preclinical evaluation of HER2-altered PDO/PDXs indicated significantly greater sensitivity to the HER2-directed ADC T-DXd compared to the HER kinase inhibitor neratinib, providing rationale for future clinical trials of HER2 ADCs in bladder cancer patients.

Clonal mapping phylogenetic and transcriptomic analysis of an M36 PDX amputation lung metastatic osteosarcoma model

Sylvester Jusu[1], Zhongting Zhang[2], Zhang Wendong[2], Zhaohui Xu[2], Michael Roth[2], Jonathan Gill[2], Richard Gorlick[2]. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Pediatrics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Introduction: Osteosarcoma is a primary malignant bone tumor characterized by the production of spindle cells resulting in immature bone formation. It has been revealed that metastatic cancers including osteosarcoma have a subset of cells with different phenotypic and genetic signatures conferring advantage to drive progression and drug resistance within the intra-tumorally heterogeneous population. However, the lack of a defined in vivo model that can identify the rare genetic subpopulation and recapitulate clonal evolution has been a challenge. In this study, we used an established model to track and identify the clonal subpopulations and assess the genetic signatures that confer specific advantages selecting for uncontrolled growth, adaptation and colonization in the lungs.
Methods: We injected barcoded M36 PDX osteosarcoma cells intratibially in ten severe combined immunodeficiency disease (SCID) mice to track the clonal population/subpopulation of cells that metastasize the established primary tumors to the lungs. Limb amputation was performed on the tumor bearing leg upon detection of palpable tumor. Lung tissue was harvested post-amputation following death from metastasis or euthanasia. DNA and RNA from frozen tissues was extracted and analyzed by PCR, NGS, WES and RNA sequencing to map clonality, mutational and evolutionary profiles.

Results: Limb amputation was performed in 7 mice with all mice surviving the surgery. The mean mouse survival following amputation was 46.9 days and the longest survival was 167 days. Four (40%) of the primary tumor bearing mice had lung metastasis. A Shannon-Wiener and Jaccard similarity index show a diversity in clonal architecture between the primary tumors of all mice injected on the same day and a diversity in clonal population in both the primary tumors and their matched lung metastatic nodules. Clonal mapping further revealed 21 unique clones shared in all primary tumors examined. However, the clonal frequencies and distribution varied within each primary tumor and across the tumor samples. Interestingly, clonal frequencies increased in the lung metastatic nodules when compared to their matched primary tumors. Four distinct clones that were present in all the primary tumors were also found in all lung metastatic samples. These unique clones, here in called "seeding clones" may play an important role in the lung metastatic process.
Conclusions: We previously showed that the barcoded osteosarcoma PDX models are inter and intratumorally heterogenous both in vitro and in vivo. In the current model, we identify the multiple tumorigenic seeding clones that potentially act as drivers in the lung metastatic process. Furthermore, we show the dynamic evolutionary relationships between the clones by reconstructing a phylogenetic map of the M36 PDX tumor model.

Trimodal molecular analysis in single cells of a primary breast cancer cohort with ResolveOME ™ amplification

Jon S. Zawistowski[1], Isai Salas-Gonzalez[1], Tia A. Tate[1], Tatiana V. Morozova[1], Katherine Kennedy[1], Durga M. Arvapalli[1], Swetha D. Velivela[1], Jamie E. Remington[1], Josh Croteau[2], Kevin Taylor[2], Jeff G. Blackinton[1], Victor J. Weigman[1], Jeffrey R. Marks[3], Eun-Sil Shelley Hwang[4], Gary L. Harton[1], Jay A. A. West[1]. *[1]BioSkryb Genomics, Durham, NC,[2]BioLegend, San Diego, CA,[3]Surgery, Duke University Medical Center, Durham, NC,[4]Duke University Medical Center, Durham, NC*

The ResolveOME™ single-cell amplification solution unites whole-genome and full-length transcriptome information from the same cell, providing critical insight between these layers not possible when analyzed in isolation. We expand here upon the core layers of ResolveOME™ with the incorporation of BioLegend TotalSeq™ antibody oligo conjugates to investigate the expression of a panel of extracellular proteins in conjunction with the genomic and transcriptomic data.

The present study demonstrates the power of exploring all tiers of the Central Dogma of Biology in a series of experiments aimed at defining the molecular characteristics facilitating the transition from Ductal Carcinoma In Situ (DCIS) to Invasive Ductal Carcinoma (IDC), sequencing single cells from mastectomy samples from twelve patients in collaboration with Duke University Medical Center. We either enriched for ductal epithelial cells by fluorescence-activated cell sorting (FACS) or dispensed single cells agnostic to marker and relied on the full transcriptome output of ResolveOME™ to report cell identity. At the genomic level, we identified oncogenic driver mutations in *PIK3CA* (H1047R, N345K) and distinct classes of copy number loss at either or both Chr. 13 and 16q/17p, harboring *BRCA2/RB1 and TP53* tumor suppressor loci—whereby both SNV and CNV both varied in frequency within single cells of each patient and between patients of the cohort. These oncogenic mutations were nearly exclusive to biopsy cells of epithelial identity. However, intriguingly, ResolveOME™ uncovered cells of stem-like identity harboring *PIK3CA* missense mutations as well as uncovered cells still formally identified as epithelial and harboring mutant *PIK3CA* but with differential expression profiles—indicative of cells morphing cell state. Finally, the TotalSeq™ antibody panel unveiled intercellular heterogeneity and interpatient heterogeneity both in cell-surface protein phenotype of immune cells and in epithelial identity and signaling.

This ongoing study continues to catalog the three omic layers in increasing numbers of single cells and significantly expanding targeted surface-protein analysis harnessing the power of the single-cell united data to determine the “penetrance” of genomic changes in the context of cognate transcript and protein information, with the ultimate goals of defining DCIS to IDC transition factors as well as novel biomarker identification that may be exploited therapeutically.

Tracking T cell clonal dynamics across time and space in metastatic colorectal cancer

Ann-Marie Baker[1], Alison Berner[2], Tahel Ronel[2], Nick Trahearn[1], Barbara Bravi[3], John Bridgewater[4], Benny Chain[5], Trevor A. Graham[1]. *[1]Centre for Evolution and Cancer, The Institute of Cancer Research, Sutton, United Kingdom,[2]Centre for Genomics and Computational Biology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom,[3]Department of Mathematics, Imperial College, London, United Kingdom,[4]UCL Cancer Institute, University College London, London, United Kingdom,[5]Division of Infection and Immunity, University College London, London, United Kingdom*

Here we tracked T cell dynamics in 15 metastatic colorectal cancer (mCRC) patients who had multiple resections (median: 3, range: 2-7) over a period of >7 years (median: 10 years, range: 7-16 years), using a novel T cell receptor sequencing (TCRseq) method. These samples had been previously characterized for DNA and methylation alterations and gene expression, enabling an integrated analysis to determine potential cellular and molecular drivers and consequences of immune dynamics. This multi-region, multi-timepoint dataset presents a unique opportunity to study the co-evolution of mCRC and the T cell response over time, across metastatic sites and in response to therapy.

T cell antigen specificity is defined by the TCR - a highly diverse sequence that enables tracking of specific T cell expansions across time and space. TCRseq quantifies the abundance of T cell clones and maps the dynamics of the TCR repertoire, however little is known about how these are altered in different metastatic sites, and post-chemotherapy. We developed and validated a new FFPE-compatible TCRseq method and sequenced 216 longitudinal samples representing the mCRC cohort described above.

We detected a median of 348 unique TCRs per sample (range 69-9700), and revealed high levels of intra-tumor spatial heterogeneity. No significant difference was detected in the number of T cell clones or the TCR clonality between primary tumors (n=40), lung metastases (n=30) and liver metastases (n=50). Furthermore, these were not significantly different between tumor regions (n=139) and surrounding stroma (n=38). We found that compared to chemo-naïve tumors (n=36), those that had been exposed

to recent chemotherapy (n=41) had a significant increase in both the number of unique T cell clones and Simpson's evenness, likely reflecting a broad T cell response to DNA-damaging agents. After more than a year had passed without chemotherapy (n=64) these returned to pre-chemotherapy levels.
In most cases the 10 most abundant TCR sequences in the primary tumor represented 15-40% of the total repertoire. We tracked these expanded clones through metastases, identifying ubiquitous clones which persisted across metastatic sites and through therapy. We found other expanded clones which were no longer present in metastases lesions, although some of these were found to expand again in later metastases. Finally, we examined correlations with tumor genomics, finding evidence in some patients that the TCR repertoire tracks closely with tumor clones even through metastasis and chemotherapy.
In summary, this project represents the first comprehensive analysis of T cell dynamics through colorectal cancer metastasis, highlighting the changing T cell landscape post-chemotherapy and correlating the TCR repertoire with tumor genomics. Our results could have important clinical implications for mCRC immunotherapy and the design of personalized T cell-based therapy.

Phenotype profiling of tumor microenvironment in EGFR mutant lung adenocarcinoma with multi-omics data

You Won Lee[1], Eun Ji Lee[2], Seung Yeon Oh[3], Kyoung-Ho Pyo[4], Seong Gu Heo[4], YoungJoon Park[5], Su-Jin Choi[1], Kyumin Lim[6], Ju-hyeon Lee[6], Jae Hwan Kim[4], Jii Bum Lee[7], Ji Yoon Lee[8], Sun Min Lim[8], Chang Gon Kim[8], Min Hee Hong[8], Mi Ran Yun[4], Byoung Chul Cho[8]. *[1]Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Department of Biomedical Science Institute, Graduate School of Medical Science, Brain Korea 21 Project, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Biomedical Science Institute, Graduate School of Medical Science, Brain Korea 21 Project,Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Yonsei Biomedical Research*

Institute,Yonsei University College of Medicine, Seoul, Korea, Republic of,[6]JEUK Institute for Cancer Research, JEUK Co., Ltd., Gumi-City, Korea, Republic of,[7]Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[8]Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: EGFR mutations holds the major targets for drug in lung adenocarcinoma (LUAD). Despite the tremendous study of EGFR mutant (MT) LUAD, the comprehensive interpretation of the heterogeneous character of LUAD harboring EGFR MT remains a key challenge. Here, we investigated the heterogeneity of EGFR MT LUAD and explored the tumor microenvironment (TME) in EGFR MT LUAD.
Method: We performed single-cell RNA sequencing (scRNA-seq) from 135 LUAD patients which consist of normal(n=24), EGFR wild (WT)(n=18), and MT(n=93). Also, we used whole genome sequencing and bulk-RNA sequencing to validate with scRNA-seq results. From 898,648 cells, main cell types were classified. To explore the various characteristics of MT LUAD tumor cells, we used two ways: i) We re-clustered epithelial cells populating the normal, WT, and MT. ii) We re-clustered only MT epithelial cells. In each analysis, we identified the tumor character in the clusters using differential expressed genes analysis, lineage tracing, clinical information, mutation, and trajectory analysis. Also, we extracted each main cell type except epithelial cells, and identified subtypes of main cell types. Finally, we revealed the interaction of cellular components in TME.
Results: In the analysis of epithelial cells, we identified characteristics of specific EGFR MT by comparing of EGFR WT and MT tumors in clusters with similar biological features. The cluster represented by alveolar type 2 (AT2) known as initiation of LUAD was populating normal, WT, and MT. In this cluster, MT- and WT-associated pathway shared but differently significant between MT and WT in the pathway analysis. The cluster represented by proliferative is mostly comprised tumor cells and we found significantly increased the expression of MDK, CD24 in the MT of the cluster. In the analysis of only MT epithelial cells, 2 of clusters were stage-specific cluster: i) The cluster annotated as early stage cluster, ii) The cluster annotated as advanced stage cluster. Trajectory showed that there is a pseudotemporal continuum, following the stage from early stage cluster to

advanced stage cluster. Also, based on the lineage tracing, 2 of clusters revealed lineage-specific clusters: i) The cluster annotated as AT2 was enriched from early stage cells, ii) The cluster annotated as basal cell known as origin of lung squamous cell carcinoma(LUSC) was enriched from advanced stage cells. Psedotemporal ordering of these cluster revealed AT2 cluster transdifferentiate into basal cell cluster which implied the possibility of LUAD to LUSC transition by drug resistance. In the interaction of MT and WT TME, the number of signaling received epithelial cells from myeloid cells, endothelial cells, and fibroblasts as sender increased compared with the interaction of normal.
Conclusion: We shed light on the ecosystem of TME according to clinical and biological feature of tumor in EGFR mutant LUAD.

Tumor-Stromal Cell (Including Immune Cell) Interactions and Therapy Responses

#5940
Enhanced mast cell abundance is associated with the enrichment of CCR2+ cytotoxic T cells and favorable prognosis in lung adenocarcinoma.

Fan Fan[1], Xiaoming Zhang[2], Haiquan Chen[1]. *[1]Department of Thoracic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China,[2]Key Laboratory of Molecular Virology and Immunology, Institute Pasteur of Shanghai, Chinese Academy of Sciences, Shanghai, China*

Mast cells constitute indispensably immunoregulatory sentinel cells in tumor microenvironment, however, their functions are poorly characterized in lung adenocarcinoma (LUAD). Here, we performed flow cytometry and single-cell RNA sequencing to comprehensively characterize LUAD infiltrating MCs. MCs exhibited remarkably functional heterogeneity and were enriched in ground-glass opacity featured LUAD (gLUAD). The MCs in gLUAD exhibited proinflammatory and chemotactic properties while the MCs in radiologically solid LUAD (sLUAD) were associated with tumor angiogenesis. MCs were an important source of CCL2 that correlated with the recruitment of CCR2+ cytotoxic T lymphocytes (CTLs), which represent a specific subcluster of pre-exhausted T cells with tissue-resident memory phenotype and enhanced cytotoxicity. Increased infiltration of

MCs-CCR2+ CTLs and their colocalization showed a strong association with favorable prognosis after surgery but were not associated with improved survival after chemotherapy. Collectively, these findings reveal a key role of MCs in LUAD and their potential crosstalk with CTLs, suggesting that targeting MCs may be a novel immunotherapeutic strategy for LUAD.

Sequencing of targeted- and immune-therapy: delineating time dependent changes in both melanoma cells and the immune microenvironment

Riyaben Patel[1], Anna Trigos[1], Nicole Haynes[1], Emily Lelliott[2], Grant McArthur[1], Karen E. Sheppard[1]. *[1]Peter MacCallum Cancer Centre, Melbourne, Australia,[2]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia*

Targeted and immune therapies have transformed outcomes for melanoma patients, nevertheless, significant challenges remain to maximize their clinical benefit. BRAF/MEK targeted therapy (TT) is associated with very high initial response rates that are typically short-lived, while in contrast Immune Checkpoint Inhibitors (ICI) provide more durable responses but have lower initial response rates. Hence, it has been proposed that sequencing ICIs with TT would lead to a higher frequency of durable responses. However, there are many unanswered questions regarding the choice of immunotherapy, the best sequencing strategy and the mechanism leading to this synergy. To address these questions, we have optimized a syngeneic mouse melanoma model, YUMMER1.7-PV1 that is sensitive to both TT and ICIs. Importantly, this model recapitulates the known three therapeutic response phases of targeted therapies: initial response, followed by drug tolerance and then resistance. Investigation of the tumor immune microenvironment (TIME) at these three drug-induced phases, demonstrates that the immune suppressive microenvironment present during the acquired resistant phase is primed at the drug tolerance phase. Utilizing this model, we have explored the time-dependent therapy-induced changes in both tumor cells and the TIME during various TT and ICI sequencing strategies. This information will determine the optimal

sequencing strategy of targeted therapy and immunotherapy that will deliver better outcomes for melanoma patients.

Mechanism and role of neutrophil recruitment in head and neck squamous cell carcinoma

Kulsoom Ghias[1], Hina Shakeel[1], Alisalman Sheikh[1], Syed Hani Abidi[1], Kiran I. Masood[2], Saira Fatima[2], Fareena Bilwani[1]. *[1]Biological and Biomedical Sciences, Aga Khan University, Karachi, Pakistan,[2]Pathology and Laboratory Medicine, Aga Khan University, Karachi, Pakistan*

The immune system plays a pivotal role in identification and clearance of tumor cells, but can also be counterproductive and enhance tumor progression. Presence of neutrophils in solid tumors, including the sixth most common cancer globally - head and neck squamous cell carcinomas (HNSCC), is associated with poor prognosis. Pro-inflammatory cytokines regulated by NF-κB promote extravasation of neutrophils into tissue; neutrophils are polarized to anti-tumor (N1) or pro-tumor (N2) phenotype through the action of various pathways, including TGF-β. The mechanism and role of neutrophil recruitment in HNSCC were explored this study. Neutrophils isolated from adult donors were co-cultured for 5 hours with conditioned media (CM) from HNSCC cells SCC-9 and Cal-27, and stained with TNF-α, ICAM-1, CCL2, CCL5 for analysis of neutrophil phenotype by flow cytometry. TGF-β blocking antibody was used to explore the role of TGF-β in polarization of neutrophils. Canonical and non-canonical TGF-β signaling pathway activation was also investigated in these neutrophils through western blots. Using HNSCC patient samples, qPCR was performed for expression of genes involved in apoptosis, epithelial-to-mesenchymal transition, metastasis, and neutrophil function.
Following co-culture with 24-hour HNSCC CM, neutrophils begin to exhibit cell surface markers indicative of N2 phenotype, which is impacted by TGF-β blocking antibody. Neutrophils co-cultured with HNSCC CM exhibited altered expression of TGF-β mediators Smad2/3, p38 and Akt, which was abrogated with the addition of TGF-β blocking antibody indicating specificity of a TGF-β induced signaling. Gene expression analysis exhibited significantly higher expression of anti-apoptotic BCL2 and neutrophil function marker alpha defensin 1 in HNSCC patient samples

with greater neutrophil infiltration, while caspase 3 was expressed at significantly higher levels in HNSCC patient samples with low neutrophil infiltration.
HNSCC cells recruit neutrophils; evidence suggests that TGF-β pathway, which typically promotes N2 phenotype in neutrophils, is involved via canonical and non-canonical mediators including p38 and Akt. Further, HNSCC patient samples have varying levels of neutrophil infiltration and differentially express genes involved in apoptosis, EMT, metastasis and invasion, inflammation.

Plasma cell repertoire in the lung cancer tumor microenvironment

Akshay J. Patel[1], Naeem Khan[1], Alex G. Richter[1], Babu Naidu[2], Mark T. Drayson[1], Gary W. Middleton[1]. *[1]University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom,[2]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom*

Background: Post-operative recurrence in lung cancer continues to pose a major clinical challenge. B cell and plasma cell presence has been shown to correlate with improved survival and lower relapse rates in solid cancers and with improved response to checkpoint blockade. The aim of this study was to identify distinct immune cell compositions in the circulation and tumor microenvironment and make correlations with clinical and disease specific outcomes.
Methods: In this study, utilizing high-dimensional deep immunophenotyping techniques (mass cytometry), multispectral immunofluorescence based imaging and bulk RNA sequencing, we explored the B cell repertoire in the circulation and tumor microenvironment in early-stage lung cancer patients undergoing radical surgical resection.
Results: We demonstrate using high-dimensional deep phenotyping, clear differences in B cell composition between the circulation and the intratumoural microenvironment. Intratumoural predominant populations include plasma cells, from $CD38^{var}$ immature to CD138+ mature cells. B cells undergoing germinal center and follicular maturation as well as class-switched memory cells were predominantly found in the circulation. Eight

key populations were significantly differentially abundant between compartments on generalized linear mixed modelling ($p<0.0001$ with BH correction). These differences were observed in an external validation set. Plasma cell infiltration existed on a phenotypic spectrum from natural regulatory suppressive cells to antibody producing effector phenotypes. The latter correlating with better outcomes. Higher B cell expression of CD138 and Ig was noted within the tumor microenvironment in patients who did not experience early relapse. Significantly higher levels of circulating ki67+ $CD27^{hi}$ $CD38^{hi}$ $CD95^{hi}$ $IL10^{int}$ plasmablasts were noted in recurrence patients ($p=0.02$). Geospatial mapping identified clusters of suppressive plasma cells localized to the tumor stroma, likely regulating entry of effector cells into the tumor nest.
Conclusions: Our data has demonstrated the unique roles of effector and suppressive B cell subsets in NSCLC and the clear difference in surrogacy between tissue compartments. The lesser infiltration of suppressive phenotypes into the tumor nest may be to prevent the subsequent infiltration of effector plasma and effector B cells into the tumor nest. This tumor line of defense would be in keeping with the observation that higher levels of suppressive B cell subsets in the circulation links to higher rates of recurrence and a higher tumor effector plasma cell infiltrate correlates with protection against recurrent disease. The ambiguous role of B cells in the tumor environment predetermines the multidirectional development of immunotherapeutic approaches, either supporting positive B cell types or inhibiting the suppressive B cell phenotypes.

Relief of chromosomal instability-induced cGAS-STING signaling sensitizes *STK11*-mutant non-small cell lung cancer to immune checkpoint blockade

Lindsay A. Caprio[1], Christy Hong[2], Amit Dipak Amin[1], Somnath Tagore[1], Johannes Melms[1], Luke Cai[1], Yiping Wang[1], Patricia Ho[1], Michael Mu[1], Hanina Hibshoosh[3], Brian Henick[1], Kwok K. Wong[4], Samuel F. Bakhoum[2], Benjamin Izar[1]. *[1]Columbia University Irving Medical Center, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Pathology and Cell Biology, Columbia University Irving Medical Center, New York, NY,[4]New York University Langone Medical Center, New York, NY*

Non-small cell lung cancers (NSCLCs) harboring deletions or inactivating mutations in *STK11* (encoding LKB1) are associated with treatment-resistance, including to immune checkpoint blockade, and poor survival, yet the underlying mechanisms are poorly understood.

Here, we combined multi-modal single-cell transcriptomics, whole-genome sequencing (WGS), and analysis of public data bases totaling >10,000 NSCLC whole-exome sequencing (WES) and when available RNA (RNA-seq) profiles of AACR GENIE, MSK IMPACT, TCGA and CPTAC, high-content imaging, and functional assays, to determine genomic and mechanistic features of *STK11*-mutant NSCLC.

Across human WES/RNA-seq data, we find that *STK11*-mutant NSCLC have a significantly higher fraction of genome altered (FGA) and score strongly for the mRNA-based *CIN70* signature compared to other NSCLC genotypes, overall indicating that these tumors have a higher degree of chromosomal instability (CIN). Using high-content imaging, we show that both human and murine STK11-mutant models have a higher rate of micronuclei and chromosome-mis-segregation events, confirming their CIN^{high} status in dynamic assays. Next, we show that tonic CIN-induced activation of cGAS-STING signaling, whose activation is typically thought of inducing type I interferon expression, results in strong suppression of anti-tumor immune signaling. Remarkably, genetic or pharmacologic suppression of cGAS, and thus depletion of the STING ligand cGAMP, results in reprogramming and re-sensitization of *STK11*-mutant models to cGAS-STING mediated type I interferon responses. Furthermore, we show that CIN promotes excessive production cGAMP in *STK11*-mutant models. We find upregulation of two ectonucleotidases (ENPP1 and CD73/*NT5E*) that hydrolyze exported cGAMP to adenosine, which may further contribute to the highly dysfunctional tumor-microenvironment observed in *STK11*-mutant tumors. Lastly, suppression of CIN through overexpression of mitotic-centromere associated kinesin (MCAK) in murine *STK11*-mutant models results in decreased tumor growth and sensitization to anti-PD1 therapy.

In summary, we define *STK11*-mutant as archetypical chromosomally form of NSCLC, provide mechanistic basis that corelates with poor clinical outcomes, and demonstrate how relief of tonic CIN-induced changes may be therapeutically leveraged.

#5945

Transcriptional analysis of TME in MC38 colon carcinoma model following checkpoint inhibition

Priyanka Singh, Dan Saims, David Draper, Sheri Barnes. *In Vitro Preclinical Oncology, Labcorp Drug Development, Ann Arbor, MI*

Colorectal cancer (CRC) is one of the most common cancers with 200,000 US cases per year. Adenocarcinoma is the most common type of CRC, making up 95 percent of all CRC cases. Checkpoint inhibitors used for CRC have shown efficacy for a specific subset of patients. MC38 is a very popular tumor model due to its characteristics as an immunologically warm tumor and response to some immunotherapies. To identify underlying factors that influence differences in treatment response, the tumor microenvironment (TME) of the MC38 model was analyzed following the treatment with anti-programmed cell death protein 1 (PD-1) and anti-cytotoxic T lymphocyte associated protein 4 (CTLA-4). The minimal tumor growth inhibition was observed in MC38 tumors treated with anti-PD-1 or anti-CTLA-4. The NanoString® nCounter system and flow cytometry were used to provide gene and cell-specific signatures of TME in response to immunomodulatory agents. NanoString® nCounter and flow cytometry analyses were complementary and demonstrated evidence of T cell recruitment and upregulation of genes associated with several immune-related pathways following treatment. Cytotoxic CD8+ T cells, CD4+ T cells, and NK cells in MC38 tumors following treatment with anti-PD-1, suggesting activation of an immune response. With treatment of anti-CTLA-4, tumors did not have demonstrable alterations to immune cell subset distribution which supports evidence that anti-CTLA-4 treatment show minimal activation of the immune system in MC38 tumors. Further, transcriptome analysis with NanoString® nCounter system revealed that the immune pathways related to signatures such as interferon signaling, cytotoxicity, antigen presentation, cytokine signaling, and chemokine signaling were upregulated with anti-PD-1 treatment compared to control or anti-CTLA-4 treatment of MC38 tumors. The transcriptome analysis also demonstrated 2-5-fold increases of interferon, cytotoxicity, cytokine, and chemokine genes such as, Gbp2, Gbp3, Irf1, Irf7, Irf8, Ifit1, Ifit2, Ifit3, Tnfsf10, Ccl2, Ccl5, Ccl7, Ccl12, Cxcl9, Cxcl10, and Cxcl11 over control

in the case of anti-PD-1 treatment. In summary, anti-PD-1 treatment increased T cell recruitment into the tumor and upregulated genes in TME. Anti-CTLA-4 treatment known to enable combination activity with anti-PD-1, but not enough to show notable monotherapy activity. Immune cell subset distribution in TME and relative gene expression are two potential types of analyses to predict anti-tumor response. These data can be used mechanistically as well as to inform rational combination strategies for checkpoint inhibitors in colon adenocarcinoma.

OBI-999, an anti-Globo H antibody drug conjugate, exhibits synergistic anti-tumor effect in combination with pembrolizumab

Chun-Chung Wang, Chi-Huan Lu, Jhih-Jie Yang, Wan-Fen Li, Ming-Tain Lai. *OBI Pharma, Inc, Taipei, Taiwan*

Background: Globo H (GH) is highly expressed in a variety of epithelial tumors with a limited expression in normal tissues rendering it a novel therapeutic target. OBI-999 is an antibody drug conjugate (ADC) consisting of a GH-specific monoclonal antibody conjugated with monomethyl auristatin E (MMAE) through a cathepsin B cleavable linker. MMAE is known to induce immunogenic cell death (ICD) which involves in the activation of cytotoxic T lymphocyte-driven adaptive immunity with long-term immunological memory.
Aim: The aim of this study was to evaluate the synergistic effects of OBI-999 + pembrolizumab on tumor growth suppression in several xenograft tumor models.
Methods: OBI-999-induced ICD was examined *in vitro* by the detection of damaging-associated molecular patterns (DAMPs) such as calreticulin (CRT), HMGB1, and ATP in incubated Globo H expressing cells. The synergistic effects with the combination of OBI-999 and pembrolizumab as well as the ICD-related immunity were assessed *in vivo* using advanced severe immunodeficient mice that were reconstituted with human peripheral blood mononuclear cells (PBMCs).
Results: Incubation of OBI-999 with high GH expression cancer cell lines (HCC-1428, NCI-N87 and NCI-H526) and mid GH expression cancer cell line (SW-480) induced the release of DAMPs including CRT, HMGB1, and ATP, in a dose- and time-dependent manner, indicating that OBI-999 is

capable of inducing ICD *in vitro*. In the high GH expression human breast cancer cell line HCC-1428 xenograft model, OBI-999+pembrolizumab exhibited significantly stronger inhibition of tumor growth compared to either OBI-999 or pembrolizumab alone. Similar synergistic effects were observed in other xenograft tumor models including gastric (NCI-N87), small cell lung (NCI-H526), and colorectal (SW-480) cancers. Analysis of tumor-infiltrating lymphocytes (TILs) in HCC-1428 humanized mice showed that OBI-999 + pembrolizumab induced populations of activated cytotoxic CD8 T-cells and mature dendritic cells. Pembrolizumab decreased PD-1 expression on CD8 and CD4 cells, and OBI-999 decreased PD-L1 expression on tumor cells, which reversed the exhausted status of immune cells and alleviated immunosuppression in the tumor microenvironment. Conclusion: We demonstrated significant synergistic effects of OBI-999 and pembrolizumab in several animal models. These synergistic effects may be attributed to the ability of OBI-999 to induce ICD, as demonstrated by the release of DAMPs *in vitro* and tumor-specific immunity *in vivo*, suggesting that OBI-999 can create a tumor microenvironment that enhances the function of pembrolizumab. The results suggest that combination therapy with OBI-999 and immune checkpoint inhibitors is warranted in human clinical studies. OBI-999 is currently in Phase 1/2 clinical trials for the treatment of advanced solid tumors with high GH expression (NCT04084366).

Tumor cells escape cell death after radiotherapy by senescence - a mechanism that can be counteracted with zinc oxide nanoparticles

Nadine Wiesmann, Rita Gieringer, Johannes Kupka, Jonas Eckrich, Sebahat Kaya, Peer Kaemmerer, Bilal Al-Nawas, Juergen Brieger. *University Medical Center Mainz, Mainz, Germany*

Radiotherapy is still an important pillar for the therapy of head and neck squamous cell carcinoma (HNSCC); however, local recurrences arise in 15-50% of patients. During radiotherapy, there is a risk that individual tumor cells survive and proliferate again after a period of dormancy. Growing evidence suggests that senescence may play a key role in this context. We investigated *in vitro* radiotherapy-induced senescence and found that quiescent tumor cells survived treatment with 16 Gy. Those cells exhibited

characteristics of senescence, yet were able to regain their proliferative capacity, and senescence was associated with radioresistance. During radiotherapy, the cells of the tumor stroma are inevitably irradiated as well. It is already known that cancer-associated fibroblasts (CAFs) can promote tumor progression. However, their contribution to the survival of senescent tumor cells after radiotherapy is unknown so far. Furthermore, the association between radiotherapy-induced senescence and recurrences raises the question of how residual, senescent tumor cells can be eliminated to prevent the development of a recurrence at an early stage. These aspects were the subject of the study presented here. To study the interaction between tumor cells and CAFs during their response to irradiation, both cell types were irradiated with 16 Gy *in vitro* individually and in co-culture. Subsequently, proliferation, cell death, morphological characteristics, and the secretome were analyzed. Additionally, we investigated whether senescent tumor cells can be targeted by treatment with zinc oxide nanoparticles. We could show that not only the tumor cells but also the CAFs go into a senescent state in response to irradiation, seen by loss of proliferation, increased senescence-associated β-galactosidase activity, and typical morphological characteristics. The secretome analysis revealed that the co-culture of tumor cells with CAFs significantly altered the repertoire of cytokines released upon irradiation, indicating intense communication between the cell types during their response to irradiation. Therefore, it is important for future studies on radiotherapy-induced senescence to include the tumor stroma as well. Finally, we demonstrated that senescent tumor cells were vulnerable to cell death induced by treatment with zinc oxide nanoparticles, which thus could potentially contribute to eliminating residual tumor cells after radiotherapy. This study revealed that radiotherapy-induced senescence in tumor cells and associated fibroblasts could well be a therapeutic problem, as senescent tumor cells are not targetable by radiotherapy anymore. In the future, zinc oxide nanoparticles may help to counteract this escape mechanism to prevent recurrences.

#5948

MAGE-A3 expression with MMR-MSH6 screening suggests MAGE-A3 as a potential target for microsatellite-stable colorectal cancer

Jina Yom[1], Rachel Gonzalez[1], Eden Zewdu[1], Aubrey Su[1], Patrick Yin[1], Bailey Gilmore[1], Dehe Kong[1], Andy Han[1], Zhaoying Guo[1], Tianli Qu[1], Zoe

Zhao[1], Eric Christenson[1], Yan Ma[1], Hailey Guo[1], Xiaomin Hu[2], Qi Ren[2], zhaohui Wu[2], Xuan Liu[1], Wei Fu[1]. *[1]OriGene Technologies, Inc., Rockville, MD,[2]OriGene Wuxi Biotechnology Co., Ltd., Binhu District, China*

Colorectal Cancer (CRC) is the second leading cause of death worldwide. Recent developments in cancer immunotherapy have obtained encouraging clinical responses, including PD-1/PD-L1 blockade therapy, although response rates vary depending on tumor type. For example, despite the lack of response by microsatellite-stable CRC, a subset of CRC with deficient mismatch repair (dMMR) and high microsatellite instability (MSI-H) responds especially well to the PD-1/PD-L1 blockade therapy. For other types of CRC which do not respond to PD-L1 therapy, new targets are being investigated. One family of targets is the cancer testis antigen MAGE-A whose expression is restricted to germline cells in normal tissue but is overexpressed in many cancer cells. In this study, immunohistochemical analysis of MAGE-A3 expression in colon cancer along with IHC screening of mismatch protein MSH6 was performed. Many of the cases in this study observed a co-expression in the tissue. In the tumors, MAGE-A3 was observed to have weak cytoplasmic expression while MSH6 had strong nuclear expression in the epithelial cells. The immune cells adjacent to the epithelial cells were also positive for MAGE-A3. This result suggests that MAGE-A3 may be a promising target for microsatellite-stable colorectal cancer immunotherapy.

Modulate TAM infiltration at cancer-immune interface by targeting at monocyte migration

Wenxuan Du[1], Adrian Johnston[1], Praful Nair[1], Jingyi Zhu[2], Khin Sandar Win[1], Bryan Zhou[1], Jude Phillip[2], Pei-Hsun Wu[3], Denis Wirtz[1]. *[1]Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, MD,[2]Biomedical Engineering, Johns Hopkins University, Baltimore, MD,[3]Institute for NanoBioTechnology, Johns Hopkins University, Baltimore, MD*

Extensive infiltration of tumor-associated macrophages (TAMs) into the solid tumor microenvironment (TME), where they promote angiogenesis,

initiate metastasis, and tune immunosuppression, has long been proven to correlate with worse patient prognosis. Thus, much significance has been attached on either impeding TAM infiltration or reversing pro-tumoral TAMs back into phagocytic M1 phenotype. Nevertheless, while revealing underlying mechanisms of blocking TAM recruitment, widely adopted *in vitro* migration assays like Transwell, μ-slides fail to distinguish cell's random migration from chemotaxis (biased migration) and introduce 3D extracellular matrix environment. Here we present data that monocytes, as major replenishment source of TAMs, massively boost their random migration via paracrine pathway to initiate early-stage infiltration using an advanced 3D multi-compartment organoid model. In addition, before re-educated into TAMs, monocytes in the TME are capable of inducing triple negative breast cancer cells' hyper-proliferation by activating their MEK/ERK signaling pathway. This work provides evidence that TAM infiltration is driven by monocytes' random/biased migration separately and identifies a potential combinational immunotherapy targeting at monocytes instead of TAMs.

Ccr2+ monocyte derived macrophages influence trajectories of acquired therapy resistance in BRAF-mutant melanoma

Dahihm Kim, Luye An, Jiwon Moon, Andrew White. *Cornell Univ. College of Veterinary Med., Ithaca, NY*

Therapies targeting oncogene addiction have had a tremendous impact on patient care, but drug resistance continues to be problematic. One method to deal with this challenge entails extending the scope of anti-cancer treatment beyond tumor cells by additionally altering their tumor microenvironment. Understanding how the tumor microenvironment can contribute to the evolution of diverse resistance pathways could aid in the rational design of sequential treatments that enforce pressure towards a more predictable resistance trajectory. Tumor associated macrophages often support neoplastic growth and are frequently the most abundant immune cell found in tumors. Here, we used clinically relevant *in vivo* Braf-mutant melanoma models and *Ccr2-RFP; Cx3cr1-GFP* mice to track the long-term changes in tumor cells and macrophages under targeted therapy with Braf/Mek inhibitors. We assessed the dynamic evolution of the macrophage

population generated by therapy pressure-induced stress. During the onset of a drug-tolerant persister state, *Ccr2*+ macrophage infiltration rises, underscoring a prominent role at this point in melanoma evolution for development of drug-resistance. Importantly, we show that a lack of melanoma infiltrating *Ccr2*+ macrophages delays onset of resistance. In this case, rebounded tumor cells from *Ccr2* knockout recipients favor the evolution of cell-extrinsic mediated resistance mechanisms, which can be reversed when these adapted melanoma cells are relocated to a microenvironment with functional Ccr2. Conversely, Ccr2 presence promotes development of cell-intrinsic drug resistance with a stable phenotype in rebounded tumor cells. Overall, this demonstrates that the development of resistance may be manipulated and directed to improve timing and probability of relapse.

The correlation between single nucleotide polymorphism of chemokine receptor and ligand and infiltrating immune cells on tumor microenvironment of gastric cancer

Sunjoo Yoon[1], Ju Hyun Lee[1], Minsu Kang[1], Hyeon Jeong Oh[2], Jiwon Koh[2], Hye Seung Lee[2], So Hyun Kang[3], Young Suk Park[3], Keun-Wook Lee[1], Jin Won Kim[1]. *[1]Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Korea, Republic of,[2]Pathology, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Korea, Republic of,[3]Surgery, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Korea, Republic of*

Objective: Chemokines play roles in many normal biological processes, such as hematopoietic cell genesis and leukocyte migration and homing. Chemokines could be responsible for eliciting local accumulation of immune cells within tumor microenvironment. In this study, we examine if genetic variations in chemokine receptor and ligand are associated with infiltrations of immune cells on tumor microenvironment in gastric cancer. Methods: In 356 gastric cancer patients who received curative surgery followed by adjuvant chemotherapy, total 105 single nucleotide polymorphisms (SNP) in a chemokine ligand and chemokine receptor locus

within 16 genes (CXCR4, CXCR2, CXCR1, CX3CR1, CCR8, CCR9, CCR3, CCR2, CCR5, CCRL2, CCR6, CXCR5, CCR6, CXCR6, CCR7, DARC) were genotyped from peripheral blood sample. Total 11 immune markers such as CD3, CD4, CD8, FOXp3, CD68, CD163, L-selectin, i-NOS, ADMA17, Arginase, CD45RO were analyzed for deposition of immune cells according to SNP of chemokine receptor and ligand. Levels of immunohistochemistry staining were quantified by Image Analysis Toolbox and density of immune cells infiltration was calculated.
Results: 32 SNP locus of 8 genes (such as CXCR1, CXCR2, CCR3, CCR2, CCR5, CCRL2, CCR6. CXCR5) were selected using 25% cut-off value of minor allele frequency (MAF). Among 8 genes, CCR5 was the most relevant gene for immune cell infiltration on tumor microenvironment. Intron1-2545G>A (rs1799987) were associated with increased accumulation of CD3+, CD68+ and FOXp3+ cells compared to recessive carriers of the common allele. In CCR5 SNP that contained the common alleles of intron1-2549 G>T (rs2734648) and exon2A-2081 A>G (rs1800023), CD3+, CD4+, CD8+ and FOXp3+ cells
were infiltrated more than minor alleles.
Conclusions: The associations between infiltration of immune cells and SNP of chemokine receptor and ligand in gastric cancer were shown. Particularly, CCR5 SNP may be most relevant for correlation with infiltration of immune cells on tumor microenvironment.

Pyroptotic adipocytes contribute to chemoresistance in advanced stage ovarian cancer

Chang-Ni Lin[1], Yu-Ling Liang[1], Keng-Fu Hsu[1], Yi-Ying Wu[2]. *[1]Obstetrics and Gynecology, National Cheng Kung University Hospital, Tainan, Taiwan,[2]Graduate Institute of Clinical Medicine, National Cheng Kung University, Tainan, Taiwan*

Background: Ovarian cancer is known the gynecologic malignancy with the highest case-to-fatality ratio. Once appear metastasis, the 5 years survival rate reduce to 30-40% in these patients. Different with hematogenously metastasizing tumors, ovarian cancer cells primarily disseminate within the peritoneal cavity. Omentum, a lipid-rich tissue, is the most common metastatic site of ovarian cancer. In addition, the adipocyte-released free

fatty acid can be used by cancer cells to fuel its growth and proliferation. In this study, we attempt to clarify the regulation between metastatic ovarian cancer cell and omental adipocytes, and find a therapeutic strategy for advanced stage ovarian cancer.
Materials and Methods: A three-cell (SKOV3, 3T3L1 and THP-1) co-culture model was established to mimic in vitro tumor microenvironment of ovarian cancer omental metastasis. Flow cytometry was performed for the adipocytes survival rate with Annexin V/PI double staining. Caspase-1 activity assay was used to detect the cleavage of substrate YVAD-AFC level in adipocytes and quantified by a fluorescence microliter plate reader. The free fatty acid assay kit was used to detect free fatty acid level in condition medium and ascites. Invasion assay and MTT assay were used to validate the invasive ability and cell viability of ovarian cancer cells. Immunohistochemistry was used to CD36 staining in clinical specimens, and correlation analysis through prism 8 software. Results: We observed the adipocyte pyroptosis in 3-cell co-culture model, and the free fatty acid increased in culture medium by flow cytometry analysis, caspase-1 activity assay kit and free fatty acid assay kit. In the meantime, the invasive ability and cisplatin resistance increased in ovarian cancer cells. The free fatty acid level in ascites positive correlated with CD36 expression (r^2=0.2189, p=0.0375). Of note, combination treatment of cisplatin and sulfosuccinimidyl oleate (SSO) can reverse chemoresistance in 3-cell co-culture model. Overall, free fatty acid released form the pyroptotic adipocytes and increase invasive ability and chemoresistance in ovarian cancer cells. Block the interaction of free fatty acid and CD36 can reverse the chemoresistance in advanced ovarian cancer.
Conclusion: In this study, we demonstrated adipocytes pyroptosis can increase the free fatty acid release to the microenvironment, and then promote ovarian cancer cell invasion and increase chemoresistance. For more important, inhibition of free fatty acid and CD36 interaction can reverse the chemoresistance in the in vitro experiments. Thus, reduce the adipocytes pyroptosis may be a novel therapeutic strategy for the omentum metastatic ovarian cancer.

#5953
Reshaping the tumor microenvironment: new application of tamoxifen in triple negative breast cancer immunomodulation

Pony Yu-Ling Lee[1], Marvin A. E. Aberin[2], Chien-Chang Shen[1], Kun-Yuan Lin[1], Chao Di Chang[1], Chih-Chieh Yang[1], Shan-Yun Cheng[1], Ya Wen Hung[1], Xin-Guo Hsu[3], Shu-Ping Wang[4]. *[1]Pharmacology Discovery Services Taiwan, Ltd., New Taipei City, Taiwan,[2]Taiwan International Graduate Program in Molecular Medicine, Academia Sinica and National Yang Ming Chiao Tung University, Taipei City, Taiwan,[3]Graduate Institute of Life Sciences, National Defense Medical Center, Taipei City, Taiwan,[4]Institute of Biomedical Sciences, Academia Sinica, Taipei City, Taiwan*

Tamoxifen is a widely known estrogen receptor (ER) modulator which has been employed in adjuvant treatment of ER^+ breast cancer for over 30 years. Interestingly, clinical observations reveal that tamoxifen is capable of inducing regression of some tumors lacking ER expression whereas tamoxifen is also capable of increasing host resistance against cancer in an ER-independent mechanism. These findings suggest the immunomodulatory effects of tamoxifen may be ER-independent, but little is known about the underlying mechanism and the potential clinical implication. Recently, we identified a novel mechanism by which tamoxifen exerts its DNA-damaging potential by re-shaping the unfavorable tumor microenvironment in breast cancer. A long-term tamoxifen administration induces downregulation of the chromatin ‘‘reader’’ RACK7/ZMYND8, which acts as a suppressor of interferon-stimulated genes (ISGs, including cytokines and chemokines) and CEACAM1 in both ER^+ and triple negative breast cancer (TNBC) cells. To investigate the immunomodulatory effects of tamoxifen in conjunction with RACK7-knockdown, the orthotopic murine TNBC 4T1 model was employed to investigate tamoxifen-mediated cellular modulation in TNBC. The control and RACK7-knockdown 4T1 cells are orthotopically implanted into the mammary fat pad of female BALB/c mice. Peripheral cytokines/chemokines and high-content biomarker studies (multiplex immunoassays, flow cytometry, and single-cell RNA sequencing) are deployed to obtain insights into the mechanistic rationale behind the immunomodulatory effects of tamoxifen and/or RACK7-knockdown. The tamoxifen-mediated cellular modulation evokes cytokine/chemokine secretion and further induces T-cell infiltration into tumor area. However, tumor reduction was limited due to extensive T-cell

exhaustion from interaction of CEACAM1 and TIM-3, a “checkpoint” receptor expressed in $CD4^+$ and $CD8^+$ T cells. The expression patterns of CEACAM1 and PD-L1 in 4T1 tumor cells and that of TIM-3 and PD-1 in $CD4^+$ and $CD8^+$ T-cells correlate with intra-tumor infiltration of T-cells and tumor cell growth. Therefore, targeting the interaction between CEACAM1 and TIM-3 to overcome T-cell exhaustion is crucial for the new therapeutic role of tamoxifen treatment in TNBC breast cancer in conjugation with RACK7-knockdown. Altogether, our findings provide direct evidence to support a new therapeutic opportunity by targeting CEACAM1-TIM-3 interaction in the tamoxifen-mediated tumor immune microenvironment for improving immune checkpoint blockade therapy in breast cancer.

Germline epitopes modulate immune surveillance informing breast cancer subtypes

Kathleen Houlahan, Aziz Khan, Christina Curtis. *Stanford University, Stanford, CA*

Cancer represents a wide spectrum of molecularly and morphologically diverse diseases. Individuals with the same histopathological classification can have tumors with drastically different molecular profiles and clinical responses to treatment. It remains unclear as to when during the disease course these differences arise and why some tumors are addicted to one oncogenic pathway over another. Somatic genomic aberrations occur within the context of an individual’s germline genome, which can vary across millions of germline polymorphisms. It is unknown the extent to which germline differences influence the somatic evolution of a tumor. Interrogating 4,912 breast cancer lesions, spanning pre-invasive to metastatic disease, we demonstrate that germline variants in highly expressed and amplified genes influence somatic evolution by modulating immunoediting at early stages of tumor development. Specifically, we show that the burden of germline-derived epitopes in recurrently amplified genes selects against somatic gene amplification in pre-invasive and invasive breast cancer. As a representative example, individuals with high burden of germline-derived epitopes in *ERBB2* are significantly less likely to develop HER2+ breast cancer than ER+ or triple negative breast cancer. The same negative association between epitope burden and somatic amplification is

observed for four recurrent amplicons observed in high risk ER+ breast tumors. No association was observed between somatic amplifications and epitope burden in metastatic breast cancer suggesting a subset of tumors are able to overcome immune-mediated negative selection. Tumors that do are more aggressive and demonstrate an "immune cold" phenotype. Taken together, these data show the germline genome plays a pivotal role in dictating somatic evolution in breast cancer. Exploiting germline-mediated immunoediting may facilitate the development of blood-based biomarkers that refine risk stratification within breast cancer subtypes.

***In Silico* dissection of immune infiltrate signatures that are detected by DetermaIO, a predictor of response to immune therapy**

Brian Z. Ring[1], Catherine T. Cronister[1], Robert S. Seitz[1], Douglas T. Ross[1], Brock Schweitzer[1], David R. Gandara[2]. *[1]Oncocyte Inc., Nashville, TN,[2]UC Davis, Sacramento, CA*

Background: The composition of tumors includes not only malignant but also immune, stromal and other cell types. Understanding this dynamic tumor immune microenvironment (TIME) is important to guide treatment and develop novel therapies and markers. We have previously validated immuno-oncology gene expression signatures (DetermaIO (DTIO) and a 101-gene algorithm), that predict efficacy of checkpoint inhibitors (ICI) based on distinguishing immunomodulatory (IM), mesenchymal stem-like (MSL), and mesenchymal (M) phenotypes. In this study we used TCGA and clinical cohorts to identify immune infiltrate populations within these defined TIME spaces and their association with ICI treatment.
Methods: We derived novel human immune infiltrate signatures from a translation of murine ImmGen cell populations and a search for conserved co-expression of immune markers across multiple tumors. In total, 20 tumors from TCGA were employed for derivation and analysis encompassing 7163 unique samples. These novel signatures were compared to published immune infiltrate signatures and then their association with ICI efficacy and each other assessed in three cohorts treated with ICI therapy, IMvigor210 and an additional bladder cohort, comprising 272 and 89 patients with censored outcome results, and a melanoma cohort (N=105).

Results: The ImmGen analysis created 35 immune cell signatures and pan-tumor conserved co-expression of immune markers created eight signatures. The co-expression signatures often contained a mixed population of cell-type markers, though largely dominated by either myeloid or lymphoid markers. These signatures showed highly reproducible proportions of samples with strong expression between train and test TCGA sets. Most immune signatures had their highest representation in IM and DTIO+ tumors, however there was also consistent identification of presumptive immune infiltrate presence in MSL, M and DTIO negative cases. Two of the conserved co-expression signatures, one comprised of B-cell markers, and the other of T cell and other lymphoid markers, were associated with ICI efficacy in IMvigor210 and validated in the other "real-world" bladder cohort (B-cell: OR=0.8, p=0.022, T lymphoid: OR=0.7, p=0.005). Both signatures also had significant association with outcome in the cohort with clinical response outcomes, being strongest in patients after treatment had initiated.
Conclusions: These cell-type signatures may be identifying novel immune infiltrate populations that co-exist within the tumor immune microenvironment and are potentially predictive of ICI response. The two signatures were not independent of DTIO in either cohort, suggesting that the 27-gene algorithm DTIO largely incorporates this information. This analysis begins to dissect the complex physiology of the tumor immune microenvironment that mediates response to immune therapy.

Tumor-infiltrating neutrophil progenitors impair homologous DNA repair and promote sensitivity to PARP-inhibition
Arianna Calcinotto. *Institute of Oncology Research, Bellinzona, Switzerland*

Tumor evolution is one of the major mechanisms responsible for acquiring therapy-resistant and more aggressive cancer clones. Whether the tumor microenvironment through immune-mediated mechanisms might promote the development of more aggressive cancer types is crucial for the identification of additional therapeutical opportunities. Here, we identified a novel subset of tumor-infiltrating neutrophils, defined as tumor-associated neutrophil progenitors (NePs). These NePs are enriched in highly proliferative hormone-dependent breast cancers and impair DNA repair

capacity. Mechanistically, succinate secreted by tumor-associated NePs inhibits homologous recombination, promoting error-prone DNA repair through non-homologous end-joining regulated by PARP-1. Consequently, breast cancer cells acquire genomic instability, resulting in tumor progression and resistance to endocrine therapies. Selective inhibition of these pathways induces increased tumor cell kill in vitro and in vivo. Intra-tumor NePs score correlates with copy number alterations in highly proliferative hormone-dependent tumors from breast cancer patients. Treatment with PARP-1 inhibitors counteract the pro-tumorigenic effect of these neutrophils and reverses endocrine resistance.

Chemotherapy-induced extracellular matrix remodeling in HGSOC

Panoraia Kotantaki, Florian Laforêts, Eleni Maniati, Chiara Berlato, Anna Malliouri, Michael John Devlin, Beatrice Malacrida, Samar Elorbany, Ranjit Manchanda, Frances R. Balkwill. *Barts Cancer Institute, London, United Kingdom*

In this study we explored the effects of chemotherapy on the extracellular matrix of high-grade serous ovarian cancer metastasis (HGSOC) at structural-textural protein level and transcriptionally, in order to identify the microenvironmental features that accompany a successful response. We studied two murine orthotopic, transplantable syngeneic models of HGSOC, one that displays excellent response to carboplatin/paclitaxel (60577) and one that is resistant to treatment (HGS2)[1]. Using immunohistochemistry, we stained omental tumors from both models for the ECM components fibronectin (FN1), collagen 1A1 (COL1A1) and versican (VCAN), also using Masson's Trichrome to stain for collagen. We analyzed their abundance, textural features (Haralick features) and structure with the image analysis softwares, QuPath and TWOMBLI respectively. A compilation of 44 ECM metrics, which we named the "structure index", correlated with response to chemotherapy, as measured by reduction in omental tumor weight. In parallel, we performed RNAseq on the omental tumors, identifying clusters of genes that change over time with chemotherapy treatment of the responsive model 60577, while the chemoresistant model HGS2 displayed limited alteration of gene expression. We integrated RNAseq and ECM structure and texture data, and

showed the structure index was correlated with 144 core matrisome genes. To identify potential therapeutic targets, we then focused our study on genes that remained highly expressed in resistant tumors post chemotherapy, but were originally low or decreased with treatment in the sensitive tumors. Members of the LOX and P4HA family were found amongst these genes. We confirmed by immunohistochemical analysis that expression of LOX, LOXL2, P4HA1 and P4HA2 was downregulated by chemotherapy in the 60577 chemo-sensitive tumors while their levels remained relatively unaffected in the resistant HGS2 tumors. This study refines our understanding of the mechanisms of microenvironmental chemoresistance in HGSOC, highlighting putative therapeutic targets to increase the efficacy of platinum-based chemotherapy in ovarian cancer.

Analysis of MDSCs as a diagnostic and therapeutic target for gastric cancer

Suguru Yamauchi[1], Takumi Iwasawa[2], Tomoaki Ito[3], Malcom V. Brock[4], Tetsu Fukunaga[1], Hajime Orita[1], Kazunori Kato[2]. *[1]Department of Upper Gastrointestinal Surgery, Juntendo University School of Medicine, Tokyo, Japan,[2]Department of Biomedical Engineering, Faculty of Science and Engineering, Toyo University, Saitama, Japan,[3]Department of Surgery, Juntendo University Shizuoka Hospital, Shizuoka, Japan,[4]Department of Surgery, The Johns Hopkins University, Baltimore, MD*

Background: Gastric cancer (GC) is the second most common cancer in Japan in terms of incidence and the third most common in terms of deaths. The onset and progression of cancer are generally suppressed by the action of immune cells, which is an inflammatory response. MDSCs are thought to promote cancer progression and invasion by suppressing the function of immune cells, making them potential therapeutic and diagnostic targets. We measured MDSCs in GC patients and observed more monocyte-derived MDSCs in peripheral blood in advanced GC than in early GC. However, granulocyte-derived MDSCs showed no difference in GC progression when markers for classical MDSCs were used. We considered that granulocyte-

derived MDSCs were much more abundant than monocyte-derived MDSCs in peripheral blood and were involved in cancer progression. We hypothesized that we had a new granulocyte-derived marker for advanced GC that did not show differences in classical markers, but may have different functions, and aimed to identify a novel subset that may be a therapeutic and diagnostic target.
Method: For GC patients, we used heparin blood samples provided by patients who consented to Juntendo University. We analyzed the expression of various cell surface proteins against populations of $CD33^{high}$, $CD66b^{high}$, and $HLA\text{-}DR^{low}$ as classical markers of MDSCs derived from granulocytes of GC patients using FACS (Melody). MDSCs were isolated by a cell sorter and used for experiments such as RNA-Seq. Novel markers and involved cytokines were quantified in plasma components by cytometric bead array.
Result: The chemokine receptors CCR2, CCR5, CXCR4, and CXCR5 were highly expressed in MDSCs of advanced GC patients. The ability to suppress T-cell activation was also found to be stronger in MDSCs with advanced GC. In addition, IL-10 produced by MDSCs was also more abundant in the plasma of patients with advanced GC, as well as chemokines according to chemokine receptors.
Conclusion: The high expression of chemokine receptors on MDSCs in advanced GC may indicate that chemokines produced at the cancer site facilitate the migration of MDSCs. These novel subsets of MDSCs found in advanced GC suggest that they may be new therapeutic targets.

Dissecting the stromal drivers of gastroesophageal adenocarcinoma chemoresistance

Kulsum Tai[1], Sanjima Pal[1], Julie Bérubé[1], Iris Kong[1], Adam Hoffman[1], Swneke Bailey[1], Aki Kirbizakis[1], Sui Huang[2], Michael Strasser[2], David Gibbs[2], Nicholas Bertos[1], Veena Sangwan[1], Lorenzo Ferri[1]. *[1]McGill University Health Centre Research Institute, Montreal, QC, Canada,[2]Institute of Systems Biology, Seattle, WA*

Gastroesophageal adenocarcinoma (GEA) is the fastest rising cancer in North America. Over the course of five years, the survival rate is <20%, creating an urgent need for appropriate treatments against GEA. Currently, providing patients with peri-operative systemic docetaxel triplet-based

chemotherapy (DCF or FLOT) is the most effective approach to treat GEA. Despite this, for 50% of patients that do present an initial response to therapy, the tumor returns due to pre-existing or newly acquired resistance (i.e., chemoresistance) by the cancer. Researchers have shifted their focus to the tumor microenvironment (TME) as one of the factors influencing chemoresistance in patients. The TME is composed of tumor cells, immune cells and their secreted products, as well as fibroblasts. The components of the TME have been shown to interact with one another to influence tumor growth and progression. Fibroblasts are wound-healing cells that can be transformed into cancer-associated fibroblasts (CAFs) in response to stress and the release of inflammatory products. CAFs are the most abundant cells in the TME, yet their role in the chemoresponse of GEA is still unclear. Previous studies on other cancer types demonstrated that CAF expression is distinct between chemoresistant and chemo-sensitive tumors and certain CAF subpopulations may confer this resistance. This project will investigate the role of CAFs in the chemo-response of GEA using patient-derived organoids (PDOs) and CAFs from >200 GEA patients. A single-cell RNA sequencing atlas developed from >30 GEA DCF- or FLOT-treated patient samples will be used to identify CAF markers and targetable processes. CAF sub-populations will then be elucidated and correlated to tumor response. IF, FACS, and ELISA will be performed for subsequent CAF marker validation and characterization. Ex vivo drug testing with DCF or FLOT will be conducted on PDO-CAF co-cultures to recapitulate their drug response.

Identification and validation of sarcoma cellular ecosystems associated with prognosis and predictive of immunotherapy response

Ajay Subramanian[1], Neda Nemat-Gorgani[1], Timothy J. Ellis-Caleo[1], David G.P. van IJzendoorn[1], Timothy J. Sears[1], Anish Somani[1], Bogdan A. Luca[1], Maggie Y. Zhou[1], Martina Bradic[2], Ileana A. Torres[1], Eniola Oladipo[1], Christin New[1], Deborah E. Kenney[1], Raffi S. Avedian[1], Robert J. Steffner[1], Michael S. Binkley[1], David G. Mohler[1], William D. Tap[2], Sandra P. D'Angelo[2], Matt van de Rijn[1], Kristen N. Ganjoo[1], Nam Q. Bui[1], Gregory W. Charville[1], Aaron M. Newman[1], Everett J. Moding[1]. *[1]Stanford*

University, Stanford, CA,[2]Memorial Sloan Kettering Cancer Center, New York, NY

The tumor microenvironment contributes to tumorigenesis, disease progression, and response to therapy in soft tissue sarcomas (STSs). However, characterizing the malignant and stromal cells that make up STSs and correlating their abundance with clinical outcomes has proven difficult in fixed clinical specimens. We employed a machine learning framework called EcoTyper (Luca et al. Cell 2021) to identify cell type-specific transcriptional states and define tumor ecotypes consisting of co-occurring cell states from bulk transcriptomes. Analyzing 292 previously published STSs profiled by bulk RNA-sequencing (RNA-Seq), we identified 23 transcriptionally-defined sarcoma cell states in malignant, immune, and other stromal cells and validated the majority of these cell states using single cell RNA-Seq. Although sarcomas originate from mesenchymal tissues, we identified four epithelial-like sarcoma cell states and observed epithelial differentiation and expression of epithelial markers within malignant sarcoma cells across histologies. Cell states reflected known and novel cell phenotypes and many were strongly associated with patient outcomes in our RNA-Seq training cohort and an independent validation cohort of STSs profiled by microarray (n=309). By identifying co-occurring cell states across STSs, we discovered 3 sarcoma ecotypes associated with underlying genomic alterations and distinct clinical outcomes. On spatial transcriptomic analysis, we observed co-localization of cell states within the same sarcoma ecotypes and spatial aggregation of ecotypes within STSs, suggesting that sarcoma ecotypes represent distinct functional units within human sarcomas. One ecotype (sarcoma ecotype 3: SE3) defined by *CLEC5A/SPP1+* M2-like immunosuppressive macrophages and MYC/MTORC1-activated epithelial-like malignant cells was associated with inferior progression-free survival (PFS) in the RNA-Seq training cohort (P=0.01) and inferior metastasis-free survival in the microarray validation cohort (P=0.002). Remarkably, SE3 was associated with improved PFS in patients with metastatic STSs treated with ipilimumab and nivolumab (n=38, P=0.003) but not patients treated with chemotherapy. Furthermore, SE3 outperformed previously reported predictors of immunotherapy response in STSs, PD-L1 expression and tertiary lymphoid structures (TLS), for predicting response to immunotherapy (AUCs: SE3

0.87; PD-L1 0.81; TLS 0.62). Finally, SE3 similarly predicted response to immunotherapy in an independent validation cohort (n=29, AUC 0.89). In summary, our findings provide a high-resolution cell atlas of STSs to guide the development of novel therapeutic strategies. In addition, we have identified a predictive biomarker of response to immune checkpoint inhibition that may enable personalization of systemic therapy in patients with advanced STSs.

#5961

Inhibition of AURKA destabilizes glioblastoma primary cilia and sensitizes cells to tumor treating fields (TTFields) in vitro and ex vivo

Jia Tian, Julianne Mallinger, Ping Shi, Dahao Ling, Loic Deleyrolle, Min Lin, Habibeh Khoshbouei, Matthew Sarkisian. *University of Florida, Gainesville, FL*

Tumor Treating Fields (TTFields) can prolong survival of patients with glioblastoma (GBM), but GBM cells still escape this therapy requiring an urgent need for new or adjunct treatments. Recently we reported that TTFields disrupt primary cilia on GBM cells which lowers resistance to standard of care temozolomide chemotherapy. Here we asked if concomitant or sequential treatment of TTFields with other agents that interfere with GBM ciliogenesis enhance TTFields efficacy. Aurora Kinase A (AURKA) plays both a role in promoting cilia disassembly and regulating GBM growth in xenograft models. We found that within 24hr of treatment with the AURKA inhibitor, Alisertib, there was surprising and significant decrease in GBM cilia frequency across multiple GBM patient derived lines. However, similar Alisertib treatment did not affect neuronal or glial cilia frequencies in mixed primary cell cultures from mouse forebrain. Notably, overnight treatment of patient GBM biopsy ex vivo with Alisertib also resulted in reduced cilia frequency within the tumor tissue. Next, we co- or sequentially treated several different GBM patient cell lines with 24hr of 200kHz TTFields together with or followed by 250nM or 1μM Alisertib and examined the subsequent expansion of cells in vitro. We observed a significant synergistic reduction in cell proliferation compared to either treatment alone. However, this synergistic effect does not appear to be cilia-dependent as dual treatment reduction in proliferation was still observed in cell lines lacking different key cilia genes or in GBM cells that

naturally lack cilia. Considering Alisertib crosses the blood brain barrier and inhibits intracranial growth of tumors, our data warrant investigation of whether concomitant or sequential treatment of TTFields and Alisertib in vivo can further prolong survival.

NUC-7738 causes reduction of soluble and exosome-associated PD-L1 in melanoma cell lines and patients

Mustafa Elshani[1], Ying Zhang[1], Boback Kaghazchi[1], Alison L. Dickson[1], Sarah P. Blagden[2], Stefan Symeonides[3], Ruth Plummer[4], David J. Harrison[1]. *[1]University of St. Andrews, St. Andrews, United Kingdom,[2]Department of Oncology, Medical Sciences Division, University of Oxford, Oxford, United Kingdom,[3]Cancer Research UK Edinburgh Centre,, Institute of Genetics and Cancer, The University of Edinburgh, Edinburgh, United Kingdom,[4]Northern Centre for Cancer Care, Newcastle Hospitals NHS Foundation Trust,, Newcastle Hospitals NHS Foundation Trust, Freeman Hospital, Newcastle upon Tyne, United Kingdom*

Background: Immune checkpoint inhibitors (ICIs), including PD-(L)1 pathway inhibitors, are now standard of care for a variety of cancers. Characterization of PD-L1 protein has revealed multiple secreted forms; soluble (sPD-L1) and exosomal (ExoPD-L1) variants. In the tumor microenvironment these interfere with T-cell activation, facilitating tumor immune evasion. High circulating levels of sPD-L1 are correlated with advanced disease, a worse prognosis and/or poor response to ICIs. High levels of ExoPD-L1 are reported to contribute to T-cell dysfunction. NUC-7738, a ProTide transformation of 3'-deoxyadenosine (3'-dA), currently in Phase 1/2 in patients with solid tumors (NuTide:701 NCT03829254), has shown encouraging efficacy signals in several tumor types, including melanoma. This study investigates the dynamic between NUC-7738 and secreted forms of PD-L1 in a melanoma cell line and patients.
Material and Methods: A375 malignant melanoma cells were treated with NUC-7738 (10 μM) or DMSO for 6 - 72 hours. Cell supernatant was collected for sPD-L1 and ExoPD-L1 analysis and cells were measured for mRNA and metabolites. sPD-L1 mRNA and protein expression were measured in supernatant using RT-qPCR and sandwich ELISA, respectively. NUC-7738 and 3'-dATP were measured by LC-MS. ExoPD-

L1 protein levels were assessed by Jess Western analysis (normalized to CD81) and PD-L1 cell surface expression by flow cytometry. Findings were validated in patient plasma samples taken before and 24 hours after C1D1 treatment with NUC-7738 and prior to C2D1of a 14-day cycle.
Results: NUC-7738 was converted into anti-cancer metabolite 3'-dATP within 6 hours of treatment with an average concentration of 80 pmoles /10^6 cells, which was maintained for at least 24 hours and decreased by approximately 50% by 72 hours. The levels are comparable to those measured in PBMCs from patients treated with NUC-7738. NUC-7738 treatment reduced sPD-L1 mRNA expression by up to 40% and caused a time dependent decrease in sPD-L1 protein in the media supernatant by up to 3-fold. NUC-7738 also reduced ExoPD-L1 protein by 50%. NUC-7738 did not alter cell surface PD-L1 expression. Preliminary studies in serum from 4 study patients treated with NUC-7738 showed reductions in Exo-PD-L1 of ≤50% compared to pre-treatment levels.
Conclusion: NUC-7738 reduces secreted forms of PD-L1 whilst having no effect on cell surface protein levels. These *in vitro* results (melanoma cell line) were validated in the clinical setting, whereby ExoPD-L1 was reduced in plasma samples from patients treated with NUC-7738. These findings indicate that, by reducing sPD-L1 levels, NUC-7738 may have the potential to act as an immune sensitizer. We propose that NUC-7738 given in combination with PD-(L)1 pathway inhibitors may offer a promising treatment option, and are currently exploring this in patients who have experienced therapeutic resistance to ICI treatment.

Germline variant positive melanoma patients exhibit an enhanced inflammatory microenvironment

Alan Shen[1], Roshan Lodha[1], Brandon Bungo[2], Michelle Arbesman[1], Nikhil Pramod[1], Jennifer Ko[3], Brian Gastman[3], C. Marcela Diaz[3], Timothy Chan[3], Joshua Arbesman[4], Pauline Funchain[1]. *[1]Cleveland Clinic Taussig Cancer Center, Cleveland, OH,[2]Northwestern Lurie Cancer Center, Chicago, IL,[3]Cleveland Clinic Center for Immunotherapy and Precision Oncology, Cleveland, OH,[4]Department of Dermatology, Cleveland Clinic, Cleveland, OH*

Germline pathogenic variants (gPV) in cancer susceptibility genes are present in roughly 15% of all melanoma diagnoses. Prior studies note improvements in checkpoint immunotherapy responsiveness in patients with a gPV, which is associated with an increased neo-antigen load in gPV patients. We have also previously reported improvements in melanoma specific survival (MSS) in gPV patients vs non-gPV. No studies to date have examined the immune environment in gPV patients which may account for improvements in survival. In our study, melanoma patients with a personal or family history of multiple cancers were offered germline testing utilizing a commercial germline cancer sequencing panel. Enrolled patients also received a blood draw with subsequent flow cytometry to analyze the immune phenotype. In a cohort of 540 melanoma patients, 80 had a gPV. Multivariable linear regression indicated that significantly fewer polymorphonuclear myeloid derived suppressor cells (PMN-MDSC's) were noted relative to non-gPV patients when adjusting for melanoma stage at germline testing [β = -.45, 95% CI (-.76, -.15), p = .0036]. This difference was most significant in cutaneous, later stage (IIB-IV) patients, primarily stage III. We also interrogated patterns in gene signature between gPV and non-gPV patients in the TCGA PanCancer cutaneous melanoma cohort. We identified reductions in CCL27 (p = .007) and CCL1 (p = .06), genes associated with MDSC recruitment, across all stages in gPV patients, as well as reductions in ARG1 (p= .05) and S100A7 (p = .08), genes associated with PMN-MDSC's, in later stage gPV patients. Pathway differences were analyzed using gene set enrichment analysis (GSEA). Analysis of Hallmark gene sets identified significantly upregulated signatures in inflammatory response, TNF-α signaling, IFN-γ signaling, and IL-2 STAT5 signaling in late stage gPV patients. KEGG pathway analysis further identified NK cell mediated cytotoxicity and TCR signaling as significantly upregulated in late stage gPV patients. Notably, fatty acid metabolism pathways, which have been implicated in immunosuppression through MDSC suppressive function, were downregulated in gPV patients. These results suggest that gPV melanoma is associated with both a depletion of PMN-MDSC's and an upregulation of inflammatory microenvironmental genes in later stages which may explain improved outcomes.

Context-dependent induction of interferon signaling by CD11b agonists supports anti-tumor immunity in mouse models and human cancer patients

Xiuting Liu[1], Graham Hogg[1], Chong Zuo[1], John Baer[1], Varintra Lander[1], Liang Kang[1], Nicholas Borcherding[1], Brett Knolhoff[1], Robin Osterhout[2], Anna Galkin[2], Jean Bruey[2], Laura Carter[2], Cedric Mpoy[1], Julie Schwarz[1], Haeseong Park[1], Vineet Gupta[3], David DeNardo[1]. *[1]Washington University in St. Louis, Saint Louis, MO,[2]Gossamer Bio, San Diego, CA,[3]Rush University Medical Center, Chicago, IL*

Chronic activation of inflammatory pathways and suppressed interferon signaling are hallmarks of myeloid cells in immunosuppressive tumors that drive poor responsiveness to conventional and immune therapies. Previous studies have identified agonistic activation of the CD11b integrin as a potential strategy to enhance anti-tumor immunity. However, the mechanisms by which CD11b-agonism reprogram tumor immunity are poorly understood, and this may impair patient selection and identification of effective treatment combinations. Here we will use a combination of in vitro systems, animal models, and samples from first in human clinical trials of the CD11b-agonist to identify the mechanism of action of this approach and identify combinations for further testing. CD11b agonism alters tumor-associated macrophage (TAM) phenotypes by simultaneously repressing NFκB/IL1-signaling and activating interferon (IFN) gene expression. Repression of NFκB/IL-1 signaling was due to rapid degradation of p65 protein by the proteosome, contributing to suppressing myeloid cells infiltration. In contrast, CD11b agonism triggers mitochondrial dysfunction to stimulate STING-induced, STAT1-mediated interferon signaling, contributing to macrophages-augmented anti-tumor T cell immunity. Tissues from phase I clinical trials shows that CD11b agonist activates STING and STAT1 signaling in TAMs in human tumors, which is in consistent with preclinical data. Furthermore, combining CD11b agonism with cytotoxic therapies, STING agonist or TLRs agonists leads to robust anti-tumor activity in PDAC models. These studies pave the way for mechanism-based therapeutic combination strategies in cancer patients.

B2M loss of heterozygosity in melanoma is associated with increased numbers of activated NK cells and higher expression of the NK cell inhibitory ligand, HLA-G

Mildred Galvez, Katie M. Campbell, Egmidio Medina, Antoni Ribas.
UCLA, Los Angeles, CA

β2-microglobulin (B2M) is a critical subunit of antigen presenting major histocompatibility complex (MHC) class I molecules. Its genetic inactivation in tumor cells has been implicated in tumor-intrinsic immune escape and immunotherapy resistance. Currently, the impact of B2M dysregulation on tumor-immune dynamics requires furthers characterization. Using a clinical dataset of patients with melanoma treated with immune checkpoint blockade (ICB), whole-exome sequencing and bulk RNA-sequencing data from baseline tumor biopsies (n=295) were analyzed to identify somatic B2M alterations and evaluate correlative clinical outcomes, infiltrating immune cells, and gene expression patterns. No loss-of-function mutations in B2M were found; however, 50% of tumors had B2M alterations in the form of homozygous loss (n=2), loss of heterozygosity (LOH; n=56), or copy number gains (n=88). B2M LOH events were overrepresented in tumors from patients who progressed during ICB therapy compared to those who responded (34% versus 19%; Pearson chi-square test, p=0.035). Additionally, tumors with B2M LOH had lower B2M expression compared to B2M-unaltered tumors (Wilcoxon test, p=0.05). Gene set enrichment analysis revealed reduced expression of immune and inflammatory signatures in B2M-LOH tumors. Furthermore, immune cell deconvolution showed that B2M-LOH tumors had lower total immune cell counts, but greater numbers and proportions of activated natural killer (NK) cells (Wilcoxon test, numbers p=0.021, proportions p=0.032). Differential gene expression analysis revealed concordant higher expression of human leukocyte antigen G (HLA-G), an NK cell inhibitory ligand, in B2M-LOH tumors (Wilcoxon test, p=0.0035). Moreover, B2M-LOH progressive tumors had the highest median HLA-G expression and trended toward a positive correlation between increasing HLA-G expression and increasing numbers of activated NK cells (Pearson correlation, r=0.55, p=0.015). In conclusion, melanoma biopsies with B2M LOH were associated with non-response to ICB, had increased presence of activated NK cells, and demonstrated a compensatory increase in HLA-G.

These results suggest that in melanoma B2M alterations may be implicated in modulating NK cell interactions and point toward HLA-G potentially playing a role in inhibiting NK cell anti-tumor activity.

Cathepsin S mediates interleukin 7 to sculpture the tumor immunity in head and neck cancer

Yung-Chieh Chang[1], Shan-Hung Chen[2], Kwang-Yu Chang[2], Jang-Yang Chang[3]. *[1]Taipei Medical University, Taipei, Taiwan,[2]National Institute of Cancer Research, National Health Research Institutes (NHRI), Tainan, Taiwan,[3]Taipei Cancer Center, Taipei Medical University, Taipei, Taiwan*

Cathepsin S (CTSS) is a lysosomal enzyme that belongs to cysteine proteases. It is associated with progression of different types of cancer, mediating the antigen presentation, extracellular matrix degradation, angiogenesis, and metastasis. In recent studies, CTSS was suggested as a therapeutic target for cancer treatment. We found that, with a CTSS inhibitor RJW-58 treatment over tumor-bearing mouse, the serum showed an enhanced anti-tumor cytokine releasing of interleukin 7 (IL-7). In the mRNA array results of 40 pair head and neck patients' sample, we found the negative correlation between CTSS and IL-7 comparing to the normal head and neck tissue. Moreover, we also found that the level of CD8 T cell infiltration is negatively correlated with the expression of CTSS in 20 head and neck cancer patients' slides. In cell model, targeting CTSS by siRNA or RJW-58 promoted IL-7 secretion in different head and neck cancer cell lines. We demonstrated that cathepsin S decreased the secretion level of IL-7 through downregulating IL-7 receptor, a receptor that mediating IL-7 secretion, protein expression level resulting in activating lysosomal degradation pathway. Promoting cell proliferation of activated CD8 T cells was proved when CD8 T cells were treated with the condition medium from CTSS-knockdown head and neck cancer cells. In conclusion, this is the first study demonstrated that CTSS acted as a negative regulator in mediating IL-7 resulting in inducing an immune cell-suppressed microenvironment in head and neck cancer cells. Advanced patient-derived lung tumoroids to identify limiting factors for oncolytic virotherapy

Le Hélène. *Transgene S.A., Illkirch-Graffenstaden, France*

Introduction: Despite major progress in its diagnosis, and treatment, lung cancer remains one of the deadliest cancers in the world. Patient-derived tumoroids offers unique advantage to integrate patients' heterogeneity, and the diversity of resistance mechanisms in the drug discovery and development pathway. Organization of the tumor microenvironment both at the tissue, and at the molecular levels, is another critical factor that regulate drug response, in particular for immunotherapy. In this study, we have focused on oncolytic virotherapy, a promising concept that still deserves optimization. Different physiological barriers might limit the efficacy of oncolytic viruses (OVs): (i) mutations limiting viral replication and spreading, (ii) structure of the tumor tissue (basement membrane, vasculature, immune cells among other actors), (iii) physical parameters (therapeutic pressure, physical barriers), and iv) anti-viral vector response (reticulo-endothelial system, neutralizing antibodies, complement).
Purpose of the Study: Development of an advanced *in vitro* model for NSCLC that would recapitulate major physical and biological barriers to the action of Vaccinia-based oncolytic vectors. Identification of major determinants of activity, and of R&D axes for the design of improved OVs.
Experimental Approach: Lung tumor biopsies, and healthy tissues were obtained from the CRB of Strasbourg, and organoids were generated after an enzymatic treatment. Dissociated cells were mixed with exogenous microvessels derived from the adipose tissue. At day seven of the culture, patient-derived tumoroids and organoids (PDTs/PDOs) were transferred and embedded in a hydrogel mimicking the extracellular matrix. OVs were applied in fluidic to mimic intravenous perfusion, and viral properties were analyzed at 24h and 96h timepoints. Specificity was demonstrated by direct comparison of PDTs and PDOs from the same patient. Addition of circulating PBMCs after 24h of infection allowed us to analyze the interaction of OV with immune effectors.
Results: Under fluidic conditions, mimicking intravenous infusion, we could confirm infection at the periphery of the lung PDT after only one hour of perfusion. IL-6 was significantly increased compared to IL-10, TNF-α and IL-1β (seven times more than the untreated condition).

Compared to a passive diffusion mode (static conditions) infection was lower, suggesting the laminar flow and the matrix become efficacy-limiting factors. Indeed, under fluidic conditions, infection and replication were observed one day later than passive diffusion mode. The contribution of endothelial cells, and of immune cells was also characterized. Some experiments are still ongoing, and results on neutralizing antibodies will be presented in the poster.

Leukemia inhibitory factor regulates macrophage immune response in head and neck squamous cell carcinoma

Yun Hua Sui, Tzu Tung Liu, Shu Chen Liu. *National Central University, Taoyuan City, Taiwan*

The high recurrence rate of head and neck squamous cell carcinoma (HNSCC) is associated with an immune suppressive tumor microenvironment (TME). Tumor-associated macrophage (TAM)-mediated immunosuppression is a critical feature in HNSCC TME. We provide evidence demonstrating that leukemia inhibitory factor (LIF) is involved in macrophage polarization and remodeling of the HNSCC microenvironment. By interrogating the head and neck squamous cell carcinoma RNA sequencing dataset extracted from the TCGA database, we found that the levels of LIF and M2 macrophage markers (CD163, CD206, VEGF) were enhanced in tumors compared to normal counterparts. Higher LIF expression in tumors was further correlated with worse overall survival. Immunohistochemical analysis found that macrophages with higher LIF immunoreactivities were located at the periphery of HNSCC tumors. In a macrophage-cancer cell coculture system, the presence of LIF promoted the proliferation and mobility of cancer cells and induced an M2-dominant macrophage polarization. Stimulating monocyte-derived macrophages (MDMs) with LIF increased the expression of several M2 markers (CD163, CD206, CD209, and IL10) but decreased the expression of M1 markers (iNOS, CD80, and CD86). Moreover, LIF-treated macrophages exhibited little cancer cytotoxicity compared to vehicle-treated macrophages. Treating macrophages with soluble LIF receptor (sLIFR), a LIF antagonist, partly reversed the LIF-mediated M2 polarization and enhanced cytotoxicity toward cancer cells. Results of RNA-sequencing data demonstrated that LIF

suppressed antigen presentation process, type I interferon production, TNFR signaling, and molecules participating in the Hippo signaling pathway in MDMs. Mechanistic studies found that LIF might trigger M2 polarization via activating YAP1, as reflected by a reduction of p-YAP1 (S127) and an enhanced YAP1 nuclear localization in macrophages. Treating macrophages with YAP1 inhibitors (Saracatinib and Verteporfin) blocked the LIF-mediated YAP1 nuclear translocation, expression of M2 markers, and tumor-promoting effects. Our findings suggest that the presence of LIF in HNSCC promotes macrophage M2 polarization through YAP1 signaling, which assists in establishing an immune-suppressive, tumor-promoting microenvironment. The blockade of LIF-mediated effects may tailor therapeutic strategies by converting the immunosuppressive microenvironment for selected HNSCC patients.
