Adenoid Cystic Carcinoma (ACC) is a rare but aggressive malignancy of salivary gland, associated with protracted clinical course and fatal outcome. Treatment modalities are restricted to surgery and/or adjuvant radiotherapy and patients develop recurrence and distant metastasis over time. The absence of effective systematic therapy makes it incurable in advanced stage. ACC display an overall low mutation frequency, therefore very few actionable genetic alterations critical to the ACC development have been recognized. *MYB* fusion/overexpression is the most frequently found genetic alteration in ACC and is present in ~70% patients. This is followed by activating *NOTCH* mutations, reported in ~20% patients. Despite the presence of few targetable genetic alterations, recent studies revealed substantial transcriptomic heterogeneity amongst ACC tumors suggesting the role of epigenetic alterations in ACC oncogenesis. Symmetric dimethylation is an important epigenetic mechanism that regulates mRNA splicing, transcription, translation, cell cycle and oncogenic signaling pathways. Protein Arginine Methyl Transferase 5 (PRMT5) is a predominant enzyme for symmetric dimethylation among a family of 9 methyl transferases. In was suggested that PRMT5 plays a role in regulating tumor progression via modulation of MYC signaling, cancer stemness, and a wide array of additional cellular and transcriptional pro-oncogenic processes. While inhibition of PRMTs showed anti-oncogenic response in several preclinical tumor models and a subset of patients with advanced solid malignancies (including ACC), preclinical studies investigating the effect of PRMT5 blockade in ACC remain inadequate. In part, due to the scarcity of ACC specimens and limited availability of the experimental

models. PRT543 is a selective and potent small molecule PRMT5 inhibitor that specifically targets PRMT5 among 37 methyl transferases. In the present study, we have investigated the effect this novel agent using a unique collection of ACC cell lines, organoids, and patient derived xenograft mouse models. To our knowledge, this is the first study investigating the therapeutic effect of PRT543 in several preclinical models of ACC. Specifically, we found that PRT543 has potent antitumor activity in in-vitro and in-vivo models with MYB expression and activating NOTCH mutations. Further, based on these observations, we have sequenced a collection of 50 ACC tumor samples to identify the subset of patients who may potentially benefit from PRT543 treatment based on their underlying genetic signatures. This study provides evidence underscoring the role of PRMT5 signaling in ACC and supports the clinical development of PRMT5 inhibitors for this indication.

Imipridones and EZH2 inhibitors induce similar changes in cytokines and regulated genes in GBM and DMG while vorinostat potentiates anti-tumor efficacy despite variability in cytokine profiles

Yiqun Zhang, Kelsey Huntington, Wafik S. El-Deiry. *Legorreta Cancer Center, Brown University, Providence, RI*

TIC10/ONC201 and ONC206 are small molecule imipridones with anti-cancer activity. ONC201, EZH2i and HDACi can modulate tumor microenvironment (TME) and antitumor immunity. We studied the impact of these drugs or their combinations on the TME or tumor immunity by investigating cytokine profiles. We treated U251 GBM and HCT116 CRC cells with vorinostat and found upregulation of CXCL11, CXCL14, INF-γ and TRAIL, and downregulation of prolactin, CXCL9, VEGF and CCL2 in U251. CXCL11 promotes anti-tumor immunity by increasing activated CD8+ T cells in tumors but was associated with metastasis of GBM. CXCL13 induces tertiary lymphoid structures and enhances infiltration of CD8+ T cells in tumors. INF-γ enhances antigen presentation and promotes activation of NK cells. Vorinostat upregulated the secretion of pro-immune cytokines and TRAIL which induces tumor apoptosis. Downregulated cytokines in U251 were prolactin, CXCL9 involved in tumor growth and metastasis, VEGF, and CCL2 involved in immunosuppression in GBM.

Cytokines upregulated in HCT116 included IL-8 contributing to CRC progression, and CXCL13, and CXCL11 which correlates with anti-tumor immunity in colon cancer. Downregulated cytokines in HCT116 were soluble TRAIL R2 functioning as a decoy receptor for TRAIL, VEGF, and prolactin. We treated DMG, GBM and HCC cells with imipridones, EHZ2i tazemetostat or HDACi panobinostat alone or combination of imipridones plus tazemetostat or panobinostat or the triple combination of imipridone plus tazemetostat and panobinostat. We observed that cytokines impairing immunity were downregulated and cytokines promoting immunity were upregulated by individual drugs or combinations. Hep3B HCC cells showed the most robust changes among the mentioned tumors with respect to the changes of cytokine profile following the treatments. Imipridone or EZH2i treated cells showed similar cytokine profile changes in tumor cells. Imipridones downregulated EZH1 and EZH2 proteins in tumor cells. We RNA-seq to investigate gene expression profiles following treatment with ONC201 or tazemetostat. In GBM and DMG, ONC201 and tazemetostat shared similar top regulated genes. GO enrichment analysis showed overlap of top regulated pathways between ONC201 and EZH2i treated cells. Shared regulated pathways in U251 included cell cycle arrest, cell adhesion, nervous system development, cell proliferation, negative regulation of proliferation, PERK-mediated unfolded protein response, extracellular matrix organization, regulation of transcription from RNA polymerase II promoter, and cellular response to hypoxia pathways. We conclude that imipridones ONC201, ONC206, and ONC212 which reduce EZH1 and EZH2 proteins share similar cytokine alterations, gene expression targets and actions with EZH2 inhibitors.

Inhibition of murine tumor growth by decitabine is correlated with enhanced expression of the mouse mammary tumor virus

Jieyu Zhang[1], Savannah Higgins[1], Riley Smith[1], Tania Reginald[1], Andrew Qi[2], Jiayi Li[1], Anna King[1], Yingguang Liu[1]. *[1]Liberty University, Lynchburg, VA,[2]Case Western Reserve University, Cleveland, OH*

The purpose of this study is to clarify the mechanisms of the antineoplastic effect of decitabine (DAC), a DNA methyltransferase inhibitor. We previously reported that DAC inhibited the proliferation of the 4T1

mammary cancer cell line *in vitro* while inhibiting MMTV *env* and *pol* expression in the same cells. Here we present findings *in vivo* using two murine tumor models. We inoculated 4T1 cells into BALB/c mice from which the cell line was derived. In addition, we inoculated the murine colon carcinoma cell line, MC38, into C57BL/6 mice, the mouse strain of its origin. We treated the mice with DAC when tumors became palpable. DAC inhibited tumor growth in both tumor models and inhibited metastasis of 4T1 cells into the lungs. Quantitative PCR detected elevated expression of MMTV genes in the tumor tissues of DAC-treated mice in both models. The levels of MMTV *env* RNA in tumor tissues were negatively correlated with tumor mass in both models, so were the levels of the MMTV Env protein in 4T1 tumors. DAC also significantly mitigated tumor-induced splenomegaly. Hepatotoxicity of DAC was observed in C57BL/6 mice. Our data suggest the possibility that decitabine inhibits tumor growth *in vivo* and *in vitro* via different mechanisms. The findings also support the current understanding of decitabine upregulating endogenous retroviruses (ERVs) which subsequently activate an interferon response. The negative correlation between tumor mass and MMTV Env protein expression suggests a possible role of ERV proteins serving as tumor-associated antigens and decitabine enhancing adaptive immunity against cancer by stimulating ERV expression on tumor cells. Further studies of the interaction between decitabine and MMTV using immunodeficient mice may help us understand the possible involvement of adaptive immunity in the pharmacodynamics of decitabine as well as the role of ERVs in tumor development.

Preclinical efficacy of targeting epigenetic mechanisms in AML with 3q26 lesions and EVI1 overexpression

Christine E. Birdwell, Warren C. Fiskus, Tapan M. Kadia, Christopher P. Mill, John A. Davis, Kaberi Das, Stephen Horrigan, Kapil N. Bhalla. *UT MD Anderson Cancer Center, Houston, TX*

EVI1 gene is located at 3q26.2 in the MECOM locus and encodes for a zinc-finger transcription factor. Chromosome translocation t(3;3) or inv(3) at 3q26 repositions the enhancer (E) of the tumor suppressor GATA2 to induce EVI1 over-expression, while concomitantly repressing GATA2.

EVI1 over-expression promotes self-renewal and blocks differentiation of leukemia stem-progenitor cells (LSCs) and causes therapy refractoriness and inferior overall survival in AML. Previous reports highlighted that targeting BRD4 with BET inhibitor (BETi) is active against AML cells with inv(3)/t(3;3). BETi treatment also represses EVI1 and its targets c-Myc and Bcl-xL. We recently reported that tegavivint (TV) (BC-2059), a disruptor of the nuclear TBL1/R1-β-catenin-TCF7L2 complex represses c-Myc, cyclin D1 and Survivin and inhibits growth and survival of AML LSCs. In present studies, a CRISPR screen in UCSD-AML1 cells (with 3q26 lesion and EVI1 overexpression) with gRNAs targeting epigenetic regulators highlighted BRD4 and p300 as dependencies. Treatment with BETi, e.g., OTX015, dose-dependently induced apoptosis of AML cell lines and patient-derived (PD) AML cells (AML191 and AML194) with inv(3) or t(3;3). OTX015 treatment repressed c-Myc, c-Myb, CDK4, MECOM, and MCL1, while inducing HEXIM1 and cleaved PARP levels. TV treatment also dose-dependently induced apoptosis in AML cell lines and PD AML cells with 3q26.2 lesions, associated with depletion of nuclear β-catenin, EVI1, TCF7L2, c-Myc, c-Myb, RUNX1, CEBPα, c-KIT, BCL2, Bcl-xL and MCL1, but increase in p21, CD11b, BIM and cleaved PARP levels. Hi-ChIP with H3K27Ac antibody demonstrated that TV treatment abolished chromatin loops between MYC and its Es within the super-E. RNA-Seq analysis showed negative enrichment (log2-fold) of gene sets of MYC, E2F and WNT targets, DNA replication/repair and reduction of the 17-gene stemness score. Confocal microscopy showed that TV treatment disrupted co-localization of EVI1 and β-catenin with TBL1, also confirmed by the Proximity Ligation Assay. CyTOF analysis confirmed that TV treatment reduced EVI1, c-Myc, RUNX1, β-catenin, Bcl-xL, BCL2, MCL1 and Ki67 but increased cleaved PARP levels in the phenotypically characterized LSCs (with high expression of CLEC12A, CD123, CD244 and CD99) harboring inv(3) with EVI1 overexpression. Co-treatment with OTX015 and TV or the p300 inhibitor GNE-049 synergistically induced *in vitro* apoptosis in the AML cell lines and the PD AML cells with 3q26.2 lesions. Notably, in the flank-implanted PDX of AML191 or tail-vein infused PDX of AML242 models in NSG mice, treatment with OTX015 and TV, compared to vehicle control or each drug alone, significantly reduced AML growth and improved survival, without any host toxicity. These findings highlight the promising pre-clinical efficacy of novel BETi-based

combinations against AML models harboring 3q26 lesions and EVI1 overexpression.

#4901

The role of protein disulfide isomerase and copper in the paraptotic cell death of clinically investigated anticancer thiosemicarbazones

Sonja Hager[1], Walter Berger[2], Christian R. Kowol[3], Eva A. Enyedy[4], Petra Heffeter[2]. *[1]Department of Food Chemistry and Toxicology/Center for Cancer Research, University of Vienna/Medical University Vienna, Vienna, Austria,[2]Center for Cancer Research, Medical University Vienna, Vienna, Austria,[3]Department of Inorganic Chemistry, Faculty of Chemistry, University of Vienna, Vienna, Austria,[4]Department of Inorganic and Analytical Chemistry, Interdisciplinary Excellence Centre, University of Szeged, Szeged, Hungary*

α-*N*-Heterocyclic thiosemicarbazones (TSCs) have long been investigated as anticancer compounds. Triapine is one of the best-known TSCs for anticancer therapy and is currently tested in a clinical phase III trial. To further improve the anticancer activity of TSCs, novel derivatives (such as DpC and COTI-2) have been developed and clinically investigated for their activity against solid tumors. These novel TSCs belong to a subclass (incl. the tetra-methylated Triapine derivative, Me_2NNMe_2) that are terminally disubstituted and demonstrated enhanced anticancer activity *in vitro* and *in vivo*. The improved activity of these TSCs correlated with their ability to form stable copper complexes as well as induce paraptosis, a form of programmed but caspase-independent cell death, that is characterized by the formation of vesicles originating from the endoplasmic reticulum (ER). However, the molecular events behind paraptosis induction are still not fully elucidated. Consequently, the aim of this study was to investigate the molecular signaling behind paraptosis as well as the reasons behind the induction of this quite unknown form of cell death by TSCs.
A whole-genome gene expression analysis of cells treated with a terminally disubstituted TSC revealed an upregulation of thiol homeostasis-related genes, copper metabolism, and metallothionein genes as well as ER stress response genes. In addition, we found an upregulation of the copper-sensitive and thiol-containing protein disulfide isomerase (PDI), which was

confirmed on protein level. In cell-free activity studies, PDI was indeed inhibited by terminally disubstituted TSCs, although only in form of their copper complexes. In agreement, removal of copper ions by specific chelators greatly reduced their anticancer activity as well as paraptotic potential in cell culture. This inhibition was hypothesized to be induced by a general disruption of the thiol redox homeostasis affecting also other responsive proteins and resulting in a more oxidative environment, especially in the ER. In confirmation, thiol-containing small molecules could reduce the compound's anticancer activity in viability assays. Furthermore, glutathione as well as PDI were detected predominantly in their oxidized form in cells treated with terminally disubstituted TSCs. Consequently, terminally disubstituted TSCs, which are characterized by higher anticancer activity, induce paraptosis due to their high copper complex stability. The formation of the complex results in the interaction with thiol-containing proteins and subsequently in the disruption of the thiol-redox homeostasis, which leads to paraptotic cell death. Overall this work shed light on the paraptotic cell death and will be of interest for future clinical development of anticancer TSCs, as paraptosis is hypothesized to overcome apoptosis-resistance of cancer cells.

Mitochondrial and cytosolic folylpolyglutamate synthetase in one-carbon metabolism and anti-tumor efficacy of mitochondrial-targeted antifolates

Carrie O'Connor[1], Jade Katinas[2], Mathew Schneider[1], Md. Junayed Nayeen[3], Xun Bao[1], Jing Li[1], Charles Dann[2], Aleem Gangjee[3], Larry H. Matherly[1], Zhanjun Hou[1]. *[1]Oncology, Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]Department of Chemistry, Indiana University, Bloomington, IN,[3]Division of Medicinal Chemistry, Duquesne University, Pittsburgh, PA*

Folates mediate one-carbon (C1) transfers, which are essential for cellular homeostasis and survival. C1 metabolism encompasses distinct cytosol (Cyto) and mitochondria (Mito) pathways connected by an interchange between serine, glycine and formate. Mito C1 metabolism provides cellular glycine and C1 units (as formate) for *de novo* synthesis of thymidylate and purine nucleotides in the Cyto. Polyglutamyl folates are the predominant

folate forms in cells and are generally preferred for C1 transfers. Thus, folate polyglutamylation is essential for cellular homeostasis. Folate polyglutamylation is catalyzed by folypolyglutamate synthetase (FPGS), including Cyto (cFPGS) and Mito (mFPGS) isoforms. C1 metabolism is critical for tumor growth and thus offers a plethora of therapeutic targets for cancer. Of particular interest are Mito C1 inhibitors including "non-classical" pyrazolopyran compounds SHIN1 and SHIN2, and "classical" pyrrolo[3,2-*d*]pyrimidine antifolate compounds typified by AGF347, all targeting serine hydroxymethyltransferase 2 (SHMT2). Both SHIN1 and AGF347 effected *in vitro* anti-tumor efficacy, and SHIN2 and AGF347 showed *in vivo* efficacy toward tumor xenografts. We systematically explored the roles of cFPGS and mFPGS levels as critical determinants of C1 inhibitor target engagement and net Cyto versus Mito C1 flux, resulting in anti-tumor efficacy. We found that FPGS transcript levels significantly correlated with the effects of AGF347 toward a panel of human pancreatic cancer cell lines including MIA PaCa-2. We engineered MIA PaCa-2 cells with FPGS gene knockout to stably express inducible mFPGS or cFPGS form. FPGS in mFPGS-transfected cells (mFPGS#32) was expressed mainly in Mito over Cyto, whereas FPGS in cFPGS-transfected cells (cFPGS#3) was expressed exclusively in Cyto. Accumulation of radiolabeled folate and AGF347 increased with increasing FPGS in both Cyto and Mito for mFPGS#32, but only in Cyto for cFPGS#3. Metabolomics with [2,3,3-^{2}H]serine in cFPGS#3 and mFPGS#32 established FPGS levels in Mito versus Cyto as important determinants of C1 fluxes. Increased FPGS levels in mFPGS#32 enhanced C1 flux in Mito far greater than in Cyto, and greater than for the increased FPGS in cFPGS#3. As a result, Cyto-targeted antifolates pemetrexed and AGF94 were only modestly impacted by increasing FPGS levels in both mFPGS#32 and cFPGS#3 (~3x). In contrast, increasing FPGS levels dramatically enhanced the inhibitory effects of Mito-targeted antifolates such as AGF347 in mFPGS#32 (~8-25x), and to a greater extent than in cFPGS#3 (~6-8x). Conversely, increasing FPGS levels substantially attenuated the cytotoxic effect of SHIN1 in mFPGS#32 (~19x). In summary, FPGS levels are an important determinant of C1 fluxes, particularly in Mito where they contribute to cytotoxic potencies of Mito-targeted C1 inhibitors at SHMT2.

#4903

Levels of folate transporters impact the compartmentalization of one-carbon metabolism in the mitochondria vs cytosol providing a unique vulnerability to SHMT inhibition

Mathew Joseph Schneider[1], Carrie O'connor[1], Xun Bao[1], Md. Junayed Nayeen[2], Zhanjun Hou[1], Jing Li[1], Aleem Gangjee[2], Larry H. Matherly[1].
[1]Oncology, Wayne State University School of Medicine, Detroit, MI,[2]Division of Medicinal Chemistry, Duquesne University, Pittsburgh, PA

These studies characterize the critical role of the Reduced Folate Carrier (RFC) and the Proton Coupled Folate Transporter (PCFT) as determinants of cancer cell reliance on mitochondrial vs cytosolic one carbon (C1) metabolism, to identify a unique susceptibility towards SHMT1 and SHMT2 inhibition in cancer cells. C1 metabolism is frequently reprogrammed in cancer cells to provide nucleotides, amino acids, and glutathione, and to maintain redox homeostasis for proliferation. The mitochondrial C1 converting enzymes serine hydroxymethyltransferase (SHMT) 2 and methylene tetrahydrofolate (THF) dehydrogenase 2 (MTHFD2) are among the top overexpressed metabolic enzymes in human cancers, suggesting these are important cancer-specific targets. We previously discovered novel 5-substituted pyrrolo[3,2-*d*]pyrimidine antifolates (with AGF347 being the lead) that potently inhibit mitochondrial SHMT2, as well as SHMT1. Folates are essential cofactors for C1 converting reactions; folates and antifolates primarily rely on the major facilitative folate transporters RFC and PCFT for internalization by tumor cells. In these studies, we explore the effects of folate transporter expression on the compartmentalization of C1 metabolism in the mitochondria and cytosol and the potential impact on SHMT1 and SHMT2 inhibition. We used a tetracycline inducible system for RFC expression in RFC/PCFT-null HeLa cells, with and without constitutive PCFT, and characterized the impact on transport and accumulation of folates and AGF347 in response to folate transporter expression. Increased accumulation of folates was observed with increasing RFC in the absence of PCFT. In the presence of PCFT, baseline folate accumulation was substantial and independent of RFC expression, indicating a major role of PCFT as a facilitative folate transporter. SHMT2 catalyzes the conversion of serine and THF to glycine and 5, 10-methylene THF in the mitochondria, while SHMT1 catalyzes the

reverse reaction in the cytosol, producing THF and serine. To determine how folate transporter expression affects the C1 flux through SHMT1 vs SHMT2, [2,3,3-^{2}H]serine tracer experiments were performed; increased mitochondrial C1 flux through SHMT2 was observed with increasing RFC in the absence of PCFT, whereas the mitochondrial flux through SHMT2 predominated in the presence of PCFT. By cell proliferation assays it was discovered that cells with lower RFC expression exhibit a hypersensitive phenotype towards AGF347 in the absence of PCFT, indicating a unique therapeutic opportunity for targeting SHMT forms in cancer cells with low folate transport activity. Here we identify RFC and PCFT as key determinants for the compartmentalization of C1 flux in the mitochondria vs the cytosol, in turn affecting the sensitivity of cancer cells towards SHMT inhibition.

#4904

Glutamine antagonist DRP-104 enhances anti-tumor responses in *KEAP1* mutant lung cancer

Ray Pillai[1], Sarah LeBoeuf[1], Ali Rashidfarrokhi[1], Shih Ming Huang[1], Triantafyllia Karakousi[1], Anastasia-Maria Zavitsanou[1], Warren Wu[1], Volkan Sayin[2], Robert Wild[3], Sergei Koralov[1], Thales Papagiannakopoulos[1]. *[1]NYU Grossman School of Medicine, New York, NY,[2]University of Gothenburg, Gothenburg, Sweden,[3]Dracen Pharmaceuticals Inc., San Diego, CA*

KEAP1 is mutated in approximately 20% of non-small cell lung cancer (NSCLC) and is associated with poor response rates to checkpoint blockade. Given the therapeutic challenge presented by *KEAP1* mutant tumors and the great potential held by immunotherapeutic approaches, there is an urgent need to identify the mechanisms that mediate immune evasion in patients with *KEAP1* mutant lung adenocarcinoma.
We previously demonstrated that metabolic rewiring in *KEAP1* mutant tumors leads to increased dependency on glutamine as a substrate for multiple anabolic pathways. DRP-104 (Sirpiglenastat) is a novel glutamine antagonist which inhibits all glutamine consuming reactions. Using pre-clinical mouse models and patient derived xenograft models we demonstrate that DRP-104 robustly impairs the growth of *KEAP1* mutant tumors. Furthermore, using an immunocompetent orthotopic lung

adenocarcinoma mouse model we find that treatment with DRP-104 increases survival of *Keap1* mutant tumor bearing mice treated with anti-PD1 therapy.
We have dissected the mechanism by which DRP-104 impacts *KEAP1* mutant tumors and the surrounding immune microenvironment. Notably, DRP-104 impairs nucleotide synthesis in *KEAP1* mutant tumors and thereby inhibits cancer cell growth. In addition, DRP-104 reduces exhausted T cell and T regulatory populations within the tumor microenvironment as well as increases effector T cell function. Overall, we find that DRP-104 impairs the growth of *KEAP1* mutant tumors through both targeting of tumor intrinsic metabolic vulnerabilities and through tumor extrinsic immunostimulatory mechanisms such as promoting the expansion of functional anti-tumor T cell populations. This data provides additional rationale for the ongoing phase I/II clinical trial (NCT04471415) using DRP-104 in NSCLC with mutations in *KEAP1* as well as for combining DRP-104 with checkpoint blockade.

Anticancer activity and paraptosis induction of novel bipyridine-silver(I) compounds against resistant colorectal and ovarian cancer cell lines

Alessia Stefanelli[1], Ricardo G. Teixeira[2], Adhan Pilon[2], Rebecca Warmers[3], Ingo Ott[4], Christian R. Kowol[5], Anamaria Brozovic[6], Ana Isabel Tomaz[2], Andreia Valente[2], Petra Heffeter[1]. *[1]Center for Cancer Research and Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria,[2]Centro de Química Estrutural, Institute of Molecular Sciences, Departamento de Química e Bioquímica, Universidade de Lisboa, Lisboa, Portugal,[3]Universität Konstanz, Konstanz, Germany,[4]Technische Universität Braunschweig, Braunschweig, Germany,[5]Institute of Inorganic Chemistry, Faculty of Chemistry, University of Vienna, Vienna, Austria,[6]Division of Molecular Biology, Ruđer Bošković Institute, Zagreb, Croatia*

Background: Platinum-based anticancer drugs (e.g. Carboplatin and Oxaliplatin) are frequently applied in chemotherapy regimens against several types of cancer including ovarian carcinoma (OC) and colorectal

carcinoma (CRC). However, intrinsic or acquired tumor resistance severely limit their clinical application. Here, we investigated the anticancer activity of several novel silver(I) 2,2'-bipyridine derivatives, containing either triphenylphosphane (PPh_3) or 1,2-bis(diphenylphosphino)ethane (dppe) ligands and tested their potential to overcome platinum resistance.
Methods: Cytotoxicity and cross resistance profiles of the newly synthesized compounds were tested against two OC models (SKOV-3 and MES-OV), a CRC model (HCT-116) and their corresponding sublines resistant to carboplatin or oxaliplatin, as well as non-malignant fibroblasts (F331) via an MTT-based cell viability assay after 72 h continuous drug exposure. Moreover, the intracellular levels of silver were measured via ICP-MS. In addition, thioredoxin reductase (TrxR) inhibition properties, impact on cell cycle distribution and apoptosis induction potential were investigated via multiple molecular biological methods. Morphological changes induced by the silver compounds were characterized via spinning disk confocal microscopy.
Results: All tested compounds displayed pronounced anticancer activity and cancer cell selectivity. Moreover, cell intrinsic resistance to carboplatin or oxaliplatin was not impacting on the cytotoxic activity of the compounds. Noteworthy, MES-OV and HCT-116 cells showed exceptional sensitivity to several silver(I) 2,2'-bipyridine derivatives with a 1,2-bis(diphenylphosphino)ethane (dppe) (AP-compounds). This sensitivity was not based on enhanced drug uptake, pronounced TrxR inhibition nor apoptosis induction or cell cycle arrest. In contrast, hypersensitive cells displayed pronounced endoplasmic reticulum (ER)-derived vesicles together with multiple others hallmarks of paraptotic cell death.
Conclusion: Our findings did not only demonstrate that the new silver compounds were unaffected by cancer cell intrinsic resistance mechanisms to platinum-based chemotherapy, but also indicated a high vulnerability of tumor (sub)types towards these bipyridine silver complexes. This hypersensitivity is based on the induction of paraptosis, a novel form of programmed cell death. To summarize, these silver compounds represent a new class of promising anticancer drugs, which demand further preclinical development.

#4907

Atovaquone-induced increase in reactive oxygen species leads to impaired glycolytic functions in ovarian cancer cells

Nicha Boonpattrawong, Sejal Sharma, Rob Schultz, Mayra A. Betancourt Ponce, Lisa M. Barroilhet, Manish Patankar. *University of Wisconsin-Madison, Madison, WI*

Atovaquone (ATO) is an FDA-approved anti-malarial drug, which has also shown potent anti-cancer effects. We have previously demonstrated ATO as an effective chemotherapy against high-grade serous ovarian cancer in cell lines and mouse model. In the present study, we aim to determine if ATO is asserting its anti-cancer properties by altering cellular metabolism. Glycolysis and oxidative phosphorylation (OXPHOS) are the two major sources of intracellular energy. ATO reduces OXPHOS energy production by inhibiting mitochondrial complex III. We first determined whether there is a shift in energy production when OXPHOS is inhibited by assessing glycolytic function in various human (OVCAR3 and OVCAR5) and mouse (ID8) ovarian cancer cell lines. Mitochondrial oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) were assessed by the Seahorse XF Analyzer. First, we pretreated cells with ATO at IC70 concentrations for 1 hour prior to metabolic analysis. As expected, pretreatment with ATO reduces OCR in all cell lines. However, ATO treatment increased basal glycolysis but decreased glycolytic capacity and glycolytic reserve. This suggests that ATO-treated cells have an impaired ability to shift energy production towards glycolysis when there is an increase in energy demand. One of the initial events that occur in ATO-treated cells is a surge in reactive oxygen species (ROS) as measured by H2DCFDA ROS assay. In the human cell lines, we found that ATO significantly increased ROS by approximately 100-fold (MFI). Whereas, in the mouse cell line, the ATO-induced increase in ROS were comparatively attenuated. We hypothesized that the increase in ROS leads to inhibition of glycolysis. We tested this by pre-treating cells with 2mM N-acetylcysteine (NAC), an oxygen radical scavenger, for 1 hour before measuring the metabolic responses to ATO. We found that NAC attenuated the inhibition of glycolytic processes in human cell lines but not in the mouse cell line. Our lab has previously shown that ATO induced activation and increased expression of p53. Studies have shown that ROS activate p53, which in turn upregulates the TP53 induced glycolysis and apoptosis regulatory phosphatase (TIGAR), inhibiting the conversion of F6P to F-2,6-BP and ultimately leads to inhibition of glycolysis. Increases in ROS also shuttle

G6P towards the phosphate pentose pathways through G6P dehydrogenase for antioxidant production. We found that long-term ATO treatment for 24 hours also resulted in increases in both TIGAR and G6PD mRNA expression. Taken together, these results suggest that ATO decreased plasticity of metabolic capacity in ovarian cancer cells through ROS and ROS associated glycolytic pathways. Further, this study provides mechanistic insights into ATO's potential as a chemotherapeutic agent.

#4908

Study on Ca $^{2+}$-mediated regulation mechanisms on chemotherapy-induced peripheral neuropathy in multiple myeloma and non-Hodgkin lymphoma

Jinny Park[1], Jong-Suk Kim[2], Kwang-Hyun Park[3]. *[1]Hematology division /Internal medicine, Gil Medical Center, Gacheon University, Incheon, Korea, Republic of,[2]Department of Biochemistry, Institute for Medical Sciences, Chonbuk National University Medical School, Jeonju, Korea, Republic of,[3]Department of Emergency Medical Rescue, Nambu University, Gwangju, Korea, Republic of*

In general, when treating cancer patients, various anticancer drugs are used in combination to enhance the anticancer effect. However, most drugs exhibit side effects. Neurotoxicity, one of the side effects commonly accompanied, greatly affects the quality of life and also reduces compliance with treatment. Calcium signal transduction, which occupies a key position in cell signal transduction, has been found to be involved in various mechanisms including proliferation, differentiation, and death of cells, beyond the existing research direction that focuses on channels. To identify the mechanisms of calcium signal regulation that can reduce chemotherapy induced peripheral neuropathy (CIPN) while maintaining anticancer functions of drugs, we study with the two drugs frequently used in non-Hodgkin lymphoma and multiple myeloma, borteozomib (BTZ) and vincristine (VIN), whose main side effects are neurotoxicity. We used the human neuroblastoma cell line, SH-SY5Y cells, and performed MTT assay after treating them with N-Acetylcysteine (NAC), an antioxidant, to determine whether the reduction in cell viability by BTZ and VIN was due to the increase in ROS. When BTZ and VIN were treated with NAC, cytotoxicity by BTZ was significantly reduced and cell viability decreased

by VIN was significantly increased. From these results, we found that ROS are involved in BTZ and VIN -induced apoptosis. In addition, we performed MTT assay using calcium inhibitors to investigate whether intracellular calcium signaling is involved in BTZ and VIN-induced apoptosis, and 8-Br-cADPR, Ned-19, Xestospongin C, and Heparin were used as calcium inhibitors. To confirm that the cell viability reduced by BTZ and VIN is recovered by calcium inhibitors, BTZ and VIN were treated together with calcium inhibitors, respectively. Cell viability was found to increase significantly. These results suggest that intracellular calcium signaling is involved in cell death induced by BTZ and VIN. The increase in [ca^{2+}]i in the cytoplasm when treated with BTZ and VIN was measured using a fluorescence spectrophotometer. It was shown that the treatment with BTZ and VIN increased the calcium concentration in the cytoplasm within 1 minute. To confirm that the concentration of intracellular calcium was reduced by the calcium inhibitor, BTZ and calcium inhibitor were treated together, and it was confirmed that the intracellular calcium concentration increased by BTZ was decreased in a concentration-dependent manner at 2uM and 3uM of the calcium inhibitor. In conclusion, this experiment suggests that intracellular calcium signaling is involved in the BTZ and VIN's reduction of neuronal cell viability (CIPN) in multiple myeloma and non-Hodgkin lymphoma. *This research was supported by NRF 2021R1A2C1091322 (J.-S.Kim) and 2021R1F1A1064120 (J. Park).*

Molecular analysis of small cell lung cancer provides insights into mechanism of action underlying the novel drug combination of lurbinectedin and TIC10/ONC201

Ashley Sanchez Sevilla Uruchurtu[1], Nicholas Liguori[2], Leiqing Zhang[3], Kelsey Huntington[1], Lanlan Zhou[3], Young Lee[4], Abbas E. Abbas[5], Christopher G. Azzoli[6], Wafik S. El-Deiry[3]. *[1]Department of Pathology and Laboratory Medicine, Brown University, Providence, RI,[2]Lewis Katz School of Medicine, Temple University, Philadelphia, PA,[3]Legorreta Cancer Center at Brown University, Providence, RI,[4]Brown University, Providence, RI,[5]Warren Alpert Medical School, Brown University, Providence,*

RI,[6]Department of Medicine, Haematology/Oncology Division, Lifespan Health System and Brown University, Providence, RI

We previously explored the combination of novel imipridone TIC10/ONC201 and small molecule RNA polymerase inhibitor lurbinectedin as a potentially effective treatment regimen for small cell lung cancer (SCLC). Data from cell viability experiments demonstrated synergistic killing of SCLC cells with minimal death of healthy control cells. Analysis of intracellular proteins via Western blot indicated that combinatorial treatment induces the integrated stress response, DNA damage/cell cycle checkpoint responses, and increased apoptosis of tumor cells. We have utilized the Luminex 200 platform to perform analyses of cytokine levels in SCLC cell lines with various genetic alterations before and after ONC201 and lurbinectedin treatment. Our results revealed significant changes in cytokine levels following treatment indicating potential immunomodulatory and angioregulatory effects of ONC201 and lurbinectedin. CCL3, known to recruit and activate granulocytes, was found to be elevated by treatment with lurbinectedin, ONC201 and combination versus control. Angiopoietin 1, which contributes to blood vessel maturation, and angiopoietin 2, which promotes neovascularisation, were elevated by all drug treatments in H1882 SCLC cells. Our ongoing studies are further analysing the importance of specific cytokines in tumor vascularity and in recruitment and killing of SCLC cells by immune cells. Results from these experiments are helping to elucidate the molecular mechanisms underlying SCLC, its immune landscape, and treatment response.

Human tumor primary culture analyses for the prediction of response to chemotherapy, targeted agents, drug combinations and metabolic inhibitors: The role of *ex vivo* analysis of programmed cell death in cancer therapy

Adam J. Nagourney[1], Steven S. Evans[1], Paulo D'Amora[1], Nise Yamaguchi[2], Paula Bernard[1], Federico Francisco[1], Joshua B. Gipoor[1], Robert Alan Nagourney[1]. *[1]Rational Therapeutics, Inc., Long Beach, CA,[2]Instituto Avancos em Medicina, Sao Paulo, Brazil*

There is growing interest in the use of human tumor primary cultures for the prediction of response to drugs and drug combinations in cancer medicine. While the field has witnessed numerous attempts to apply human tissue for the prediction of response, fundamental errors in methodologic approaches severely limited the predictive validity and clinical applicability of these important technologies. The first error was a focus upon drug induced cell growth inhibition. This lead to the failure of the clonogenic (human tumor stem cell) and H3*Thymidine incorporation platforms in the 1970's and 1980's. As the concept of apoptosis arose following landmark observations in 1972, cell death endpoints became predominant including mitochondrial function (MTT, XTT), ATP content (luciferase) and delayed loss of membrane integrity (DISC, EVA/PCD) among others. These improvements led to more biologically relevant measures. However, a second hurdle arose as investigators chose to amplify subculture and propagate tumors into what are now referred to as human tumor organoids. While these 3-D cultures are more reflective of tumor cell-cell interactions found in cancers, they cannot recreate the cell-vasculature, cell-stroma, inflammatory environment nor cancer associated fibroblast interactions with human cancer cells required for accurate response prediction. To address these shortcomings we developed the ex vivo analysis of programmed cell death (EVA/PCD) platform that applies native state tumor explants directly from surgical specimens to select drugs and combinations. To date we have reported 11,680 individual analyses. Positive prospective results have been reported in breast cancer (TTP $p < 0.03$); ovarian cancer (TTP $p = 0.05$), lung cancer (2-fold improvement in ORR; TTP $p = 0.035$) and recently ovarian and uterine cancer (DFS $p = 0.038$) with two meta-analyses confirming the predictive validity in hematologic and solid tumors. With over 20 years of CLIA-approved laboratory experience in the study of human tumor primary culture explants, the EVA/PCD platform provides improved response and time to progression and offers the opportunity to streamline drug development, curtail costs and avoid futile care in patients with advanced and refractory malignancies.

A novel C-terminal of HSP90 inhibitor NCT-547 eliminates cancer stem-like subpopulation in triple-negative breast cancer

Eunsun Jung, Seojin Jang, Daeil Sung, Soeun Park, Minsu Park, Dongmi Ko, Seongjae Kim, Juyeon Seo, Kee Dal Nam, Yoon-Jae Kim, Ji Young Kim, Jae Hong Seo, Yong koo Kang, So Ra Seock, Jung Min Park. *Korea University Guro Hospital, Seoul, Korea, Republic of*

Triple-negative breast cancer (TNBC) harbors a higher cancer stem cell (CSC)-like population and exhibits a more aggressive metastatic phenotype. Due to the limitations of currently available targeted therapies, there remains a significant unmet need for the development of new targeted therapies for TNBC. Molecular chaperone heat shock protein 90 (HSP90) is attracting attention as an ideal therapeutic target due to it regulates essential biological functions such as cell proliferation, angiogenesis and metastasis. Although N-terminal HSP90 inhibitors have had little clinical success to date, C-terminal HSP90 inhibitors have received relatively little attention. We sought to investigate the effects of a new rationally designed NCT-547 on apoptosis, breast cancer stem cell (BCSC)-like properties, migration ability and heat shock response (HSR) *in vitro* and tumor growth and metastasis in CSC-enriched allograft model *in vivo*. NCT-547 inhibits TNBC cell proliferation by simultaneously inactivating several survival factors including AKT, MEK, and STAT3. In addition, NCT-547 effectively targets BCSC-like properties with impairment of ALDH1 activity, CD44+/CD24- phenotype, and 3D mammosphere-forming ability. The expression of HSF-1 target genes such as Hsp90, Hsp70, Hsp27, Hsp40 and Hsp65 is highly overexpressed in TNBC patients. The mRNA abundances of target genes were significantly decreased after NCT-547 challenge. NCT-547 effectively targets both the proliferating TNBC tumor cells and CSCs, markedly reducing tumor growth, coinciding with decreased Ki-67 proliferation index and enhanced apoptosis. Anti-tumor effect of NCT-457 was independent of heat shock response as evidenced by significant downregulation of HSF1 phosphorylation and expression of downstream targets HSPs members. It is noteworthy that NCT-547 did not affect markers of hepatic and renal acute toxicity and was not cytotoxic in non-malignant cells. NCT-547 may therefore have potential to address current limitations in the treatment of TNBC.

Anticancer activity of Hsp90 inhibitor AUY922 in nasopharyngeal carcinoma and non-small cell lung cancer cells

William C. S. Cho, Chi F. Wong. *Department of Clinical Oncology, Queen Elizabeth Hospital, Hong Kong SAR, China*

Introduction: Nasopharyngeal carcinoma (NPC) and non-small cell lung cancer (NSCLC) are two of the most prevalent cancers in Southern China. Although cisplatin therapy may be initially successful, its effectiveness is often significantly reduced in patients with relapsed disease. There is an urgent need to overcome cisplatin resistance in the treatment of NPC and NSCLC. Luminespib (AUY922) is an experimental drug candidate for the treatment of cancer. It is an inhibitor of heat shock protein 90 (Hsp90), a chaperone protein that plays a role in modifying a variety of proteins involved in tumorigenesis. Hsp90 inhibitors have demonstrated potent activity in preclinical testing and clinical trials against various cancer types. We sought to investigate the preclinical efficacy of AUY922 and evaluate its anticancer effect in cisplatin-resistant NPC and NSCLC cells.
Materials and Methods: Two NPC cells (HK1 and Hone1), four NSCLC cells (A549, SW900, NCI-H1975, and HCC4006), one normal lung cells (CCD11Lu), two cisplatin-resistant NPC cells (HK1-R and Hone1-R), and one cisplatin-resistant NSCLC cells (A549-R) were cultured and treated with 100 nM AUY922 for 48 hours. A cell proliferation assay was performed in triplicate to determine the antiproliferative effects of AUY922 on cancer cells. Flow cytometry was used for cell cycle analysis. The apoptotic cells were evaluated by Annexin V and Western blot analysis. Nude mice were used to test the effects of intraperitoneal injection of AUY922 on tumor growth.
Results: We found that AUY922 significantly inhibited *in vitro* growth in all the two NPC (44% and 40%) and four NSCLC (53%, 77%, 50%, and 62%) cells in comparison to the normal lung cells (4%). The two cisplatin-resistant NPC cells (63% and 37%) also showed significant inhibition of viability after treatment with AUY922. However, there was only a slightly reduced viability in the cisplatin-resistant NSCLC cells (14%). Flow cytometry revealed that AUY922 induced G2/M and S phase arrest in HK1 and HK1-R cells. On the other hand, AUY922 also induced pro-apoptotic peaks in A549, A549-R, Hone1, and Hone1-R cells. Interestingly, Annexin V and Western blot analysis showed that cell death was not caused by

apoptosis. *In vivo*, both AUY922 alone and the combination of AUY922 with cisplatin treatments inhibited NPC and NSCLC tumor growth without significant weight loss. In addition, the administration of AUY922 significantly reduced NPC and NSCLC tumor growth in the cisplatin-resistant mouse models.
Conclusion: AUY922 exhibits potent anticancer activities *in vitro* and *in vivo*. These findings provide evidence that AUY922 could be useful for the treatment of NPC and NSCLC as a single agent or in combination with cisplatin. Most importantly, our results provide a preclinical proof of concept for the efficacy of AUY922 in cisplatin-resistant NPC and NSCLC treatment.

Enhancer RNA profiles predict sensitivity to a novel GPX4 inhibitor
Timothy Read, David Simpson, Jenna Rimel, Christy Rhine, Casey Pham, Cole Liechty, Eric Martin, Joey Azofeifa. *Arpeggio Biosciences, Boulder, CO*

Inhibition of the GPX4 enzyme leads to the rapid accumulation of toxic lipid peroxides and cell death through a process known as ferroptosis. This mechanism has recently garnered significant attention in the field of oncology because many difficult-to-treat tumor types are particularly susceptible to this non-canonical form of cell death. However, robust biomarkers that predict sensitivity to ferroptosis are needed to help select well-defined tumor subtypes and patient segments that are likely to respond to GPX4-targeting. Our nascent RNA platform measures the active transcription of not only protein-coding transcripts, but also transcripts initiating from enhancer regions (enhancer RNAs) critical for defining cell type. We reasoned that these data could afford the unique opportunity to identify non-coding transcripts that could serve as novel biomarkers of sensitivity to ferroptosis. We recently discovered a potent and selective GPX4 inhibitor and profiled the compound for its ability to induce ferroptosis across a diverse group of cancer cell types. We chose several of the most sensitive and resistant cell lines for further examination using our nascent RNA platform and identified novel relationships between sensitivity to ferroptosis and cell-specific enhancer RNA profiles. Importantly, enhancer RNA profiles were more effective at stratifying

sensitive and resistant cell lines than protein-coding gene expression. Using enhancer RNA expression profiles as biomarkers of drug sensitivity represents a novel strategy that could ultimately improve our ability to select patient cohorts more likely to benefit from emerging drug candidates and established therapeutics.

Role of ClpP in the anti-cancer effects of imipridone ONC201 and ONC206

Andrew Lee, Cristina Maranto, Scott Foster, Sara Morrow, Joshua E. Allen, Randall Lanier, Phiroze Sethna, Varun V. Prabhu. *Chimerix, Inc., Durham, NC*

ONC201 is the first bitopic dopamine receptor D2 (DRD2) antagonist and allosteric mitochondrial protease ClpP agonist. Downstream of target engagement, ONC201 activates the integrated stress response pathway resulting in selective tumor cell death. ONC201 is well tolerated and induces durable tumor regressions in H3 K27M-mutant glioma patients. ONC206, a derivative of ONC201 currently in Phase I trials for adult and pediatric brain tumors, is also a bitopic DRD2 antagonist and ClpP agonist with nanomolar potency. We further evaluated in vitro efficacy and mechanism of action specific to ClpP for ONC206 and investigated acquired resistance to ONC201 and ONC206. FITC-casein and peptide degradation assays confirmed that ONC206 acts as an agonist of human ClpP with enhanced potency relative to ONC201. Broad efficacy in the nanomolar range for ONC206 (GI50 <78-889nM, 72h) was observed in 1,088 Genomics of Drug Sensitivity in Cancer (GDSC) cancer cell lines with increased sensitivity in cell lines exhibiting high ClpP mRNA expression. Among solid tumors, nervous system-related cell lines were particularly sensitive. Gene Expression Profiling Interactive Analysis (GEPIA) database analysis showed ClpP mRNA was overexpressed in glioblastoma cells relative to normal cells. GDSC observations were confirmed in glioblastoma (GBM) (T98G, A172, U87MG), H3.3 K27M mutant diffuse intrinsic pontine glioma (DIPG) (SF8628, SF7761) and astrocytoma (H4, U118MG) cell lines. ONC206 was more potent than ONC201 in cell viability assays for all glioma lines tested. SF8628 cells with a CRISPR-mediated ClpP knockout were shown to demonstrate

resistance to both ONC201 and ONC206. Polyclonal resistant cell lines were generated through prolonged passaging in increasing concentrations of ONC201 or ONC206 (SF8628 and T98G cells). Cells with acquired resistance to ONC201 (ONC201Res) or ONC206 (ONC206Res) showed cross resistance to both imipridones. Time-stability of resistance was confirmed by removing drug for 2 to 4 weeks and retesting. RNAseq analysis revealed upregulation of the integrated stress response with imipridone treatment in T98G parental cells but not resistant clones. Whole genome sequencing revealed ClpP mutations in both ONC201Res and ONC206Res cells. Our results confirm the role of ClpP in the mechanism of action of ONC201 and ONC206 in tumor cells.

Sensitivity to NAMPT inhibition: *In vitro* and *in vivo* characterization in ovarian cancer

Jenny J. Hong, Martina S. J. McDermott, Neil A. O'Brien, Enrique Guandique, Tong Luo, Dennis J. Slamon. *UCLA David Geffen School of Medicine, Los Angeles, CA*

Previous *in vitro* work on determining the unique sensitivities of various cancers to nicotinamide phosphoribosyltransferase inhibitors (NAMPTis) has demonstrated promising effects of treating cancer cells with NAMPTis such as FK866 and KPT9274. These inhibitors act by disrupting cellular energy metabolism and reducing intracellular NAD^+ levels. NAMPT inhibition thereby suppresses the proliferation of cancer cells which depend more heavily on the NAMPT enzyme to produce NAD^+ than noncancerous cells. Using pan-cancer in vitro screens in a large panel of molecularly characterized cell lines (n = 496) we identified a subset of ovarian cancer, a cancer with a high unmet need due to lack of diverse targeted therapies, as being extremely sensitive to NAMPT inhibition. Subsequent *in vivo* work using CD-1 nude mice demonstrate that NAMPT inhibitors can successfully reduce the ovarian tumor burden and may be an effective treatment option of some ovarian cancers.

Moreover, NAD^+'s function as a substrate to the poly ADP-ribose polymerase (PARP) enzyme makes NAMPTis rational candidates for including in combination therapies with PARP inhibitors, several of which are approved for maintenance therapy for ovarian cancer. By using

NAMPTis to disrupt the cellular metabolic process while simultaneously inhibiting PARP activity, an essential DNA damage repair enzyme, it is possible to exploit the dependence of ovarian cancer cells on functional PARP activity. This is particularly important in homologous recombination deficient subtypes. In addition to a synergistic growth inhibitory response in ovarian cancer cells, preclinical combination studies of NAMPTis with olaparib, an approved PARP inhibitor, exhibited higher levels of DNA damage accumulation than with single drug treatments. Our *in vitro* and *in vivo* characterizations of NAMPT inhibition suggest that NAMPTis as either single agents or in combination treatments with PARP inhibitors should be investigated further as potential treatment options for ovarian cancer patient populations.

Spatial analysis of local drug induced changes in tumor microenvironment predicts effective treatment combinations in breast cancer

Zuzana Tatarova[1], Dylan C. Blumberg[2], Gordon B. Mills[2], Lisa M. Coussens[2], Oliver Jonas[1], Joe W. Gray[2]. *[1]Brigham and Women's Hospital, Boston, MA,[2]Oregon Health & Science University, Portland, OR*

Anticancer therapeutics primarily designed to target tumor intrinsic mechanisms may also affect components of tumor microenvironment (TME) - immune cells and non-immune stroma. Recent literature reenforces the concept that complex interactions between drugs, neoplastic cells and cells of TME determine the efficacy of anticancer therapies. Systems understanding of these interactions can serve to predict effective treatment combinations simultaneously attacking tumor cell vulnerabilities, enhancing immune surveillance, and mitigating stromal mediators of resistance. The key challenge is to find such TME-modulating combinations in a fast and more informative way. We have developed an integrated analytical platform termed Multiplex Implantable Microdevice Assay (MIMA) to rapidly decompose cancer complexity in drug response and find biomarkers with predictive value for combination therapy efficacy including immunotherapy efficacy. The system deploys a (i) miniaturized implantable microdevice for localized intratumoral drug delivery and (ii) multiplex immunostaining to measure 30+ proteins in single cells at each

drug well. Computational analyses of local drug-induced changes provide information about the composition, functional state and spatial cell organization of the tumor and associated TME ultimately bringing new insights into drug mechanisms of action. We used MIMA in genetically engineered mouse models of breast cancer to evaluate effects of five targeted anticancer agents (olaparib, palbociclib, venetoclax, panobinostat, lenvatinib) and two chemotherapies (doxorubicin, paclitaxel) and predicted synergistic antitumor effects with anti-PD-1, anti-CD40, anti-CSF1R immunotherapies and vasculature modulating agents. Some of the most effective combinations were not reported before. A pan-HDAC inhibitor, panobinostat, that synergized with anti-PD-1, induced immunogenic cell death and infiltration of antigen presenting neutrophils. Further longitudinal spatial analyses revealed that mechanisms of resistance co-emerged with these response phenotypes and became prominent over time. We measured fibroblast, protumorigenic macrophage and cytotoxic B cell recruitment associated with heavy deposition of collagen VI, increased immune suppression and emergence of invasive and cancer stem cells. Combination with stroma modulating agent, losartan, improved the efficacy of panobinostat/anti-PD-1 in systemic studies implying that normalization of non-immune stroma might favorably alter aspects of TME for immune and targeted therapy efficacy. All in all, MIMA may represent a new approach to predict effective combination regimens for individual cancer patients. Extended MIMA use and computational modeling of the spatial cell patterns could provide actionable information for development of effective drug doses and schedules.

High-frequency irreversible electroporation ablation of glioma alters extracellular vesicles and disrupts the blood-brain barrier endothelium

Kelsey Murphy[1], Kenneth Aycock[2], Spencer Marsh[3], Alayna Hay[4], Christine Chang[5], Shay Bracha[6], Robert Gourdie[3], Rafael Davalos[2], John H. Rossmeisl[4], Nikolaos Dervisis[4]. *[1]Biomedical and Veterinary Sciences, Virginia-Maryland College of Veterinary Medicine, Blacksburg, VA,[2]Biomedical Engineering and Mechanics, Virginia Polytechnic and State Institute, Blacksburg, VA,[3]Fralin Biomedical Research Institute, Roanoke, VA,[4]Small Animal Clinical Sciences, Virginia-Maryland College*

of Veterinary Medicine, Blacksburg, VA,[5]Veterinary Small Animal Clinical Sciences, Texas A&M University College of Veterinary Medicine, College Station, TX,[6]The Ohio State University College of Veterinary Medicine, Columbus, OH

High-frequency irreversible electroporation (H-FIRE) is a nonthermal tumor ablation technology that kills cancer cells via pulsed electric fields. H-FIRE has been shown to precisely and nonthermally ablate brain tumors while transiently disrupting the peritumoral blood-brain barrier (BBB). The enhanced BBB permeability post-tumor ablation can be exploited to enhance therapeutic delivery to invasive tumor margins, but the mechanisms of H-FIRE-induced BBB disruption remain incompletely characterized. We hypothesize that bystander effects of H-FIRE tumor cell ablation, specifically the release of tumor-derived extracellular vesicles (TDEVs), mediate peritumoral BBB endothelium disruption. F98 glioma and bEnd.3 cerebral endothelial cell lines modelled primary brain cancer and the BBB endothelium, respectively. F98 glioma cells were treated *in vitro* with sham treatment, a sub-ablative (1,500 V/cm), or an ablative (3,000 V/cm) electric field dose of H-FIRE, and TDEVs were isolated from the supernatants via filtration and ultracentrifugation. Post-H-FIRE TDEVs were characterized via nanoparticle tracking analysis and transmission electron microscopy, with ablative doses of H-FIRE resulting in decreased release of TDEVs compared to sub-ablative H-FIRE and sham treatment. Post-H-FIRE TDEVs were then applied to Transwell models of the BBB endothelium to evaluate the effect of H-FIRE-induced TDEVs on BBB endothelium permeability. TDEVs released after the ablative H-FIRE dose (3,000 V/cm) significantly increased permeability of the BBB endothelium *in vitro* compared to TDEVs released after sub-ablative and sham H-FIRE treatment. TDEVs were then fluorescently labelled with CFSE, and confocal microscopy was used to characterize internalization of post-H-FIRE TDEVs by cerebral endothelial cells. The TDEVs released after ablative doses of H-FIRE were significantly internalized by bEnd.3 cerebral endothelial cells, while TDEVs released after sub-ablative and sham treatment were not internalized. The proteomic payloads of the post-H-FIRE TDEVs were characterized using mass spectrometry, and clustering analysis demonstrated that the *in vitro* BBB-modulatory TDEVs released after 3,000 V/cm H-FIRE had distinct proteomic payloads compared to the

non-BBB-modulatory TDEV populations released after sham and 1,500 V/cm H-FIRE treatment. Proteins associated with proteasomal degradation, cellular adhesion, and modulation of junctional integrity were increased in the BBB-modulatory group of TDEVs. Taken together, our results suggest that H-FIRE ablation of glioma significantly alters the proteomic cargo of TDEVs to increase internalization of TDEVs by cerebral endothelial cells and increase permeability of the BBB endothelium.

#4918

Natural compounds ursolic acid and digoxin exhibit anti-cancer effects through nuclear receptor RORγ-dependent and -independent mechanisms

Hongye Zou, Yatian Yang, Demin Cai, Hong-Wu Chen. *Department of Biochemistry and Molecular Medicine, UC Davis, Sacramento, CA*

Natural compounds such as ursolic acid (UA) and digoxin isolated from fruits and other plants display potent anti-cancer effects in preclinical studies. UA and digoxin have also been at several clinical trials for treatment of different cancers including prostate cancer, pancreatic cancer and breast cancer. However, they displayed limited benefit to patients. Currently, a poor understanding of their direct targets and mechanisms of action (MOA) in tumor cells severely hinders their further development. We previously identified nuclear receptor RORγ as a novel therapeutic target in castration-resistant prostate cancer (CRPC) and triple-negative breast cancer (TNBC). Previous studies implicated UA and digoxin as potential RORγ antagonists in modulating the functions of immune cells such as Th17 cells. Here we showed that UA displays a strong activity in inhibition of RORγ-dependent transactivation function, while digoxin exhibits no effect at clinically relevant concentrations. In prostate cancer cells, UA down-regulates RORγ-stimulated AR expression and AR signaling, whereas digoxin up-regulates AR signaling pathway. UA also showed potent anti-growth effects in AR-positive prostate cancer cells compared to AR-negative prostate cancer cells. In TNBC cells, UA but not digoxin alters RORγ-regulated cell proliferation and apoptosis gene programs. Together, our study shows for the first-time that UA, but not digoxin, acts as a natural antagonist of RORγ in prostate cancer and TNBC cells. Our finding that

RORγ is a direct target of UA in specific type of cancer will help select patients with tumors that likely respond to UA treatment.

#4919

Estrogen regulates the immune microenvironment and immunotherapy response of colorectal liver metastases

Yasmine Benslimane[1], Sarah Lapin[1], Julien Chambon[2], Stephanie Perrino[2], Pnina Brodt[1]. *[1]McGill University, Montreal, QC, Canada,[2]Research Institute of the McGill University Health Centre, Montreal, QC, Canada*

Liver metastases (LM) remain a major cause of cancer-related death and many cancers preferably metastasize to the liver due to its unique anatomical location, rich blood supply and immune-tolerant microenvironment. Up to 50% of colorectal carcinoma patients develop LM during their disease and this is associated with a poor prognosis. Our laboratory previously identified a sexual dimorphism in the regulation of the immune microenvironment (IME) of LM and showed that estrogen could promote the accumulation of myeloid-derived suppressor cells (MDSCs) and Tregs in the liver in response to invading cancer cells. The objective of this study was to elucidate the role of estrogen in the recruitment and polarization of other immune cells and to determine the therapeutic potential of Selective Estrogen Receptor Degrader (SERD) therapy in CRCLM bearing female mice, and evaluate if SERD would improve anti PD-1 immunotherapy efficacy. In estrogen-competent female mice bearing CRCLM, we found increased gene and protein expression of the immunosuppressive cytokine TGF-β, and inversely a decrease in the pro-inflammatory cytokine TNF-alpha. Furthermore, we identified a significant decrease of immunosuppressive CD68+CD163+ M2 macrophages, and an increase of the pro-inflammatory CD68+TNF-alpha+ M1 macrophages in estrogen-depleted (ovariectomized) mice as compared to estrogen-competent mice. This observation was reversed upon estradiol supplementation. Moreover, treatment of female mice with the SERD Fulvestrant, markedly reduced the number of CRCLM compared to vehicle-treated mice, reduced the cell frequencies and counts of M2 macrophages, significantly increased NK cells recruitment in the liver. The addition of SERD to immunotherapy has a better therapeutic effect than both therapies alone, and increased CD8+ T-cells, NK cells, and M1/M2 macrophages

ratio. Taken together, our results identify estrogen as a critical regulator of an immunosuppressive TME in the liver and a potential therapeutic target to enhance immunotherapy efficacy.

Drug Resistance in Molecular Targeted Therapies 3

#3851

Targeting RET solvent-front mutants with an alkynyl nicotinamide-based inhibitor

Ujjwol Khatri[1], Neetu Dayal[2], Xueqing Hu[1], Elizabeth Larocque[2], Nimishetti Naganna[2], Tao Shen[1], Xuan Liu[1], Frederick W. Holtsberg[3], M. Javad Aman[3], Herman O. Sintim[2], Jie Wu[1]. *[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]Purdue University, West Lafayette, IN,[3]KinaRx, Rockville, MD*

Selpercatinib (LOXO-292, LY3527723) and pralsetinib (BLU-667) are first-in-class RET-targeted cancer therapy drugs. However, secondary RET mutations that confer selpercatinib/pralsetinib resistance have been identified, necessitating development of next-generation RET Tyrosine kinase inhibitors (TKIs). While the G810C/R/S/V mutations located at the RET kinase solvent-front site were detected in selpercatinib-treated patients, it was unclear whether all of these and other potential G810 mutants are resistant to selpercatinib and pralsetinib. We profiled selpercatinib and pralsetinib on all six possible G810 mutants derived from single nucleotide substitution. Surprisingly, the G810V mutant found in a clinical study was not resistant to selpercatinib or pralsetinib. Besides G810C/R/S, G810D also conferred selpercatinib/pralsetinib resistance. We found that alkynyl nicotinamide compounds such as HSN608 have better drug-like properties than alkynyl benzamides. HSN608 inhibited RET and RET V804M gatekeeper mutant, and all six G810 mutants with low nanomolar IC_{50}s in the BaF3/KIF5B-RET mutant cell model. In cell derived xenograft (CDX) tumors driven by KIF5B-RET(G810C), HSN608 caused regression of the selpercatinib-resistant tumors. This study clarifies the sensitivities of different RET solvent-front mutants to selpercatinib and pralsetinib, and identifies an alkylnyl nicotinamide-based RET TKI for inhibiting selpercatinib/pralsetinib-resistant G810 mutants.

#3852

IK-930, a paralog-selective novel TEAD-inhibitor, effectively attenuates drug-tolerant persister cell proliferation

Daniel Hidalgo, Marta Sanchez-Martin, Mihir Rajurkar, George Punkosdy, Jeffrey Ecsedy, Lan Xu. *Ikena Oncology, Boston, MA*

The Hippo pathway is commonly mutated or altered in human cancers. In addition to the primary genetic driving mutations, the downstream effectors of the Hippo pathway comprising the transcriptional coactivators YAP1 and TAZ and the TEAD transcription factors can be activated upon prolonged inhibition of other oncogenic pathways such as EGFR and MAPK. We showed that combining the novel, paralog selective TEAD inhibitor, IK-930, with osimertinib or trametinib in EGFR or KRAS mutated tumors, led to enhanced apoptosis *in vitro* and beneficial antitumor activity *in vivo*. Experimental models demonstrated that upon inhibition of EGFR with osimertinib, a subpopulation of drug tolerant cells defined as ‘persisters’ can survive treatment allowing for the accumulation of additional genetic and epigenetic alterations. These alterations in the persister cells can give rise to resistant tumors and cancer relapse. Previous studies have implicated YAP/TEAD signaling in the emergence and survival of the persister cells. To investigate the role of YAP/TEAD signaling in persister cell emergence, EGFR and KRAS mutant NSCLC cell lines were engineered to express a TEAD luciferase reporter. Treatment with EGFR or MEK inhibitors, at concentrations that do not elicit significant cell death, induced TEAD-mediated transcription after several days of treatment, indicative of an adaptive response to chronic target inhibition. Concurrent treatment with the TEAD inhibitor, IK-930, abolished TEAD-mediated transcription. Using time lapse microscopy, the cell cycle and proliferation of EGFR mutant cultured cells, engineered to express a fluorescence-based cell-cycle indicator (FUCCI), were quantified when treated with osimertinib alone or combined with IK-930. Treatment with osimertinib led to a rapid induction of cell death. However, after several days, a drug tolerant population emerged and reentered the cell cycle even with chronic osimertinib treatment. Interestingly, the emergence of these persister cells coincided with maximum TEAD activity. Concurrent addition of IK-930, as well as addition of IK-930 after the emergence of the osimertinib-tolerant persister

cells, attenuated cell proliferation and expansion, demonstrating the potential for IK-930 to prevent resistance to EGFR inhibitors and even reverse the effect when given after resistance has already emerged. Current efforts are focused on the characterization of the persister population and on evaluating the role of YAP/TEAD signaling in resistance to other targeted therapies.

The TWIST1-p27 signaling pathway is a critical determinant of MET TKI cell cycle arrest and resistance in *MET* altered non-small cell lung cancer

Vinod Kumar[1], Zachary A. Yochum[1], Princey Devadassan[1], Eric Huang[1], Ethan Miller[1], Vasavi Ayyala[1], Purva H. Rumde[1], Roja Baruwal[1], James O'Brien[1], Laura P. Stabile[2], Timothy F. Burns[3]. *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Pharmacology and Chemical Biology, University of Pittsburgh School of Medicine, Pittsburgh, PA,[3]Hematology-Oncology, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Advancement in classifying NSCLC into molecularly defined subgroup that respond to specific therapies have shifted the treatment paradigm towards personalized targeted therapy approach. A major obstacle for the treatment of oncogene driven non-small cell lung cancer (NSCLC) patients is both *de novo* and acquired resistance to targeted therapies. Approximately 4-6% of NSCLC patients harbor *MET* amplifications/mutations which are important targetable oncogenic drivers in the clinic. In addition, *MET* amplification has also emerged as a common mechanism of acquired resistance to EGFR TKIs as well as other targeted therapies. Crizotinib, tepotinib and capmatinib are FDA approved MET TKIs for *MET* exon 14 skipping mutant NSCLC and have shown activity against *MET* amplified NSCLC as well. Despite high response rates with these newer TKIs, the majority of patients with targetable *MET* alterations fail to respond and acquired resistance is inevitable. Multiple molecular mechanisms of MET TKIs resistance encompassing both on-target (HGF overexpression) and bypass have been identified. Furthermore, at the time of resistance, an epithelial-to-mesenchymal (EMT) phenotype is often observed. We have found that HGF/MET pathway is a major regulator of the TWIST1, TWIST1 is required for *MET* altered NSCLC and cooperatives with HGF *in vivo* during

tumorigenesis. Here, we reported that EMT transcription factor TWIST1 mediates a bypass of a MET TKI-mediated p27-dependent growth arrest. To study the mechanism of TKI resistance in *MET* altered NSCLC, we used multiple *MET* dysregulated human cell lines (H1437, H596, H1993, and H1648), a novel acquired resistance model of MET TKI resistance (H1993-CR cells), two syngeneic tobacco carcinogen induced mouse lung cell lines (FVBW-17 and FVBCH-17), and three different animal models (mouse xenografts, PDXs, transgenic animals). We found that TWIST1 overexpression led to MET TKI resistance *in vitro* and *in vivo* in *MET* altered cell lines by overcoming cell cycle arrest. This was accompanied by a failure to induce p27 in the presence of TWIST1 overexpression. Similarly, loss of p27 induction and G1 arrest was also observed in our model of acquired MET TKI resistance. Conversely, TWIST1 inhibition restore sensitivity to TKIs *in vitro* and *in vivo* and lead to induction of p27. p27 appears to be require for MET TKI induced cell cycle arrest and sensitivity as silencing p27 lead to MET TKI resistance. Our findings suggest that targeting TWIST1 may be an effective therapeutic strategy to overcome HGF-MET-driven resistance in *MET*-driven NSCLC.

TNIK inhibition as a novel therapeutic in cMyc high/TTF1 low SCLC

Azusa Tanimoto[1], Robert J. Cardnell[1], Benjamin B. Morris[1], Kavya Ramkumar[1], Shen Li[2], Qi Wang[2], Allison C. Stewart[1], Carl Michael Gay[1], Jing Wang[2], Lauren Averett Byers[1]. *[1]Center Department of Thoracic/Head & Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics & Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background**:** Small cell lung cancer (SCLC) is a highly lethal malignancy, with rapidly acquired chemotherapy resistance. Some studies have reported that Wnt signaling pathway activation promoted cell proliferation and was correlated with chemo-resistance in SCLC. None of the therapies targeting Wnt pathway components of the transmembrane and the cytoplasm have been successful in a clinical application due to toxicity and insufficient efficacy. However, targeting Wnt signaling inside the nucleus has been drawing increasing attention as cancer therapeutics. TRAF2 and NCK-interacting protein kinase (TNIK), which interacts with downstream

effectors, TCF4/β-catenin transcriptional complex, is an essential activator of Wnt target genes. TNIK is highly expressed in several cancers for cell proliferation, thus TNIK is expected as a novel druggable target. On the other hand, the question remains whether TNIK is a critical target in SCLC. We hypothesize that a TNIK inhibitor has potent anti-tumor effects in SCLC and its promising biomarkers exist.
Methods: We used 29 SCLC cell lines including all four subtypes defined by differential expression of transcription factors ASCL1, NEUROD1, POU2F3, and inflamed gene signature (SCLC-A, N, P, and I, respectively) to evaluate the effect of a TNIK inhibitor, NCB-0846 in vitro. We correlated NCB-0846 IC50 values with proteomic profiling (Reverse Phase Protein Array, RPPA) data. Protein expression was examined by western blotting.
Results: NCB-0846 markedly reduced cell proliferation in SCLC-N and P cell lines. There was a strong positive correlation between cMyc and the efficacy of NCB-0846 ($r=-0.484$, $P<0.01$), while a negative correlation between TTF1 and the efficacy ($r=0.569$, $P<0.01$). Additionally, NCB0846 decreased the expression of cMyc in cMyc-high/TTF-1 low SCLC cells.
Conclusions: These findings indicate that TNIK inhibitors may be a new personalized molecular-targeted therapy in cMyc-high/TTF-1-low SCLC.

Establishment and characterization of a panel of breast XPDX models representing innate or acquired resistance to trastuzumab deruxtecan (T-DXd)
Maci DeBoer[1], Albert Paez[1], Johnnie Flores[1], Robyn Baeza[1], Alyssa Simonson[1], Jim Lund[1], Kyriakos Papadopoulos[2], Thomas Gribbin[3], Amy Lang[4], Gladys Rodriguez[4], Lorena Mozas[1], Lorena Gonzalez[1], Manish Sharma[5], Emiliano Calvo[6], Tatiana Hernandez[7], Michael J. Wick[1].
[1]XenoSTART, San Antonio, TX,[2]START San Antonio, San Antonio, TX,[3]CHCWM, Grand Rapids, MI,[4]START Center, San Antonio, TX,[5]START Midwest, Grand Rapids, MI,[6]START Madrid, Madrid, Spain,[7]START Barcelona, Barcelona, Spain

Background: Trastuzumab deruxtecan (T-DXd) is an ADC consisting of an anti-HER2 antibody linked to a novel topoisomerase I inhibitor payload approved for T-DM1-refractory, HER2+ breast cancer (BC) and metastatic,

recurrent HER2-low BC. While this therapy is effective in some patients, resistance often develops. To aid in developing new therapies for T-DXd-resistant BC and better understand potential resistance mechanisms, we established a panel of six breast XPDX models representing innate or acquired resistance to T-DXd. These models, designated ST4565C, ST4565D, STM148B, STM148C, STM148D, and ST4480B/EHR were developed and characterized for receptor expression, genomics, and drug sensitivities toward chemotherapies and targeted agents including T-DXd, T-DM1, and margetuximab.

Methods: ST4565C/D was established from a patient with ER+/HER2+, metastatic BC who was T-DXd treatment naïve. ST4565C was collected post chemo- and HER2-targeted therapies; ST4565D was collected following eribulin/margetuximab. STM148B/C/D were established from a patient with ER-/HER2+ metastatic BC following trastuzumab, T-DM1, and eleven months of T-DXd. ST4480B/EHR was established by chronic in vivo T-DXd dosing to the parent ST4480B ER+/HER2+ model until resistance developed. Resulting models were passaged and receptor expression confirmed by IHC and genomic analyses, including WES and RNA_{seq}, were performed to further characterize models. In vivo, models were tested with agents including: trastuzumab, T-DM1, and T-DXd; endpoints included tumor volume (TV) and time from treatment initiation (TTI) with %T/C values and tumor regression reported at study completion; a %T/C of ≤ 20 versus control was considered sensitive. Tumor regression (%T/C=<0) versus Day 0 TV was also reported.

Results: Models retained receptor expression and similar histology comparable with archival clinical or model samples. In vivo, all ST4565 and STM148 models were refractory to trastuzumab, T-DM1, and T-DXd up to 10 mg/kg weekly with an average %T/C of 75%. ST4480B/EHR showed similar resistance to trastuzumab and T-DM1 at 10 mg/kg, and T-DXd at 3 mg/kg; T-DXd tested at 3 mg/kg in the ST4480B parent model resulted in tumor regressions. Sequencing of ST4565C/D identified a novel fusion, MTAP/CDKN2A/B deletions and elevated expression of FGFR1 and CCND1. In STM148 models an AKAP8L-NOTCH3 fusion and PIK3CA and CCNE1 mutations were reported. ST4480B/EHR reported $PIK3CA^{E545K}$ and an ESR1-CCDC170 fusion identical to the parent model, but differential expression was noted in several genes in the RICTOR/TORC2 pathway.

Conclusion: We established and characterized six breast XPDX models representing innate or acquired resistance to T-DXd. These models are valuable tools in understanding resistance mechanisms and in developing novel therapies for T-DXd-resistant patients.

Evaluation of replication protein A inhibitor, NERx329 in combination with EGFR mutant targeted therapy

Reshma Bhowmick[1], John J. Turchi[1], Shadia I. Jalal[2]. *[1]Indiana University School of Medicine, Indianapolis, IN,[2]Hematology Oncology, Indiana University School of Medicine, Indianapolis, IN*

Lung cancer is the leading cause of cancer related deaths worldwide with the majority (~80%) of patients diagnosed with non-small lung cancer (NSCLC). Targeted therapies directed against tumor initiating growth factor receptors are effective treatment options for driver mutation positive NSCLC. Osimertinib is a third-generation EGFR-Tyrosine Kinase inhibitor (TKI) that has activity against EGFR exon 19, exon 21, and T790M mutations. Unfortunately, Osimertinib treated patients acquire resistance and median progression free survival is 18 months. Moreover, Osimertinib does not cure stage IV EGFR mutant NSCLC. The acquisition of secondary mutations leading to activation of bypass pathways, MET amplification, EMT, compensatory pathway activation and histological transformation to small cell phenotype are major causes of acquiring resistance to EGFR TKIs. Proliferating cancer cells regularly experience a low level of replication stress. Additionally, receptor tyrosine kinases such as EGFR are known to interact with DNA repair proteins and impact DNA damage repair following chemotherapy, radiation therapy, and EGFR TKI treatment. However, the role of DNA repair pathways in EGFR-TKI resistance is unknown and the interaction between EGFR pathway, DNA damage, and repair pathways has not been fully elucidated. At low-level replicative stress promotes genomic instability but at a high level through mitotic catastrophe it causes cell death. Replication protein A is a critical sensor of the DNA damage response detecting replication stress. The small molecule inhibitor of RPA, NERx 329, sequesters active RPA and induces replication catastrophe and cell death. Here we demonstrate that NERx329 in combination with Osimertinib enhanced Osimertinib mediated cell death.

CCk-8 assays performed after 48h of NERx329 and Osimertinib combination treatment result in a robust decrease in IC_{50} compared to single agent therapy. Dissection of signaling pathways leading to this death-promoting effect of NERx329 showed a combination of bypass pathway marker (AXL) and compensatory pathway marker (STAT) inhibition in AXL-high expressing EGFR mutant lung cancer cells. Whereas inhibition of STAT pathway was responsible for the death-promoting effect of NERx329 in AXL-low expressing EGFR mutant lung cancer cells. AXL and STAT inhibition are associated with induced DNA damage and impaired DNA repair. From these data, we infer that DNA damage repair pathways could be involved in TKI resistance and NERx329 could be a promising drug candidate for combination targeted therapy.

Exploring mechanisms of resistance to elraglusib in pancreatic cancer PDX models

Taylor Weiskittel[1], Ding Li[1], Lingling Han[1], Joseph McDermott[2], Benedito Caneiro[3], Hu Li[1], Daniel Billadeau[1], Andrew Mazar[4]. *[1]Mayo Clinic, Rochester, MN,[2]Latern Pharma Inc., Dallas, TX,[3]Brown University, Providence, RI,[4]Actuate Therapeutics Inc., Forth Worth, TX*

Metastatic pancreatic cancer patients who previously progressed on nab-paclitaxel/gemcitabine (average of 3 previous lines if treatment) were treated with elraglusib in combination with a rechallenge of this combination. The majority of patients demonstrated a prolonged progression free survival. While this early clinical evidence is highly encouraging, the biological determinants of elraglusib response are unknown. *In vitro* screens of elraglusib on pancreatic PDX cell lines showed that some tumor cells possess modest intrinsic resistance to elraglusib as measured by LD50 which ranged from 316.9 nM to 1080 nM in a screen of 10 cell lines. To explore this phenomena further, we induced resistance in three cell line models by growing cells in the presence of increasing concentrations of elraglusib. We then sequenced the transcriptome of the parental and resistant lines to identify potential mechanisms of elraglusib resistance. Comparison of RNA sequencing profiles identified upregulation of the Aldo-keto reductase (AKR) family of genes. This upregulation was confirmed by qRT-PCR and by immunoblot

demonstrating that AKRs were upregulated at both the transcriptomic and protein level. We further quantified the AKR levels in the remainder of the 10 cell lines and found that many of the more resistant lines had high expression of AKR1C2. However, not all of the resistant lines had high expression which could be because they have a separate mechanism of resistance to elraglusib. A large body of literature has found that AKR genes provide resistance to many other small molecule inhibitors either by direct metabolism or by indirectly relieving oxidative stress. Given these results, we identify aldo-keto reductases as potentially associated with elraglusib resistance, but further investigation is warranted to establish a causal link between AKR and the resistant phenotype.

Exploring Exportin-1 as a therapeutic vulnerability in squamous cell carcinoma

Vidushi Durani[1], Rebecca Caeser[2], Charles M. Rudin[3], Alvaro Quintanal-Villalonga[2], Harsha Sridhar[2], Parvathy Manoj[2], Sam E. Tischfield[2], Marina Asher[2], Umeshkumar Bhanot[2], Jacklynn V. Egger[2], Nicholas D. Socci D. Socci[2], Nisargbhai S S. Shah[2], Elisa de Stanchina[2], Natasha Rekhtman[2].
[1]Weill Cornell Grad. School of Medical Sci., New York, NY,[2]Memorial Sloan Kettering, New York, NY,[3]Memorial Sloan Kettering Cancer Center, New York, NY

Introducti**on:** Squamous cell carcinomas (LUSCs) account for 25-30% cases of non-small cell lung cancers, making them the second most common histology of lung cancer after adenocarcinomas. For the latter, molecular characterization has defined tumor subsets with discrete driver alterations sensitive to targeted inhibitors, leading to significant improvement in patient survival. However, for LUSCs, to date no specific drivers have been described that are amenable for pharmacological targeting and no targeted therapies are approved for use in this setting. Despite decades of research, LUSCs are still treated with cytotoxic chemotherapy, and now concomitant immunotherapy, which does not achieve durable responses in most patients. Thus, identification of targetable vulnerabilities in this setting remains a critical unmet clinical need. Preliminary data from our lab has identified the nuclear exporter exportin 1 as a therapeutic vulnerability in small cell lung carcinomas.

Exportin 1 (XPO1) inhibition with Selinexor, a drug approved for clinical use in the setting of hematological malignancies, induces significant sensitivity in combination with cisplatin and irinotecan. Here, we explored the role of XPO1 as a therapeutic target in LUSC.
Methods: We performed a comprehensive multi-omic molecular characterization of a library of LUSC patient-derived xenografts (PDXs) (N=28, with 17 clinical samples being matched pairs). IHC, RNA-seq and NGS via MSK-IMPACT were performed on 27 samples. To examine the potential of XPO1 inhibition as sensitizer to chemotherapy in LUSC, we performed genetic and pharmacological inhibition experiments in LUSC cell lines exhibiting high XPO1 expression.
Results: Of the 28 models, 19 samples (68%) were from primary tumors and 9 samples (32%) from metastasis. The sample set were roughly split in half with regard to treatment status; 15 samples (54%) were treatment naïve and 13 sample were treated (46%).XPO1 is highly expressed in LUSCs clinical specimens compared to other tumor types, and its knockdown reduces tumorigenic features of LUSC cell lines with high XPO1 expression, including proliferation and anchorage-independent growth. Targeted XPO1 inhibition with selinexor induces chemotherapy sensitization to carboplatin and paclitaxel, drugs currently used in the treatment of LUSC, as depicted by high cytotoxic synergy scores of selinexor with either drug.
Conclusion: Our data suggest that XPO1 expression may exert pro-oncogenic effects in LUSC, consistent with its upregulation in this tumor setting, and that its inhibition with selinexor may strongly sensitize to chemotherapy. Assessment of efficacy of combination therapies with selinexor *in vivo* will assess the potential of these combinations as a therapeutic approach for LUSC tumors. The clinical availability of selinexor would allow immediate clinical translation of the results generated in this project.

Alterations in hormone receptors regulome following response to kinase inhibitors in lethal prostate cancer
Remi M. Adelaiye-Ogala[1], Surendra Gulla[1], Jonathan E. Bard[2], David J. VanderWeele[3], Kathleen Kelly[4]. *[1]Medicine/ Division of Hematology and Oncology, University at Buffalo, Buffalo, NY,[2]Genomics and Bioinformatics*

Core, New York State Center of Excellence for Bioinformatics and Life Sc, University at Buffalo, Buffalo, NY,[3]Hematology and Oncology, Northwestern University, Chicago, IL,[4]Laboratory of Genitourinary Cancer Pathogenesis, NCI/NIH, Bethesda, MD

The androgen receptor (AR) signaling axis is critical for prostate cancer (PCa) pathogenesis and all subsequent phases of disease progression. Although initial success with androgen deprivation therapy and AR-targeted agents such as enzalutamide or abiraterone, most patients inevitably relapse due to therapeutic resistance. Previous studies have shown that genomic AR is unchanged despite resistance to AR antagonists, and its gene expression is unaltered. Therapeutic resistance is broadly classified into two categories; restoration of AR activity and tumor progression despite AR blockade. Indeed, others have noted an extensive reprogramming of the AR cistrome in clinical and preclinical specimens, where a shift in canonical to non-canonical AR cistrome is associated with an increase in Gleason grade. In previous studies, we observed increases in known AR target genes following exposure to kinase inhibitors which was marked by a decrease in tumor growth. We hypothesized that restoration of canonical AR cistrome can be mediated through kinase inhibition and is associated with re-sensitization to AR-targeted therapy. In addition, we treated cell lines and patient-derived xenograft models of advanced prostate cancer with kinase signaling pathway inhibitors, AR signaling inhibitors, or a combination of both for 24 hours (in vitro) or five days (in vivo). In addition, samples were collected and processed for RNA-seq and ChIP-seq. Our transcriptomic analysis showed enrichment of previously published non-canonical AR target genes in cells resistant to AR-targeted agents. When resistant cells were exposed to kinase inhibitors, we observed an enrichment of canonical AR target genes. In addition, we identified unique AR-enriched peaks at active sites associated with resistance. Through GSEA of gene annotated peaks, we found unique regulatory transcription factor targets, some of which are associated with cell proliferation and differentiation and may play a functional role in AR cistrome adaptation to resistance and survival. Overall, our data suggest that AR transcription adapts to the therapeutic resistance of AR antagonists via the enrichment of non-canonical AR cistrome. Furthermore, restoration of canonical AR cistrome is achieved

following kinase signaling pathway inhibition and is associated with re-sensitization to AR-targeted therapy.

ERK1/2 inhibition overcomes resistance to venetoclax in AML by altering mitochondrial metabolism

Priyanka Sharma[1], Lauren Ostermann[1], Sujan Piya[1], Natalia Baran[1], Anudishi Tyagi[1], Christopher Hindley[2], Kim-Hien Dao[3], Martin Sims[2], V. Lokesh Battula[1], Michael Andreeff[1], Gautam Borthakur[1]. *[1]Departments of Leukemia, UT MD Anderson Cancer Center, Houston, TX,[2]Astex Pharmaceuticals, Cambridge, United Kingdom,[3]Astex Pharmaceuticals, Inc., Pleasanton, CA*

Background: Primary or secondary resistance to venetoclax is pervasively associated with mutational/non-mutational activation of RAS/RAF/ERK pathway which confers metabolic alterations as a compensatory adaptation. Preclinical models of venetoclax resistance and primary patient samples (n=8) were used to assess the synergy of concomitant Bcl2 and ERK1/2 inhibition followed by RNAseq analysis to identify molecular mechanisms responsible for overcoming resistance to venetoclax.
Results: ERK1/2 inhibition using Compound 27 (ERKi, Heightman et al., J Med Chem. 2018), an analog of ASTX029, was highly synergistic with venetoclax at inducing apoptosis in AML. NRAS-mutant OCI-AML3 and THP1 cells, that are inherently resistant to venetoclax, were sensitized to venetoclax when combined with ERKi with ~90% apoptosis compared to 20% by venetoclax alone (Combination Index = 0.008). Synergy was also confirmed using isogenic OCI-AML2 cells with lab-generated acquired resistance to venetoclax, resulting in 75% apoptosis versus 22% by venetoclax (CI=0.6). Leukemia progenitor cells in primary AML samples were also depleted by the ven+ERKi combination (CI:0.03-0.23). In line with our in-vitro findings, treatment with ASTX029 as a single agent or in combination with venetoclax significantly inhibited leukemia burden and increased survival in an OCIAML3 xenograft model ($p<0.05$). Single agent ERKi and combination treatment using an NRAS-mutant PDX resulted in significantly impaired clonogenic potential and decreased expression of cMyc and CD44 in CD34+CD38- population as demonstrated by CyTOF, indicating depletion of progenitors. Transcriptomic profiling of OCIAML3

cells revealed upregulation of 6 pathways in response to venetoclax including oxidative phosphorylation (OXPHOS), electron transport chain, Myc targets, E2F targets, epithelial mesenchymal transition and KRAS signaling. Interestingly, these pathways were downregulated after ERKi+venetoclax treatment along with decrease in glycolysis and fatty acid metabolism (FDR<0.05). Since, venetoclax treatment significantly enriched for OXPHOS, we examined the metabolic effect of ERKi to overcome venetoclax resistance. Seahorse analysis showed increased basal and maximal respiration, and ATP production in OCIAML2 venetoclax resistant versus parental cells. Combining ERKi with venetoclax reduced OCR and ATP production in OCIAML3 and OCIAML2-venetoclax resistant cells. This was accompanied by an increase in membrane depolarization ($p=0.001$) as well as enhanced mitochondrial ROS ($p<0.001$).
Conclusion: The inhibition of ERK1/2 alters mitochondrial metabolism and functional integrity to overcome resistance to venetoclax by causing apoptosis in venetoclax resistant AML cells. These data provide a strong rationale for the combination of ERK1/2 and Bcl-2 inhibitors in treatment of AML and warrant further investigation in the clinic.

#3861
c-MYC mediated resistance to trametinib plus hydroxychloroquine in pancreatic cancer is overcome by CDK4/6 and lysosomal inhibition
Mark Silvis, Dilru Silva, Rohweder Riley, Sophia Schuman, Swapna Gudipaty, Amanda Truong, Jeffery Yap, Kajsa Affolter, Martin McMahon, Conan Kinsey. *University of Utah Huntsman Cancer Institute, Salt Lake City, UT*

Pharmacological inhibition of KRAS>RAF>MEK>ERK signaling has provided no clinical benefit to patients with pancreatic ductal adenocarcinoma (PDA). Interestingly, combined inhibition of MEK1/2 (with trametinib, T) plus autophagy (with chloroquine, CQ, or hydroxychloroquine, HCQ) demonstrated striking anti-tumor effects in preclinical models and in a patient (Patient 1). However, not all patients respond to the T/HCQ regimen, and Patient 1 eventually developed resistant disease. Here we report that primary or acquired resistance is associated with focal DNA copy number gains encompassing *c-MYC*. Furthermore, ectopic expression of c-MYC in PDA cell lines rendered them T/HCQ

resistant. Interestingly, a CDK4/6 inhibitor, palbociclib (P), also induced autophagy and overrode c-MYC-mediated T/HCQ resistance, such that P/HCQ promoted regression of T/HCQ resistant PDA tumors with elevated c-MYC expression. Finally, P/HCQ treatment of Patient 1 resulted in a biochemical disease response. These data suggest that elevated c-MYC expression is both a marker and a mediator of T/HCQ resistance, which may be overcome by the use of palbociclib plus hydroxychloroquine.

IGFBP3 promotes resistance to olaparib via modulating EGFR signaling in advanced prostate cancer

Amy R. Leslie, Shu Ning, Leandro S. D'Abronzo, Cameron Armstrong, Masuda Sharifi, Zachary A. Schaaf, Wei Lou, Christopher P. Evans, Hong-Wu Chen, Alan Lombard, Allen C. Gao. *Urologic Surgery, UC Davis, Sacramento, CA*

Background: Castration-resistant prostate cancer (CRPC) is an incurable disease and a leading cause of cancer death in men worldwide. Olaparib (Lynparza) was among the first PARP inhibitors (PARPi) approved for the treatment of CRPC tumors harboring DNA repair defects. However, clinical resistance to PARPi's has been documented. The mechanisms underlying resistance to PARPi's remain elusive. To study acquired resistance, we developed olaparib-resistant LN-OlapR and 2B-OlapR cell lines generated through chronic olaparib treatment of the olaparib-sensitive cell lines LNCaP and C4-2B, respectively. RNA-seq revealed IGFBP3 is overexpressed in both OlapR cell lines. IGFBP3 overexpression is correlated with poor clinical outcome and is thought to participate in DNA repair pathways. IGFBP3 plays a key role in nonhomologous end joining (NHEJ) repair through a ternary complex with EGFR and DNA-PKcs. The IGFBP3/EGFR signaling axis is thought to modulate NHEJ repair and could have implications for PARPi sensitivity. We hypothesize that increased IGFBP3 expression promotes PARPi resistance by enhancing DNA repair capacity.
Methods: RNA-sequencing and gene set enrichment analysis were used to determine the expression profile changes in resistant cells compared to parental cells. Real time PCR and western blots confirmed the expression of DNA damage repair genes such as γH2AX, EGFR, and DNA-PKcs. ELISA

was used to determine IGFBP3 secretion. RNAi was used to inhibit IGFBP3 and EGFR expression. Gefitinib was used to inhibit EGFR activity. Cell viability assays were used to assess cell growth.
Results: Transcriptomic profiling revealed that IGFBP3 is highly expressed in resistant models. We verified increased levels of IGFBP3 RNA and protein in both OlapR models. We found that RNAi inhibition of IGFBP3 increases γH2AX and cleaved-PARP protein levels in the resistant models, which suggests accumulation of DNA double strand breaks (DSBs) leading to genomic instability and cell death. We discovered increased phosphorylation of EGFR and DNA-PKcs in the resistant cells. Furthermore, silencing/inhibiting IGFBP3 and EGFR reduces OlapR cell viability and resensitizes resistant cells to treatment.
Conclusions: Our findings demonstrated that inhibiting IGFBP3 and EGFR aids in PARPi sensitivity in the resistant setting. Future work will utilize OlapR models to study how the IGFBP3/EGFR/DNA-PKcs protein complex promotes the development of resistance. Understanding the role of IGFBP3 in PARPi resistance will enhance our ability to re-sensitize resistant CRPC to PARPi therapeutics.

#3863
Aminoflavone confers activity against aromatase inhibitor-resistant breast cancer cells in part via miR125b2-3p restoration
Eileen J. Brantley, Nicole Mavingire, Salma Khan, Gayathri Nagaraj, Shawnee Angeloni, Charles Wang, Ubaldo Soto. *Loma Linda Univ. School of Medicine, Loma Linda, CA*

Aromatase inhibitor therapy is the most crucial adjuvant treatment option for postmenopausal women with hormone receptor-positive (HR+) non-metastatic breast cancer. However, up to 30% of these patients will experience relapse due in part to aromatase inhibitor resistance. We recently identified miR125b2-3p as a putative tumor suppressor in HR+ breast cancer. We also found that small molecule Aminoflavone (AF) induces miR125b2-3p expression in HR+ breast cancer cells. In the current study, we hypothesized that AF confers anticancer actions in breast cancer cells resistant to aromatase inhibitors via miR125b2-3p reactivation. Using the Alamar Blue and colony forming assays, we discovered that AF demonstrated anticancer activity in estrogen-deprived resistant (EDR) cells

designed to mimic aromatase inhibitor resistance. AntagomiR125b2-3p enhanced, while miR125b2-3p mimics diminished colony formation of EDR cells. AF-mediated suppression of colony formation in EDR cells was attenuated during co-treatment with antagomiR125b2-3p and was enhanced during co-treatment with miR125b2-3p mimics. Both miR125b2-3p mimics and AF suppressed EDR cell migration. AntagomiR125b2-3p counteracted AF-mediated suppression of cell migration. Our in silico profiling studies identified the alpha6-integrin, a mediator of breast cancer stem cell activity and metastasis, as one miR-125b2-3p target. Immunohistochemistry of patient tumor samples revealed that alpha 6-integrin protein expression intensified following relapse on the aromatase inhibitor anastrozole. MCF-7 cells transfected to overexpress the alpha 6-integrin were less responsive to anastrozole than those transfected with empty vector. These data suggest that AF restores the tumor suppressor function of miR125b2-3p to inhibit the alpha 6-integrin and confer activity against aromatase inhibitor-resistant breast cancer.

#3864

Targeting IL-6/STAT3 signaling in EGFR-mutant drug tolerant persister cells

Sonia A. Patel, Monique Nilsson, Yan Yang, Li Shen, Jing Wang, Alissa Poteete, Xiaoxing Yu, Xiaoyang Ren, Xiuning Le, John Heymach. *The University of Texas MD Anderson Cancer Center, Houston, TX*

While the majority of epidermal growth factor receptor (EGFR) mutant non-small cell lung cancer (NSCLC) patients initially respond to treatment with an EGFR tyrosine kinase inhibitor (TKI), most will eventually develop acquired resistance to these agents. The evolution of tumor cells with acquired resistance to targeted agents initially involves the persistence of a drug-tolerant subpopulation of tumor cells which display a transient and flexible resistant state. These persister cells can remain quiescent for prolonged periods of time, but eventually give rise to fully drug resistant tumor cells that resume growth and metastatic spread. The signaling pathways that allow persister cells to remain viable or to re-activate expansive growth are poorly understood. We and others have reported that EGFR TKI resistance that occurs independent of secondary EGFR mutations or MET amplification is associated with an epithelial to

mesenchymal transition (EMT). Our analysis of tumor cells that had undergone EMT-mediated resistance to the EGFR TKI osimertinib revealed that interleukin-6 (IL-6) was highly upregulated in resistant cells as compared to parental cells. We find that in the setting of EGFR mutant NSCLC, IL-6 suppresses the anti-tumor cell activity of T cells and NK cells. To assess the role of IL-6 in the early events of EGFR TKI resistance, we generated drug-tolerant persister cells by treating EGFR mutant HCC4006 and HCC827 NSCLC cells with the EGFR TKI osimertinib for 10 days and then assessed IL-6 expression. We observed that IL-6 was upregulated at both the RNA and protein levels in EGFR-TKI persister cells as compared to parental cells. While the cell surface expression of IL6R was not significantly increased in EGFR-TKI persister cells as compared to parental cells, we observed increased secretion of soluble IL6R in persister cells by ELISA assay. We next assessed changes in protein expression and activation in drug tolerant persister cells by reverse phase protein array (RPPA) and observed that p-STAT3, a key component of the IL-6 signaling pathway, was significantly elevated in persister cells as compared parental cells or cells treated with osimertinib for 24 hours. Using genetically engineered mouse models (GEMM) of $EGFR^{L858R}$ mutant lung cancer, we also observed a similar upregulation of both IL-6 and p-STAT3 expression at the RNA and protein levels in EGFR-mutant tumors treated with osimertinib for 2 or 4 weeks. Additionally, circulating levels of IL-6 also are elevated in $EGFR^{L858R}$ GEMMs treated with osimertinib for 2 or 4 weeks. Collectively, our data indicates that upregulation of IL-6 is an early event in the evolution of drug resistance. Given the role of IL-6 in promoting EGFR TKI resistance, further studies investigating whether targeting of IL-6 signaling may impair the survival or outgrowth of persister populations are warranted.

#3865

Multiple cancer types rapidly escape from multiple MAPK inhibitors to generate mutagenesis-prone subpopulations

Timothy E. Hoffman, Chen Yang, Varuna Nangia, Christopher Ryland Ill, Sabrina L. Spencer. *Biochemistry, University of Colorado, Boulder, CO*

Many cancers harbor pro-proliferative mutations of the mitogen-activated protein kinase (MAPK) pathway and many targeted inhibitors now exist for

clinical use, but drug resistance remains a major issue. We previously showed that BRAF-driven melanoma cells treated with BRAF inhibitors can non-genetically adapt to drug within 3-4 days to escape quiescence and resume slow proliferation. Here we show that this phenomenon is not unique to melanomas treated with BRAF inhibitors but rather is widespread across many clinical MAPK inhibitors and cancer types driven by EGFR, KRAS, and BRAF mutations. In all treatment contexts examined, a subset of cells can escape drug-induced quiescence within four days to resume proliferation. These escapee cells broadly experience aberrant DNA replication, accumulate DNA lesions, spend longer in G2-M cell cycle phases, and mount an ATR-dependent stress response. We further identify the Fanconi anemia (FA) DNA repair pathway as critical for successful mitotic completion in escapees. Long-term cultures, patient samples, and clinical data demonstrate a broad dependency on ATR- and FA-mediated stress tolerance. Together, these results highlight the pervasiveness with which MAPK-mutant cancers are able to rapidly escape drug and the importance of suppressing early stress tolerance pathways to potentially achieve more durable clinical responses to targeted MAPK pathway inhibitors.

Targeting AXL can effectively inhibit c-Met-induced therapeutic resistance in renal cancer

Akash Sabarwal[1], Laxminarayan Rawat[1], Johannes Wedel[1], Yuzuru Sasamoto[1], Sabina Signoretti[2], Toni K. Choueiri[3], Murugabaskar Balan[1], Soumitro Pal[1]. *[1]Nephrology, Boston Children's Hospital, Boston, MA,[2]Pathology, Brigham and Women's Hospital, Boston, MA,[3]Medicine, Dana-Farber Cancer Institute, Boston, MA*

Advanced stage renal cell carcinoma (RCC) often becomes resistant to the currently available therapeutic options. Receptor Tyrosine Kinase (RTK), c-Met, is overexpressed and hyperactivated in renal cancer; and it promotes tumor-promoting pathways following binding with its ligand, Hepatocyte Growth Factor (HGF). Cabozantinib (Cabo), an inhibitor of c-Met/few other RTKs (like, AXL and KDR), is being used for the treatment of RCC. However, acquired therapeutic resistance is a major hurdle in its clinical use. Mechanism(s) of drug resistance against c-Met inhibition is largely

unknown. Although Cabo (XL184) can effectively inhibit c-Met/RTK phosphorylation, very interestingly, we found that, prolonged treatment of Cabozantinib (24 hours, *in vitro*) increased the expression of total c-Met and AXL in renal cancer cells in a dose-dependent manner. AXL is also overexpressed in RCC and has a novel cross-talk with c-Met. We found that silencing AXL (either by gene knock-down approach or using a specific inhibitor (TP-0903)) markedly down-regulates Cabo-mediated total c-Met expression and enhances apoptosis of human RCC cells. We have also utilized murine model(s) of renal cancer growth (both xenograft and syngeneic), and found that Cabo treatment increases the levels of c-Met and AXL in tumor tissues, and the inhibition of AXL using TP-0903 can markedly inhibit the expression levels of total c-Met and AXL. We observed that HGF-mediated c-Met phosphorylation is short-lived when AXL is silenced. We also found that a lower concentration of Cabo can mediate cancer cell survival; and either the knock-down of AXL or using AXL inhibitor in combination with Cabo can reverse these effects. We have studied the downstream signaling pathways (Akt, ERK1/2 and STAT3) of c-Met, and found that AXL inhibition is crucial to down-regulate c-Met-induced signaling molecules following Cabo treatment. Our observations indicate that Cabo-mediated increase in total c-Met in RCC cells is not regulated at the transcriptional level; however, Cabo can interfere with the receptor degradation pathway leading to increased accumulation of c-Met. We have also studied the levels of c-Met and AXL in renal tumor tissues (archived specimens) from renal cancer patients before and after Cabozantinib treatment. Interestingly, we found increased levels of total c-Met and AXL in tumor tissues following Cabo treatment. Together our data suggest that AXL plays a critical role in mediating therapeutic resistance against c-Met inhibitor; and a combination of Cabo and an AXL/other RTK inhibitor can effectively block the resistance.

Chromatin modification driving sub-clonal resistance to KRAS G12C combination therapies in KRAS mutant non-small cell lung cancer

Chendi Li[1], Qian Qin[1], Mohammed Usman Syed[1], Anahita Nimbalkar[1], Barbara Karakyriakou[1], Sarah E. Clark[1], Anne Y. Saiki[2], Paul E. Hughes[2], Chris Ott[1], Luca Pinello[1], Aaron N. Hata[1]. [1]*Massachusetts General*

Hospital, Charlestown, MA,[2]Amgen Research, Amgen Inc., Thousand Oaks, CA

The FDA approval of the KRAS G12C inhibitor (G12Ci) sotorasib and the advancement of similar drugs into clinical trials marks a major milestone in treating KRAS G12C non-small cell lung cancer (NSCLC). However, not all patients respond (sotorasib - ORR = 37.1%, adagrasib - 43%, JDQ443 - 35%), motivating preclinical and clinical investigation into mechanisms of intrinsic and acquired resistance. For instance, clinical studies have reported on-target KRAS mutations and preclinical studies have demonstrated mitogen-activated protein kinase (MAPK) feedback reactivation including EGFP, SHP2, and WT RAS signaling. In response to targeted therapies, sub-populations of cells can enter quiescence or specific epigenetic-driven states that confer drug tolerance. However, epigenetic states defining drug-tolerant persister populations and contributing to adaptive resistance to KRAS G12Ci have not been reported. Using a lineage tracing barcoded system, we identify distinct and reversible subpopulations defined by specific chromatin and transcriptional states in KRAS NSCLC cell lines that contribute to KRAS G12Ci resistance *in vitro*, even prior to drug treatment. We observed that specific states, including activation of histone demethylation and SWI/SNF complex, may contribute to MAPK reactivation-driven resistance. These results suggest potential epigenetic vulnerabilities that can be exploited to improve the response to KRAS G12Ci. Moreover, we observed distinct persister subpopulations with resistance to KRAS G12Ci combination co-targeting orthogonal pathways (SHP2, CDK4/6, PI3K, and MCL-1), raising the possibility that distinct epigenetic-transcriptional states contribute to differential drug response and clonal evolution of persisters. Collectively, these results suggest that more complete tumor regression may be achieved by orthogonal strategies that target different resistant populations within the same tumor.

Aurora kinase A inhibition overcome adaptive resistance to KRAS G12C inhibitor by G1-checkpoint induced apoptosis in KRAS non-small cell lung cancer

Chendi Li[1], Jeremy Chang[2], Mohammed U. Syed[1], Anahita Nimbalkar[1], Yi Shen[1], Steve Altschuler[2], Lani Wu[2], Xueqian Gong[3], Aaron Hata[1].

[1]Massachusetts General Hospital, Charlestown, MA,[2]University of California San Francisco, San Francisco, CA,[3]Eli Lilly and Company, Indianapolis, IN

Cancer cells gain drug-tolerant states and evade therapy. In response to KRAS G12C inhibitor (G12Ci), KRAS mutant non-small cell lung cancer (NSCLC) cells maintain a drug-tolerant state by aurora kinase A (AURKA). AURKA can phosphorylate c-Raf to maintain new KRAS signaling, however, how AURKA becomes activated to cause KRAS G12Ci resistance is unclear. We show here that KRAS G12C + AURKA inhibition cause synthetic lethality in KRAS G12C NSCLC cells. LY3499446 (KRAS G12Ci) and LSN3321213 (aurora kinase A inhibitor) induced apoptosis that is independent of inhibited MAPK reactivation. Using high-content imaging that tracks single-cell fate during treatment, we observed that single-agent KRAS G12Ci induces G1 arrest in a sub-population of cells. Upon co-treatment with G12C + AURKAi, cells that are halted in G1 phase undergo early apoptosis, while those that initially evade G1 arrest and proceed through G2/M undergo apoptosis in subsequent G1. These data suggest the hypothesis that AURKA inhibition may increase the probability of G1 checkpoint-induced apoptosis by facilitating chromosomal misalignment and genomic instability. In summary, we provide clinical rationale for clinical testing of KRAS G12C + AURKA inhibitors. We also suggest a novel mechanism explaining the dependency of KRAS G12C resistant subpopulations on AURKA, leading to the opportunity to investigate the role of genomic instability in conferring KRAS G12Ci adaptive resistance.

Short or long-term treatment with CDK4/6 inhibitors in patients with ER+ breast cancer: characterization and comparative analysis of resistance in seventeen XPDX models

Alyssa Simonson[1], Johnnie Flores[1], Morgan Lynch[1], Emily Carpenter[1], Justine Hruzek[1], Jim Lund[1], Natalia Baños Herraiz[1], Kyriakos Papadopoulos[2], Amy Vander Woude[3], Gladys Rodriguez[2], Sreenivasa Chandana[4], Thomas Gribbin[3], Nehal Lakhani[4], Tatiana Hernandez[5], Maria Jose de Miguel[6], Amy Lang[2], Michael J. Wick[1]. *[1]XenoSTART, San Antonio, TX,[2]START Center, San Antonio, TX,[3]CHCWM, Grand Rapids, MI,[4]START*

Center, Grand Rapids, MI,[5]START Center, Barcelona, Spain,[6]START Center, Madrid, Spain

Background: Mechanisms of resistance to CDK4/6 inhibitors (CDK4/6i) have been well studied and several alterations identified including RB loss and altered expression of related genes including CCNE1, E2F4 and CDK6. However, whether duration of clinical treatment might elicit specific mechanism(s) of CDK4/6i resistance is unclear. To better understand if duration of clinical treatment correlates with unique resistance mechanisms, we established, characterized, and compared a panel of ER+ breast XPDX models from patients who benefitted then progressed on a CDK4/6i. Patients were separated into two groups by time to progression (TTP): those who responded up to twelve months (RES12) and patients with clinical response greater than one year (RES13+).
Methods: Seventeen breast cancer XPDX models were analyzed, including eight previously described (7xRES12; 1xRES13+: SABCS2021: T Hernandez et al). Nine new models were established from seven patients: six from fluid samples with three designated as ductal (ST3105B, ST3105C, STM001B) and three lobular carcinoma (STM182, STM229, STM229B); two from lymph node biopsies (ST5676, STM127) and one from a liver core biopsy (ST4887B), all reported as ductal carcinoma. STM182 was classified as RES12 and the remaining eight as RES13+. These models were passaged and challenged with CDK4/6i to confirm resistance. Receptor expression was determined by IHC and genomic analyses including WES and RNA_{seq}, were performed to identify mechanisms of resistance. For in vivo studies, CDK4/6i were dosed PO once daily at 50 mg/kg; endpoints included tumor volume (TV) and time from treatment initiation (TTI) with %T/C values and tumor regression reported at study completion; a %T/C of ≤20 versus control was considered sensitive. Tumor regression (%T/C<0) versus Day 0 TV was also reported.
Results: Clinical TTP for RES12 (n=8) was four to twelve months and RES13+ (n=9) from thirteen to forty-two months. All models retained ER expression in evaluated passages with similar histology compared with archival clinical samples. Sequencing identified several variants including RB1 truncations or deletions and increased gene expression in CCND1, CCNE1 and the PIK3CA/AKT pathway. Interestingly, 5/8 RES12 models reported ESR1 mutations or fusions versus 1/9 RES13+ and PIK3CA

mutations were reported in 1/8 RES12 versus 5/9 RES13+. Several RES13+ models also reported variants and increased amplification in the RICTOR/TORC2 pathway versus RES12.
Conclusion: We have established, characterized, and compared a panel of seventeen breast XPDX models from fourteen female patients representing early or late acquired resistance to CDK4/6i therapy and identified potential differences in each set. These models and resulting data are useful in developing novel therapies for CDK4/6i-resistant patients.

TNF-MK2 signaling drives protective autophagy following MAPK pathway inhibition in pancreatic cancer
Iftikhar Ali Khawar, Qing Wei, Timothy Hung-Po Chen, Lin Lin, Patrick M. Grierson, Kian-Huat Lim. *Washington University School of Medicine in St. Louis, St. Louis, MO*

Targeting the oncogenic KRAS-RAF-MEK-ERK (MAPK) pathway has remain unsuccessful in the clinic for patients with pancreatic ductal adenocarcinoma (PDAC), a highly lethal cancer with few effective treatment options. To identify novel, effective therapeutic strategies, we investigated the impact of MEK and ERK inhibitors on production of inflammatory cytokines in PDAC cells. We found that both MEK and ERK inhibitors dramatically upregulated production of TNF, leading to activation of multiple TNF signaling pathways which include the pro-death and pro-survival NF-kB and p38.MK2 cascades. Silencing of TNF receptor 1 (TNFR1) abrogated the pro-apoptotic effect of MAPK inhibitors, suggesting that pro-death effect driven by TNF signaling is required for the therapeutic effect of MAPK inhibitors. However, targeting the NF-kB and MK2 pathways greatly augment the suppressive effect of MAPK inhibitors. Notably, the mechanisms via which MK2 promotes PDAC cell survival are mediated through phospho-activation of Heat shock protein 27 (Hsp27) and Beclin1, a critical mediator of autophagy. Intriguingly, silencing of TNFR1 abrogated induction of proactive autophagy following MAPK inhibition, strongly suggesting autocrine signaling as the inciting event of autophagy. Mechanistically, we showed that TNF signaling upregulate unfolded protein response (UPR) in PDAC cells, which is required for autophagy induction. Targeting MK2 abrogated transcription of key UPR genes and blocks

subsequent autophagy. The combination of MK2 inhibitor ATI-450 and ERK inhibitor ulixertinib was more effective in curbing the growth of PDAC patient-derived xenograft in vivo and prolonged the survival of autochthonous PDAC mice (KPC model). Overall, our study provided novel insights on the mechanisms that drive protective autophagy following MAPK pathway inhibition and a rationale and feasible therapeutic combination that can be tested in clinical trials for PDAC patients.

#3871

KRAS G12C **mutant allele amplification drives resistance to sotorasib in vitro**

Deanna Mohn[1], Anne Y. Saiki[1], Pragathi Achanta[1], Andres Plata Stapper[2], J. Russell Lipford[1], Rati Verma[1]. *[1]Amgen Research, Amgen Inc., Thousand Oaks, CA,[2]Amgen Research, Amgen Inc., South San Francisco, CA*

Sotorasib is an approved $KRAS^{G12C}$-selective inhibitor for the treatment of *KRAS* p.G12C-mutant advanced and previously treated non-small cell lung cancers (NSCLC). Acquired resistance due to genomic alterations following sotorasib treatment has been observed in 28% of lung cancer patients (CodeBreaK100, ASCO 2022) and can include bypass signaling, inactivation of negative feedback loops, or compensatory mutations in $KRAS^{G12C}$ including amplification of *KRAS*.
Preclinical studies on the mechanisms of acquired resistance are critical for understanding these resistance patterns and can reveal new therapeutic or combination strategies in the clinic. For that reason, we developed an NCI-H358 lung cancer model of acquired resistance to $KRAS^{G12C}$ inhibition in vitro. NCI-H358 cells were continuously cultured in the presence of elevated concentrations of sotorasib (IC90) until resistance to $KRAS^{G12C}$ inhibitor was achieved. Expression analyses of the resistant cells by ddPCR and immunoblotting showed increases in both KRAS gene and protein levels, resulting in enhanced MAPK signaling. siRNA knockdown of *KRAS G12C* expression re-sensitized the resistant cells to an analog of sotorasib. Further characterization of this cell line by whole exome sequencing (WES) and fluorescence in situ hybridization (FISH) showed that resistance was not due to genetic co-alterations but amplification of the mutant allele specifically. In comparison to DMSO-treated and parental controls, the

sotorasib-resistant NCI-H358 cells contained an approximately 50-fold increase in *KRAS G12C* mutant allele copy numbers.
Preclinical data generated using a $KRAS^{G12C}$ inhibitor-resistant lung cancer cell line is consistent with clinical observations of acquired *KRAS* amplification following $KRAS^{G12C}$ inhibitor treatment as a mechanism of resistance. This model further provides an opportunity to study acquired *KRAS* amplification and investigate combination treatment options in vitro.

Targeting of YAP overcomes trastuzumab-resistance and promotes immune responses in HER2-positive cancers

Ah Rong Nam[1], Jeesun Yoon[2], Kyoung-Seok Oh[1], Jae-Min Kim[3], Ju-Hee Bang[1], Yoojin Jeong[1], Sea Young Choo[1], Hyo Jung Kim[1], Su In Lee[1], Tae-Yong Kim[1], Do-Youn Oh[2]. *[1]SNU Medicine, Cancer Research Institute, Seoul, Korea, Republic of,[2]Department of Internal Medicine, SNU Medicine, Seoul, Korea, Republic of,[3]SNU Medicine, Integrated Major in Innovative Medical Science, Seoul, Korea, Republic of*

Background: HER2 (Human epithelial growth factor receptor 2)-targeting therapies have been approved for patients with HER2-positive breast and gastric cancer and use have been attempted in various solid tumor types, including biliary tract cancer. However, resistance mechanism remains as a major challenge of HER2-targeting therapies. YAP (Yes-associated protein) is a major downstream effector of Hippo pathway, and it plays an essential role in cancer cell proliferation, survival and differentiation. Moreover, YAP is emerging as a key player of resistance mechanism of cytotoxic and targeted drugs. Yap is also an important immunosuppressive molecule as it works as a negative regulator of T cell tumor infiltration. In this study, we intend to elucidate the role of YAP in mechanism of trastuzumab resistance and T cell immune response in HER2-positive cancer cells.
Methods: We established four trastuzumab-resistant (HR) cell lines (N87HR, SNU216HR, SNU2670HR and SNU2773HR) from HER2-postive gastric and biliary tract cancer cell lines. To inhibit the function of YAP, siRNA and Verteporfin (YAP-TEAD inhibitor) were used. MTT assay, cell cycle analysis, western blot and migration assay were performed to analyze the antitumor effects through YAP downregulation. In order to

evaluate immune-modulation by YAP, human PBMC co-culture was used and immune markers were analyzed by RT-PCR and flow cytometry. Mouse xenograft models were established using SNU2773 and SNU2773HR cells. Results: We confirmed that the expressions of pYAP and YAP were elevated in HR cells (SNU216HR, SNU2670HR and SNU2773HR) compared to parental cells. Reducing the expressed YAP in HR cells inhibited tumor cell growth and migration and induced apoptosis. Immune suppression markers such as PD-L1, CD155, and galectin-9 were effectively decreased, while CD80, a stimulation marker, was increased by verteporfin treatment. Also, when YAP was decreased, CCL5 and CXCL10, well known $CD8^+$ T cell recruitment cytokines, were increased. In HR cells treated with siYAP and verteporfin, there was a trend of increasing $CD4^+$ and $CD8^+$ T cells when co-culture with PBMC. In vivo experiment data showed greater tumor growth inhibition effects with SNU2773HR than SNU2773 xenograft models when treated with verteporfin.
Conclusion: The expression of YAP is elevated in trastuzumab-resistant (HR) cells and inhibition of YAP shows anti-tumor effects and activation of T cell responses. Collectively, our data suggests that the inhibition of YAP is one of many promising strategies to overcome trastuzumab resistance and T cell regulatory mechanisms in HER2-positive cancers.

Candidate drug screening for TP53-mutated AML

Daehyeon Gwak[1], Dong Chan Kim[1], Heejun Jang[1], Jun Liu[1], Ja Min Byun[2], Junshik Hong[2], Dong Yeop Shin[2], Sung-Soo Yoon[2]. *[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of*

Acute myeloid leukemia (AML) is a clonal blood malignancy characterized by arrested maturation and abnormal proliferation of hematopoietic precursor cells. This paralysis of normal bone marrow function leads to severe decreased immune function and bleeding tendency, and if not treated, it is an acute disease that dies within a few months due to rapid progression of AML. *TP53* mutations occur in 5% to 10% of patients with de-novo acute myeloid leukemia (AML), with higher frequency in patients with relapsed/refractory AML. The treatment approach for many years has used combination chemotherapy, with usually an anthracycline and

cytarabine as the foundation. These induction therapy's complete response is achieved in 60 to 85% of adults who are 60 years of age or younger. In patients who are older than 60 years of age, complete response rates are inferior 40 to 60%. *TP53* mutated acute myeloid leukemia (AML) responds poorly to the conventional induction therapy and has a short overall survival rate with a median of 5-9 months. Poor outcomes in *TP53* mutated AML following chemotherapy have been observed and treatment options remain limited. Therefore, this study attempted to explore the drug candidates for effective treatment of *TP53* mutated AML. To study the cellular response to *TP53*-targeted therapy, we used the human AML cell line Kasumi-1, which harbors a homozygous *TP53* mutation. We treated Kasumi-1 cells with cytarabine and Idarubicin combi-treatment. And we produced Drug Tolerant Persisters (DTPs) which is a minor population of cancer cells may evade cell death from chemotherapy and targeted therapy by entering a reversible slow proliferation state. Similar to a previously described DTP phenotype the DTPs that survive cytarabine and Idarubicin combi-treatment displayed cell-cycle arrest and resistance to further cytarabine and Idarubicin combi-treatment. And we selected 125 drug candidates that would be effective for *TP53* mutated AML through in silico analysis and therapy strategies targeting p53. The drug candidates are composed of Compounds with the ability to reactivate mutant p53, Compounds directly target mutant p53, Synthetic lethal partners with mutant p53, and Compounds with the ability to anti-Leukemic Stem Cell and antineoplastic. We single out 46 of the 125 compounds for functional validation in DTPs. We chose these compounds because many of them are similar subtypes, suggesting they may have a common effect and mechanism. Using in vitro Cytotoxicity assay, we screened 46 candidate compounds at multiple doses and confirmed several drugs that effectively eliminate DTPs. Collectively, our study indicates that the combination of conventional drug and validated drug has the potential to eliminate DTPs and therefore prevent minimal residual disease, mutational drug resistance, and relapse in *TP53*-mutant AML.

#3874

Genomic mechanisms of resistance to tyrosine kinase inhibitors (TKIs) in HER2+ metastatic breast cancer (HER2+ MBC)

Heather A. Parsons[1], Conor Messer[2], Katheryn Santos[1], Brian P. Danysh[2], Melissa E. Hughes[1], Ashka Patel[1], Raquel A. Jacobs[2], Kara Slowik[2], Julian Hess[2], Chip Stewart[2], Kristy Schlueter-Kuck[2], Kahn Rhrissorrakrai[3], Filippo Utro[3], Chaya Levovitz[3], Nikhil Wagle[1], Jose Pablo Leone[1], Rachel Freedman[1], Laxmi Parida[4], Ian E. Krop[5], Gad Getz[2], Nancy U. Lin[1].
[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Broad Institute of MIT and Harvard, Cambridge, MA,[3]IBM Research, Yorktown Heights, NY,[4]IBM Research, Cambridge, NY,[5]Yale University, New Haven, CT

Background**.** Despite substantial progress in the treatment of HER2+ MBC, most patients (pts) still experience disease progression and cancer-related death. HER2-directed TKIs are highly effective therapies for pts with HER2+ MBC; however, an understanding of resistance mechanisms is needed. Pts receiving HER2-directed TKIs with cell-free DNA (cfDNA) sampling across the treatment spectrum present a unique opportunity to examine genomic alterations.
Methods. Pts with biopsy-proven HER2+ MBC were selected from DF/HCC approved protocols for ultra-low pass whole genome sequencing if ≥1 cfDNA and/or tissue sample had been collected prior to and after at least six weeks of TKI treatment. Only pts with ≥ 1 sample with tumor fraction (TFx) ≥ 9.5% and ≥ 1 additional sample with TFx ≥ 4.5% were analyzed. Whole exome sequencing (WES) was performed on 19 tumor biopsies and 64 cfDNA samples from 25 pts. WES samples were analyzed, variants called and annotated, copy number profiles inferred, and TFx estimated. *PhylogicNDT* was used to detect the phylogenetic architecture, and clones were identified as growing, stable, shrinking, or truncal; mutational signatures were called using *SignatureAnalyzer*. After filtering likely benign variants, mutations were labeled likely resistance mechanisms if there was known evidence of resistance to anti-HER2 therapy in a human breast cancer cell line, breast cancer mouse models, or in vivo. Findings were correlated with pt clinicopathologic data.
Results. In 4/8 pts with acquired resistance (TKI treatment ≥ 180 days), we identified alterations in previously characterized pathways and genes that could explain treatment resistance (e.g. *PIK3CA, ERBB2, FGFR2).* Mutations in growing subclones identified potential novel mechanisms of

resistance and included inactivating mutations in *CDK12*, *KMT2D*, *KMT2C*, *CHEK2*, *BRCA2*, and *FAT1* genes. In 7/17 pts with intrinsic resistance, we identified mutations in overlapping pathways and genes such as *ERBB2* and *PIK3CA,* which were present in both growing subclonal and truncal clones. Four pts with hormone receptor positive disease - two of whom had not received prior aromatase inhibitors - had an activating *ESR1* hotspot mutation (D538G). This raises the possibility that activating *ESR1* mutations may be involved in resistance in these cases. Mutational signature analysis revealed a subset of samples with widespread APOBEC activation (with and without hyper mutation), subclonal HR/MMR-related signature, and capecitabine-related 5FU signature.
Conclusions. Genomic analysis of paired samples from pts with HER2+ MBC identifies candidate resistance mechanisms to anti-HER2 TKIs and clonal evolution over time in the context of heterogeneity in treatment and sample timing. Additional studies will determine the functional role and clinical utility of assessing these alterations to overcome resistance.

Evaluation of resistance mechanisms to ARV471, an ER-targeted PROTAC
Delia Margaret Friel[1], Zachary Sandusky[1], Yijia Jiang[2], Xintao Qiu[2], Rong Li[2], Henry Long[1], Rinath Jeselsohn[1], Myles Brown[1]. *[1]Medical Oncology, DFCI/Harvard Medical School, Boston, MA,[2]Center for Functional Cancer Epigenetics, DFCI/Harvard Medical School, Boston, MA*

Estrogen receptor alpha (ER) is a ligand activated transcription factor and a driver of ER+ breast cancer. The discovery of activating mutations in ER (gene name ESR1), in patients with advanced endocrine-resistant ER+ breast cancer, has ignited a large pharmaceutical effort to develop next-generation ER antagonists that also target the mutant protein. Here, we profiled the potency and selectivity of many next-generation ER antagonists currently in clinical trials, including ER-targeted proteolysis-targeting chimeras (PROTACs), selective ER modulators (SERMs), and selective ER degraders (SERDs). To contextualize these antagonists, we evaluated their activity against the only FDA-approved SERD, Fulvestrant, at the level of chromatin, transcriptome, proteome, and cell viability, using cells expressing wild-type ER as well as activating mutant ER (ER^{Y537S} and

ER^{D538G}). Overall, we find that many of the novel oral SERDs are potent ER antagonists, including against mutant ER. To anticipate resistance mechanisms to these next-generation ER antagonists, we developed a strategy initially focused on ARV471 (the most clinically advanced ER PROTAC), with two approaches. First, we performed whole-genome CRISPR/Cas9-knockout screening in ER+ breast cancer cell lines treated with ARV471. Among the enriched gRNAs were PTEN, NF2, and CRBN. Loss of PTEN and NF2 results in activation of the PI3K and MAPK pathways, respectively, and CRBN is the ubiquitin E3 ligase required for ER protein degradation by ARV471. PTEN and NF2 are known mechanisms of endocrine resistance but it is not yet known if CRBN loss in response to PROTACs is a predominant clinical resistance mechanism. Therefore, in a second approach we generated ARV471 resistant breast cancer cell lines through long term exposure (LTE-ARV471). These cells developed an ER-independent resistance mechanism, with decreased ER expression and increased expression of pathways associated with Ras/MAPK and EMT. Therefore, as more potent ER degraders enter the clinic, such as PROTACs and oral SERDs, it may be important to monitor resistance mechanisms that involve loss of ER. Currently, we are following up our findings with LTE-ARV471 cells and performing CRISPR screening to identify targetable dependencies and combination therapies for endocrine resistant breast cancer.

Kinetics of RTK activation determine ERK signaling dynamics and resistance to BRAF and MEK inhibitors

Sungsoo Kim, Richard Carvajal, Minah Kim, Hee Won Yang. *Columbia University Irving Medical Center, New York, NY*

Combination treatment of BRAF inhibitor (BRAFi) and MEK inhibitor (MEKi) produces remarkable response rates and is expected to prevent ERK activation in *BRAF*-mutant melanoma. However, sporadic ERK reactivation occurs in melanoma models, and efficacy is severely limited by the emergence of drug resistance. The underlying molecular mechanisms that drive ERK reactivation and adaptation to BRAFi/MEKi remain elusive. Here, using single-cell imaging and optogenetic approaches, we show that the strength and duration of receptor tyrosine kinase (RTK) activation

determines ERK reactivation and the development of BRAFi/MEKi-resistant cells. Single-cell data reveal that despite global RTK activation by the same external stimuli, only small subsets of melanoma cells induce effective RTK and ERK activation to develop BRAFi/MEKi resistance. Furthermore, by directly controlling RTK activity, we demonstrate that the kinetics of RTK activation determine ERK signaling dynamics and the percentage of drug-resistant cells. While these drug-resistant cells are rare during early stages of drug treatment, they eventually become the dominant population through sustained RTK-mediated ERK activation that drives cell proliferation. Thus, RTK activation in established drug-resistant cells causes effective ERK activation and cell proliferation. Importantly, limiting RTK signaling activation reverses the BRAFi/MEKi-resistant state. We show that targeting SHP2, a mediator of RTK signaling, effectively suppresses RTK-mediated ERK activation and cell proliferation in BRAFi/MEKi-resistant cells. Our results provide mechanistic insights into the contribution of heterogeneity in RTK activation kinetics to ERK reactivation and BRAFi/MEKi resistance, also highlighting SHP2 activity as a promising target to overcome drug resistance in *BRAF*-mutant melanoma.

#3877

Systematic functional and phenotypic characterization of HER2 missense mutants and their impact in ER+ metastatic breast cancer

Nelson Vicente Guevara[1], Zirui Zhu[1], Esha Jain[2], Jennifer Kavran[1], Selime Arslan[1], Nikhil Wagle[2], Utthara Nayar[1]. *[1]Biochemistry and Molecular Biology, Johns Hopkins University, Baltimore, MD,[2]Broad Institute of MIT and Harvard, Cambridge, MA*

The estrogen receptor-positive (ER+) subtype accounts for 70% of breast cancer, and endocrine therapies that target ER are effective in the early-stage clinical setting. However, endocrine resistance is ubiquitous in late-stage metastatic breast cancer (MBC). The chief mechanism is the acquisition of ER mutations (ERmuts) in 25% of endocrine-resistant tumors; ERmuts are strongly resistant to aromatase inhibitor (AI) endocrine therapy. We previously identified four novel acquired activating mutations in human epidermal growth factor receptor 2 (HER2) by whole exome sequencing (WES) of paired ER+ MBC in a clinical cohort. These HER2

mutations (HER2muts) were enriched in multiple resistant tumors, and like ERmuts, were resistant to AIs. In contrast to ERmuts, these HER2muts also conferred complete resistance to all other classes of endocrine therapy, as well as cross-resistance to combination therapy with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors; the latter is standard-of-care in the refractory setting in ER+ MBC. At the same time, these HER2muts had variable responses to HER2-targeting therapies used in HER2+ breast cancer. Thus, HER2muts represent only the second validated mechanism of clinical endocrine resistance in ER+ MBC, accounting for ~8% of cases, and that is therapeutically intractable. Systematic phenotypic characterization of HER2muts in ER+ MBC is a prerequisite for effective targeting of this class of resistance. We used cBioPortal to identify >20 novel HER2 variants of unknown significance (VUS) that were frequent pan-cancer, in ER+ breast tumors, or annotated in a domain-restricted HER2 saturation mutagenesis screen, and that had not been previously characterized in ER+ MBC. We also identified a novel HER2 VUS by WES in an ER+/HER2+ tumor with resistance to HER2 therapy, from a clinical cohort of breast cancer patients. We phenotypically characterized all VUS through clinically comprehensive targeted therapy viability assays, and downstream activation assays. In sum, we identified seven novel activating HER2muts, spanning domains, with clinically important phenotypes in ER+ MBC. We found these HER2muts also conferred complete resistance to all classes of endocrine therapies, and cross-resistance to CDK4/6 inhibition. While novel HER2muts had variable responses to HER2-targeting therapies, they could be endocrine re-sensitized by combination with an irreversible tyrosine kinase inhibitor. Lastly, we report that constitutive HER2 homodimerization via reduction-sensitive disulfide bridges that occur as a consequence of mutations in the extracellular and juxtamembrane domains is a more common mechanism of HER2 hyperactivation than previously appreciated. This finding has unique functional consequences, and provides important structure-function insight into HER2 biology, beyond its immediate clinical ramifications in ER+ MBC.

Targeting Hippo-YAP, BRD4 and RAS-MAPK interplay in lung cancer to forestall drug resistance

Nilanjana Chatterjee[1], Victor Olivas[1], Wei Wu[1], Ben Powell[2], Trever Bivona[1]. *[1]UCSF - University of California San Francisco, San Francisco, CA,[2]Kinnate Biopharma, San Francisco, CA*

Introduction: Identifying parallel survival pathways or compensatory mechanisms that limit the response to targeted therapy is critical to discover effective combinatorial strategies for the treatment of lung cancer and to prevent emergence of drug resistance
Results: Using combination drug screening in a panel of cell line models of non-small cell lung cancer (NSCLC), we identified the tumor suppressor STK11 (aka LKB1) as a molecular biomarker of sensitivity to BET and RAS-MAPK pathway inhibitors combination in NSCLC. We found a small molecule inhibitor of BET (bromodomain and extra terminal) family proteins (BRD4, 3, 2), PLX51107, suppressed BRAF and KRAS mutant NSCLC cell proliferation and in combination with RAS (KRAS G12C), RAF or MEK inhibitor led to pronounced loss in cell viability with potent MYC downregulation and synergistic apoptosis induction *in vitro* and potent tumor regression or stasis *in vivo* in several KRAS mutant CDX and PDX mouse models of NSCLC. However, BRAF and KRAS mutant NSCLC cells with co-occurring mutations in STK11 were resistant to BET and RAS, RAF or MEK co-inhibition. To unravel the underlying mechanism of resistance to BET and RAS-MAPK inhibitors upon STK11 loss we modeled STK11 deficiency in BRAF and KRAS mutant NSCLC cells and tumors. We found that STK11 loss creates an unprecedented dependence on YAP/TEAD TFs. STK11 silencing in BRAF and KRAS mutant NSCLC cells resulted in nuclear transfer/ activation of the HIPPO pathway effector, YAP, upregulation of the YAP target BIRC5 (aka Survivin) and rescued the synthetic lethality due to BET and RAS, RAF or MEK co-inhibition. Phenocopying STK11 loss, constitutively active YAP (YAP5SA), but not transcriptionally inactive YAP (YAPS94A), mitigated the deleterious effects of BET and RAS, RAF or MEK co-suppression in BRAF and KRAS mutant NSCLC cells with potent upregulation of the pro-survival factor BIRC5. Conversely, we found that co-silencing YAP or TEADs with BETs re-sensitized BRAF and KRAS mutant NSCLC cells with co-occurring mutations in STK11 to BET and RAS-MAPK inhibitors combination and caused synthetic lethality.

Conclusion: This study uncovered a functional interaction between BET proteins, STK11, HIPPO-YAP and RAS-MAPK signaling pathways in lung cancer. These results will help identify combinatorial strategies for treating aberrant RAS-MAPK pathway driven lung cancer more effectively and forestall drug resistance.

#3879

SETD2 is a novel and druggable dependency in IMiD/CELMoD resistant multiple myeloma models

Sarah Anne Bird[1], Marco Licciardello[1], Yakinthi Chrisochoidou[1], James Smith[1], Amy Barber[1], Jack Cheung[1], Yura Grabovska[1], Shannon Martin[1], Fernando Sialana[1], Harvey Che[1], Habib Bouguenina[1], Benjamin Bellenie[1], Brian Walker[2], Paul Clarke[1], Charlotte Pawlyn[1]. *[1]Institute of Cancer Research, Sutton, United Kingdom,[2]Indiana University School of Medicine, Indianapolis, IN*

Immunomodulatory agents (IMiDs) and cereblon E3 ligase modulators (CELMoDs) are a cornerstone of Multiple Myeloma (MM) treatment. They bind to the cereblon (CRBN) component of the CRL4 E3 ubiquitin ligase complex and designate a new set of substrates for proteasomal degradation. Most patients initially respond well to IMiD/CELMoD therapy but over time will become resistant. Understanding resistance mechanisms will enable the development of new targeted treatment strategies to overcome this pressing clinical challenge.
Acquired IMiD/CELMoD resistant human MM cell lines were generated by treating IMiD/CELMoD sensitive MM1s and H929 cells with lenalidomide (Len), pomalidomide (Pom) or iberdomide (Iber) at ~10x GI50 concentration for ~12 weeks until resistance was achieved. Cell lines were characterized by whole exome sequencing, RNA-Seq and proteomics. All resistant lines had reduced CRBN expression and some had *CRBN* mutations, reflecting patient data.

A genome-wide loss-of-function CRISPR screen (Brunello library) was carried out in Iber-resistant MM1s. Gene effect scores were calculated with the Chronos algorithm and compared to parental MM1s using data from the Broad Institute DepMap portal. Potential new dependencies in the resistant setting (defined as gene effect score <-1 in resistant cells and >-0.5 in parental cells) were identified in 47 genes including SETD2, a histone 3 lysine 36 methyltransferase (H3K36me2 -> H3K36me3).
The specific SETD2 inhibitor EPZ-719 reduced viability to a greater extent in the IMiD/CELMoD resistant lines compared to their controls in a 14-day trypan blue exclusion assay. This was most pronounced in the Pom- and Iber-resistant H929 lines. For example in Iber-resistant H929 compared to its control line the viability with EPZ-719 was 13% vs 66% at 1μM, 5% vs 46% at 5μM and 2% vs 45% at 10μM, $p<0.0001$ (% viability compared to DMSO control at day 14).
To investigate whether this novel dependency was related to reduced CRBN expression a *CRBN* knockout MM1s cell line was generated using CRISPR/Cas9. These cells showed a markedly greater reduction in viability with EPZ-719 compared to control MM1s (viability 20% vs 32% at 1μM, 8% vs 25% at 5μM and 2% vs 18% at 10μM, $p<0.001$).
A reduction in H3K36me3 was seen on immunoblotting after EPZ-719 incubation across all cell lines suggesting an on-target effect. ChIP-Seq and RNA-Seq experiments are underway to identify downstream mechanisms.
In conclusion, SETD2 inhibition is more active in IMiD/CELMoD-resistant cell lines compared to sensitive counterparts. Rapid clinical translation of these findings would be possible as a SETD2 inhibitor is currently in a phase 1 trial which includes MM patients. Previous pre-clinical data suggests the t(4;14) MM subgroup may be more sensitive to SETD2 inhibition but our data highlights a novel vulnerability in the IMiD/CELMoD resistant setting that should be explored further.

Drug Resistance in Molecular Targeted Therapies 4 / Regulation of Gene Expression in Drug Resistance

#3882
tumor adaptations to PI3K inhibition increases and its reversibility decreases as a function of time in drug

Radha Mukherjee[1], Kiran Gireesan Vanaja[2], Malvika Sharma[1], Yangjingyi Ruan Ruan[1], Hilla Solomon[1], Elisa deStanchina[1], Sarat Chandarlapaty[1], Neal Rosen[1]. *[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Northeastern University, Boston, MA*

The PI3K pathway is a key regulator of metabolism, cell proliferation and migration and some of its components (e.g. PIK3CA, HER2 and PTEN) are frequently altered in cancer by genetic events that deregulate its output. However, inhibitors of components of the pathway have only modest antitumor effects and, in some instances, have resulted in “tumor flares” in patients upon cessation of therapy. Low efficacy has been attributed to toxicity and to adaptive resistance due to relief of feedback. Inhibition of the PI3K pathway has been associated with increased receptor expression and decreased expression of the PTEN phosphatase, a major negative regulator of the pathway. Now we show that changes in expressions of RTKs, PTEN, anti-apoptosis proteins like Mcl1, and transcription factors known to drive oncogenic and survival programs in tumors like c-Myc, c-Jun, FOXOs are induced upon continuous long-term PI3K inhibition (2 weeks and longer). These changes increase as a function of duration of inhibition and become less reversible with time in drug. Unbiased clustering of RNA seq data of cells treated with PI3K inhibitors revealed clusters of gene expression changes based upon short or long-term inhibition. Correspondingly the mRNA of the RTKs and transcription factors change with similar kinetics as that of the proteins and become less reversible with duration of inhibition. Moreover, the persister cells treated with PI3K inhibitors for 2 weeks or longer grow faster than the treatment naive cells upon drug removal both *in vitro* and *in vivo* and the degree of reversibility of the increased proliferation rate is inversely proportional to the duration of inhibition. Persister cells treated with PI3K inhibitors for more than two weeks have higher levels of expression of a oncogenic transcription factors, RTKs, Mcl1, and of pAKT after one week of drug wash-out and are less sensitive to re-inhibition of PI3K. However, combined and staggered inhibition of PI3K with Mcl1/Bcl2 inhibitors lead to greater reduction of cell survival and increased cell death selectively in the models that upregulate Mcl1 in response to PI3K inhibitors. The data suggests that induction of adaptive resistance is in part responsible for the continued persistence of tumor masses after the initial response to targeted therapy but

also selectively sensitizes them towards Mcl1/Bcl2 inhibitors due to the upregulation of an anti-apoptotic program. Therefore, pulsatile targeted inhibition of PI3K in combination with anti-apoptotic BH3 domain protein inhibitors in a subset of breast cancer patients may provide a wide therapeutic window and can circumvent chronic adaptation induced resistance and drive potent cell death thereby improving therapeutic outcomes.

Overcoming tamoxifen resistance by re-activating cAMP-Ca^{2+}-ROS-ferroptosis axis in ER+ breast cancer

Rashedul Alam[1], Ozge Saatci[1], Meral Bugadyci Uner[2], Kim-Tuyen Huynh-Dam[3], Metin Cetin[1], Mustafa Emre Gedik[1], Nevin Belder[4], Hilal Bal[4], Unal Metin Tokat[4], Elisabetta Marangoni[5], Sercan Aksoy[6], Aysegul Uner[6], Aytekin Akyol[6], Ozgur Sahin[7]. *[1]The Medical University of South Carolina (MUSC), Charleston, SC,[2]Department of Pathology, Hacettepe University Medical Faculty, Ankara, Turkey,[3]Department of Drug Discovery and Biomedical Sciences, University of South Carolina, Columbia, SC,[4]Department of Molecular Biology and Genetics, Bilkent University, Ankara, Turkey,[5]Translational Research Department, Institut Curie, PSL Research University, Paris, France,[6]Department of Medical Oncology, Hacettepe University Cancer Institute, Ankara, Turkey,[7]Department of Biochemistry and Molecular Biology, The Medical University of South Carolina (MUSC), Charleston, SC*

Estrogen receptor (ER) positive breast cancer accounts for about 75% of all breast cancer cases. Tamoxifen has been the mainstay therapy for over 40 years that is used to treat early, locally advanced, and metastatic ER-positive breast cancers. Despite the initial clinical success, approximately 20-30% of high-risk, advanced ER-positive breast cancer patients are resistant to tamoxifen or develop resistance over time which significantly decreases survival. Long-noncoding RNAs (lncRNAs) are a class of non-coding RNAs that are more than 200 nucleotides in length and are involved in tumorigenesis via carrying out diverse functions by interacting with DNA, RNA or proteins. Here, we identified a lncRNA (LINC00152) that is upregulated in tamoxifen resistant (TamR) cell lines by RNA sequencing,

and we validated its upregulation in endocrine resistant, ER-positive patient-derived xenografts (PDXs) as well as in tamoxifen-treated ER-positive breast cancer patient tumors. We performed in-situ hybridization of the LINC00152 in our own cohort of tamoxifen-treated ER+ breast cancer patients and demonstrated a significant association of high LINC00152 expression with worse disease-free survival and treatment response. Inhibiting LINC00152 using either siRNAs or anti-sense oligonucleotides or shRNAs restored tamoxifen sensitivity in TamR cells. Mechanistically, we demonstrated that LINC00152 knockdown in combination with tamoxifen increases the expression of TRPC1, a calcium channel located on the plasma membrane, and thereby causes the cytoplasmic accumulation of excessive amounts of Ca^{2+}, which ultimately leads to the generation of reactive oxygen species (ROS), lipid peroxidation and cell death by ferroptosis. Notably, we identified a cyclic AMP (cAMP)-specific phosphodiesterase, PDE4D as a novel interactor of LINC00152. We showed that PDE4D mRNA is stabilized by LINC00152 and reduces cAMP levels which then decreases the intracellular Ca^{2+} and blocks ROS generation, lipid peroxidation, and ferroptosis, ultimately leading to tamoxifen resistance. Therefore, targeting the LINC00152-PDE4D-cAMP-Ca^{2+} axis may represent a promising therapeutic approach to tackle tamoxifen resistance and improve clinical outcome in refractory ER-positive breast cancer.

Targeting the ARID1A mutations overcomes primary resistance to ALK inhibitors in EML4-ALK posistive NSCLC

Seung Yeon Oh, You Won Lee, Eun Ji Lee, Ju Young Kim, Sewon Park, Ju Yeon Park, Su-Jin Choi, Mi Ra Yu, Jii Bum Lee, Jiyun Lee, Chang Gon Kim, Sun Min Lim, Min Hee Hong, Mi Ran Yun, Byoung Chul Cho. *Yonsei University College of Medicine, Seoul, Korea, Republic of*

Introducti**on:** Anaplastic lymphoma kinase (ALK)-tyrosine kinase inhibitors (TKIs) have improved an initial clinical response of non-small-cell lung cancer (NSCLC) patients with ALK-rearrangements. However, a subset of patients shows a poor response to ALK-TKIs. Here, we aimed to identify novel mechanism of primary resistance in preclinical model from a

patient who presented an impressive resistance to sequential treatment with ALK TKIs.

Experimental design: The PDC YU-1076 cells were established from pleural effusion of the patient at the time he was receiving chemotherapy and radiotherapy after failure of ALK-TKI treatment. Sanger sequencing confirmed ML4-ALK variant 1 detected at the initial diagnosis. No resistance mutations in the ALK kinase domain were detected. To investigate co-occurring genetic alterations, we performed whole exome sequencing (WES) on YU-1076 cells and the matched blood sample. We further investigated the molecular profile of YU-1076 cells using RNA-sequencing analysis.

Results: YU-1076 cells exhibited cross-resistance to clinically available ALK-TKIs including crizotinib, ceritinib, alectinib, and lorlatinib. However, immunoblot analysis of YU-1076 cells treated with incremental doses of TKIs unexpectedly revealed an effective reduction of ALK activity and downstream signals. We noticed that YU-1076 cells gradually changed from a small, round shape to a fibroblast-like shape following the treatment of ALK-TKIs. Transcriptome analysis confirmed enrichment for gene signatures related epithelial-to-mesenchymal transition (EMT) in ALK TKI-treated YU-1076 cells, suggesting that ALK-TKIs treatment promotes YU-1076 cells toward a more mesenchymal phenotype. WES analysis identified a major chromatin remodeling complex subunit, AT-rich interacting domain 1A (ARID1A), as well as MYC amplification, CDKN2A loss, and TP53 mutations. We focused on a synthetic lethal strategies using the SFK inhibitor dasatinib and the EZH2 inhibitor GSK126 in ARID1A mutant cancers. The combination of dasatinib with ALK-TKIs restored the sensitivity to the ALK TKIs in YU-1076 cells, accompanied by suppression of EMT marker genes VIM and CDH2 and increase of apoptotic markers BIM, PARP, and CAS3. Congruently, dasatinib significantly impaired tumor growth in YU-1076-xenografts. GSK126 also induced synergistic inhibition of cell growth with upregulation of apoptosis marker genes in YU-1076 cells, but did not affect the expression of EMT marker genes.

Conclusion: Our data indicate that ARID1A could be potentially used as a predictive biomarker for unfavorable ALK-TKI response. In this context, a combination strategy of ALK TKI with dasatinib may be effective in overcoming primary resistance.

A secondary Gαq mutation confers resistance to Gαq inhibitors in uveal melanoma

Jiafang Ma[1], Meng Wang[1], Aashish Manglik[2], Boris C. Bastian[1], Xu Chen[1].
[1]Department of Dermatology, UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[2]UCSF School of Pharmacy, San Francisco, CA

Uveal melanoma (UM) is a rare subtype of melanoma that originates from melanocytes of the choroidal plexus, ciliary body and iris. Despite successful treatment of the primary by radiation or surgery, 50% of UM patients develop metastases, mostly in the liver, as an invariably lethal complication. Over 90% of UM harbor activating mutations in the closely related GNAQ or GNA11 genes, mainly at codons Q209, compromising the GTPase activity. Mutant GNAQ and GNA11 can be successfully targeted by the cyclic depsipeptide YM-254890. To anticipate mechanisms of resistance that might arise under treatment with this novel class of Gαq inhibitors, we generated UM cell lines resistant to YM-254890 using an in-vitro cell culture system. Upon chronic growth suppression of a $GNA11^{Q209L}$ mutant UM cell line, we established 12 YM-254890 resistance clones. We identified a secondary $GNA11^{F75Y}$ mutation in one clone and $GNA11^{Y192H}$ mutations in the other 11 clones. The secondary mutations were present *in cis* with the original $GNA11^{Q209L}$ mutations. To validate the functional role of these secondary mutations in conveying resistance, we engineered two double mutants, $GNA11^{Q209L/F75Y}$ and $GNA11^{Q209L/Y192H}$, and introduced them into 293FT cells respectively and confirmed that both F75Y and Y192H convey resistance to YM-254890 treatment. The proliferation of YM-254890-resistant cell lines was still dependent on GNA11 and downstream PKC/MAPK signaling. Combined inhibition of PKC and MEK synergistically reduced cell viability in YM-254890 resistant UM cells. Analysis of the crystal structure of YM-2548890 in complex with GNAQ predicts both F75Y and Y192H mutations directly affect the binding of YM-254890 to Gαq. Our data suggest that direct targeting mutant GNAQ/11 is promising but will select for secondary mutations within GNAQ /11 that will result in resistance. Combinatorial

targeting of other components in the Gαq signaling pathway will increase clinical efficacy.

Analysis of concomitant genetic alterations in advanced EGFR-mutated lung adenocarcinoma by targeted NGS : A multicenter prospective and real world study

In Ae Kim[1], Seung Joon Kim[2], Sung Yong Lee[3], Chang Min Choi[4], Jae Cheol Lee[5], Tae Won Jang[6], Seung Hun Jang[7], Chan Kwon Park[8], Wan Seop Kim[9], Jae Young Hur[9], Hee Joung Kim[10], Young Whan Kim[1], Key Young Lee[11]. *[1]Precision Medicine Lung Cancer Center, Konkuk Universtity Medical Center, Seoul, Korea, Republic of,[2]Division of Pulmonology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[3]Department of Internal Medicine, Korea University Guro Hospital, Seoul, Seoul, Korea, Republic of,[4]Department of Pulmonology and Critical Care Medicine & Oncology, Asan Medical Center, University of Ulsan, College of Medicine, Seoul, Korea, Republic of,[5]Department of Oncology, Asan Medical Center, University of Ulsan, College of Medicine, Seoul, Korea, Republic of,[6]Pulmonary division, Dept of Internal Medicine, Kosin University Gospel Hospital, Seoul, Korea, Republic of,[7]Division of Pulmonary, Allergy, and Critical Care Medicine, Department of Medicine, Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Seoul, Korea, Republic of,[8]Precision Medicine Lung Cancer Center, Yeouido St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[9]Department of Pathology, Konkuk Universtity Medical Center, Seoul, Korea, Republic of,[10]Precision Medicine Lung Cancer Center,3Department of Pulmonary Medicine, Konkuk Universtity Medical Center, Seoul, Korea, Republic of,[11]Precision Medicine Lung Cancer Center,Department of Pulmonary medicine, Konkuk Universtity Medical Center, Seoul, Korea, Republic of*

Background**:**The response of 1st-line EGFR-TKI treatment in advanced EGFR-mutated lung adenocarcinoma patients are highly effective, but its sustainability and clinical course are quite variable from patient to patient. In this study, we investigated the clinical impact of concomitant genetic

mutations analyzed by targeted NGS on PFS and acquired resistance in advanced EGFR-mutated lung adenocarcinoma patients.
Methods: Eighty-five advanced NSCLC patients harboring *EGFR* mutations were enrolled prospectively in multi-centers from 2019 to 2022 (NCT04122833). We performed the targeted next generation sequencing on 324 cancer-related genes by Foundation One CDx with pre-treated tumor samples. First- or second-generation *EGFR*-TKIs(gefitinib, afatinib, or erlotinib) were administered in 1st-line setting. After the progression, tissue re-biopsy or plasma liquid biopsy (FoundationOne Liquid CDx) for NGS if tissue biopsy is difficult or risk was performed.
Results: Of the 85 patients (70.6% of female, 65.8% of nonsmoker, 56.4% of E19del and 38.8% of E21 L858R mutation), 50 patients experienced a disease progression in November, 2022. The median PFS was 20 months (95 %CI: 15.2-24.8). The most frequent co-mutations were *TP53* (47.1%), *CDKN2A/B* loss (34.1%), *MTAP* loss (20%), *NKX2-1amp(15.3%), MDM2amp (14.1%), RMB10, CCNE/CCND1 amp, NFKB1 amp (11.8%)* and *CDK4/6* amp (10.6%). Patients with *TP53, CDK4/6* amp and *MYC* amp were independently associated with shorter PFS. In a multivariate analysis, tumors with copy number alterations such as *CDK4/6* amp or Myc amp were also independently associated with shorter PFS. However, the CDKN2A/2B loss, MTAP loss, and MDM amp were not related with the PFS. In the number of co-mutations, patients harboring ≥5 co-mutations identified by NGS had shorter median PFS than patients with 0-1 or 2-4 co-mutations. (mPFS 0-1 : 2-4: ≥5 co-mutations=35: 18 : 9.3 months, $p<0.001$). At progression, 22 patients harbored an acquired T790M mutation (25.8%). Before TKI treatment, patients with *CDKN2A/B* loss, *MTP* loss or *CCND/CCNE1* amp in pretreatment tumor have more acquired T790M mutation after progression significantly ($p<0.05$)
Conclusion: We have demonstrated that concomitant mutations detected by targeted NGS analysis provide significant impact on the drug response and clinical course of advanced EGFR-mutated adenocarcinoma patients treated by 1st-line EGFR-TKIs. It is suggested that targeted NGS along with PCR-based detection will be necessary for precision medicine-based individualized practice of 1st-line EGFR-TKI-based combination treatment.

Raut[12], Adrian Marino-Enriquez[3], Suzanne George[13], Daniel Rauh[2], Jonathan A. Fletcher[3], Sebastian Bauer[1]. *[1]Internal Medicine (Tumor Research), Essen University Hospital, Essen, Germany,[2]Chemistry and Chemical Biology, Technical University Dortmund, Dortmund, Germany,[3]Pathology, Brigham and Women's Hospital, Boston, MA,[4]Hematology/Oncology, Fox Chase Cancer Center, Temple Health System, Philadelphia, PA,[5]Medical Oncology, Essen University Hospital, Essen, Germany,[6]Medical Oncology, Centre Leon Berard, Lyon, France,[7]Portland VA Health Care System and OHSU Knight Cancer Institute, Portland, OR,[8]Sarcoma Translational Research Laboratory, Vall d'Hebron Institute of Oncology, Barcelona, Spain,[9]Institute of Pathology, Essen University Hospital, Essen, Germany,[10]Compound Management and Screening Center, Max Planck Institute of Molecular Physiology, Dortmund, Germany,[11]Visceral and Transplantation Surgery, University of Duisburg-Essen Medical School, Essen, Germany,[12]Surgery, Brigham and Women's Hospital, Boston, MA,[13]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Introduction: Ripretinib (Rip) is a kinase inhibitor with broad preclinical activity against mutant KIT. Based on the INVICTUS trial, Rip was approved for patients with Gastrointestinal Stromal Tumors (GIST) after treatment with 3 or more kinase inhibitors. Most patients in this ≥4th-line setting progress on Rip within one year. Here, we characterized Rip-progressing GIST samples to identify resistance mechanisms.
Methods: Progressing lesions in 25 patients were analyzed by NGS after Rip failure. KIT mutations (muts) were recapitulated by gene editing. Activities of Rip, sunitinib (SU), and novel TKIs were characterized by cell

viability assays and immunoblot. Mutagenesis experiments were performed using ENU. SU- and Rip-resistant cell lines were pooled and treated with various regimens, with clonal composition deconvoluted by cDNA-based amplicon sequencing.
Results: 19/25 Rip-progressing GISTs displayed muts in the ATP-binding pocket (ATP-BP; e13/14). Four of these had pre-existing muts in the activation loop (AL; e17/18), which were confirmed to be in-cis with the primary and ATP-BP muts (triple in cis; TIC). Mutagenesis screens using a double KIT-mutant GIST line (e11 + AL) as a starting point confirmed that TIC-muts are a predominant escape mechanism when treated with Rip. A GIST subline (T1-triple) with TIC-muts in e11, e18 (A829P), and e13 (V654A) was highly resistant to Rip (GR50 > 2μM). Structural analyses of ATP-BP muts suggest steric interference and loss of van der Waals interactions that impede Rip binding and thereby confer Rip resistance. Another 3/25 Rip-progressing GISTs harbored pathogenic *KIT* muts in e9 only. A novel GIST cell line with primary *KIT* e9 mut (T1-e9) was 14-fold less sensitive to Rip than isogenic e11-driven cells (GR50 = 115 vs 8nM). Notably, adding a typical AL mut to T1-e9 (T1-e9-N822K) sensitized the cells to Rip (GR50 = 20nM). Immunoblots showed >95% inhibition of phospho-KIT in AL-mutant cell lines at Rip 100nM, whereas inhibition was weaker in T1-e9 (77%) and T1-V654A (46%), and absent in T1-triple. A compound screen of FDA-approved kinase inhibitors identified Nintedanib (NIN) as the most active compound against T1-triple. Clonal outgrowth assays of mixed cultures revealed SU (93% inhibition), and a weekly switch between Rip and either SU (96%) or NIN (79%) as the most effective inhibitors of pooled cell growth.
Conclusions: *KIT* e9 primary muts and e13/14 (ATP-BP) secondary muts are enriched in post-progression biopsies following Rip treatment. *KIT* TIC-muts are novel frequent events driving GIST clinical progression and confer a high degree of resistance. Strategies to overcome resistance may include combinations or sequences of approved drugs, and novel drugs that more efficiently inhibit TIC-mutant KIT.

N-glycosylation-defective IL6 activates the SRC-YAP-SOX2 signaling to potentiate metastasis and TKI resistance in NSCLC

Chun Hua Hung[1], Shang-Yin Wu Wu[1], Hsuan-Heng Yeh Yeh[2], Chien-Chung Lin[3], Wu-Chou Su[1]. *[1]Department of Oncology, National Cheng Kung Univ. Medical College, Tainan, Taiwan,[2]Center of Applied Nanomedicine, National Cheng Kung University, Tainan, Taiwan,[3]Department of Internal Medicine, National Cheng Kung Univ. Medical College, Tainan, Taiwan*

The IL6-GP130-STAT3 signaling pathway facilitates lung cancer progression and resistance to tyrosine kinase inhibitors. Although glycosylation alters the stability of GP130 receptor, its effect on the ligand IL6 remains unclear. In this study, we found that N-glycosylated IL6 primarily triggers JAK-STAT3 signaling and prolongs STAT3 phosphorylation, whereas N-glycosylation-defective IL6 (DeNG-IL6) induces shortened STAT3 activation and changes the downstream signaling preference for the SRC-YAP-SOX2 axis. This signaling shift promoted epithelial plasticity *in vitro* and metastasis *in vivo*, which were suppressed by specific inhibitors and shRNAs targeting SRC, YAP, and SOX2. EGFR TKI-resistant lung cancer cells secrete high levels of DeNG-IL6 via reduced N-glycosyltransferase gene expression and showed SRC-YAP activation. DeNG-IL6 contributes to drug resistance, as confirmed by *in silico* analysis of cellular and clinical transcriptomes, and signal expression in patient specimens. In summary, cell behaviors can be altered by modifying the N-glycosylation of IL6, and the glycosylation status of circulating IL6 might be a promising biomarker for monitoring the dynamics of lung cancer evolution.

The role of CXCL1 in crosstalk between breast cancer cells with ESR1 mutations and lymphatic endothelial cells

Daniel Galke, Kideok Jin. *Albany College of Pharmacy & Health Sciences, Albany, NY*

Various endocrine therapies have been developed such as selective estrogen receptor modulation (SERM), selective estrogen receptor downregulator (SERD) and ligand deprivation using aromatase inhibitors (AI). Tamoxifen, fulvestrant, and AIs are the most used adjuvant treatment for pre- and postmenopausal women with early-stage estrogen receptor positive breast

cancer. Tamoxifen and AIs have widespread anti-neoplastic and chemopreventive effects, yet despite this, many breast cancers that are initially receptive ultimately become resistant and recur. There are many known underlying molecular processes that result in resistance, but no overarching pattern has yet been identified. Our previous research demonstrates that the crucial molecular and cellular players secreted from a crosstalk between stromal cells and breast cancer cells can control the development of the tumor and the metastatic process in breast cancer. Breast cancer metastasis involves lymphatic dissemination in addition to hematogenous spreading. Although stromal lymphatic vessels (LVs) serve as initial metastatic routes, roles of organ-residing LVs are underinvestigated. In this report, we demonstrated that crosstalk between ESR1 mutant cells (Y537S and D538G), and lymphatic endothelial cells (LECs), a component of lymphatic vessels, promoted ESR mutant cell growth and migration. To identify a critical secreted factor in this crosstalk, we performed the cytokine array in secretome of crosstalk between ESR1 mutant cells and LECs, and found that CXCL1 is highly secreted from LECs. Knockdown of CXCR2 in ESR1 mutant cells attenuated ESR1 cell migration in the conditioned media of LECs crosstalked with ESR1 mutant cells. To investigate a potential impact given the current clinical landscape of endocrine resistant breast cancer with ESR1 mutations, we performed a cell viability assay and migration assay using reparixin, CXCR1/2 inhibitor in co-culture with ESR1 mutant cells and LECs. Significantly, reparixin decreased ESR1 mutant cell viability and migration compared to vehicle. We found that the combination treatment of reparixin and Palbociclib and ribociclib significantly inhibited ESR1 mutant cell growth and migration compared the single treatment. These findings implicate CXCL1-CXCR1/2 signaling as a critical event in the growth of breast cancer with ESR1 mutation and metastasis. Therefore, we have provided evidence that supports the hypothesis that functional inhibition of the CXCL1 and CDK4/6 signaling pathway has the potential to circumvent endocrine resistant tumor growth and metastasis.

TMPRSS2 serin protease is a novel biomarker for ER+ breast cancer patient prognosis and survival and mediates resistance to anti-estrogen treatment in ER+ breast cancer

Rumeysa Ozyurt, Nermin Kahraman, Pinar Atalay Dundar, Bulent Ozpolat.
Nanomedicine, Houston Methodist Research Institute, Houston, TX

Breast cancer (BC) is the most commonly diagnosed cancer in women and the second leading cause of cancer related deaths in the US. About 70-80% of patients have ER+ BC and initially respond to anti-estrogen (ie, Tamoxifen) or endocrine/homonal treatments. However, about 60% of the patients inevitably develops resistance to anti-estrogen therapies (due to intrinsic (15-20%) and acquire resistance (30-40%), representing a major clinical problem, resulting in relapses and metastasis, leading to significant patient mortality. Therefore, understanding the underlying mechanisms causing resitance to hormonal or anti-estrogen treatments is needed the for developing highly effective threapies and improving patient survival. Cell surface proteases, including serine proteases, are proteolytic modifiers of particular targets, including growth factors and protease-activated receptors, which are critical for the activation of oncogenic signaling pathways. TMPRSS2, a member of type II transmembrane serine protease (TTSP) family, has been shown to be highly expressed in prostate cancer cells and its role in carcinogenesis. We found that TMPRSS2 is highly upregulated well established tamoxifene resistant cell lines derivative of MCF7 (LCC2 and LCC9) compared to MCF7 cells. Performing Kaplan-Meier survival analyses in TCGA-BC database we also found that TMPRSS2 expression is associated with poor prognosis and significantly shorter patient survival in ER+ BC patients ($p=0.015$, $n=221$ patients). In addition, we found that TMPRSS2 is regulated by Estrogen/ Estrogen Receptor-alpha (ERα) signaling as in vitro inhibition of estrogen/ ERα signaling by ERα siRNA, tamoxifen or faslodex reduced TMPRSS2 protein expression ER+ MCF7 BC cells. Moreover, we found that inhibition of TMPRSS2 by 3 different siRNA molecules suppressed cell proliferation of MCF7 cells and reduced expression critical proteins for cell cycle and proliferation, including cyclin D1, c-Myc and pERK/MAPK signaling, suggesting that TMPRSS2 promotes the oncogenic signaling pathways in ER+ BC cells. Currently, we are targeting TMPRSS2 in in vitro and in vivo Tamox-resistant LCC2 and LCC9 models in mice by siRNA alone and in combination with Tamoxifen or faslodex to demostrate inhibition of TMPRSS2 sensitize tumors to anti-estrogen treatments. In conclusion, TMPRSS2 is a potential biomarker for poor patient survival and anti-estrogen resistance, and targeting TMPRSS2

alone as a monothreapy and in combination with anti- Tamoxifen or faslodex may be a promising approach for overcoming resistance to estrogen thereapies in ER+ BC patients.

Epigenetic rewiring promotes antiandrogen resistance and metastasis via heterogenous oncogenic drivers in prostate cancer

Xiaoling Li, Su Deng, Julisa Gonzalez, Carla Rodriguez Tirado, Choushi Wang, Nickolas A. Johnson, Lauren Metang, Ping Mu. *Molecular Biology, UT Southwestern Medical Center, Dallas, TX*

Prostate cancer (PCa) is the most diagnosed cancer among American men, which has traditionally been treated through hormone therapy. However, after hormone therapy many patients with PCa still develop a more aggressive stage of PCa, called metastasis castration resistant prostate cancer (mCRPC). The second- generation antiandrogens, such as enzalutamide or apalutamide, are used to competitively inhibit the androgen receptor (AR) signaling and achieved great clinical success. However, most of the mCRPC patients would develop resistance to the targeted therapy drugs within 6 months to 2 years after initial administration. Consequently, understanding the molecular mechanism of antiandrogen resistance, has become a critical endeavor to provide a greater benefit to patients. mCRPC is characterized by extensive heterogeneity of genomic copy number alterations, which may lead to antiandrogen resistance. TP53 and RB1 alterations have been reported to be dramatically enriched in mCRPC neuroendocrine cancer and we have previously found that inactivation of both TP53 and RB1 confers resistance to antiandrogen through lineage plasticity, where cancer cells can transdifferentiate from a luminal lineage to a mixture of basal and neuroendocrine lineages, which is no longer dependent on AR signaling. Despite these exciting discoveries, only 10% of patients have TP53 and RB1 loss and it is estimated that approximately 40% of patients develop antiandrogen resistance through an undiscovered mechanism.To identify more genomic alterations which confer antiandrogen resistance, we performed an *in vivo* library screening and identified some of the frequently depleted genes as top candidates mediating antiandrogen response, including the chromatin helicase DNA-binding factor (CHD1). Strikingly, the loss of CHD1 establishes an altered

chromatin landscape and enables the activation of heterogenous resistant subclones to emerge, including clones with ectopic NR3C1/GR, POU3F2/BRN2, TBX2, and NR2F1. This work provided an innovative model to explain the dramatically increased tumor heterogeneity in therapy resistant prostate cancer and suggested potential druggable targets to overcome resistance. Building on those exciting results, we are now examining the underlying mechanism how the epigenetic rewiring in resistant tumor clones confer resistance and monitoring the evolution of those heterogenous resistant subclones. Furthermore, we are revealing the collaborative function of those four resistant driver genes in promoting metastasis to various distal organs through multidisplinary approaches including single cell transcriptomics and 3D organoid modeling. The completion of this study will not only add clarity to the mechanism of antiandrogen resistance but may also lead to the development of novel biomarker and therapeutic approaches to overcome resistance.

EZH2 mediated kinome reprogramming drives AR phosphorylation and activation in receptor tyrosine kinase inhibitors resistant renal carcinoma models

Christopher Rupert[1], Stephanie Metcalf[2], Saranya Rajendran[2], Sean Colligan[1], Peter Hollenhorst[2], Roberto Pili[3]. *[1]University at Buffalo, Buffalo, NY,[2]Indiana University, Bloomington, IN,[3]Medicine, University at Buffalo, Buffalo, NY*

Systemic treatment of recurrent/metastatic renal cell carcinoma (RCC) largely uses receptor tyrosine kinase inhibitors (RTKI), as single agents or in combination with immune checkpoint inhibitors. Unfortunately, patients commonly develop resistance to RTKI's, leaving few options for further treatment. Therefore, understanding the mechanisms responsible for drug resistance is critical to improve the clinical outcome in this disease. Our previous studies of acquired resistance to the RTKI sunitinib identified two major regulators, EZH2 and androgen receptor (AR). Inhibition of EZH2 or AR in combination with sunitinib re-sensitizes cells to sunitinib both *in vitro* and *in vivo*. To further explore the link between EZH2 and AR in drug resistance, 786-0 RCC cells with acquired resistance to sunitinib (786-0^{RS}) was compared to drug naive 786-0 cells with exogenous AR (786-0^{AR}).

Chromatin immunoprecipitation sequencing (ChIP-seq) showed that AR and EZH2 bind the same genomic locations, but only in the resistant strain. Interestingly, treatment of 786-0^{AR} cells with sunitinib caused AR to translocate to the nucleus observed by the presence of AR at EZH2 bound sites. Additionally, mass spec of AR purified from 786-0^{RS} cells and 786-0^{AR} cells found high phosphorylation of S81 and S213, two markers associated with ligand independent activation, in 786-0^{RS} cells, but not in 786-0^{AR} cells. Previously, our lab has reported that 786-0^{RS} cells display a reprogramming of the tyrosine kinome which is dependent on EZH2 likely *via* a non-canonical mechanism. Consistent with this, EZH2 with a phosphomimetic mutation in Serine 21 (S21D) could promote sunitinib resistance when over-expressed with AR, whereas wild-type and phosphonull (S21A) EZH2 could not. We have also expanded the serine/threonine phosphoproteomic analysis and found extensive rewiring of these signaling networks in 786-0^{RS} cells with an enrichment of EGFR mediated MAPK and AKT signaling when compared to 786-0 cells. Finally, our lab has generated 786-0 strains resistant to other RTKI including pazopanib and lenvatinib, and found that AR is expressed in these resistant models, solidifying AR activation as a conserved feature of RTKI resistance. Overall, our results suggest that AR activation is driven by phosphorylation induced by EZH2 dependent kinome reprogramming. Untangling the cross talk between AR and EZH2 in RTKI resistant RCC will provide the rationale for novel therapeutic strategies to improve the clinical outcome in patients with this disease.

#3893
KRAS G12C colon cancer resistance to vertical MAPK inhibition converges on FOS-JUN signaling through orthogonal mechanisms
Mohamad Karim Koleilat, Lawrence Kwong. *UT MD Anderson Cancer Center, Houston, TX*

KRAS G12C mutations in cancer can be targeted by G12C-specific inhibitors, but resistance develops rapidly. Preclinical studies suggested multiple drug combinations to improve efficacy, including CDK4/6, MEK, ERK, EGFR, and SHP2 inhibitors, collectively called vertical MAPK inhibition (“vMAPKi”). To identify mechanisms of resistance to vMAPKi, we treated the G12C-mutant colon cancer cell line SW837 with different

vMAPKi triple combinations incorporating G12C, MEK, ERK, EGFR, SHP2, and/or S6K1 inhibitors until resistance developed. Notably, we identified two modes of resistance: fast growing colonies and slow growing or quiescent persisters. Unlike other fast growing resistant models that have pre-existing resistance mutations (e.g. EGFR-T790M for EGFR inhibitors), we did not identify any obvious resistance mutations by targeted exome sequencing in 6 separate colonies, each derived from a different vMAPKi combination. Instead, Reverse-Phase Protein Array revealed robust JNK pathway activation across all colonies, regardless of initial drug combination. Indeed, all colonies showed cross-resistance to all vMAPKi combinations, and sequence analysis revealed shared non-oncogenic mutations across colonies, suggesting that they pre-existed in the parental population. These data suggest that such pre-existing clones are fated for dominance, regardless of the vMAPKi combination used – implying that vertical pathway inhibition has intrinsic limitations. However, all colonies also gained exquisite sensitivity to single-agent JNK inhibition ("JNKi") compared to parental controls (with identical results in a second cell line, SW480), suggesting a gained vulnerability. Indeed, brief high-dose JNKi treatment completely eliminated colonies, as they did not grow back when JNKi was switched back to vMAPKi. By contrast, JNKi had no effect on quiescent persisters. To understand the differences between colonies and persisters, we conducted RNA-seq on the isolated populations. Although persisters showed no evidence of upstream JNK activation, they showed high expression of FOS, FOSB, and FOSL1, the binding partners of JUN. Indeed, expression of any FOS paralog was sufficient to confer vMAPKi resistance. Thus, both colonies and persisters converge on FOS-JUN signaling, one through upstream JNK activation and the other through transcriptional upregulation of FOS family members. Interestingly, pre-treatment of parental SW837 with high-dose JNKi has no effect on later resistance development, contrasted to the elimination of colonies if JNKi is given after resistance developed. This implies that colonies must undergo a reprogramming step to gain sensitivity to JNKi. We are currently conducting longitudinal single cell and barcoding sequencing assays to understand how such reprogramming occurs and whether this can reveal earlier therapeutic vulnerabilities.

The role of ELF3 in acquired resistance to endocrine therapy in ER-positive breast cancer

Na Zhang[1], Rongbin Zheng[2], Myles Brown[1]. *[1]Dana-Farber Cancer Institute, Brookline, MA,[2]Boston Children's Hospital, Boston, MA*

Endocrine therapies targeting the estrogen receptor (ER) are the major treatments of ER+ breast cancer, however acquired resistance to endocrine therapy is almost unavoidable and is the main cause of death with breast cancer. The only FDA-approved selective estrogen receptor degrader (SERD) fulvestrant has been used in the second line treatment to overcome aromatase inhibitor- or tamoxifen-resistance. However, fulvestrant has poor pharmacokinetic properties, which has inspired the development of a new generation of oral SERDs including amcenestrant and giredestrant. To understand the mechanisms of acquired resistance to SERDs in ER+ breast cancer, we established ER+ breast cancer cell lines (MCF7 and T47D) resistant to fulvestrant, amcenestrant or giredestrant. We found that all of our MCF7 and T47D SERD-resistant cell lines showed cross-resistance to each of the three SERDs. We then performed multiple genome-wide profiling assays including CRISPR-KO screen, whole exome sequencing (WES), RNA-seq, ATAC-seq and H3K27ac ChIP-seq on the parental and SERD resistant cell lines. Our findings from the CRISPR-KO screens suggest that ETS transcription factor ELF3 is a potential driver of resistance to SERDs. ELF3 expression is negatively regulated by estrogen signaling. Cells that developed acquired resistance to different SERDs consistently show depletion of ER expression but also a dramatic increase of ELF3 expression, while knockdown of ELF3 in the resistant cells leads to cell growth inhibition, suggesting that ELF3 can drive cell survival in the SERD resistant cells. When comparing the open chromatin regions and active enhancer regions between SERD resistant and parental cells via ATAC-seq and H3K27ac ChIP-seq respectively, ELF3 DNA binding motif was found significantly enriched in SERD resistant cells versus parental cells further indicating that ELF3 may play an important role in the SERD resistant cells. ELF3 ChIP-seq was also performed to identify genes enriched with ELF3 binding sites in SERD resistant and parental cells. Pathway analysis of ELF3-targeted genes reveals that ELF3 may regulate cell metabolism specifically in SERD resistant cells but not in parental cells. Our study

suggests that ELF3 may be a novel driver of acquired resistance to SERDs in ER+ breast cancer.

New potential mechanism of mnx1-as1 in the regulation of the carboplatin chemoresistant phenotype in ovarian cancer cell lines

Tamara Alejandra Viscarra Alvarez[1], Kurt Leopoldo Buchegger Mena[2], Daniela Inés León Garrido[1], Carmen Gloria Ili Gangas[1], Jorge Sapunar Zenteno[1], Marcela Berrios Flores[3], Ramón Silva Pezoa[4], Sindy Paola Cabarca Barreto[1], Priscilla Brebi Mieville[1]. *[1]Universidad de La Frontera, Temuco, Chile,[2]Ciencias Básicas, Universidad de La Frontera, Temuco, Chile,[3]Fundación Arturo López Pérez, Santiago, Chile,[4]Universidad Autónoma de Chile, Temuco, Chile*

Introduction: Ovarian cancer (OC) is one of the most lethal diseases in the female population worldwide, being considered by 2020 the eighth most common type of cancer and the eighth cause of cancer death in that population. The most widely used chemotherapy treatment is based on the application of platinum based drugs, carboplatin (CBDCA) being one of the most common, in combination with taxanes and cisplatin. Unfortunately, a high percentage of the population relapses shortly after chemotherapy treatment, presenting a drug resistant phenotype. This phenotype reduces overall survival in patients with OC. In this context, various mechanisms have been investigated to understand and study these chemoresistant phenotypes. In the last decade, lncRNAs have been identified in multiple biological processes, including the development of drug-resistant phenotypes in malignant tumors, however, little is known about their role in carboplatin resistance in OC. This study seeks to characterize the effect of lncRNA expression on the chemoresistant phenotype and its potential molecular mechanism involved.
Materials and Methods: Ovarian cancer cell lines corresponding to: A2780-R-CBDCA, A2780-P, UCI-101, OVCAR3 and SKOV3 were used. Drug susceptibility assays were performed using MTT. Relative expression was performed via RTqPCR. RNAseq was performed on a CBDCA resistance model in vitro using the Illumina HiSeq 4000 platform. Gene Ontology (GO) was analyzed using ClueGO. Gene set enrichment analysis (GSEA) was performed to define enriched biological pathways. Triplexator was

used to predict the triplex forming oligonucleotides (TFO) and triplex target sites (TTS) that may be involved in the formation of RNA-DNA triplexes. Results: RNAseq analysis showed 156 differentially expressed protein coding genes (DEGs). The most enriched and deregulated signaling pathway was Wnt/β-catenin. In this context, several regulators of this pathway were found to be altered, including sFRP1, sFRP4, PCDHB6, CTNNA2, DACT1, PCDHB6, WNT3A, and CER1. In addition, 17 lncRNAs involved in CDBCA resistance were found to be deregulated. In this sense, MNX1-AS1 showed high levels of expression in CBDCA resistant cell lines. Interestingly, it has been shown that MNX1-AS1 has the ability to form a triplex with the PCDHB6 gene, which is a tumor suppressor gene and whose expression was found to be decreased in CBDCA resistant cell lines.
Conclusions: Our results indicate that MNX1-AS1 expression could contribute to the modulation of platinum drug resistance through regulation of PCDHB6 expression via triplexes formation in OC. This finding could explain a new mechanism in CBDCA resistance in OC.

#3896

Alteration of malignancy and histone-H3 lysine-methylation status in osteosarcoma cells which acquire methotrexate resistance *in vitro*

Yusuke Aoki[1], Yasunori Tome[1], Hiromichi Oshiro[1], Ryo Katsuki[1], Kohei Mizuta[1], Kotaro Nishida[1], Robert M. Hoffman[2]. *[1]Department of Orthopedic Surgery, Graduate School of Medicine, University of the Ryukyus, Nishihara, Japan,[2]Department of Surgery, University of California, San Diego, La Jolla, CA*

Since methotrexate (MTX) resistance of osteosarcoma is a frequent cause of poor prognosis, new treatment strategies are needed to overcome this recalcitrant problem. The present study investigated if MTX resistance increased malignancy of osteosarcoma cells and its possible mechanism, via histone-H3 lysine-methylation status. We also propose a new therapeutic strategy for MTX resistant osteosarcoma. MTX resistant 143B osteosarcoma cells (143B-MTXR) were established from 143B parental osteosarcoma cells (143B-P) by culturing the cells with increasing concentrations of MTX stepwise (0.04 μM to 100 μM) for 12 months. The degree of malignancy of the isogenic pair of 143B-MTXR and 143B-P cells

was compared by testing clonogenic capacity in cell culture, on both plastic and soft agar. Malignancy was also compared by tumor growth in orthotopic xenograft mouse models by implantation of 2.5×10^5 cells in the tibia of nude mice. Histone-H3 lysine-methylation status was determined by Western immunoblotting. 143B-MTXR and 143B-P cells were also tested for methionine addiction by sensitivity to recombinant methioninase (rMETase). Welch's t-test was performed to statistically evaluate results and a probability value ≤ 0.05 was defined as statistically-significant difference. The mouse studies were approved by Institutional Animal Care and Use Committee of AntiCancer Inc. After 12 months selection in increasing concentrations of MTX, we isolated 143B-MTXR cells, which had an MTX IC_{50} of 384 μM compared to 143B-P cells, which had an IC_{50} of 0.27 μM, demonstrating that the 143B-MTXR cells acquired a 1422-fold resistance to MTX. In cell culture, 143B-MTXR cells had reduced clonogenic capacity on plastic and in soft agar ($P < 0.01$), indicating reduction in malignancy. In orthotopic xenograft nude-mouse studies, 143B-MTXR cells formed much smaller tumors than 143B-P cells ($P < 0.01$), further indicating that 143B-MTXR cells lost malignancy. 143B-MTXR cells showed an increase of histone H3K9me3 ($P = 0.01$), H3K27me3 ($P < 0.01$), and H3K79me3 ($P < 0.01$) methylation, which may account in part for their decreased malignancy. However, there was no difference in methylation of H3K4me3 ($P = 0.12$) or H3K36me3 ($P = 0.29$). The 143B-MTXR cells had an IC_{50} of 0.358 U/ml for rMETase, similar to an IC_{50} of 0.38 U/ml for 143B-P cells, indicating the 143B-MTXR cells did not lose their methionine addiction. The increase in histone H3K9me3, H3K27me3, and H3K79me3 shown in the present study in 143B-MTXR cells suggested potential biomarkers of methotrexate-resistance. MTX resistant osteosarcoma may be treated by methionine restriction with rMETase, as the MTX-resistant osteosarcoma cells are highly methionine addicted.

#3897

MNX1-AS1 expression is positively correlates with expression of drug efflux pumps in ovarian cancer

Kurt Buchegger Mena[1], Tamara Viscarra Alvarez[2], Daniela León Garrido[2], Ramón Silva Pezoa[3], Carmen Ili Gangas[2], Sindy Cabarca Barreto[2], Marcela Berrios Flores[4], Jorge Sapunar Zenteno[2], Priscilla Brebi Mieville[2].

[1]Ciencias Básicas, Universidad de La Frontera, Temuco, Chile,[2]Universidad de La Frontera, Temuco, Chile,[3]Universidad Autónoma de Chile, Temuco, Chile,[4]Fundación Arturo López Pérez, Santiago, Chile

Introduction: Ovarian cancer is one of the most lethal diseases in the female population worldwide. Indeed, the survival rate of ovarian cancer is very low when diagnosed lately and the success rate of current chemotherapy regimens is not very efficient. One of the main chemotherapy treatment regimens is the use of platinum drugs, specifically carboplatin (CBDCA). Nevertheless, one of the main reasons for this low success rate is the acquired chemoresistance of these cancers during their progression. The mechanisms responsible for this chemoresistance are numerous, including efflux pumps, repair mechanisms, survival pathways and tumor suppressors. In the last decade, lncRNAs have been identified as a new element responsible in the regulation of chemoresistant phenotype since they have been linked to multiple biological processes and acting in combination with other mechanism involved in chemoresistant. However, little is known about their role in carboplatin resistance in OC. This study seeks to characterize the effect of lncRNA expression on the chemoresistant phenotype and its correlation with the hyperactivation of drug efflux pumps.
Materials and Methods: Ovarian cancer cell lines A2780-R-CBDCA, A2780-P, UCI-101, OVCAR3 and SKOV3 were used in this study. Chemosensitivity to carboplatin was measured by MTT Assay in 96-well plates after 24, 48 and 72h treatment for determinating IC50 values. Relative expression of MNX1-AS1 associated with CBDCA-resistant phenotype and efflux pumps were evaluated by qRT-PCR.
Results: It was observed that A2780-R-CBDCA, SKOV3 and OVCAR3 cell lines presented the highest resistance indices in contrast to UCI-101 and A2780-P, which turned out to be highly sensitive to treatment with CBDCA. The relative expression of MNX1-AS1 was found elevated in those lines that presented higher levels of resistance to the drug, while in those more sensitive to treatment, the expression of MNX1-AS1 was found to be decreased. On the other hand, the expression levels of the ABCB1 and ABCC1 efflux pumps showed contradictory results in relation to their expression compared to the resistance index shown in each cell line. Mainly, it could be observed that ABCB1 presented a decreased expression

in A2780-R-CBDCA, while ABCC1 was found to be increased in the same line.
Conclusion: Our results indicate that the expression of MNX1-AS1 could contribute to the development or maintenance of a chemoresistant phenotype to platinum drugs. Meanwhile, the effect of the expression of MNX1-AS1 on the efflux pumps is not yet possible to relate as a modulator of its hyperactivation. However, their potential participation in this mechanism is not ruled out and new analyzes are necessary to rule out this possible relationship.

Synergistic combination of the iron chelator deferasirox with cisplatin and doxorubicin chemotherapies against nonsmall cell lung carcinoma

Natalia I. Ortiz Alvelo[1], Grace Torres[1], Sthephanie Estrada[2], Daraishka Pérez[3], Yancy Ferrer[3], Yamixa Delgado[1]. *[1]San Juan Bautista School of Medicine, Caguas, Puerto Rico,[2]University of Puerto Rico Cayey, Cayey, Puerto Rico,[3]Universidad Central del Caribe, Bayamon, Puerto Rico*

Lung cancer is the second most common and leading cause of cancer-related deaths worldwide with 85% of these cases being non-small cell lung carcinoma (NSCLC). Unfortunately, despite improvements in NSCLC outcomes, many of these tumors develop resistance against principal chemotherapies (e.g., cisplatin (CisPt) and doxorubicin (Doxo)), inducing abysmally low survival prognosis. Deferasirox (Def), an FDA-approved iron chelation therapy, is a drug under study for cancer therapy due to iron plays a key role in cell growth and energy production. Herein, we determined the effect of Def alone and in combination with CisPt and Doxo on NSCLC A549 cells. Viability assays results showed that Def has synergistic cytotoxic effects in combination with CisPt and Doxo at low uM concentrations after 24 h of incubation using the Chou Talalay method. In addition, qPCR gene expression studies showed that Def induced a significant downregulation of EGFR, VEGF, MMP9, MMP2, CHD4 genes related to resistance and metastatic process. In addition, we determined the overexpression of NDRG1 gene mediated by Def confirming the chelation of iron and disruption of iron metabolism. Overall, this work will set the basis for adjuvant therapies against chemoresistance and metastasis processes using an iron chelator.

CHST11 mediated SEMA7A expression contributes to TKI resistant in lung cancer

Chien-Hsiu Chris Li[1], Ming-Hsien Chan[1], Yu-Chan Chang[2], Michael Hsiao[1]. *[1]Academia Sinica - Genomics Research Center, Taipei, Taiwan,[2]Department of Biomedical Imaging and Radiological Sciences, National Yang Ming Chiao Tung University, Taipei, Taiwan*

An extracellular matrix has been demonstrated to be one of the substances that promote tumor cells to become driven by external stimuli to change their biology or malignancy. The main component of extracellular matrix, chondroitin sulfate, has been confirmed as a factor in the progression of tumors. Nevertheless, a great deal remains unknown regarding the precise mechanisms that drive Chondroitin sulfate production and how these details are communicated to cancer cells. According to our previous studies, the main enzyme responsible for Chondroitin sulfate synthesis, carbohydrate sulfotransferase 11 (CHST11), plays a crucial role in lung cancer cell metastatic spread. Nevertheless, the relationship between CHST11 expression and regulatory mechanism in response to lung cancer treatment is unclear, especially for tyrosine kinase inhibitor (TKI). A clinical correlation analysis was used in this study to identify molecules which were highly correlated with the overexpression of CHST11 and identified GPI-anchored protein semaphorin 7A (SEMA7A) as a candidate. According to the TCGA database, expression of upregulated SEMA7A is correlated with poor prognosis and cellular malignancy in lung cancer patients. A SEMA7A-based gene correlation analysis finds that the affected gene ontology is highly similar to CHST11, particularly integrin signaling, which may contribute to Gefitinib resistance. A GSEA analysis reveals a significant effect of CHST11 overexpression on mitotic spindle processes, some of which molecules are clinically relevant to CHST11 or SEMA7A. These molecules have been reported to be involved in TKI resistance events such as MARCKS, MYO1E, and PDLIM5. Based on the TCGA database, these molecules and integrins also display significant clinical relevance in lung cancer patients. A CHST11-mediated increase in SEMA7A in the mitotic spindle process of cells may serve as one of the possible means of reducing TKI-induced mitotic cell death, and thereby promoting the ability

of lung cancer cells to become resistant to TKIs. Hence, targeting the CHST11-SEMA7A axis may offer a therapeutic strategy option that could be used to target drug resistance in lung cancers. [Keywords: CHST11, SEMA7A, Integrin, Drug resistant, Lung cancer] (Reference: https://pubmed.ncbi.nlm.nih.gov/35985204/ ; https://pubmed.ncbi.nlm.nih.gov/36181245/)

***In vivo* inhibition of metastatic HER2 positive trastuzumab resistant breast cancer using engineered destabilized 3UTR ARE of HER2 improves survival outcomes**

Chidiebere U. Awah, Joo Sun Mun, Baris Boylu, Alooka Paragodaarachchi, Chika Ochu, Hiroshi Matsui, Olorunseun O. Ogunwobi. *The City University of New York, New York, NY*

Breast cancer is the most common form of cancer in women with mortality of about 58% in developing countries. HER2+ breast cancers are treated with trastuzumab in various forms in combination with chemotherapy and has been successful in targeting HER2 overexpression in HER2+ breast cancer and improving survival as a standard first line therapy for more than a decade. However, about 25% of early and 75% of late stage HER2 driven breast cancers are resistant to trastuzumab. For these patients, the clinical outcomes are grim. We report the destabilization of HER2 3‘UTR ARE which degraded oncogene HER2 transcript, protein expression, HER2 dependent kinases and interactome. *In vitro*, we transfected the engineered destabilizing HER2 constructs into BT474 clone 5 trastuzumab resistant breast cancer and within days, we inhibited cancer cell growth and degraded HER2 transcript and protein. The degradation of HER2 leads to loss of many kinases especially YES1 and WNK1 that are known causes of chemoresistance in HER2 positive trastuzumab resistant breast cancer. *In vivo*, we administered the destabilizing constructs as naked constructs or as complexed with nanocages to mice bearing tumors of BT474 clone 5 trastuzumab resistant cells. We found that our constructs, both the naked and nanocage-delivered, conferred significant survival (p values: 0.0178 and 0.00492) to about 60% of the exceptionally surviving mice compared to the controls. Taken together, we have developed a new therapy to target

trastuzumab resistant HER2+ metastatic breast cancers with increased survival outcomes.

Identification of genomic pathways associated with resistance of NSCLC to immunotherapies containing granzyme B
Ana Alvarez-Cienfuegos, Lawrence H. Cheung, Khalid A. Mohamedali, Ganiraju C. Manyam, Jing Wang, John V. Heymach, Michael G. Rosenblum. *UT MD Anderson Cancer Center, Houston, TX*

Immuno-oncologic (IO) approaches have completely transformed lung cancer treatment. Unfortunately, most patients with NSCLC develop primary resistance during IO and less than 20% achieve partial or complete response. Understanding the pathways to resistance is a significant challenge that requires a focused approach combining both clinical and basic research. Because resistance to IO is complex and likely multimodal, it is vital to find alternative strategies to overcome these challenges. IO generally employs cellular-mediated delivery of granzyme (GrB) as the final toxic payload and fusion proteins containing GrB serve as a targeted therapeutic with an identical mechanism of cytotoxic action. Subsequent development of resistance to GrB-based fusions may provide a look into the intrinsic mechanism of resistance related to cell signaling and gene expression for IO agents. The human fusion protein GrB-Fc-IT4 contains a single chain variable fragment targeting the Fn14 (fibroblast growth factor-inducible 14) receptor for TWEAK that is overexpressed in several tumor types, including NSCLC. GrB-Fc-IT4 exhibits high affinity and selective cytotoxicity within the nanomolar range when tested against a large panel of Fn14+ human cancer cell lines including NSCLC. We generated 3 resistant clones from a NSCLC GrB-sensitive cell line (A549) by exposing the cells to increasing concentrations of GrB-Fc-IT4. We then conducted a comprehensive genomic characterization of the GrB-sensitive A549 and compared to the GrB-Fc-IT4 resistant clones (A549R-F5, A549R-F7 and A549R-F8) to identify significant differentially expressed genes (DEGs) and pathways involved in GrB-resistance mechanisms. By mapping gene expression changes we have established that clones A549R-F5 and A549R-F7 have a very similar genomic profile, while the clone A549R-F8 displays a distinctive genomic profile. These results suggest that clones A549R-F5

and A549R-F7 shared a similar mechanism of resistance whereas clone A549R-F8 mechanism of resistance might be different. Comparison of the GrB-resistant clones with 7 NSCLC cell lines sensitive to GrB-Fc-IT4 revealed 43 significant DEGs (padj<0.05), suggesting these genes could be involved in the GrB response. From these DEGs, 34 genes had a higher basal expression in the GrB-resistant clonal cell lines while 9 DEGs were downregulated. Significantly, sensitivity of GrB-resistant cell lines to the chemotherapy agent cisplatin showed that the GrB-resistant clones were 6-fold more resistant than the parental cell line. We found that 13 DEGs of the 43 DEGS have also been described to be involved with cisplatin- or damage-response. These novel candidates for GrB resistance could prove to be important prognostic markers or targets for tailored combined therapy in the future. Research conducted, in part, by the Clayton Foundation for Research and Lung Spore (P50CA070907).

Glutathione as a potential marker of tamoxifen resistance in breast cancer

Yazan I. Hamadneh[1], Mohammad AlWahsh[2], Jawad Alrawabdeh[1], Roland Hergenröder[3], Lina A. Dahabiyeh[4], Lama Hamadneh[2]. *[1]School of Medicine, University of Jordan, Amman, Jordan,[2]Department of Pharmacy, Al-Zaytoonah University of Jordan, Amman, Jordan,[3]Leibniz-Institut für Analytische Wissenschaften - ISAS - e.V., Dortmund, Germany,[4]Faculty of Pharmacy, University of Jordan, Amman, Jordan*

Glutathione (GSH) is an antioxidant with an important protective intracellular role against reactive oxygen species. Increased glutathione level is associated with higher rates of metastases and a more aggressive behavior in breast cancer. This study aims to study the molecular and metabolic changes in glutathione synthesis in tamoxifen resistant (TAM-R) MCF-7 breast cancer cell lines.Methods: Three tamoxifen resistant MCF-7 cell lines were produced by using two methods. The first was achieved by treating the cells with tamoxifen and gradually increasing the amount until reaching a predetermined concentration of tamoxifen. The second was achieved by giving multiple fixed concentrations of tamoxifen, the third model was produced from the second by treating the cells with continuous 1μM of tamoxifen. mRNA and metabolites were extracted from the cell

lines. cDNA was synthesized from the extracted mRNA, and gene expression of glutathione synthetase (*GSS*) was measured using real-time PCR. Nuclear Magnetic Resonance technique with PABO probe was used for metabolic profiling of extracted metabolites from the resistant and sensitive MCF-7cells and Chenomix software for quantification. Additionally, Kaplan Meier plotter (https://kmplot.com/) was used to predict the significance of GSS gene expression to overall survival of breast cancer patients. Results: A significant increase in glutathione accompanied with significant decrease in cysteine levels were found in TAM-R cells compared to control TAM sensitive cells. However, there was a 2 times reduction in the expression of *GSS* in TAM-R cells. Correlation of *GSS* gene expression among ER +ve, PR +ve patients who received tamoxifen in their therapy showed that its down regulation is significantly linked to poor overall survival (*p-value* 0.022 and HR of 0.7). Conclusion: The significant increase of glutathione in TAM-R cells may contribute to their increased resistance to oxidative stress and exhibition of a more aggressive behavior. Moreover, the decrease in *GSS* expression is a strong indicator of decreased glutathione synthesis in TAM-R cells as a result of cysteine depletion in the cells that was correlated to poor overall survival among BC patients. However, high glutathione levels in TAM-R cells could be due to increased glutathione regeneration in TAM-R cell lines compared to control.

Role of the miR-301a/Fra-2/GLIPR1 axis in lung cancer cisplatin resistance

Francesca Lovat[1], Gian Luca Rampioni Vinciguerra[1], Marina Capece[1], Rosario Distefano[1], Giovanni Nigita[1], Andrea Vecchione[2], Carlo M. Croce[1]. *[1]The Ohio State University, Columbus, OH,[2]University of Rome 'Sapienza', Rome, Italy*

Lung cancer is the leading cause of cancer-related mortality in both men and women worldwide. Despite the administration of platinum compounds represents the main treatment, the majority of tumors remains intrinsically resistant. In lung cancer, miR-301a exerts a main role by modulating the activity of transcription factors like NF-kB and Stat3. Here, we dissected the contribution of miR-301a in the regulation of its new identified target Fos-related antigen-2 (Fra-2), a transcription factor that belongs to the

Fos/AP-1 family. By microarray analysis, we discovered that Fra-2 overexpression increased glioma pathogenesis-related protein 1 (GLIPR1) levels, a mediator of cisplatin resistance in lung cancer. Its mechanism of regulation is still unclear. We demonstrated that GLIPR1 is also a miR-301a target. In vitro, modulation of miR-301a reduced Fra-2 and GLIPR1 levels; conversely, Fra-2 overexpression significantly increased GLIPR1 and miR-301a. Then, by chromatin immunoprecipitation assay, we confirmed that Fra-2 interacts with the promoter regions of both GLIPR1 and MIR301A genes, supporting that miR-301a/Fra-2/GLIPR1 axis could be autoregulated by feedback loop in which Fra-2 promotes the transcription of MIR301A gene. Investigating the effect of this new axis on the response to cisplatin, we observed that both Fra-2/GLIPR1 overexpression and miR-301a silencing induced cisplatin resistance in lung cancer cells. By contrast, silencing of GLIPR1 and combined administration of low doses of Fos/AP-1 inhibitor restored the cisplatin sensitivity in Fra-2 overexpressing cells. In the lung adenocarcinoma samples from the TCGA dataset, miR-301a overexpression inversely correlated with Fra-2 and GLIPR1 expression. Consistently, the overexpression of miR-301a identified a fraction of tumors with low expression of Fra-2 and GLIPR1 in an internal cohort of lung cancer samples. Altogether, our findings identify the miR-301a/Fra-2/GLIPR1 axis that contributes to cisplatin resistance in lung cancer cells and could serve as biomarker to stratify patients who may benefit from cisplatin administration, alone or in combination with Fos/AP-1 inhibitors.

Simvastatin intensifies anti-androgen efficacy against treatment-resistant prostate cancer cells

Aino Siltari, Olga Korhonen, Paavo Raittinen, Merja Bläuer, Heimo Syvälä, Teuvo L. Tammela, Teemu J. Murtola. *Prostate Cancer Research Center, Tampere University, Tampere, Finland*

Androgen receptor (AR) signaling inhibitors (ARSIs) bicalutamide (Bic) and enzalutamide (Enza) are used in the treatment of castration resistant prostate cancer (CRPC). Prostate cancer (PCa) cells eventually develop treatment resistance against these drugs causing clinical challenges. The mechanisms behind treatment resistance are complex and only partially known. Androgen signaling is linked to lipid and cholesterol metabolism,

and they likely play a role in the development of treatment resistance. Cholesterol producing mevalonate pathway can be inhibited by statins, but it is unknown whether statin treatment could enhance effects of ARSIs. We studied combined effects of simvastatin (Sim) with or without Bic or Enza in VCaP originated PCa cell lines resistant to these ARSIs. Unique treatment resistant cell lines were created with long-term cultures of VCaP cells. The cells were kept under anti-androgen influence until the cells were growing normally despite the ARSIs. We analyzed changes in cell growth, RNA expression, and relevant AR signaling and cholesterol metabolism protein expression. Prostate-specific antigen (PSA) secretion was measured as a marker of AR signaling activity. In Bic or Enza resistant cell lines, combination of 2.5 or 5 μM simvastatin + 10 μM Bic/Enza decreased cell growth more than Sim alone, i.e., ARSIs demonstrated efficacy in combination therapy against ARSI resistant cells. In Bic and Enza resistant cells, combination treatment increased the expression of 60 and 26 and decreased the expression of 33 and 48 genes, respectively, compared with simvastatin alone. Altogether, 16 genes expression changed similarly in both cell lines in response to combination therapy. In both cell lines, over 70% of all gene changes were seen on AR-regulated genes. In Bic resistant cells, Sim decreased PSA levels with or without Bic. On the contrary, in Enza resistant cells PSA levels were increased with combination of Sim and Enza. We showed that combined treatment with ARSI and Sim inhibited cell growth more than Sim alone in ARSI resistant cell lines. This suggests that inhibition of the mevalonate pathway could enhance androgen signaling inhibition and potentially circumvent ARSI resistance mechanisms. This phenomenon is supported by epidemiological studies as patients treated with anti-androgens responded better during simultaneous statin treatment. Gene expression differed in combination treatment compared to Sim alone. Future studies are needed on whether interventions on lipid and cholesterol metabolism could enhance treatment of CRPC. Knowledge about the precise mechanisms behind the treatment responses and resistance might lead to new therapeutic applications.

Epigenetic primming reveals the central role of epigenetic state in the anti-tumor activity of vitamin D in pancreatic ductal adenocarcinoma

Bo He, Lauren Stoffel, Clifford Jiajun He, Albert Mao Li, Haowen Jiang, Kumsun Cho, Brittany M. Flowers, Sofia Ferreira, Laura D. Attardi, Jiangbin Ye. *Department of Radiation Oncology, Stanford University School of Medicine, Stanford, CA*

Pancreatic ductal adenocarcinoma (PDAC) has a dismal prognosis, which is largely due to the intrinsic resistance to a broad spectrum of therapies. Vitamin D (VD) has been extensively studied as a potential preventive or therapeutic agent for PDAC treatment. Although accumulating evidence supports that VD has beneficial effects on PDAC treatment, controversies still exist. The major reason for this inconsistency is that VD resistance widely occurs in PDAC. However, the underlying mechanism by which the VD resistance occurs remains largely unknown. Here, we report that epigenetic primming by glyceryl triacetate (GTA) and 5-azacytidine (5-Aza) overcomes VD resistance in PDAC. Mechanistically, increasing global H3K27 acetylation with GTA and reducing global DNA methylation with 5-Aza not only elevate the VDR expression but also reprogram the VD responsive genes. Consistently, combination treatment with VD analogue calcipotriol (CPT) and epigenetic primming overcomes the VD resistance to inhibit cell proliferation and migration through activating genes involved in negative regulation of cell proliferation and cell migration, while CPT treatment alone has the opposite effects. Intriguingly, further studies in mouse PDAC cells suggest that VDR expression does not always corelate with VD responsiveness. Using the gain and loss of function experiments, we demonstrate that VDR is necessary but not sufficient to trigger the anti-tumor activity of VD, highlighting that epigenetic state is the key determinant of VD responsiveness in PDAC. Collectively, these data reveal a previously undefined mechanism for VD resistance in PDAC and has the potential to guide VD clinical trials in the future.

The mRNA translational plasticity of small cell lung carcinoma is associated with its phenotypic transdifferentiation

Haoning Peng[1], Mengyao Wang[1], Lu Li[2], Lunxu Liu[3], Shensi Shen[1]. *[1]Institute of Thoracic Oncology, West China Hospital, Sichuan University, Chengdu City, China,[2]Lung Cancer Center, West China Hospital, Sichuan*

University, Chengdu City, China,[3]Department of Thoracic Surgery, West China Hospital, Sichuan University, Chengdu City, China

Small cell lung carcinoma(SCLC), classified as a recalcitrant cancer type, accounts for 13-15% of all lung cancers with a median overall survival less than 10 months in patients with extensive stage SCLC. SCLC was once considered as molecularly homogeneous due to nearly universal loss of TP53 and RB1, whereas subsets of MYC-driven, non-neuroendocrine (non-NE) SCLC variants, possess chemoresistance, suggesting its high plasticity and intertumoral heterogeneity related to rapid refractory to first-line chemotherapies. Current pathognomonic classification stratifies SCLC into two NE subtypes (ASCL1+, NEUROD1+) and two non-NE subtypes (POU2F3+ and triple negative), associated with different expression patterns of MYC family proteins. MYC is a master regulator of mRNA translation, whether translational regulation actively tunes SCLC plasticity and the associated chemosensitivity remains an enigma. Here, we delineate the translation landscape of NE and non-NE SCLC cells by using paired human NE SCLC cell line and constitutive or induced non-NE SCLC cells. As expected, non-NE SCLC cells are more resistant to the clinically relevant first-line chemotherapy than NE SCLC cells. With polysome profiling in combination with polysome RNA-seq, we showed differential expression at both transcription- and translation-level. However, transcription-level changes minimally overlapped with the translational changes between NE and non-NE SCLC cells, with a global reduction of translation activity observed in non-NE SCLC cells. Through analyzing the polysome profiles, we observed a striking accumulation of 60S monosomes and diminishment of 80S ribosomes derived from non-NE SCLC cells compared to those from NE SCLC cells. This unique translational pattern in non-NE SCLC cells was correlated with an increased expression of eIF6, a ‘sitting on the bench’ member of eukaryotic initiation factor (eIF) family. The eIF6 couples 60S monosome maturation and recycling, enrolling a quintessential role in functional 80S ribosome formation. Positive correlation between eIF6 expression and non-NE SCLC tumors was observed in 81 tumor samples derived from patients with limited stage SCLC and CCLE cell consortium, in which c-MYC expression was also positively correlated with eIF6 level. By using both ultracentrifugation and fraction analysis from polysome profiling, we found that less association of

eIF6 with 60S may mitigate 80S ribosome assembly in non-NE SCLC cells. In addition, in vivo xenograft models showed that eIF6 expression was higher in residual tumors upon chemotherapy.
Taken together, these data revealed an eIF6-dependent translational regulation in non-NE transdifferentiation of SCLC subtypes, suggesting an underappreciated function of translational regulation of SCLC plasticity and the potential therapeutic value of eIF6 for overcoming SCLC resistance to chemotherapy.

Targeting adaptive resistance to EGFR and KRAS G12C inhibitors by TT125-802, a novel and specific CBP/p300 bromodomain inhibitor
Thomas Bohnacker, Dorothea Gruber, Sara Laudato, Martin Schwill, Charles-Henry Fabritius, Raquel Herrador, Katrin Westritschnig, Thushara Pattupara, Vikram Ayinampudi, Stefanie Flückiger-Mangual. *TOLREMO therapeutics AG, Muttenz, Switzerland*

Resistance to targeted therapies is a major challenge in oncology. Disease progression is caused by multiple resistance mechanisms. Besides pre-existing and acquired genetic alternations, adaptive non-mutational reprogramming as well as modulation of phenotypic plasticity have emerged as drivers of disease progression. For example, in epidermal growth factor receptor (EGFR)-mutated non-small cell lung cancer (NSCLC) patients who were treated with osimertinib, ~50% of progressive disease could not be attributed to genetic mutations (Leonetti et al., *BJC* 2019). Similarly, in ~ 40% of patients suffering from KRAS G12C-mutated NSCLC and colorectal cancer (CRC), disease progressed under sotorasib treatment without identifiable acquired mutations (Zhao et al., *Nature* 2021). Thus, targeting non-genetic adaptive resistance mechanism such as drug-induced transcriptional reprogramming might be of great therapeutic benefit. Here we identified small molecules, that interfere with cancer drug-induced transcriptional escape mechanisms using a phenotypic screen based on an SRY-Box Transcription Factor 2 (SOX2) reporter system. The screen led to the development of TT125-802, a highly specific and potent, orally available small molecule inhibitor of the bromodomain of the transcriptional and epigenetic regulator CBP [cyclic adenosine monophosphate response element binding protein (CREB) binding protein]

and its paralogue p300. TT125-802 dose-dependently prevented osimertinib resistance development in EGFR-mutated NSCLC cell lines HCC827 and HCC4006, as well as sotorasib resistance development in KRAS G12C-mutated NCI-H358 (NSCLC), SW837 and SNU-1411 (CRCs) as assessed by label-free long-term live microscopy assays. Data generated in mouse xenograft studies confirmed the ability of TT125-802 increasing response rates and prolonging the duration of response to osimertinib and sotorasib *in vivo*. In cells and tumours which were already resistant to osimertinib or sotorasib, TT125-802 could still delay cell or tumor growth. Complementary and longitudinal analysis of transcriptional changes using RNA sequencing *in vitro* and *in vivo* identified several early adaptive and late acquired resistance signatures that were reversed by TT125-802. A first-in-human study of TT125-802 in cancer patients is on track to start in 2023.

M^{6}A RNA modifications regulate expression of transcripts that promote transition to cisplatin resistance in bladder cancer

Emmanuelle Hodara, Aubree Mades, Tong Xu, Amir Goldkorn, Suhn Rhie.
Keck School of Medicine of USC, Los Angeles, CA

BACKGROUND**:** Chemotherapy resistance is recognized to occur not only through selection of pre-existing genetically resistant clones, but also through rapid phenotypic plasticity mechanisms. We previously reported that bladder cancer cells can rapidly transition to and from a chemo-resistant phenotype. Recently, N6-methyladenosine (m^{6}A) RNA modifications were shown to dynamically and reversibly regulate mRNA processing, differentiation, and cell fate. Here, we tested the hypothesis that m^{6}A modifications regulate phenotypic plasticity and transition to cisplatin resistance in bladder cancer (BC).
METHODS: We utilized methyl-RNA-immunoprecipitation followed by sequencing (MeRIP-seq) and by RNA-seq to identify transcripts that were both differentially methylated and differentially expressed between cisplatin-sensitive and cisplatin-resistant BC cell lines. Candidate transcripts were annotated using Gene Ontology (GO) enrichment analysis and Gene Set Enrichment Analysis (GSEA). Clinical relevance was evaluated using databases such as The Cancer Genome Atlas (TCGA) and

the Oncology Research Information Network (ORIEN) avatar. Cancer-relevant genes were then validated in vitro by targeted immunoprecipitation and PCR (MeRIP-PCR) and qPCR. Candidate genes were then functionally validated in cell lines and in patient derived organoids (PDOs) by siRNA-mediated knockdown and cisplatin treatment, as well as by m6A measurement after short-term cisplatin treatment.
RESULTS: MeRIP-seq and RNA-seq revealed that cisplatin-sensitive and cisplatin-resistant BC cells have distinct m^6A profiles, with 130 transcripts that were both differentially methylated and differentially expressed. Using clinical and functional database tools, we filtered this list to 37 transcripts and ranked them based on clinical relevance in BC. Of the top 15 candidates, eight were successfully validated in vitro via repeat qPCR and MeRIP-PCR. In cisplatin-resistant cells, one candidate, SLC7A11, was found to have decreased m6A level, which was associated with increased RNA stability and elevated transcript and protein levels. Consistent with this, 48 hr cisplatin treatment of cisplatin-sensitive cells led to SLC7A11 hypomethylation, increased RNA stability, and elevated transcript and protein levels. Furthermore, depletion of SLC7A11 by siRNA-knockdown re-sensitized BC cell lines and PDOs to cisplatin.
CONCLUSIONS: Using unbiased transcriptome-wide m^6A profiling followed by targeted validation, we demonstrated that m^6A modifications regulate expression of clinically relevant gene transcripts in BC, and that a subset of these modifications may promote resistance to chemotherapy. Collectively, these results implicate epitranscriptomic plasticity as a driver in potentiating cisplatin resistance in bladder cancer.

THY1 regulates therapy resistance in glioblastoma recurrence
Sunita Shankar, Visweswaran Ravikumar, Hanxiao Wang, Sunjong Ji, Zainab Hasan, Ziad Fehmi, Yacoub Haydin, Daniel R. Wahl, Arvind Rao, Alnawaz Rehemtulla, Wajd Al-Holou. *University of Michigan, Ann Arbor, MI*

Glioblastoma (GBM), is the most common primary brain tumor. It is a lethal disease with a median survival of 15 months characterized by treatment resistance, aggressive brain invasion, and inevitable recurrence. Less than 10 percent of patients survive beyond 5 years. Here, we

developed an intracranial longitudinal *in vivo* recurrence model using HF2303, a patient derived explant, to produce paired specimens (pre- and post-recurrence) following temozolomide(TMZ) and radiation(IR) treatment. Mouse brain tissues from the two groups were compared to identify genes and pathways driving treatment resistance. This analysis showed an elevated THY1 expression in recurrent HF2303 tumors compared to naïve tumors. Increased Thy1 expression was also associated with a more mesenchymal phenotype. THY1 expressing cells from naïve HF2303 were also resistant to TMZ/IR treatment in an intracranial model. In U87 neurospheres, overexpression of THY1 increased resistance to TMZ/IR. Interestingly, stable knockdown of Thy1 in GBM cells and human derived GBM organoids (GBOs) expressing high THY1 levels led to reduced cell proliferation. Yet, an inducible knockout of THY1 using CRISPR/Cas9 in human GBOs showed increased sensitivity to TMZ/IR. This suggests a clear link between THY1 expression and TMZ/IR resistance.Single cell RNA sequencing of over 25 primary GBM and 4 recurrent tumors (spanning over 120,000 cells) shows that cells expressing high levels of THY1 are associated with two distinct populations; neuronal precursor-like (NPC-like) and mesenchymal-like (MES-like). Furthermore spatial transcriptomics from 3 primary GBMs suggests that high THY1 expressing cells are colocalized with macrophages within the perivascular niche contributing to the mesenchymal phenotype. We will present these studies and our more recent work analyzing spatial recurrent GBM samples. Particularly, we will address how THY1 expression in these spatially distinct NPC-like and MES-like differ and how each of these states may contribute towards TMZ/IR resistance.

Identification of Molecular Targets 1

Genomic loss of UQCR11 creates therapeutic vulnerability in triple-negative breast cancer

Samantha Sharma[1], Tao Yu[1], Abhinav Achreja[2], Xinna Zhang[1], Deepak Nagrath[2], Xiongbin Lu[1]. *[1]Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN,[2]Department of Biomedical Engineering, University of Michigan, Ann Arbor, MI*

Recurrent loss-of-function deletions are prevalent genomic alterations in tumors; nonetheless, these deletions occasionally create conditional therapeutic vulnerabilities in tumors. Our previous study used The Cancer Genome Atlas High-Grade Serous Ovarian Carcinoma (TCGA-HGSOC) dataset to identify the 19p13.3 locus as the most pervasive deletion in the high-grade serous ovarian carcinoma (HGSOC). Subsequently, the machine learning integrated-precision oncology platform identified that the loss of UQCR11, a gene located within the chromosome 19p13.3 locus, created a therapeutic collateral target, the MTHFD2. Furthermore, pharmacological inhibition of MTHFD2 in the UQCR11-deleted cells led to complete tumor remission in our in vivo mouse model (Nature metabolism, 2022). Encouraged by the promising anti-tumor effect of the MTHFD2 inhibitor, we extended our research to other tumor types. By analyzing the TGCA datasets, we found that UQCR11 deletion was a common occurrence among humans' most prevalent solid tumors, especially in pan breast and lung cancer. Within the pan breast cancer dataset, we found that over 50% of patients with triple-negative breast cancer (TNBC), the most difficult-to-treat breast cancer subtype in women, displayed either heterozygous or homozygous deletions in the UQCR11 gene. Moreover, the TGCA-TNBC dataset analysis revealed that the genomic copy loss of UQCR11 positively correlates with the deceased mRNA expression of the gene, bringing our interest to validate the collateral lethal targets in this breast cancer subtype. We first analyzed The Cancer Cell Line Encyclopedia (CCLE) database and further explored the correlation between the copy number alteration and mRNA expression of UQCR11 in several breast cancer cell lines. Then, we selected seven human TNBC cells with copy number neutral or deletion UQCR11 and validated the copy number and gene expression of UQCR11 and MTHFD2 using qPCR and western blot. We next treated these cells with a selective MTHFD2 inhibitor, DS18561882, and found that UQCR11-deleted cells showed a more favorable response than the UQCR11-intact cells. Finally, to test the therapeutic potential of targeting MTHFD2-null tumors in vivo, we generated isogenic mouse breast cancer cell lines using shRNA-mediated UQCR11 knockdown. Consistent with our previous findings, the MTHFD2 expression level was upregulated upon UQCR11 knockdown, suggesting a compensation function of MTHFD2 in UQCR11-deleted cells. Furthermore, the UQCR11 knocked-down cells showed better responses to MTHFD2 inhibitor treatment than the parental control cells. In

summary, our study provides evidence that targeting MTHFD2 holds strong therapeutic potential in over 50% of the TNBC patients with UQCR11 deletion and highlights the broad efficacy of targeting MTHFD2 for individualized therapeutic strategy in different tumor types co-occurring with UQCR11 deletion.

#3914

BTK and MALT1 are critical for cell adhesion and dissemination in mantle cell lymphoma

Vivian Changying Jiang, Yang Liu, qingsong Cai, Joseph M. McIntosh, Yijing Li, Zhihong Chen, Heng-Huan Lee, Wei Wang, Yixin Yao, Lei Nie, Michael Wang. *UT MD Anderson Cancer Center, Houston, TX*

Bruton's tyrosine kinase (BTK) is a great target in mantle cell lymphoma (MCL). This is evident by multiple FDA approvals of covalent BTK inhibitors (BTKi, e.g. ibrutinib, acalabrutinib and zanubrutinib) and recent exciting clinical data on non-covalent BTKi pirtobrutinib. However, resistance to BTKi is a major clinical challenge and the resistance mechanism is not yet fully understood. To address this, we generated JeKo BTK KD cells via *BTK* knockdown (KD) through by CRISPR Cas9 in BTKi-sensitive JeKo-1 cells, which resulted in superior resistance to BTKi and cell growth defects in vitro. Interestingly, JeKo BTK KD cells demonstrated early tumor cell engraftment and growth in subcutaneous xenograft models, while parental JeKo-1 cells showed much later engraftment but with much faster growth kinetics. To understand this and the BTKi-resistance mechanism, we first performed bulk RNA sequencing analysis and identified *MALT1*, but not its well-known binding partners *CARD11* and *BCL10*, as one of the top overexpressed genes in BTKi-resistant MCL cells, including JeKo BTK KD cells. Genetic knockout (KO) of *MALT1* or *CARD11* by CRISPR Cas9 in JeKo-1 resulted in defects in cell growth in vitro and delayed tumor engraftment and growth in vivo. In contrast, *MALT1* KO, but not *CARD11* KO, in JeKo BTK KD cells remarkably suppressed cell growth in vitro, and tumor engraftment and growth in vivo. These data demonstrate that MALT1 overexpression can drive ibrutinib resistance via bypassing BTK-CARD11 signaling. BTKi-resistant cells including JeKo BTK KD cells showed much higher potency in adhesion to extracellular matrix or stromal cells compared to BTKi-

sensitive cells. BTK inhibition or MALT1 inhibition significantly suppressed cell adhesion and migration to extracellular matrix or stromal cells. Furthermore, *BTK* KD and *MALT1* KO but not *CARD11* KO in JeKo-1 cells remarkably suppressed tumor cell dissemination and growth in spleen, liver, bone marrow and peripheral blood. *MALT1* KO in JeKo BTK KD cells further suppressed tumor cell dissemination. Consistent with this, MALT1 inhibition greatly suppressed tumor cell dissemination and growth in spleen, bone marrow and peripheral blood of an ibrutinib-resistant patient-derived xenograft model. Therefore, both BTK and MALT1 are critical for tumor cell adhesion and dissemination in vivo in a CARD11-independent manner. Furthermore, co-targeting MALT1 with safimaltib and BTK with pirtobrutinib induced potent anti-MCL activity in BTKi-resistant MCL cell lines and patient-derived xenografts. Therefore, we conclude that (1) BTK and MALT1 are key molecules that control MCL cell growth and dissemination, (2) MALT1 overexpression drives resistance to BTKi in MCL, (3) targeting MALT1 is a promising therapeutic strategy to overcome BTKi resistance, and (4) co-targeting of BTK and MALT1 improves efficacy and durability beyond single agents.

RNAseq analysis reveals differentiation gene drivers as potential therapeutic targets in anaplastic thyroid cancer

Kaci Kopec[1], Tara Jarboe[1], Michael Guo[1], Nicole R. DeSouza[1], Sarnath Singh[1], Augustine Moscatello[2], Humayun K. Islam[1], Jan Geliebter[1], Raj K. Tiwari[1]. *[1]New York Medical College, Valhalla, NY,[2]Westchester Medical Center, Valhalla, NY*

Papillary thyroid cancer (PTC) is a well-differentiated and highly treatable cancer with a 5-year survival rate of almost 99%. In contrast, anaplastic thyroid cancer (ATC) lacks differentiation and loses its thyroid-like functions, including lack of response to radioiodine therapy. Due to ATC's aggressive metastatic phenotype, it is always diagnosed as stage IV with a 5 year survival rate of less than 3%. ATC lacks targetable genetic lesions making it a difficult cancer to treat, therefore RNAseq analysis was performed in an effort to investigate the differentially expressed genes between ATC to PTC. Exploration of differential gene expression between ATC and PTC was undertaken to further elucidate the differences in

expression that drive the aggressive nature of ATC phenotype. RNA was isolated from human thyroid cancer cell lines T238 (ATC) and K1 (PTC) and RNA sequencing was conducted by Azenta Life Sciences. Our analysis resulted in 4,931 significant differentially expressed genes between ATC and PTC. Looking at the gene ontology analysis, pathways involving cell differentiation, proliferation, and migration revealed 90, 70, and 47 genes differentially expressed in ATC vs PTC respectively. These pathways putatively give rise to ATC's aggressive phenotype when compared to PTC, therefore, we narrowed down the focus from 4,931 genes to 207. Through RNAseq analysis, Homeobox D4 (HOXD4) was observed to significantly increase in ATC (7.69 log2 fold change) compared to PTC. HOXD4 is a transcription factor that plays a crucial role in cell differentiation and has been associated with a worse prognosis in cancers such as ovarian serous carcinoma. As loss of differentiation is essential to ATC's refractory nature and therapeutic resistance, targeting pathways involved in differentiation can be crucial in making ATC amenable to therapy. Other differentiation regulatory genes identified include BLK and LAMA5. BLK (3.95 log2 fold change) is a Src family tyrosine kinase proto-oncogene that is not only involved in cell proliferation but also differentiation. LAMA5 (4.76 log2 fold change) is an extracellular glycoprotein that has been linked to differentiation, migration and metastasis. Validation of the RNAseq results was completed via western blot analysis of multiple ATC and PTC cells lines. We found that HOXD4 expression was higher in ATC cell lines T238, 8505C, and SW1736 than PTC cell lines K1, TPC1, and BCPAP. Further validation was carried out by immunohistochemistry of human thyroid tissue. Preliminary IHC on ATC, PTC, and normal thyroid patient samples showed ATC has significantly increased HOXD4 expression (27.5%) compared to PTC (8.7%) and normal thyroid tissue (2.3%). Ongoing studies in the laboratory to identify novel genetic drivers of cell differentiation and proliferation so as to discover a therapeutic target to fulfill an unmet clinical need is underway.

role of her3 v104l mutation on tumor growth and her3 stabilization

Rosalin Mishra[1], Mary Kate Kilroy[1], Wasim Feroz[1], Hima Patel[2], Samar Alanazi[1], Joan T. Garrett[1]. *[1]James L.Winkle College of Pharmacy,*

University of Cincinnati, Cincinnati, OH,[2]UTSW Simmons Comprehensive Cancer Center, Dallas, TX

We aimed to determine if naturally occurring HER3 mutations could drive oncogenic activity of HER2+ HCC1569 cells in which endogenous HER3 was knocked out using CRISPR-Cas9 technology. A series of HER3 mutations found in breast cancer patients (F94L, V104L, G284R, D297Y, T355I, and E928G) were introduced via lentiviral transduction and stable cell lines were generated in HER3 knock out (KO) HCC1569 cells and were maintained in 0.5 mg/mL puromycin. Our data indicated that cells stably transduced with HER3V104L mutation had significantly higher cell growth with higher p-HER3 expression versus wild-type (wt) and empty-vector (EV) HER3. We found that HCC1569HER3KO cells with WT and V104L were sensitive to increasing concentration of neratinib (0.1-0.5 μM) as indicated by crystal violet assay. Next we examined if V104L mutation rendered resistance to another FDA- approved irreversible HER2 tyrosine kinase inhibitor, tucatinib. Our results showed that V104L cells were sensitive to higher concentration of tucatinib compared to neratinib. In other experiments, we used COS7 cells to examine the signaling pathways of HER3V104L mutation. Our western blot data demonstrated that transient transfection of COS7 cells with HER3V104L mutant significantly upregulated p-HER3 and p-HER2 expression versus WT HER3 in a NRG-dependent manner. In addition, we found that the V104L mutation stabilizes HER3 protein expression independent of ligand stimulation. Our western blot data showed that V104L induced HER3 stabilization is independent on HER3 binding partners HER1, HER2 and HER4. Our cycloheximide chase data indicated that V104L mutation stabilizes HER3 expression in COS7 cells as well as low HER3 expressing colon cancer cell line, SNUC5. Our western blot data indicates that V104L mutation activates ERK signaling in NRG dependent manner over AKT pathway in COS7 cells. In addition, we are using various PDXs with different HER3 mutations (V104M and E928D) to determine the role of these driver HER3 mutations in cancer and how this can be targeted in the clinic using HER targeted therapy.

Kinase domain duplications of *FGFR1* and *MET* are potential therapeutic targets

Chaelin Lee[1], Sungyoung Lee[2], Hongseok Yun[2], Jeonghwan Youk[3], Tae Min Kim[3], Soyeon Kim[4], Bhumsuk Keam[3], Miso Kim[3], Dong-Wan Kim[3].
[1]Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of,[2]Department of Genomic Medicine, Center for Precision Medicine, Seoul National University College of Medicine and Seoul National University Hospital, Seoul, Korea, Republic of,[3]Department of Internal Medicine, Seoul National University College of Medicine and Seoul National University Hospital, Seoul, Korea, Republic of,[4]Integrated Major in Innovative Medical Science, Seoul National University, Seoul, Korea, Republic of

Background: Kinase domain duplication (KDD) is recently recognized as an oncogenic driver. Therapeutic potential has been established in *EGFR*-KDDs in non-small cell lung cancer, and our group recently showed resistance mechanism in lung cancers harboring *EGFR*-KDDs treated with EGFR tyrosine kinase inhibitors (TKIs). However, the frequency and oncogenic role of KDDs in other receptor tyrosine kinases has been elusive.
Methods: To investigate the frequency of KDDs in advanced cancer patients, we developed in-house algorithm to detect KDDs in high-depth panel sequencing dataset and evaluated its performance using large-scale panel sequencing data from Seoul National University Hospital (SNUH). In short, the algorithm collects reads with soft clips from a modified GATK best practice pipeline for clinical NGS data processing. The collected reads are then grouped according to their matched position and insert size, and evidences of each group (number of splitting and spanning reads) are collected to yield a set of initial candidates. Finally, the initial candidates were manually inspected after quality control by removing false-positive candidates, such as non-target genes or consistent findings. Then, we established cell lines transfected with KDDs of *FGFR1* and *MET* to validate oncogenic role of identified KDDs in the cohort. Using these transformed cell lines, we investigated carcinogenicity with cell viability assay, immunoblot assay and colony formation assay. FGFR TKIs and MET TKIs were used to uncover the possibility of therapeutic targets in the KDDs.
Results: Using the in-house algorithm, we identified *FGFR1*-KDDs from brain tumors (n=4), *EGFR*-KDDs from lung (n=1) and brain (n=2) tumors, and *MET*-KDD from a lung tumor (n=1) in a total of 3,932 cancer samples, with 0.2% frequency. All three kinds of KDDs contained full-length of

kinase domains of each gene. Ba/F3 cells transfected with the *FGFR1*-KDD constructs proliferated well without IL-3 (1239- and 1019-fold higer than wild-type *FGFR1*), while wild-type *FGFR1* Ba/F3 cells did not. This growth potential was diminished by FGFR TKIs BGJ398 (IC50, 0.063 ± 0.065nM), PD173074 (IC50, 1.498 ± 1.021nM), and ponatinib (IC50, 5.69 ± 3.05nM). Reduced expressions of downstream pathway proteins including phospho-FGFR1, phospho-Akt, and phospho-Erk were confirmed by immunoblot assays. NIH-3T3 cells transfected with *MET*-KDD construct also showed growth advantage compared to wild-type *MET* NIH-3T3 cells. Capmatinib, a MET TKI, inhibited colony formation of *MET*-KDD NIH-3T3 cells with reduced phospho-MET expression.
Conclusion: In this study, we validated newly developed KDD-detection computational methods using targeted DNA sequencing data. Using this algorithm, we found 0.2% of KDDs in 3,932 cancer samples, including *EGFR*, *FGFR1*, and *MET*. In addition to *EGFR*-KDDs, our study reveals that both *FGFR1*- and *MET-KDD* can be oncogenic and therapeutic targets in brain and lung cancer patients.

SHP2-DDX3X complexes contribute to translational control of CD274 mRNA in KRAS-active non-small cell lung cancer

Palapoom Wongsaengpiboon. *University of Kentucky, Lexington, KY*

Background: Immune checkpoint inhibitors (ICIs) have shifted the landscape in management for non-small cell lung cancer (NSCLC) and improve treatment outcomes. However, the 5-year overall survival rate of 23.2% for treatment-naïve patients with late-stage NSCLC on Pembrolizumab therapy can likely be improved. Clinical benefit is correlated with tumoral expression of PD-L1 and mutation burden. Many groups seek to identify other therapeutic targets that could improve response and overall survival. Ongoing work from our group demonstrated that SHP2, a tyrosine phosphatase, can negatively regulate PD-L1 expression in KRAS-active NSCLC, and we seek to understand the mechanism by which this occurs. SHP2 was ectopically expressed in H460 cells, immunoprecipitated and identification of interacting proteins was achieved by mass spectrometry. DDX3X, an RNA helicase, and eukaryotic translation initiation factor 1a (eIF-1a) were identified as high-ranking,

potential partners of SHP2. We hypothesized that SHP2 complexes with DDX3X and eIF-1a on newly transcribed CD274 mRNA to negatively regulate PD-L1 expression.
Materials and Methods: To confirm SHP2 interactions with DDX3X and eIF-1a, two pull-down assays were performed: 1. bacterially-expressed, his-tagged and immobilized proteins was used as bait for proteins contained in A549 and H460 extracts, and 2. immunoprecipitation of each endogenous protein in A549 and H460 cell extracts. Western blot analysis was performed to evaluate interacting proteins. To determine whether phosphatase activity of SHP2 is required for these interactions, immunoprecipitation was also carried out in the presence of allosteric inhibitors of SHP2 (SHP-099 and RMC-0455). SHP2 ablation was carried out with CRISPR and siRNA to examine PD-L1 expression, also determined by western blot assay.
Results: His-tagged DDX3X from bacterial expression systems was able to capture SHP2 protein from both A549 cells and H460 cells, and vice versa with his-tagged SHP2. Immunoprecipitation of endogenous SHP2 was able to co-precipitate DDX3X and vice versa. Phosphatase activity of SHP2 was not required for complex formation nor does it change PD-L1 expression in A549 or H460 cells. Ablation of SHP2 leads to increased PD-L1 expression.
Conclusion: A complex containing SHP2 and DDX3X may regulate the translation of CD274 in concert with eukaryotic initiation factors. Other groups have previously reported the control of translation of CD274 mRNA carried out at the 3' UTR, and we believe this is novel evidence of a translation initiation complex monitoring the expression of CD274. Ribosome footprint and RNA immunoprecipitations are underway to address these questions.

Functional analysis of the role of RAP1GDS1 and RhoA in KRAS-driven lung adenocarcinoma

Marta Roman Moreno[1], Kaja Kostyrko[1], Kari Herrington[2], Michael Bassik[3], Peter Jackson[4], Alejandro Sweet-Cordero[1]. *[1]Pediatrics, UCSF - University of California San Francisco, San Francisco, CA,[2]Biochemistry and Biophysics Center for Advanced Light Microscopy, UCSF - University of California San Francisco, San Francisco, CA,[3]Genetics, Stanford*

University, Stanford, CA,[4]Baxter Laboratory for Stem Cell Biology, Stanford University, Stanford, CA

While KRAS is among the most frequently mutated oncogenes, our understanding of the mechanisms of KRAS-driven oncogenesis remains limited. A significant remaining gap is a lack of understanding of tissue-specific effectors of Ras activation and the role of specific KRAS mutations in determining downstream vulnerabilities. Previously, we used a combination of proteomics and CRISPR/Cas9 screens in human lung adenocarcinoma (LUAD) cells to identify a KRAS-specific vulnerability induced by the combined loss of RHOA and the long isoform of RAP1GDS1, suggesting a potentially novel approach for targeting KRAS-driven cancer. Here we use biochemical, proteomic, and genetic approaches to dissect the isoform-specific roles of RAP1GDS1 to elucidate its synthetic lethal interaction with RHOA in KRAS-driven LUAD.
We performed AP/MS in KRAS-mutant A549 cells using both the long (RAP1GDS1-607) and the short (RAP1GDS1-558) isoforms of RAP1GDS1 as bait to identify overlapping and isoform-specific RAP1GDS1 interactors. We enriched this analysis with orthologous datasets from DepMap, published protein-protein interaction (PPI) data and RAP1GDS1-specific prenylome. This comprehensive analysis identified a cluster of RAB GTPases, proteins involved in vesicular transport and lysosomal function, as specific interactors of RAP1GDS1-607. We subsequently used the proximity ligation assay (PLA) to confirm the direct interaction between RAP1GDS1-607 and two of the strongest interactors - RAB7A and RAB22A – according to the PPI data. We also depleted either or both RAP1GDS1 isoforms in cells expressing GFP-tagged RAB7A, RAB22A or KRAS and used live cell imaging to determine how loss of RAP1GDS1 changes their subcellular localization. We found that depletion of both RAP1GDS1 isoforms and, to a lesser extent, single loss of RAP1GDS1-607, significantly decreased KRAS localization at the plasma membrane. We also used PLA to confirm that RAP1GDS1-607 has a stronger interaction with KRAS compared to the short isoform. Moreover, we demonstrated that loss of the long RAP1GDS1 isoform significantly decreased the membrane localization levels of GTP-bound KRAS, compared to the control or RAP1GDS1-558 knock-down. Finally, to identify the molecular mechanism of R1G1/RhoA synthetic lethality with

KRAS, we performed a Genome Wide-CRISPR screen in R1G1-607 and RhoA knock-out cells. We identified the strongest hits and designed a focused CRISPR library of approximately 400 genes to screen a larger panel of KRAS-mutant LUAD cell lines (H23, A549 and H358). The aim is to identify other genes that are synthetic lethal in combination with RhoA or R1G1-607 loss and genes that could mediate the lethal effect of their combined loss.
In conclusion, these data demonstrate a specific role of the long RAP1GDS1 isoform in the membrane-localization and activation of KRAS, which supports its role as a potential therapeutic target for KRAS mutant tumors.

Malic enzyme 2 identified as metabolic target in triple-negative breast cancers with increased serine biosynthesis

Mark D. Slayton[1], Jin Heon Jeon[2], Abhinav Achreja[2], Zackariah A. Farah[1], Brisilda Nilaj[1], Yi-Hsien Eu[1], Alisa Lui[1], Mason Collard[1], Liwei Bao[1], Celina Kleer[3], Deepak Nagrath[2], Sofia D. Merajver[1]. *[1]Internal Medicine, University of Michigan, Ann Arbor, MI,[2]Engineering, University of Michigan, Ann Arbor, MI,[3]Pathology, University of Michigan, Ann Arbor, MI*

Background **& Hypothesis:** Triple-negative breast cancer (TNBC) is a difficult to treat and deadly form of breast cancer. Pyruvate is an essential intermediate component of cellular metabolism which cancerous cells, including breast cancer cells, rely upon. Importantly, pyruvate and phosphoenolpyruvate are important nodes in the glycolytic pathway that support serine synthesis, lactate production and the TCA cycle. As a result of this, inhibition of the metabolic enzymes which regulate pyruvate production is currently used for cancer therapy. Apart from the glycolytic pathway, malic enzyme 2 (ME2) contributes to pyruvate and NADPH production through the oxidation of malate. Therefore, ME2 is a critical pathway supporting multiple metabolic needs of TNBC. Here, we investigate TNBC cell lines and assess their reliance on ME2 to drive accelerated growth, and thus potentially making ME2 a therapeutic target in TNBC.

Methods: We investigated four TNBC lines (HCC1806, Hs578T, BT20, MDAMB468) with distinct serine synthesis activity assessed via western blotting of serine metabolism enzymes. To knockdown ME2 in TNBC cell lines, we used siRNA transient transfection and shRNA-encoding lentiviral vectors. The growth rates of TNBC cells were determined by cell counting in the BioTek BioSpa 8. Lastly, we used immunohistology to analyze the expression of ME2 and serine metabolic genes in a TNBC tumor microarray.
Results: Modulation of the serine synthesis pathway revealed an unexpected synergy between serine metabolism and ME2. Knockdown of ME2 reduced the expression of serine metabolism genes but did not affect the expression of ME1 or ME3. The proliferative rate of cells with elevated serine synthesis, BT20 and MDAMB468 - was significantly reduced under ME2 knockdown, while Hs578T and HCC1806 experienced a modest reduction. Immunohistologic staining of TNBC tumors corroborated the link between ME2 and serine metabolism.
Conclusions: We observed that TNBC cell lines with elevated, but not reduced, expression of serine synthesis genes were growth-inhibited in the absence of ME2. Our results indicate that ME2 is required for optimal growth in some forms of TNBC and may serve as a therapeutic target for the treatment of cancers with elevated serine biosynthesis. Ongoing studies are aimed at discerning additional biomarkers of sensitivity to ME2 inhibition in TNBC and other aggressive cancers.

Assessing clonal evolution of myeloid neoplasms by flow cytometry guided, cell-enriched next generation sequencing

Sarah Johnson, Keegan Vaughan, Alexis Kurmis, Zeni Alfonso, Nathan Riccitelli. *Navigate BioPharma Services, Carlsbad, CA*

Introduct**ion:** Genetic information is highly relevant to the classification and risk assessment of myeloid neoplasms, especially myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML). Next generation sequencing (NGS) is increasingly used to track mutations and monitor measurable residual disease, but with the increased data comes a need to distinguish driver mutations from potentially unrelated variants caused by age-related clonal hematopoiesis (ARCH) or clonal hematopoiesis of

indeterminant potential (CHIP). Herein, we evaluate a combined flow cytometry and NGS approach to identify oncogenic driver mutations within specific cell populations and increase variant accessibility by NGS.
Methods: Proof of cell enrichment methodology was performed with a cell line expressing CD34 (hallmark of myeloid blasts). The cell line was spiked into healthy donor PBMCs at defined levels to create samples with varied tumor percentage. Purchased AML patient samples were also analyzed. CD34 expression of samples was confirmed by flow cytometry prior to- and following enrichment by anti-CD34 magnetic cell sorting technology. Sequencing libraries were prepared using the Archer VariantPlex Core Myeloid kit and sequenced on Illumina MiSeqs. Mutations were characterized using Archer software. The association between NGS and flow cytometry data was assessed through mapping the VAF data to the tumor population determined by flow cytometry.
Results: Identified mutations in tested samples included known oncogenic mutations as well as mutations associated with ARCH/CHIP events. In a subset of samples, at least one mutation was identified at a VAF correlating to the tumor percentage determined by flow cytometry analysis; these mutations were enriched in the CD34+ cell fraction following magnetic cell sorting. Sequencing the enriched tumor fraction increased the VAF of these mutations, and simultaneously revealed additional tumor-associated mutations that were previously below the detection limit of the assay. Conversely, potential ARCH/CHIP mutations were present in both CD34+ and CD34- cell populations.
Conclusion: Using a combination of flow cytometry, magnetic cell sorting, and NGS, variants specific to the tumor fraction of samples were identified. For patient specimens, the presence of ARCH/CHIP mutations in both enriched and residual cell populations indicate these variants evolved prior to the emergence of true leukemic progenitor cells; the identification of the flow-matched mutations only in the enriched population indicates the key role of these changes in the disease progression. Together, flow cytometry and cell-enriched NGS have the potential to enhance detection of disease-driving mutations earlier, thus, could be used as novel approaches to identify and treat myeloid neoplasms early with existing therapies and/or support development of new investigational agents.

Identification of membrane-expressed CAPRIN-1 as a novel and universal cancer target and generation of a therapeutic anti-CAPRIN-1 antibody TRK-950

Fumiyoshi Okano[1], Takanori Saito[1], Yoshitaka Minamida[1], Shinichi Kobayashi[1], Takayoshi Ido[1], Yasushi Miyauchi[2], Ukei Wasai[1], Jiang Ke[3], Alexandra Aicher[4], Christopher Heeschen[5], Tetsu Yonehara[1]. *[1]New Frontiers Research Laboratories, Toray Industries, Inc., Kamakura, Japan,[2]Kamakura Techno–Science, Inc., Kamakura, Japan,[3]Center for Single-Cell Omics and Key Laboratory of Oncogenes and Related Genes, Shanghai Jiao Tong University School of Medicine, Shanghai, China,[4]Graduate Institute for Biomedical Sciences Precision Immunotherapy Group, China Medical University, Taichung City, Taiwan,[5]Pancreatic Cancer Heterogeneity, Candiolo Cancer Institute - FPO - IRCCS, Candiolo, Italy*

Specific targets for cancer treatment are highly desirable, but still remain to be discovered. While previous reports suggested that CAPRIN-1 localizes in the cytoplasm, here we now show that part of this molecule is strongly expressed on the cell membrane surface in most solid cancers, but not normal tissues. Notably, the membrane expression of CAPRIN-1 extended to the subset of highly tumorigenic cancer stem cells and EMT induced metastatic cancer cells. In addition, we revealed that cancer cells with particularly high CAPRIN-1 surface expression exhibited enhanced tumorigenicity. We generated a therapeutic humanized anti-CAPRIN-1 antibody (TRK-950), which strongly and specifically binds to various cancer cells and shows anti-tumor effects via engagement of immune cells. TRK-950 was further developed as a new cancer drug and a series of pre-clinical studies demonstrates its therapeutic potency in a tumor bearing mouse model and safety in a relevant cynomolgus monkey model. Together our data demonstrate that CAPRIN-1 is a novel and universal target for cancer therapies. A phase I clinical study of TRK-950 (NCT02990481) has been completed and a phase Ib study (combination with approved drugs) is currently underway (NCT03872947).

Cooperation between mutant IL7R and TLX3 generates mixed myeloid lymphoid leukemia from thymocyte progenitors

Gisele Rodrigues. *National Cancer Institute, Frederick, MD*

Acute lymphoblastic leukemia (ALL) is the most common cancer in children. Despite the current pediatric treatment protocols have resulted in 5-year overall survival rates of up to 90%, treatments have substantial side effects. Therefore, it is important to identify more specific therapeutic targets and develop more effective and less toxic drugs and drug combinations. We have shown that overexpression of TLX3 in association with mutant IL7R (mutIL7R) is sufficient to generate aggressive leukemia from transduced CD4-CD8- (DN) thymocyte progenitors. To better understand mutIL7R/TLX3-mouse leukemia, we combined single cell RNA sequencing (scRNAseq), Cellular Indexing of Transcriptomes and Epitopes by Sequencing (CITE-seq), DNA Next Generation Sequencing (NGS) Chromatin Immunoprecipitation Sequencing (ChIP-Seq) and flow cytometry to explore the cooperation of mutIL7R and TLX3 in orchestrating leukemogenesis. We found that mutIL-7R+TLX3 induced murine mixed T/myeloid leukemia. Myeloid cell clones (CD11b+) expressed identical TCR rearrangements as the T cell clones (CD8+), indicating that mutant IL-7R+TLX3 generated mixed leukemia from T cell progenitors. Moreover, the passaged leukemia lost the T-cell phenotype and acquired a pro-B-like phenotype, suggesting preferential expansion of pro-B cells (CD19+, B220+ IgM-), which were not detected in the founder leukemia presumably due to its low frequency. We next sought to determine whether the oncogene combination is sufficient to drive a similar immunophenotype profile *in vitro*. We showed that ectopic expression of mutIL7R and TLX3 in DN primary thymocytes growing on OP9-DL4 pushed the cells to myeloid (CD11b+, Gr1+) and B-cell (B220) phenotype over a time course of 4, 8 and 20 days, while T-cell development was blocked, suggesting that TLX3 expression prevented differentiation into CD4+/CD8+ T-cells. To better understand the genes regulated by TLX3 on driving a mixed phenotype leukemia we performed ChiP-seq of D1 cell line ectopically expressing mutIL7R and TLX3. We identified RUNX as a possible key mediator of the mixed-phenotype-leukemia induced by TLX3 in combination with mutIL7R. Additionally, scRNAseq showed upregulation of PU.1 in mice leukemia, suggesting PU.1 as a potential therapeutic target. To assess whether targeted therapy could successfully treat mutIL7R/TLX3-mouse leukemia, we treated mice that had been

injected with the thymocytes transduced with mutIL-7R+TLX3 genes. We found that PU.1 inhibition reduced spleen weights, indicating decreasing of leukemia engraftment. Taken together, we generated a high-resolution dataset with detailed information about the transcriptional landscape and immunophenotype of leukemia generated by mutIL-7R+TLX3, a combination that is observed in patient samples, and suggests new therapeutic drug strategies.

#3925

JunB regulates expression of HPV genes in head and neck cancer

Hina Rehmani, Travis P. Schrank, Natalia Issaeva, Wendell G. Yarbrough.
Otolaryngology, University of North Carolina at Chapel Hill, Chapel Hill, NC

The incidence of HPV-positive head and neck squamous cell carcinoma (HNSCC) is now being considered an epidemic in the US and Western Europe as rates have surpassed those for cervical cancer. For approximately 14,400 patients per year in the US, initial therapy is aggressive and often results in adverse lifelong side effects such as difficulty swallowing and speaking. Despite having a higher cure rate than HPV-negative HNSCC, the recurrence rate is still approximately 30%. Therefore, new treatment options need to be available for these relapsed patients. Our lab was prompted to explore demethylation as a therapeutic option as HPV-positive HNSCC have a more hypermethylated genome than HPV-negative cancers. 5-azacytidine (5-aza) is a synthetic cytidine analog that causes DNA demethylation by trapping methyltransferases to chromatin; it is FDA-approved for the treatment of myelodysplasia and acute myeloid leukemia. Our lab found that low doses of 5-aza delayed HPV-positive xenograft tumor growth and that HPV-positive tumor samples from patients treated with 5-aza in a window trial had increased apoptosis. They also observed a marked downregulation of HPV gene expression after 5-aza. Decreased HPV E6 expression, followed by reactivation of tumor suppressor p53, induced p53-dependent apoptosis in HPV-positive HNSCC. To further explore the mechanism of this sensitivity to 5-Aza, we first determined that 5-aza regulates the transcription of HPV genes, but not the stability of HPV transcripts. We found that the transcriptional regulation of HPV genes after 5-aza depends on the proto-oncogene JunB, a component of the

transcription factor Activator Protein 1 (AP-1). Additionally, silencing of JunB abolished the expression of HPV E6/E7 genes and reactivated tumor suppressor p53 in HPV-positive HNSCC. Furthermore, we revealed that clonogenic survival of HPV-positive head and neck cancer cells is dependent on JunB expression. Our study exposes an important component of 5-Aza-associated sensitivity and toxicity in HPV-positive HNSCC and identifies a novel dependency on JunB, potentially providing a new rational targeted therapy.

Activating missense mutations in ROS1 receptor harbor oncogenic potential and are sensitive to tyrosine kinase inhibition

Sudarshan R. Iyer[1], Kevin Nusser[1], Kristen Jones[1], Pushkar Shinde[2], Catherine Z. Beach[1], Clare Keddy[1], Erin Aguero[1], Jeremy Force[3], Ujwal Shinde[2], Monika A. Davare[1]. *[1]Pediatrics, Oregon Health and Science University, Portland, OR,[2]Chemical Physiology, Oregon Health and Science University, Portland, OR,[3]Duke University, Durham, NC*

ROS1 encodes the largest receptor tyrosine kinase (RTK) in the human genome. Chromosomal rearrangements of the *ROS1* gene generate oncogenic ROS1 fusion proteins that have been successfully targeted with tyrosine kinase inhibitors (TKIs), most notably in lung cancer. To date, ROS1 fusions are the only known biomarkers for therapeutic implementation of ROS1 TKIs. However, unlike known oncogenic mutations in EGFR and ALK RTKs, the functional impact of point mutations within the full-length ROS1 RTK is unknown. Here we queried the AACR Genie database, which consists of pan-cancer clinical genomic sequencing data from thousands of patient samples, for ROS1 aberrations and nominated thirty-four missense mutations residing in the ROS1 tyrosine kinase domain for functional interrogation. Immunoblotting revealed distinct impact of the mutations on kinase function, ranging from complete loss to significant increase in catalytic activity. Notably, Asp and Gly substitutions at the D2113 position within the ROS1 kinase domain dramatically increased autophosphorylation and activation of downstream signaling pathways. ROS1$^{D2113N/G}$ were found to be ROS1 TKI-sensitive transformative oncogenes in independent cell-based models. Molecular

dynamic simulations of ROS1^{D2113N} kinase revealed dramatic alterations in the activation loop of the mutant kinase as compared to wildtype. Global proteomics and phosphoproteomics showed that ROS1^{D2113N} upregulates signaling via phosphorylation of known effectors (SHP2 and STAT3) similar to ROS1 fusions, but also upregulates other pathways, including mTORC2, JNK1/2, AP-1 and TGFB1. *In vivo,* ROS1^{D2113N} drove tumor formation that was inhibited with ROS1 TKIs. Taken together, these data demonstrate for the first time that select point mutations within ROS1 drive tumorigenesis and can be therapeutically targetable with existing FDA-approved ROS1-TKIs.

Genome-wide screening and validation of molecular targets and biomarkers for lung cancer

Yataro Daigo, Atsushi Takano, Yusuke Nakamura. *Institute of Medical Science, The University of Tokyo, Tokyo, Japan*

The number of lung cancer patients who respond well to currently available standard therapies is still small, new molecular targeted therapies with companion diagnostics are eagerly needed. We have been developing new molecular therapies targeting oncoproteins with their cancer biomarkers as follows, i) To identify strongly expressed genes in 120 lung cancers by genome-wide gene expression profile analysis, ii) To verify the candidate genes for their scarce expression in 23 normal organs, iii) To validate the clinicopathological significance of their protein expression by tissue microarray covering about 400 lung cancers (non-small cell lung cancers (NSCLCs) and SCLCs), iv) To examine their importance in the growth and/or invasion of cancer cells by siRNA, small molecule inhibitor, cell permeable peptides targeting their function and/or antibody assays, and v) To analyze the oncogenic function of the target molecules. By this system, we identified 50 oncoproteins and selected a LSERT (lung cancer-specific receptor tyrosine kinase) as a candidate. Immunocytochemical and immunohistochemical analyses confirmed that LSERT protein was expressed in cytoplasm and cytoplasmic membrane of lung cancer cells, but it was hardly expressed in normal lung cells. Strong LSERT expression was associated with poorer prognosis for surgically-treated NSCLC patients, and it was an independent prognostic factor. Exogenous expression of

LSERT increased the cell growth and invasion probably through its elevated kinase activity and subsequent phosphorylation of downstream proteins. Inhibition of LSERT expression by siRNAs or treatment with anti-LSERT antibody suppressed the growth of lung cancer cells. Our genome-wide screening might be a useful approach to identify target molecules for developing new therapeutics and diagnostics. LSERT could be a candidate cancer biomarker and therapeutic target for lung cancer.

#3928

Therapeutic targeting of NOTCH1 and neddylation pathway in T cell acute lymphoblastic leukemia

Carla Bertulfo, Pablo Perez-Duran, Teresa Palomero, Adolfo Ferrando.
Columbia University Irving Medical Center, New York, NY

T-cell Acute Lymphoblastic Leukemia (T-ALL) is hematologic tumor characterized by the diffuse infiltration of the bone marrow by malignant hematopoietic cells expressing immature T cell markers. Although T-ALL currently has better cure rates primarily due to multiagent or intensified chemotherapy, the prognosis for patients who are resistant or develop relapse to therapy remains very poor. Aberrant Notch homolog-1 (NOTCH1) signaling is a major driver of T-ALL pathogenesis as more than 60% of T-ALL cases harbor activating mutations in the NOTCH1 gene. Gamma Secretase Inhibitors (GSIs) which effectively block the activation of oncogenic protein NOTCH1 are potential candidates for the treatment of T-ALL. However, the clinical application of GSIs is hampered by severe gastrointestinal toxicity due to the inhibition of NOTCH1 signaling in the gut. Here we demonstrate that combination therapy of GSIs and a small molecule inhibitor of the neddylation pathway circumvents the GSI-induced gut toxicity in vitro and in vivo. Genome-wide CRISPR loss-of-function screen in LS174T adenocarcinoma cells revealed neddylation pathway as a main regulator of massive goblet cell differentiation upon NOTCH1 inhibition. Genetic and pharmacologic inhibition of the neddylation pathway in LS174T cells rescued GSI-induced differentiation and cell death. Mechanistically, neddylation inhibition increases the protein stability of Hairy and enhancer of split-1 (HES1), a known regulator of absorptive and secretory cell fate decisions. Combination treatment of GSI and neddylation inhibitor in C57/BL6 mice showed a profound decrease in the

number of goblet cells and maintained HES1 protein levels in the intestinal epithelium compared to GSI treatment alone. Remarkably, combined treatment of GSI and neddylation inhibitor in NOTCH1-induced T-ALL mice showed leukemia regression and improved overall survival without any associated gut toxicity. Overall, these results substantiate the potential of targeting NOTCH1 and neddylation pathway in the treatment of NOTCH1-induced T-ALL.

#3929

MDMX overexpression in cancer cells confers significant resistance to MDMX inhibitor XI-006 and may modulate chemosensitivity through suppressing p53 activation of pro-apoptotic factors

Andrew George[1], Arielle De La Cruz[1], Shengliang Zhang[1], Ilyas Sahin[2], Praveen Srinivasan[1], Maximilian Schwermann[1], Morgan Turcotte[1], Taylor Arnoff[1], Wafik S. El-Deiry[1]. *[1]Legorreta Cancer Center, Brown University, Providence, RI,[2]Division of Hematology/Oncology, University of Florida, Gainesville, FL*

MDM2 inhibition has gained popularity in recent years as a therapeutic strategy in targeting both solid tumors and hematological malignancies, and several small molecule inhibitors of the p53-MDM2 binding interface have progressed into clinical trials in recent years. Alongside direct stabilization of p53, MDM2 has further been identified to have immune implications in terms of CD8+ T-cell mediated anti-tumor immunity and checkpoint-blockade therapies. However, little work has been done to explore the therapeutic targeting potential of related protein MDMX (MDM4). Pan-cancer analyses conducted by our lab (in part presented at the ASCO 2022 Annual Meeting) identify an important role of MDMX in several tumor types. Particularly, MDMX amplification is associated with a higher risk of brain and liver metastasis, and MDMX amplification itself also presents with significant frequency (10%) in glioblastoma multiforme (GBM). Notably, MDMX amplification also served as a better predictor of reduced overall survival in NSCLC following checkpoint-blockade. We have also previously reported on associations between MDMX amplification and CDKN2A deep deletions in melanoma, a predictor of favorable response to checkpoint blockade. Such findings establish the need for further exploration to be done and the role of MDMX both in cell phenotype and

potential immune regulation to be better characterized. Preliminary data acquired from transient overexpression experiments using lipofection of MDMX cDNA and MDMX inhibitor XI-006 (NSC207895) alone and in combination with chemotherapy further supports the viability of MDMX-inhibition as a therapeutic strategy in several cell lines. Overexpression of MDMX in HCT116 $p53^{WT}$ cells demonstrably confers remarkable resistance to MDMX inhibitor XI-006 at a 72-hour timepoint (IC50 of 104.75 uM in overexpressing cells versus 29.03 uM in WT), and treatment with oxaliplatin reveals both reduced basal and post-treatment expression of p53-upregulated modulator of apoptosis (PUMA). Further mechanistic workup of this phenomenon is underway, particularly with an emphasis on immuno-oncological therapeutic translations. Altogether, initial findings ultimately establish the need for further investigation into the mechanistic basis of MDMX-correlated clinical outcomes and the therapeutic potential of MDMX inhibition.

#3930

MCT1 as a potential target in the progression of oral premalignant dysplasia to invasive squamous cell carcinoma

Ethan J. Wong[1], Ali Khammanivong[1], Ravi Maisuria[2], Erin B. Dickerson[3], Raj Gopalakrishnan[2]. *[1]Veterinary Clinical Sciences, University of Minnesota, Saint Paul, MN,[2]Division of Oral and Maxillofacial Pathology, University of Minnesota, Minneapolis, MN,[3]University of Minnesota, Saint Paul, MN*

Introducti**on:** Most oral squamous cell carcinomas (OSCC) progress through clinically identifiable stages, starting from premalignant epithelial dysplasia to early invasive OSCC. How cells transform from premalignant dysplasia to early invasive OSCC is unknown. High monocarboxylate transporter 1 (MCT1; *SLC16A1*) expression is correlated with poor outcomes in OSCC patients, where it is thought to promote tumor growth by supporting metabolic coupling between cancer cells and tumor stroma. Because expression of MCT1 is markedly increased in OSCC patients, we sought to determine if MCT1 played a role in the progression of oral dysplasia in early invasive OSCC.

Methods: Immunohistochemistry (IHC) was used to evaluate changes in the levels of MCT1 expression across adjacent normal, dysplasia, and

OSCC tissues to identify expression patterns during cancer progression. Genetic knockout (KO) of *SLC16A1* via CRISPR/Cas9 and pharmacological blockade by the MCT1 inhibitor AZD3965 were used on OSCC (TR146) and dysplastic (DOK) cell lines. KO was confirmed by qRT-PCR and immunoblotting. MCT1-KO and AZD3965-treated cells were assayed for changes in cell invasion using Matrigel-coated transwell assays. Correlative changes in gene expression based on MCT1 staining and disease progression were also observed in adjacent normal, dysplasia, and OSCC regions in each tissue section using Nanostring GeoMx Digital Spatial Profiler.
Results: Expression of MCT1 was directly correlated to the progression of disease from dysplasia to early superficially invasive OSCC relative to normal adjacent epithelium. KO of MCT1 significantly decreased the invasion of dysplastic and OSCC cell lines compared to the wild-type (parental) controls. AZD3965 also decreased invasion in the parental dysplastic and OSCC lines. To identify progressive changes in gene expression across normal, dysplasia, and early invasive OSCC, transcripts for cancer-related genes were quantified in the epithelial and stromal compartments from patient samples. Compared to the normal epithelium, upregulation in gene expression, including *SLC16A1*, was observed in the cell cycle and metabolic pathways in OSCC tissues.
Conclusions: Our data suggest that MCT1 plays a key role in breaching of the basement membrane and facilitating tumor cell migration and invasion. Targeting MCT1 in oral dysplasia may prevent progression to OSCC in oral cancer patients.

BRD4, BRD3, NSD3, and ZNF532 fusions in histologies beyond NUT carcinomas: Investigation of a large pan-cancer cohort
Ian R. Nykaza[1], Christopher A. Febres-Aldana[2], Sabrina T. Lin[3], Ryma Benayed[2], Kerry Mullaney[3], Emiliano Cocco[4], Alexia Iasonos[3], Marc Ladanyi[5], Alexander E. Drilon[6], Yonina R. Murciano-Goroff[6]. *[1]Weill Cornell Medical College, New York, NY,[2]Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Epidemiology & Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY,[4]University of Miami Miller School of Medicine and Sylvester Comprehensive Cancer Center, University of Miami Miller School of*

Medicine, Miami, FL,[5]Department of Pathology, Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Weill Cornell Medical College and Memorial Sloan Kettering Cancer Center, New York, NY

Background**:** *NUT* rearrangements drive NUT carcinomas (NCs), which are rare, poorly differentiated tumors with a survival from diagnosis of ~6-7 months. Common NUT fusion partners (NCFPs) include *BRD4*, *BRD3*, *NSD3*, and *ZNF532*, which are associated with epigenetic changes leading to tumor growth. Recent clinical trials have aimed to address NCs, but little is known about fusions involving NCFPs in other histologies. We characterized NCFPs in a large, pan-cancer cohort.
Methods: The MSK-IMPACT (DNA sequencing; n=71,423) and MSK-Fusion (RNA sequencing; n=10,897) clinical cohorts were mined to identify patients (pts) with all forms of structural variants (SVs) involving NCFPs, detected between April, 2015 and June, 2022. The targeted NGS panels included *BRD4* and *NSD3* only; detection of *BRD3* and *ZNF532* SVs was possible for fusions with a partner present on either panel. SVs were manually reviewed to identify in-frame fusions with oncogenic potential if critical domains present in NC fusions were conserved. Pts were followed through July 2022 and manual chart review enabled assessment of treatment history and clinical outcomes.
Results: SVs involving NCFP genes were detected in 182 (*BRD4*=110, *NSD3*=61, *BRD3*=8 and *ZNF532*=3) pts (0.002%). Putative NCFP fusions not involving any of the NUT gene family members comprised a total of 20 fusions with likely oncogenic potential including 11 with *BRD4* (55%), 5 with *NSD3* (25%), 3 with *ZNF532* (15%), and 1 with *BRD3* (5%). *BRD4::NOTCH3* and *ZNF532::MALT1* were the most enriched fusions, present in 3 samples each. The most common histologies were breast (3 ductal; 1 lobular), lung (2 squamous cell carcinoma, 1 adenocarcinoma and 1 mixed histology), and colon and esophageal adenocarcinoma (2 samples each). Median age at diagnosis was 62. 11 (55%) pts were female and 9 (45%) were male. 13 (65%) pts ultimately were diagnosed with stage IV disease and had a median overall survival from stage IV diagnosis of 2.5 years (95% CI: 1.41, NR). DNA sequencing in 19/20 tumors revealed a mean tumor mutational burden (TMB) of 5.0 mut/Mb including 15 with low TMB (<10) and 3 with high TMB (>10). No tumor showed

microsatellite instability (MSI-high). *TP53* mutations were the most common co-alteration, found in 11 (58%) cases. 18/20 pts received systemic therapy; 18 (90%) received cytotoxic chemotherapy and/or mAb therapy, including 13 (65%) who received a platinum. 8 pts (40%) received immunotherapy (IO), and 4 (20%) received small molecule inhibitors. No pts received BET inhibitors. Among pts who received IO, median time to treatment discontinuation was 64 days (95% CI: 20, NR).
Conclusion: Tumor sequencing from a large cohort reveals potential oncogenic fusions involving *BRD4*, *BRD3*, *NSD3*, and *ZNF532* across multiple histologies. Further biological characterization of their oncogenicity and potential targetability is warranted.

#3932
Targeting cyclin K in pancreatic cancer
Yi Xiao, Jixin Dong, Yuanhong Chen. *University of Nebraska Medical Center, Omaha, NE*

This study focuses on investigating the role of Cyclin K in pancreatic cancer growth and chemotherapeutic sensitivity, aiming to provide pre-clinical evidence for Cyclin K-targeted therapy in pancreatic cancer. Unlike other well-known cyclins, Cyclin K is largely understudied in cancers. Data extracted from the TCGA database indicated that Cyclin K was overexpressed in pancreatic ductal adenocarcinoma (PDAC) and associated with reduced overall survival. Consistently, western blotting showed that Cyclin K was abundantly expressed in human and mouse PDAC cell lines. By using a Tet-On inducible system, we established Cyclin K-depleted and Cyclin K-overexpressed cell lines to evaluate the function of Cyclin K in pancreatic cancer. The proliferation assay showed that Cyclin K depletion led to retarded PDAC cell proliferation, whereas Cyclin K overexpression boosted cell growth. We further confirmed that Cyclin K was required for pancreatic cancer growth *in vivo*. In addition, cell cycle analysis showed that Cyclin K deficiency resulted in G1-S arrest, while Cyclin K overexpression promoted G1-S progression. By using an RT2 cell cycler array, we identified CDC20 as an important target of Cyclin K that mediated Cyclin K-induced PDAC cell proliferation. To investigate the influence of Cyclin K on chemo-sensitivity, we treated the PDAC cell lines with two newly synthesized Cyclin K molecular glue degraders (HQ461

and NCT02). We found that these degraders specifically ablated Cyclin K and its cognate kinase CDK12 in a very efficient manner. Importantly, we demonstrated that Cyclin K abrogation, either by Cyclin K degrader or Cyclin K knockdown, rendered PDAC cells more sensitive to GemTaxol (gemcitabine plus Taxol) treatment and PARP inhibitors (olaparib or niraparib), as indicated by increased cleavage of PARP or caspase 3. Together, our current results suggest: 1. Cyclin K promotes cell proliferation and G1-S transition in pancreatic cancer; 2. CDC20 mediates the function of Cyclin K on pancreatic cancer cell proliferation; 3. Cyclin K depletion synergizes with GemTaxol or PARP inhibitor in pancreatic cancer treatment. Our study revealed for the first time that Cyclin K plays an essential role in pancreatic cancer growth and chemo-sensitivity, and targeting Cyclin K may offer a great therapeutic avenue for pancreatic cancer patients.

RRM2 inhibition by COH29 is a potential therapeutic strategy for atypical teratoid rhabdoid tumors

Le Hien Giang, Tai-Tong Wong, Che-Chang Chang. *Taipei Medical University, Taipei, Taiwan*

Introduction: Atypical teratoid rhabdoid tumors (ATRT) are a rare but aggressive malignancy in central nervous system, commonly occurring in early childhood. ATRT patients face a dismal prognosis despite aggressive therapy. Development of both effective and protective targeted therapy is an emerging necessity. It has been reported that RRM2 is a master driver of aggressiveness and a poor prognosis biomarker in several cancers. However, little is known about RRM2 function in ATRT. The aim of this study is to assess the roles of RRM2 in ATRT and elucidate the therapeutic potential of RRM2 to cure the ATRT.
Methods: Expression of RRM2 was evaluated by molecular profiling analysis and was confirmed by IHC in both ATRT patients and PDX tissues. Follow-up *in vitro* studies used 3 different cell lines to elucidate the oncogenic role of RRM2 in ATRT cells. The efficacy of COH29, an RRM2 inhibitor, was assessed *in vitro*. ATRT model of SCID mice orthotopically injected with ATRT cells were used to test the efficiency of COH29 for *in*

vivo. Western blot and RNA-sequencing were used to determine the mechanisms of RRM2 transcriptional activation in ATRT.
Results: Molecular profiling results revealed that RRM2 was relatively highly expressed in ATRT tissues and cell lines. Clinical relevance analysis results showed that the RRM2 expression level was associated with poor prognosis among ATRT patients. Knockdown of RRM2 by shRNAs significantly reduced ATRT cells colonies formation, proliferation and migration. A similar but more pronounced inhibitory effect was observed when COH29 was used to target RMM2. Inhibition of RRM2 by shRNAs or COH29 significantly induced cell death via DNA damage and/or apoptosis pathways. *In vivo* results demonstrated that COH29 could suppressed ATRT tumor growth and extend mice overall survival.
Conclusion: Our study identified RRM2 as a potential mediator of oncogenic cellular functions in ATRT cell lines. We propose that highly expressed RRM2 is associated with poor patient outcomes, and inhibition of RRM2 by COH29 may present a significant therapeutic value in ATRT.

#3934

PRMT5 is an actionable target in CDK4/6 inhibitor-resistant ER+/Rb-deficient breast cancer

Chang-Ching Lin[1], Tsung-Cheng Chang[2], Yunguan Wang[3], Yanfeng Zhang[3], Andrew Lemoff[4], Yisheng V. Fang[5], He Zhang[3], Dan Ye[1], Isabel Soria-Bretones[6], Alberto Servetto[7], Kyung-min Lee[8], Xuemei Luo[4], Joseph J. Otto[4], Hiroaki Akamatsu[9], David W. Cescon[10], Lin Xu[3], Yang Xie[3], Joshua T. Mendell[2], Ariella B. Hanker[1], Carlos L. Arteaga[1]. *[1]Harold C. Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX,[2]Department of Molecular Biology, UT Southwestern Medical Center, Dallas, TX,[3]Department of Population & Data Sciences, UT Southwestern Medical Center, Dallas, TX,[4]Department of Biochemistry, UT Southwestern Medical Center, Dallas, TX,[5]Department of Pathology, UT Southwestern Medical Center, Dallas, TX,[6]Repare Therapeutics, Montreal, QC, Canada,[7]Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy,[8]Department of Life Science, Hanyang University, Seoul, Korea, Republic of,[9]Third Department of Internal Medicine, Wakayama Medical University, Wakayama, Japan,[10]Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada*

RB1 loss-of-function genomic alterations confer resistance to CDK4/6 inhibitors (CDK4/6i) and are enriched post treatment of CDK4/6i in estrogen receptor-positive (ER+) metastatic breast cancer. ER+/Rb-deficient breast cancer is a rising patient population in need of novel therapeutic strategies. Herein, we used a genome-wide CRISPR screen and identified protein arginine methyltransferase 5 (PRMT5) as a molecular vulnerability in this refractory breast cancer subtype. sgRNA-induced depletion of *PRMT5* arrested growth of MCF-7 and T47D *RB1* knockout (RBKO) cells. PRMT5 catalyzes symmetric dimethylation of arginine (SDMA). In RBKO cells carrying doxycycline-inducible shRNA targeting the 3'UTR of *PRMT5*, rescue with wild-type but not an enzymatically dead mutant of PRMT5 restored cell growth, supporting that PRMT5 methyltrasferase activity is essential for growth of these cells. Gene set enrichment analysis (GSEA) of RNA-seq data revealed significant downregulation of cell cycle-related Hallmark gene signatures in RBKO cells treated with *PRMT5* siRNA versus control siRNA. Both gene silencing and pharmacological blockade of PRMT5 with the small molecule inhibitor pemrametostat impeded G1-to-S cell cycle progression in MCF-7 and T47D RBKO cells and in lung, prostate, and triple-negative breast cancer cells with natural *RB1* mutations or deletions, suggesting that PRMT5 inhibition can block the G1-to-S transition even in the absence of Rb. To identify the protein interactome of PRMT5 and the mechanism by which it promotes cell cycle progression in Rb-deficient cells, we performed proteomics analysis of Co-IP mass spectrometry and an SDMA post-translational modification scan and pinpointed FUS (fused in sarcoma) as a putative downstream effector of PRMT5. FUS is known to regulate RNA polymerase II (Pol II)-mediated transcription. Inhibition of PRMT5 with pemrametostat significantly reduced SDMA levels on FUS and dissociated FUS from Pol II as evidenced by FUS Co-IP and immunoblot analysis. ChIP-seq analysis revealed that treatment of RBKO cells with pemrametostat derepressed phosphorylation of Ser2 in the C-terminus of Pol II at transcription start sites (*TSS*) of genes involved in cell cycle progression. In accordance with the abnormal accumulation of pSer2 Pol II at *TSS*, pemrametostat treatment also resulted in an increased Pol II pausing index and an enrichment of intron retention splicing variants. Finally, therapeutic inhibition of PRMT5 with pemrametostat synergized with fulvestrant (a selective ER degrader)

against growth of ER+/Rb-deficient breast cancer cell line- and patient-derived xenografts in mice, suggesting this combination as a novel therapeutic strategy for ER+/Rb-deficient metastatic breast cancers.

CRISPR/Cas9 screens to identify proliferation and resistance mechanisms in uveal melanoma

Richard L. Bennett[1], Darby Monagle[1], Katelyn R. Raburn Smith[1], Amin Sobh[1], Keiran S. M. Smalley[2], J. William Harbour[3], Jonathan D. Licht[1].
[1]University of Florida Health Cancer Center, Gainesville, FL,[2]Department of Tumor Biology, Moffitt Cancer Center and Research Institute, Tampa, FL,[3]Department of Ophthalmology, UT Southwestern Medical Center, Dallas, TX

Purpose: Uveal (ocular) melanoma (UM) is a highly aggressive and frequently fatal cancer of the eye. While only 2-4% of patients have metastases at diagnosis, up to 50% of develop metastatic disease, overwhelmingly to the liver. Almost all UM harbor an initiating mutation in the Gαq signaling pathway, most commonly in GNAQ. Most UM also contain secondary mutations that drive tumor progression, the most common being BAP1 loss. Targeted therapies such as MEK inhibitors have been utilized in UM, but tumors rapidly become refractory. The aims of this study were to identify novel mechanisms specifically activated in UM cells that drive proliferation and escape from MEK inhibitor therapy.
Procedures: We performed CRISPR-Cas9 mediated gene disruption screening of UM cell lines 92.1, Mel202 and Mel270 using the Brunello sgRNA library targeting the whole genome. Cells were transduced at 0.3 MOI and 500X coverage then split into two groups to compare treatment with the MEK inhibitor (MEKi) trametinib (6nM) vs. untreated control cells. Cell pellets were collected at day 2 (baseline) and after every 3 cell divisions for 21 cell divisions (treated and control). In addition, we generated 92.1 and Mel270 cell lines stably expressing Cas9 and transduced cells at 1000x coverage with a sgRNA library targeting either 192 epigenetic regulators or 482 kinases. At least two replicates for each screen were performed. sgRNA representation between samples was compared using MAGeCK. Genes specifically essential in UM cell lines were distinguished from commonly essential genes using the Broad institute

dependency map (DepMap). These hits were validated by individual sgRNAs and pharmacological inhibition.
Results: Whole genome screens revealed a set of 84 genetic dependencies unique for UM cells that were required for proliferation. Among these genes were those required for the lipoic acid biosynthesis pathway: MCAT, MECR, LIPT2, LIAS as well as genes encoding the MITF-SOX10-TFAP2 transcription factors, the H3K9 methyltransferase SETDB1, and members of the MLL3/4 complex. Screening of UM cell lines with a focused guide RNA library targeting epigenetic regulators revealed that BRD2, TRIM28, KMT2D, SETD1B and HDAC1 were specifically required for UM survival. Screens with a sgRNA library targeting the kinome revealed CDK2, CDK4 and TRRAP were required for UM survival. After 1 week of treatment with MEKi trametinib, we identified 112 genes whose disruption increased the anti-proliferative effects of trametinib in Mel202 and Mel270 cells and 10 of these genes were essential only in UM. These genes included metabolic enzymes critical for fatty and lipoic acid synthesis such as MECR, MCAT and TAZ. By contrast disruption of TP53, NF1, or PTEN led to MEKi resistance.
Conclusions: These results identify novel mechanisms of proliferation and therapy resistance specifically required in GNAQ mutant UM cells that may represent new therapeutic targets.

#3936
ALK fusion oncogene driven *SERPINB4* expression enhances tumor survival in NSCLC
Tzu-Po Chuang[1], Wei-Yun Lai[1], Jonatan L. Gabre[1], Dan E. Lind[1], Ganesh Umapathy[1], Abdulmalik A. Bokhari[1], Bengt Bergman[2], Linnea Kristenson[1], Fredrik B. Thorén[1], Anh Le[3], Robert Doebele[3], Jimmy V. D. Eynden[4], Ruth H. Palmer[1], Bengt Hallberg[1]. *[1]University of Gothenburg, Gothenburg, Sweden,[2]Sahlgrenska University Hospital, Gothenburg, Sweden,[3]University of Colorado School of Medicine, Aurora, CO,[4]Ghent University, Ghent, Belgium*

Anaplastic lymphoma kinase (ALK) fusion variants in non-small-cell-lung cancer (NSCLC) consist of numerous dimerising fusion partners, with the most common being EML4. Clinical data suggests that the degree of treatment benefit in response to ALK tyrosine kinase inhibitors (TKIs)

differs among the variant present in the patient tumor. Therefore, a better understanding the oncogenic signaling networks driven by different ALK-fusion variants is important. Here, we developed highly controlled doxycycline-inducible cell models bearing four different ALK fusion proteins, namely EML4-ALK-V1, EML4-ALK-V3, KIF5B-ALK, and TFG-ALK, in the context of non-tumorigenic NL20 human bronchial epithelial cells. These were complimented by patient-derived NSCLC cell lines harboring either EML4-ALK-V1 or EML4-ALK-V3 fusions. RNA-seq and phosphoproteomics analysis were employed to identify dysregulated genes and hyper/hypo-phosphorylated proteins associated with ALK fusion expression. Among ALK fusion induced responses, we noted a robust inflammatory signature that included up-regulation of the Serpin B4 serine protease inhibitor in both NL20-inducible cell models and ALK-positive NSCLC patient-derived cell lines. We show that STAT3 is a major transcriptional regulator of SERPINB4 downstream of ALK fusions, along with NF-kB and AP1. The upregulation of SERPINB4 promotes survival of ALK fusion expressing cells and inhibits natural killer (NK) cell-mediated cytotoxicity. In conclusion, our study reveals a novel ALK downstream survival axis that regulates Serpin B4 expression and identifies a molecular target that has potential for therapeutic impact targeting the immune response together with ALK TKIs in NSCLC.

An intracellular variant of zona pellucida glycoprotein 3 is expressed in cancer

Iman J. Schultz[1], Yvette Zimmerman[1], Cathy B. Moelans[2], Marcin Chrusciel[3], Jan Krijgh[1], Paul J. van Diest[2], Ilpo T. Huhtaniemi[4], Herjan J. T. Coelingh Bennink[1]. *[1]Pantarhei Bioscience B.V., Zeist, Netherlands,[2]University Medical Center Utrecht, Utrecht, Netherlands,[3]University of Turku, Turku, Finland,[4]Imperial College London, London, United Kingdom*

This study describes the expression of an intracellular variant of the Zona Pellucida glycoprotein 3 (ZP3) that is predominantly expressed in cancer. ZP3 is an important constituent of the Zona Pellucida (ZP), the extracellular layer surrounding oocytes. It is highly expressed in maturing oocytes, but not in other adult human tissues. As ZP3 protein has also been detected in

cancer, it may serve as an interesting diagnostic and therapeutic target. Here, we extend the cancer-related ZP3 expression data using immunohistochemistry (IHC) of tumor biopsies, interrogating publicly available RNA-sequencing (RNA-seq) data of cancer cell lines (CCLs) and tumor and normal tissues, as well as computational analysis and real-time quantitative PCR (qPCR) of CCLs. IHC data for several cancer types shows abundant ZP3 protein expression, which is confined to the cytoplasm, contradicting the extracellular ZP3 localization in oocytes. An alternative *ZP3* mRNA variant, which we term 'ZP3-Cancer', is annotated in the NCBI and Ensembl databases, and lacks the genetic information encoding the N-terminal signal peptide that governs extracellular secretion. Analysis of publicly available RNA-seq data of 1339 CCLs indicates that ZP3-Cancer is the dominant variant as compared to ZP3-Oocyte, which was validated by independent computational analysis. Expression of ZP3-Cancer in CCLs was confirmed by qPCR. Publicly available RNAseq data of tumor and normal tissues confirms strongly enhanced expression of ZP3-Cancer in cancer cells. In addition, ZP3-Cancer expression is upregulated in advanced stages and shows a relationship with patient survival in a number of cancer types. The folliculogenesis specific transcription factor FIGLA, which activates transcription of ZP3-Oocyte in maturing oocytes, appears absent in cancer as inferred from publicly available transcriptome data, indicating alternative ZP3-Cancer transcriptional activation mechanisms in this disease. The cancer restricted expression of this *ZP3* transcript variant renders it an attractive tumor specific antigen for the development of a therapeutic cancer vaccine, particularly using mRNA technology.

In vivo genome-wide CRISPR screen in pancreatic ductal adenocarcinoma defines HSPE1 as a potential oncogene by acting through G_2/M cell cycle arrest

Julien Boudreault, Ni Wang, Gang Yan, Meiou Dai, Sophie Poulet, Girija Daliah, Jean-Jacques Lebrun. *McGill University Health Centre Research Institute, Montreal, QC, Canada*

Superior knowledge of cancer biology has enabled unprecedented innovations in therapies targeting mutated driver genes. Despite the attempt of targeting cancer-inducing genes such as KRAS, the life expectancy of

patients diagnosed with pancreatic ductal adenocarcinoma (PDAC) has poorly improved. We performed an unbiased genome wide *in-vivo* loss-of-function CRISPR screen to discover novel oncogenes and identified heat-shock protein HSPE1, whose function is still unknown in PDAC. By decreasing HSPE1 expression with shRNA and CRISPR technology, we detected a slowdown in cell growth of PDAC cancer cells. HSPE1 knock-out cells injected in mice displayed a drastic reduction in tumor volume. We exploited this vulnerability by disrupting HSPE1 function by using KHS101, a validated HSPD1-HSPE1 complex inhibitor. Several PDAC cell lines cultured *in vitro* were sensitive upon KHS101 treatment and *in vivo* administration of KHS101 reduced tumorigenesis. Compiling the negative fitness scores from DepMap database revealed a co-dependency between HSPE1 and PLK1, a protein involved in regulating G_2/M checkpoint. Indeed, we detected a protein-level decrease of PLK1 in our experimental model of PDAC cells having either a drug-induced HSPE1 deficiency by KHS101 exposure or a HSPE1 gene-expression reduction by shRNA. We found that the cell cycle was disrupted through G_2/M arrest in PDAC cells treated with KHS101. Our findings highlight a new role underlying PDAC tumorigenesis for HSPE1 and could unlock a new area of research towards precision medicine.

#3939

Inhibition of USP7 upregulates USP22 through desuppression of transcriptional activity of Sp1 in human cancer cells

Keqiang Zhang, Ting Sun, Wendong Li, Jun Wu, Dan Raz. *City of Hope National Medical Center, Duarte, CA*

Deubiquitinases (DUBs) play important roles in various human cancers and targeting DUBs is considered as a novel anticancer therapeutic strategy. Overexpression of ubiquitin specific protease 7 and 22 (USP7 and USP22) are associated with malignancy, therapy resistance, and poor prognosis in many cancers. Although both DUBs are involved in the regulation of similar genes and signaling pathways, such as histone H2B monoubiquitination (H2Bub1), c-Myc, FOXP3, and P53, the interdependence of USP22 and USP7 expression has never been described. In the study, we found targeting USP7 via either siRNA-mediated knockdown or pharmaceutical inhibitors dramatically upregulates USP22 in

cancer cells. Mechanistically, the elevated USP22 occurs through a transcriptional pathway, possibly due to desuppression of the transcriptional activity of SP1 via promoting its degradation upon USP7 inhibition. Importantly, the elevated USP22 leads to significant activation of downstream signal pathways including H2Bub1 and c-Myc, which may potentially enhance cancer malignancy and counteract the anticancer efficacy of USP7 inhibition. Importantly, targeting USP7 further suppresses the *in vitro* proliferation of USP22-knockout (USP22-Ko) A549 and H1299 lung cancer cells and induces a stronger activation of P53 tumor suppressor signaling pathway. In addition, USP22-Ko cancer cells are more sensitive to a combination of cisplatin and USP7. USP7 inhibitor treatment further suppresses the *in vivo* angiogenesis and growth and induced more apoptosis in USP22-Ko cancer xenografts. Taken together, our findings demonstrate that USP7 inhibition can dramatically upregulate USP22 in cancer cells; and targeting USP7 and USP22 may represent a more effective approach for targeted cancer therapy, which warrants further study.

Validation of *TFX1*, a first-in-class target for cancer metastasis

Arnab Roy Chowdhury[1], Manoj Pandre[1], Chinmaya Amarkanth[1], Debabani Roy Chowdhury[1], John Ellingboe[2]. *[1]Mestastop Solutions, Bangalore, India,[2]Mestastop Inc., Marlton, NJ*

Most of the drugs approved for metastatic epithelial carcinomas treat the proliferation of the tumor and not the biology of metastasis. To date, all clinical trials around metastasis that focused on proteases, kinases, or integrins have failed in clinics. As a result, metastasis biology-focused drug discovery has been deprioritized.We asked the question as to what the rate-limiting steps of metastasis were. To answer it, we created a cell-based functional assay platform, METAssay™, that dissected all metastasis biology steps into thirty cellular assays and characterization steps. The platform identified the functional differences between metastatic and proliferating cells. This platform was normalized with patient tumor cells, and a machine learning algorithm, METSCAN™, was subsequently applied to identify the weighted steps that contributed towards successful metastasis. This led to the identification of four first-in-class targets; two transcription factors, one cytokine receptor and one nuclear hormone

receptor.We then validated the relevance of the first target, *TFX1,* by overexpressing it in both colorectal and triple-negative breast cancer cell lines. Interestingly, apart from the expected increase in migration and invasion, all cell lines showed an increase in ROS, Autophagy, PDL-1, CD-73, quiescence, exosome uptake and a decrease in apoptosis, mitosis, and exosome secretion. Conversely, the downregulation of *TFX1* showed the opposite effect. *TFX1* was purified, and a biochemical isothermal calorimetry (ITC) assay was standardized with a tool compound with a K_D of 107 nM. The compound effectively reduced metastatic properties in the cell lines and in multiple patient samples, as analyzed by the METAssay™ platform. Colorectal cancer cell lines overexpressing *TFX1* also showed increased platelet binding, which was reduced by the tool compound, but not triple-negative cancer cell lines. Also, the effect of overexpression in non-metastatic cells was more profound than in metastatic cells, suggesting a saturating effect. Further characterization of the tool compound is currently ongoing to help establish a baseline for a novel discovery programme.The ideal drug to delay metastasis should be given to primary tumor patients with no evidence of clinical metastasis, irrespective of their pathological grading. Therefore, it should have a high bar for safety. Our goal is to collaborate on a discovery journey to identify candidates and create a companion diagnostic that will identify primary tumor patients at high risk of metastasis, thereby selecting the right patient cohort for clinical trials.

Enzymatic nitration in oncology

Arun Kashyap, Sami Hussein, Sahar Mazar, Kate Markham, Anthony Mastracci, Ritu Sharma, Sheerin K. Shahidi-Latham, Irene Griswold-Prenner. *Nitrase Therapeutics, Inc., Brisbane, CA*

Background: We have discovered a new class of enzymes, that we name the nitrases, that catalyze the post-translation nitration of specific tyrosine residues of key proteins, several of which regulate important oncogenic pathways and are negatively prognostic in multiple cancer types.
Materials And Methods: To identify protein substrates for 31 candidate nitrases, we incubated each nitrase with a 23,000 protein chip in a nitrase assay containing peroxynitrite and using anti-nitrotyrosine antibodies to

detect the proteins that were nitrated. We then confirmed this nitration in separate biochemical assays and determined the specific site of nitration by LC-MS. Further, nitrases were evaluated in silico against TCGA gene expression and GISTIC copy number databases for specific cancer associations.
Results: We have discovered that several proteins known to regulate tumor cell survival and/or evasion of immune surveillance are specifically nitrated by different nitrases and that their biochemical activities are regulated by this nitration. Pak4, a protein that has been implicated as an oncogenic driver, as well as in immune evasion is specifically nitrated by Nitrase #3 and increases its kinase activity. Interestingly, Nitrase #3 also nitrates Pak5, but not any of the other Pak family members, demonstrating high enzymatic specificity. Targeted inhibition or degradation of nitrated Pak4 or inhibition of Nitrase #3 may have therapeutic potential in oncology. Similarly, RhoA, a protein implicated in the oncogenic state of tumors is nitrated by Nitrase #12. This nitration activates RhoA biochemically and in cells. Bax is a specific substrate for Nitrase #11. Nitration of Bax reduces the cytochrome C release from the mitochondria induced by Bax. For each of these enzymes, we will develop specific inhibitors to determine their therapeutic potential in tumorigenesis.
We further performed in silico analysis of nitrases for overall survival association in 17 cancer types. Utilizing TCGA RNA expression data and The Human Protein Atlas, nitrases were screened for association with overall survival in relation to nitrase RNA expression. Nitrases showing higher overall survival with low nitrase RNA expression and p. value <0.001 were identified as negatively prognostic. 10 nitrases showed negative prognostic association, suggesting that they could be favorable therapeutic targets. Three nitrases, N11, N12, N18, were negatively prognostic in renal clear cell carcinoma and nitrases N1 and N13 were negatively prognostic in liver cancer.
Conclusions: A new class of enzymes we discovered offers multiple opportunities for development of effective chemotherapeutic agents against a variety of oncogenic targets and in specific cancers that show negative association of high nitrase expression.

#3942

Differential expression of a novel transport receptor, SORT1 (sortilin), in cancer versus healthy tissues that can be utilized for targeted delivery of anti-cancer drugs

Guylaine Roy[1], Pratik Kadekar[1], Lynn Marie Douglas[1], Maude Frappier[1], Jean-Christophe Currie[1], Jess Dhillon[2], Gregory Cesarone[2], Richard Siderits[2], Karen Kirchner[2], Michel Demeule[1], Christian Marsolais[1].
[1]Theratechnologies Inc., Montreal, QC, Canada,[2]Discovery Life Sciences LLC, Newton, PA

Sortilin (SORT1), or neurotensin receptor-3, is a scavenging receptor in the Vacuolar Protein Sorting 10 protein (Vps10p) family. SORT1 is involved in the internalization and trafficking of its ligands through an endocytic process and is associated with cancer cell survival and progression, making SORT1 a candidate for novel drug delivery. We recently reported on the pattern and prevalence of SORT1 expression in endometrial, breast, ovarian, colorectal, pancreas cancers, and skin melanoma. To better understand SORT1 expression, we screened tissues from different cancer types using the same immunohistochemistry (IHC) method. A total of 19 cancer tissue microarrays (TMAs) with 1394 evaluable cancer cores were screened. Each cancer core was scored using an H-score ranging from 0 to 300, where 0 corresponds to no cell stained for SORT1, while 300 corresponds to strong SORT1 staining in all cells. The table below summarizes the % of cores with moderate to high SORT1 expression (defined as H-score ≥100) as well as the average H-Score for each cancer type evaluated. Sub-analyses of SORT1 expression by tumor histological sub-type, stage and grade are also being performed.

Cancer Type	**No. evaluable cores**	**% of indication with H-score ≥ 100**	**Average H-Score**
Endometrial	94	90	197
Thyroid	108	92	188
Melanoma	155	83	184
Lung	152	58	112
SCLC	*44*	*95*	*183*
NSCLC	*108*	*43*	*82*
Bladder	118	81	156

Testis	40	100	116
Small intestine	54	63	102
Eye	26	46	83
Cervix	376	38	75
Prostate	150	39	71
Liver	121	23	52

A total of 234 healthy or normal adjacent tissues cores were also assessed. Weak or null staining was observed in these tissues. Moderate staining was observed in specific cell types in kidney tubules and glomeruli, colonic mucosa, splenic sinusoidal spaces in red pulp, blood vessels in smooth muscle of spleen and colon, dendritic and axonal extensions of pyramidal-type neurons in brain, and testicular seminiferous tubules. SORT1 is currently being studied as a cancer target in a first-in-human (FIH) study of a peptide-drug conjugate (clinicaltrial.gov: NCT04706962). These results suggest that SORT1 is highly expressed in multiple tumors and is a promising target for the delivery and internalization of cancer therapeutic agents.

Identification of Molecular Targets 2 / New Nonclinical Models for Targets

Radiolabeled αvβ3 analog ^{177}Lu-EB-RGD is an effective therapeutic agent in thyroid cancer xenograft mouse model

Sonam Kumari[1], Zhantong Wang[1], Shilpa Thakur[1], Laura Abaandou[1], Oksana Gavrilova[1], Huiyan Lu[1], Lixin Lang[1], Dale Kiesewetter[1], Vasyl Vasko[2], Joanna Klubo-Gwiezdzinska[1]. *[1]National Institutes of Health, Bethesda, MD,[2]Uniformed Services University of the Health Sciences, Bethesda, MD*

Background: Integrins are cell adhesion receptors consisting of 18α and 8β subunits. A subset of integrins (αvβ3) recognizes Arg-Gly-Asp (RGD) peptide motifs which are involved in the neovascularization and progression

of various cancers. The aim of the study was to investigate if αvβ3 can serve as a molecular target for the treatment of thyroid cancer (TC) with a novel radiolabeled RGD analog ^{177}Lu-EB-RGD.
Methods: Integrin αvβ3 mRNA and/or protein expression was evaluated in 496 TC included in The Cancer Genome Atlas, tissue microarray including 70 TC and 10 normal thyroid samples, and 14 TC cell lines. *BRAF*-like or *RAS*-like expression profile was determined through standard BRS scores ranging from -1 to 0 for *BRAF*-like and 0 to 1 for *RAS*-like TC. The association between BRS and the αvβ3 expression was tested by the Spearman correlation (r). Nude mice xenografts developing αvβ3 expressing TC after subcutaneous injection of 5*10^6 TC cells were subjected to monotherapy with 0.5 mCi ^{177}Lu-EB-RGD (^{177}Lu) or in combination with Lenvatinib (^{177}Lu+L). The therapeutic efficacy of ^{177}Lu-EB-RGD was compared with standard-of-care Lenvatinib alone (L) and placebo (P). The continuous data were presented as medians with [25-75% interquartile ranges] and compared using Kruskal-Wallis test. The mixed-effects models were used for longitudinal data analysis with adjusted $p \leq 0.05$ considered statistically significant.
Results: We found a moderate negative correlation between BRS and αv ($r=-0.5$, $p<0.001$), and β3 ($r=-0.27$, $p<0.001$), revealing that *BRAF*-like tumors have a higher mRNA expression of αvβ3 integrins. Consistently, the highest αvβ3 mRNA and/or protein expression was found in the *BRAF*-like TC cell lines OCUT2 (BRS=-0.56), TPC1 (BRS=-0.4), K1 (BRS=-0.29), and Hurthle TC cell line XTC1 (BRS=-0.46). The immunostaining revealed a higher αvβ3 expression in papillary TC compared with follicular TC ($p=0.002$), and in normal thyroid ($p<0.001$). Poorly differentiated TC had a similar αvβ3 expression to papillary TC ($p=0.14$). In the thyroid cancer xenograft mouse model, all treatment modalities were more effective than the placebo in decreasing tumor size as early as 5 days after therapy initiation. A significant difference in growth curve and tumor volume was maintained at the study endpoint (L 0.584 cm^3 [0.196-0.984] vs P 0.911 cm^3 [0.183-1.68], $p=0.001$; ^{177}Lu 0.259 cm^3 [0.103-0.376] vs P, $p<0.001$; and ^{177}Lu+L 0.274 cm^3 [0.108-0.406] vs P, $p<0.001$). The combination therapy (^{177}Lu+L) resulted in decreased tumor volume as compared with monotherapy with Lenvatinib ($p=0.05$) but had a similar effect as compared with ^{177}Lu-EB-RGD monotherapy ($p=0.99$).

Conclusions: The radiolabeled αvβ3 analog ^{177}Lu-EB-RGD has potent growth inhibitory effects in TC characterized by a high integrins expression. The αvβ3 integrin could potentially serve as a molecular target for therapy with radiolabeled RGD analogs in TC.

#3947

S100A8/A9-RAGE pathway and chronic airway inflammation in cigarette smoke-induced lung carcinogenesis

Hye Seon Kang[1], In Kyoung Kim[2], Chang Dong Yeo[3], Jin Woo Kim[4], Sang Haak Lee[3]. *[1]Bucheon St. Mary's Hospital, The Catholic University of Korea, Bucheon, Korea, Republic of,[2]Cancer Research Institute, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[3]Eunpyeong St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of,[4]Uijeongbu St. Mary's Hospital, The Catholic University of Korea, Uijeongbu, Korea, Republic of*

Background**:** Cigarette smoke-induced chronic airway inflammation increases the risk of lung cancer, and plays a multifaceted role in lung cancer initiation and progression, and RAGE-ligand axis (HMGB1, S100A8/A9) contributes Cigarette smoke-induced persistent and progressive inflammation. The aim of the present study was to determine the inflammatory effect on S100A8/A9-RAGE pathway in smoke-induced carcinogenesis in lung cancer.
Methods: Human alveolar adenocarcinoma cells (A549) and normal bronchial epithelial cells (BEAS-2B) were co-cultured for 24 h with the PBMC and then, cells were incubated in the presence or absence of 1.5% cigarette smoke extract (CSE) for 24 h. The cells transfected with siRNA targeting S100A8/9 or RAGE. The cell viability, colony-forming ability, migration, invasion, metastasis and morphological changes were assessed. Female A/J mice were given a benzo(a)pyrene (100mg/kg) in 0.1 ml corn oil via oral gavage at once a week for 3 weeks, and administrated CSE (1.25 ul/g) via intratracheal (IT) at twice a week for 4 weeks. Tumor load was determined by averaging the total tumor volume in each group. BAL differential cells were counted to analyze inflammatory cells.
Results: Cellular growth and colony-forming were promoted by exposure to CSE, and significantly inhibited by S100A8/9 and RAGE-siRNA transfection, especially in A549 cells than BEAS-2B. Cell migration,

invasion, MMP-2/9 activities, and the mRNA and protein expression of TLR4, NF-κB, RAGE, S100A8/9 and HMBG1 were higher in CSE exposed A549 cells. S100A8/9 and RAGE-siRNA transfection attenuated those expression, significantly. B(a)P induced an average tumor volume 7.28 mm^3 per mouse, and CSE significantly increased tumor volume (8.10 mm^3) compared to the B(a)P group. The total cell number and lymphocytes in BAL fluids tended to increase after CSE administration in lung cancer mouse group. Moreover, CSE significantly induced the levels of S100A8/9 and RAGE, p38 and p-ERK, and decreased JNK in serum and tumors with adjacent lung tissues ($p < 0.05$).
Conclusions: We identified cigarette smoke-induced S100A8/A9-RAGE pathway promoted airway inflammation and lung carcinogenesis *in vitro* and *in vivo*. Although S100A8/A9 protein contributes to many types of disease, this study will help us gain a better understanding of the complexities of cancer progression. Further studies are needed for therapeutic target of cigarette smoke-induced inflammation and immunosuppression in tumor microenviornment.

DDX5 helicase resolves G-quadruplex and transactivates MYC expression
Guanhui Wu, Zheng Xing, Luying Chen, Elizabeth J. Tran, Danzhou Yang.
Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN

DDX5 (DEAD-box protein 5) plays an important role in cell proliferation, differentiation, and tumorigenesis. DDX5 is a founding member of the DEAD-box RNA helicase family and known as a non-processive RNA helicase. It acts as a transcriptional co-activator of many cancer-associated genes, such as *MYC,* however, the underlying molecular mechanism is unknown. *MYC* is one of the most critical oncogenes and has a DNA G-quadruplex in its proximal promoter region (MycG4) that functions as transcriptional silencer. Guanine-rich DNA and RNA sequences can form G-quadruplex, a non-canonical secondary structure. However, MycG4 is highly stable and its regulatory role in transcription requires active unfolding. Here, we report that DDX5 unfolds MycG4 with extreme efficiency, and thereby transactivates *MYC* expression. To understand the

effects of DDX5 on MycG4, we characterized the unfolding of MycG4-DNA within the DDX5-MycG4 complex using DNA footprinting, FRET and CD spectroscopy. While DDX5 is known as a dsRNA helicase, our results showed that DDX5 is a highly active DNA G4-resolvase. Strikingly, MycG4 unfolding requires neither ATP hydrolysis nor extended loading of single-stranded flanking. Our protein-binding-ELISA experiments revealed specific and high-affinity binding of DDX5 to G4 structures regardless of whether the substrate is DNA or RNA. To elucidate the cellular functions of DDX5, we analyzed publicly available DDX5 ChIP-seq data and identified G-rich sequences in cancer cells as chromatin binding sites of DDX5. Moreover, our ChIP and Western Blot results showed that DDX5 is enriched at the *MYC* promoter and activates *MYC* transcription. Importantly, G-quadruplex interactive small molecules can inhibit the DDX5 interaction with the promoter MycG4 and DDX5-mediated transcriptional activation of the *MYC* gene. In addition, knock-down of DDX5 expression with DDX5-specific siRNA in cancer cells resulted in downregulation of *MYC* expression and sensitization to G4-interactive small molecules. In summary, we identified resolving DNA and RNA G-quadruplexes as novel function of DDX5. Our results establish that the *MYC*-transactivation by DDX5 is mediated through unfolding of the *MYC* promoter quadruplex and thereby establish a new molecular target to suppress *MYC* for cancer intervention.

CYR61, a member of the CCN protein family, regulates IGF-1 in metastatic prostate cancer

Greisha L. Ortiz-Hernandez[1], Mya Walker[2], Leanne Woods-Burnham[3], Rick A. Kittles[4], Carlos A. Casiano[5], Susan L. Neuhausen[1]. *[1]Population Sciences, City of Hope National Medical Center, Duarte, CA,[2]Diabetes and Cancer Metabolism, City of Hope National Medical Center, Duarte, CA,[3]Physiology, Morehouse School of Medicine, Atlanta, GA,[4]Community Health and Preventive Medicine, Morehouse School of Medicine, Atlanta, GA,[5]Center for Health Disparities and Molecular Medicine, Loma Linda University School of Medicine, Loma Linda, CA*

The cysteine-rich angiogenic inducer 61 (CYR61) is a member of the cellular communication network (CCN) protein family that can be induced

by growth factors. CYR61-specific functions are dependent on cellular context. In prostate cancer (PCa), CYR61 contributes to cell growth and survival through its interactions with extracellular ligands, such as integrins avb3 and a6b4, in the extracellular matrix space. Interestingly, CYR61 contains an insulin-like growth factor-binding protein domain suggesting that it may interact with insulin-like growth factor-I (IGF-1). High serum levels of IGF-1 are directly linked to PCa development and recently have been studied as a predictor of metastatic disease. Given the important roles that IGF-1 and CYR61 play in PCa and their potential interaction, it is critical to investigate their molecular interplay. This study is designated to specifically determine and characterize the molecular interaction between CYR61 and IGF-1 in metastatic PCa and to determine if this interaction contributes to aggressive tumor properties (e.g., proliferation, tumorsphere formation). Using immunoblotting, we demonstrated that CYR61 is upregulated in the metastatic cell line PC3 and downregulated in the docetaxel-resistant cell line PC3-DR. Furthermore, optimized knockdown of CYR61 using siRNA significantly reduced PC3 cell proliferation, viability, and prostasphere formation. To examine the underlying mechanisms associated with IGF-1 signaling, we assessed the activation of either the PI3/Akt and MAPK pathways in PC3 cells with CYR61 silencing. CYR61 siRNA-mediated knockdown decreased activation of the PI3/Akt pathway but did not affect the MAPK pathway. We also initiated studies to determine the co-localization of CYR61 and IGF-1 using immunofluorescence microscopy (IF). Based on the initial IF observations, we will proceed to examine if their interaction is primarily intra- or extra-cellular. For intracellular interactions, we will co-immunoprecipitate CYR61 with IGF-1 and for extracellular interactions, we will use the AVidity-based EXtracellular Interaction Screen (AVEXIS) system. Our goal is to establish the contribution of CYR61-IGF1 protein-protein interaction to PCa cell proliferation. Specifically, the correlation between PCa aggressiveness and circulating levels of CYR61 and IGF-1 is poorly studied. Their combined role may explain a proportion of aggressive PCa.

Sensitizing oncogenic mutant p53-expressing non-small cell lung cancer to proteasome inhibitors

Kranthi Kumar Chougoni[1], Victoria L. Neely[2], Boxiao Ding[1], Eziafa Oduah[2], Khanh Nguyen[2], Bin Hu[2], Jennifer Koblinski[2], Bradford Windle[2], Hisashi Harada[2], Steven Grossman[1]. *[1]University of Southern California, Los Angeles, CA,[2]Virginia Commonwealth University, Richmond, VA*

Background: Lung cancer is the leading cause of cancer deaths worldwide, with non-small cell lung cancer (NSCLC) accounting for ~80% of all lung cancers. Up to 69% of NSCLC are mutated for the tumor suppressor gene *TP53,* and of these, 84% are missense mutations, where wild-type (WT) *TP53* tumor suppressor function is lost and in most cases, emergent cancer-promoting oncogenic activities are acquired. Due to the poor draggability of mutated p53 protein, the focus of therapeutics targeting NSCLC tumors with oncogenic missense mutant p53 has been on vulnerabilities that are not present in normal cells expressing WT p53. One such vulnerability involves oncogenic mutant p53-dependent attenuation of the oxidative stress response. The ability of cancer cells to survive oxidative stress depends on the regulated synthesis and activity of cellular antioxidants, including glutathione (GSH). Proteasome inhibitors (PIs) are known to induce cellular stress at multiple levels, including proteotoxic, autophagic, and oxidative stress, but the clinical utility of PIs has been limited by lack of efficacy in patients with solid tumors, including unselected lung cancer patients. Methods and Results: We now show bortezomib (BTZ) and other PIs are preferentially cytotoxic in oncogenic mutant p53-expressing lung cancer cells in culture. Furthermore, BTZ-treated oncogenic mutant p53-expressing cells display elevated levels of reactive oxygen species and BTZ's cytotoxic effects were rescued by antioxidants such as N-acetyl cysteine, indicating that oxidative stress is the critical driver of BTZ cytotoxicity. Upon BTZ treatment of oncogenic mutant p53-expressing NSCLC cells, but not in WT p53 expressing NSCLC cells, we also observed the transcriptional induction of pro-apoptotic BH3-only BCL-2 family protein NOXA, consistent with an apoptotic mechanism of BTZ-induced cell death. Furthermore, in combination with BTZ, the use of BH3-mimetics such as venetoclax (ABT-199) or navitoclax (ABT-263) to inhibit the function of pro-survival proteins BCL-2/BCL-X_L synergistically enhanced BTZ cytotoxicity, but only in oncogenic mutant p53-expressing NSCLC cells. *In vivo* mouse xenograft studies demonstrated that combination treatments of BTZ + venetoclax or BTZ + carboplatin (a

standard of care chemotherapy for NSCLC) significantly attenuated oncogenic mutant p53-expressing tumor growth.
Conclusions: Our data suggest that the preferential cytotoxicity of BTZ, and potentially other PIs, in oncogenic mutant p53-expressing NSCLC cells depends on the induction of toxic oxidative stress leading to NOXA-dependent apoptosis. Thus, combining PIs with drugs that limit antioxidant responses and/or sensitize cells to NOXA-induced apoptosis (e.g., BH3-mimetics) should synergistically and selectively kill NSCLC cells expressing oncogenic mutant p53 and open novel therapeutic avenues for the treatment of NSCLC.

Unprecedented forward genetic screens reveal mechanisms of action, drug resistances, and hidden efficacies at amino acid resolution: combination of 5-ALA and Artesunate as a treatment option for glioblastoma multiforme

Michael Orthofer[1], Jasmin Taubenschmid-Stowers[2], Marianna Rozsova[1], Anna Laemmerer[3], Daniela Loetsch[3], Johannes Gojo[3], Andreas Peyrl[3], Walter Berger[3], Ullrich Elling[4], Moritz Horn[1], Josef M. Penninger[5]. *[1]JLP Health GmbH, Vienna, Austria,[2]Altos Labs Cambridge Institute, Cambridge, United Kingdom,[3]Medical University Vienna, Vienna, Austria,[4]Institute of Molecular Biotechnology, Vienna, Austria,[5]Life Sciences Institute, UBC, Vancouver, BC, Canada*

Forward genetic screens have revolutionized the field of target discovery, target deconvolution, and target validation, particularly in the cancer field. However, most approaches are limited to the interrogation of non-essential factors and identify gene networks rather than direct target structures. Inspired from work in the nematode *C. elegans,* we perform forward genetic screens based on chemical mutagenesis. This approach randomly introduces single nucleotide variants into the entire genome resulting in cell populations which carry substitutions in statistically more than 90% of all amino acids. Challenging such mutagenized cell populations with a drug candidate of interest, followed by next generation sequencing and analysis, reveals drug resistance mechanism, direct drug target interactions, and potential concealed efficacies. The alteration of single amino acids thereby allows interrogation of non-essential as well as most essential factors and

increases screening resolution to the amino acid level. From such screens we inferred and tested a novel treatment option for glioblastoma multiforme. The natural compound Artemisinin and its derivative Artesunate are widely used anti-malarial drugs. Based on theircytotoxic activity, they are also tested as anti-cancer therapies, while the definite mechanism of action and critical host cell targets have remained largely elusive. Using forward genetic screening approaches, we demonstrate that porphyrin biosynthesis governs Artemisinin's cytotoxicity. Genetic or pharmacological modulation of porphyrin production is sufficient to alter Artemisinin cytotoxicity in multiple eukaryotic cells, including human cancer cells. Combining Artesunate with 5-ALA treatment we translated the screening results to clinically relevant model systems of brain tumor development, such as glioblastomas in engineered cerebral organoids, patient-derived brain tumor spheroids, and orthotopic xenograft models. 5-ALA is a clinically approved photodynamic porphyrin enhancer and surgical fluorescence marker, which specifically marks tumorigenic brain areas. With this additional level of selectivity, we demonstrate a strong antineoplastic effect of the 5-ALA-Artesunatecombination in all tested model systems. These findings extend to the triple combination with temozolomide and urgently await further testing in clinical setups.

Preclinical anti-tumor effects of MDM4/MDMX inhibitor XI-006 in breast cancer and prostate cancer cell lines mediated through reduced tumor cell migration

Arielle De La Cruz[1], Andrew George[1], Payton De La Cruz[1], Maximilian P. Pinho-Schwermann[1], Kimberly S. Meza[1], Taylor Arnoff[1], Ilyas Sahin[2], Stephanie L. Graff[1], Benedito A. Carneiro[1], Wafik S. El-Deiry[1]. *[1]Brown University, Providence, RI,[2]University of Florida, Gainesville, FL*

MDM2 and MDM4/MDMX have emerged as potential mediators of tumor progression, organ-specific metastasis, and hyper-progression after immune checkpoint blockade therapy. While there are currently a number of MDM2 inhibitors in clinical trials, we found no pure MDM4/MDMX inhibitors under clinical investigation. Because hormone-resistant cancers pose a significant challenge for clinical intervention, the identification of translatable novel therapeutic targets remains an important goal. Analysis of

triple-negative breast cancer (TNBC) and castration-resistant prostate cancer (CRPC) reveals overexpression of p53 negative regulator MDM4/MDMX as a frequent alteration in these cancers. There is an urgent need to study and target MDM4/MDMX in cancer therapy and this may ultimately include dual MDM2 and MDM4/MDMX inhibitors. However, it is clear that MDM4/MDMX is a primary oncogenic driver that requires specific therapeutic targeting. As metastasis is often observed clinically in patients diagnosed with breast and prostate cancer, we sought to expand our understanding of the metastasis reduction potential of a previously described preclinical MDM4/MDMX inhibitor, a 4-nitrobenzofuroxan derivative, XI-006 (NSC207895). In a scratch assay using breast and prostate cancer cell lines, increasing doses of XI-006 decreased tumor cell migration in a time and dose-dependent manner, demonstrating the benefit of MDMX inhibition in preventing the induction of tumor cell migration. The exact mechanism of this result remains unclear, and further investigation is needed to elucidate the impact of XI-006 on TNBC and CRPC cell proliferation and migration. Our future directions include identifying the synergistic potential of combining MDM4/MDMX inhibitor XI-006 with other cancer therapies, assessing the impact of XI-006 on immune responses in co-culture studies, and testing therapeutic efficacy *in vivo*.

Evaluation of long mononucleotide repeat markers for detection of microsatellite instability

Suping Chen[1], John H. Lin[1], Aparna Pallavajjala[1], Tamara L. Lotan[1], Jeffery W. Bacher[2], James R. Eshleman[1]. *[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Promega Corporation, Madison, WI*

Microsatellite instability (MSI) and mismatch repair immunohistochemistry are biomarkers of defective MMR (dMMR) that predict response to immune checkpoint inhibitor therapy in solid tumors. The microsatellites in the Promega MSI Analysis System Version 1.2 may not be ideal to detect MSI in certain cancer types. Long mononucleotide repeat (LMR) markers may improve detection of microsatellite instability in early colorectal lesions and non-colorectal cancers.In this study, we compared the performance of the current gold standard, MSI Analysis System Version 1.2

(Promega), which consists of 5 mononucleotide repeat markers (21-27 bases), with a new LMR kit (Promega), which consists of 4 markers from the MSI V1.2 panel and 4 LMR loci (52-60 bases). We studied five cohorts including 24 MMR proficient (pMMR) and 24 dMMR colorectal cancer (CRC) samples, 24 pMMR and 42 dMMR endometrial cancer (EC) samples, 12 dMMR prostate cancer (PC) samples, 22 MSI-high (MSI-H) samples of other cancer types, and 12 MSI-low (MSI-L) samples, where MMR status was confirmed by immunohistochemical (IHC) staining and/or MSI Analysis System Version 1.2.The specificity and sensitivity of the LMR MSI panel for dMMR detection were both 100% in CRC. The specificity of the MSI V1.2 and LMR MSI panels in EC was both 100%, and the sensitivity was 88% versus 98%, respectively. The 22 MSI-high (MSI-H) samples of other cancer types, these include cholangiocarcinoma, appendix, duodenal, pancreatic and gastric cancer, which were previously classified as MSI-H by using the MSI V1.2 panel were also classified as MSI-H by using the LMR MSI panel. Among 12 samples that were previously classified as MSI-L by the MSI V1.2 panel, 9 of the samples were classified as MSI-L, and 3 of the samples were diagnosed as MSI-H using the MSI LMR panel. The LMR panel has performed well on 80 samples over the past 6 months.The LMR MSI panel is highly concordant with the MSI V1.2 panel for dMMR detection in colorectal cancer and showed increased sensitivity in endometrial cancer. The LMR MSI panel showed improved dMMR detection in non-colorectal cancers.

Functional evaluation of pancreatic cancer prognostic marker, LXN, utilizing multiomics analysis based on patient-derived cancer model

Chan Hee Park, Hee Seung Lee, Jin Su Kim, Yoo Keung Tae, Jin Young Lee, Seungmin Bang. *Yonsei University College of Medicine, Seoul, Korea, Republic of*

Background: Pancreatic cancer is the most dreadful malignant tumor and expected becoming the second cause of death in 2030. Despites of vigorous studies, there were no definitive prognostic biomoleculars marker for pancreatic cancer. Herein, we already established primary pancreatic cancer cell lines from the real patients of pancreatic cancer, using conditionally reprogrammed cell culture (CRC). We tried to find novel prognostic

biomarkers with multi-omics analysis of our primary pancreatic cancer cell lines.
Methods: In this study, we selected pancreatic cancer prognostic markers using established CRCs and FFPE samples and validated the molecular mechanism of LXN. As the first step, we performed both transcriptome and proteome analysis using RNA sequencing and liquid chromatography-tandem mass spectrometry (LC/MS-MS) with 6 primary pancreatic cancer cell lines established by CRC. After analysis, we mined several candidate markers of prognosis including latexin (LXN) and sialic acid acetylesterease (SIAE). And we validated these markers clinicopathologically using immunohistochemical (IHC) staining of 136 tissues from a different set of pancreatic cancer patients. And we confirmed the knock-down effect of LXN using siLXN in pancreatic cancer cells.
Results: We selected 2 highly prognostic markers with LXN and SIAE after transcriptome and proteome analysis. In these genes, high LXN expression group showed longer median overall survival (OS) than low expression group, respectively (14.8 vs. 10.4 months, *P*-value=0.28), respectively. For the evaluation of IHC, we established 3D organoid model using CRCs and confirmed the correlation between mRNA expression and protein expression with western blotting and IHC. The expression of Akt/mTOR was decreased after siLXN treatment compared to control groups. In order to validation as a prognostic marker, we stained formalin-fixed, paraffin-embedded (FFPE) slide from 136 pancreatic cancer patients. After IHC analysis, LXN high group (H-score > 12) showed significantly longer OS than low LXN group (52 vs. 28 months, *P*-value = 0.043).
Conclusion: In this study, we found LXN as a prognostic marker with inhibition of proliferation utilizing patient-derived cancer model and FFPE samples.

#3956
Identifying PIKfyve as potential target in clear cell renal cell carcinoma with a loss of the von Hippel-Lindau tumor suppressor gene
Nadia Bouhamdani, Sandra Turcotte. *Université de Moncton, Moncton, NB, Canada*

Background**.** Clear cell renal cell carcinoma (ccRCC) is the most frequent type of cancer in the kidney. These tumors are highly vascular and correlate

with poor prognosis. Biallelic inactivation of the von Hippel-Lindau (VHL) tumor suppressor gene is a truncal event of ccRCC carcinogenesis, which yields new insights for targeted therapy. Our studies identified a small molecule, STF-62247, that is toxic to cells lacking VHL compared to RCC with a functional gene. We reported that STF-62247 blocks late stages of autophagy by targeting lysosome dynamics. Moreover, we identified lysosomal vulnerability in VHL-mutated ccRCCs, which could lead cells to death.
Goal. This study aims to recognize and characterize STF-62247 potential targets.
Results. Using biochemical approaches, our results indicated that STF-62247 cytotoxicity is driven by PIKfyve inhibition. Binding affinity between PIKfyve and STF-62247 is around 5 nM. Intracytoplasmic vacuoles and enlargement of endolysosomes were observed, which was prevented by adding exogenous $PI(3,5)P_2$. Moreover, PIKfyve inhibitors such as apilimod, YM201636, Vacuolin-1, APY0201 sensitize ccRCC with a loss of VHL. Finally, genetic knockdown of PIKfyve was achieved by CRISPR/Cas9 leading VHL-inactivated cells to death.
Conclusion. Altogether, our studies identified, for the first time, PIKfyve as potential target for kidney cancer cells with a loss of VHL.

#3957
Anticancer effect of novel 1,4-benzodiazepine derivatives through tubulin polymerization inhibition
Alzbeta Srovnalova[1], Jiri Rehulka[1], Sona Gurska[1], Pavel Polyshchuk[1], Sergey Bachinsky[2], Petr Dzubak[1], Marian Hajduch[1]. *[1]Palacky Univ. Faculty of Medicine, Olomouc, Czech Republic,[2]A.V. Bogatsky Physico-Chemical Institute of NAS of Ukraine, Odessa, Ukraine*

Benzodiazepines are well known as a key scaffold in medicinal chemistry, providing bioactive compounds for a wide variety of biological targets. Among their primary use as anxiolytics and sedatives, the 1,4-benzodiazepine derivatives and their metabolites play a role as antitumor, antithrombotic, antiviral and antimalarial agents. Recent studies revealed the influence of the benzodiazepine derivatives on microtubule assembly or stability with subsequent mitotic failure. These microtubule-targeting effects were evaluated in novel benzodiazepine derivatives. The

antiproliferative activities of novel derivatives were tested against a panel of 10 cancer cell lines and 2 non-cancer cell lines. The compounds with IC50<10 μM were further analyzed for the cell cycle. Flow cytometry and fluorescent cell cycle indicator (FUCCI) assays were performed to evaluate the effects of derivatives on the cell cycle phases. The immunofluorescence alpha-tubulin assay and tubulin polymerization assay were accomplished to detect the changes in the mitosis. Implementation of molecular docking revealed the specific binding site of the derivatives. All tested derivatives reveal the G2/M block in the cell cycle and 3 of them were identified as M-phase blockers. The immunofluorescence alpha-tubulin assay detected the disruption of the cellular microtubule network, and the tubulin polymerization assay uncovered the potential of the tested compounds to inhibit tubulin polymerization. Molecular docking confirms that benzodiazepine derivatives fit the colchicine site best and are partially overlaid with the native colchicine binding pose. This suggests that these compounds may adapt to the tubulin binding site in a conformation induced by colchicine The inhibition of tubulin polymerization by novel derivatives is one of their possible mechanisms of action on antiproliferative effect on cancer cell lines. More rigorous studies will be performed further to establish pose stability and explain structure-activity relationships. This work was supported by European Union - Programme EXCELES, ID Project No. LX22NPO5102, the Czech Ministry of Education, Youth and Sports (CZ-OPENSCREEN - LM2018130, EATRIS-CZ - LM2018133), and by the internal grant of Palacky University Olomouc (IGA_LF_2022_033) and European Regional Development Fund - Project ENOCH (No. CZ.02.1.01/0.0/0.0/16_019/0000868).

Transcriptome analysis of Small Cell Osteosarcoma reveals an embryonic stem cell-like phenotype

Maria Antonella Laginestra[1], Alessandro Parra[1], Elisa Simonetti[1], Laura Formentini[1], Michela Pasello[1], Alberto Righi[2], Davide Maria Donati[3], Cristina Ferrari[1], Laura Pazzaglia[1], Katia Scotlandi[1]. *[1]Experimental Oncology Laboratory, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy,[2]Department of Pathology, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy,[3]Third Orthopaedic Clinic and Traumatology, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy*

Introducti**on:** Small round cell osteosarcoma (SCOS) is a very rare type of osteosarcoma, composed by small cells producing bone matrix, with limited studies that mainly focus on histological features. In this study we employed RNA sequencing to discover the transcriptional profile of SCOS in order to find a specific gene signatures useful to find new potential therapeutic targets. To date, the tumor is treated according to the osteosarcoma protocols.

Material and Methods: We studied 15 primary tumor including 6 SCOS and 9 high grade Osteosarcoma (OS) by RNASeq . Pair-end libraries were synthesized using TruSeq RNA Library Prep Kit for Enrichment and loaded on NextSeq 500 platform (Illumina). After FastqQC quality control, fastq data were aligned to Homo_sapiens GRCh38 with STAR algorithm and counted by featureCounts. In Addition we randomly selected 30 muscle-skeletal normal tissues from 800 available samples from Genotype-Tissue Expression repository (GTEX). Using surrogate variables to remove batch effects and other unwanted variations, we performed differentially expression analysis employing DESeq2 (R package). We considered as differentially expressed genes those BH adj p-value <0.01 and absolute $|\log_2 FC|=2$. We then performed preranked Gene set Enrichment analysis (GSEA) for biological function assessment

Results: To elucidate the transcriptome landscape of SCOS we first performed differential gene expression analysis between SCOS and normal tissue identifying 5061 deregulated genes (2516 up-regulated and 2545 down-regulated in SCOS). Then, from this signature we filtered out the signature differentially expressed between OS and normal tissue, obtaining a specific SCOS signature of 1371 genes (1013 up-regulated and 358 down-regulated). To study the biological function behind SCOS we performed GSEA and we found that SCOS gene signature resulted enriched in epigenetics mechanisms as well as in embryonic stem cell (ES) gene sets. In particular, we found the overexpression of *EZH2, ASXL1, HDAC9, MYCN, MYB* genes involved in Polycomb group complex. This on one side confirms the highly undifferentiated nature of this tumor that could explain the more aggressive behaviour of SCOS in comparison to OS; on the other side, offers in epigenetic drugs a new therapeutic perspective. Validation studies are in progress.

Conclusions: This work firstly profiled the transcriptome of SCOS and identifies new pathways that can be of interest for diagnostic and/or therapeutic purposes.

Novel spliced isoform of the proteasome subunit ADRM1/Rpn13 promotes hepatocellular carcinoma (HCC) development through selective degradation of tumor suppressor p53
Yanmei Sun, Mingjing Xu, Ho Lee Wan, Alissa M. Wong, Kelvin K. C. Ng, Nathalie Wong. *Faculty of Medicine, Department of Surgery, Sir Y.K. Pao Centre for Cancer, Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, NT, Hong Kong*

The Ubiquitin-Proteasome System (UPS) is the major pathway in eukaryotic cells that regulates intracellular protein degradation and turnover. Cumulative evidence has suggested that defects in the UPS machinery are involved in the pathogenesis of human diseases, including cancer. The proteasome-associated polyubiquitin receptor ADRM1 (also known as Rpn13) orchestrates the process of substrate recruitment with deubiquitination in the proteasome through its N-terminal ubiquitin-binding domain and C-terminal activation of deubiquitinating enzyme. Using long-read SMRT-seq to profile the RNA splicing landscape in hepatocellular carcinoma (HCC), we previously reported on an unannotated alternative spliced variant of ADRM1 in human hepatocellular carcinoma (HCC) (*Hepatology 2019*). This novel isoform exhibits an exon 9 skipping (ADRM1-ΔEx9) that resulted in an altered C-terminus of the protein. In this study, we undertook further investigations to characterize the detailed functional effects of ADRM1-ΔEx9 in HCC biology and the underlying mechanism. Initial study by junction-specific Taqman PCR assay showed that ADRM1-ΔEx9 is more frequently upregulated in HCC tumors than the canonical full-length counterpart (ADRM1-FL). There is an interchange between the two isoforms as tumor develops which underscores an isoform-switch in favor of HCC development. Indeed, our result showed that ADRM1-ΔEx9, but not ADRM1-FL, correlated significantly with inferior patient survival. Functionally, ADRM1-ΔEx9 knockdown profoundly

suppressed proliferation by inducing spontaneous apoptosis in HCC cell lines and patient-derived HCC organoids. The corresponding effects were less apparent from ADRM1-FL knockdown. Consistently, overexpression of ADRM1-ΔEx9 in normal human liver organoids promoted pre-malignant features alongside increased in-vitro propagation time. Ubiquitin Proteome profiling revealed that ADRM1-ΔEx9 led to a reduced expression of the pivotal tumor suppressor p53. A parallel transcriptome also substantiated that ADRM1-ΔEx9 modulated genes involved in the p53 and apoptosis pathways. Collectively, our study demonstrated that the non-canonical spliced isoform ADRM1-ΔEx9 confers growth and pro-survival advantages in HCC through mediating selective degradation of tumor suppressor p53 protein.

Therapeutic targeting of HIF-1 alpha induced CD73 expression in experimental esophageal adenocarcinoma

Md Sazzad Hassan[1], Aktar Ali[2], Saisantosh Ponna[3], Dimitri Scofield[4], Niranjan Awasthi[1], Mark Jantz[5], Urs von Holzen[1]. *[1]Department of Surgery, Indiana University School of Medicine - South Bend, South Bend, IN,[2]Warren Family Center for Drug Discovery, University of Notre Dame, South Bend, IN,[3]Department of Chemistry, University of Notre Dame, South Bend, IN,[4]Indiana University (South Bend, IN), South Bend, IN,[5]Department of Biology, University of Notre Dame, South Bend, IN*

Introduction: Esophageal adenocarcinoma (EAC) is one of the most aggressive human cancers with poor prognosis, and the overall 5-year survival rate is less than 20 percent. Prognosis for EAC remains poor even with modern combination therapies due to high resistance to chemotherapy. Therefore, new therapeutic approaches for EAC treatment improvements are urgently needed. Hypoxia or insufficient tissue oxygenation contributes to cancer aggressiveness and poor clinical prognosis. Overexpression of hypoxia-inducible factor 1-alpha (HIF-1 alpha) and immunosuppressive CD73, an ecto-5'-nucleotidase enzyme in cancer can give rise to tumor progression with drug resistance. CD73 has never been proposed as a therapeutic target in EAC and its relationship with hypoxia or HIF-1 alpha has not also been investigated in EAC. In this study, we therefore

investigated the therapeutic targeting of HIF-1 alpha and CD73 by acriflavine in experimental EAC.
Methods: Hypoxia in EAC cells were induced by 3D culture and hypoxic exposure. NanoCulture® plates and dishes were used for 3D cultures. For hypoxic exposure, cells were placed in a sealed modular incubator chamber flushed with a gas mixture containing 1% O2, 5% CO2 and 94% N2. Hypoxic status was detected by adding hypoxia probe LOX-1 and fluorescent microscopy. Nanoparticle albumin-bound paclitaxel (NPT) was used as chemotherapeutic agent, whereas acriflavine was used as hypoxia-targeting agent. In vitro cell growth was detected by WST-1 and Cell Titer-Glo (CTG) luminescent assays, in vivo tumor growth was detected by measuring subcutaneous xenografts, apoptosis was detected by cleaved caspase 3/PARP expressions and hypoxia-targeting was detected by HIF-1 alpha/CD73 expressions.
Results: We observed overexpression of both HIF-1 alpha and CD73 in 3D culture and hypoxic exposure of EAC cells. Interestingly acriflavine treatment drastically inhibited both HIF-1 alpha and CD73 expression in EAC 3D culture and hypoxic exposure. 3D culture was more resistant to antiproliferative effect of chemotherapeutic agent NPT over 2D monolayer culture. Contrary to that, hypoxia-targeting agent acriflavine showed stronger antiproliferative effects in 3D culture than in 2D culture. We also observed hypoxia inside the 3D culture spheroids. In addition, acriflavine showed significant in vivo antitumor efficacy both as monotherapy and in combination with NPT. In subcutaneous xenografts using OE19 EAC cells, acriflavine monotherapy exhibited a significant decrease in relative tumor volume to 55.02% compared to control ($p=0.04$) and addition of NPT with acriflavine also showed a significant enhancement effect of tumor regression as tumor size decreased to 32.70% compared to control ($p=0.002$).
Conclusion: These results support the potential of acriflavine as HIF-1 alpha and CD73 targeting and its combination with chemotherapy NPT as an effective option for EAC therapy.

Identification of lncRNAs as potential novel therapeutic targets in triple negative breast cancer

Megan O'Malley[1], Zohaib Rana[2], Debina Sarkar[1], Jolyn Chia[1], Sarah Diermeier[1]. *[1]Department of Biochemistry, University of Otago, Dunedin, New Zealand,[2]University of Otago, Dunedin, New Zealand*

Triple negative breast cancer (TNBC) lacks targeted therapies. Recently, our laboratory and other groups described long non-coding RNAs (lncRNAs) as new drivers of TNBC progression, which represent an exciting new avenue for targeted treatments. LncRNAs are the most versatile and diverse class of non-coding RNAs with roles in the progression of TNBC development, including cell proliferation, differentiation, apoptosis, metastasis and drug resistance. LncRNAs have greater tissue-specific expression compared to proteins and can be targeted using nucleotide sequence-specific RNA therapeutics, leading to reduced systemic toxicities when used as a cancer target. Using a combined approach of computational analysis of patient data and CRISPR functional screening, we identified hundreds of lncRNAs as novel drivers of TNBC. We prioritized one lncRNA target (*lncTNBC3*) with high translational potential. *LncTNBC3* knockdown lead to reduced TNBC cell proliferation in two different loss-of-function models. To gain initial insights into the mechanism via which *lncTNBC3* functions, RNA sequencing was carried out on knockdown cells, revealing that *lncTNBC3* impacts cell cycle and DNA repair pathways. Cell cycle analysis confirmed an increase in G2/M cell cycle arrest upon *lncTNBC3* knockdown. In conclusion, we have identified a promising novel lncRNA target with a role in TNBC growth.

Development of selection-free HER4-mutated CRISPR/Cas9 knock-ins in cutaneous melanoma cell lines

Marta Valenti[1], Yonglun Luo[2], Neil T. Conlon[1], Lisa D. Eli[3], Alvin Wong[3], John Crown[4], Denis M. Collins[1]. *[1]National Institute of Cellular Biotechnology, Dublin City University, Dublin, Ireland,[2]Department of Biomedicine, Aarhus University, Aarhus, Denmark,[3]Puma Biotechnology, Los Angeles, CA,[4]St. Vincent's University Hospital, Dublin, Ireland*

Background: Cutaneous melanoma showed the highest HER4 genomic alteration frequency (17.34%) across 33 different cancer types (cBioPortal). HER4 is a tyrosine kinase receptor belonging to the human epidermal growth factor receptor (HER/ErbB) family. The role of HER4 in cancer has not been fully studied, potentially due to its complex biology (four isoforms, different stability/tissue-specific expression patterns, and oncogenic/tumor suppressor roles). Using computational analysis, we identified two potentially oncogenic HER4 mutations in melanoma (HER4 R106C and R711C). We then developed CRISPR/Cas9-modified selection-free melanoma cell lines for interrogating the role of these mutations as biomarkers of response to the oral, irreversible pan-HER (EGFR, HER2, HER4) tyrosine kinase inhibitor (TKI) neratinib (NER).
Methods: Two melanoma cell lines (WM115, SKMEL24) were genome-edited by using a selection-free CRISPR/Cas9 approach. Single guide RNAs (sgRNAs) were designed by using the CRISPRon (v1.0) web tool, and Homology Directed Repair (HDR) single-stranded OligoDeoxyriboNucleotides (ssODNs), containing the HER4 mutations, were designed with the SnapGene Software (v6.1.1). The RNP complex (Cas9 and sgRNAs) and the HDR_ssODNs, for each HER4 mutation, were delivered into the melanoma cells through electroporation. Upon validation of the CRISPR/Cas9-efficiency via PCR and Sanger Sequencing, the CRISPR/Cas9-modified cells were single-cell sorted via FACS, by using two singlets gating (FSC-A/FSC-H and SSC-A/SSC-H) and a live/dead (propidium iodide) gating, to perform single-cell cloning. Colonies were then amplified and screened via PCR and Sanger sequencing to isolate pure selection-free HER4 CRISPR/Cas9 knock-ins clones of melanoma cells.
Results: The WM115 and SKMEL24 melanoma cell lines were found to be wild-type for the HER4 receptor in the Depmap Portal (mutation 22Q2, 2022 data release 2). R106C and R711C CRISPR/Cas9 knock-ins were created in the melanoma cell lines three days after the electroporation of the CRISPR/Cas9 complex. The efficiency of the HER4 R106C CRISPR/Cas9 knock-in was 22% and 7% in the SKMEL24 and WM115 melanoma cells, respectively, with a respective total indel percentage of 76% (SKMEL24) and 55% (WM115). The HER4 R711C CRISPR/Cas9 knock-in efficiency was 15% in the SKMEL24 (with 26% total indels) and 1% in the WM115 (with 33% total indels). Single-cell colonies of the HER4 CRISPR/Cas9-

mediated knock-ins (HER4 R106C and R711C), were formed at four days (SKMEL24) and at one week (WM115) after single-cell sorting.
Conclusions: CRISPR/Cas9 technology can be utilised to introduce single-point mutations in HER4 to melanoma cell lines. *In vitro* functional characterisation of the isolated HER4 CRISPR/Cas9-edited melanoma cell lines will be performed in order to understand the activating potential of HER4 R106C and R711C and their sensitivity to NER.

Mass spectrometry reveals a downregulation of calreticulin after neoadjuvant chemotherapy in pancreatic cancer

Michael C. Stoffel, Elisabeth BH Dingendorf, Dahlia L. Kittel, Glen Kristiansen, Tristan Lerbs. *Institute of Pathology, University of Bonn, Bonn, Germany*

Introduction: Pancreatic ductal adenocarcinomas are one of the deadliest cancer types with limited response to current therapies. Thus, this study examined changes in the proteome of epithelial cells in pancreatic cancer after neoadjuvant chemotherapy with gemcitabine, to identify new therapeutic targets.
Methods: Upon receiving patient consent, fresh pancreatic cancer tissue was received from surgical tumor resections at the University Hospital of Bonn. We mechanically and enzymatically digested and purified the tissue to create single-cell suspensions. After staining the cells against CD45 und CD326, we purified epithelial cells, blood cells, and stroma through FACS. To analyze their proteome, the sorted cells were lysed in TEAB buffer and the protein lysates were measured by the mass spectrometry core facility at the University of Bonn. We then analyzed the data using DAVID and Shiny GO.
Results: Gene enrichment analyses showed a significantly reduced expression of calreticulin after neoadjuvant chemotherapy in epithelial cells. A direct comparison between untreated and treated epithelium cancer cells using a heat map showed a decreased expression of actin and enzymes of glycolysis in treated cancer cells. Moreover, untreated epithelial cells showed an increase of proteins related to MHC class Ib protein complex assembly and antigen processing and presentation of endogenous peptide antigen via MHC class. In contrast, treated cells showed a higher presence

of proteins for nutrient supply from the blood. Furthermore, untreated stroma cells exhibited an increased number of proteins responsible for mesenchymal migration and for actin filament fragmentation.
Conclusion: This study shows that neoadjuvant chemotherapy with gemcitabine leads to distinct changes in the proteome of tumor cells in pancreatic cancers. In particular, a decreased expression of the “eat-me-signal” calreticulin impairs macrophage-mediated cancer cell phagocytosis, thereby indicating a mechanism by which cancer cells protect themselves after chemotherapy.

#3964

APE1 protects SMAD3 against ROC1 ubiquitin mediated degradation in esophageal adenocarcinoma cells

Farah Ballout, Heng Lu, Dunfa Peng, Wael El-Rifai. *University of Miami Miller School of Medicine, Miami, FL*

Background: The incidence of esophageal adenocarcinoma (EAC) has increased more than six-fold over the past three decades and continues to rise in the Western world. The 5-year survival rate for EAC patients is less than 20% which underscores the need to better understand the underlying mechanisms to identify new therapeutic approaches. This study aimed at investigating the potential role of APE1 in regulating SMAD3 and promoting EAC progression.
Methods and Results: Western blot data showed that APE1 and SMAD3 were highly expressed in EAC cell lines. APE1 silencing reduced SMAD3 nuclear expression and downregulated its downstream targets SERPINE1 and c-myc. These results were confirmed by immunofluorescence staining showing loss of nuclear accumulation of SMAD3 after APE1 knockdown. Mechanistically, immunoprecipitation and proximity ligation assays revealed a direct binding between APE1 and SMAD3 in the nucleus. Further investigation showed that APE1 binds to the C-terminal MH2 domain of SMAD3, and this binding protects SMAD3 from ubiquitin mediated proteasomal degradation by blocking its interaction with the RING finger protein, ROC1. Interestingly, APE1-redox-specific inhibition (APX2009) downregulated SMAD3 expression and the APE1 redox-deficient mutant (C65A) disrupted APE1-SMAD3 binding indicating that this regulation depends on APE1 redox activity.

Conclusion: Our findings establish a role of APE1 in regulating SMAD3 in EAC. These findings provide a potential therapeutic approach for the treatment of EAC by the pharmacological inhibition of APE1.

#3965

KIFC1 is a therapeutic target in lung cancers with extra centrosomes

Christopher Z. Zhang[1], Benson Z. Wu[1], Yin Fang Wu[1], Caterina di Ciano-Oliveira[1], Ju-Yoon Yoon[1], Tak W. Mak[2], David W. Cescon[2], Kelsie L. Thu[1]. *[1]Keenan Research Centre, St. Michael's Hospital, Toronto, ON, Canada,[2]University Health Network, Toronto, ON, Canada*

Introducti**on:** Lung cancer is a deadly malignancy and new treatments targeting mechanisms promoting its growth and progression are needed. Genomic instability (GIN) is a recurrent feature of lung tumours that promotes drug resistance and other cancer hallmarks. One mechanism that enables tumour-promoting GIN is centrosome amplification (CA). Centrosomes are organelles involved in chromosome segregation during cell division and two centrosomes in a bipolar arrangement normally ensure equal division of the genome during mitosis. CA, an abnormal increase in centrosome number, is frequently observed in lung and other cancers despite the fact that it can cause lethal multipolar mitotic spindles that potentiate aneuploidy. To mitigate detrimental consequences of CA, cancer cells can cluster extra centrosomes into pseudo-bipolar mitotic spindles. This process is facilitated by a protein called KIFC1 which is upregulated in a large proportion of lung cancers. However, KIFC1's potential as a therapeutic target in lung cancers with CA has not been explored. Here we investigate the hypothesis that lung cancers with CA are dependent on KIFC1 and sensitive to its inhibition.

Methods: Western blotting for KIFC1 and immunofluorescence (IF) for the centrosomal protein, CEP192, were used to measure basal expression and CA, respectively, across a panel of 21 lung adenocarcinoma (LUAD) and 3 non-malignant (NM) cell lines. KIFC1 loss-of-function (LOF) in H1299 and PC9 (LUAD), and BEAS-2B (NM) was achieved using CRISPR/Cas9 and siRNA. *In vitro* competition assays were done to assess the relative fitness of mCherry-tagged wild-type and GFP-tagged KIFC1-LOF cells in mixed populations over 3-4 cell passages using flow cytometry. CA was potentiated in cells using low doses of the compound, CFI-400945.

Clonogenic survival and IF experiments were also done to determine the consequences of KIFC1 LOF.
Results: Our findings suggests that basal KIFC1 expression and CA across 21 LUAD cell lines and 3 NM controls are variable. However, we observed a positive correlation ($R^2 = 0.52$, $p = 0.01$) between KIFC1 expression and CA in LUAD lines. Competition assays revealed that KIFC1 LOF sensitizes LUAD cells with high KIFC1 expression, but not LUAD with low KIFC1 expression or NM cells, to pharmacologically-induced CA. Complementary siRNA experiments confirmed that KIFC1 LOF impairs the survival of cells with CA. Finally, we found that KIFC1 LOF was associated with an increase in multi-polar spindles.
Conclusion: These findings support our hypothesis that LUAD with CA are dependent on KIFC1. We suspect its role in centrosome clustering explains this phenotype. Ongoing work is focused on validating these observations in additional models and clinical tumours to confirm its therapeutic potential in LUAD with CA, since combining KIFC1 inhibition with standard of care therapies that induce CA (eg. cisplatin, radiation) could represent an effective therapeutic strategy.

#3966

Targeting S100A10, a SOX9 binding protein, for the treatment of triple negative breast cancer

Yanxia Ma[1], Jing Qian[1], Cassandra Moyer[1], Amanda Lanier[2], Jamal Hill[1], Darian Coleman[1], David H. Hawke[3], Abhijit Mazumdar[1], Powel H. Brown[4]. *[1]Department of Clinical Cancer Prevention, UT MD Anderson Cancer Center, Houston, TX,[2]University of Texas Health Science Center Medical School, Houston, TX,[3]Department of Systems Biology, UT MD Anderson Cancer Center, Houston, TX,[4]Department of Clinical Cancer Prevention, Department of Breast Medical Oncology, UT MD Anderson Cancer Center, Houston, TX*

Background: Triple-negative breast cancers (TNBCs) are the most aggressive breast cancers and have a very poor prognosis. Since TNBCs lack the expression of the estrogen receptor (ER), human epidermal growth factor receptor 2 (HER2), and progesterone receptor (PR), development of new TNBC treatment strategies is an urgent clinical need. Our previous

studies have demonstrated that high expression and activity of SOX9 transcription factor positively related to TNBC cell growth and tumor metastasis *in vivo*. It may be possible to target the SOX9 transcription factor by targeting upstream SOX9-activating proteins.
Hypothesis: SOX9-binding protein, S100A10, regulates SOX9 activity and control TNBC growth.
Material and Methods: Immunoprecipitation (IP) in combination with mass spectrometry (IP-MS) analysis was used to identify SOX9 binding proteins, with support from MD Anderson's proteomics core. The Mascot Score is a statistical score used as a measure of the reliability of identifying a specific protein by IP-MS. The data was summarized based on the Mascot Score. IP-Western Blotting analysis was used to confirm that S100A10 bound SOX9 in TNBC cells. We then treated TNBC cells with or without siRNAs of S100A10 to evaluate its effect on TNBC growth. Cell growth was measured using an automated cell counting assay. Protein and mRNA levels were examined by western blotting and qRT-PCR assays. SOX9 activity on regulating β-catenin pathway was measured using TOP/FOP luciferase activity analysis. Data are presented as mean values ± SD. Statistical significance was calculated using the Student's *t*-test unless otherwise indicated.
Results: Using immunoprecipitation combined with mass spectrometry (IP-MS), we identified multiple SOX9-binding proteins. One of the identified SOX9-binding proteins was S100A10 (S100A10). Knockdown of S100A10 decreased TNBC cell growth *in vitro*. Using TOP/FOP luciferase activity analysis, we demonstrated that S100A10 regulates the β-catenin pathway. Thus, S100A10 is a potential activator of SOX9 that can be targeted to inhibit SOX9 downstream signaling and TNBC growth.
Conclusion: Our results demonstrate that S100A10 is a SOX9-binding protein, that regulates SOX9 downstream signaling and controls TNBC cell growth.
Implications: Inhibition of S100A10 represents a novel strategy to treat TNBCs. S100A10 inhibitors should be developed as promising new drugs to treat these aggressive breast cancers.
Grant Support: These studies were supported by a Breast Cancer Research Foundation (BCRF) grant (PB). The Proteomics and Metabolomics Facility was supported in part by Cancer Prevention Research Institute of Texas

(CPRIT) grant number RP130397 and NIH grant numbers 1S10OD012304-01 and P30CA016672.

CRISPR/Cas9 screening identified novel membrane targets sensitizing hepatocellular carcinoma cells to natural killer cell-mediated cytotoxicity

Shuo Li, Lin Han, Siyao Zhang, Guangfeng Geng, Lei Huo, Dawei Huang, Zhaoren He, Shuoran Li, Zhaoshi Jiang, James X. Rong. *BioMap, Beijing, China*

Natural killer cells (NK) play a central role in cancer immune surveillance by directly killing cancer cells and producing pro-inflammatory cytokines to stimulate and recruit other immune cells to elaborate long-lasting anti-tumor responses. However, little is known about the immune escape mechanisms and regulatory proteins, particularly those for NK, involved in hepatocellular carcinoma (HCC), one of the most common and lethal cancers. To identify the determinants of NK killing function, we performed an HCC cell line-based CRISPR/Cas9 loss-of-function genetic screen, using a human whole membrane protein library containing ~7000 genes curated from 3 public membrane protein datasets. The human SNU449 was chosen as a representative HCC cell line for CRISPR/Cas9 editing based on the genetic profile analysis, representing one HCC patient subpopulation (> 30%) in the TCGA cohort. The cell line was incubated with NK92 cells at ratios of 2:1, 1:1, and 0.5:1. Bioinformatics methods for prioritizing genes (e.g., MAGeCK) were applied on 3 tested groups with different ratios. Single guide RNAs targeting genes in the antigen presentation machinery were depleted, including HLA-C, B2M, and TAP1/2, whereas components of the tumor-immune synapse, such as NCR3LG1 and ICAM1, were enriched, confirming the validity of the screen. SLC33A1 (an endosomal acetylCoA transporter) and SLC31A1 (the major copper influx transporter) were also depleted, previously unknown as NK regulators. The effects of SLC33A1 and SLC31A1 were validated in individual gene knockout cells generated respectively by lentiviral sgRNA expression. Furthermore, knockout of either transporter in SNU449 cells increased IFNγ secretion, confirming NK92 activation. Our results revealed that CRISPR/Cas9-based functional genomics screens in HCC cell lines could identify novel targets

modulating NK-mediated killing. Further analysis of mechanisms of action, and particularly functional validation in *in vivo* systems, will potentially provide novel targets for the treatment of HCC.

#3968

Conophylline-target ARL6ip1 regulates Ran-mediated cellular migration and invasion in human colorectal cancer cells

Yinzhi Lin[1], Sivasundaram Karnan[2], Hideaki Ito[3], Kazuo Umezawa[4].
[1]Department of Microbiology and Immunology, Aichi Medical Univ., Nagakute, Japan,[2]Department of Biochemistry, Aichi Medical Univ., Nagakute, Japan,[3]Department of Pathology, Aichi Medical Univ., Nagakute, Japan,[4]Department of Molecular Target Medicine, Aichi Medical Univ., Nagakute, Japan

Introduction: Conophylline is an alkaloid isolated from the leaves of *Ervatamia microphylla*. We isolated conophylline as an inhibitor of K-Ras functions. It is known to ameliorate various disease models in animals, including cancer, diabetes mellitus, NASH, and hepatic cirrhosis. On the other hand, its molecular target was determined to be ADP-ribosylation factor-like 6-interacting protein 1 (ARL6ip1) using a conophylline-biotin conjugate. ARL6ip1 is located in the endoplasmic reticulum (ER) membrane, and the conophylline-binding domain was determined by deletion mutation analysis. Known functions of ARL6ip1 include inhibition of apoptosis, inhibition of glutamate transporter, and modulation of the ER structure. However, whether ARL6ip1 is involved in the mechanisms of various biological activities of conophylline has not been proven, since knockdown of ARL6ip1 has often failed to change the cellular phenotypes. Therefore, in the present research, we knocked out ARL6ip1 in human colon carcinoma cells by CRISPR-Cas9 and studied the involvement and mechanism of ARL6ip1 in the anticancer activity of conophylline. Ran activity was measured by a pull-down assay with Ran-GTP antibody.
Materials and Methods: Conophylline was isolated from the leaves of *Ervatamia microphylla*. We employed HCT116 and DLD1 cells as human colorectal cancer cells. Tumorigenicity was measured by soft agar colony formation. Cellular migration was measured by a wound healing assay and cell tracking analysis. Cellular invasion was measured by a Matrigel chamber assay.

Results: Conophylline inhibited soft agar colony formation in HCT116 and DLD1 cells. It inhibited migration and invasion in HCT116 and DLD1 cells at nontoxic concentrations. Knockout of ARL6ip1 also decreased tumorigenicity, migration, and invasion in HCT116 and DLD1 cells. The mechanistic study was carried out with HCT116 cells. ARL6 and Ran are both G-proteins and are reported to interact with ARL6ip1. Although knockdown of ARL6 did not change the cell migratory activity, knockdown of Ran inhibited the migration. Conophylline inhibited the interaction of ARL6ip1 to Ran in the proximity ligation assay. Moreover, conophylline inhibited the Ran activity.
Conclusion: CRISPR-Cas9 knockout of ARL6ip1 showed a similar anticancer activity as treatment with conophylline. It is likely that the anticancer activity of conophylline would be mediated by the ARL6ip1-Ran system. Thus, ARL6ip1 would be a useful molecular target for the treatment of cancer.

Screening of kinase inhibitors as bioenergetic metabolism modulator using the XF Real-Time ATP Rate Assay
Yoonseok Kam, Lisa Winer, Natalia Romero. *Agilent Technologies, Inc., Lexington, MA*

Cancer cells are metabolically reprogrammed through tumor initiation and progression, and there are increasing developments in cancer therapies exploiting the potential metabolic vulnerability. A better understanding of cancer cell metabolic regulation can also contribute to modulating the harsh tumor microenvironment, which strongly affects the efficacy of emerging anti-cancer immunotherapies. As one of the critical contributors to cancer therapy design, there is increasing demand for time-efficient and reliable analytic tools when searching for drugs and genes modulating cancer cell metabolism. The XF Real-Time ATP Rate Assay measures ATP production from glycolysis and mitochondrial respiration simultaneously and provides a quantitative overview of the bioenergetic phenotype of the cells. By using ATP production rate as a universal unit of bioenergetic metabolism, this assay quickly detects metabolic modulations induced by chemical stimuli or genetic modifications. It allows the identification of potential targets for therapy design. In this study, we used the Seahorse XF Pro Analyzer

combined with the XF ATP Rate assay to screen 80 kinase inhibitors for the suppressive effects on energy metabolism and/or inducing a metabolic phenotype shift in THP-1 cells, a monocytic leukemia cell line, using PBMC as the control. We identified four mitochondrial and two glycolytic suppressors using the screening and dose-response views available in Seahorse Analytics, a cloud-based data analysis tool for Seahorse XF assays. These compounds showed moderate or no effects on the net ATP production rates but induced a significant shift in the metabolic phenotype of THP-1 cells. Among the selected kinase inhibitors, AG-879 (ErbB2 inhibitor), SU-1498 (VEGFR inhibitor), and U-0126 (MEK1/2 inhibitor) showed the most potent inhibitory effect on mitochondrial energy production in THP-1 cells. Dose-response studies indicated that SU-1498 and U-0126 have higher potency in THP-1 than PBMC, and thus they can be considered good cancer-cell targets for mitochondrial suppressors. In contrast, AG-879 showed a similar or higher inhibitory effect on PBMC even though it is the most potent mitochondrial suppressor among the selected compounds. These results demonstrate that the XF Real-Time ATP Rate Assay can be used as a primary assay for screening and validating drug candidate(s) targeting the bioenergetic metabolism of cancer cells.

NCG-hIL15 humanized mice: an ideal model for human immune reconstitution of NK cells

Xing Liu[1], Meirong Wu[1], Huiyi Wang[1], Weiwei Yu[1], Jianming Xu[1], Hongyan Sun[1], Cunxiang Ju[1], Hongyu Wang[1], Santi Suryani Chen[2], Zhiying Li[2], Mark Wade Moore[2], Jing Zhao[1], Xiang Gao[1].
[1]Gempharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA

Introduction: IL-15 is a four α-helix bundle cytokine which is produced by dendritic cells, monocytes, and epithelial cells. IL-15 is necessary for the development, survival, and activation of natural killer (NK) cells. NK cells are unable to persist in immunodeficient NCG mice reconsituted with human NK cells, but after knocking in human *IL-15* (*hIL-15*), NCG-hIL15 mice can support the reconstitution and survival of human NK cells. Results: Compared with NCG mice, the level of hIL-15 was significantly increased in NCG-hIL15 mice. After transplanting human PBMC

(huPBMC) or NK (huNK) cells into NCG-hIL15 mice, the peripheral blood level of NK cells in huNK-NCG-hIL15 mice was much higher than in huPBMC-NCG-hIL15 mice. The expression of perforin in peripheral blood of huNK-NCG-hIL15 mice was significantly higher than that in huPBMC-NCG-hIL15 mice. Considering the obvious ADCC of rituximab acting on Raji cells *in vitro*, we evaluated the efficacy of rituximab in huNK-NCG-hIL15 mice subcutaneously engrafted with Raji cells. Rituximab significantly inhibited the tumor growth in huNK-NCG-hIL15 mice. Conclusion: NCG-hIL15 is a great mouse model to evaluate the anti-tumor efficacy of drugs targeting human NK cells without the interference of T cells.

Developing cancer cell based *in vitro* and *in vivo* models with CRISPR-mediated knock-in technology for anti-tumor drug discovery

Nengwei Xu, Reifeng Wang, Jian Xiang, Qingyang Gu, Xiangnan Qiang.
WuXi AppTec, Suzhou, China

Human cancer cell lines have long been applied for anti-tumor drug discovery considering their acquired genomic diversity of different carcinomas. Genetic engineering based on cancer cell lines is no doubt a useful and promising approach in induction of new therapeutic targets/elements while maintaining intrinsic characteristics of original cell in parallel. Recently, the emergence of CRISPR knock-in technology has accelerated precise editing across whole genome, from gene depletion, small fragment insertions to site-direct mutations, thereby prompting our understanding of the influence of a specific oncotarget in given tumor genetic background. Herein, by employing CRISPR/Cas9 system, two human cancer cell line-based, inheritable drug resistance models were established where the mutation site C481S of BTK in REC-1 conferred resistance to Ibrutinib and the mutation site R537S/D538G of ESR1 exerted resistance to Fulvestrant in MCF-7. In addition, the engineered cell models also enable the mechanism characterization and development of viable therapeutic agents targeting those oncogenic-driver mutations in a subtype of cancers. The murine colon cancer cell line CT26, which harbors $KRAS^{G12D}$ mutation, was genetically modified to express $KRAS^{G12C}$ protein to allow for an expandable pocket providing opportunities for

compound recruitment. The resultant $KRAS^{G12C}$ CT26 cell line showed pronounced inhibitory effect after treatment with AMG510. More interestingly, the therapeutic combination involving both AMG510 and anti-PD1 antibodies demonstrated more effective anti-tumor activities when compared to monotherapy. Moreover, CRIPSR-mediated engineered knock-in cells with a traceable tag linked to endogenous oncotarget also exhibit capability in new therapeutic modality discovery. Based on HiBiT protein tagging technology, we generated a series of HiBiT knock-in cell lines for real-time cell-based protein degradation analysis on various compelling targets, such as ESR1, KRAS, and BRD4, *et al*. Thereby, the construction of these *in vitro* and *in vivo* models with the ease of CRISPR KI technology is indispensable in new generation of therapeutic drug exploration.

Novel renal cell carcinoma therapy targeting glutaminolysis

Yoshinari Muto[1], Akihito Takeuchi[1], Kenji Zennami[2], Eiji Sugihara[3], Ryoichi Shiroki[2], Hideyuki Saya[3], Makoto Sumitomo[1]. *[1]Fujita Cancer Center and Department of Urology School of Medicine, Fujita Health University, Toyoake, Japan,[2]Department of Urology School of Medicine, Fujita Health University, Toyoake, Japan,[3]Fujita Cancer Center, Fujita Health University, Toyoake, Japan*

Objective: Metabolic reprogramming of cancer cells contributes to tumor development and provides a target for cancer therapy ASCT2 is a glutamine transporter on the plasma membrane. Glutamine is converted into the cell to glutamate by glutaminase (GLS) and utilized by the TCA cycle. This glutaminolysis has been implicated in tumor progression in various malignancies, including renal cell carcinoma. In the present study, we investigated whether the unique strategy that effectively targets glutamine addiction would be effective as a treatment for RCC.
Methods: Tumor tissue (T) and normal renal tissue (N) from surgical specimens of 66 patients with RCC were collected, and metabolomic analysis using liquid chromatography-mass spectrometry (LC/MS) to calculate the T/N ratio of Gln and Glu, respectively, were performed. In addition, immunohistological (IHC) staining of paraffin-embedded sections of 106 metastatic RCC cases was used to compare GLS and ASCT2 expression in tumor and normal tissue. In vitro, cell viability of the human

RCC cell lines 786-O and 769-P was assessed by WST-8 assays. The protein expression was detected by Western blotting. Intracellular concentrations of glutamine and glutamate were analyzed using LC/MS. V9302 was used as the specific ASCT2 inhibitor, and CB839 as the specific GLS inhibitor. As the xenograft model in vivo, athymic nude mice were injected subcutaneously with 786-O cells and given various doses of V9302 and CB839 intraperitoneally.
Results: LC/MS assays using surgical specimens showed a notable increase in glutamine concentration in tumor tissue. IHC assays confirmed high expression of ASCT2 in tumor tissue, and patients with high expression of ASCT2 had a poorer prognosis than those with low expression. Treatment of V9302 with 786-O and 769-P resulted in a limited decrease in cell viability. LC/MS analysis confirmed that V9302 treatment reduced glutathione metabolites. V9302 administration was shown to increase intracellular glutamine levels, presumably by compensatory mechanisms, whereas the combination of V9302 and CB839 significantly decreased glutamine levels in 786-O cells. Western blot analysis showed that the expression levels of ASCT2 and GLS1 decreased after the combination therapy. The xenograft study confirmed that the combination of V9302 and CB839 significantly inhibited 786-O tumor growth compared with controls within three weeks after treatment ($p < 0.001$).
Conclusion: It has been shown that ASCT2 expression is a marker of poor prognosis in RCC and that suppression of ASCT2 has an antitumor effect by affecting glutathione metabolism. On the other hand, the administration of V9302 raised the issue that a compensatory mechanism increases intracellular glutamine levels. Our results suggest that a novel combination strategy using CB839 in addition to V9302 could overcome the tolerance for the monotherapy and effectively target glutamine addiction in RCC.

Precision RNAi using synthetic shRNAmir target sites

Ralph Neumüller[1], Thomas Hoffmann[2], Alexandra Hörmann[1], Maja Corcokovic[1], Johannes Zuber[2]. *[1]Boehringer Ingelheim RCV GmbH & Co. KG, Vienna, Austria,[2]Institute of Molecular Pathology (IMP), Vienna, Austria*

Genetic loss-of-function methods including short-hairpin RNAs (shRNAs) and CRISPR are key methods for target gene validation across a variety of different disease areas. While these methods have revolutionized target gene discovery and characterization, both methods suffer from limitations in the context of *in vivo* target validation due to off-target effects and insufficient knock-down for shRNAs and resistant clones for CRISPR. In this study, we describe a method, artificial RNA interference (ARTi) that overcomes these limitations by fundamentally changing the basic experimental strategy of RNAi-based loss-of-function studies. Instead of newly designing gene-specific shRNA for individual target genes, ARTi utilizes ultra-effective and selective artificial miRNA-based shRNAs that do not match any transcribed gene in the target genome. In addition, these sequences are optimized for ultra-efficient miRNA processing and knockdown of synthetic target genes, and are deeply characterized to not trigger major off-target effects, enabling highly stringent target validation in vivo with unprecedented temporal control, selectivity and potency. We validate the approach by studying the *in vitro* and *in vivo* phenotypes of EGFR, KRAS and STAG1, genes relevant to cancer biology. This loss-of-function strategy will enable novel experimental strategies in therapeutic target validation and will be instrumental in guiding the lead optimization process by establishing genetic benchmark phenotypes.

Discovery and validation of therapeutic targets in immune cells by mass spectrometry-based proteomics

Yu-Wah Au[1], David Satijn[1], Martin Mehnert[2], Amaury Lachaud[2], Yuehan Feng[2], Jakob Vowinckel[2], Hélène Bon[1]. *[1]Genmab A/S, Utrecht, Netherlands,[2]Biognosys AG, Schlieren, Switzerland*

Immuno-oncology (IO) has substantially improved the survival of cancer patients over the past several years encouraging the discovery of novel IO targets which are typically proteins expressed on the surface of immune cells. Sensitive quantification of proteins in complex biological samples is routinely achieved by immunoassays that use antibodies specific to target proteins. Such approaches can be a limitation in IO drug discovery and development as de novo development of antibodies is associated with long lead times, high costs, and high failure rates.

Protein quantification using mass spectrometry (MS) is agnostic to species and matrices and removes the barriers of availability or specificity of antibody-based assay. Further, MS proteomics workflows can support both large scale discovery studies but also represent an attractive alternative to targeted quantitative studies.
The main purpose of this work is to assess the performance of the TrueDiscovery™ and TrueSignature™ MS-proteomics platforms for the deep proteome and surfaceome profiling of human primary and immortalized immune cells compared to flow cytometry solutions. We assess the number of quantified proteins and specifically the coverage of immune cell marker proteins in primary human immune cells across cell count groups from 2 million down to 2500 immune cells. In addition, we compared the quantification of a multiplexed surface antigens panel using TrueSignature™ and QIFI® flow cytometry platforms.
We found that the applied MS-based proteomics workflows achieve high sensitivity and robustness in detection and quantification of immune cell markers down to 2500 primary immune cells. Additionally, we observed a strong correlation of the quantitative data derived from our MS-based proteomics workflows with flow cytometry supporting the substitution of immunoassays by MS-based proteomics workflows in target discovery and validation.

The USP1 inhibitor I-138 kills BRCA1-deficient tumor cells and overcomes PARP inhibitor resistance

Alexandre Andre B. A. Da Costa, Arindam Bose, David Martignetti, Cecilia Ayala-Zambrano, Ramya Ravindranathan, Golbahar Sadatrezaei, Yuqing Jiao, Bose Kochupurakkal, Huy Nguyen, Jean-Bernard Lazaro, Kalindi Parmar, Geoffrey I. Shapiro, Alan D. D'Andrea. *DFCI/Harvard Medical School, Cambridge, MA*

Targeting BRCA-deficient tumors with PARP inhibitors has improved the progression-free survival of ovarian and breast cancer patients in the clinic. However, the majority of patients develop acquired resistance. PARP inhibitor (PARPi) resistance in tumors can occur by restoration of

homologous recombination (HR) or replication fork stability and/or by suppression of single-stranded DNA (ssDNA) gaps at replication forks. USP1 is a ubiquitin specific protease which deubiquitinates PCNA and FANCD2. We have previously shown that USP1 deficiency causes replication fork instability and is synthetic lethal with BRCA1 deficiency, suggesting USP1 as a potential therapeutic target for overcoming PARPi resistance (Lim et al, Mol Cell, 2018). Accordingly, USP1 inhibitors are now undergoing preclinical and clinical development. Here, we evaluated the activity of the novel USP1 inhibitors such as I-138 (Simoneau et al, Mol Cancer Ther, 2022) and TNG-6132 in preclinical models of BRCA1-deficient tumors. I-138 preferentially killed BRCA1-deficient ovarian and breast cancer cells and increased the cellular level of ubiquitinated PCNA. An aniPOND analysis demonstrated an accumulation of ubiquitinated PCNA specifically at the replication fork in I-138-treated cells. Consistent with our previous study (Lim et al, Mol Cell, 2018), I-138 treatment led to replication fork instability and DNA damage in BRCA1-deficient cancer cells. I-138 exposure also resulted in the accumulation of ssDNA gaps, as detected by an S1 nuclease assay. Interestingly, the induction of ssDNA gaps was detected in I-138-sensitive but not in I-138-resistant BRCA1-deficient cells, suggesting a mechanism of cytotoxicity by USP1 inhibition. Persistent monoubiquitinated PCNA accumulation was the cause of cell killing after USP1 inhibition. Knockdown of RAD18, the E3 ubiquitin ligase known to ubiquitinate PCNA, in BRCA1-deficient ovarian cancer cells resulted in reduced PCNA-Ub levels, resistance to I-138, and suppression of ssDNA gaps. Notably, I-138 exhibited monotherapy activity in ovarian and breast cancer cell lines with acquired PARPi resistance and re-sensitized the cells to PARP inhibition. Similarly, PARPi-resistant *BRCA1*-mutated organoids, derived from patient-derived xenograft (PDX)-derived models of ovarian cancer, were also sensitized by USP1 inhibition by TNG-6132. Interestingly, the ssDNA gap accumulation induced by I-138 strongly correlated with the drug sensitivity of both PARPi-sensitive and PARPi-resistant cells. In conclusion, I-138 exhibits monotherapy activity in both PARPi-sensitive and -resistant preclinical models of BRCA1-deficient cancer, induces ssDNA gaps and overcomes PARP inhibitor resistance. Taken together, these data support use of a USP1 inhibitor, with or without a PARP inhibitor, as a therapeutic strategy for a subset of PARP-inhibitor-resistant BRCA1-deficient tumors.

Pan-cancer proteogenomics expands the landscape of therapeutic targets

Jonathan T. Lei[1], Sara R. Savage[1], Xinpei Yi[1], Bo Wen[1], Hongwei Zhao[2], Lauren K. Somes[1], Paul W. Shafer[1], Yongchao Dou[1], Qiang Gao[2], Valentina Hoyos[1], Bing Zhang[1]. *[1]Baylor College of Medicine, Houston, TX,[2]Fudan University, Zhongshan Hospital, Shanghai, China*

Background: Molecularly targeted therapies are critical for improving cancer treatment. Since proteins are the targets of these therapies and functional effectors of genomic aberrations, proteogenomics data from the Clinical Proteomics Tumor Analysis Consortium (CPTAC) provides an unprecedented opportunity to characterize existing and future therapeutic targets for cancer treatment.
Approach: CPTAC proteogenomics data from >1000 cancer patients spanning 10 cancer types was used to evaluate current and potential therapeutic targets curated from four databases. Cell line data from DepMap was further integrated to distinguish causations from associations. Computational pipelines were deployed to identify synthetic lethality for targeting tumor suppressor loss and to prioritize tumor associated antigens as immunotherapy targets.
Results: We systematically collected 3050 druggable proteins and classified them into 5 tiers to facilitate different applications such as companion diagnostics, drug repurposing, and new therapy development. Many druggable proteins showed poor mRNA-protein correlation, including secreted proteins and proteins whose abundance was correlated with their interaction partners instead of cognate mRNA, highlighting the necessity of direct proteomic quantification of drug targets. 618 druggable proteins showed both overexpression in tumors compared to normal and significant dependency in CRISPR-Cas9 screens of cell lines of the same lineage. Notably, PAK1, a kinase targeted by investigational drugs, demonstrated both overexpression and dependency in all cancer types. A similar analysis of phosphoproteomics data focusing on known activating sites of druggable proteins further revealed targetable dependencies driven by protein hyperactivation. The phosphosite pS50 on PTPN1, a phosphatase targeted by experimental drugs, was increased in 7 cancer types and PTPN1

demonstrated dependency in related cancer cell lines. Based on tumor proteogenomic data and cell line CRISPR-Cas9 screen data, we identified synthetic lethality for difficult to target tumor suppressor losses, revealing TP53 mutations as a candidate biomarker to select breast cancer patients for CHEK1 inhibition, and endometrial cancer patients for treatment with doxorubicin. We identified 140 proteins whose expression was restricted in normal tissues but abnormal in tumors. Experimental analysis of peptides predicted to have high binding affinity to the most common allotype HLA-A02 for 7 prioritized proteins identified 21 peptides from 5 proteins with both strong binding affinity and immunogenicity which could be further investigated as immunotherapy targets.
Conclusion: We generate a comprehensive resource of protein and peptide targets that covers multiple therapeutic modalities. This unique resource will pave the way for repurposing of currently available drugs and developing new drugs for cancer treatment.

Identification of synthetic lethal vulnerabilities in cancers with loss of function mutations in NOTCH

Deli Hong[1], Matthew A. Booker[2], Sidrah Anjum[2], Yixiang Li[1], Tran C. Thai[1], Michelle Y. Wang[3], David A. Barbie[1], Michael Y. Tolstorukov[2], Jun Qi[3], Matthew G. Oser[1]. *[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[2]Informatics, Dana-Farber Cancer Institute, Boston, MA,[3]Cancer Biology, Dana-Farber Cancer Institute, Boston, MA*

Loss of Function (LOF) mutations in the *NOTCH* receptors are found in several different cancers most notably in small cell lung cancer (SCLC) and squamous cell carcinomas (SCC). We previously developed genetically engineered mouse models (GEMM) of SCLC using CRISPR/Cas9 engineered to be *NOTCH1*-Mutant, *NOTCH2*-Mutant, and *NOTCH*-WT. Synthetic lethality provides a paradigm for targeting cancers with LOF mutations in tumor suppressor genes. In applying this paradigm, one looks for specific vulnerabilities that are created upon loss of the gene of interest. Using 6 cell lines developed from these CRISPR-based SCLC GEMMs which are isogenic to *NOTCH*, we performed CRISPR/Cas9 LOF negative selection screens (using an sgRNA library enriched in druggable enzymes) to identify synthetic lethal interactors with LOF *NOTCH* mutations. Our

CRISPR/Cas9 screen identified TRIM28 (Tripartite Motif Containing 28, or KAP1) as a highly significant synthetic lethal interactor with NOTCH1 or NOTCH2. We validated the synthetic lethal interaction between NOTCH1/2 and TRIM28 using both human and mouse NOTCH-isogenic cell lines. Interestingly, RNA-sequencing of *NOTCH2*-Mutant or *NOTCH*-WT SCLC cell lines after TRIM28 CRISPR inactivation showed robust increases in endogenous retroviral (ERV) expression and the MDA5/RIG-I/MAVS RNA-sensing machinery leading to hyperactivation of the TBK1/IRF3/7 innate immune signaling pathway and the pro-inflammatory cytokine CXCL10 selectively in cells with NOTCH inactivated. Notably, inactivation of TBK1 activity or JAK-STAT activity using specific small molecule inhibitors of TBK1 or JAK completely reversed the synthetic lethality between NOTCH and TRIM28 suggesting that the synthetic lethality phenotype is a consequence of hyperactivation of innate immune signaling, which is known to be cytotoxic. Together our findings uncover a novel vulnerability in SCLCs with LOF *NOTCH* mutations and perhaps other cancers with LOF NOTCH mutations and suggest a strategy that could also potentiate anti-tumor immunity by increasing innate immune signaling in tumor cells.

Inhibition of TACC3 blocks the growth of highly aggressive breast cancers with centrosome amplification

Ozge Saatci[1], Ozge Akbulut[2], Metin Cetin[1], Vitali Sikirzhytski[2], Ozgur Sahin[1]. *[1]The Medical University of South Carolina (MUSC), Charleston, SC,[2]University of South Carolina, Columbia, SC*

Centrosome amplification (CA) is a hallmark of cancer that is strongly associated with highly aggressive disease and worse clinical outcome. Clustering extra centrosomes into opposite spindle poles during mitosis is critical for preventing multipolar cell division and apoptosis in cancer cells with CA. However, the underlying molecular mechanisms have largely been unexplored. Here, we identified Transforming Acidic Coiled-Coil Containing Protein 3 (TACC3) as a novel CA-directed dependency, driving highly aggressive cell growth by forming distinct functional interactomes during cell cycle progression. We demonstrated, for the first time, that TACC3 interacts with the Kinesin Family Member C1 (KIFC1) via its

TACC domain in mitotic cells with CA to promote centrosome clustering (CC) and facilitate mitotic progression. On the other hand, TACC3 interacts with the members of the nucleosome remodeling and deacetylase (NuRD) complex (HDAC2 and MBD2) in the nucleus of interphase cells with CA, thereby suppressing the transcription of key tumor suppressors to facilitate G1/S progression and cell survival. Inhibiting TACC3 in mitotic cells blocks the formation of TACC3/KIFC1 complex, leading to formation of multipolar spindles and activation of spindle assembly checkpoint (SAC)/CDK1/p-Bcl2 axis that ultimately results in mitotic cell death; whereas TACC3 inhibition in interphase cells blocks TACC3/HDAC2/MBD2 complex, leading to enhanced transcription of cyclin-dependent kinase inhibitors (e.g., p21 and p16) and apoptosis regulators (e.g., APAF1), ultimately causing p53-independent G1 arrest and strong apoptosis. Notably, inducing CA by chemical (cytochalasin D) or genomic (PLK4 overexpression or p53 loss) modulations renders cancer cells highly sensitive to TACC3 inhibition, showing the dependency of cells with CA to TACC3. Targeting TACC3 by small molecule inhibitors or CrispR-CAS9-mediated knock-out significantly reduces colony formation ability, inhibits the growth of organoids of patient-derived xenografts (PDXs) with CA, and strongly inhibits tumor growth in breast cancer cell line xenografts and PDXs with CA via induction of mitotic arrest and inhibition of G1/S progression. Notably, we demonstrated that high CA tumors express much higher levels of TACC3, and high TACC3 expression leads to drastically worse clinical outcome in cancer patients with CA. Altogether, our results show, for the first time, that TACC3 is a multifunctional driver of the growth of the highly aggressive breast tumors with CA and that targeting TACC3 is a promising approach to tackle this aggressive disease.

#5729

Imiqualines for pancreatic cancer: first-in-class potent and synergistic inhibitors of microtubule polymerisation

Kevin Bigot[1], Véronique Garambois[1], Nadia Vie[1], Marine Bruciamacchie[1], Pierre-Emmanuel Colombo[2], Diego Tosi[2], Cindy Patinote[3], Yann Maggipinto[1], Pierre-Antoine Bonnet[3], Céline Gongora[1], Carine Deleuze-Masquefa[3], Christel Larbouret[1]. *[1]Team Drug Resistance and New Cancer Therapy, IRCM INSERM U1194, Montpellier, France,[2]Institut du Cancer de*

Montpellier, Montpellier, France,[3]équipe F16, IBMM, Univ Montpellier, CNRS, ENSCM, Montpellier, France

Background : The survival rate for patients with Pancreatic Ductal Adenocarcinoma (PDAC) is dramatically poor with a five-year survival rate less than 10%. The research of new treatments, which could complement the current therapeutic arsenal constituted by Gemcitabine, FOLFIRINOX (fluorouracile, leucovorin, irinotecan, oxaliplatin) and nab-paclitaxel, is a major challenge. Imiqualines are new original small heterocyclic chemical molecules based on the quinoxalinic moiety. Among these first in class compounds, the lead EAPB02303 (1) displays outstanding nanomolar activities comparable to those of the current best anticancer agents on a panel of human cancer cell lines, notably on poorly sensitive cancer like PDAC and melanoma. We tested here if EAPB02303 could be an attractive first in class molecule in PDAC and we conducted in-deep molecular characterization and bioinformatics studies to decipher its mechanism of action.
Methods: We characterized EAPB02303 effect on tumor growth *in-vitro* by conducting sulforhodamine B assay on a panel of PDAC cells including cells derived from PDX (Patient Derived Xenograft) and 3D models with Cancer Associated Fibroblasts. We assessed in-vivo activity on subcutaneous PDAC xenografts mouse models. We then studied EAPB02303 effect on cell cycle, apoptosis and microtubule polymerisation by flow cytometry and immunofluorescence. We analyzed mRNAseq and Reverse Phase Protein Assay (RPPA) data of PDAC cell lines treated with EAPB02303 at multiple time points and concentrations to identify signaling pathways and key proteins implicated in EAPB02303 effect. We performed differential gene expression and gene set enrichment analysis by using EdgeR, Deseq2 and fgsea packages. We also used PharmacoGx package to seek for similar transcriptomic profiles among the CMAP perturbational database.
Results : We showed that EAPB02303 exerts activity at low nanomolar concentrations *in-vitro* in PDAC cell lines and 3D models, and is able to reduce tumor growth in our xenografts *in-vivo* mouse models. We also found a potent synergy with Paclitaxel at lower concentrations of both compounds. Furthermore, we found that EAPB02303 induces mitosis arrest and impairment of spindle assembly after 24h treatment. Cells also

underwent apoptosis after 48h treatment. mRNAseq and RPPA data showed activation of several signaling pathways including MAPK kinases. CMAP database mining revealed a high connectivity score of transcriptomic signatures between EAPB02303 and inhibitors of microtubule polymerization.
All these data suggest that EAPB02303 is a new microtubule-disrupting agent with *in-vivo* activity in PDAC and *in-vitro* synergy with Paclitaxel, showing potential for future clinical investigations.
(1) Imidazo[1,2a]quinoxalines and derivatives thereof for treating cancers. WO 2009 043934A1. Deleuze-Masqeufa C. et al.

Targeting intrinsically disordered protein βII-spectrin prevents metabolic syndrome and hepatocellular carcinoma on a sex-based bias
Xiaochun Yang, Krishanu Bhowmick, Xiyan Xiang, Kazufumi Ohshiro, Anil Vegesna, Lopa Mishra. *Institute for Bioelectronic Medicine, Department of Medicine, Div of Gastroenterology and Hepatology, The Feinstein Institutes for Medical Research, & Cold Spring Harbor Laboratory, Northwell Health, New York, NY*

Background**:** Hepatocellular carcinoma (HCC) is a lethal cancer that affects males 2-4 times more than females. HCC incidence is rising in parallel with risk factors such as non-alcoholic steatohepatitis (NASH) and alcohol induced cirrhosis. A major enzyme in alcohol metabolism, aldehyde dehydrogenase 2 (ALDH2) deficiency affects ~560 million people globally. In males, different ALDH2 genotypes exhibit significant metabolic differences from females. Yet the mechanism for the sex differences remains unclear. We have found that targeting an intrinsically disordered protein and TGF-β signaling Smad3/4 adaptor, βII-spectrin (Sptbn1) blocks NASH and HCC in a liver-specific knockout (LSKO) mice and siRNA to human NASH microfluidic cultures (*Sci Transl Med. 2021. 13(624): eabk2267*). In mouse mutants of Smad3/Sptbn1 with HCC, stem cell proteins are markedly altered. Here, we sought to examine this further by intercrossing Sptbn1 deficient mice with ALDH2 deficient mice.
Methods: Global heterozygous knockout of *Sptbn1* mice were intercrossed with *Aldh2* knockout mice (ASKO) to explore the role of βII-spectrin in aldehyde-related liver injury. LSKO mice were intercrossed with ALDH2

deficient mice (ALSKO) and siRNA treatment to explore the therapeutic effects of targeting *Sptbn1* during the progression of metabolic syndrome (MetS) or HCC induced by Western diet (WD)/chemical (DEN) in the context of ALDH2 deficiency in both male and female mice. We performed phenotypic analyses of metabolic state, liver pathology, intestinal pathology, and gut microbiomes.
Results: LSKO displayed obvious therapeutic effects against liver steatosis in male mice, whereas female mice did not. ASKO mice developed NASH spontaneously and showed impaired glucose handling, disordered lipids metabolism, with increased intestinal permeability and pro-inflammatory species of *Bacteroidetes* and *Firmicutes*. ALDH2 deficiency exacerbated toxic reactive aldehydes accumulation. LSKO mice were protected from WD induced MetS and NASH, including decreased body weight and fat weight, decreased serum triglyceride and AST/ALT, downregulated expression of proinflammatory genes and profibrotic genes and improved NAS Score. LSKO mice were also protected from WD/DEN-induced HCC: mice had less tumor number, smaller tumor size and less proliferation. siRNA targeting *Sptbn1* also showed similar therapeutic effects as LSKO. Further, LSKO and siRNA targeting *Sptbn1* also improved NASH phenotypes resembling MetS in $Aldh2^{-/-}$ mice: decreased liver fat accumulation, improved glucose handling and reduced inflammatory cell infiltration.
Conclusions: Our data suggest that βII-spectrin, an intrinsically disordered protein, is a potential therapeutic target for diet/chemical-induced Mets/NASH and preventing HCC development and could provide new insight into sex-based differences in HCC.

Apoptosis Inducing Agent 1 enhances cancer therapy-induced apoptosis by direct interaction with BAX and BAK

Xingping Qin[1], Cameron Fraser[1], Adam Presser[1], Johan KE Spetz[1], Stacey J. Yu[1], Gary A. Bradshaw[2], Marian Kalocsay[2], Bo R. Rueda[3], Tudor Moldoveanu[4], Kristopher A. Sarosiek[1]. *[1]Harvard T.H. Chan School of Public Health, Boston, MA,[2]Harvard Medical School, Boston, MA,[3]Department of Obstetrics and Gynecology, Vincent Center for Reproductive Biology, Massachusetts General Hospital, Boston,*

MA,[4]Department of Biochemistry and Molecular Biology, University of Arkansas for Medical Sciences, Little Roeck, AR

Many of the most effective anti-cancer therapies induce apoptosis in cancer cells by damaging DNA. Even when effective at eradicating primary cancers, DNA-damaging anti-cancer agents cause mutations that can lead to the development of secondary cancers. Furthermore, DNA damage responses are dependent on wild-type p53, which is mutated in over 50% of cancers and causes resistance to therapies. Fortunately, many p53 mutant cancers continue to express high levels of the pro-apoptotic, pore-forming proteins BAX and BAK and are consequently "primed for apoptosis." Primed cells are highly sensitive to pro-apoptotic signals and this vulnerability can be exploited using inhibitors of pro-survival BCL-2 family proteins such as the BCL-2 inhibitor ABT-199, which has been successful as therapy for chronic lymphocytic and acute myeloid leukemias (AML). Furthermore, most irreplaceable cells within healthy tissues are apoptosis resistant and express low levels of BAX and BAK. We therefore hypothesized that direct activators of BAX or BAK could be effective single-agent therapies for primed cancers and chemo-/radio-sensitizers for unprimed cancers. Using WT versus BAX -/- BAK -/- HeLa cells, we performed a high-throughput screen of nearly 100,000 compounds to identify small molecules that could directly activate BAX or BAK. 196 compounds were identified as hits and multiple orthogonal validation studies identified Apoptosis Inducing Agent 1 (AIA1) as the most specific and potent putative activator of BAX and BAK. Further validation studies demonstrated that AIA1 directly induces cytochrome c release from mitochondria in a BAX/BAK dependent manner and strongly enhances BIM-mediated activation of BAX and BAK and permeabilization of liposomes. Single-agent AIA treatment triggers apoptotic cell death in a broad panel of cancer cell lines and also sensitizes cancer cells to chemotherapeutic agents and especially BH3 mimetics targeting pro-survival BCL-2 family proteins. Importantly, AIA1 sensitizes ovarian cancer cells to BCL-X_L inhibitors and AML cells to BCL-2 inhibitors regardless of p53 status. In vivo, AIA1 suppresses tumor growth and prolongs overall survival in both ovarian cancer and AML xenograft models without causing weight loss, thrombocytopenia or leukopenia. Notably, unprimed cancer cells that don't immediately undergo apoptosis in

response to single-agent AIA1 treatment upregulate expression of BAX and BAK, pro-survival proteins (BCL-$X_{L,}$ BCL-2, MCL-1) and pro-apoptotic proteins (BIM, BID, PUMA, Noxa) to produce a more highly primed apoptosis pathway and setting the stage for increased sensitivity to BH3 mimetics. Based on these findings, AIA1 may exploit and induce apoptotic vulnerabilities in cancers in a p53-independent manner and represent a safer strategy to target primed cancer cells while eliminating the potential for secondary malignancies and p53-mediated resistance.

New Tricks for Known Targets: Novel Approaches to Inhibit Oncogenic Signaling

#5733
Combining KRAS^{G12C}(ON) inhibition with SHP2 and immune checkpoint blockade to enhance anti-tumor immunity and overcome development of resistance in lung cancer

Panayiotis Anastasiou, Mona Tomaschko, Jesse Boumelha, Sareena Rana, Christopher Moore, Miriam Molina-Arcas, Julian Downward. *The Francis Crick Institute, London, United Kingdom*

The recent approval of KRAS^{G12C} mutant-specific inhibitors has transformed the clinical practice of lung cancer patients harboring KRAS^{G12C} mutations. However, clinical data show that resistance develops rapidly after initial responses, suggesting that combination therapies will be needed. Ideally, these combinations should not only overcome adaptive or acquired resistance but also maintain or even enhance the positive immunomodulatory effects that KRAS^{G12C} inhibitors (G12Ci) have in the tumor microenvironment (TME). Most of the G12Ci being tested in clinical trials target GDP-bound KRAS (OFF state), which makes them vulnerable to upstream pathway reactivation. In this study we use a covalent tri-complex KRAS^{G12C}(ON) inhibitor, RM-029, which targets KRAS^{G12C} in the active state. Treatment with RM-029 still resulted in some degree of adaptive RAS pathway reactivation, which can be blocked using the SHP2 inhibitor RMC-4550. In vivo, this combination enhanced tumor regressions and improved overall survival in two different KRAS^{G12C} lung cancer models. In an immunogenic KRAS^{G12C} lung cancer model both

$KRAS^{G12C}$(ON) and SHP2 inhibitors remodel the TME and are able to drive durable responses, which are enhanced when both compounds are combined. However, in this anti-PD1 sensitive model the combination of RM-029 with anti-PD1 generated more complete responses than the combination of RM-029 and RMC-4550. In an immune-excluded anti-PD1 resistant model, $KRAS^{G12C}$(ON) and SHP2 inhibitors also promoted a profound remodelling of the TME, with increased infiltration and activation of T cells accompanied by a reduction of tumor-promoting myeloid cells. Importantly, only the combination of both $KRAS^{G12C}$(ON) and SHP2 inhibitors sensitized these immune-excluded tumors to anti-PD1 blockade, resulting in durable responses and immune memory. Our preclinical results show that RM-029 as single agent or in combination with RMC-4550 and/or anti-PD1 can induce anti-tumor immunity and generate complete responses, especially in immunogenic models. To study if this immunological response could also target G12Ci-resistant subpopulations within the tumor, we used our immunogenic cell line (KPAR) to generate reporter-traced G12Ci sensitive ($KPAR^{G12C}$) and resistant ($KPAR^{G12D}$) cells that can be monitored over time via in vivo luciferase imaging and end point flow cytometry. We find evidence of bystander immune mediated killing of G12Ci-resistant cells in response to the different treatment combinations. Overall, our preclinical results demonstrate the potential of the combination of $KRAS^{G12C}$(ON) inhibitors with SHP2 and/or immune checkpoint blockade not only by targeting KRAS-driven proliferation in tumor cells but by stimulating anti-tumor immunity to target both G12Ci sensitive and resistant cells.

Designing RAF and MEK inhibitor combinations based on their biochemical properties to effectively target MAPK-driven cancers

Ana Orive-Ramos[1], Christos Adamopoulos[1], Beau Baars[1], Jason Lam[1], Ankita Punetha[2], Jason Huang[1], Vasileios I. Petrou[2], Stuart A. Aaronson[1], Poulikos I. Poulikakos[1]. *[1]Oncological Sciences, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY,[2]Microbiology, Biochemistry, and Molecular Genetics, New Jersey Medical School, Rutgers Biomedical Health Sciences, Newark, NJ*

Oncogenic alterations of the RAS/RAF/MEK/ERK signaling pathway drives growth of over 40% of human tumors, frequently due to activating mutations of components of the pathway, such as RAS or BRAF. Targeting the pathway using BRAF inhibitors (BRAFi) in combination with MEK inhibitors (MEKi) is now the standard of care for metastatic melanoma patients harboring the BRAF(V600E) mutation. However, effective targeted therapies are lacking for most cancers driven by other pathway alterations, including those with RAS activating mutations. The effectiveness of current clinical BRAFi relies on the fact that they bind selectively and inhibit the mutationally activated monomeric form of the BRAF(V600E) kinase in tumors but not wild-type BRAF in normal tissue where BRAF signals in its dimeric form. Yet, the development of adaptive resistance, frequently due to RAF dimerization, limits BRAFi therapeutic effectiveness. Another class of BRAFi equipotent for both monomeric and dimeric BRAF have been developed, but are predicted to have lower therapeutic index due to inhibition of dimeric wild-type BRAF in normal tissues as well. Recently, we identified and characterized a novel class of BRAFi that preferentially binds and inhibits dimeric BRAF over monomeric BRAF(V600E) (i.e. RAF dimer-selective inhibitors). Furthermore, we rationally designed a combinatorial approach utilizing a BRAF monomer-selective plus a BRAF dimer-selective inhibitor plus a MEK inhibitor, that potently disrupts the BRAF/MEK complex, to maximally inhibit BRAF(V600E) signaling in tumors while retaining a broad therapeutic index. This triple combination potently suppressed tumor growth of multiple BRAF(V600E) colorectal cancer and melanoma models resistant to the current clinical BRAFi and MEKi combinations both *in vitro* and *in vivo*. To design effective therapeutic approaches for RAS-mutated tumors, we also assessed the effectiveness of RAF and MEK inhibitors belonging to diverse biochemical and structural classes, either alone or in combination in RAS-mutant tumor models and normal cells with wild-type RAS signaling. We found that RAF dimer-selective inhibitors potently antagonized MAPK signaling and growth in various RAS mutant cancer models as compared to normal cells. We found further that RAF and MEK inhibitor combinations belonging to certain biochemical classes resulted in more potent MAPK suppression in RAS-mutant tumor as compared to wild-type RAS normal cells (“therapeutic synergy”) and should be prioritized for clinical testing. In contrast, those combinations which are more potent in normal over tumor

cells (“adverse synergy”) are unlikely to be clinically successful. Thus, rationally designed combinations of selected RAFi and MEKi, based on their distinct biochemical properties, can uncover new therapeutic opportunities tailored for more effective targeting of BRAF or RAS mutant tumors.

Novel KRAS G12D degrader ASP3082 demonstrates in vivo, dose-dependent KRAS degradation, KRAS pathway inhibition, and antitumor efficacy in multiple KRAS G12D-mutated cancer models

Takeyuki Nagashima, Tomohiro Yoshinari, Yoshihiro Nishizono, Mamoru Tasaki, Kohei Inamura, Hiroki Ishioka, Atsushi Suzuki, Fumio Osaki, Yosuke Yamanaka, Masahiko Hayakawa. *Astellas Pharma, Inc., Tsukuba-shi, Japan*

KRAS is one of the most frequently mutated oncogenes in various cancers. Among KRAS mutations, KRAS G12D is the most frequent driver mutation and is found in approximately 34% of patients with pancreatic ductal adenocarcinoma (PDAC), 12% of patients with colorectal cancer (CRC), 4% of patients with lung adenocarcinoma, and in a subset of patients with other solid tumors. We have identified ASP3082 as a novel KRAS G12D degrader with high potency and selectivity. Here, we have evaluated in vivo antitumor activities and pharmacodynamic properties of ASP3082 in various KRAS G12D-mutated xenograft models. ASP3082 was intravenously administered to KRAS G12D-mutated cancer-xenograft-bearing mice, and plasma and tumors were collected at defined time points. The drug concentration and KRAS-related signal transduction were measured in the xenograft model. The in vivo efficacy of ASP3082 monotherapy was confirmed in multiple xenograft mouse models following intravenous administration. Once-weekly intravenous administration of ASP3082 induced dose-dependent and significant growth inhibition of KRAS G12D PDAC tumors, resulting in profound tumor regression without body weight loss. ASP3082 showed sustained concentrations in the xenograft tumors after a single intravenous administration and decreased KRAS G12D-mutated-protein levels according to the duration of the sustained ASP3082 concentrations. ASP3082 also demonstrated marked inhibition of extracellular signal-

regulated kinase phosphorylation and its downstream genes, and potently induced cleavage of caspase 3. In addition, ASP3082 exhibited potent antitumor activities in not only PDAC but also CRC and non-small cell lung cancer KRAS G12D-mutated mouse models. These studies demonstrated that ASP3082 induced degradation of KRAS G12D protein, inhibition of KRAS downstream molecules, and an apoptotic response to show dose-dependent antitumor activity in multiple KRAS G12D-mutated cancer models. ASP3082 is a potential therapeutic agent for patients with tumors harboring the KRAS G12D mutation. Currently, a phase 1 clinical trial is underway in patients with previously treated, locally advanced or metastatic solid tumors with KRAS G12D mutation (NCT05382559).

AZD9592: An EGFR-cMET bispecific antibody-drug conjugate (ADC) targeting key oncogenic drivers in non-small-cell lung cancer (NSCLC) and beyond

Frank Comer[1], Yariv Mazor[1], Elaine Hurt[1], Chunning Yang[1], Ryan Fleming[1], Harini Shandilya[1], Balakumar Vijayakrishnan[2], Meghan Sterba[1], Ruoyan Chen[1], Edward Rosfjord[1], Nicolas Floch[3], Anton I. Rosenbaum[4], Yue Huang[4], Jiaqi Yuan[4], Kevin Beaumont[5], Lisa Godfrey[6], Lara McGrath[7], Fernanda Arnaldez[1], Puja Sapra[1]. *[1]AstraZeneca, Gaithersburg, MD,[2]AstraZeneca, London, United Kingdom,[3]AstraZeneca, Cambridge, United Kingdom,[4]AstraZeneca, South San Francisco, CA,[5]AstraZeneca, Chesterford, United Kingdom,[6]AstraZeneca, Melbourn Science Park, United Kingdom,[7]AstraZeneca, Waltham, MA*

De novo and acquired drug resistance can limit the long-term efficacy of targeted cancer therapies such as tyrosine kinase inhibitors targeting key oncogenic drivers like EGFR and cMET. Mechanisms of resistance include secondary mutations of EGFR and cMET and other downstream oncogenic pathways such as KRAS and amplification of alternate growth factor receptors. MET amplification or protein overexpression has been established as the most common mechanism of clinical resistance to EGFR inhibitors such as osimertinib. AZD9592 is a first-in-class bispecific ADC designed to target EGFR and cMET, while overcoming pathway-mediated resistance mechanisms that limit other targeted agents. Here we describe the

generation, characterization and preclinical evaluation of AZD9592. The ADC was constructed on the backbone of the clinically validated DuetMab monovalent bispecific IgG platform and was engineered with higher affinity for cMET compared to EGFR (>15 fold), with the aim of reducing EGFR-driven toxicity in normal tissues. The antibody is conjugated via a cleavable linker to a proprietary topoisomerase 1 inhibitor (TOP1i) payload (AZ14170132). The internalization and *in vitro* cytotoxicity (IC_{50} in the low nM range) of AZD9592 were found to be optimal when both EGFR and cMET were engaged. When EGFR alone was engaged, cytotoxicity was significantly reduced, consistent with the lower affinity for EGFR. Treatment of cells with AZD9592 induced multiple DNA damage response pathway markers (like ATM, ATR, γH2AX), consistent with the proposed primary mechanism of action (MOA) of direct tumor-cell killing caused by double strand DNA breaks. AZD9592 monotherapy showed activity *in vivo* in patient-derived xenograft (PDX) models representing multiple EGFR and cMET expressing tumor types, including both EGFR mutant (m) and wild-type NSCLC and head and neck squamous cell carcinoma. Responses (≥30% regression from baseline tumor volume) were observed across a wide range of clinically relevant dose levels, including a 41% response rate in EGFRm NSCLC tumors treated at the lowest tested dose of 2 mg/kg. AZD9592 combined with osimertinib also showed benefit in PDX models derived from patients who progressed on osimertinib alone, as well as models representing primary resistance (EGFR ex20ins). AZD9592 was well tolerated in cynomolgus monkeys over a 6-week period (dosing every 3 weeks). The key safety findings were limited hematological effects, consistent with the MOA of the TOP1i payload. Plasma pharmacokinetics in cynomolgus monkeys showed an acceptable profile at tolerated doses, in line with other EGFR and cMET directed antibodies. These results demonstrate that AZD9592 has a promising efficacy and safety profile in preclinical models representing diverse opportunities in multiple clinical settings.

Evaluation of the relationship between target expression and *in vivo* anti-tumor efficacy of AZD9592, an EGFR/c-MET targeted bispecific antibody drug conjugate

Lara McGrath[1], Ying Zheng[2], Simon Christ[3], Christian C. Sachs[3], Sihem Khelifa[3], Claudia Windmüller[3], Steve Sweet[2], Yeoun Jin Kim[2], Daniel Sutton[4], Michal Sulikowski[4], Arthur Lewis[4], Ivan Inigo[2], Nicolas Floch[4], Edward Rosfjord[2], Fernanda Arnaldez[2], Frank Comer[2]. *[1]AstraZeneca, Waltham, MA,[2]AstraZeneca, Gaithersburg, MD,[3]AstraZeneca Computational Pathology GmbH, Munich, Germany,[4]AstraZeneca, Cambridge, United Kingdom*

AZD9592 is a bispecific antibody drug conjugate (ADC) designed to deliver a topoisomerase 1 inhibitor (TOP1i) cytotoxic payload (AZ14170133) to tumor cells. AZD9592 selectively binds to epidermal growth factor receptor (EGFR) and c-MET, two cell surface receptors highly expressed in solid tumors including non-small-cell lung cancer (NSCLC) and head and neck squamous cell carcinoma (HNSCC). Here we evaluate the pharmacodynamic activity of the TOP1i payload delivery by AZD9592 in an NSCLC-derived xenograft model using immunohistochemistry (IHC) approaches. Treatment-induced DNA double-strand breaks (DSB) and apoptotic cell death were measured using γH2AX, phospho-RAD-50 (pRAD50), and cleaved-caspase-3 (CC3) across increasing exposure to AZD9592. Furthermore, we report *in vivo* antitumor efficacy of AZD9592 in a panel of NSCLC and HNSCC patient-derived xenograft (PDX) models that were characterized for somatic tumor alterations, including oncogenic driver mutations in EGFR, tumor cell expression of EGFR and c-MET by IHC and deep-learning based image analysis, and targeted proteomics by mass spectrometry. Results demonstrate dose-dependent increases in pRAD50 and γH2AX upon treatment with AZD9592, signifying induction of DNA damage. Increased CC3 and reduced tumor volume (TV) in all treatment groups compared with control groups supports that AZD9592 induces tumor cell death due to formation of DNA DSB. In PDX experiments, tumor growth inhibition (TGI), defined as ≥30% reduction in TV from baseline after a single dose of AZD9592 8 mg/kg, was observed in 73% (16/22) of EGFR mutant NSCLC models. The models evaluated included tumors with or without prior exposure to EGFR tyrosine kinase inhibitors, and harboring diverse mutational profiles and heterogeneous expression levels of EGFR and c-MET. In EGFR wildtype NSCLC and HNSCC PDX, TGI was observed in 60% (12/20) and 44% (4/9) of models, respectively. IHC demonstrated an

association of target expression and response to treatment, suggesting a potential predictive feature of response in tumors with elevated antigen expression. Targeted proteomics demonstrated an association between the expression of SLFN11, a known TOP1i sensitivity marker, and treatment response. Collectively, these results support the hypothesized mechanism of action of AZD9592: TOP1i induced tumor cell death due to formation of DNA DSB, and suggest opportunities in the treatment of tumors with a range of molecular features. AZD9592 is currently in a Phase 1 clinical trial in advanced solid malignancies.

A pan-ras mRNA vaccine elicits specific immune responses and inhibits tumor growth in the mouse model of colon cancer

Renxiang Chen[1], Wei Liu[2], David M. Brown[1], Yong-Sik Bong[1], Jiaxi He[1], Dong Shen[1], Cun Yu Wang[2]. *[1]RNAimmune, Inc., Germantown, MD,[2]Jonsson Comprehensive Cancer Center and School of Dentistry, UCLA, Los Angeles, CA*

KRAS mutations are present in about 25% of tumors, making them one of the most common mutated oncogenes among human cancers. Specifically, KRAS G12 mutation (89%) is the most common in tumors, followed by G13 (9%) and Q61 (1%). These mutations were once considered "undruggable" for many years until appearance of sotorasib . However, it was developed only for G12C mutation.

We designed a Pan-Ras neoantigen mRNA vaccine (mRNA-1521), which covers all prevalent RAS mutations to achieve broad-spectrum cancer therapy. We synthesized a multiepitope neoantigen KRAS mRNA vaccine (mRNA-1521) and examined its immune response and anti-tumor efficacy in the colon cancer of Balb/c mice . Two groups (A, B) of mice were immunized with mRNA-1521 on days 0, 21, and 49, while PBS was given to two other groups (C, D) as the control on the same days. All mice were inoculated with CT26 cells (colon carcinoma cell line harboring G12D mutation) on day 56. Afterward, anti-PD1 antibodies were administered to groups A and C every two days. Tumor sizes were measured every 3 days after inoculation until anyone exceeded 1500mm^3 in the control group. The serum IgG titer and T cell response of mice were explored using ELISA and splenocyte ELISpot assay after euthanasia. Tumor tissues were harvested

and embedded in paraffin for the immunohistochemistry (IHC) test. Next-generation sequencing (NGS) was also applied to investigate the whole transcriptome analysis.
Tumor growth rates in all treatment groups were slower than in the control group. Among them, the mean tumor size and weight in the combination group of mRNA-1521 and anti-PD1 (372mm^3, 0.48g) were only 25% of the PBS group (1488mm^3, 2g). On average, the anti-PD1 and vaccine groups had moderate tumor size and weight (1100mm^3/1.5g and 886mm^3/1.26g, respectively). The splenocytes from the mice in each group were collected. The IFN-γ secreting splenocytes in the combination group were 50% higher than the mRNA-1521 group. Furthermore, the total IgG titer of vaccine-immunized mice (OD450nm>2) was 3 and 4 times higher than the anti-PD1 and control groups. The IHC showed that the tumor tissues in the vaccine groups had more CD8+ and granzyme B+ CD8+ T cell infiltrations than in the control group. Whole transcriptome analysis showed that RAS downstream gene expressions were significantly lower in the vaccine group, indicating that the RAS vaccine was effective in inhibiting signaling pathways accounting for tumor proliferation, progression, and migration. In conclusion, prophylactic immunization of mRNA-1521 inhibited tumor growth in the mouse model of colon cancer. Its inhibitory effects on tumor growth were more remarkable in the combination of anti-PD1 antibodies. Moreover, the vaccine could elicit specific T and B cell responses, which are crucial in anti-cancer immunotherapy.

Targeting WEE1 to improve the therapy of KRAS G12C mutant non-small cell lung cancer

Gaku Yamamoto, Kosuke Tanaka, Ryo Kamata, Shunta Mori, Jie Liu, Toyohiro Yamauchi, Yuta Sakae, Akihiro Ohashi, Susumu S. Kobayashi.
National Cancer Center Japan, Kashiwa, Chiba, Japan

Background: While sotorasib is the first clinically approved small-molecule inhibitor of KRAS G12C in non-small-cell lung cancer (NSCLC), efficacy of sotorasib alone is limited, presumably due to adaptive resistance mechanisms in cancer cells. To expand therapeutic potential of sotorasib, combination strategies need to be developed. In this study, we conducted a large-scale screening to identify novel combination candidates with

sotorasib. In addition, molecular mechanisms of synergistic effects were investigated in multiple preclinical models.
Methods: To identify novel combination partners of sotorasib, we conducted high-throughput screening using a kinase inhibitor library containing 1,400 chemical compounds. Anti-proliferative and apoptotic effects in vitro were assessed by ATP-based cell viability assay and/or clonogenic assay, and caspase 3/7 assay and/or Annexin V assay, respectively. Synergistic effects were evaluated by calculating the BLISS index and visualized by SynergyFinder Plus. Immunoblotting was performed using antibodies against pCDK1 (Tyr15), pERK, pAkt, MCL1, BIM, PUMA, BCL2, or BCL-xL. In vivo efficacy studies were performed using a KRAS G12C mutant H358 xenograft nude mouse model.
Results: Through the large-scale unbiased combination screening of -1,400 kinase inhibitors, we identified a WEE1 inhibitor (AZD1775), a G2/M checkpoint abrogator in clinical-stage development, as a promising combination partner of sotorasib in KRAS G12C mutant NSCLC. The synergistic effects in vitro were broadly observed in multiple KRAS G12C mutant NSCLC cell lines, regardless of single-agent sensitivity to sotrasib or co-occurring oncogenic mutation profiles. The combination treatment upregulated pro-apoptotic protein BIM, leading to apoptosis. In vivo efficacy studies in H358-xenografted models also demonstrated remarkable tumor regression and durable response in mice treated with sotorasib and AZD1775 compared to ones with a single agent alone.
Conclusion: We identify AZD1775, a WEE1 inhibitor, as a novel combination candidate, which enhanced the anti-tumor activity of sotorasib both in vitro and in vivo preclinical models. These findings can lead to a novel therapeutic strategy for KRAS G12C mutant NSCLC.

Novel Antitumor Agents, PI3K/AKT Inhibitors, Proteasome Inhibitors, and Topoisomerases

Prostaglandin E2 receptor EP2: A novel target for high-risk neuroblastoma

Ruida Hou[1], Ying Yu[2], Jun Yang[3], Jianxiong Jiang[2]. *[1]University of Tennessee Health Science Center, Memphis, TN,[2]Pharmaceutical Sciences,*

University of Tennessee Health Science Center, Memphis, TN,[3]Surgery, St. Jude Children`s Research Hospital, Memphis, TN

Neuroblastoma (NB) is the most common pediatric extracranial solid tumor. Based on tumor stage and histological features, 50% of NBs are classified as high-risk diseases, a subtype characterized by a quite unsatisfactory long-term survival even with the striking advances in NB management that have been achieved in the past decades. Cyclooxygenase-2/prostaglandin E2 (COX-2/PGE_2) cascade has been reported to foster a proinflammatory tumor-nourishing microenvironment in NB. However, the specific downstream PGE2 receptor (EP) subtype which directly mediates this tumor promoting effect remains elusive. Therefore, in our research, we aim to 1) elucidate the culprit EP receptor that is directly involved in NB development; 2) evaluate the feasibility of inhibiting the PGE_2 receptor subtype as a novel treatment strategy for high-risk NB. To start with, we analyzed the gene expression profiles of the COX2/PGE_2/EP pathway from four major NB datasets (Versteeg, Kocak, SEQC, and NRC) on R2 platform. It indicates that the COX-2/PGE_2/EP2 signaling axis is highly associated with the expression of high-risk NB markers, as well as an abysmal overall survival rate. Moreover, a time resolved fluorescence resonance energy transfer (TR-FRET) method was adopted to reveal that EP2 receptor is the key Gαs-coupled receptor that mediates PGE2-initiated cAMP signaling in high-risk NB cell lines. Genetic interference of EP2 receptor expression by CRISPR/Cas9-mediated genome editing and doxycycline induced conditional knockdown significantly inhibited high-risk NB development and progression both in neuro-sphere formation assay and in nude mice xenograft models. Finally, we tested the anti-NB efficacy of our recently developed selective and bioavailable small-molecule EP2 antagonists. With a consecutive treatment of three weeks, decreased tumor size and weight have been observed in both high-risk NB xenograft model and immunocompetent allograft model, simultaneously with decreased inflammation, angiogenesis, and enhanced apoptosis. Collectively, our results suggest that the PGE2/EP2 pathway contributes to the growth and malignant potential of high-risk NB; pharmacological inhibition on EP2 receptor by our drug-like compounds might provide a novel therapeutic strategy for this deadly pediatric cancer.

#4924

Alternative lengthening of telomeres is associated with hypersensitivity to topoisomerase 1 inhibition in glioblastoma xenograft models

Stephen T. Keir, Heng Liu, Justin T. Low, Christopher J. Pirozzi, Nathan Reynolds, Eric S. Lipp, Annick Desjardins, Henry S. Friedman, Mustafa Khasraw, Darell D. Bigner, David M. Ashley, Matthew S. Waitkus. *Duke University School of Medicine, Durham, NC*

Glioblastoma (GBM), the most common primary malignant brain tumor in adults, is an incurable disease that has an inevitable tendency to recur following standard of care surgery, radiotherapy, and temozolomide chemotherapy. There is an urgent need for improved medical therapies. The topoisomerase I inhibitor irinotecan has been investigated and used in the treatment of GBM for over 20 years. Clinical trials investigating irinotecan as monotherapy and in combination with temozolomide and bevacizumab have failed to show an overall survival benefit for newly diagnosed and recurrent GBM. Consequently, irinotecan is not commonly recommended for GBM treatment. However, these trials were conducted prior to the advent of molecularly-guided GBM subtyping, which is now a cornerstone of glioma diagnostics according to the updated WHO 2021 classification. To understand the extent to which molecularly-defined glioma subgroups differentially respond to clinically relevant therapies, we investigated the sensitivity of GBM patient-derived xenografts (PDXs) against a panel of chemotherapeutic agents, including temozolomide, bevacizumab, and irinotecan. All GBM PDXs (n=9) were responsive to irinotecan when grown as subcutaneous tumors. Two PDX lines exhibited hypersensitivity to irinotecan, which was marked by treatment-induced regression of subcutaneous tumors and increased median survival of 61 and 90+ days. Molecular analyses revealed that these hypersensitive lines were both ATRX-deficient tumors that displayed the alternative lengthening of telomeres (ALT) phenotype, while the less sensitive lines were all ATRX-intact and demonstrated *TERT* activation. One of the hypersensitive lines was $IDH1^{R132H/WT}$ while the other was $IDH1^{R132H/-}$ (historically termed secondary GBM; grade 4 astrocytoma per 2021 WHO classification). Cell-based studies showed that irinotecan sensitivity did not correlate with D-2HG producing capacity of the cells and was not impacted by inhibition of

the mutant IDH1 enzyme. Irinotecan treatment significantly prolonged survival of orthotopic ALT+ PDXs relative to a vehicle control (64 days versus 41.5 days median survival). These results suggest that ALT+ gliomas may be particularly sensitive to topoisomerase inhibitor therapy. Our study highlights the need to interpret glioma clinical trial results in light of key molecular biomarkers, including indicators of ALT activity (e.g. ATRX deficiency, ultrabright telomeric foci, and C-circles). In addition, our results suggest that ALT-related biomarkers may be useful for identifying glioma patients who may benefit from topoisomerase inhibitor therapy.

#4925

Cannabidiol and *Cannabis Sativa* as a potential treatment in vitro prostate cancer cells silenced with RBBp6 and PC3 xenograft

Lesetja Raymond Motadi, Zodwa E. Jantjies. *University of Johannesburg, Johannesburg, South Africa*

Background: Prostate cancer is the second most frequently occurring carcinoma in males worldwide and one of the leading causes of death in men around the world. Recent studies estimate that over 1.4 million males are diagnosed with prostate cancer on an annual basis, with approximately 375 000 succumbing to the disease annually. With current treatments continuing to show severe side effects, there is a need for new treatments. In this study we looked at the effect of *cannabis sativa* extract, cannabidiol and cisplatin on prostate cancer cells, PC3.
Methods: In addressing the above questions, we employed the MTT assay to measure the antiproliferative effect on PC3 cells following treatment with varying concentrations of *Cannabis sativa* extract, cisplatin and cannabidiol. xCELLigence was also used to confirm the IC50 activity in which cells were grown in a 16 well plate coated with gold and monitor cell attachment. Caspase 3/7 activity was also measured using 96 well-plate following treatment. Western-blot and qRT-PCR was also used to measure the gene expression of tumor suppressor genes, p53, Bax and Bcl2. Animal studies were employed to measure the growth of PC3-mouse derived cancer to evaluate the effect of compounds *in vivo* .
Results: From the treatment with varying concentrations of *Cannabis sativa* extract, cannabidiol and cisplatin, we have observed that the three compounds induced antiproliferation of PC3 cancer cell lines through the

activation of caspase 3/7 activity. We also observed induction of apoptosis in these cells following silencing of retinoblastoma binding protein 6 (RBBP6), with upregulation of p53 and bax mRNA expression, and a reduction in Bcl2 gene expression. The growth of tumors in the mouse models were reduced following treatment with cisplatin and cannabidiol. Conclusion: We demonstrated that cannabidiol is a viable therapy to treat prostate cancer cells, in combination with silencing of RBBP6. This suggests that cannabidiol rather *Cannabis sativa* extract may play an important role in reducing cancer progression.

Alpelisib in combination with trastuzumab and pertuzumab as maintenance therapy in patients with HER2+, *PIK3CA*-mutant advanced breast cancer: EPIK-B2 Study Part 1 safety and efficacy results

Sara A. Hurvitz[1], François-Clement Bidard[2], Wei Li[3], Xichun Hu[4], Sonia Pernas[5], Joseph Thaddeus Beck[6], Mario Campone[7], Kevin Punie[8], Michelle Miller[9], Mathilde Kaper[9], Yu Han[9], Farhat Ghaznawi[9], Guy Jerusalem[10].
[1]Department of Medicine, UCLA David Geffen School of Medicine, Jonsson Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Medical Oncology, Institut Curie, UVSQ/Université Paris-Saclay, Saint-Cloud, France,[3]Cancer Center, The First Hospital of Jilin University, Changchun, China,[4]Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China,[5]Department of Medical Oncology, Institut Català d'Oncologia, L'Hospitalet, Barcelona, Spain,[6]Highlands Oncology, Springdale, AR,[7]Institut de Cancérologie de l'Ouest, Saint Herblain, France,[8]Department of General Medical Oncology and Multidisciplinary Breast Centre, Leuven Cancer Institute, University Hospitals Leuven, Leuven, Belgium,[9]Novartis Pharmaceuticals Corporation, East Hanover, NJ,[10]CHU Sart Tilman Liège and Liège University, Liege, Belgium

Introduction: Current standard first-line (1L) treatment (tx) for patients (pts) with human epidermal growth factor receptor 2 (HER2)-positive advanced breast cancer (ABC) includes taxanes plus trastuzumab (T) and pertuzumab (P). Mutations (mut) in phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha (*PIK3CA*) gene encoding PI3Kα have been reported

in 12%-39% of HER2+ BCs and associated with worse prognoses and lower pathological complete response to anti-HER2 tx in the neoadjuvant setting. Alpelisib (ALP) is an oral, α-specific PI3K inhibitor approved at 300 mg per day (QD) in combination with fulvestrant in hormone receptor (HR)-positive, HER2−, *PIK3CA*-mut ABC following progression on/after endocrine therapy. EPIK-B2 is a 2-part Phase 3 study to evaluate ALP plus T+P as 1L maintenance tx in pts with HER2+, *PIK3CA*-mut ABC, without progressive disease at study entry. Here, we report results of Part 1, the safety run-in of EPIK-B2.

Methods: Part 1 of EPIK-B2 was open label and assessed safety of ALP plus T+P in pts with HER2+ ABC and confirmed the recommended Phase 3 dose of ALP for the randomized Part 2. Pts with HER2+ ABC, with or without a *PIK3CA* mut, who had completed induction taxane chemotherapy plus T+P were eligible for Part 1. Part 2, currently enrolling, allows only *PIK3CA*-mut pts. Pts in Part 1 received 300 mg (Cohort A) or 250 mg (Cohort B) ALP QD plus 6 mg/kg T and 420 mg P, on Day 1 of each 21-day cycle. The primary endpoint of Part 1 was incidence of dose-limiting toxicities (DLTs) in the first 6 wk of tx; secondary endpoints included safety/tolerability and ALP exposure by dose level. Preliminary confirmed overall response rate (ORR; best overall response [BOR] of CR/PR) and clinical benefit rate (CBR; BOR of CR/PR/SD lasting ≥24 wk) were evaluated per RECIST v1.1 during the on-treatment period.

Results: Three pts in Cohort A and 12 in Cohort B received 300 mg and 250 mg ALP, respectively. DLTs, 1 event each of hyperglycemia and dermatitis acneiform, were seen in Cohort A, none were reported in Cohort B pts given 250 mg ALP; however, Part 2 of EPIK-B2 will be initiated with 200 mg ALP with the option of intrapatient dose escalation to 250 mg QD, the maximum tolerated dose, per FDA feedback to consider a lower toxicity threshold in 1L maintenance setting. No unexpected AEs were reported; most common AEs were diarrhea, decreased appetite, and hyperglycemia. Six of 15 pts (40%; 2 in Cohort A, 4 in Cohort B) had *PIK3CA*-mut disease. Among these, ORR was 50% (n/N=3/6) and CBR was 100% (n/N=6/6). Tumor response was maintained in 5 of 6 pts with *PIK3CA* mutations (83%) after ≥21 cycles of tx (range, 21-31).

Conclusions: ALP plus T+P combination is safe; reported AEs align with those in previous ALP studies. Preliminary efficacy data suggest promising

clinical benefit with ALP plus T+P for pts with HER2+ *PIK3CA*-mut disease.

#4927

Exarafenib (KIN-2787) is a potent, selective pan-RAF inhibitor with activity in preclinical models of BRAF class II/III mutant and NRAS mutant melanoma

Tim S. Wang[1], Catherine Lee[1], Paul Severson[2], Robert J. Pelham[2], Richard Williams[2], Nichol L. G. Miller[1]. *[1]Kinnate Biopharma, San Diego, CA,[2]Kinnate Biopharma, San Francisco, CA*

Background: MAPK activating mutations are common in melanoma, with 40% of cases attributed to oncogenic BRAF mutations and 20-25% NRAS mutations. Secondary MAPK activation is a known resistance mechanism to approved BRAF inhibitors in BRAFV600 melanoma. While BRAF inhibitors are approved for Class I BRAFV600 melanomas, patients with dimer-driven BRAF Class II/III and RAF1-dependent NRAS activated melanomas lack approved targeted therapy. Development of next-gen pan-RAF inhibitors targeting all RAF proteins and mutant dimers remains a priority. Emerging clinical data from pan-RAF inhibitors combined with MEK inhibitors suggests increased benefit for MAPK-altered melanoma patients. Exarafenib (KIN-2787) is a clinical stage, novel, highly selective pan-RAF inhibitor designed to be effective in RAF-dependent cancers.Methods: KIN-2787 was evaluated using enzyme assays across the human kinome and activity against oncogenic RAF alterations were validated in BaF3 cells. MAPK pathway suppression and cell growth inhibition were assessed across a panel of human tumor cell lines. Combination dose matrices were performed with KIN-2787 and binimetinib (bini) to evaluate synergistic cell growth inhibition. Extended cell growth studies were performed by Incucyte. In vivo KIN-2787 efficacy was evaluated in cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models of human BRAF and NRAS mutant cancer.Results: Exarafenib demonstrated exceptional kinome selectivity with minimal off-target kinases significantly inhibited relative to BRAF. Exarafenib potently inhibited a broad panel of oncogenic BRAF mutations in biochemical and BaF3 cell assays. Functional MAPK signaling and viability studies in human tumor cell lines highlighted exarafenib activity in

BRAF and NRAS mutant melanoma with minimal activity in normal (BRAF WT) cells. Synergy with the MEK inhibitor bini was determined and the exarafenib + bini combination durably inhibited growth in NRAS mutant melanoma cell lines. In line with cellular studies, treatment with exarafenib demonstrated significant tumor growth inhibition at 30 mg/kg BID in CDX and PDX models of human NRAS mutant melanoma. 10 mg/kg BID exarafenib combined with a clinically relevant dose of bini resulted in combination benefit and durable suppression of the MAPK pathway, relative to either agent alone.Conclusions: The superior kinome selectivity of exarafenib and its activity across multiple RAF-dependent melanoma models position it as a potentially class-leading pan-RAF inhibitor. In addition to efficacy in BRAF mutant tumors, these data support use of exarafenib in combination therapy with MEK inhibitors in NRAS mutant melanoma. A Ph I dose escalation clinical trial evaluating the safety and efficacy of exarafenib in monotherapy and in combination with binimetinib is ongoing (NCT04913285).

#4928

Gedatolisib, a well-tolerated pan-PI3K/mTOR inhibitor, exhibits potent therapeutic effects on gynecological cancer models regardless of their PI3K pathway mutational status

Stefano Rossetti, Aaron Broege, Ian MacNeil, Ben Rich, Jhomary Molden, Brian Sullivan, Lance Laing. *Celcuity, Minneapolis, MN*

Background: The PI3K, AKT, and mTOR (PAM) pathway is one of the most commonly activated oncogenic pathways in gynecological cancers. Loss of PTEN function and PIK3CA activating mutations are especially frequent in endometrial cancer (EC). Targeting the PAM pathway, in combination with other cooperative oncogenic pathways (e.g., the estrogen pathway), is a promising EC treatment strategy. Currently, everolimus, an mTORC1 inhibitor, in combination with letrozole, an aromatase inhibitor, is one of the available hormonal therapy options for patients with advanced endometrioid EC. Most PAM inhibitors (PAM-i) selectively spare (or weakly inhibit) one or more key PAM pathway components, which can lead to drug resistance. To minimize drug resistance, a more comprehensive inhibition of the PI3K isoforms and downstream mTOR complexes may be required. We hypothesized that gedatolisib, which potently inhibits all Class

I PI3K isoforms, mTORC1, and mTORC2, can potentially be an effective and well tolerated therapy for patients with EC.
Methods: A panel of endometrial, ovarian and cervical cancer cell lines with different PI3K pathway mutational status were assayed for their sensitivity to gedatolisib and other PAM inhibitors (PI3K-α: alpelisib, pan-PI3K: copanlisib; AKT: capivasertib; mTORC1: everolimus; pan-PI3K/mTOR: gedatolisib). Cell viability, cell proliferation, and flow cytometry analytical assays were conducted. Xenograft studies evaluating gedatolisib in EC cell lines were also performed.
Results: Gedatolisib strongly inhibited PAM pathway activation, and reduced cell cycle progression and cell viability in the endometrial, ovarian, and cervical cancer cell lines. Compared to the other PAM-i, Gedatolisib exhibited superior anti-proliferative potency and efficacy in almost all the cell lines tested, regardless of the PI3K pathway mutational status or cancer type. In EC xenografts, gedatolisib substantively inhibited tumor growth irrespective of the cell line models' PI3K pathway mutational status.
Conclusions: We demonstrated that, gedatolisib induces superior anti-proliferative activity compared to the other PAM pathway inhibitors, regardless of the PI3K pathway mutational status of the cancer cell lines evaluated. Gedatolisib as a single agent and in combination with other therapies has previously reported promising preliminary clinical efficacy and safety in various solid tumor types, including EC. In summary, nonclinical and preliminary clinical data supports the development of gedatolisib in combination with hormonal therapy for treatment of patients with EC.

ICX-101, a novel MYC inhibitor, shows antitumor activity in patient-derived cells of advanced lung cancer with high MYC expression
Wonyoung Choi, Kyung-Chae Jeong, Seog-Yun Park, Sunshin Kim, Eun Hye Kang, Mihwa Hwang, Ji-Youn Han. *National Cancer Center, Goyang, Korea, Republic of*

Background: MYC is an attractive therapeutic target in lung cancer. ICX-101 is a novel potent, selective small molecule that directly inhibits the binding of MYC/MAX dimers to the DNA binding sequence E-box. Here, we show that ICX-101 shows antitumor activity in patient-derived cells

(PDC) of advanced lung cancer and that the drug responses are correlated with the MYC expression levels.
Methods: PDCs of lung cancer were treated with ICX-101, and the area under the dose-response curve (AUC) was measured as the readout for antitumor efficacy. MYC expression level of each PDC was measured with the fold expression of mRNA compared to the normal lung tissue. The patient's clinical data and survival outcomes were analyzed to correlate with the drug responses of PDCs.
Results: We collected 100 PDCs from 82 lung cancer patients. The histologic types included adenocarcinoma (N = 82), squamous cell carcinoma (N = 10), non-small cell lung cancer (NSCLC) not otherwise specified (NOS) (N = 4), and small cell lung cancer (SCLC, N = 4). PDCs derived from SCLC showed higher MYC expression levels than NSCLC ($P = 0.004$). MYC was a prognostic factor, as the patient groups with the top and bottom 25 percentiles of MYC mRNA expression had an overall survival of 932.5 and 256 days, respectively ($P = 0.029$). However, MYC expression was predictive for the response to ICX-101, as the PDCs with the top 25 percentiles of MYC levels showed markedly lower AUC values than those with the bottom 25 percentile ($P < 0.001$). Additionally, the MYC mRNA levels and AUC values were inversely correlated with statistical significance ($R = -0.46$, $P < 0.001$).
Conclusion: ICX-101 is a potent MYC inhibitor that shows antitumor activity in lung cancer PDCs. Our results suggest the potential of ICX-101 as a possible therapeutic option in advanced lung cancer with high MYC expressions.

#4930
Foldamers mimicking the B-DNA surface as a new class of DNA topoisomerase I inhibitors
Aurélie Garcin[1], Valentina Corvaglia[2], Madeleine Bossaert[3], Marie-Jeanne Pillaire[3], Ivan Huc[2], Sébastien Britton[3], Vincent Parissi[4], Philippe Pourquier[1]. *[1]INSERM U1194 - IRCM (Montpellier), Montpellier, France,[2]Department of Pharmacy and Center for Integrated Protein Science, Ludwig-Maximilians-Universität, Munich, Germany,[3]Institut de Pharmacologie et Biologie Structurale, IPBS - CNRS, Toulouse, France,[4]Laboratoire de Microbiologie Fondamentale et Pathogénicité (MFP) UMR 5234 CNRS, Bordeaux, France*

DNA mimicry has been the subject of intensive research and resulted in the development of DNA analogues such as PNAs and LNAs. There are also examples of proteins with structural and/or charge distribution analogies with respect to the DNA double helix which allow them to interfere with other DNA-binding proteins and modulate the biological processes in which they are involved. We previously characterized a new class of DNA-surface mimic molecules constituted by repetitions of dimeric units of 8-amino-2-quinolinecarboxylic acid (Q) and 8-aminomethyl-2-quinolinecarboxylic acid (mQ). The helical folding of these entities can mimic a B-DNA molecule, displaying a minor and a major groove that can be modulated depending on the dimers and of the nature of their side chains. In vitro, these DNA mimics could inhibit, in a relative selective manner, the catalytic activity of DNA topoisomerase I (Top1), whereas they had no effect on the activity of DNA polymerases or DNAses. Inhibition of Top1-mediated relaxation of supercoiled DNA plasmid increased with the length of the DNA mimics. Here, we further characterized the mechanism of Top1 inhibition by these DNA mimics. We found that, conversely to camptothecin (CPT) and its derivatives that poison Top1 via the inhibition or the re-ligation step of the reaction, DNA mimics inhibited Top1-mediated DNA cleavage *in vitro* by preventing the binding of the enzyme to its substrate, a mechanism of Top1 competitive inhibition that was formerly referred to as catalytic inhibition. We also found that co-incubation of DNA mimics with CPT had an additive effect on the inhibition of Top1-mediated relaxation of supercoiled DNA, further suggesting a mechanism that is different from CPT. Because transfection of DNA mimics could inhibit the growth of various cancer cell lines, we further investigated whether Top1 could play a role in this cytotoxicity. We found that Top1 knock-down in OVCAR4 ovarian cancer cells resulted in decreased sensitivity to the (mQQ4)8 DNA mimic as compared to OVCAR4 control cells, suggesting that Top1 is a target of DNA mimics in cells and is involved in their cytotoxic effects. Conversely to CPT, transfection of HCT116 cells with the (mQQ4)8 DNA mimic was not associated with an increase in γH2AX, suggesting that DNA mimics do not induce DNA breakage. We are currently analyzing whether the (mQQ4)8 can have an impact on CPT-induced Top1-DNA complexes formation. Interestingly, we also showed that several SN38-resistant HCT116 cell clones characterized by specific

Top1 mutations were still sensitive to the (mQQ4)8 DNA mimic. Together our results demonstrate that DNA mimics can be considered as a new class of competitive inhibitors of Top1. Further studies are ongoing to identify the structural features that are essential for Top1 inhibition in order to generate more potent derivatives that could be used to counteract resistance to CPT derivatives used in the clinic.

Novel cancer suppressing role of REIC/DKK3 protein through a downregulation of cell surface PD-L1 in breast cancer cells

Yuma Gohara, Nahoko Tomonobu, Rie Kinoshata, Lena Audebert, Youyi Chen, Ni Luh Gede Yoni Komalasari, Fan Jiang, Chikako Yoshizawa, Hitoshi Murata, Ken-ichi Yamamoto, Masakiyo Sakaguchi. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan*

Adenovirus vector carrying REIC gene (Ad-REIC) is currently in clinical evaluation. The anti-cancer effect of Ad-REIC is mainly caused by two ways, cancer specific apoptosis via endoplasmic reticulum stress with an abundant REIC protein and indirect immune effects by the secreted REIC protein. The former had been well studied that gave us general comprehension of its mechanisms, however latter has still not been fully elucidated. To clear this, we have aimed to identify putative receptor(s) to the extracellularly secreted REIC protein, and have fortunately succeeded to identify five candidates. Surprisingly, the identified receptors all worked to bind with PD-L1 and hold it to stabilize on the plasma membrane, and the REIC binding to the receptors induced liberation of PD-L1 from the receptors' lock, resulting in an accelerated degradation of PD-L1. This novel insight may lead to the elucidation in important part of the REIC-mediated indirect anti-cancer role.

#4932

The role of KB-S in treating pancreatic cancer

Sadia Noosrat Boshra, Kirpal Bisht, Mildred Acevedo-Duncan. *Chemistry, University of South Florida, Tampa, FL*

Pancreatic cancer remains one of the most lethal malignant cancers because the symptoms of this cancer do not exhibit until the disease progresses to an advanced stage. Late diagnosis may result in metastasis. When metastasis occurs, cancer can no longer be removed with surgery and therefore, requires treatment with FDA approved chemotherapeutic drugs or radiotherapy and they often fail to treat the disease. KB-S is a synthetic thymidine nucleoside analogue which is broadly used for the treatment of Human Immunodeficiency Virus (HIV). In this work, we explored the therapeutic potential of KB-S as an anticancer drug, with focused against pancreatic cancer. Our aim is to establish a connection between cellular kinase of KB-S and atypical protein kinase C (aPKC) to decipher signaling pathways. Pancreatic adenocarcinoma, ASPC-1 cell line was used for the study. Hemocytometer was used for cell counting for the dose response curve after treating with KB-S. Immunoprecipitation study was conducted using anti-PKC-iota beads. Western blot assay was performed using primary antibody PKC-zeta and a secondary antibody. Our results showed that KB-S decreases cell proliferation significantly on AsPC-1 cells over increasing the concentrations. KB-S decreased the proliferation by 20% for 0.5 μM ($P \leq 0.09$), 37% for 5 μM ($P \leq 0.02$), 44% for 10 μM ($P \leq 0.01$), 48% for 20 μM ($P \leq 0.002$) and 54% for 50 μM ($P \leq 0.001$) in AsPC-1 cells. We used the lowest concentration of 10 μM with significant inhibition for further experiments. We immunoprecipitated for PKC-ι and immunoblotted for PKC-ζ and the immunoblots showed that there is no association between PKC-ι and PKC-ζ in pancreatic cancer cell line (AsPC-1). But when we performed reverse immunoprecipitation, we found that there is an association between PKC-ι and PKC-ζ. Again, we immunoprecipitated for thymidine kinase and immunoblotted for PKC-ι and immunoblots showed that there is an association between thymidine kinase and PKC-ι. But when we did the reverse immunoprecipitation, we did not find any association between thymidine kinase and PKC-ι in pancreatic cancer cell line. Based on our preliminary studies, we report the anti-cancer effect of KB-S in treating a pancreatic cancer cell line leading to further future investigations. To the best of our knowledge, this is the first demonstration of therapeutic efficacy of KB-S against a cancer. Given that, KB-S is already approved by FDA for the treatment of HIV, it carries the potential to be repurposed for difficult to cure cancerous diseases such as pancreatic cancer.

#4933

Duvelisib eliminates CLL B Cells, impairs CLL-supporting cells, and overcomes ibrutinib resistance in a patient-derived xenograft model

Shih-Shih Chen[1], Jacqueline C. Barrientos[1], Gerardo Ferrer[1], Priyadarshini Ravichandran[1], Michael Ibrahim[1], Yasmine Kieso[1], Jeffery L. Kutok[2], Marisa Peluso[2], Sujata Sharma[2], David T. Weaver[3], Jonathan A. Pachter[3], Kanti R. Rai[1], Nicholas Chiorazzi[1]. *[1]The Feinstein Institutes for Medical Research, Manhasset, NY,[2]Infinity, Cambridge, MA,[3]Verastem Oncology, Needham, MA*

Duvelisib (IPI-145), a first-in-class, oral, dual PI3K-δ,γ inhibitor, has been approved by the FDA for the treatment of patients with chronic lymphocytic leukemia (CLL), small lymphocytic and follicular lymphoma. Duvelisib potently inhibits PI3K-δ and PI3K-γ, thereby offering a novel therapeutic approach. Here we aimed to understand how duvelisib targets CLL cells and the tumor microenvironment (TME) and hence how it affects CLL, even with BTK-resistant disease.

We first assessed the distinct contributions of PI3K-δ and PI3K-γ on CLL cell survival, proliferation, and migration *in vitro* by using PI3K-δ (PI3K-δi) or PI3K-γ (PI3K-γi) specific inhibitors in addition to duvelisib. We found a significant reduction in viable CLL cells after exposure to PI3K-δi and duvelisib. By measuring Ki67 and p-AKT levels, we found duvelisib and PI3K-δi more potently block CLL cell proliferation than PI3K-γi. PI3K-δi and duvelisib also significantly reduced the migration of CLL B cells into the spleen relative to control. In contrast, PI3K-γi inhibited T cell not B cell homing in vitro and in vivo.

We then investigated the impact of single versus dual inhibitory agents on myeloid cells. Tumor-associated macrophages (TAMs) of the "M2 phenotype" contribute to a pro-tumor TME by preventing the induction of T cell mediated anti-tumor immunity. We expanded murine bone marrow derived monocytes and then polarized them to M2 macrophages, in the absence or presence of PI3Ki. At 100nM, PI3K-γi, but not PI3K-δi, significantly inhibited M2 polarization. Duvelisib significantly reduced *Arg1* expression at doses equal to or above 10nM. While co-culturing leukemic B cells with M2-polarized murine macrophages increased CLL-cell survival, addition of duvelisib to such co-cultures significantly reduced

CLL cell survival. Altogether, duvelisib sensitizes primary CLL cells to apoptosis and abrogates M2 cell-mediated CLL-cell survival.
Finally, in a patient-derived xenograft mouse model (PDX), we demonstrated the essential roles of PI3K-δ and PI3K-γ in the CLL TME. Specifically, we found a more efficacious inhibition in CLL cell burden by dual inhibition of PI3K-δ,γ. Also, samples from patients whose disease progressed on ibrutinib were responsive to duvelisib therapy in PDX, irrespective of *BTK* mutations. In support of this, we identified an ibrutinib resistant CLL patient, with a clone exhibiting *BTK* and *PLCγ2* mutations who responded immediately to single agent duvelisib with redistribution lymphocytosis followed by a partial clinical remission associated with subsequent modulation of T and myeloid cells.
In conclusion, our data define the mechanism of action whereby dual inhibition of PI3K-δ,γ affects CLL B cell numbers and T and myeloid cell pro-leukemia functions, supporting the use of duvelisib as a potentially valuable therapeutic intervention, including for patients refractory to BTKi.

#4934

CAPAC: a modular platform that can improve the safety and efficacy of existing cancer therapies

George Coricor, Jesse M. McFarland, Masa Aleckovic, Sangeetha Srinivasan, John Lee, Leslie Priddy, Matthew Tso, Tri-Hung Nguyen, Jose M. Mejia Oneto. *Shasqi Inc, San Francisco, CA*

Click chemistry is a Nobel Prize winning technology that has been widely used in research across the life sciences. Shasqi's Click Activated Protodrugs Against Cancer (CAPAC^{TM}) platform is pioneering the therapeutic application of click chemistry reactions in humans. The 1st gen CAPAC technology enables activation of potent anti-cancer agents at the tumor site while reducing systemic exposure and is comprised of a tetrazine-modified biopolymer (tumor targeting agent) injected intratumorally and a systemically administered trans-cyclooctene-modified payload, named a protodrug. Our lead clinical candidate SQ3370 (SQL70 biopolymer + SQP33, doxorubicin protodrug), is being evaluated in a Phase 2a study in solid tumors (NCT04106492). CAPAC platform is highly modular and can be applied to multiple cancer drugs especially those with narrow therapeutic index(s) due to toxicity. Because the tumor targeting

agent (i.e., biopolymer) is separate from the protodrug, it enables the flexibility of interchanging different protodrugs with different mechanism of actions such as tubulin inhibitors (e.g., paclitaxel), topoisomerase inhibitors (e.g., exatecan), immune activators (e.g., TLR agonists), and others. This benefit can be translated in the clinic with tailored combinations for individual patients. Here we will present data on protodrugs of paclitaxel, exatecan, and TLR7/8a agonist. These therapeutics have shown considerable safety concerns either alone or in combination with other therapies in the clinic and may benefit from the precise activation at the tumor site that can be achieved by the CAPAC platform. *In vitro* cytotoxicity assays showed ≥20 fold-attenuation of both paclitaxel and exatecan protodrugs in various cancer lines. In a proliferation assay using mouse splenocytes we observed ≥100-fold attenuation of a TLR7/8a protodrug. These results suggest that the protodrugs may exhibit higher therapeutic indeces with enhanced safety profile. We tested the anti-tumor efficacy of paclitaxel protodrug in combination with SQL70 biopolymer in NCI-N87 gastric cancer xenograft tumor model. The doses of paclitaxel protodrug were 4x or 10x molar equivalent to the MTD of conventional paclitaxel. We observed significant reduction of tumor growth compared to vehicle ($p<0.0001$) and minimal body weight loss suggesting enhanced safety profile. *In vivo* studies to determine the safety and efficacy of these protodrugs are ongoing and will be presented. The data presented illustrates how the CAPAC platform is modular and expands the therapeutic window of different cancer therapies to achieve greater effect. This modularity enables the rapid access of therapeutic combinations. Moreover, as the click chemistry activation is independent of biological characteristics of tumors, CAPAC payloads are highly translatable across species and accelerate the path to the clinic.

Cannabidiol and cannabis extract protect cells against platinum-based chemotherapy via cellular uptake

Tereza Buchtová, Lucie Beresova, Katarina Chroma, Martin Mistrik.
Faculty of Medicine and Dentistry, Institute of Molecular and Translational Medicine, Palacky University, Olomouc, Czech Republic

Cannabinoids including cannabidiol belong between constituents of cannabis sp. (marijuana plant). Purified or as a part of cannabis products, the compounds are frequently used by cancer patients to attenuate chemotherapy-induced side effects such as pain, nausea, and vomiting. The presence of cannabis products on the public market expands each year while the illegality status weakens in an increasing number of countries. U.S. Food and Drug Administration has approved several cannabis-based drugs for seizures induced by Lennox-Gastaut syndrome, Dravet syndrome, or tuberous sclerosis complex, also for the lost appetite of AIDS patients, and chemotherapy-induced nausea and vomiting. Oncological patients are further and strongly motivated to take the drugs in combination with chemotherapy by numerous reports demonstrating the anticancer effects of cannabinoids. Nevertheless, here we present unsettling data that cannabis extract together with CBD negatively interferes with worldwide approved platinum-based drugs cisplatin, carboplatin, and oxaliplatin. The phenomenon is proven across three cellular models including primary cells. Even low concentrations of cannabidiol or cannabis extract reduced the toxicity of platinum-based drugs using long-term colony forming assay and/or short-term crystal violet assay. Increased resistance of cells was also accompanied by decreased cellular stress as evaluated by quantitative immunofluorescence microscopy and immunoblotting. Most importantly, concomitant cannabidiol and cisplatin exposure results in the decreased presence of cisplatin-modified DNA. Following the information, we determined platinum content in cells by ICP-MS. The experiment uncovered significantly decreased intracellular platinum content indicating an effect on cellular transport. Furthermore, the mechanism is translational independent as shown by the experiment with cycloheximide. This study offers crucial information that patients and physicians should take into account regarding possible interactions between platinum-based drugs and cannabis-based products. Furthermore, the study on the contradictory effects of cannabis products in cancer treatment may be motivated by this project.

#4936

Activity of carfilzomib in head and neck cancer cell lines in vitro

Abdullah S. Eldaly[1], Douglas B. Stairs[2], Mitchell Machtay[1]. *[1]Radiation Oncology, Penn State Hershey Cancer Institute, Hershey, PA,[2]Pathology*

and Laboratory Medicine, Penn State Hershey Cancer Institute, Hershey, PA

Background: Carfilzomib (CF) is a 2nd generation proteasome inhibitor with activity in hematologic cancer, but its study in solid tumors like squamous cell carcinoma of the head and neck (SCCHN) is limited. We investigated its antitumor activity in three SCCHN cell lines.
Methods: Cells: We studied two human tongue cell lines (CAL27; SCC-25) and one pharynx line (FaDu); all HPV-negative and p53-mutant. MTT assays: We utilized MTT assays to evaluate cytotoxicity of CF, cisplatin, and their combination. The IC_{50} of CF and Combination Index (CI) of varying concentrations of combined CF and cisplatin were calculated. Clonogenic assays: Cells were seeded at low density and after 24 hours, cells were treated with varying concentrations of CF. Plates were incubated for 10 days. The cells were fixed and stained with crystal violet dye and colonies counted. Wound Healing assays: After cells reached 100% confluence, a scratch was created using a 200 µL micropipette. Cells were treated with CF and images were acquired at 0, 24, 48, and 72 hours post-scratch.
Results: MTT assays: IC_{50} values as a function of exposure lengths are shown in Table 1. CAL27 was the most sensitive while SCC-25 was the most resistant. In all cell lines, the results of combined CF and cisplatin were complex: at lower doses there was evidence of antagonism, while at higher doses there was synergy. Clonogenic assays: CF significantly inhibited clonogenicity compared to DMSO control ($P \leq 0.05$). The surviving fraction for CF 2.5, 5, and 10 nM were 0.411. 0.151, 0.051, and 0.5, 0.339, 0.102 in CAL27 and SCC-25 cell lines, respectively. Wound Healing assays: Wound closure % after treatment with CF5 was significantly different from DMSO control ($P \leq 0.05$). Wound closure % for CF5 were 30.97, 56.75, and 28.03% compared to 94.65, 75.88, and 42.05% for control in CAL27, FaDu, and SCC-25 cell lines, respectively.
Conclusion: CF exhibits antitumor effects in SCCHN in vitro. Our findings support further investigation of CF in combination with conventional agents in vitro and in vivo.

IC50 values for carfilzomib in head and neck cancer cell lines

Cell line	24 hours	48 hours	72 hours

CAL27	18.02 (11.76- 28.22)	9.364 (7.189- 12.45)	6.401 (5.579- 7.373)
FaDu	57.34 (41.98-84.90)	16.22 (13.438- 19.446)	8.237 (7.260- 9.365)
SCC25	77.78 (67.18- 91.30)	12.87 (11.36- 14.64)	11.49 (10.51- 12.58)

#4937

Immunoproteasome inhibitors for the treatment of t(4;11)-driven ALL

Alexei F. Kisselev[1], Tyler W. Jenkins[2], Elise Fitzerald[2], Andrey V. Maksimenko[3], Peter Panizzi[2], Jennifer L. Fields[4], Steven N. Fiering[4], Amit K. Mitra[2]. *[1]Auburn University Harrison College of Pharmacy, Auburn, AL,[2]Drug Discovery and Development, Auburn University Harrison College of Pharmacy, Auburn, AL,[3]Drug Discovery and Developmentpment, Auburn University Harrison College of Pharmacy, Auburn, AL,[4]Norris Cotton Cancer Center, Geisel School of Medicine at Dartmouth College, Lebanon, NH*

The t(4;11)(q21;q23) chromosomal translocation that creates the MLL-AF4 fusion protein, confers a poor prognosis in infant acute lymphoblastic leukemia (ALL). This translocation also sensitizes cells to proteasome inhibitors bortezomib and carfilzomib, which are approved by the FDA for the treatment of multiple myeloma. Clinical activity of bortezomib in combination with standard chemotherapy has been documented in several clinical trials of ALL patients, and a case of a single-agent activity against relapsed leukemia driven by the MLL-AF4 translocation has been described. However, toxicities of bortezomib and carfilzomib may be unacceptable to pediatric patients. We found that the overwhelming majority of proteasomes in this subtype of ALL are lymphoid tissue specific immunoproteasomes. Cells with MLL-AF4 translocations were sensitive to pharmacologically relevant concentrations of specific immunoproteasome inhibitors ONX-0914 and M3258. Furthermore, both compounds dramatically delayed growth of orthotopic xenograft tumors in mice. Thus, immunoproteasomes are therapeutic targets in ALL and replacing bortezomib and carfilzomib with immunoproteasome inhibitors in ALL should reduce toxicities associated with inhibition of the proteasomes in non-lymphoid tissues.

#4938

DP-9024, an investigational small molecule modulator of the integrated stress response kinase GCN2, synergizes with asparaginase therapy in leukemic tumors

Gada Al-Ani, Kristin M. Elliott, Qi Groer, Aaron J. Rudeen, Patrick C. Kearney, Jeffery D. Zwicker, Yu Mi Ahn, Stacie L. Bulfer, Cale L. Heiniger, Molly M. Hood, Salim Javed, Joshua W. Large, Max D. Petty, Kristen L. Stoltz, Bertrand Le Bourdonnec, Bryan D. Smith, Daniel L. Flynn. *Deciphera Pharmaceuticals, LLC, Lawrence, KS*

Background: The integrated stress response (ISR) is a major adaptive pathway stress response pathway and plays an important role in cell fate determination in response to stress. Oncogene addicted tumors are under high levels of stress, both extrinsic as well as intrinsic, and are dependent on a well-balanced ISR to cope with the high metabolic demands for accelerated growth. The ISR is a double edge sword of survival and cell death, and depending on context, activation of the ISR kinase GCN2 can have either cytoprotective or cytotoxic effects. Activation of GCN2 was identified as a resistance mechanism to asparaginase (ASNase) in asparagine synthetase (ASNS)-low leukemic cells and MAPK-driven solid tumors.[1-3] The inhibition of GCN2 in the context of ASNase-resistant leukemic cells can be pharmacologically leveraged to induce anti-tumoral effects.

Methods: Modulation of ISR kinases was characterized using enzymatic assays. Kinome selectivity profiling was determined using enzymatic and cellular assays. ISR pathway modulation was assessed using cellular assays of phospho-GCN2 and ATF4 by Western blot or ELISA under basal, ASNase-treated, or amino acid starvation conditions. Re-sensitization of leukemic cells to ASNase was tested in cell proliferation assays *in vitro*. *In vivo* compound-mediated reversal of ASNase-induced upregulation of tumoral ATF4 was determined in a leukemia PK/PD xenograft model. Inhibition of tumor growth was determined in leukemia xenograft models *in vivo*.

Results: DP-9024 was designed as a selective and potent modulator of PERK and GCN2. DP-9024 was found to reverse ASNase-mediated upregulation of ISR readouts (phospho-GCN2 and ATF4) in leukemic cells *in vitro*. Additionally, DP-9024-mediated inhibition of GCN2 was found to

re-sensitize leukemic cells to ASNase *in vitro*. *In vivo* asparagine depletion by Leunase (L-asparaginase) led to upregulation of ATF4 in leukemia tumors in a PK/PD xenograft model and oral dosing of DP-9024 reversed Leunase-mediated upregulation of tumoral ATF4 down to basal levels. Importantly, we found that DP-9024-mediated inhibition of GCN2 strongly synergized with ASNase *in vivo*, leading to potent inhibition of tumor growth in leukemic xenografts and causing a reversal of ASNase resistance in leukemic tumors *in vivo*.
Conclusions: The ISR kinase GCN2 was identified as a resistance mechanism to ASNase in ASNS-low leukemic cells. Inhibition of the ISR pathway through the potent and selective small molecule modulator of GCN2, DP-9024, synergized with ASNase and re-sensitized leukemic cells to amino acid withdrawal *in vitro* as well as in leukemic xenograft models *in vivo*.

Combinatorial approach using covalent menin inhibitor, BMF-219, and/or covalent FLT3 inhibitor, BMF-500, with MEK or BCL2 blockade potentiates therapeutic use in AML
Brian Law. *Biomea Fusion, Inc., Redwood City, CA*

Introduct**ion:**
Acute myeloid leukemia (AML) is a clinically and genetically heterogeneous disease characterized by a highly diverse genomic landscape. Despite recent advances in therapies, treatment outcome remains variable and largely defined by genomic abnormalities such as gene fusions, copy number alterations and point mutations. Mutations in epigenic modifiers, nucleophosmin (NPM1c), signaling and kinase pathway such as KMT2A-re-arrangements (KMT2A-r), internal tandem duplication (ITD) insertions in FLT3, and NRAS mutations are amongst the highest alterations in AML patients with a propensity towards poor response to treatment and overall disease outcome. Such limitations impact the ability to achieve long-lasting response to treatment and result in therapy-induced resistance eventually

leading to relapse. Combinatorial strategies are required to combat resistance and maximize duration of antitumor activity.
BCL2 and MEK blockade in combination with menin and/or FLT3 inhibitors potentiates an improved therapeutic strategy to achieve increased antitumor activity and overcome AML resistance. Here we explored the use of our clinical-stage covalent menin inhibitor, BMF-219, and BMF-500, a covalent FLT3 inhibitor, in combination with each other and in combination with BCL2 and MEK inhibitors in MV-4-11 and MOLM-13 cell lines for 4-days, then viability was measured using CellTiter Glo.
Results:
BMF-219 and BMF-500 as single agents induce effective antitumor activity on MOLM-13 and MV-4-11 cells lines. When dosed in combination, BMF-219 and BMF-500 show beneficial effects affording higher cell killing at lower concentrations. Repeated experiments revealed patterns of increased cell killing is achieved when trametinib, MEK inhibitor, and venetoclax, BCL2 inhibitor, are combined with BMF-219 treatment.
Conclusions:
Collectively, our studies demonstrate the utility of combination strategies to achieve higher antileukemic cell killing with reduced concentrations of menin and FLT3 covalent inhibitors. Additionally, we show benefit of combinatorial approaches of menin and FLT3 covalent inhibitors with MEK and BCL2 blockade. These data provide initial pre-clinical evidence for combining pathway specific inhibitors as a promising therapeutic strategy for further investigation in acute leukemia.

Proteasome and survivin inhibitors synergize to inhibit the growth of oral cancer organoids
Muhammad Furqan[1], Iffat Aleem[2], Muhammad Tahseen[3], Raza Hussain[3], Asif Loya[3], Muhammad Tariq Mahmood[3], Philippe Gautier[4], Kevin Myant[4], Saira Saleem[3], Amir Faisal[1]. *[1]Life Sciences, Lahore University of Management Sciences, Lahore, Pakistan,[2]Basic Sciences, Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan,[3]Pathology, Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan,[4]Department of Pathology, Institute of Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom*

Oral squamous cell carcinoma (OSCC) is the most prevalent subtype of head and neck cancers that has a disproportionately high incidence and mortality in developing countries in South-Central Asia, including Pakistan. The standard treatment for OSCC generally consists of surgery combined with radiotherapy or chemotherapy; however, the overall survival rates have not improved, and only ~50% of patients survive the disease. Therefore, identifying and validating new drug targets can provide new therapeutic options for improved treatment and better prognosis for OSCC patients. The present study aimed to develop an organoid model from patient-isolated primary tumour cells and determine their drug sensitivity profile coupled with mutational analysis. New combinations of targeted drugs with synergistic activity in oral cancer cells were identified through high-throughput screening followed by validation of their activity in oral cancer cells in 2D monolayer and 3D organoid cultures. Results indicate a synergistic activity of proteasome (PR-171) and survivin (YM155) inhibitors in all tested patient-derived tumour cells and four oral cancer cell lines. Moreover, chitosan-based nanocapsules harboring these drugs showed therapeutic efficacy comparable to free drug combinations, indicating a potential for efficient and targeted delivery. Next-generation sequencing data identified missense mutations in eleven cancer-related genes that encode BRAF, EGFR, KRAS, NRAS, HRAS, MEK1, PIK3CA, PTEN, NOTCH1, TP53 and TERT. The ongoing research aims to correlate the drug sensitivity data with the mutational profile of patient-derived tumour cells to find novel targets. In conclusion, we have developed 3D organoids from patient-derived primary tumours and utilized them to validate the synergistic combination between screen-identified proteasome and survivin inhibitors. Our preclinical study provides a rationale for further evaluation of the novel drug combination in vivo and in clinical settings.

Development of small molecule RPN13 inhibitors for treatment of glioblastoma

Yung-Nien Chang[1], Ravi K. Anchoori[1], Alex Shimura Yamashita[2], Marina da Costa Rosa[2]. *[1]Up Therapeutics LLC, Frederick, MD,[2]Neurosurgery, Johns Hopkins University, Baltimore, MD*

Glioblastoma (GBM) is an aggressive and deadly brain cancer with a one-year median survival due to the lack of effective targeted treatments. Our goal is to develop a small molecule inhibitor targeting RPN13 protein in the 19S proteasome complex as a new drug for GBM. RPN13 is a proteasome ubiquitin receptor that recognizes ubiquitin-conjugated proteins that are thus tagged for degradation via the 20S proteasome enzymatic complex. GBM is highly sensitive to proteasome inhibition due to its aggressive growth and accumulation of misfolded polyubiquitinated proteins that is insufficiently managed despite increased proteasome levels and enhanced proteasome activity (i.e. proteotoxic stress). Up Therapeutics judiciously designed drug-like RPN13 inhibitors to overcome limitations in the prototype RPN13 inhibitor RA190 identified at Johns Hopkins University. We selected Up284 as lead compound based upon our preliminary studies showing drug-like characteristics, specificity (binding to Cys88 of RPN13), and proteasome inhibition that produces a cytotoxic accumulation of polyUb proteins, ER stress, and reactive oxygen species. Up284 treatment selectively triggers apoptosis in solid tumor types including GBM cell lines and oncospheres. A suitable Up284 formulation was selected by measuring aqueous solubility, stability and on-target activity in mice imaged using a proteasome-dependent in vivo reporter. Up284 can be administered i.v. or orally, and it penetrates through the BBB. As a proof of concept for treatment of GBM, Up284 demonstrated on-target activity in intracranial syngeneic GL261 tumor model by inhibiting proteasome function in tumor tissues. Up284 also well tolerated and regressed tumors in syngeneic, xenograft and spontaneous models of ovarian and breast cancers with acceptable safety profile. Up284 also synergize with current frontline chemotherapeutics and can be used as a single agent or in combination for the treatment of wide range of cancers.

Heme targeting and its mechanistic role in triple-negative breast cancer suppression

Eranda Berisha, Maria del Carmen Chacon Castro, Adnin Ashrafi, Narges Salamat, Parinaz Sadat Alemi, Li Zhang. *UT Dallas, Richardson, TX*

Breast cancer is the second leading cause of cancer-related deaths and comprises of approximately 30% of all cancer cases affecting women in the

United States. There are three subtypes of breast cancer based on receptor profiles, with the third subtype being triple-negative breast cancer. TNBC accounts for about 10-15% of all breast cancers. The TNBC subtype lacks estrogen, progesterone, and HER2 receptors; it is associated with BRCA1 and BRCA2 mutations. This type of cancer has poor prognosis, tends to be more aggressive, and has limited treatment options compared to the other two subtypes. Heme is an essential molecule in the oxidative phosphorylation pathway and in the generation of reactive oxygen species (ROS). ROS generation causes oxidative stress and induces DNA damage in breast cancer. Therefore, targeting its activity potentially suppresses TNBC tumors. Heme-sequestering protein 2 (HeSP2) binds and sequesters heme. It has been shown that HeSP2 treatment of MDA-MB-231 cells inhibited cell proliferation and colony formation. Moreover, HeSP2 suppresses tumor growth in subcutaneously implanted TNBC MDA-MB-231 xenografts in NOD/SCID mice. Furthermore, in vitro studies using murine TNBC cell models 4T1-fluc Neo and EMT6-fluc Puro cells have also shown that cell proliferation and colony formation were inhibited after HeSP2 treatments of increasing concentrations. Thus, these results encourage the potential use of HeSP2 for breast tumor suppression. To further explore the effects of heme targeting and sequestration, we will determine heme flux in TNBC cell models by measuring the levels of heme uptake, export, synthesis, and degradation. Moreover, we will examine mitochondrial markers for OXPHOS complexes in HeSP2 treated TNBC xenografts using immunohistochemical analysis. Further studies are still underway to understand the role of heme in breast cancer, with preliminary results indicating that heme targeting, and sequestration effectively suppress triple-negative breast cancer and its progression.

SP-1-39 as a novel tubulin inhibitor overcomes taxane resistance in castration-resistant prostate cancer model

Rui Wang, Kelli L. Hartman, Satyanarayana Pochampally, Duane D. Miller, Wei Li. *University of Tennessee Health Science Center, Memphis, TN*

Colchicine binding site inhibitors have proven to have potent anti-cancer efficacy in many cancer types. Inhibition of tubulin polymerization, a popular mechanism of action for anti-cancer activities, will be activated

once the inhibitor interacts with the colchicine binding site. We have previously developed and reported a potent tubulin inhibitor (SB-216). One of its derivatives, the compound SP-1-39, a pyrimidine dihydroquinoxalinone derivative, has been recently designed to further improve the potency and therapeutic properties. Here, we examined the impact of SP-1-39 on preclinical prostate cancer models in vitro and in vivo. EBI competition assay confirmed that SP-1-39 binds to colchicine-binding site and inhibits the formation of EBI:β-tubulin adduct. The anti-proliferation abilities of SP-1-39 was tested against melanoma, breast cancer, pancreatic cancer, prostate cancer, and paclitaxel-resistant prostate cancer cell lines by MTS assay, and defined IC50 values of 0.2-4 nmol/L. Other in vitro results showed SP-1-39 disrupted microtubule network, induced cell cycle arrest at G2/M phase, and caused apoptosis in paclitaxel-resistant human prostate cancer cells (PC-3/TxR). For in vivo study, 2.5mg/kg SP-1-39 significantly attenuated tumor growth in PC-3/TxR xenograft mouse model, inhibited angiogenesis, and overcame taxane resistance. Our findings demonstrate the preclinical therapeutic efficacy and safety of SP-1-39, and provide support for further exploration of novel tubulin inhibitors as anti-cancer agent for cancer therapy.

Evaluating the efficacy of spermine analogue ivospemin (SBP-101) in combination with chemotherapy in ovarian cancer

Cassandra E. Holbert[1], Jackson R. Foley[1], Tracy Murray Stewart[1], Michael J. Walker[2], Elizabeth M. Bruckheimer[2], Jennifer K. Simpson[2], Robert A. Casero[1]. *[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Panbela Therapeutics, Waconia, MN*

Polyamines are small cationic alkylamines that play critical roles in essential cellular processes governing growth and proliferation. As such, cancers are fully reliant on increased polyamine pools maintained through dysregulation of polyamine metabolism. Pharmaceutical modulation of polyamine metabolism is a promising avenue in cancer therapeutics and has been attempted with enzyme inhibitors, including DFMO (difluoromethylornithine), and polyamine analogues. Ivospemin is a spermine analogue that has shown efficacy in slowing pancreatic and ovarian tumor progression both *in vitro* and *in vivo* and demonstrated

encouraging results in pancreatic cancer clinical trials. We have shown that ivospemin decreases polyamine content through depression of the activity of the polyamine biosynthetic enzyme ornithine decarboxylase (ODC) in a variety of cancer cell lines. Treatment of the VDID8$^+$ murine ovarian cancer model with ivospemin resulted in a marked increase in survival. Here we examine the potential of combining ivospemin and chemotherapeutic agents that are used to treat cisplatin-resistant ovarian cancer. Treatment with gemcitabine, topotecan, and doxorubicin increased the *in vitro* toxicity of ivospemin, while paclitaxel and docetaxel did not have any added benefit over ivospemin alone. Using the VDID8$^+$ model, we further evaluated the efficacy of ivospemin in combination with gemcitabine, topotecan, and doxorubicin *in vivo*. Ascites fluid was used as a marker of tumor burden and evaluated for polyamine content. Addition of ivospemin improved the survival of mice treated with any of the three chemotherapeutics. The ivospemin and doxorubicin combination mice had the greatest median survival time; this combination is being further evaluated in mechanistic studies and additional murine studies. Ovarian cancers have extremely immunosuppressive tumor microenvironments (TME) and metabolic reprogramming of the TME to reduce immunosuppressive phenotypes is a promising approach for treatment. Sustained elevation of polyamine levels supports an immunosuppressive TME, and evidence suggests that pharmacologic depletion of polyamines may reduce immunosuppressive phenotypes. DFMO treatment in the immunosuppressive VDID8$^+$ model influences the immune cells of the TME, and we therefore are investigating the combination of ivospemin and DFMO in ovarian cancer. In addition to the cooperativity of ivospemin and chemotherapeutic agents, we have observed a cooperative antiproliferative response in ovarian cancer cells following DFMO and ivospemin cotreatment. Together, these studies suggest the potential of polyamine modulation by ivospemin and DFMO in combination with standard of care chemotherapy. Future studies will determine influences on the immune microenvironment and will evaluate cooperativity between ivospemin, DFMO, and chemotherapy.

Inhibition of wild-type PI3Kα signaling is required for durable efficacy in PI3Kα mutant cancer cells due to robust re-activation of wild-type

PI3Kα signaling

John R. MacDougall, Mengqi Zhong, Hanne Merritt, Joselyn S. Del Cid, John Bradley, Raymond Mak, Neil Dhawan, Wei Chen. *Totus Medicines Inc., Emeryville, CA*

PI3Kα is the most mutated oncogene with a high mutation rate in breast, lung, colorectal, gastric, bladder, and other tumor types. However, current inhibitors have had little efficacy in the clinic due to their inability to achieve maximal PI3Kα target engagement in a highly specific and durable manner. Contributing to this is that most PI3Kα mutant cancer cells are prone to robust pathway feedback and re-activation of remaining wild type PI3Kα signaling upon initial inhibition. We have analyzed pathway feedback in a variety of PI3Kα mutant cancer cell lines across multiple diverse indications and found this to be a common trait among PI3Kα mutant cancer cells. Additionally, when the mutant PI3Kα protein alone is targeted in these cells using mutant-specific inhibitors, we observed robust pathway re-activation and tumor cell proliferation. In contrast, TOS-358, a highly selective first-in-class covalent PI3Kα inhibitor, achieved complete inhibition of both PI3Kα mutant and wild type signaling and this correlated with the induction of cell cycle arrest and cell death across a wide variety of PI3Kα mutant tumor types. Furthermore, stimulation of PI3Kα signaling with serum rapidly re-activated the PI3K-AKT pathway in the presence of reversible and mutant specific inhibitors. Covalent molecules (namely TOS-358) achieved complete inhibition of pathway signaling in this format. Overall, this reveals the need to achieve sustained inhibition of both PI3Kα mutant and wild type signaling to achieve durable efficacy in PI3Kα mutant tumors.

TOS-358, a first-in-class covalent PI3Kα inhibitor, demonstrates superior efficacy and does not induce significant hyperglycemia at efficacious doses in multiple animal models

John R. MacDougall, John Bradley, Raymond Mak, Neil Dhawan, Wei Chen. *Totus Medicines Inc., Emeryville, CA*

PI3Kα is frequently mutated in a variety of cancer types, and the PI3K-AKT signaling axis also plays a role in insulin signaling and glucose

homeostasis. TOS-358 is a highly selective first-in-class covalent inhibitor of PI3Kα and is currently in clinical development in multiple solid malignancies. Interestingly, TOS-358 potently and specifically inhibits PI3Kα deeply and durably, but does not induce significant hyperglycemia in a variety of animal models. TOS-358 has consistently demonstrated superior efficacy comparing to reversible PI3Kα inhibitors (ATP-competitive and Allosteric) across 30+ different PDX and CDX mutant PI3Kα dependent cancer models. Detailed metabolic studies also revealed TOS-358 does not induce significant hyperglycemia effects in mice, rats and dogs at efficacious doses, which mirrors previous finding that show that PI3Kα knockout does not induce significant hyperglycemia. Furthermore, we elucidate that previous reversible PI3Kα inhibitors lead to dramatic hyperglycemia due to their potent inhibition of multiple PI3K isoforms at effective concentrations of the molecules in a cellular setting. This data reveals that highly specific and potent covalent inhibition of PI3Kα leads to dramatically superior efficacy and an improved safety profile.

Exploration of Annamycin Organotropism to Target Primary and Metastatic Liver Cancers

Rafal J. Zielinski, Krzysztof Grela, Shaohua Peng, Edd Felix, Roberto Cardenas-Zuniga, Damian Grybowski, Stanislaw Skora, Izabela Fokt, Waldemar Priebe. *UT MD Anderson Cancer Center, Houston, TX*

Background. Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer and is responsible for more than 12,000 deaths per year in the US. In addition to primary tumors, the liver is a common site for metastases of many types of cancer, including colorectal, and pancreatic cancer. The life expectancy and outlook for people with liver metastases are typically poor.Annamycin (ANN) is a novel anthracycline of our design that is clinically evaluated as a liposome formulated drug product, L-ANN. ANN and L-ANN display unique organotropism that differs from doxorubicin (DOX). In addition, ANN was shown to have increased potency against multidrug resistant cancer cell lines, and, importantly, L-ANN appeared to be non-cardiotoxic. Objective. The objective of this study was to analyze the pharmacokinetics of two formulations of ANN in the liver in comparison with DOX and to determine its tumoricidal potential in

an HCC model in situ and in an experimental model of liver metastasis. Methods. The pharmacokinetics and tissue-organ distribution studies of L-ANN, free ANN, or DOX were performed in mice and rats. The levels of ANN and DOX in plasma and tissue homogenates were assessed using LC/MS. The antitumor efficacy of L-ANN was studied using HEPA 1-6 hepatocellular carcinoma models (subcutaneous, orthotopic, and experimental liver metastatic models) and compared with CT26 colon cancer liver metastasis experiments.Results. ANN exhibited dramatically higher accumulation in the liver parenchyma when compared to DOX (6-fold higher AUC values). We found that the increased liver uptake of the drug had a direct effect on activity of the drug in vivo. First, we observed clear, dose-dependent inhibition of the subcutaneous tumor growth after systemic (IV) administration of L-ANN. Next, remarkable activity of L-ANN was observed in orthotopic models. For instance, significant inhibition of the tumor growth and extension of the survival of L-ANN treated mice vs. vehicle-receiving animals was observed in HEPA 1-6 models (median survival 29.5 vs 50 days ($p<0.0001$) and 28 vs 59 days ($p<0.0001$), respectively). The significant delay in tumor progression was similar to that recorded in the CT26 experimental metastatic models, and L-ANN treatment strongly correlated with survival in this model as well (median survival 32 vs 53 days in L-ANN and vehicle groups, respectively, $p<0.0001$).Conclusions. Annamycin is a potent, non-cardiotoxic anthracycline with proven in vivo activity against different types of tumors. It showed increased penetration and accumulation in the liver, which correlated with high antitumor activity in HEPA 1-6 hepatocellular carcinoma and CT26 colon cancer liver metastasis models. Expanded studies to assess L-ANN activity in different tumor liver metastasis models as well as HCC models are being planned. It should be noted that L-ANN is currently undergoing clinical trials in patients with pulmonary metastasis soft tissue sarcoma and acute myeloid leukemia.

The role of zafirlukast and isoquercetin in thiol isomerase inhibition in relation to cancer and its complications

Justine A. Gelzinis, Daniel R. Kennedy. *Western New England University, Springfield, MA*

High levels of thiol isomerases in cancer patients have been correlated with increased tumor growth and an increased risk of cancer-induced thrombosis. Inhibition of major extracellular thiol isomerases, which include the enzymes PDI, ERp57, ERp72 and ERp5 in both cancer and thrombosis, have strong therapeutic potential to treat cancer while also inhibiting cancer-induced thrombosis. In this study, we explored the effects of two thiol isomerase inhibitors, isoquercetin (IsoQ) and zafirlukast (Zafi) against OVCAR8 ovarian cancer cells and a xenograft mouse model created from those cells. To explore the potential of these drugs to inhibit tumor growth and cancer-induced thrombosis, multiple *in vitro* and *in vivo* experiments were performed. Alterations of cellular OVCAR8 thiol isomerase activity were measured using a DI-E-GSSG assay where, after drug treatment separately with both drugs, DTT and the PDI specific fluorescent probe were added to OVCAR8 cells and then monitored kinetically at $520_{nm}/550_{nm}$. Further, the ability of the drugs to inhibit the coagulative potential of OVCAR8 cells was measured by monitoring Factor Xa generation as a marker for tissue factor release. Cells were seeded at a concentration of 100,000 cells, then monitored for Factor Xa generation after addition of a fluorescent probe that is a Factor Xa substrate, Factor VIIa, calcium and Factor X. To explore the effects of IsoQ and Zafi *in vivo,* an OVCAR8 xenograft mouse model was created. Tumors were allowed to grow to an average of $30mm^2$ and mice were then treated with 10 mg/kg IsoQ, 30 mg/kg IsoQ or 30 mg/kg Zafi for 46 days via oral gavage. Blood was collected on Day 46, plasma was isolated and examined for alterations in p-selectin expression via ELISA and alterations in thiol isomerase activity by the DI-E-GSSG assay. Cell surface thiol isomerase activity on OVCAR8 cells was inhibited by 32% after with Zafi and by 35% after treatment with IsoQ. OVCAR8 cell induced Factor Xa generation was significantly reduced by 79% after Zafi treatment and by 35% after IsoQ treatment. In the xenografts, 10mg/kg of IsoQ, 30 mg/kg of IsoQ, and 30 mg/kg of Zafi were all separately able to suppress tumor growth by approximately 85% compared to controls. P-selectin expression decreased by approximately 50% and thiol isomerase activity was decreased by approximately 40% under all 3 treatment conditions. These results demonstrate the potential of thiol isomerase inhibitors to not only treat cancer-induced thrombosis but also the cancer itself, as cancer induced

thrombosis markers and tumor size were both significantly reduced in these experiments.

Identification of novel regulators of response to PI3Ka inhibition in PIK3CA mutant gastric cancer

Lyla Stanland[1], Hazel Ang[2], Jacob Hoj[3], Yunqiang Chu[4], Patrick Tan[4], Kris Wood[3], Micah Luftig[1]. *[1]Molecular Genetics and Microbiology, Duke University School of Medicine, Durham, NC,[2]Pharmacology and Cancer Biology, Duke University School of Medicine, Durham, NC,[3]Duke University School of Medicine, Durham, NC,[4]Duke National University Singapore, Singapore, Singapore*

PIK3CA, encoding the active alpha isoform of PI3K, is the second most commonly mutated gene in cancer leading to aberrant PI3K/AKT/mTOR signaling and increased protein translation, glucose metabolism, cellular proliferation, survival and migration. Some 4-25% of gastric cancers (GC) display activating *PIK3CA* mutations including 80% of the EBV-associated GC subset. Small molecules including pan-PI3K, dual PI3K/mTOR, and pan-AKT inhibitors have shown only moderate clinical success, primarily due to high toxicity and off target effects. Even isoform specific PI3K inhibitors, such as PI3Kα inhibitors, have displayed similar clinical problems. Importantly, PI3Kα mutation-selective inhibitors are on the horizon and will be key for treatment of *PIK3CA* mutant tumors. However, single agent drug resistance is still an anticipated clinical problem and both intrinsic and acquired resistance will affect success of new drugs. There has been a concerted effort to define mechanisms of resistance as well as identify synergistic drug combinations. In this study we aimed to identify mechanisms of sensitivity and resistance to the PI3Kα-specific inhibitor, BYL719, in *PIK3CA* mutant gastric cancers by using a CRISPR/Cas9-based screening approach. We found that loss of either NEDD9 or BCL-XL was synergistic with BYL719 and led to increased cell cycle arrest and apoptosis, respectively. In addition to identifying these sensitizer genes, the screening approach allowed us to model intrinsic resistance, and we discovered that knockout of the translation and transcription factor, CBFB, conferred resistance to BYL719. To model acquired resistance, we cultured cells in increasing concentrations of BYL719 over three months and

generated clones that were resistant when compared to parental cells. We found that in the clones with acquired resistance, CBFB was significantly down-regulated at the protein and RNA level suggesting a conserved mechanism of drug resistance. We found that CBFB loss led to up-regulation of the serine/threonine protein kinase PIM1, which can phosphorylate and activate several of the same downstream substrates as AKT thereby maintaining pathway activity in the presence of PI3Kα inhibition. Furthermore, a pan-PIM inhibitor re-sensitized both *CBFB* knockout and acquired resistant cells to BYL719. In the TCGA clinical dataset, we found that CBFB is over-expressed in gastric tumors, specifically in the EBV-associated subset, compared to normal tissue and is significantly over-expressed in *PIK3CA* mutant compared to wild type tumors. Consistently, we found that PIM1 expression displays the inverse phenotype. These data suggest that while *CBFB* loss is a key step in the development of PI3Kα inhibitor resistance, *PIK3CA* mutant gastric tumors may be good candidates for clinical success with BYL719 alone and resistance could be prevented with combination with a PIM kinase inhibitor.

#4950

Discovery of potent and selective CK1α molecular degrader with a favorable safety profile for acute myeloid leukemia and solid tumors

Jinuk Kong[1], Jisu Park[1], Heekyu Lee[1], Hyunseok Kang[2], Deokjae Lee[1], Hyunsun Jo[1]. *[1]Pin Therapeutics, South San Francisco, CA,[2]Hematology and Oncology, UCSF School of Medicine, San Francisco, CA*

CK1α, an isoform of casein kinase 1 (CK1), promotes tumor growth by enhancing negative effects of MDM2 and MDMX on p53. Unlike other cancer types, the frequency of *TP53* mutations is relatively low (< 20%) in acute myeloid leukemia (AML). Therefore, promoting apoptosis by activation of p53 pathway has been a promising strategy for treatment of AML with wild-type (WT) *TP53*. However, preclinical activities of p53 activators have not been fully translated into clinic, partly due to their on-target hematological toxicities. We hypothesized that inhibition of CK1α can be an alternative strategy. To develop a small molecule targeting CK1α, we identified a novel CK1α-selective molecular glue degrader (MGD), PIN-A1 through screening of compounds hijacking cereblon (CRBN) E3 ligase. Here, we report its robust pharmacological activities in various

preclinical AML models as a single agent or in combination with other targeted therapies along with its superior safety profile to MDM2 inhibitors. First, we demonstrated PIN-A1 can form a ternary complex with CK1α and CRBN using TR-FRET assay. Selective degradation of CK1α by PIN-A1 was also confirmed by global proteomics analysis. PIN-A1 induced rapid degradation of CK1α in human AML MV-4-11 cells harboring WT *TP53*, followed by increasing the level of p53 protein and its downstream target genes, ultimately leading to apoptotic cell death. Consistent with these results, preferential sensitivity of AML cells with WT *TP53* to the CK1α degrader was demonstrated in screening assay of broad panel of liquid cancer cell lines. When combined with other targeted therapies agents used for AML, PIN-A1 displayed strong synergistic effects in cell killing. To evaluate its pharmacological activity *in vivo*, PIN-A1 was tested in a xenograft model engrafted with MV-4-11 and a dissemination model of MOLM-14, respectively. Systemic administration of PIN-A1 alone resulted in robust antitumor activity consistent with > 90% CK1α degradation in tumor tissues, comparably achieved at a much lower dose in combo treatments. Importantly, animals remained tumor-free (5/8) in the MV-4-11 model or prolonged survival in the disseminated model even after they were no longer on the combination treatment of PIN-A1 with a targeted agent X. Lastly, while PIN-A1 had negligible effects on the viability of human PBMC with minimal activation of the p53 pathway at an efficacious dose range for MV-4-11 (Therapeutic index= 8,333), agent X induced p53 pathway and enhanced anti-leukemic activity to a similar extent in two cell types (Therapeutic index=4). Also, we found that the combination treatment of PIN-A1 with agent X had a substantial effect on several solid tumors driven by enhancing the stability and activity of p53. In summary, these results suggest that a CK1α MGD with its favorable safety profile has a potential to become an effective treatment option for advanced AML and solid tumors.

Proteasome inhibitor carfilzomib induces apoptosis via downregulation of AKT pathway in HPV negative HNSCC

Woo-Jin Jeong[1], Jiyeong Kim[2], Hye-yeon Lee[2], Zhiyong Wang[3], Walt Amornphimoltham[4], Silvio Gutkind[3]. *[1]Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of,[2]Seoul National University*

Bundang Hospital, Seoul, Korea, Republic of,[3]University of California San Diego, San Diego, CA,[4]Walailak University, Bangkok, Thailand

Background Head and neck squamous cell carcinoma (HNSCC) presents in heterogenous sites, varied etiology and risk factors, and has diverse genetic background which confer dissimilar response to treatments, including chemotherapy. Here we tested the hypothesis that investigation of HPV presence in a HNSCC cell line would identify pathway contributing to oncogenesis of other HNSCC. We sought to identify pathways that differentially affect HNSCC according to the genetic background, therefore identifying targets and suitable candidate for treatment. We used genetic and pharmacological approaches to inhibit AKT pathway in HNSCC cell lines.
Materials & methods Chemical genetic library screening against 6 HNSCC cell lines were performed. The high throughput combinatorial small molecule screening for cell viability and apoptosis was carried out. Candidate agents were validated in both CAL-27 (HPV-negative) and UM-SCC-47 (HPV-positive) cell lines. Identified pathways and representative targeted agents were validated *in vitro*. Expression of related protein were confirmed by western blot assay.
Results EGFR, PIK3CA, mTOR, CDK1, HSP90AB1, HDAC1, and PSMD1 pathways were identified to be susceptible pathways in HNSCC using high throughput chemical genetic library screening. *In vitro* validation of carfilzomib showed IC50 of 7.07nM in CAL-27 cells and IC50 of 26.3nM in UM-SCC-47 cells. Knockdown of PSMD1 transcripts by transfected siRNAs reduced CAL-27 cells viability. Carfilzomib regulates the AKT pathway by decreasing t-AKT, p-AKT, p-ERK, p-S6 proteins and increasing p21 in CAL-27.
Conclusion Inhibition of AKT pathway treatment with proteasome inhibitor carfilzomib is effective in HPV-negative HNSCC cells. Taken together, our findings reveal carfilzomib induced the apoptotic pathway and suggest that carfilzomib, the representative of a new class of chemotherapeutic drug, may be utilized for overcoming cisplatin-resistance in human SCC.

Novel Targets and Pathways

Kurarinone, a natural notch signaling inhibitor and modulator of breast cancer stemness

Prem Prakash Kushwaha[1], Mohd Shuaib[2], Kumari Sunita Prajapati[2], Atul Kumar Singh[2], Mahesh Kulharia[3], Shashank Kumar[2], Sanjay Gupta[1].
[1]Urology, Case Western Reserve University School of Medicine, Cleveland, OH,[2]Biochemistry, Central University of Punjab, Bathinda, India,[3]Central University of Himachal Pradesh, Kangra, India

Aberrant activation of Notch signaling pathway plays an important role in breast cancer development, progression, and stem cell renewal. Activation of Notch signaling is triggered by the interaction of Notch receptors with different ligands expressed on neighboring cells that bind and induce a second cleavage by a membrane-tethered metalloprotease. The remaining membrane-bound fragment is cleaved by γ-secretase (GS) releasing the Notch Intracellular Domain (NICD), which translocate to the nucleus to activate the expression of Notch target genes. Current indirect approaches to inhibit Notch signaling are based on agents that bind to GS substrates. In the search of novel Notch signaling inhibitor(s), we screened a number of plant flavonoids for their binding potential to GS substrate. Our *in-silico* study identified kurarinone (KU), a lavandulyl flavanone, having ability to bind to GS complex. The KU-GS complex was structurally and energetically stable during the molecular dynamics simulation period. Interestingly, dose and time dependent toxicity of KU was observed in T47D and MDA-MB-231 breast cancer cells at 1-25μM concentration. KU treatment of cells led to inhibition in cyclin D1 expression, arrest of cells in the G1 phase of the cell cycle and subsequently undergoes apoptosis. KU-mediated apoptosis was a result of altered mitochondria membrane potential and increased ROS production. In dual-luciferase Notch promoter assay, KU inhibited GS-mediated NICD production in transfected HEK293 cells. Furthermore, KU treatment decreased the mammosphere formation potential of MCF-7 cells through altered gene expression involved in self-renewal and stemness. KU treated MDA-MB-231 cells and MCF-7 derived mammosphere showed downregulation of Notch signaling through alteration in the expression of downstream genes such as Hey1, Hes1, and E-cadherin at both transcript and protein levels. Taken together, the present study identified KU as a novel natural Notch signaling inhibitor that could

provide a novel and safer approach for the treatment of breast cancer through reduction in stemness and self-renewal properties.

Discovering novel targetable pathways by combining functional and multi-omic data from primary ovarian cancer samples

Irene Gutierrez-Perez[1], Bekir Ergüner[1], Pisanu Buphamalai[1], Joost Van Ham[1], Paul Heinz[1], Valentin Aranha[1], Rin Okumura[1], Elisabeth Waltenberger[1], Isabella Alt[1], Claudia Baumgaertler[2], Maja Stulic[2], Edgar Petru[3], Christoph Minichsdorfer[4], Judith Lafleur[5], Lukas Hefler[5], Laudia Hadjari[5], Lucia Dzurillova[6], Jozef Sufliarsky[6], Nikolaus Krall[7], Thorsten Füreder[4], Gregory Ian Vladimer[1], Bojan Vilagos[1], Robert Sehlke[1].
[1]Translational Research, Exscientia, Vienna, Austria,[2]Clinical Operations, Exscientia, Vienna, Austria,[3]Department of Obstetrics and Gynecology, Medical University of Graz, Graz, Austria,[4]Internal Medicine I, Medical University of Vienna, Vienna, Austria,[5]Ordenslinikum Linz - Barmherzige Schwestern, Linz, Austria,[6]National Oncology Institute of Slovakia, Brataslava, Slovakia,[7]Precision Medicine, Exscientia, Vienna, Austria

Background: There is a critical necessity to reveal novel and tractable targets for anti-cancer treatments in indications with high unmet medical need, such as high grade serous ovarian cancer (HGSOC). However, standard process for target discovery using models such as outgrown cell lines and well-averaged readouts has yielded a less than 5% approval rate for drugs entering trials (Thomas *et al.* 2016 Bio.org).
Here, we describe patient-centric target discovery through the use of disease relevant primary OC samples and single cell functional characterization using a platform with proven hemonc translatability (Kornauth *et al.* 2021, Snijder *et al.* 2017). We integrate data from our functional drug testing platform under multiple drug perturbations with matching genomic and transcriptomic data to reveal associations with novel downstream regulators of sensitivity.
Methods: Sensitivity of the cancer cell compartment in primary malignant ascites samples (n = 20; 75% HGSOC) to 85 small molecule drugs, was evaluated using a proprietary and translatable deep learning-driven single cell imaging platform (Vladimer *et al.* 2017). Cancer cell sensitivity from

the drugs was combined with WES, bulk-RNAseq and drug induced changes in phosphoproteome, and single cell RNAseq transcriptome to identify perturbed targets and pathways.
Results: Here we describe a family of TKIs including ALKi that induce cytotoxicity of cancer cells in primary samples, not previously captured in publicly available cell line drug sensitivity screening data (Iorio *et al.* 2016). We report novel sensitivity of OC driven by non-canonical targets of ceritinib such as FAK1 or IGF1R, mediated by the downstream signaling hub YBX1 (Kuenzi *et al.* 2017), involved in NFB pathway regulation (Motolani *et al.* 2021). Indeed, transcriptomic scRNA analysis upon ceritinib treatment of primary OC cells revealed rapid perturbation of numerous NFB pathway members, alongside YBX1 inactivation.
Conclusions: Combining functional endpoints and single cell-based differential expression analysis of primary OC samples, we have identified the NFB pathway and the regulator YBX1 as a promising novel sensitivity for HGSOC treatment development. These and several other important targetable nodes identified, sit outside the recently suggested JAK/STAT pathway (Izar *et al.* 2020), thereby demonstrating a pipeline towards novel drug target and pathway discovery driven by patient-centric, disease relevant models of high-need indications.

The targeting drug conjugate Tye1001 displayed its potent anti-tumor efficacy in lymphoma

Lichun Sun[1], Mengli Yang[2], Haihua Xiao[1], Yuan Tian[2], Natalya Vasilevich[2], Joseph Fuselier[1], David Coy[1]. *[1]Tulane Univ. Health Sciences Ctr., New Orleans, LA,[2]Tyercan Bio-Pharm Company, Shenzhen, China*

Multiple drug-targeting strategies have been applied to drug development in order to reduce the toxic side effects of the traditional chemotherapy while enhancing its anti-tumor efficacy. Various peptides, proteins and antibodies are usually used to conjugate cytotoxic agents via acting as drug delivery vehicles. In our previous studies, we identified that peptides displayed their efficacious functions to deliver small molecules or oligo DNA to the target sites through ligand-receptor interactions and quick internalization. In our present study, we attempt to synthesize serial drug conjugates via coupling these compounds to peptide or protein vehicles. Tye1001, one of these

conjugates, displayed similar potent anti-proliferation activities in lymphoma cells and many other cancer cells compared to the small molecule itself. In particular, this conjugate significantly enhanced its potent anti-tumor efficacy in xenografts. Meanwhile, this conjugate has much less toxic side effects. In our in vivo assays, the similar results were also observed in multiple other tumors such as gastric cancer and leukemia. Our findings provide a more potential druggable opportunity in the clinical applications of cancer patients and the treatment of different types of cancers.

TIC10/ONC201 activates ClpP to degrade ALAS1 while PG3 does not degrade ALAS1 in pathway to HRI, ATF4 and CHOP activation leading to tumor cell death

Xiaobing Tian, Wafik S. El-Deiry. *Brown University, Providence, RI*

TRAIL-inducing compound TIC10/ONC201 binds and activates mitochondrial protease ClpP leading to integrated stress response (ISR) and ATF4 transcription factor activation. Our lab previously reported that ONC201 activates HRI (heme-regulated inhibitor) kinase but does not signal eIF2-alpha phosphorylation through PERK or GCN2. However, the connection between ClpP activation of HRI remains unknown. PG3, a prodigiosin analog that bypasses a defective p53 pathway potently induces ATF4 and pro-apoptotic PUMA. Our data indicate that PG3 activates ATF4 through ISR via HRI as knockdown of HRI but not PKR blocked upregulation of ATF4 and CHOP in several tumor cell lines. We have been exploring how ClpP activation leads to HRI and ISR activation, and the mechanism by which PG3 leads to HRI activation. We find that activation of HRI by PG3 or ONC201 is not through the OMA1/DELE1HRI activation pathway. Moreover, ROS and NO are not responsible for ONC201- or PG3-induced HRI activation. ALAS1 (5'-aminolevulinate synthase 1) catalyzes the first rate-limiting step in heme (Iron-protoporphyrin) biosynthesis. ONC201 treatment leads to potent downregulation and inhibition of ALAS1, indicating that ONC201 inhibits heme biosynthesis. It is well known that reduced heme results in activation of the HRI kinase. We show that an inhibitor of heme biosynthesis or knockdown of ALAS1 results in HRI activation, while knockdown of HRI

blocks upregulation of ATF4 by ONC201. Knockdown of ClpP rescues ONC201-induced downregulation of ALAS1 which blocks ONC201-induced upregulation of CHOP. Our studies identify a novel link between ClpP activation induced by ONC201 treatment and ATF4 upregulation, via the ClpP/ALAS1HRIATF4/CHOP pathway. However, PG3 does not inhibit ALAS1, reduce its expression or therefore signal through ClpP. PG3 treatment did not lead to degradation of ALAS1, indicating that PG3 does not activate ClpP as ALAS1 is a known ClpP direct substrate. We are further investigating the signaling pathway that leads to PG3-induced activation of HRI. Our results suggest that different small molecule inducers of the ISR such as ONC201 and PG3 can achieve an anti-tumor effect through different pathways involving kinase HRI ultimately leading to ATF4/CHOP activation and tumor cell death.

#4960

Fascin inhibitor decreases gynecological cancer cell growth through cell cycle regulation

Wanyi Chen[1], Yufeng Wang[1], Liangliang Ji[2], Ming O. Li[2], Xin-Yun Huang[3]. *[1]Weill Cornell Medical College, Cornell University, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Weill Cornell Medical College, New York, NY*

The actin cytoskeleton is essential for maintaining cell morphology and architecture. Actin-bundling proteins such as fascin cross-link actin filaments into bundles and play critical roles in regulating cell protrusion and motility. Fascin protein expression is low or absent in normal human epithelial cells but high in cancer cells. Elevated fascin levels are correlated with aggressive clinical progression, poor prognosis, and shorter survival outcomes. It is regarded as a cancer progression biomarker and a therapeutic target. We have developed a small molecule fascin inhibitor and shown its efficacy in blocking tumor cell migration, invasion, and metastasis, as well as prolonging the overall survival of mice bearing different types of cancers. Our recent data reveals a new mechanism of this fascin inhibitor in cell cycle regulation of gynecological cancer cells. It blocks the G2/M progression and decreases the mitotic index. Fascin inhibitor treatment also results in aneuploidy, which is a well-known factor for triggering downstream apoptosis. Our data suggests that fascin is

involved in maintaining the fidelity of chromosome segregation and cell division. This will advance our understanding of the interplay between actin and microtubule cytoskeleton during cell mitosis.

#4961

Novel biased PAR2 inhibitors with best-in-class properties reduce resistance to both chemotherapy and immunotherapy in oncology models

Thibaut Brugat[1], Francesco Bergami[1], Baptiste Rugeri[1], Aurélie Janvier[1], Edith Steinberg[1], Luc Baron[1], Mandy Recolet[1], Xavier Wirth[1], Meriem Semache[2], Antoine Mousson[1], Camille Dietsch[1], Quentin Ruet[1], Orphée Blanchard[1], Célia Jacoberger-Foissac[3], Isabelle Cousineau[3], Maleck Kadiri[3], Anne-Laure Blayo[1], Christel Franchet[1], Stanislas Mayer[1], John Stagg[3], Nathalie Lenne[1], Stephan Schann[1]. *[1]Domain Therapeutics, Illkirch, France,[2]Domain Therapeutics NA, St-Laurent, QC, Canada,[3]Centre hospitalier de l'Université de Montréal (CHUM), Montréal, QC, Canada*

A large-scale meta-analysis has recently identified Protease-activated receptor 2 (PAR2) gene expression to be significantly associated with resistance to immune checkpoint blockade (ICB) in cancer patients and preclinical models. PAR2 and its ligands (proteases) are indeed upregulated in different cancer types and are expressed by various cells in the tumor microenvironment. In cancer cells, the PAR2 receptor controls cell migration, proliferation, survival, and expression of inflammatory cytokines. In immune cells, it influences the infiltration and phenotype of macrophages and T cells. Therefore, PAR2 represents a promising therapeutic target in oncology and immuno-oncology. A novel series of potent and selective PAR2 inhibitors has been developed at Domain Therapeutics. *In vitro* experiments demonstrated unique properties of our PAR2 small molecule antagonists when compared to those of competitors. The antagonists inhibit pathogenic signaling pathways (i.e. Gz, G13, Gq, G14 and G15 protein activation as well as intracellular calcium) but not βarrestin2 recruitment, potentially reducing the risks of drug resistance. Furthermore, they maintain high potency and insurmountability in conditions that mimic the tumor microenvironment (high concentration of proteases and acidic pH). Finally, their pharmacokinetic properties are

compatible with a once-a-day oral administration and demonstrate no signs of *in vivo* toxicity except at high doses (>500 mg/kg). Proof-of-concept experiments showed that PAR2 antagonists prevented PAR2-mediated resistance to Gefitinib *in vitro* and increased the potency of anti-PD1 therapy *in vivo* in pre-clinical syngeneic mouse models. Immunohistochemistry analyses from cancer patient biopsies confirmed that high expression levels of PAR2 in cancer and stromal cells within the tumor microenvironment significantly associates with the patient overall survival. In conclusion, new potent and selective negative allosteric modulators of PAR2 have been developed, they demonstrate strong potency by alleviating the resistance to both chemo- and immunotherapy in cancer models. These findings confirm the high value of PAR2 as a therapeutic target and demonstrates the relevance of small molecule inhibitors targeting this receptor to treat cancer.

Discovery of cancer-specific E3 ligase ligands for targeted protein degradation

Zhaofu Wang, Lynette Zhang, Zhen Chang, Mengxi Zhao, Guobin Li, Fang Qin, Shichao Ma, Yunfeng Li, Zhongguo Zhang, Xinghao Wang, Ying Kong, Shidi Lou, Sheng Chen, Lanzhen Liu, Shuaijie Xu, Hailong Zhang.
Blueray Biopharma, Shanghai, Shanghai, China

F-box/WD repeat-containing protein 7 (FBXW7) is the substrate recognition component of SCF (SKP1-CUL1-F-box protein) E3 ubiquitin-protein ligase complex which mediates the ubiquitination and subsequent proteasomal degradation of target proteins. FBXW7 recognizes and binds phosphor-degrons within target proteins and capture them to SCF complex for ubiquitination. Know FBXW7 substrates include cyclin-E, DISC1, JUN, MYC, NFE2L1, NOTCH2, MCL1, RICTOR, and NOTCH1 released notch intracellular domain (NICD). FBXW7 is frequently mutated in cancer, results in loss of substrate recognition and binding. R465C is a one of the major FBXW7 mutations and is found in over 70,000 cancer patients worldwide. From a high-throughput screen, we discovered compounds that selectively bind to FBXW7 R465C mutant. PROTACs against various protein targets have been made with these mutant specific ligands. Some of these PROTACs could induce targeted protein degradation in cells carrying

FBXW7 R465C mutant but not wild-type FBXW7. Targeted protein degradation with these PROTACs could represent a novel therapeutic approach against FBXW7 R465C mutant cancer.

Heme Sequestration as an effective strategy for the suppression of tumor growth and progression of SCLC

Adnin Ashrafi, Narges Salamat, Eranda Berisha, Parinaz Sadat Alemi, Maria Del Carmen Chacon Castro, Zakia Akter, Li Zhang. *UT Dallas, Richardson, TX*

Small-cell lung cancer (SCLC) accounts for 15% of all lung cancers with exceptionally high proliferative rate, early metastasis, and poor prognosis. Chemotherapy has provided SCLC patients considerable survival benefits over the past three decades. Etoposide-platinum (EP) is the preferred first-line regimen. SCLC is initially highly responsive to cisplatin and etoposide chemotherapy, but in almost every case becomes rapidly chemo resistant. Despite attempts to improve outcomes utilizing multiple different strategies, drug resistance remains a major obstacle in clinical consequences of patients with SCLC. Recent research aims to elucidate mechanisms of resistance to improve drug response and treatment outcomes. Our lab has shown that limiting heme via inhibition of heme uptake using heme sequestering peptide (HeSP2) can delay growth and progression of NSCLC tumors. This HeSP2 can also effectively inhibit angiogenesis, normalize tumor vasculature, and alleviate tumor hypoxia in NSCLC tumors and thereby inhibit lung tumor advancement. Here we aim to determine if HeSP2 can be used to enhance the therapeutic efficacy of traditional chemotherapy in the treatment of SCLC. Our preliminary results show that HeSP2 can effectively reduce cell proliferation of SCLC cells like H889 and H720. To understand the mechanism by which the heme sequestering protein limit tumor development, we generated human SCLC H889 xenograft lung tumor model in NOD/SCID mice subcutaneously. Mice were treated with saline (control), HeSP2 alone, cisplatin-etoposide, and HeSP2-cisplatin-etoposide in combination. Tumor growth was monitored using caliper measurements. Tumors tissues were harvested, processed and paraffin embedded for immunohistochemistry (IHC) and histology experiments. The results imply that heme sequestration can be a potential

strategy for suppressing small cell lung cancer tumor progression and improve survival outcome of patients.

#4964

SW-682: A novel TEAD inhibitor for the treatment of cancers bearing mutations in the Hippo signaling pathway

Lei Chen[1], Paula Milani de Marval[1], Kendall Powell[1], Mark Johnson[1], Greg Falls[1], Brian Lawhorn[1], Aurélie Candi[2], Amuri Kilonda[2], Bart Vanderhoydonck[2], Arnaud Marchand[2], Matthias Versele[2], Georg Halder[3], Stephen L. Gwaltney[1], Adeela Kamal[1]. *[1]SpringWorks Therapeutics, Stamford, CT,[2]Cistim Leuven vzw & Centre for Drug Design and Discovery (CD3), Leuven, Belgium,[3]VIB Center for Cancer Biology and Department of Oncology, University of Leuven, Leuven, Belgium*

Many cancers harbor mutations in the Hippo pathway that lead to constitutive activation of the transcriptional co-activators YAP/TAZ that then bind the transcription factor TEAD and drive aberrant transcription of target genes involved in cell proliferation and tumor progression. Hyperactivation of YAP/TAZ has also been associated with resistance to targeted therapies, including MAPK pathway inhibitors. To target cancers that bear mutations in the Hippo pathway or are resistant to therapies due to YAP/TAZ activation, we developed SW-682, a pan-TEAD small molecule inhibitor that blocks TEAD-dependent transcription by binding to the palmitoylation pocket of all TEAD isoforms. *In vitro*, SW-682 inhibited the proliferation of human Hippo-mutant mesothelioma cells with nanomolar potency, with little to no effect on Hippo wild-type tumor cells. SW-682 down-regulated TEAD-dependent reporter gene expression in a dose-dependent manner, while having no effect on reporters monitoring other pathways. *In vivo,* daily oral administration of SW-682 to adult mice resulted in tumor regression in Hippo-mutant mesothelioma models and caused down-regulation of expression of the TEAD-dependent genes CCN1 and CCN2 and a YAP gene signature, as measured by qPCR or RNA-seq analysis. SW-682 has a favorable PK profile with good oral bioavailability in the mouse and was well tolerated with no signs of body weight loss. To test the hypothesis that TEAD inhibition can overcome YAP-driven resistance mechanisms, we explored SW-682 in combination with MEK inhibitors in several *in vitro* and *ex vivo* patient-derived tumor models

including BRAF and NRAS mutated melanoma. Moreover, to identify new indications that may benefit from TEAD inhibition, we screened patient-derived 3D organoid tumor cells and matching patient-derived xenograft models that have been molecularly profiled. In summary, SW-682 is a potent and selective investigational TEAD inhibitor which demonstrated anti-tumor effects in models harboring aberrant expression of the Hippo pathway, suggesting therapeutic potential in multiple Hippo-mutant solid tumors.

Targeting the mitotic kinesin, KIF18A, in chromosomally unstable cancers

James D. Joseph[1], Katherine Schutt[2], Kira Fisher[2], Katelyn Queen[2], Olivia Budington[2], Weifeng Mao[3], Wei Liu[3], Zhengqing Zhu[3], Xiangping Zhang[3], Yisong Xiao[4], Kunmin Lai[4], Xiaohui Gu[4], Jason Stumpff[2], Fred Aswad[5].
[1]Biology, Apeiron Therapeutics, Durham, NC,[2]Department of Molecular Physiology and Biophysics, University of Vermont, Burlington, VT,[3]Biology, Apeiron Therapeutics, Shanghai, China,[4]Chemistry, Apeiron Therapeutics, Shanghai, China,[5]Biology, Apeiron Therapeutics, San Francisco, CA

Background**:** Chromosome instability (CIN), characterized by frequent and ongoing loss or gain of chromosome number, is commonly observed in tumor cells. Although long recognized as a vulnerability of cancer cells, potential CIN-selective therapeutic targets have only recently been discovered. Genetic studies from multiple groups have identified the mitotic kinesin, KIF18A, as selectively essential for the proliferation of CIN and aneuploid cells. By targeting KIF18A genetically and with novel small molecule inhibitors here we present data supporting KIF18A as therapeutic target in CIN tumors.
Methods and Materials: To explore the therapeutic potential of KIF18A, we evaluated the effects of KIF18A genetic depletion and small molecule inhibition in both CIN-positive and CIN-negative cell lines. Biochemical, cell proliferation and phenotypic assays were used to characterize the potency and cellular activity of reference and novel KIF18A small molecule inhibitors. Anti-tumor activity of KIF18A inhibitors was assessed in CIN-positive cell line xenograft models.

Results: In triple negative breast and colorectal CIN positive cancer cell lines siRNA mediated *KIF18A* knockdown and small molecule inhibition of the KIF18A ATPase activity both lead to a reduction in proliferation associated with an increase in mitotic index and multi-polar spindles. Consistent with *KIF18A* knockdown, KIF18A inhibition results in increased spindle length and chromosome alignment defects. Importantly, these effects are not observed with *KIF18A* knockdown or KIF18A inhibition in non-transformed, near diploid cells. In vivo, treatment of CIN-positive xenograft tumors with potent, novel KIF18A inhibitors results in robust anti-tumor activity with minimal impact on body weight.
Conclusions: Collectively our data support KIF18A as a therapeutic target and provide rationale for the continued development of potent selective small molecule KIF18A inhibitors for the treatment of CIN positive cancers.

#4966

Targeting LIF/LIFR autocrine loops with EC359 in ovarian cancer: A novel LIFR targeted therapy

Behnam Ebrahimi[1], Suryavathi Viswanadhapalli[1], Uday P. Pratap[1], Rahul Gopalam[1], Xue Yang[1], Bindhu Santhamma[2], Swapna Konda[2], Xiaonan Li[1], Hui Yan[3], Gangadhara R. Sareddy[3], Zhenming Xu[3], Edward R. Kost[3], Rajeshwar R. Tekmal[3], Hareesh B. Nair[4], Ratna K. Vadlamudi[5]. *[1]ObGyn, UT Health Science Center at San Antonio, San Antonio, TX,[2]Evestra Inc, San Antonio, TX,[3]UT Health Science Center at San Antonio, San Antonio, TX,[4]Evestra, San Antonio, TX,[5]UT Health Science Center at San Antonio, Helotes, TX*

Background**:** Of all gynecologic cancers, ovarian cancer (OCa) has the highest mortality rates. Nearly 90% of patients who receive standard surgical and cytotoxic treatment experience disease recurrence. Leukemia inhibitory factor (LIF) and its receptor LIFR are implicated in the progression of several cancers. A knowledge gap exists on whether LIF/LIFR plays a role in the evolution of OCa. We recently developed EC359, a first-in-class LIFR inhibitor. Here, we examined whether autocrine loops of LIF/LIFR contribute to OCa progression and tested the utility of EC359 as a potential targeted therapy.

Methods: Eighteen different OCa model cells, both established and primary, were used to profile the expression of LIF and LIFR. Cell viability, colony formation, apoptosis, and reporter assays were used to assess EC359 impact on OCa cells. Mechanistic studies were carried out using RNA-seq and RT-qPCR analysis. Using cell-based xenografts, syngeneic xenografts, patient derived organoids (PDO), and patient derived xenograft (PDX) models, the effectiveness of LIFR inhibitor EC359 as a targeted therapy was examined.
Results: Kaplan-Meier survival analysis (KMplot) revealed increased expression of LIF and LIFR was linked to poor progression-free survival in OCa patients. The levels of LIF and LIFR were considerably greater in OCa chemotherapy non-responders than responders. We validated the existence of LIF/LIFR autocrine signaling using 18 distinct OCa cells. Treatment with the LIFR inhibitor EC359 dramatically decreased OCa cell viability, cell survival and increased apoptosis, with an IC50 of 5 to 50 nM. The activation of STAT3, mTOR, AKT, and p42/44 MAPKs as well as other downstream LIFR signaling was markedly decreased by EC359 treatment. Treatment with EC359 also decreased the stemness of OCa cells, slowed PDO development, and sensitized chemotherapy-resistant OCa cells to chemotherapy. One of the significant pathways elevated by EC359, according to RNA-seq data, is the regulation of apoptosis. In six different cell-based xenografts and PDX tumors, we demonstrated that the EC359 at 5mg/kg dose significantly reduced the OCa xenograft growth. In comparison to the vehicle control, the tumor volume was significantly reduced by EC359 treatment of murine ID8 xenografts in C57BL6 mice. Our findings indicated that EC359 had both intrinsic and extrinsic effects on tumors. Tumor-associated macrophages (TAMs) with a significant M1 polarity (CD11b+Gr1-CD68^{high} /phosphoSTAT1+/cMAF-) and robust tumor infiltration by (CD45+) leukocytes were enhanced with EC359 therapy of ID8 xenograft tumors. Importantly, normal T, B, and other immune cells in the blood demonstrated that EC359 had no effect on immune cell homeostasis.
Conclusions: Together, our findings support the existence of LIF/LIFR autocrine loops, and EC359 is a viable treatment option for OCa.

Investigating the therapeutic efficacy of EO3001 in clear cell carcinoma of the ovary

Amal M. EL-Naggar[1], Yuchen Ding[1], Lucy Li[2], Forouh Kalantari[1], Jeffrey Bacha[3], Dennis Brown[3], David Huntsman[1]. *[1]Department of Molecular Oncology, BC Cancer Research Institute, Vancouver, BC, Canada,[2]Department of Molecular Oncology, University of British Columbia, Vancouver, BC, Canada,[3]Edison Oncology Holding Corp., Menlo Park, CA*

Introducti**on** Clear cell ovarian cancer (CCC) accounts for 5-11% of ovarian cancers in North America with a higher frequency reported in cohorts from Japan. CCC usually arises directly from endometriosis, which is associated with oxidative stress. The latter plays a critical role in the pathogenesis of both endometriosis and CCC. CCC is inherently resistant to standard chemotherapies, and the outcomes for patients with advanced stage CCC have not changed in several decades. Therefore, there is an urgent need for new treatment options for advanced CCC. CCC possess a distinct genetic profile; >50% harbour ARID1A mutations typically resulting in loss of protein function and often with co-occurrence of PIK3CA mutation or gene amplification leading to PI3K/AKT pathway hyper-activation. ARID1A mutations leads to accumulation of ROS, decrease in GSH due to downregulation of SLC7A11 and related reduction in the GSH precursor cystine thereby rendering cancer cells highly dependent on oxidative phosphorylation. EO3001 is a small molecule drug candidate with selective activity against ARID1A-deficient cell lines *in vitro*. It has been shown that EO3001 directly binds and inhibits FDX-1 function to block iron-sulfur cluster formation in complex I, a critical component of the mitochondrial electron transport chain. Iron-sulfur clusters play a critical role in the oxidation-reduction reactions of electron transport in mitochondria relied on by cancer cells that have made an adaptive shift from glycolysis to high mitochondrial dependence. Complex I plays a role in redox control and the biosynthesis of macromolecules and nucleic acids necessary for cell proliferation. It is suggested that these complex I-dependent events contribute to tumor formation, resistance to cell death, and metastasis of cancer cells in part by causing an increase in ROS levels

Methods We generated isogenic ovarian cancer cell lines (RMG-1 and OVCA438, -/+ ARID1A loss) using CRISPR/Cas9. We will assess

therapeutic effects of EO3001 on cells' tumorigenic potential *in vitro* -under ambient and stress conditions, notably endometriotic cyst content which derives malignant transformation, and in vivo on cell viability, cell proliferation, ROS levels, migration, invasion, and metastasis. We will use the organoids modeling system -using primary endometrial cells harboring ARID1A mutations- to assess the impact of EO3001 on organoid growth and response to stress conditions and evaluate the effect of EO3001 on cancer metastesis by the ex vivo pulmonary metastasis assay (PuMA). **Conclusions** Exploiting the vulnerability in reliance on OXPHOS in ARID1A-deficient CCC using EO3001 might represent a promising strategy for the treatment of these patients as well as patients harboring other ARID1A-deficient malignancies.

#4968

Characterization of the clinical development candidate TNG348 as a potent and selective inhibitor of USP1 for the treatment of BRCA1/2mut cancers

Antoine Simoneau, Hsin-Jung Wu, Madhavi Bandi, Katherine Lazarides, Sining Sun, Shangtao Liu, Samuel Meier, Ashley Choi, Hongxiang Zhang, Binzhang Shen, Douglas Whittington, Sirimas Sudsakorn, Wenhai Zhang, Yi Yu, Yong Liu, Colin Liang, Michael Palmieri, Yingnan Chen, Brian Haines, Alice Tsai, Minjie Zhang, Alan Huang, Jannik Andersen, Tianshu Feng, Scott Throner, John Maxwell. *Tango Therapeutics, Boston, MA*

TNG348 is a selective and potent inhibitor of the deubiquitinating enzyme USP1 specifically designed to target BRCA1/2mut vulnerabilities in breast and ovarian tumors. Here we present the biochemical, mechanistic, and in vitro and in vivo characterization of TNG348, an oral, allosteric and highly potent inhibitor of USP1. Upon treatment, TNG348 causes loss of viability in a panel of breast and ovarian BRCA1/2mut cancer cell lines and displays dose-dependent tumor growth inhibition in BRCA1/2mut xenograft models. Furthermore, TNG348 activity extends beyond BRCA1/2mut models with PARP inhibitor (PARPi) sensitivity and oncogene-induced replication stress being additional features correlating with USP1 inhibitor sensitivity based on cell line panel and CRISPR screening results. We show that TNG348 induces cell death through a pathway that is distinct from PARPi and TNG348 demonstrates robust synergy when combined with first- or second-

generation PARPi. The clinical development plan intends to evaluate TNG348 in patients with BRCA1/2 mutations as single agent and in combination with PARP1i in patients naïve to PARPi and with prior PARPi treatment history.

#4969

Enhancing the efficacy of small molecule inhibitor of TRIP13 in prostate cancer using thymoquinone

Santosh K. Singh[1], Manoj K. Mishra[2], Sooryanarayana Varambally[3], Rajesh Singh[1]. *[1]Morehouse School of Medicine, Atlanta, GA,[2]Alabama State University, Montgomery, AL,[3]The University of Alabama at Birmingham, Birmingham, AL*

Prostate cancer (PCa) is one of the leading causes of cancer-related death in men worldwide. Chemotherapy is effective in the early management of PCa; long-term use activates drug efflux pumps, resulting in resistance and recurrence. In this context, finding the genetic changes causing PCa development could significantly alter therapeutic results. The approach has been to search for specific molecular targets for the selective elimination of cancer cells. Small molecule inhibitor drugs have successfully targeted cancer cell growth and metastasis promotion. Still, small molecule inhibitors bind to multiple molecular targets, including cell surface receptors and other intracellular proteins, thus increasing the risk of toxicity and having a short life span. Therefore, it is crucial to identify new anti-cancer agents that work with small molecule inhibitors to target cancer cells while preventing normal cells. It has been reported that overexpression of the Thyroid hormone receptor interactor 13 (TRIP13) gene, a critical mitosis regulator, plays a role in many cancers. Our analysis using **UALCAN** (ualcan.path.uab.edu) showed overexpression of TRIP13 in PCa and it plays a role in PCa biology. When TRIP13 is overexpressed, it phosphorylates EGFR and activates a downstream pathway, making cancer cells more aggressive. Recently, DCZ0415, a small molecule TRIP13 inhibitor, was reported to prevent cell proliferation and invasion in several malignancies. Nevertheless, the therapeutic targeting of TRIP13 driving PCa is not well understood. In this study, we demonstrated Thymoquinone (TQ), a natural compound with multifaceted chemo-preventive potential and anti-cancer agent, could reinforce the effect of DCZ0415 in PCa cell

lines (DU145 and PC3). PCa cells were treated with TQ or DCZ0415 alone or combined, followed by cell viability (MTT assay) to determine the optimal IC_{50} values. In a western blot, RT-qPCR analysis, and flow cytometry assays, the combined drug treatment was most effective in blocking TRIP13, inhibiting cell proliferation, and inducing apoptosis. Furthermore, this study determines the combination can upregulate the expression of cell cycle inhibitor (p21WAF1/CIP1), which, in turn, inhibits the expression of CDK4/ Cyclin D1 complex, resulting the cell cycle arrest. In addition, TQ, in combination, downregulates the activation of EGFR-dependent PI3K/Akt-1/ ERK1/2 and epithelial-mesenchymal transition (EMT) pathways in both cell lines. In conclusion, these findings show thymoquinone's potential to improve DCZ0415 effectiveness and suggest a new promising anti-cancer strategy for treating patients with prostate cancer.

TNG462 is a potential best-in-class MTA-cooperative PRMT5 inhibitor for the treatment of MTAP-deleted solid tumors

Kimberly J. Briggs, Alice Tsai, Minjie Zhang, Matthew R. Tonini, Brian Haines, Alan Huang, Kevin M. Cottrell. *Tango Therapeutics, Cambridge, MA*

MTAP deletions occur in 10-15% of all human cancers, which provides one of the largest precision oncology patient populations. MTA-cooperative PRMT5 inhibitors leverage the well-characterized synthetic lethal relationship between PRMT5 inhibition and MTAP deletion. TNG908 is a clinical stage MTA-cooperative PRMT5 inhibitor for the treatment of MTAP-deleted solid tumors. TNG462 is an investigational stage MTA-cooperative PRMT5 inhibitor with significantly enhanced potency, selectivity, and extended target coverage designed to be a best-in-class treatment for patients with MTAP-deleted cancer. In vitro, TNG462 is 45X selective for MTAP-deleted cancer cell lines over isogenic MTAP WT cell lines and has marked selectivity for MTAP-deleted cancer cell lines independent of lineage in a large, diverse cell line panel. Oral administration of TNG462 drives dose-dependent antitumor activity including durable tumor regressions and complete responses in cell line- and patient-derived xenograft models representative of clinically relevant

histologies. Preclinical data suggest a low risk for drug-drug interactions, supporting clinical combination strategies. With enhanced potency and selectivity for MTAP-deleted cancer cells and improved pharmacokinetic properties to extend target coverage, TNG462 has the potential for broader and deeper clinical activity in MTAP-deleted solid tumors than the MTA-cooperative PRMT5 currently being evaluated in clinical trials.

#4971

Identification of statins as a potential treatment for ovarian cancer

Brendan M. Reilly, Sarah J. Miseirvitch, Sarah R. Walker. *University of New Hampshire, Durham, NH*

Late-stage diagnoses make ovarian cancer extremely hard to treat. This leads to ovarian cancer accounting for 5% of female cancer deaths and 2.5% of female cancer incidence. Since there are few options for early detection of ovarian cancer, targeted therapies could lead to better outcomes. One target that has been implicated in ovarian cancer, is the transcription factor Signal Transducer and Activator of Transcription 3 (STAT3). STAT3 function is associated with tumor growth, metastasis, drug resistance, angiogenesis, and resistance to apoptosis. These many STAT3 controlled, cancer-associated cellular functions, make it an ideal and versatile target for cancer therapy. Using the Broad institute's online C.L.U.E. tool and a STAT3 gene signature, we identified statin drugs as potential inhibitors of STAT3 activity. To assess the ability of statins to inhibit STAT3, we treated ovarian cancer spheroids with statins and analyzed STAT3 activity. We have found that statins do not induce a change in the phosphorylation of STAT3 on either tyrosine 705 or serine 727 residues, the two major sites of phosphorylation on STAT3. However, there are other poorly understood post-translational modifications of STAT3, that have previously shown effects on STAT3 function, that may be involved. Importantly, we have observed that statin treatment reduces the viability of Ovcar8 and Heya8 ovarian cancer cell spheroids. We also found that statin treatment induced apoptosis of ovarian spheroids by measuring Annexin V staining. A major problem for ovarian cancer patients is metastasis. Our preliminary evidence suggests that statins reduce the ability of ovarian cancer spheroids to clear a mesothelial monolayer of cells, an early step in ovarian cancer metastasis. There are several membrane-associated signaling

proteins, including RAF and RAS, that affect STAT3 activity. Both Ovcar8 and Heya8 spheroids showed a decrease in cell viability with statin treatment, which is partially rescued by geranylgeranyl pyrophosphate (GGPP), a downstream metabolite in the mevalonate pathway. The partial recovery by GGPP indicates a mechanism involving the prenylation of membrane associated proteins. This data shows statins may provide effective treatments for ovarian cancer and defining the mechanisms behind the effects of statins may lead to better therapies and outcomes for ovarian cancer patients.

Anti-tumor activity of Helicon inhibitors of B-catenin-TCF interaction in patient-derived xenograft models

YaGuang Si[1], Minjung Choi[1], Xinwei Han[1], Brian White[1], Ziyang Wu[1], Erica Visness[1], Pieter Beerepoot[1], Elizabeth Jaensch[1], Jessica Ramirez[1], Charles Ponthier[1], Xiaogang Han[1], Paula Ortet[1], Peicheng Du[1], Sorabh Agarwal[1], Mirek Lech[1], Aaron Fulgham[1], Sarah Cappucci[2], Zhi Li[3], John McGee[4], Lihua Yu[4], Martin Tremblay[4], Keith Orford[4], Gregory Verdine[4], Jonathan Hurov[1]. *[1]FogPharma, Inc., Cambridge, MA,[2]Prime Medicine, Inc, Tyngsborough, MA,[3]Georgetown University, Washington, DC,[4]Fog Pharmaceuticals, Cambridge, MA*

Genetic and epigenetic alterations in the Wnt signaling pathway leading to constitutive activation of the driver oncogene B-catenin occur in at least 20% of all human cancers. We have developed conformationally hyperstabilized α-helical peptides (Helicons) that bind directly to B-catenin with picomolar affinity and block its interaction with TCF transcription factors. We describe here the characterization of anti-tumor efficacy, pharmacodynamic biomarkers and mechanism of action using multiple in vivo patient-derived xenograft (PDX) models treated with Helicons. Helicon treatment leads to dose-dependent anti-tumor effects and durable regressions in PDX models from multiple indications with Wnt pathway activating mutations. Anti-tumor responses are seen in the presence of additional driver mutations, including KRAS and PIK3CA. RNA-sequencing and Gene Set Enrichment Analysis confirm Helicon treatment inhibits both Wnt/B-catenin and MYC-regulated gene sets. Inhibiting B-

catenin-TCF interaction with Helicons represents a first-in-class therapeutic approach for the treatment of cancers resulting from aberrant transcriptional signaling via B-catenin.

Investigating the role of non-canonical NF-kappaB signaling in tumor cells and macrophages in ovarian cancer

Andrew J. Wilson[1], Dominique Parker[2], Robert Cheng[2], Todd Giorgio[2], Marta Crispens[1], Fiona Yull[2]. *[1]Vanderbilt University Medical Center, Nashville, TN,[2]Vanderbilt University, Nashville, TN*

Background**:** Ovarian cancer is the most lethal gynecologic malignancy, with a 5-year survival rate of less than 50%. To have a major impact on improving clinical outcomes, a better understanding of the progression of disease and identification of truly novel treatment strategies is critical. Canonical nuclear factor-kappaB (NF-κB) signaling has been extensively studied in preclinical ovarian cancer models; however, systemic NF-κB inhibitors have had disappointing results in early clinical trials. Whether the alternative, non-canonical NF-κB signaling pathway (nc-NF-κB) represents a distinct and improved target for therapy in ovarian cancer is unknown. Here, we aim to investigate the role played by nc-NF-κB signaling both in malignant epithelial cells and in macrophages, a key immune cell component in the tumor microenvironment. Repolarizing tumor-associated macrophages (TAMs) away from pro-tumor M2-like functions towards an anti-tumor M1-like phenotype is a critical priority in macrophage-directed therapies.

Methods: In ovarian cancer cell lines, mouse ovarian TAMs cultured *ex vivo*, and immortalized bone marrow-derived macrophages (BMDMs), nuclear levels of p52 were measured by western blot as a read-out of active nc-NF-κB signaling. Effects of macrophage polarization on nc-NF-κB signaling were determined in unpolarized (M0), M1 polarized (LPS/IFNγ treated) or M2 polarized (IL-4 treated) BMDMs. Finally, effects of inhibiting nc-NF-κB using a specific peptide inhibitor of p52 nuclear import (SN52) on cancer cell growth and macrophage phenotype were determined in sulforhodamine B growth assays and by western blot analysis of PCNA (proliferation marker) and arginase-1 (M2 macrophage marker).

Results: We observed high levels of p52 expression in the majority of ovarian cancer cell lines, and in our cultured macrophage models. The functional relevance of these observations was confirmed by experiments showing reduced growth in ovarian cancer cells treated with SN52 and reduced expression of arginase-1 in SN52-treated macrophages. We saw similar results in breast cancer cells and mouse mammary TAMs, showing that nc-NF-κB signaling may also have pro-tumor effects in other cancer types. Complementary studies showed that M2 polarized macrophages expressed markedly higher levels of nuclear p52 than observed in M0 or M1 cells. Based on these promising results, experiments (i) using transgenic mice to allow targeted, inducible activation of nc-NF-κB in macrophages during ovarian cancer progression and (ii) testing the therapeutic effects of SN52 in these cancer models are underway.

Conclusions: Although further studies are required to establish the translational relevance of our findings, we hope to identify non-canonical NF-κB signaling as a new therapeutic target in malignant epithelium and macrophages in ovarian cancer and potentially other cancer types.

Development of novel pyrimido-pyrazolo-quinolone derivative, IND-2 as multi-targeted inhibitor for the treatment of prostate cancer

Swapnaa Balaji[1], Rabin Neupane[1], Chandrabose Karthikeyan[2], Jayachandra Babu Ramapuram[3], Amit K. Tiwari[1]. *[1]The University of Toledo, Toledo, OH,[2]Indira Gandhi National Tribal University, Lalpur, India,[3]Auburn University, Auburn, AL*

Prostate cancer (PC) is the most commonly diagnosed cancer in men. In PC, multiple molecular signaling networks are perturbed, so monotherapies are less effective, creating an urgent need to discover chemotherapeutic agents that target multiple tumor-promoting proteins simultaneously. Drug discovery research is increasingly embracing poly-pharmacology, in which one drug targets multiple oncogenic targets concurrently. We have identified a novel quinoline derivative, IND-2 (4-chloro-2-methylpyrimido[1″,2″:1,5]pyrazolo[3,4-b]quinolone), that has been shown to significantly inhibit the expression of several oncogenic and epigenetic targets in PC cells. It was observed that IND-2 significantly inhibited the proliferation of PC-3 and DU-145 with IC_{50} values of 3 μM and 3.5 μM, respectively. Furthermore, 5 and 10 μM of IND-2 produced morphological changes in PC-3 cells characteristic of apoptosis. The levels of reactive oxygen species (ROS) increased significantly after IND-2 was added to PC cells. Additionally, 5 and 10 μM of IND-2 reduced mitochondrial membrane potential in PC-3 cells. Furthermore, IND-2 increased the expression of cleaved caspase-3, cleaved caspase-7, and cleaved poly (ADP-ribose) polymerase (PARP). The PC-3 cells incubated with 5 μM of IND-2 showed a significant reduction in expression of B-cell lymphoma 2 (Bcl-2). These data convincingly show that IND-2 inhibits PC cells through apoptosis induction. It is interesting to note that IND-2 (2.5, 5 and 10 μM) also induces mitotic catastrophe in PC-3 cells. Wound healing assay and expression of several EMT (epithelial to mesenchymal) markers indicated significant anti-metastatic activity of IND-2. Target identification studies

have demonstrated that IND-2 mimics etoposide (VP-16) and binds more specifically to Topoisomerase IIβ. In our preliminary studies, we found that IND-2 inhibits several oncogenic and epigenetic targets including Topoisomerase II-Hsp90 complex and LSD1/HDAC1 of the transcriptional corepressor CoREST complex. However, these targets need to be validated to understand IND-2's mechanism. Overall, IND-2 may lead to the development of more effective poly-targeted compounds for PC treatment.

Anti-cancer effect of a probiotic bacteria-derived compound, 1,4-Dihydroxy-2-naphthoic acid in prostate cancer

Shreeja Srinivas Bitla, Gnanasekar Munirathinam. *Biomedical Sciences, University of Illinois College of Medicine (Rockford), Rockford, IL*

Cancer incidence has been increasing globally and the major cause for mortality associated with this disease is due to metastasis development. Followed by skin and lung cancer, prostate cancer (PCa) is one of the most common cancers prevailing among older men in the United States. Although androgen deprivation therapy (ADT) is the mainstay treatment for PCa, most patients undergoing ADT eventually develop metastatic PCa. Moreover, other treatment options, such as chemotherapy and radiotherapy, have toxic side effects and are ineffective in controlling advanced PCa. Hence, there arises a need for identifying alternative agents with possibly fewer side effects. The gut biome plays a significant role in regulating many bodily functions like digestion, immunity, and including cancer prevention. Probiotics, commonly known as 'good bacteria,' are living microorganisms that provide health promoting benefits. A probiotic metabolite, 1,4-Dihydroxy-2-naphthoic acid (DHNA), is an anti-inflammatory aryl hydrocarbon receptor (Ahr) agonist which is yet to be explored for its anticancer activity. Inhibiting the inflammatory signaling axis and activating Ahr by DHNA could be a promising strategy to counteract metastatic PCa. Cell viability assays revealed that 1,4-DHNA is highly toxic in metastatic prostate cancer cell lines such as DU145 and PC3 compared to normal prostate epithelial cells like RWPE-1 and human prostate stromal myofibroblast cell line, WPMY-1, with an approximate IC50 value of 5 μM in DU145 and PC3 and about 20 μM and 75 μM in WPMY-1 and RWPE-1 respectively. DHNA reduced the colony forming

abilities of BPH-Cd, PC3, and DU145 in clonogenic assay and suppressed the BPH-Cd spheroid growth in spheroid formation assay, revealing its anti-tumorigenic potential. Trans-well migration assay using BPH-Cd, PC3, and DU145 showed a decrease in cell migration, hinting at the drug's anti-metastatic ability. G2/M phase arrest in cell cycle analysis and dose-dependent increase in apoptosis of DHNA-treated DU145, PC3, and LNCaP cell lines reiterated its anti-cancer potential. Western blot results in PC3 and DU145 showed significant dose-dependent inhibition of protooncogene β-catenin expression. Downregulation of cell cycle proteins like cyclin D1 and increased expression of effector caspase, cleaved caspase 7 support cell death promoting effects of DHNA via an intrinsic apoptotic pathway. Our pre-clinical data suggest that DHNA can be a potential drug for inhibiting both prostate tumor growth and metastasis. Further research is warranted to ascertain the anti-metastatic and underlying anti-cancer mechanisms to help translate the findings to clinical use.

Preclinical characterization of BGI-9004, a covalent TEAD inhibitor with exceptional anti-cancer activity and combination potential

Shirley Guo, Shashank Shrishrimal, Jason Cui, Guoqing Wang, Vivian Zhang, Ning Deng, Iris Dong, Anna Chen, Steve Luo, David Sperandio, Ping Cao, Wolf R. Wiedemeyer. *BridGene Biosciences, Inc., San Jose, CA*

Pharmacological inhibitors of TEAD transcription factors have emerged as a promising novel class of anti-cancer agents. TEAD inhibitors disrupt oncogenic YAP/TAZ signaling, resulting in cell cycle arrest and cell death in susceptible cancers. In preclinical models, cancer cell lines with alterations in the Hippo signaling pathway, such as mutations or loss of NF2 or LATS, are particularly sensitive to inhibition of TEAD signaling. In addition, YAP/TAZ-TEAD signaling is thought to play a role in resistance to several targeted therapies, such as EGFR inhibitors and MEK inhibitors. BGI-9004 is a covalent inhibitor of TEAD1-4 with low nanomolar potency in a TEAD reporter cell line and anti-cancer activity *in vitro* and *in vivo*. In the NF2-deficient NCI-H226 and the NF2-wildtype, LATS-mutant MST-O211H mesothelioma xenograft models, BGI-9004 treatment resulted in sustained tumor regressions over a 28d treatment course. Anti-cancer activity was accompanied by significant inhibition of TEAD-mediated

transcription in BGI-9004-treated tumors, and no adverse effects on the body weight of treated mice were observed. Moreover, proteome-wide protein binding of BGI-9004 was assessed by Isobaric Mass Tagged Affinity Characterization (IMTAC^{TM}), which confirmed its high selectivity for TEAD. In line with this, BGI-9004 had a clean profile in a panel of protein targets that present potential safety liabilities (CEREP safety panel). These findings prompted us to explore the combination potential of BGI-9004 with other targeted therapies, including inhibitors of EGFR, MEK and mutant KRAS^{G12C}. Here, we found that BGI-9004 potentiated the effect of other targeted therapies. In particular, we generated dose response matrices for BGI-9004 and inhibitors of KRAS^{G12C} and KRAS^{G12D} in several KRAS-mutant cell lines, including three lung cancer cell lines, and demonstrated synergy for the combination. These results suggest that inhibition of YAP/TAZ-TEAD signaling may improve the efficacy of KRAS-targeted therapy. Taken together, the covalent TEAD inhibitor BGI-9004 has demonstrated promising activity both as a single agent and in combination with other targeted agents, a favorable pharmacokinetic profile and high target selectivity in preclinical models, supporting its evaluation as a novel anti-cancer agent in clinical trials.

Development of small molecule inhibitors of protein interaction with glycosaminoglycans

Tahir N. Sheikh, Elgilda Musi, Alex J. Rai, Gary K. Schwartz. *Columbia University Irving Medical Center, New York, NY*

Glycosaminoglycans (GAGs), such as heparan sulfate and chondroitin sulfate, are an important component of the tumor microenvironment (TME). These carbohydrates are attached to proteoglycans at the surface of tumor cells and play a vital role in malignant transformation. Heparan sulfate (HS) glycosaminoglycans have been demonstrated to play a pleiotropic role in regulating the activity of important cellular receptors and downstream signaling pathways, and are implicated in cancer cell proliferation, angiogenesis, invasion, and metastasis. Heparinase, an endoglycosidase that specifically cleaves heparan sulfate side chains of heparan sulfate proteoglycans is expressed in several sarcoma subtypes. We measured heparinase activity in several cell lines and found that A673, CHP100,

CHLA9 and RD-ES Ewing's sarcoma cell lines have significantly higher levels of heparinase activity compared to the heparinase-deficient CHO-K1 psgD-677 cell line. Interference with heparinase or heparin sulfate function(s) may represent a therapeutic approach in sarcoma. To this end, we tested these cell lines by measuring cell growth using a cell viability assay, in the presence or absence of GTC3300P, a small molecule inhibitor of protein interaction with glycosaminoglycan. We demonstrate that the Ewing's sarcoma cell lines exhibit potent and significant inhibition in cell growth *in vitro*, in the presence of drug. Western blot analysis shows induction of cleaved Poly-ADP Ribose Polymerase (PARP), yH2AX, as well as cleaved caspase-3, known markers of apoptosis and down regulation of mTORC1 targets such as phospho-S6 (p-S6), in Ewing's sarcoma. Apoptosis was confirmed by the induction of sub-G1 population in Ewing's sarcoma by cell cycle analysis. Previous reports have indicated that heparinase activity is strongly implicated in cell migration and invasion and is associated with tumor metastasis, angiogenesis and inflammation. This was confirmed by LC-MS/MS proteomics and bioinformatics (gene ontology and gene set enrichment) analysis of these multiple cell lines, which identified alterations in numerous biomarkers in these pathways, including multiple ribosomal protein subunits, spliceosomes components, and complement coagulation cascade. We further conducted a cell migration assay and demonstrate that GTC3300 significantly inhibits cell migration in Ewing's sarcoma cell lines, but not in heparinase-deficient psg677 cells. Taken together our data strongly suggests that targeting protein interaction with glycosaminoglycans including heparan sulfate in Ewing's sarcoma represents a novel approach and merits further investigation

#4978

Combination of a clinical stage-hedgehog inhibitor, GT1708, improves Venetoclax-induced apoptosis by down-regulating MCL-1 proteins in AML cells

Liandong Ma, Qianxiang Zhou, Honghua Yan, Min Dong, Xiahe Han, Jiangwie Li, Jie Qu, Weidong Qian, Youzhi Tong. *Suzhou Kintor Pharmaceuticals, Inc, Suzhou, China*

Acute Myeloid Leukemia (AML) is the third hematological malignancies with the worst relative overall 5-year survival rate (11.7%) in hematological malignancies. AML is a heterogeneous disease with a broad spectrum of genomic changes and molecular mutations that lead to a poor prognosis and clinical outcome. Leukemic stem cells progress to myoblasts that continue to proliferate without differentiating, namely, immature blasts in AML. The hedgehog (HH)/glioma-associated oncogene homolog (GLI) signaling pathway is essential for embryonic and stem cell developments. This pathway has been one of the most promising targets for drug discovery and developments for AML. Although HH inhibitor Glasdegib in combo with low-dose cytarabine achieved FDA approval for AML, Venetoclax (BCL-2 inhibitor/ABT-199) plus a hypomethylating agent (HMA) have been dominating the regimens in AML recently. Here we reported GT1708, a HH inhibitor, improves ABT-199 (venetoclax)-induced apoptosis by down-regulating MCL-1 proteins in AML cells. GT1708 is a potent HH inhibitor (IC50=0.11 nM in HH pathway-driven cellular assay) and inhibited GLI expression with doses of 1, 3 and 10 mpk in a HH-dependent medulloblastoma animal models. In Molm-13 (AML) cells, GT1708 was shown to down-regulate the expression of MCL-1 proteins (anti-apoptotic proteins). In contrast, ABT-199 increased the expression of MCL-1. Furthermore, ABT+Aza (Azacidine/HMA drug) induced more MCL-1 expression than ABT-199. Importantly, GT1708 was shown to induce the expression of cleaved-PARP (c-PARP/apoptotic marker) and to increase c-PARP expression when combined with ABT-199. Due to ABT+Aza induced MCL-1 overexpression, the combination of both agents failed to induce c-PARP, suggesting MCL-1 overexpression conferring resistance to ABT+Aza therapy in Molm-13 cells. GT1708 was further evaluated in flow cytometry-based apoptotic assays. GT1708, ABT-199 and Aza were demonstrated to induce an early apoptosis by 9.98%, 47.5%, and 8.64%, respectively. In comparation, ABT+GT1708 were revealed to induce a 61% of apoptosis superior to 47% or 48.5% of apoptosis induced by either ABT or ABT+Aza in Molm-13 cells. These results confirm the role of MCL-1 overexpression in conferring resistance to ABT+Aza therapy, which can be overcome by ABT+GT1708 combo. GT1708/ABT combo were also shown a marginable superior antitumor activity than ABT along in Molm-13 animal models. GT1708 has been testing in a phase I study in AML patients with previous multiple lines of regimens. GT1708 has been shown to

reduce blast counts in three of 13 AML patients treated with higher doses and demonstrated favorite PK and safety profiles. In brief, these results support the clinical development of GT1708 in combination with ABT-199 in AML patients.

Evaluation of heme inhibitory therapy in combination with radiation of lung cancer

Narges Salamat[1], Tianyuan Wang[2], Eranda Berisha[1], Maria Del Carmen Chacon Castro[1], Adnin Ashrafi[1], Debabrata Saha[2], Ralph P. Mason[2], Li Liu[2], Li Zhang[1]. *[1]UT Dallas, Richardson, TX,[2]Radiology, UT Southwestern Medical Center, Dallas, TX*

Lung cancer is the leading cause of cancer-related death in the United States, with a 5-year survival rate of less than 25%. While most lung cancer patients receive radiation therapy, radioresistance severely impacts treatment outcomes. Thus, development of therapeutics to potentiate durable response to radiation therapy may be key to improving treatment outcomes. Research in our lab has previously implicated heme, a central biosynthetic molecule with important functions in diverse molecular and cellular processes, in lung cancer development and progression. To target heme, we designed heme-sequestering protein 2 (HeSP2) which displays potent anti-tumor activity in mouse tumor models. By decreasing tumor metabolic demand through heme sequestration, HeSP2 can significantly alleviate tumor hypoxia, a dominant radioresistance mechanism. Tumor hypoxia correlates with poor clinical outcomes by acting via multiple mechanisms such as inhibiting radiation-induced DNA damage and inducing the HIF-1 pathway that leads to antioxidant generation. Here, our preliminary data show that HeSP2 potentiates the antitumor efficacy of ionizing radiation. To see the effect of HeSP2 in combination with radiotherapy, in summary we subcutaneously implanted A549-luc, NSCLC cell lines with mutation in Kras and KLB1 in SCID mice. After 1-2 weeks mice were treated with saline (Control), HeSP2(25 mg/kg, i.v, twice a week), radiation (5 Gray, once per week at week 2 and 3), and HeSP2 combined with radiation (25 mg/kg, i.v, twice a week plus 5 Gray, once per week at week 2 and 3. Tumor tissues were harvested, processed and paraffin embedded for immunohistochemistry (IHC). Preliminary results

indicate HeSP2 in combination with radiation reduce the levels of multiple angiogenic markers and vascular markers as well as microvessel density. These results indicate that heme sequestration in combination with radiation can be an effective strategy for suppressing lung tumors.

#4980

Design and functional characterization of a first-in-class irreversible inhibitor of HOIL-1-interacting protein (HOIP) with selective antitumor activity against B-cell non-Hodgkin lymphoma

Ana Maria Montagut[1], Marc Antoni Armengol Cubillos[2], Gema Gorjón-de-Pablo[1], Judith Farrés[3], Laia Huguet Garcia[2], Núria Profitós-Pelejà[2], Juliana Carvalho Santos[2], Marcelo Lima Ribeiro[2], Miranda Fernández-Serrano[2], Roger Estrada Tejedor[1], José I. Borrell[1], Gaël Roué[2]. *[1]Group of Pharmaceutical Chemistry, IQS School of Engineering, Barcelona, Spain,[2]Lymphoma translational group, Josep Carreras Leukaemia Research Institute, Badalona, Spain,[3]Anaxomics Biotech SL, Barcelona, Spain*

Activating single-nucleotide polymorphisms of HOIL-1-interacting protein (HOIP), the catalytic subunit of the linear ubiquitin chain assembly complex (LUBAC), have recently been shown to promote myeloid differentiation primary response 88 (MYD88)-mediated B-cell lymphomagenesis. To assess the relevance of targeting HOIP in the activated B-cell-like (ABC) subtype of diffuse large B-cell lymphoma (DLBCL) with *MYD88* mutation, we used systems biology to build a mathematical model aimed at evaluating the impact of HOIP depletion on DLBCL. From this model, an AI-mediated query demonstrated that HOIP blockade was associated with the suppression of three main pathophysiological motifs in malignant B cells, i.e., cell growth and proliferation, apoptosis evasion and deregulated metabolism. We then undertook a computational study that consisted of a combinatorial substitution of several α-β unsaturated moieties to be used as covalent binding warheads to the catalytic cysteine residue of HOIP. The resulting chemical library was used on subsequent molecular docking to assess the best HOIP binding candidates. Out of the four candidates synthesized from this library, we isolated compound A (Cpd A), a covalent irreversible inhibitor of HOIP with a pyrido[2,3-*d*]pyrimidine core, which exerted

selective antitumor activity in a panel of ABCL-DLBCL cell lines (mean IC_{50} at 48hours: 90.7± 13.09 μM) while sparing normal B cells. Immunoprecipitation studies demonstrated that Cpd A was able to modulate the interaction between HOIP and the LUBAC component, SHARPIN, leading to the blockade of NF-κB signaling and to the downregulation of several downstream effectors, including CCL3, IL6 and IRF4. Specificity of Cpd A towards HOIP was confirmed by a drug affinity responsive target stability (DARTS) assay based on the immuno-detection of persistent HOIP peptides after Cpd A-mediated blockade of enzymatic proteolysis, and thereafter in a CRISPR-engineered HOIP-knockout ABC-DLBCL model. Finally, efficacy of the compound was confirmed *in vivo* in a chicken embryo chorioallantoic membrane (CAM)-derived model of ABCL-DLBCL subjected to a twice weekly dosing with Cpd A, in which the compound achieved a 25% tumor growth inhibition, associated with a 60.5% and 89% reduction in brain and bone marrow infiltration by lymphoma cells, respectively. Altogether, our results confirm that HOIP represents a promising therapeutic target for ABC-DLBCL with activating MYD88 mutation, and that a pyrido[2,3-*d*]pyrimidine derivative can successfully and specifically block HOIP, resulting in NF-κB disruption and selective antitumor activity in this aggressive subtype of B-cell lymphoma.

#4981

The potent quadruplex-binding compound QN-302 down-regulates the S100P gene in *in vitro* and *in vivo* models of pancreatic cancer: a potential therapeutic target and biomarker for PDAC

Nicole Williams[1], Jenny Worthington[1], Ahmed Ahmed[2], Tariq Arshad[3], Stephen Neidle[2]. *[1]Axis Bioservices, Coleraine, United Kingdom,[2]School of Pharmacy, University College London (UCL), London, United Kingdom,[3]Qualigen Therapeutics Inc, San Diego, CA*

The compound QN-302, a tetra-substituted naphthalene diimide (ND) derivative has been designed to have high affinity for G-quadruplex (G4) nucleic acids. It has single-digit nM anti-proliferative activity in a panel of human pancreatic cancer cell lines (Ahmed et al., ACS Med Chem Lett, 2020, 11, 1634-1644) and anti-tumor activity in xenograft, orthotopic and genetic (KPC) models for pancreatic cancer (PDAC). Its mode of action involves the targeting of G4-forming sites in promoter regions of cancer-

associated genes, where their prevalence is over-represented compared to other genes. Transcriptome analyses of QN-302 in MIA-PACA2 cells have confirmed genes involved in cancer-associated pathways and carry G4 motifs in their promoters as targets. We have found that expression of the S100P gene, a well-authenticated indicator of PDAC disease and progression, is highly down-regulated in QN-302 treated cells. The S100P gene contains at least five putative G4 motifs, including a classic G4 promoter site just upstream of the transcription start site. We have observed that transcriptome analyses on tumor material from human PDAC patients, and those from poorly differentiated as well as more highly differentiated tumors, have shown that the S100P gene is highly over-expressed (especially in poorly differentiated tumors). We now report on gene expression analysis of S100P using control and treated tumor tissues from a therapeutic study in PDAC MIA-PACA2 xenografts in mice, by means of RT-qPCR and Western blot analyses. The data shows statistically significant dose-dependent decreases in expression of S100P at both the mRNA (to ca 25% of control values) and protein levels (to ca 22% of control values), giving added confidence to the concept that the S100P gene is a therapeutic target in PDAC and may also be useful as a marker of QN-302 response in future clinical use. QN-302 is bio-available at therapeutic doses and is well tolerated at these levels in the animal models. It is being developed for clinical evaluation by Qualigen Therapeutics Inc and is currently at the pre-IND stage.

The somatic mutation signature detected in gynecological mucosal melanoma

Zhongwu Li[1], Lianyi Shen[1], Siyao Liu[2]. *[1]Peking University Cancer Hospital, Beijing, China,[2]ChosenMed Technology Co. Ltd, Beijing, China*

Background: Gynecological Mucosal Melanoma(GMM) is aggressive disease with a poor prognosis, where few studies focusing on its target drug and mutation signatures. Cancer as outcome of DNA mutagenesis process and can be inferred from somatic mutations signature by analyzing the genome sequence. Due to the rapid development of next-generation sequencing (NGS) and molecularly driven targeted therapy, discovering

different mutation signature in cancer plays an important role in precision medicine.
Methods: The study was conducted at a high-volume melanoma center, the Peking University Cancer Hospital. We enrolled female patients with melanoma (n = 22) from 2017 to 2021. Subsequently, whole-exome sequencing performed on the Formalin-fixed paraffin-embedded (FFPE) specimens from 22 GMM patients and match normal tissues of patients. Tumor mutational burden (TMB) was measured as the number of nonsynonymous somatic mutations of whole-exome sequence coding region. Mutation signature detection base pair of six substitution subtypes: C>A, C>G, C>T, T>A, T>C, and T>G. NMF can be used to decompose matrix A into two nonnegative matrices.
Results: In all mutations of 22 GMM patients, we screen two mutation signatures. Signature 1 showed a strong correlation [0.77;cosine similarity value (CSV)] to the signature 3 from the COSMIC database, which represents failure of DNA double-strand break-repair by homologous recombination, which predominated in 55%(12/22) GMM patients. Signature 2 showed a strong correlation to Cosmic signature 1 (CSV = 0.791), which is has been found in all cancer types correlated with age cancer diagnosis. Patient-18 did not any treatment in our hospital, follow-up was lost. Kaplan-Meier revealed that Signature 2 was associated with longer overall survival in GMM patients and later recurrence or progression.
Conclusions: This study aimed to identify prognostic markers and the development of targeted therapy for the treatment of GMM.

#4983
Anaplastic thyroid cancer cells upregulate mitochondrial one-carbon metabolism to meet purine demand, eliciting a targetable vulnerability
Adam J. Sugarman, Luong Do Huynh, Antonio Di Cristofano. *Albert Einstein College of Medicine, Bronx, NY*

Anaplastic thyroid cancer (ATC) is one of the most aggressive and lethal tumor types, characterized by loss of differentiation, epithelial-to-mesenchymal transition, extremely high proliferation rate, and generalized resistance to therapy. To identify novel relevant, targetable molecular alterations, we have analyzed gene expression profiles from a genetically

engineered ATC mouse model and from two human patient datasets, and have found consistent and coordinated upregulation of several genes encoding enzymes involved in the one-carbon metabolic pathway, which uses serine and folates to generate nucleotides, glutathione and glycine. We have used a combination of cell line and in vivo approaches to assess the role of this pathway in the progression and maintenance of ATC and the effect of its inhibition on tumor behavior. Genetic and pharmacological inhibition of both *MTHFD2* and *SHMT2*, key enzymes of the mitochondrial arm of the one-carbon pathway, rendered mouse and human ATC cells auxotroph for glycine and led to significant inhibition of tumor cell proliferation and colony forming ability, which was primarily caused by depletion of the purine pool leading to arrest in S phase. Notably, these growth-suppressive effects were significantly amplified when cells were grown in the presence of physiological types and levels of folates. Genetic blockage of the one-carbon pathway dramatically impaired tumor growth in vivo, both in immunocompetent allograft models and in immunocompromised xenograft models of ATC. Together, these data establish the upregulation of the one-carbon metabolic pathway as a novel and targetable vulnerability of ATC cells, which can be exploited for therapeutic purposes.

Integrated platform enables KRAS-targeted drugs discovery

Beibei Liu, Lian Li, Xiangyang Zuo, Jie Yang, Ruifeng Wang, Feifei Fan, Wenting Shi, Qingyang Gu. *WuXi App Tec, Suzhou, China*

The Kirsten rat sarcoma viral oncogene homolog (KRAS) is mutated in approximately 25% of all human cancers and is known to be a major player promoting and maintaining tumorigenesis through the RAS-MAPK pathway. Activating mutations in KRAS increase the ability for GTP-loading, making it difficult to displace, thus constitutively activate downstream MAPK pathway and promote cancer formation. Fortunately, a revolutionary strategy to use covalent allosteric inhibitors that target a shallow pocket on the KRAS surface has provided new impetus for KRAS inhibitor development efforts. These inhibitors, such as AMG510 and MRTX849, show promising results in patients with tumors harboring KRAS G12C mutation. While the approval of AMG510 was a major

breakthrough for those patients harboring KRAS G12C mutations, G12C only accounts for a fraction of those with KRAS mutations and eventual resistance to G12C inhibitors is unavoidable. Therefore, develop new drugs direct various KRAS mutants and combination strategies that target resistance mechanisms have become vital in the war against KRAS-mutant tumors.
To enable the discovery of novel KRAS inhibitors, we established a one-stop service platform, covering affinity detection of compounds to KRAS mutants, KRAS upstream and downstream protein-protein interaction detection, pathway activation detection, cell proliferation assay (2D/3D culture system), and *in vivo* efficacy evaluation in KRAS mutant xenograft models. Our platform provides assays on nearly all the current mainstream mutants of KRAS, such as G12C/G12D/G12R/G12S/G13D, and engineered Ba/F3 cell lines that harboring single or double KRAS mutation. In addition, we developed a panel of resistant models to KRAS G12C inhibitor that bringing a better understanding of the biological basis of drug resistance, and will serve as a new tool to optimize KRAS-G12C inhibitor regimens and combinatorial strategies. The comprehensive KRAS-targeted drug discovery platform is empowering new drug research and development.

Oncogenes and Tumor Suppressor Genes as Targets for Therapy 3

The growth inhibitory effect of MDV3100 on hormone receptor-positive, HER2-negative breast cancer cell lines with low DYRK2 expression
Yoshimi Imawari[1], Rei Mimoto[2], Kiyotsugu Yoshida[2]. *[1]Univ. of Tokyo Inst. of Medical Science, Tokyo, Japan,[2]Jikei Univ. Sch. Med., Tokyo, Japan*

Introduction: Tumor progression is the main cause of death in patients with breast cancer. Accumulating evidence suggests that dual-specificity tyrosine-regulated kinase 2 (DYRK2) functions as a tumor suppressor by regulating cell survival, differentiation, proliferation and apoptosis. Recently, we reported for the first time that DYRK2 inhibits breast cancer stem cells and tumor cell proliferation through transcriptional downregulation of KLF4 and CDK14, respectively.Our previous study

showed that Androgen receptor (AR) was a DYRK2-dependent transcriptional activator. In this context, we hypothesized that MDV3100, an inhibitor of AR, may be effective for breast cancer with low DYRK2 expression.
Methods: We established stable DYRK2-depleted cells. MCF-7 cells, hormone receptor-positive, HER2-negative breast cancer cell line, were transfected with pSuper-puro vector (pSuper control) or pSuper-puro DYRK2 shRNAs (shDYRK2) along with puromycin to isolate stable cell lines.These manipulated cells were compared with the control cells by various assays. We analyzed the activity of AR by Androgen receptor reporter assay. MTS assays were used to assess growth inhibition after treatment with MDV3100.
Results: Androgen receptor reporter assay showed that knocking down DYRK2 induced AR transcription activity in MCF-7 cells.In MCF-7 DYRK2-depleted cells, MTS assays revealed that the treatment by MDV3100 was more effective than that in MCF-7 control cells.
Conclusion: These findings demonstrate that reduced DYRK2 expression in hormone receptor-positive, HER2-negative breast cancer increases the activity of AR and significantly inhibits the growth by treatment with MDV3100.

Tandem peptides targeting HER2 for delivery of CD44 siRNA into HER2+ breast cancer cells *in vitro*

James W. Kalogeros, Audreanna Miserendino, Angela Alexander-Bryant, Brian Booth. *Bioengineering, Clemson University, Clemson, SC*

Introduction: This research aims to characterize and evaluate the potential of two novel tandem peptides for their ability to mediate the delivery of CD44 siRNA into HER2+ breast cancer cell lines. HER2+ cancer accounts for 20%-25% of invasive breast cancers and shows overexpression of HER2 protein. The tandem peptides examined consist of P51 or P25 targeting peptide sequences that bind to the HER2 protein, and DIV3W, a fusogenic peptide that allows for siRNA protection, cellular internalization, and endosomal escape. We hypothesize that delivery of tandem peptide will result in the observation of mRNA knockdown of CD44, a reduction of

CD44 protein expression, and a decrease in metastatic properties of breast cancer cells.
Methods: Western blot analysis was used to determine the basal expression of CD44 in HER2+ breast cancer cell lines, SKBR3 and BT474, and breast epithelial cell line MCF10A. Tandem targeting/fusogenic peptides termed P51-DIV3W and P25-DIV3W were electrostatically complexed with non-targeting siRNA (siNT) at increasing N:P ratios to determine the minimum ratios needed to complex free siRNA. Various ratios of peptide-siRNA complexes were also treated with FBS and RNase A to determine whether the peptides protected siRNA from degradation. MTS assays were performed in SKBR3, BT474, and MCF10A cells to determine cytotoxicity using increasing peptide concentrations. Dynamic light scattering was performed using a Zetasizer to determine the size of the peptide-siRNA nanocomplexes.
Results: Western Blot data of the three cell lines showed that CD44 protein was present in cancerous and normal cells, whereas HER2 protein was only present in SKBR3 and BT474 cells. Peptide-siRNA complexes for both P51-DIV3W and P25-DIV3W formed at a minimum N:P ratio of 20:1. Both peptide complexes protected siRNA from degradation in FBS and RNase A at N:P ratios ranging from 20:1 to 60:1. DLS results showed that P25-DIV3W-siRNA complexes had an average diameter of 200.23 nm and a zeta-potential of 24.7 mV.
Conclusions: The data collected shows that the tandem peptides successfully complex with siNT and protect siNT from degradation. The peptide complexes formulate at a size that serves as an effective carrier for siRNA to breast cancer cells. Future work will focus on evaluating the ability of the tandem peptides to target HER2 and effectively silence CD44 in HER2+ breast cancer cells.
Acknowledgements: This research was supported in part by the Dabo Swinney All In Foundation and Materials Assembly and Design Excellence in South Carolina (MADE in SC) under the National Science Foundation EPSCoR Program under NSF Award # OIA-1655740. We also thank SC BioCRAFT, NIH award P30 GM131959, for the use of core equipment and facilities.

Anti-Stanniocalcin 1 antibody as a potential therapeutic strategy for liver fibrosis and hepatocellular carcinoma

Alfred Long-Hin Suen[1], Kristy Kwan-Shuen Chan[1], Regina Cheuk-Lam Lo[2]. *[1]Department of Pathology, The University of Hong Kong, Hong Kong, Hong Kong,[2]State Key Laboratory of Liver Research, The University of Hong Kong, Hong Kong, Hong Kong*

Introduction: Hepatocellular carcinoma (HCC) is the sixth most frequently diagnosed cancer and the third leading cause of cancer deaths. Liver fibrosis (LF) is a progressive disease and cirrhosis, the advanced stage of LF, is *per se* a risk factor for HCC. Moreover, LF persists after the development of HCC. Stanniocalcin 1 (STC1), as a serum biomarker of both HCC and LF as we previously reported, was found to be secreted from HCC cells and hepatic stellate cells (HSCs). STC1 promoted cell migration and invasion of HCC and activation of HSCs, suggesting that STC1 could be an actionable target of both diseases. As a secretory protein, STC1 could potentially be targeted by an antibody approach.
Objectives: This study aims to investigate the therapeutic values of targeting secretory STC1 in HCC and LF models using antibody approach, including in the interplay between HSCs and HCC cells.
Methods: Human anti-STC1 antibody was harvested and purified from a hybridoma cell line of a designed epitope. *In vitro* transwell migration and invasion assays were performed on human HCC cell lines. Co-culture assays were set up with HCC cells cultured in conditioned medium (CM) collected from LX2, a human HSC cell line. Expression of fibrogenic markers were measured by western blotting, qPCR and ELISA.
Results: Enforcement of STC1, either by viral transfection of STC1-overexpressing vector or by the treatment of recombinant STC1 protein, increased the migration and invasion of HCC cells. The effects were abrogated by the co-treatment of anti-STC1 antibody. The enhanced migratory and invasive abilities of HCC cells induced by activated HSC CM were abolished by anti-STC1 antibody. In addition, anti-STC1 antibody suppressed the secretion of type I collagen (COL1) and the intracellular expression of fibrogenic markers alpha-smooth muscle actin (αSMA) and TIMP metallopeptidase inhibitor 1 (TIMP1) in TGFβ1-activated HSCs.
Conclusion: Anti-STC1 antibody displays therapeutic effects on HCC *in vitro*. It is also shown to suppress the expression of fibrogenic markers in

activated HSCs. Anti-STC1 antibody is a potential therapeutic strategy for both HCC and LF.

Defining the role of FANCA in breast cancer development and cell cycle progression

Liang Luo[1], Wenjun Liu[2], Anna Palovcak[1], Fenghua Yuan[1], Fang Li[1], Daniel Calkins[1], Yan Li[1], Karoline Briegel[1], Daniel Bilbao[1], Evan Roberts[1], Christian Mason[1], Zhao-Jun Liu[1], Sylvia Daunert[1], Yanbin Zhang[1].
[1]University of Miami Miller School of Medicine, Miami, FL,[2]Zhejiang University School of Medicine, Hangzhou, China

FANCA is one of the 22 known Fanconi anemia (FA) pathway genes and is indispensable for interstrand crosslink (ICL) repair. It is reported that FANCA is responsible for about 64% of FA cases and one important clinical characterization of FA patients is predisposition to cancer. However, analysis of TCGA database reveals that FANCA level is elevated in breast cancer patients, especially in ER- breast cancer, which is associated with the methylation status at the S-shore of CpG island ahead of FANCA gene. Moreover, the FANCA level is negatively correlated with the survival rate of breast cancer patients. To understand the implication of FANCA in breast cancer development, we have targeted FANCA by either CRISPR mediated knock-out (KO) or shRNA mediated knockdown (KD) in MDA-MB-231 breast cancer cells. Our data suggest that depletion of FANCA protein inhibits breast cancer growth both in vitro and in vivo. On the other hand, overexpressing FANCA in low-FANCA breast cancer cell line MDA-MB-468 promotes cancer cell proliferation. Cell cycle profiling reveals an inefficiency of MDA-MB-231 FANCA KO cells in G1 to S transition due to p21 and p27 upregulation in FANCA KO cells. In addition, the proliferation inefficiency in MDA-MB-231 FANCA KO cells is caused by Rb hypophosphorylation. Therefore, we conclude that FANCA contributes to the breast cancer development by promoting cell cycle progression through Rb/E2F signaling pathway. Our immunoprecipitation (IP) results indicate that in MDA-MB-231, FANCA is interacting with HES1, which is a transcription suppressor that binds to the promoter region of CDKN1A and CDKN1B to promote cell cycle progression, explaining how FANCA participates in cell cycle progression in breast cancer.

NB compound FOXM1 inhibitors have potent anti-cancer activity in high-grade serous ovarian carcinoma

Makenzie Vorderbruggen[1], Cassie Liu[1], Catalina Muñoz Trujillo[1], Sung Hoon Kim[2], John A. Katzenellenbogen[2], Benita S. Katzenellenbogen[2], Adam R. Karpf[1]. *[1]University of Nebraska Medical Center, Omaha, NE,[2]University of Illinois Urbana-Champaign, Champaign, IL*

Introduction: High-grade serous ovarian carcinoma (HGSC) is characterized by frequent overexpression and activation of the Forkhead Box M1 (FOXM1) transcription factor, suggesting it as a therapeutic target. This study focused on characterizing the activity of 1,1-diarylethylene FOXM1 inhibitors (NB compounds) against HGSC models.
Methods: We assessed the effects of three NB compounds (NB-55, NB-73, and NB-115) on FOXM1, transcriptionally active p-FOXM1-T600, FOXM1 targets, and other FOX family members using western blotting. We used RT-qPCR to assess the effect of NB compounds on mRNA expression of *FOXM1* and its canonical targets. We used CyQuant, colony formation, and apoptosis assays to determine the effects of NB compounds on cell viability. We compared the effects of NB compounds and other FOXM1 inhibitors on HGSC cells vs. non-transformed fallopian tube epithelial (FTE) cells. We determined the relationship between FOXM1 degradation and apoptosis and conducted drug washout to determine the length of FOXM1 reduction following NB compound treatment. We used Compusyn to determine whether NB compounds synergize with carboplatin.
Results: NB compounds caused a dose- and time-dependent decrease in FOXM1 and p-FOXM1 and reduced expression of FOXM1 targets with effects on FOXM1 maintained up to 72 hours post-washout in HGSC cells. In contrast, other FOX family members, including FOXA1 and FOXO3A, were minimally affected. RT-qPCR confirmed decreased mRNA levels of *FOXM1* and its target genes, including CCNB1, SKP2, and CDC25B, in HGSC cells treated with NB compounds. As determined by CyQuant, NB compounds were potent in HGSC cells, with nanomolar IC50 values, and impaired both 2D and 3D HGSC cell colony formation. Compared to other FOXM1 inhibitors, e.g., thiostrepton and FDI-6, NB compounds were more potent in HGSC cells with reduced effects in non-transformed FTE cells

(FT282). NB compounds promoted HGSC cell apoptosis, while FT282 cells were unaffected at similar concentrations. Additionally, ectopic FOXM1 expression sensitized FT282 cells to NB compound mediated reduced cell viability. Co-treatment with the pan-caspase inhibitor Q-VD-OPh abrogated apoptosis but not FOXM1 degradation in HGSC cells. NB compounds synergized with carboplatin following simultaneous treatment, and to a greater extent when HGSC cells were treated with NB compounds prior to carboplatin. *In vivo* toxicity studies using C57/BL6 mice indicate that NB compounds are tolerable when administered intraperitoneally. Ongoing studies are assessing the *in vivo* activity of NB compounds using the ID8, p53-/- syngeneic mouse HGSC model.
Conclusions: NB compounds target FOXM1 and the FOXM1 pathway, are potent inhibitors of HGSC cell viability, have a favorable therapeutic index *in vitro,* and are tolerable in mice *in vivo*. These data support NB compound FOXM1 inhibitors as a novel therapeutic approach for HGSC.

#3985
S100A10 promotes HCC development and progression via transfer in extracellular vesicles and regulating their protein cargos
Lu TIAN, Xia WANG, Jingyi LU, HongYang Huang, Goofy Yu-Man Tsui, Karen Man-Fong Sze, Tan-To Cheung, Irene Oi-Lin NG. *The University of Hong Kong, Hong Kong, Hong Kong*

Growing evidence indicates that tumor cells exhibit characteristics similar to their lineage progenitor cells. We found that S100 calcium binding protein A10 (S100A10) exhibited an expression pattern similar to that of liver progenitor genes. However, the role of S100A10 in hepatocellular carcinoma (HCC) progression is unclear. Furthermore, extracellular vesicles (EVs) or exosomes are critical mediator of tumorigenesis and metastasis, but the extracellular functions of S100A10, particularly those related to EVs (EV-S100A10), are unknown. In this study, we observed that S100A10 was upregulated at mRNA level in patients' HCC tumors as compared to the corresponding non-tumorous livers, associated with a copy-number gain. Overexpression of S100A10 was correlated with more aggressive tumor features and poor prognosis. Furthermore, functional assays demonstrated it promoted HCC initiation and progression, including increased sphere forming ability in vitro, enhanced chemoresistance, upregulated liver cancer

stemness markers and activated AKT and ERK pathways. In addition, in orthotopic injection mouse model, S100A10 enhanced both the intrahepatic and pulmonary metastasis of HCC xenografts, with upregulated epithelial-mesenchymal transition (EMT) changes. Of significance, we found that S100A10 was present in EVs secreted by HCC cells. Functionally, the EVs secreted by HCC cells promoted the migratory and invasive abilities of recipient HCC cells. Consistent with the oncogenic role of S100A10 in HCC, EVs from S100A10-overexpressing HCC cells enhanced the tumor promoting effects, while the S100A10-depleted HCC cells abrogated the effects, as compared to the vector control group. To further consolidate the tumor promoting role of S100A10-EV, we blocked the effects using neutralizing antibody (NA) by pretreating HCC cells with S100A10 NA together with EV. Indeed, the NA significantly abrogated the stemness and metastatic properties induced by S100A10-EVs both in vitro and in vivo. In addition, the EMT changes and activation of AKT and ERK were also validated in the recipient HCC cells with the S100A10-EV treatment, while they were abolished with the NA treatment. Moreover, we found that S100A10 governed the protein cargos in EVs and mediated the binding of MMP2, fibronectin and EGF to EV membranes through physical binding with integrin αV to promote the motility of recipient cells. Of note, we observed a simultaneous change of p-EGFR, indicating potential activation of AKT and ERK induced by EGFR. On the other hand, we found the plasma EV-S100A10 level was relatively higher in HCC patients than healthy donors. Collectively, the data showed that S100A10 could be transferred among cells through EVs and activated signaling pathways to facilitate metastasis. Targeting S100A10 may be a potential therapeutic strategy for HCC.

Novel LIPA targeted therapy for treating ovarian cancer

Alexia B. Collier[1], Suryavathi Viswanadhapalli[1], Tae-Kyung Lee[2], Kara Kassees[2], Karla Parra[3], Gaurav Sharma[3], Tanner Reese[3], Michael Hsieh[3], Xihui Liu[3], Xue Yang[1], Behnam Ebrahimi[1], Uday P. Pratap[1], Rahul Gopalam[1], Chia Yuan Chen[2], Scott Terry Elmore[2], Gangadhara Reddy Sareddy[1], Edward R. Kost[1], Jung-Mo Ahn[2], Ganesh V. Raj[3], Ratna K. Vadlamudi[1]. *[1]UT Health Science Center at San Antonio, San Antonio,*

TX,[2]UT Dallas, Richardson, TX,[3]UT Southwestern Medical Center, Dallas, TX

BACKGROUND**:** Ovarian cancer (OCa) is the deadliest of all gynecologic cancers in the United States. Currently approved therapies have improved OCa survival for clinically localized disease, however, the majority (~90%) of patients with high-grade serous OCa (HGSOC) experience relapse with incurable metastases. There is a dire need for new therapeutic approaches. We hypothesized that the high basal endoplasmic reticulum stress (ERS) in OCa represents a critical and targetable vulnerability and may overcome the tumor heterogeneity. The objective of this project is to exploit increased ERS in ovarian cancer cells by engaging the novel target LIPA using the unique compound ERX-41.
METHODS: The utility of ERX-41 as a new therapy was evaluated using MTT and CellTiter-Glo Cell Viability Assays. We used multiple established and patient derived OCa cell lines. The effect of ERX-41 on the Cell viability of patient-derived organoids (PDO) was measured using CellTiter-Glo 3D Assay. Long term effects of ERX-41 on cell survival were measured using colony formation assays. Apoptosis was measured using Annexin V and Caspase-Glo® 3/7 Assays. Cell cycle analysis was analyzed by Flow Cytometry. Mechanistic studies were done using LIPA knockout (KO) cells, RT-qPCR, and western blotting. Status of LIPA in OCa was determined using TNMplot database. *In vivo* efficacy of ERX-41 was tested using both cell line derived (CDX) and patient derived (PDXs) xenografts.
RESULTS: TNM plot results showed that LIPA is highly expressed in OCa tumors compared to normal tissues and LIPA expression correlated with clinical grade. Kaplan-Meier plotter analyses of TCGA data revealed that LIPA expression is negatively correlated with overall survival in OCa patients. MTT and CellTitre-Glo assay results showed that ERX-41 significantly reduced the cell viability of both established and primary OCa cells, and PDO's with an IC_{50} of ~500nM. ERX-41 treatment also significantly reduced the cell survival, increased S-phase arrest, and promoted apoptosis of OCa cells. A time course study revealed a robust and consistent induction of ERS markers (CHOP and sXBP1) in OCa cells by ERX-41 within 4h. Western blotting analyses also confirmed increased expression of ERS markers including CHOP, elF2α, PERK, and ATF4 upon ERX-41 treatment confirming that ERX-41 induces ERS. In xenograft

studies, ERX-41 treatment resulted in ~66% reduction of tumor volume measured by Xenogen-IVIS. Further, in studies using PDX tumors, treatment with ERX-41 resulted in a significant reduction (~60%) of tumor volume and tumor weight.
CONCLUSION: Collectively, our results suggest that ERX-41 is a novel therapeutic agent that targets the LIPA with a unique mechanism of action and implicate ERX-41 binding to LIPA induces ER stress, and apoptosis of OCa cells. Further molecular characterization of how ERX-41 binding to LIPA induces ER stress in OCa cells is ongoing.

#3987
Targeting nucleotide synthesizing enzyme dUTPase (DUT) represents a metabolic weakness and therapeutic opportunity in liver cancer
Yue Liu, Mingjing Xu, Ho Lee Wan, Alissa M. Wong, Xiaofan Ding, Kelvin K. C. Ng, Nathalie Wong. *Surgery, Sir Y.K. Pao Centre for Cancer, Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, NT, Hong Kong*

Hepatocellular carcinoma (HCC), the most common type of primary liver cancer, has an overall 5-year survival rate of around 20%, making it the third leading cause of cancer-related death worldwide. Upregulated nucleotide metabolism is frequently identified in HCC and represents a metabolic weakness of tumor cells. The enzyme dUTPase (DUT) catalyzes the synthesis of nucleotide precursor and prevents undesired uracil misincorporation into DNA, and thus plays an important role in the maintenance of DNA integrity and cell viability. Although common upregulation of DUT has been reported in cancers, its role in HCC remains largely unknown. In this study, we investigated the mechanism underlying DUT biology in HCC and tumor susceptibility to drug targeting dUTPase. Overexpression of DUT was found in 42% of HCC cases and significantly correlated with advanced stage tumors. CRISPR-Cas9 mediated knockout of DUT resulted in growth retardation, cell cycle arrest and a spontaneous induction of DNA damage in multiple HCC cell lines. A protective effect from oxidative stress was also demonstrated in both knockout and overexpression DUT assays. Metabolomics analysis showed altered DUT expression in HCC cells resulted in profound impact on pyrimidine and purine metabolism. In addition, levels of DUT protein strongly correlate

with cellular level of dUTP and dTDP, which suggested its critical role in dNTP homeostasis. Interestingly, hepatic organoids overexpressing DUT showed drug resistance to tyrosine kinase inhibitor (TKI) Sorafenib. Both *in vitro* and *in vivo* assays confirmed that targeting dUTPase activity with TAS-114 synergized the effect of Sorafenib in suppressing HCC growth. In conclusion, our study showed that upregulated DUT conferred growth advantage to HCC cells by reducing uracil misincorporation and favoring nucleotide synthesis. Targeting DUT with its first-in-class inhibitor TAS-114 in combination with Sorafenib represents an effective treatment regime for HCC.

The role of HER3 mutations in the progression of colon cancer and modulation of drug sensitivity and resistance

Mary K. Kilroy, Rosalin Mishra, Anastasia Stupecki, Wasim Feroz, Samar Alanazi, Joan T. Garrett. *Pharmaceutical Sciences, University of Cincinnati, Cincinnati, OH*

Colorectal cancer is a disease of the colon and rectum that will claim about 52,580 American lives in2022. The most common treatment of colorectal cancer is surgery plus chemotherapy, although thereare some FDA approved targeted therapies such as regorafenib (targeting VEGF) or cetuximab (targetingEGFR). EGFR, along with HER2, HER3, and HER4 are members of the HER family of receptor tyrosinekinases that upon homo- or heterodimerization activate downstream signaling, growth, and survivalpathways. In recent years, more attention has been paid to HER2 and HER3's roles in colorectal cancers,as they may cause resistance to targeted therapies. OWe are investigating naturally occurring mutantHER3's role in colorectal cancer, as about 6% of all colorectal cancers contain a HER3 mutation. We arecurrently investigating how HER3 mutations may affect sensitivity to current therapies through HERfamily receptor dimerization and be involved in tumor metastasis. We are assessing the degree to whichmutant and wild-type HER3 have the ability to dimerize with EGFR, HER2, MET, and IGF1R the resultingeffects in colon cancer, as these receptor tyrosine kinases are HER3 binding partners. As HER3 bindingpartners are diverse, it may be that the pathway HER3 and its binding partner activate may influencetreatment strategy. It has been noted

that mutant HER2 and HER3 could confer sensitivity to HER familyinhibitors, i.e. afatinib, in bladder cancer, and we have seen a difference in IC50 values of afatinibbetween cell lines containing wild-type or mutant HER3. If mutant HER3 is involved in therapeuticresistance or sensitivity and tumor progression, our findings may present a new biomarker for targetedtreatments in colorectal cancer with the eventual goal of increased overall patient survival.

EVI1 oncogenic role in non-canonical AR driven lethal prostate cancer

Surendra Gulla[1], Jonathan E. Bard[2], David J. VanderWeele[3], Kathleen Kelly[4], Remi Adelaiye-Ogala[1]. *[1]Department of Medicine/Division of Hematology and Oncology, University at Buffalo, Buffalo, NY,[2]Genomics and Bioinformatics Core, University at Buffalo, Buffalo, NY,[3]Hematology and Oncology, Northwestern University Feinberg School of Medicine, Chicago, IL,[4]Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background**:** Androgen receptor (AR) remains active in castration-resistant prostate cancer (CRPC), and AR cistrome can become extensively reprogrammed with disease progression. Recent findings from our group and others have shown an association with non-canonical AR signature with resistance to enzalutamide. However, the complete mechanism is not fully revealed. EVI1 belongs to the zinc-finger transcription factor family, and overexpression of EVI1 is associated with poor patient outcomes. However, its role in the context of resistance to AR-targeted therapy remains unclear. Our preliminary data from ChIP-seq and GSEA analysis shows a significant enrichment of EVI1 target gene-set captured from annotated enzalutamide-resistant AR binding sites.
Hypothesis: EVI1 cooperates in regulating the non-canonical AR activity associated with resistance to AR targeted therapy and blocking EVI1 may overcome resistance to target therapy.
Methods: Using a PDX model of advanced enzalutamide-resistant CRPC, we performed single-cell ATAC-seq + gene expression multi-omic assay. Next, we determined the enrichment of canonical vs. non-canonical AR signatures across cell populations. Using motif analysis and transcription

factor foot printing, we determine EVI1 (MECOM) motif z score and enrichment.
Results: Our findings demonstrate enrichment of non-canonical AR signatures in distinct population of cells following exposure to enzalutamide. In addition, the subpopulation of cells enriched for non-canonical AR cistrome also exhibited high EVI1 (MECOM) motif z-scores.
Conclusion: Our data suggests a potential link between EVI1 and non-canonical AR signaling. Ongoing mechanistic studies will provide insight mechanism by which EVI1 controls non canonical AR activity and its vulnerabilities.

Imaging molecular alterations during tucatinib response in preclinical models of HER2+ breast cancer
Patrick Song, Ameer Mansur, Anna Sorace. *University of Alabama at Birmingham, Birmingham, AL*

Introduction**:** Human epidermal growth factor receptor 2 (HER2) is overexpressed in 25% of breast cancers. Tucatinib, a small molecule HER2 inhibitor, was FDA approved for inoperable or metastatic HER2+ breast cancer. As many of these patients have inoperable tumors, there is a need to identify imaging metrics that can characterize response to tucatinib. Positron emission tomography (PET) imaging can quantify changes in the tumor microenvironment that precede changes in tumor size through imaging with radiopharmaceuticals that target proliferation (fluorothymidine, [^{18}F]-FLT), hypoxia (fluoromisonidazole, [^{18}F]-FMISO) and HER2 expression ([^{89}Zr]-Pertuzumab). The goal of this study is to use advanced PET imaging to non-invasively monitor response to tucatinib in HER2+ primary breast cancer and quantify the subsequent tumor microenvironment modulation.
Methods: HER2+ cell line (BT474) and patient derived xenograft (BCM 3472) tumor models were engrafted and developed to 270 ± 166.4 mm^3 before being enrolled into experiments. Mice were treated with 50 mg/kg tucatinib via PO and were imaged with [^{18}F]-FLT PET (N = 8) on days 0, 3 and 7, [^{18}F]-FMISO PET (N = 6) on days 0, 3 and 7, or [^{89}Zr]-Pertuzumab PET (N = 5) on days 0 and 14. Intratumoral proliferation, hypoxia and HER2 expression were quantified with standardized uptake value (SUV).

Following the final imaging timepoint, tumors were excised for immunohistochemistry against Ki-67 (proliferation), pimonidazole (hypoxia), and HER2. A non-parametric T-test was used to assess for significance.

Results: Tucatinib treated BT474 and BCM3472 tumors had a 2.07 and 2.63 fold decrease in tumor volume, respectively ($p<0.01$). Tucatinib treated BT474 and BCM3472 tumors had significantly decreased hypoxia and proliferation, relative to control tumors ($p<0.05$). Tucatinib treated BT474 tumors had significantly decreased HER2 expression ($p<0.05$); however, no significant change in HER2 expression was observed in tucatinib treated BCM3472 tumors.

Conclusion: Tucatinib significantly decreases tumor volume and decreases intratumoral proliferation and hypoxia in both cell-line and patient-derived xenograft models of HER2+ breast cancer. Our data suggests molecular imaging may drive understanding of and predict response to tucatinib therapy.

NOS inhibition enhances docetaxel-mediated anti-tumor effect in obese mice with triple negative breast cancer

Ivonne Uzair, Kai Sun, Ann Anselme, Wei Qian, Jianying Zhou, Roberto Rosato, Jenny Chang. *Houston Methodist Research Institute, Houston, TX*

Purpose of **the study:** To evaluate the role of obesity in tumor progression and tumor microenvironment (TME) dynamic after the inhibition of nitric oxide synthase (NOS) in syngeneic murine models engrafted with triple negative breast cancer (TNBC) tumors. For this study, we wanted to deepen the results of our recently completed phase I/II clinical trial, where treatment with NG-methyl-L-arginine (L-NMMA, a pan-NOS inhibitor) increased the response rate to chemotherapy (docetaxel) in obese metastatic TNBC (ER-/PR-/HER2-) patients to 86% vs. 60% in normal weight individuals. TME analysis from responders revealed a neutrophil phenotype shift from protumor N2 to antitumor N1. We thus hypothesize that combined treatment with L-NMMA and docetaxel enhances antitumor effect by modulating TME in obese mice with TNBC.

Experimental procedures: 3-week old female C57BL/6 mice were fed for 10 weeks either with high fat diet (HFD) or normal diet (ND). At week 13, TNBC mouse E0771 tumor cells were injected into the mice mammary fat pad. Once tumors reached 100 mm^3, the animals were randomized to four groups: vehicle; docetaxel; L-NMMA; and docetaxel plus L-NMMA treatment. Tumor volume was measured throughout the experiment and growth rate was compared between groups at the end of treatment. Blood, tumor and perigonadal white adipose tissue (pgWAT) were collected. Cytokines and nitrite/nitrate levels (NO2-/NO3-, a NO indicator) were measured from blood and conditioned media (CM) from pgWAT using appropriate kits. Tumor immune cell infiltration was evaluated by immunohistochemistry. GraphPad software was used for statistical analysis and P-values <0.05 were considered to describe statistically significant differences between groups.
Results: Tumor growth rate was significantly higher in HFD mice compared to ND mice. Treatment with the docetaxel/L-NMMA combination significantly slowed tumor growth in HFD mice (p=0.015), and showed a similar trend in ND mice (p=0.92) vs. the corresponding vehicle-treated groups. The reduction of tumor growth was significantly higher in HFD mice vs. ND mice (median of differences -2.0, p=0.031). HFD mice presented higher levels of pro-inflammatory cytokines, [IL-1b (p=0.011), IL-6 (p<0.0001) and TNFa (p<0.0001)] vs ND mice in pgWAT CM, as well as increased levels of NO2-/NO3- and expression of iNOS in tumors and in perigonadal adipose tissue.
Conclusion: HFD mice had a pro-inflammatory profile with a significantly faster tumor growth and higher expression of iNOS in tumor and adipose tissues. Treatment with the docetaxel/L-NMMA combination resulted in a more significant anti-tumor effect in HFD mice, likely through remodeling of TME. Spatial analysis, including CODEX and immunophenotyping are being conducted to determine the TME influence in obesity associated TNBC and the effect of NOS inhibition.

Elucidating reciprocal interactions between bone marrow stromal cells and a novel γδ CAR T cell therapy in the context of bone metastatic prostate cancer

Jeremy S. Frieling[1], Xiomar Bustos[2], Ryan T. Bishop[1], Leticia Tordesillas[2], Daniel Abate-Daga[2], Conor C. Lynch[1]. *[1]Tumor Biology, Moffitt Cancer Center, Tampa, FL,[2]Immunology, Moffitt Cancer Center, Tampa, FL*

Bone metastatic castrate resistant prostate cancer (CRPC) generates tumors hallmarked by extensive bone formation due to enhanced mesenchymal stem cell (MSC)-osteoblast differentiation. These lesions are at present incurable and substantially diminish patient quality of life, but exciting preclinical studies by our group have shown that these metastases are highly sensitive to gamma delta (γδ) T cell-based CAR-T therapies. However, the impacts of CAR-T cell therapies on the bone microenvironment are presently unknown. Because MSCs are an important stromal component of the cancer-bone microenvironment with emerging immunoregulatory activities, we have recently focused on characterizing the interactions between γδ CAR-T cells and the MSC compartment and their implications for bone metastatic CRPC. Our data show that: 1) γδ CAR-T cells or conditioned media (CM) did not significantly alter MSC viability, 2) MSCs were robustly chemotactic to CM derived from tumor-activated γδ CAR-T cells, 3) MSCs treated with tumor-activated γδ CAR-T CM showed a significant induction of ICAM-1 (9.12-fold, P=0.00640) compared to controls, 4) ICAM-1 silencing significantly reduced γδ CAR-T educated MSC migratory ability, 5) tumor-activated γδ CAR-T CM differentially regulated key genes involved in MSC-osteoblast differentiation, a finding supported by Alizarin red S staining and alkaline phosphatase functional assays, and 6) tri-cultures of MSCs, CRPC cells, and γδ CAR-T cells demonstrate that MSCs significantly enhanced γδ CAR-T mediated CRPC killing. Taken together, we have shown that γδ CAR-T cells promote MSC recruitment in an ICAM-1 dependent manner, and MSCs enhance γδ CAR-T targeted CRPC killing. Reciprocally, γδ CAR-T can promote MSC commitment to osteoblast lineage without impacting their viability. These data are the first to interrogate how bone stromal components regulate γδ CAR-T mediated killing in the context of bone metastatic CRPC. We are currently investigating the mechanisms underpinning the bi-directional interplay between these cell populations.

In vivo efficacy of an anti-human IL11RA antibody in B-hIL11RA mice with APAP-induced liver damage

Fang He[1], Rufeng Zhang[1], Mari Kuraguchi[2], Lei Zhao[1], Zhaoxue Yu[2].
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Biocytogen Boston Corp, Wakefield, MA

Acetaminophen (*N*-acetyl-*p*-aminophenol; APAP) overdose is a common cause of drug-induced acute liver injury, thereby making APAP administration a frequently used experimental model due to its highly reproducible and dose-dependent hepatoxicity. APAP-induced liver injury (AILI) mouse models exhibited upregulated IL11 expression, indicating that targeting IL11 or its cognate receptor, IL11RA, could have therapeutic potential. To evaluate the *in vivo* efficacy of anti-human IL11RA antibodies in AILI mouse models, we first generated a human IL11RA knock-in mouse model (B-hIL11RA), in which human *IL11RA* replaced murine *Il11ra, in situ*. Human IL11RA mRNA and protein levels were detected in B-hIL11RA mice. We next examined whether therapeutic inhibition of IL11 signaling was effective in reducing AILI following administration of an anti-human IL11RA antibody. *In vivo* efficacy data showed that anti-human IL11RA antibody inhibited all aspects of AILI, including hepatocyte death (ALT, AST and TUNEL) and centrilobular necrosis. These data suggest that B-hIL11RA mice are an effective tool for preclinical *in vivo* efficacy evaluation of therapeutic anti-human IL11RA antibodies.

Differential regulation of hormone receptors and Ki67 in luminal breast carcinomas and tumor-adjacent mammary glands by mifepristone treatment

Leo Saldain[1], Silvia Vanzulli[1], Paula Martinez Vazquez[2], Javier Burruchaga[2], Eunice Spengler[3], Claudia Lanari[1], Paola Rojas[1]. *[1]IBYME-CONICET (Institute of Biology and Experimental Medicine), Buenos Aires, Argentina,[2]Breast and Gynecological Surgery, Magdalena V. Martinez Hospital, General Pacheco, Argentina,[3]Pathology, Magdalena V. Martinez Hospital, General Pacheco, Argentina*

Since antiprogestins inhibit the growth of preclinical mammary tumor models expressing higher levels of progesterone receptor (PR) isoform A (PRA) than isoform B (PRB), we designed a window-of-opportunity trial (MIPRA; NCT02651844) to study the benefits of mifepristone (MFP) in luminal breast carcinomas from postmenopausal patients selected by their PR+ expression (>50%) and their PR isoform ratio (PRA/PRB>1.5; PRA-H). A decrease in the cell proliferation marker Ki67 was registered after treatment in 14 out of the 20 tumors evaluated. This inhibition was associated with a decrease in PR, estrogen receptor (ER) and pSer118ER evaluated by immunohistochemistry while no changes in pSer167ER expression were observed (PMID: 36269797). In selected tissues from these samples we observed that the staining intensity in trapped glands within the MFP-treated tumors did not follow a similar trend as that of tumor cells. Thus, the aim of this study was to evaluate the expression of hormone receptors and Ki67 in non-neoplastic human mammary glands (nnMG) adjacent to the PRA-H tumor tissue of postmenopausal patients, treated (n=8) or not (n=9) with MFP. No differences in PR, ER and pSer118ER expression were observed between MFP-treated nnMG and those from untreated patients. Notably, contrarily to what occurred in tumors, there was a significant decrease of pSer167ER expression (p=0.008) in the MFP-treated nnMG compared to the untreated glands, suggesting a selective modulation in the AKT-mediated activation of ER. Regarding the proliferative state of the nnMGs, there was a slight but significant increase (p=0.02) in Ki67 expression in MFP-treated *vs.* non-treated nnMG. Data regarding the effect of antiprogestins in normal mammary glands is limited and points, in premenopausal women, to a decrease in the Ki67 index after treatment. The basal quiescent status of nnMG in postmenopausal women may explain this slight stimulatory effect. In conclusion, our results show that MFP exerts a specific regulatory effect in PRA-H tumors that is not observed in the nnMG, probably due to the fact that nnMG have presumably equimolar levels of PRA and PRB. In addition, to counteract the possible stimulatory effect that MFP may induce on nnMG, the combination of MFP and tamoxifen treatment is suggested.

Trastuzumab deruxtecan, antibody-drug conjugate targeting HER2, effectively inhibits growth of patient-derived xenograft model with

CIC-rearranged sarcoma

Yuki Kojima[1], Shigehiro Yagishita[2], Kazuki Sudo[1], Tatsunori Shimoi[1], Shintaro Iwata[1], Shun-ichi Watanabe[1], Chitose Ogawa[1], Akihiko Yoshida[1], Yasushi Yatabe[1], Kan Yonemori[1], Akinobu Hamada[1]. *[1]National Cancer Center Hospital, Tokyo, Japan,[2]National Cancer Center Research Institute, Tokyo, Japan*

Background: Capicua-double homeobox 4 (CIC-DUX4)-rearranged sarcomas (CDS) are extremely rare and highly aggressive sarcomas. There is no standard therapy for the patients with advanced CDS, and therapeutic development is needed. We evaluated preclinical efficacy of trastuzumab deruxtecan (T-DXd), a humanized monoclonal HER2-targeting antibody conjugated to a topoisomerase 1 inhibitor, DXd, in patient-derived xenograft (PDX) models with CDS.
Methods: Patient-derived tumor tissue was transplanted into subcutaneous around the flank of female NOG mice, which were treated with vehicle or T-DXd (3 mg/kg, intravenous, Day0) when the mean tumor volume reached 200 mm^3. Tumor volume was assessed twice weekly for 3 weeks to assess the efficacy of T-DXd.
Results: This study included 3 CDS-derived PDXs. HER2 expression was low in one PDX and not expressed in two PDXs. One PDX was established from a specimen at initial diagnosis, two were established from specimens after prior-chemotherapy. T-DXd demonstrated significant tumor growth delay compared to vehicle in all PDX models investigated. One PDX with no efficacy was HER2-negative and had a treatment history of topoisomerase I inhibitor. In contrast, PDX of HER2-negative topoisomerase I inhibitor-resistant Ewing sarcoma was also administered T-DXd under the same conditions and was found to be refractory.
Conclusion: The present study showed that a therapeutic potential of T-DXd in CDS patients, including HER2-negative.

The impact of HER3 dynamics on the efficacy of HER3-DXd, a novel HER3 directed antibody-drug conjugate

Nagiho Komatsu, Saori Sato, Sumie Muramatsu, Ryuichi Nakamura, Kumiko Koyama. *Daiichi Sankyo Co., Ltd., Tokyo, Japan*

Background**:** HER3 is broadly expressed in various solid tumor types, and its expression can be upregulated by treatment with receptor tyrosine kinase inhibitors (RTKi) such as EGFR TKIs used to treat *EGFR*-mutated NSCLC. HER3-DXd, a novel antibody-drug conjugate (ADC) composed of a human anti-HER3 IgG1 monoclonal antibody (patritumab) covalently linked to a topoisomerase I inhibitor payload (DXd), is currently being studied in clinical trials for breast cancer and NSCLC. As previously reported, HER3-DXd treatment transiently decreases HER3 expression levels in tumors and EGFR TKIs increase HER3 membrane expression. However, the impact of HER3 dynamics on payload delivery has not been clarified yet. In this study, we investigated HER3 dynamics including HER3 receptor turnover and payload delivery in cancer cells using HER3-DXd both as a single agent and in combination with RTKi including osimertinib, which is in clinical trials in combination with HER3-DXd.
Methods: HER3/ADC internalization was evaluated by using confocal imaging in MDA-MB-453 cells treated with HER3-DXd. Internalization and payload release were quantitatively measured in 3 cancer cell lines treated with HER3-DXd. HER3 turnover on the cell surface was also evaluated upon wash-out of HER3-DXd. In xenograft models, mice were administered two doses of HER3-DXd at different doses and dosing intervals, and membrane HER3 expression and tumor payload concentration were examined over time. NSCLC cell lines harboring *EGFR* activating mutations, *ROS1* fusions, or *ALK* fusions were used to evaluate the effect of osimertinib, lorlatinib, or ceritinib on cell surface HER3 expression and payload release (osimertinib only).
Results: HER3-DXd was rapidly transferred to early endosomes after binding to HER3. HER3 dynamics varied among the cell lines tested in vitro, and payload release reflected cell surface HER3 expression levels, HER3 internalization speed and turnover rates. In xenograft models, a higher dosage of HER3-DXd resulted in a larger decrease in membrane HER3 expression. Dosing interval also affected membrane HER3 expression levels; the degree of tumor payload concentration increase after the second dose was dependent on the recovery of HER3 expression after the first dose. Furthermore, we confirmed that RTKi increased the cell surface HER3 expression in NSCLC cell lines with targetable driver genomic alterations and that osimertinib increased payload delivery in PC-9 cells through the upregulation of cell surface HER3 expression.

Conclusion: HER3 expression was dynamically changed by HER3-DXd dosing regimen and by RTKi treatment, resulting in a substantial impact on payload release. These findings support our strategy of clinical studies using HER3-DXd after drugs that increase HER3 expression including EGFR TKI and indicate that HER3 dynamics may play a key role in achieving optimal efficacy of HER3-DXd.

Preclinical characterization of ARX517, a next-generation anti-PSMA antibody drug conjugate for the treatment of metastatic castration-resistant prostate cancer

Lillian Skidmore, David Mills, Ji Young Kim, Prathap Shastri, Nick A. Knudsen, Jeff Steen, Jay Nelson, Ying Buechler, Feng Tian, Shawn Zhang.
Ambrx Biopharma Inc., La Jolla, CA

Prostate cancer is the most common cancer, and the second leading cause of cancer death, among men in the United States. Metastatic castration-resistant prostate cancer (mCRPC) is an advanced stage of disease in which patients ultimately fail androgen-deprivation therapies and exhibit a poor survival rate. Recently, prostate-specific membrane antigen (PSMA) has been validated as a prostate cancer tumor antigen with its over-expression in prostate tumors and low level of expression in select normal tissues. Using an expanded genetic code to create Engineered Precision Biologics (EPBs), Ambrx has developed ARX517, an anti-PSMA targeted next-generation antibody drug conjugate (ADC), for treatment of mCRPC patients. ARX517 is composed of a humanized anti-PSMA antibody site-specifically conjugated to drug linker AS269 (a potent tubulin inhibitor), yielding a drug-to-antibody ratio of 2. After binding to PSMA expressed on the surface of tumor cells, ARX517 is internalized and delivers a cytotoxic payload which inhibits tubulin polymerization and induces cellular apoptosis. In vitro testing of ARX517 in prostate cancer cell lines with variable PSMA expression demonstrated highly specific and potent sub-nanomolar activity in cells with high PSMA expression. To minimize premature payload release, ARX517 employs a non-cleavable PEG linker and stable oxime conjugation chemistry to enhance stability in circulation. ARX517 exhibited a long terminal half-life and high serum exposure in mice. The serum stability of ARX517 should effectively deliver more

payload to target tumor cells, and in multiple CDX and PDX prostate cancer models, ARX517 showed dose-dependent anti-tumor activity in both enzalutamide-sensitive and enzalutamide-resistant models. Repeat dose toxicokinetic studies in non-human primates demonstrated ARX517 was tolerated at exposures well above therapeutic exposures in mouse pharmacology studies, indicating a wide therapeutic index. In summary, ARX517 elicited highly specific, potent cell killing in cell lines with high PSMA expression, inhibited tumor growth in enzalutamide-sensitive and enzalutamide-resistant CDX and PDX models, demonstrated a tolerable safety profile in cynomolgus monkeys, and has a clear therapeutic index based on preclinical serum exposure data. The strong preclinical data and recent clinical validation of PSMA as a mCRPC target provide rationale for evaluation of ARX517 as a potential prostate cancer treatment. ARX517 is currently in a Phase 1 dose escalation trial (ARX517-2011 [NCT04662580]) in the United States.

Metronomic gemcitabine plus neratinib effectively inhibits the growth of human Her-2 positive breast cancer cells intracranially implanted into immunodeficient mice

Serina Batson[1], Alejandro Sanchez[1], Hector M. Padilla[1], Diana L. Prospero[1], Brenda Lugo[1], Valeria V. Lopez[1], Daniella E. Estrada[1], Nydia De Avila[1], Saeedeh Darvishi[1], Arlene Levario[1], Shan Man[2], Ping Xu[2], Robert S. Kerbel[2], Guido Bocci[3], Giulio Francia[1]. *[1]The University of Texas at El Paso, El Paso, TX,[2]The University of Toronto, Toronto, ON, Canada,[3]The University of Pisa, Pisa, Italy*

Metastatic breast cancer is a major cause of death for women in the US, and breast cancers that metastasize to the brain have a particularly poor prognosis. To treat brain metastases of Her-2 positive breast cancers a number of Her-2 targeting drugs are now clinically available, including lapatinib, neratinib and tucatinib, among others. However, in part as a consequence of poor penetration of many drugs into the brain, combinations of standard chemotherapy plus targeted agent have only modest impact on progression free survival for such patients. We have developed preclinical models of human Her-2 positive breast cancer brain metastases to help address these issues. We selected human MDA-MD-361 and BT474 breast

cancer cells lines by in vivo passaging in SCID mice, followed by molecular tagging of the derived variants (MDA361R and BT474R respectively), and then the stereotactic implantation of such cells into the brain of female SCID mice. Using luciferase-tagged BT474R we implanted 75,000 cells into the brains of the mice, and thereafter confirmed by luminescence the growth of the cells, which allowed for randomization of the mice to receive control saline (n=7), metronomic gemcitabine (100mg/kg/3days; i.p.; n=8), neratinib (40mg/kg/3 days; p.o.; n=7), or the combination of gemcitabine plus neratinib (n=8), which continued for 5 months largely in the absence of overt toxicity. The gemcitabine plus neratinib combination prolonged survival over the controls (150 days vs 65 days, $p<0.5$), although eventually all mice succumbed to disease. Tumors cells have been isolated from these therapy-administered mice for further characterization. Neratinib alone did not result in an increase in survival compared to controls, whereas metronomic gemcitabine improved survival but was inferior to the combination. We confirmed these findings using MDA361R tagged with human chorionic gonadotropin (hCG), which allows for the growth of cells to be monitored by assessment of hCG in the mouse urine, and these cells were implanted intracranially into female SCID mice. After urine hCG levels confirmed the presence of growing cells in the brain, the mice were randomized to the above 4 therapies (n=4/group), which showed an increase in survival of the combination compared to controls. These results point to intriguing effects of chemotherapy when used at continuous low (metronomic) doses, that in these studies involved gemcitabine administration every 3 days, and which in these models can be effectively combined with neratinib to suppress the growth of Her-2 positive breast cancer cells implanted into the mouse brain. These results highlight promising combination that could be used to suppress Her-2 positive breast cancer brain metastatic growth, and the developed models should facilitate the study of this subset of breast cancers.

Background: Trastuzumab deruxtecan (T-DXd) has been approved for advanced or metastatic breast, gastric and lung cancers. It has been postulated that irreversible tyrosine kinase inhibitors (TKIs) increase HER2 internalization, thus enhancing T-DXd efficacy. Here we report studies evaluating the combination of TKIs with T-DXd in preclinical models of HER2-low disease.
Methods: Surface HER2 was measured with flow cytometry quantifying fluorescently labelled trastuzumab on the surface of HER2-low cell lines HCC38 and HCC1171 treated with afatinib, neratinib, lapatinib or tucatinib for 12 h. HER2 receptor dynamics on cell surface was also measured in NCI-N87 (HER2 IHC 3+) and HCC38 at 24, 48, 72 and 96 h post-treatment with afatinib, and recovery was measured up to 72 h after drug washout. *In vivo* efficacy was established with T-DXd alone and in combination with

afatinib or tucatinib in two gastric patient-derived xenograft (PDX) models, HD-2 (HER2 IHC 1+) and FU (HER2 IHC 2+), and one lung PDX model, MEDI-NSCLC-04 (HER2 IHC 1+).
Results: In both HER2-low cell lines, treatment with irreversible inhibitors neratinib or afatinib led to enhanced internalization with a greater than 50% surface HER2 reduction, while treatment with the reversible inhibitors lapatinib or tucatinib led to 13-35% higher surface HER2 levels. Washout experiments indicated that receptor recovery at the plasma membrane begins between 4-12h post-washout of afatinib, with complete recovery at about 72h. Tumor shrinkage was significant in HER2-low gastric PDXs when T-DXd was combined with afatinib, but not with tucatinib. In HD-2, T-DXd 10mg/kg with afatinib 20mg/kg, and T-DXd 3mg/kg with tucatinib 25mg/kg combinations resulted in 74% and -3% (with respect to T-DXd) tumor growth inhibition (TGI), respectively. In FU, T-DXd 3mg/kg with afatinib 20mg/kg, and T-DXd 3mg/kg with tucatinib 25mg/kg combinations resulted in 80.3% and 24.7% TGI, respectively. Similarly, in MEDI-NSCLC-04 PDX model, benefit was observed in 5mg/kg T-DXd combination with 20mg/kg QD afatinib (95.3% TGI with respect to monotherapy T-DXd), but not with tucatinib (0.37% TGI). Intermittent schedules (QW, MWF) were also tested for afatinib in combination with T-DXd, with the MWF showing 49.2% TGI and QW showing 33.0 %TGI. In tissue samples from MEDI-NSCLC-04 efficacy study, γH2AX was detected by IHC in T-DXd and T-DXd+afatinib combination. In western blots, a decrease in HER2 as well as pHER2 was observed in response to T-DXd and 20mg/kg afatinib treatment, but not with tucatinib.
Conclusions: In HER2 low gastric and lung preclinical models, T-DXd combined with irreversible pan-HER inhibitor induced superior antitumor effects compared to single agents or the combination of T-DXd with reversible inhibitors. These data support the rationale to test combination of T-DXd and pan-HER irreversible inhibitors in the clinical setting.

#4000
A novel pegylated bispecific antibody-drug conjugate (P-BsADC) targeting Her2+ cancers with improved efficacy and therapeutic window
Yu (Yvonne) Wen, Shuqiang Yin, Weidong Lyu, Yang Lei, Qiudong Zhuo, Zibin Wu, Bin Sun, Shuangyu Tan, Lidong Jiang, Teng Zhang, Bo Gao, Rui

Xu, Yong Li, Liling Zheng, Shumin Liu, David (Dechun) Wu. *Shenzhen Enduring Biotech, Ltd., Shenzhen, China*

Despite the fact that ADCs improve the efficacy and target selectivity comparing to the non-specific small molecule cytotoxicity drugs in cancer treatment, traditional ADCs still suffer from many issues which include low tumor penetration and accumulation, inefficient internalization, undesired efflux of ADC from tumor cells, significant on-target off-tumor toxicity, Fc mediated uptake that results in off-target toxicity, limited extravasation across capillary walls due to big molecular size, poor diffusion into the tumor masses due to increased tumor interstitial fluid pressure, and the binding-site-barrier. To address these issues, we previously reported that the compound JY201, a Polyethylene Glycol (PEG)-based bispecific ADC (P-BsADC) targeting two epitopes of Her2, demonstrated advantages in tumor penetration, internalization efficiency, lysosome trafficking effectiveness, no Fc related toxicity, and better efficacy in tumor inhibition than transtuzumab deruxtecan (Ds-8201). Continuing from our previous study, here we further reveal that JY201 can penetrate the tumor deeply and distribute more homogeneously in entire tumor masses while Ds-8201 limits its diffusion to the regions very close to the blood vessels in the tumor. Furthermore, JY201 shows better efficacy than Ds-8201 in inhibiting tumors with low expression of Her2 in pdx (patient derived xenograft) and cdx models. In addition, JY201 can effectively inhibit tumors resistant to Ds-8201. In an in-vitro plasma stability test, JY201 demonstrated high stability in cynomolgus monkey and human serums. JY201 also has a biodistribution profile advocating better safety than Ds-8201 in tumor bearing mice. In the repeated-dosing toxicological study in Her2 transgenic mice, JY201 with the dose of 50mg/kg was well tolerated and did not induce any tissue/organ damage to the animals. Due to much shorter half-life (5 times shorter) in mice for PEGylated proteins than in primates, we expect JY201 will have much higher tolerated dose than the 50mg/kg in primates. In summary, the findings from this study provide solid preclinical evidence for JY201 to be developed further as an efficacious and safe clinical treatment for patients with Her2 positive cancers.

Targeting Protein Kinases and Phosphatases for Therapy 1

A tailored platform enables BRAF-targeted drug discovery and precision medicine

Hui Qi, Fuyang Wang, Bingrui Han, Xiaomin Wang, Xiangnan Qiang, Zhixiang Zhang, Qingyang Gu. *WuXi AppTec, Shanghai, China*

Mutant BRAF, one of the most frequently mutated serine/threonine kinase, drives tumorigenesis via activating MAPK signaling across various tumor types. Expanded genomic and mechanistic studies over the past two decades have revealed the heterogeneity regarding BRAF mutation status and characterized a classification system for BRAF mutations based on their mode of action. Class I (V600 mutants) and class II (K601 mutants, G469A/V/R, etc) BRAF mutants function as RAS-independent active monomers or dimers to amplify MAPK signaling, whereas class III (G466 mutants, D594 mutants, G469E, etc) mutants, which are kinase impaired or dead, promote MAPK signaling via enhanced RAS binding and subsequent CRAF activation. To date, combination therapies of BRAF and MEK inhibitors have been approved for treatment of patients harboring class I BRAF mutations, while viable therapeutic options for those with class II and III BRAF mutations are still ambiguous. Therefore, developing new drugs and personalized therapeutic strategies directing different classes of BRAF mutations, especially class II and III subtypes, have become vital in the war against BRAF-mutant tumors. To enable BRAF-targeted drug discovery and precision medicine, we developed a tailored platform based on the classification of BRAF mutations, which integrates whole exome sequencing (WES) for identification of mutant BRAF subtypes with *in vivo* efficacy evaluation in patient-derived tumor xenograft (PDX) models. Our platform covers all three classes of BRAF mutants, such as V600E/G469A/D594N/G469E. Moreover, this platform faithfully recapitulate the responses of multiple targeted therapies, such as BRAF, MEK and EGFR inhibitors, reported for treating BRAF-mutant tumors in preclinical and clinical studies, highlighting the potential translation values. Taken together, the platform reported in this study empowers the discovery of novel BRAF inhibitors that can be translated into clinical trials and provides personalized therapeutic options for patients who have poorly responded to standard clinical therapies.

Discovery and evaluation of ISM6466A, a novel covalent CDK12 inhibitor for the treatment of cancer

Lihua Min[1], Hongfu Lu[1], Yihong Zhang[1], Jianping Wu[1], Xin Cai[1], Min Zheng[1], Hui Cui[1], Junwen Qiao[1], Xiao Ding[1], Sujata Rao[2], Feng Ren[1], Alex Zhavoronkov[1]. *[1]Insilico Medicine, Shanghai, China,[2]Insilico Medicine, New York, NY*

Cyclin-dependent kinase 12 (CDK12) belongs to the cyclin-dependent kinase (CDK) family of serine/threonine protein kinases. The CDK12/cyclin K complex regulates the elongation step of RNA transcription by phosphorylating Ser2 on the carboxy-terminal domain (CTD) of the largest subunit of RNA polymerase II, and selectively affects the expression of genes, such as BRCA1 and BRCA2, involved in DNA Damage Response (DDR). CDK12 mutations as well as overexpression have been reported in different types of malignancies, making it an attractive cancer target. In this study, a series of covalent CDK12 inhibitors were designed and profiled in biochemical and cellular assays. ISM6466A was identified as a lead compound, demonstrating good *in vitro* efficacy, ADME properties, safety pharmacology profile (e.g., CYP, hERG), and a reasonable *in vivo* PK profile. Biochemically, ISM6466A exhibited reasonable selectivity over other CDKs, and inhibited cell proliferation in a panel of tumor cell lines with IC_{50} values in the nanomolar range (e.g., IC_{50} of ~100nM in the TNBC and AML cell lines, SUM149PT and MV4-11, respectively). Cell-based assays showed that ISM6466A has a selective inhibitory action for the phosphorylation of Ser2 on the CTD, but not for that of Ser5 or Ser7. Notably, ISM6466A demonstrated excellent *in vivo* anti-tumor efficacy in the SUM149PT breast cancer CDX model (Tumor Growth Inhibition, TGI, of 114% at 60 mg/kg QD) and in the MV4-11 AML CDX model (TGI of 95% at 30 mg/kg QD), without body weight loss. Data from an endpoint PKPD study in the MV4-11 CDX model revealed that ISM6466A inhibited phosphorylation of Ser2 on the CTD, and also inhibited DDR genes such as BRCA1 and ATR. Results from a 28-day rat DRF study revealed that the compound did not show evident signs of toxicity at the tested doses, suggesting a reasonable safety window for ISM6466A.In summary, the novel, covalent, small-molecule CDK12 inhibitor, ISM6466A, demonstrated excellent preclinical efficacy along

with favorable drug-like properties. Our results underscore the therapeutic potential of ISM6466A for the treatment of cancer.

#4990

Dual inhibitor of ACVR1 and MEK 1/2 E6201 and PI3K/mTOR inhibitor paxalisib synergistically inhibit cell growth in DMG

Hyuk Jean Kwon[1], Abigail Tindall[1], Charles Eberhart[2], Jeffrey Rubens[1], Eric Raabe[1]. *[1]Pediatric Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Neuropathology, Johns Hopkins University School of Medicine, Baltimore, MD*

Diffuse midline glioma (DMG) is an aggressive pediatric glioma with no curative treatment options. Mutation in MAPK pathway is common in many DMG tumors, however, has not been largely explored before. E6201 is a dual inhibitor of ACVR1 and MEK 1/2. It is currently in a phase 1 clinical trial for BRAF/MEK mutant melanoma. E6201 achieves higher levels in brain compared to other MEK inhibitors, suggesting it might be a promising therapeutic option for DMG. Previously, E6201 was effective in DMG cell lines with ACVR1 mutation, such as HSJD007. We have evaluated the effect of E6201 in two MAP kinase pathway activated, novel DMG cell lines, DIPG2JA and JHH-DIPG17. DIPG2JA has a *KRAS* mutation, leading to upregulation of MAPK pathway, and JHH-DIPG17 has two *NF1* alterations predicted to disrupt this tumor suppressor, resulting in activation of MAPK pathway. Treatment of DIPG2JA with E6201 identified an IC50 of 44 nM, which is comparable to an IC50 of 71nM in the ACVR1 mutant DMG HSJD007. E6201 suppressed phospho—ERK and induced apoptosis as measured by cPARP western blot in DMG cells. Evaluation of cell viability by CellTiterBlue viability assay demonstrated that E6201 suppressed DMG growth between 0.05uM to 1uM concentrations. (DIPG2JA $p=0.0004$, JHH-DIPG17 $p<0.0001$ by *t-test* compared to control). Compensatory upregulation of mTOR pathway is often associated with downregulation of MAPK pathway, and we hypothesized that E6201 will synergize with a PI3K/mTOR inhibitor to induce DMG cell death. We selected the brain-penetrant PI3K/mTOR inhibitor paxalisib, because this drug is currently being tested in early phase clinical trials for DMG. Through CellTiterBlue cell viability assay, we showed that E6201 synergizes with paxalisib to inhibit cell growth. The ZIP

synergy scores were 13.1 for HSJD007 and 12.7 for DIPG2JA according to the SynergyFinder program, suggesting synergistic interaction between E6201 and paxalisib. In *vitro* experiments for further evaluation of the combination treatment of E6201 and paxalisib are underway and in vivo studies are pending. From our data, E6201 as a single agent is a promising therapeutic option for DMG. With further evaluation of combination of E6201 and paxalisib, we believe that combination therapy will be an even more effective treatment option for DMG.

#4991

Phosphorylation of MERTK is required for nuclear localization in non-small cell lung cancer (NSCLC)

K.M. Tanim[1], Deborah DeRyckere[2], Douglas K. Graham[2]. *[1]Emory University, Atlanta, GA,[2]Department of Pediatrics, Emory University, Atlanta, GA*

MERTK is a transmembrane receptor that belongs to the TAM (TYRO3, AXL, MERTK) family of receptor tyrosine kinases. The role of MERTK in cancer progression and resistance to therapies are reported in many cancer types, including non-small cell lung cancer (NSCLC). In canonical signaling, MERTK is localized at the cell membrane and mediates intracellular signal transduction pathways. Non-canonical signaling of receptor tyrosine kinases (RTKs) has been reported, including signaling which occurs when RTKs translocate to the nucleus. Our group previously reported nuclear localization of MERTK in leukemia cells and we now extend these findings to non-small cell lung cancer. We found exogenous MERTK localized to the nucleus in cells transfected with a plasmid expressing wild-type MERTK. Additionally, endogenous nuclear MERTK was phosphorylated, suggesting that MERTK may have a functional role in the nucleus. MERTK kinase inhibitor MRX-2843 modulates its nuclear translocation. Introducing point mutations to MERTK autophosphorylation sites diminished nuclear translocation in comparison to cells transfected with wild-type MERTK. Our analysis of proteins that may interact with MERTK to regulate nuclear localization and function demonstrated co-immunoprecipitation of nuclear MERTK and STAT1. Current studies are underway to further explore nuclear MERTK functions and how these roles may be modulated upon interaction with STAT1.

Taxol-elevated PLK1 overcomes BETi-resistant in prostate cancer via triggering phosphorylation-dependent degradation of BRD4

Yanquan Zhang, Ka Will Fong, Fengyi Mao, Ruixin Wang, Yifan Kong, Chaohao Li, Jinghui Liu, Zhiguo Li, Derek B. Allison, Dana Napier, Daheng Li, Jinpeng Liu, Chi Wang, Yeqing Zhang, Guangbing Li, Xiaoqi Liu. *University of Kentucky, Lexington, KY*

Background: Bromodomain-containing protein 4 (BRD4) has been widely studied as an attractive therapeutic target of prostate cancer (PCa). Currently, a number of BRD4 inhibitors or degraders have been discovered. However, recent studies revealed that *SPOP* mutant of prostate cancer patients leads to BRD4 stabilization and resulted in JQ1-resistant. Therefore, to reveal the mechanism underlying BRD4 stability may improve the clinical response rate and efficacy of BRD4-targeted therapy in PCa patients.

Methods: To evaluate the level of BRD4 during the mitosis phase, we applied a Confocal microscope and WB. *In vitro* kinase assay and Mass spectrometry were applied to test the phosphorylation of BRD4 by PLK1. A homemade phosphorylation-specific antibody was used to verify p-BRD4 in PCa cells and a tissue micro-array. A PDX-tumor model was used to evaluate the combination efficacy of Taxol to overcome JQ1-resistant.

Result: We found that the level of BRD4 obviously decreased during the mitosis phase of PCa cells. Upon releasing from M-phase arrest, BRD4 level increased along with PLK1 decreasing in PCa cell lines, suggesting PLK1 might be involved in the degradation of BRD4 in the M-phase. We found that PBD domain of PLK1 was responsible for interacting with CTD of BRD4. Enforced overexpression of PLK1 promoted BRD4 dramatically reduced. Reversely, tet-induced depletion or inhibition of PLK1 led to BRD4 stabilization. Furthermore, applying gain or loss of function assay, we found that PLK1 directly phosphorylated BRD4 and triggered its phosphorylation-dependent degradation in M-phase, which was confirmed in clinical samples that high level of PLK1 was negatively correlated with BRD4. Accordingly, we found that overexpression of PLK1 lowered the stabilized BRD4 caused by *SPOP* mutant in PCa cells and consequently made cells sensitive to JQ1. Intriguingly, upon treated with Taxol, a

commonly used medicine for PCa patients, PLK1 level was dramatically elevated as well as p-BRD4 status but total BRD4 downregulated in PCa cells. Moreover, sequential treatment of Taxol and JQ1 resulted in significant inhibition of proliferation, colony formation, and PDX tumor carrying *SPOP* mutant, indicating application of Taxol overcame JQ-1 resistant.
Conclusion: Collectively, our results suggested that PLK1 phosphorylates BRD4 and consequently triggers its phosphorylation-dependent degradation in PCa cells. Sequential treatment of Taxol and JQ1 overcomes *SPOP* mutant-related BETi-resistant in prostate cancer.

Development of abbapolin inhibitors of the PLK1 PBD as potential therapeutics for prostate and other challenging cancers

Jessy Stafford, Danda Chapagai, George Merhej, Justin Pressley, Chintada Nageswara-Rao, Michael Wyatt, Campbell Mcinnes. *University of South Carolina, College of Pharmacy, Columbia, SC*

Polo-like kinase 1 (PLK1) has a plethora of roles within the cell of which mitotic regulation is the best characterized. This kinase is overexpressed and upregulated in cancer cells, making it an attractive target for therapeutics. Drug discovery efforts have mainly focused on the ATP binding site however have met with little clinical success to date. Targeting substrate recognition and subcellular localization through the Polo-Box domain represents an attractive alternative to generating PLK1 specific compounds and to avoid the tumor suppressor functions of PLK3. REplacement with Partial Ligand Alternatives through Computational Enrichment, REPLACE, is validated strategy used to convert peptide inhibitors of protein-protein interactions into more drug like compounds. Through the use of this methodology, we have discovered promising non-ATP competitive inhibitors based on a 2-(4-AlkylBenzamido) Benzoic Acid (ABBA) pharmacophore which bind to the polo-box domain of PLK1. These compounds, designated as abbapolins, engage PLK1 as evidenced by their ability to block phosphorylation of TCTP, a key substrate of PLK1, induce PLK1 degradation and are potently anti-proliferative in prostate cancer cell lines. Based on these observations, lead compounds were investigated further for their pharmacokinetic properties and *in vivo*

efficacy and key compounds showed development potential based upon preliminary results. To further investigate their potential in other tumors, selected abbapolins were tested against the NCI-60 tumor cell panel and other cancers with poor prognosis. Results indicate that neuroblastoma, lung, colorectal and certain leukemias are the most sensitive cell lines and thus provide impetus to investigate the abbapolins for difficult to treat and resistant tumors. We present the further optimization of the abbapolins to determine their structure-activity relationship and identify compounds with novel structures and improved drug-like properties. This includes their ability to engage PLK1 and anti-proliferative activities against selected cell lines that represent therapeutically challenging cancers. Furthermore, these compounds serve as chemical biology probes to elucidate roles of the PBD in conformationally regulating PLK1 activity, through *in vitro* experiments and specifically in the abbapolin sensitive cell lines.

Crizotinib enhances the efficacy of BX-795 identified by high-throughput screening of pan-active drugs in colorectal cancer cells

Susmita Ghosh[1], Fan Fan[1], Jason Roszik[2], Reid Powell[3], Yong Park[3], Clifford Stephan[3], Lee M. Ellis[4], Rajat Bhattacharya[1]. *[1]Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Melanoma Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Translational Medical Sciences, Texas A&M College of Medicine, Houston, TX,[4]Surgical Oncology, Molecular and Cellular Oncology, UT MD Anderson Cancer Center, Houston, TX*

Background: Colorectal cancer (CRC) is a heterogeneous disease with various driver genetic mutations. Recent improvements in targeted therapies have shown some benefit in patients with BRAF mutated metastatic CRC (mCRC), while several efforts focusing on $KRAS^{G12C}$ inhibitors (alone or in combination) are being examined with outcomes pending. Immunotherapies have shown efficacy in only ~5% of patients with mCRC having MSI-H. Hence, it is important to utilize unbiased approaches in order to identify novel therapies that have the potential to improve the outcomes in a large proportion of patients with mCRC.
Aim: We aimed to perform high-throughput screening (HTS) using “pan-active” drugs to identify novel effective therapeutic combinations for

patients with KRAS/BRAF mutated mCRC.
Methods: We performed unbiased HTS with a set of 250 drugs that were either approved by the FDA or are currently in clinical trials. The effect of these drugs on cell growth inhibition were determined as single agents in 2D and 3D cultures using KRAS or BRAF mutated CRC cell lines. Drugs that decreased cell proliferation in both 2D and 3D cultures and effective in both HCT116 (KRAS mutated) and HT29 (BRAF mutated) cell lines, were termed as "pan-active" drugs. 57 "pan active" drugs were identified that primarily fall into 9 classes based on targets/pathways they inhibit. Next, the efficacy of the top three candidate drugs from each class of "pan-active" drugs were determined by pairing with drugs of other classes to identify combinations that are most effective in inducing cell death in CRC cells. Using the Bliss model of synergy, BX-795 was identified to be synergistic with Crizotinib. Effects of combining BX-795 with Crizotinib were further validated *in vitro* by 1) cell growth assays, and 2) measuring changes in cell signaling pathways and apoptotic mediators by western blotting and flow cytometry.
Results: Pairwise HTS studies using "pan-active" drugs demonstrated that combining BX-795 with Crizotinib was synergistic in multiple CRC cell lines. This combination was further validated *in vitro* by MTT and colony formation assays. Analyses of markers for apoptosis by western blotting demonstrated that the drug combination increased cell death in multiple CRC cell lines as compared to single agents. Flow cytometry results using FITC Annexin V and PI confirmed that the combination increased apoptotic cell death in multiple CRC cell lines when compared to the monotherapies.
Conclusions: Our unbiased HTS along with *in vitro* validation studies demonstrated that the combination of BX-795 with Crizotinib can serve as a possible novel effective therapeutic combination in patients with mCRC. Our preclinical *in vitro* studies serve as the basis for *in vivo* efficacy studies and future clinical studies in order to determine the efficacy of this drug combination in patients with mCRC.

Targeting PLK1 effectively suppresses growth of small cell lung cancer

John C. Schmitz[1], Guojing Zhang[1], Andrey A. Ivanov[2], Abbe Pannucci[1], Maya Ridinger[3], Taofeek K. Owonikoko[1]. *[1]Medicine, Univ. of Pittsburgh,*

Pittsburgh, PA,[2]Pharmacology and Chemical Biology, Emory University School of Medicine, Atlanta, GA,[3]Cardiff Oncology, San Diego, CA

Small cell lung cancer (SCLC) is an aggressive neuroendocrine tumor characterized by rapid disease progression and poor patient survival. Key transcription factors implicated as drivers of unique biological phenotypes of SCLC include ASCL1, NEUROD1, YAP1, and POU2F3. Strategies to exploit these phenotypes for innovative precision medicine approaches will be impactful. Using an unbiased agnostic preclinical drug screen to uncover therapeutic opportunities in SCLC, we identified a strong signal with PLK1 inhibitors (PLK1i) with low nanomolar IC50. We extended the *in vitro* findings by testing the efficacy of PLK1i *in vivo* using traditional xenograft of SCLC H526 cell line and patient derived xenografts (PDX). Volasertib achieved significant tumor growth inhibition relative to control in H526 xenografts. Also, onvansertib significantly inhibited growth of platinum-resistant and platinum-sensitive PDXs. The combination of PLK1i with standard chemotherapeutic agents identified promising synergy of the combination of onvansertib and paclitaxel. We further interrogated for predictive biomarkers of PLK1i sensitivity using gene expression profile comparing highly sensitive to less sensitive cell lines. High expression of *C-MYC* but not *PLK1*, *TP53* or *RB* was associated with resistance to PLK1i. Conversely, while *TP53* expression level did not correlate, TP53 gene mutation status (inactivating disruptive mutations) correlated with cell sensitivity to PLK1i. We queried the publicly available CCLE and the Cancer Therapeutics Response Portal to evaluate whether any of the SCLC subtypes have therapeutic vulnerability to PLK1i. In general, high expression of YAP1 in SCLC cell lines correlated with greater sensitivity to PLK1i. A YAP1 positive cell line, SW1271, with strong TP53 expression was particularly resistant to PLK1i. CRISPR knockout of YAP1 in this cell line enhanced SW1271 sensitivity to PLK1i suggesting that YAP1 expression as a marker of vulnerability to PLK1i could be context dependent especially when co-occurring with TP53 mutations. The mechanism of this interaction will be discussed.

Axl inhibition sensitizes cholangiocarcinoma cells to cytotoxic chemotherapy

Shohei Takaichi[1], Dong-Gi Mun[2], Jennifer L. Tomlinson[1], Amro M. Abdelrahman[1], Danielle M. Carlson[1], Alaa Abou Daher[1], Nathan W. Werneburg[1], Xinyan Wu[2], Akhilesh Pandey[2], Gregory J. Gores[3], Rory L. Smoot[1]. *[1]Division of Surgery, Division of Surgery, Mayo Clinic, Rochester, MN,[2]Division of Laboratory Medicine and Pathology, Division of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN,[3]Division of Gastroenterology and Hepatology, Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN*

Background: Cholangiocarcinoma (CCA) is a lethal disease with limited therapeutic options. We have previously discovered LCK driving signaling through AXL, a TAM receptor tyrosine kinase (RTK), by phosphoproteomic analysis of CCA (*J Hepatol* 2022). AXL mediates acquired drug resistance in solid cancers. However, the exact role of AXL in CCA still remains to be elucidated. Here, we investigated the significance of AXL expression as a potential therapeutic target in CCA and the role of phosphorylated AXL Y866.
Methods: We first evaluated the expression levels of AXL in CCA and its associations with patient outcomes using The Cancer Genome Atlas (TCGA) database. Next, to evaluate whether AXL inhibition sensitizes CCA cells to gemcitabine and cisplatin (GemCis) therapy, AXL downregulation was achieved via the siRNA approach and the selective inhibitor bemcentinib. We examined the 50% inhibitory concentration (IC_{50}) value of HuCCT1, a well-characterized CCA cell line, on GemCis therapy with or without AXL knockdown using cell viability assay. Then we assessed the efficacy of the combinatorial therapy of GemCis and bemcentinib utilizing Calcusyn software. Apoptosis was evaluated by Annexin V assay. I*n vivo* efficacy was assessed using an SB-1 (murine CCA cell line) and a syngeneic murine model of CCA treated with vehicle, GemCis, bemcentinib, and the combination of GemCis and bemcentinib. Finally, to investigate the role of AXL Y866 in CCA, we performed BioID to identify and compare the interactomes of AXL WT and AXL Y866F in HuCCT1 cells.
Results: In the TCGA cohorts, AXL is significantly expressed in CCA ($P < 0.01$), and disease-free survival and overall survival in the low AXL expression group are significantly longer than those in the high AXL

expression group (P = 0.04, 0.01). In *in vitro* study, the IC_{50} value of GemCis was decreased from 685nM to 129nM after AXL knockdown. A synergistic effect was observed with CI = 0.17 and Fa = 0.50 in the combinatorial therapy. The combinatorial therapy caused significantly increased apoptosis compared to GemCis or bemcentinib alone (P < 0.01, P < 0.01). In *in vivo* study, the combinatorial therapy significantly suppressed the tumor growth compared to GemCis or bemcentinib alone (P = 0.04, 0.01), and the expression levels of Ki67 and the phosphorylation levels of PEAK1 decreased in the combinatorial therapy group compared to other groups in immunostaining examination. In BioID experiments, among the 222 proteins detected in both AXL WT and AXL Y866F interactomes, PEAK1 kinase, which localizes to actin cytoskeleton and focal adhesions, was the kinase most affected by AXL Y866. In gene ontology analysis to characterize the interactome of AXL Y866, cell-cell adhesion and focal adhesion-related proteins were enriched.
Conclusions: AXL inhibition sensitizes CCA cells to cytotoxic chemotherapy in the preclinical model. AXL Y866-PEAK1 signaling axis is a potential target for the treatment of CCA.

#4997

PLK1 promotes the metastasis and drug resistance in melanoma

Fengyi Mao, Yifan Kong, Chaohao Li, Yanquan Zhang, Xiongjian Rao, Qiongsi Zhang, Xinyi Wang, Zhiguo Li, Xiaoqi Liu. *Toxicology and Cancer Biology, University of Kentucky, Lexington, KY*

Melanoma is one of the most frequently diagnosed cancers in the caucasian population of both genders. The survival rate of advanced melanoma patients will be exceedingly poor, as low as 27.3%. BRAF-V600E is the most common mutation found clinically, resulting in the constitutive activation of the MAPK signaling pathway. Vemurafenib, a specific inhibitor of mutant BRAF, has shown an impressive response in phase 3 clinical trials and was approved by FDA in 2011. However, due to the rapid development of resistance, the duration of response under a single treatment is frequently short, highlighting the urgent requirement for novel therapy in melanoma treatment. Polo-like kinase 1 (PLK1), a crucial cell cycle regulator, participates in multiple mitotic processes, including centrosome maturation, mitotic entry, spindle assembly, sister chromatid segregation,

mitotic exit, and cytokinesis. Compared to normal tissues, the expression level of PLK1 significantly upregulates in multiple cancers. More importantly, the expression level of PLK1 negatively correlates with the melanoma patients' survival rate based on the TCGA database. Besides, PLK1 is identified as an oncogene to promote proliferation, motility, and resistance to various drugs. In the present study, we found that overexpression of PLK1 promotes tumor growth, metastasis, metabolic reprogramming, and vemurafenib resistance in the $Braf^{CA}/Pten^{loxp}$ mouse melanoma model. Through phosphorylation, overexpressed PLK1 stabilizes BACH1, a critical transcriptional factor of multiple metastatic and metabolic genes, and protects it from degradation. Subsequently, a higher level of BACH1 leads to increasing metastasis, upregulation of glycolysis, and suppression of OXPHOs. Besides, we have validated the strong synergy between PLK1 inhibitor volasertib and vemurafenib in treating melanoma carrying BRAF-V600E. Our in vitro and in vivo experiments have shown an improved efficacy of this combined therapy on inhibition of cell proliferation, induction of cell death, and suppression of cell metastasis compared to mono-treatment. In short, our data has indicated PLK1 as a potent and promising target in cancer treatment.

#4998

Selective PLK4 inhibition demonstrates synthetic lethality in TRIM37 amplified neuroblastoma and breast cancer models while less selective inhibitors do not

Siobhan K. McRee, Chelsea Chen, Christophe Colas, Wie Fang, Wayne Kong, Fang Liu, Jason Long, Jared Moore, Alex Pankov, Dan Shore, Joanne Tan, Robert Warne, Rakesh Vekariya, Amy Young, Anneleen Daemen, Anthony Romero, Melissa R. Junttila, Lori S. Friedman, Kyle A. Edgar. *ORIC Pharmaceuticals, South San Francisco, CA*

Amplification and copy number gains of the 17q23 amplicon are common in breast cancer and neuroblastoma and have been associated with early relapse and poor prognosis (Ganesan et al 2012; Takita et al. 2017). A synthetic lethal interaction of PLK4 with 17q23 amplicon-driven overexpression of TRIM37 was discovered in these tumor types (Meitinger et al. 2020; Yeow et al. 2020). High levels of TRIM37 prevented acentrosomal spindle assembly and rendered cells mitotically vulnerable to

inhibition of polo-like kinase 4 (PLK4), a serine/threonine protein kinase that controls centriole duplication. We have discovered that exquisitely selective small molecule inhibitors of PLK4, which are highly selective against the kinome including against the closely related aurora kinases and PLK1-3, display this synthetic lethal interaction with TRIM37, while less selective inhibitors do not. PLK4 protein levels are regulated through proteasomal degradation induced by PLK4 trans-autophosphorylation of the phosphodegron. PLK4 inhibition results in blocked trans-autophosphorylation leading to stabilization of PLK4, thus directly demonstrating target engagement in cells. Importantly, PLK4 protein stabilization correlated with cell viability for selective PLK4 inhibitors but not for less selective compounds, providing a quantifiable pharmacodynamic (PD) association with antitumor activity. Cell viability assessment in cancer cell lines revealed that highly selective PLK4 inhibitors showed greater potency in TRIM37 high cancer cell lines as compared to TRIM37 low cell lines. In contrast, less selective compounds, including from the clinical literature, did not display differential potency in TRIM37 high versus low cancer cell lines. Additionally, selective PLK4 inhibition induced significantly greater apoptosis in TRIM37 high versus low cancer cell lines as measured with a caspase 3/7 assay. We confirmed that only selective PLK4 inhibitors are synthetic lethal with TRIM37 amplification using an engineered cell line system of PLK4 G95L, in which the Leucine mutation blocks compound binding but allows the PLK4 enzyme to function. In cell viability assays, selective PLK4 inhibitors were potent in the parental G95 cells and lost activity in L95 cells, unlike less selective inhibitors whose potency did not depend on PLK4. Oral dosing of a selective PLK4 inhibitor resulted in tumor growth inhibition in TRIM37 high xenograft tumors with no body weight loss.
In summary, we have discovered that highly selective small molecule inhibitors of PLK4 confirm the potential of the synthetic lethal impact in treating tumors with high levels of TRIM37.

#4999
Preclinical evaluation of MCLA-129, a bispecific antibody targeting EGFR and c-MET on solid tumor cells, in comparison with amivantamab

David J.J. de Gorter[1], Alexandre Deshiere[1], Arjen Kramer[1], Martijn van Rosmalen[1], Franziska Mortensen[1], Cecile Geuijen[2]. *[1]Merus N.V., Utrecht, Netherlands,[2]Merus US Inc., Utrecht, Netherlands*

The HGF/c-MET pathway is frequently upregulated in tumors that are resistant to EGFR tyrosine kinase inhibitors. MCLA-129 is an antibody-dependent cellular cytotoxicity (ADCC) enhanced Biclonics® that targets epidermal growth factor receptor (EGFR) and c-MET in non-small cell lung cancer (NSCLC) and other solid tumors. MCLA-129 is a potent inhibitor of tumor growth applying various mechanisms of action (MOA), including inhibition of c-MET and EGFR signaling, antibody-dependent cellular phagocytosis (ADCP) and ADCC. Here we compared the MOA of MCLA-129 with the MOA of the EGFR-c-MET bispecific antibody amivantamab. The binding of MCLA-129 to tumor cells expressing different levels of EGFR and c-MET was quantified using radiolabeled antibodies. Scatchard plot analysis showed that the affinity of MCLA-129 for both c-MET and EGFR is in the low nanomolar range. In FACS, MCLA-129 and amivantamab show similar binding to tumor cells harboring *EGFR* or *c-MET* exon14-skipping mutations. Crossblock experiments with the c-MET binding antibody onartuzumab analog showed that MCLA-129 competes for the same HGF-binding region of c-MET, which is distinct from the binding site of amivantamab according to Neijssen et al, 2021 (PMC8113745). MCLA-129 and amivantamab did not downmodulate EGFR or c-MET. ADCP was also comparable for MCLA-129 and amivantamab, as measured with monocyte-derived macrophages incubated with pHrodo-labeled target cells with readout of tumor cell phagocytosis on the Incucyte® system. In contrast, MCLA-129 displayed ADCC activity similar to or more potently than amivantamab in an ADCC reporter assay with either high affinity FcγRIII 158V-variant or low affinity 158F-variant effector cells in absence or presence of soluble EGFR and soluble c-MET. MCLA-129-induced ADCC appears to be less affected than amivantimab by the presence of soluble EGFR and soluble c-MET. In conclusion, MCLA-129 is a Biclonics® common light chain bispecific antibody with multiple MOA including inhibition of c-MET and EGFR ligand binding, ADCP and ADCC comparable or more potent than amivantamab. A phase 1/2 clinical trial of MCLA-129 in solid tumors is ongoing. These data

support the further clinical development of MCLA-129 in patients with NSCLC and other solid tumors.

#5000

MYTX-011: A novel cMET-targeting antibody drug conjugate (ADC) engineered to increase on-target uptake in and efficacy against cMET expressing tumors

Nimish Gera, Kyle Fitzgerald, Vijay Ramesh, Purvi Patel, Lena Kien, Deepak Kanojia, Simon Aoyama, Federico Colombo, Amit Deshpande, William Comb, Thomas Chittenden, Brian Fiske. *Mythic Therapeutics, Waltham, MA*

MET alterations can act as an oncogenic driver in non-small cell lung cancer (NSCLC) and elevated cMET expression occurs in many cancers. Antibody drug conjugates targeting cMET (cMET-ADCs) have been developed as a strategy to treat cMET+ tumors irrespective of dependency on cMET signaling. cMET- ADCs have shown promising clinical activity, but largely in a subset of NSCLC patients having the highest cMET levels, indicating tumor cMET levels may be limiting for efficacy. We sought to create an ADC with the potential to benefit a broader population of patients including those expressing moderate cMET levels. Here, we describe MYTX-011, an ADC incorporating the clinically validated vcMMAE linker-payload conjugated to a novel, pH-dependent anti-cMET antibody. We hypothesized that engineering the antibody to rapidly lose affinity at acidic endosomal pH would boost ADC uptake and efficacy in cMET+ tumor cells by avoiding non-productive ADC recycling. We conducted mutagenesis of anti-cMET antibodies, screening for variants that selectively lost binding under acidic conditions, and, in parallel, assessed antibody internalization in cell-based assays. The resulting lead humanized IgG1 antibody was conjugated to vcMMAE at engineered cysteine residues (DAR=2) to create MYTX-011, which exhibited rapid dissociation from cMET at pH5.4 but retained high affinity binding at pH7.4 and 6.4. MYTX-011 showed markedly higher (>3 fold) internalization in cMET+ tumor cells and broader, more potent cytotoxicity across a large panel of cMET+ cancer cell lines *in vitro* compared to a matched ADC based on the unmodified parent antibody lacking pH-dependent binding, or an in-house version of a clinical stage cMET ADC. These findings translated *in vivo*

where MYTX-011 showed superior efficacy (>3 fold based on dose titration) in NSCLC xenograft models with high (EBC-1) or only moderate cMET expression levels (H1373, H1975) compared to the matched parent ADC or an in-house version of a clinical stage cMET ADC. PK and toxicity studies in cynomolgus monkeys revealed that MYTX-011 exhibited favorable PK characteristics, and a toxicity profile similar to previously described MMAE-based ADCs. Together, these findings highlight the potential of MYTX-011 as a therapeutic candidate for treating a broader range of cMET+ malignancies than other cMET-ADCs.

Repurposing passenger amplifications for specific therapeutic targeting of solid cancers

Sonia Jiménez Vázquez[1], Christos Patsis[2], Luise Butthof[1], Joan Crous Masó[2], Hendrik Wiethoff[3], Matthias Gaida[4], Thomas Longerich[3], Rosella Pellegrino[3], Ilse Hofmann[2], Judith Feucht[5], Darjus Felix Tschaharganeh[1].
[1]Cell Plasticity and Epigenetic Remodeling, German Cancer Research Center, Heidelberg, Germany,[2]German Cancer Research Center, Heidelberg, Germany,[3]University Hospital Heidelberg, Heidelberg, Germany,[4]University Medical Center Mainz, Mainz, Germany,[5]Cellular Therapies, University Hospital Tübingen, Tübingen, Germany

Current cancer therapies focus on targeting driver alterations responsible for tumorigenesis - either oncogenic point mutations or oncogenic driver events within large somatic copy number alterations (SCNAs). However, these alterations are often not actionable or are only present in a small subset of patients. Thus, new therapeutic targets are urgently needed. Apart from oncogenic drivers, SCNAs usually also comprise neutral bystander genes without an active role in neoplastic transformation. We hypothesized that passenger events, specifically in amplified regions, could be therapeutically exploited by providing actionable molecules on the cell surface. Using publicly available multi-omics data, we screened cell surface protein-coding genes for their genomic status and expression levels in liver cancer. This screen identified *MPZL1* (*Myelin protein zero-like 1*), a gene amplified in 75% of hepatocellular carcinomas, accompanied by high mRNA expression in tumors compared to normal livers. *MPZL1* is located on chromosome 1q,

one of the most commonly amplified regions across several solid cancer types, and codes for a glycosylated cell surface receptor. We further validated MPZL1 protein expression in a wide range of human cancer entities (n=2038 samples) and normal tissues (n=163 samples) by immunohistochemistry and assigned expression scores analogous to the clinically implemented HER2-score. A high percentage of tumors showed scores 2 or 3 (e.g. 48% of HCCs or 89% of TNBCs), whereas healthy tissues were mostly negative or just faintly positive (scores 0 or 1). Moreover, in order to target MPZL1-expressing cells, we generated a highly specific monoclonal antibody directed to the extracellular domain of human MPZL1 protein and thoroughly characterized its binding capacity. Next, the scFv sequence of this antibody was used to generate a CAR (chimeric antigen receptor) construct targeting MPZL1. Luciferase-based cytotoxic assays showed that T cells transduced with this construct can kill various MPZL1-high human cancer cell lines *in vitro* (liver, breast and lung malignant cell lines, among others), whereas they fail to kill respective isogenic cell lines harboring knockout of *MPZL1*. Upon antigen-specific exposure, MPZL1-28ζ CAR-T cells underwent antigen-dependent proliferation and showed increased cytokine production (IFNγ, TNFα, IL-2, GZMB), further confirming their specificity. In summary, our findings reveal MPZL1 as a new target for treatment of 1q-amplified cancers and implement a novel immunotherapeutic strategy based on MPZL1-28ζ CAR-T cells. Furthermore, our work provides a proof of concept that passenger events within large chromosomal amplifications can serve as potent therapeutic targets and thus opens a new avenue for innovative approaches in anti-cancer drug development.

#5004

DDR-targeting small molecule inhibitor as a novel therapeutic for treating pancreatic ductal adenocarcinoma

Trong Phat Do[1], Sajid Khan[1], Daohong Zhou[1], Matthew Hart[2], Stanton McHardy[3], Manjeet Rao[1]. *[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]The University of Oklahoma Health Science Center, Oklahoma City, OK,[3]UT San Antonio, San Antonio, TX*

Background: Pancreatic ductal adenocarcinoma (PDAC) is the second most significant cause of cancer-related mortality, with a 5-year survival rate of

just 11%. PDACs are one of the most difficult to treat cancers, mainly because of the desmoplastic tumor microenvironment enriched with tumor-supportive extracellular matrix (ECM) and stromal cells. Unfortunately, the efficacies of current pancreatic cancer therapies are limited partly by stroma-mediated drug resistance. We reason that Discoidin Domain Receptors, which belong to the receptor tyrosine kinase family and bind to fibrillar collagens present in the ECM, may be a critical promoter of PDAC growth and progression. Though several drugs targeting DDR proteins have been developed, no inhibitors specific to DDR proteins have been developed. Moreover, those drugs have not been approved for treating PDACs.
Methods. A high throughput screen using small molecule inhibitors was performed to identify bonafide inhibitors of DDR proteins. Structural and reported-based essays were done to determine the specificity. Functional assays were performed to test the potency of the candidate inhibitors. Mechanistic studies were done using RNA-seq, real-time PCR, and western blot.
Results: Using an unbiased screening approach, we identified inhibitors that specifically target DDR proteins. Our studies revealed that small molecule inhibitors blocked the short and long-term viability as well as migration/invasion of PDAC cells. In addition, they induced apoptosis and halted the cell cycle at the G1-S checkpoint. Mechanistic studies revealed that the pro-growth signaling cascade was significantly inhibited.
Conclusions: Our results showing specific DDR inhibitors blocking the growth and progression of PDAC cells without affecting the viability of normal cells suggest that these inhibitors may serve as a safe and potent regimen for treating pancreatic cancers.

Targeted down regulation of FGFR1 through G-quadruplex stabilization in metastatic breast cancer
Muhammad Hassan Safdar, Hang Lin, Sarah Dagher, Jonathan Dickerhoff, Danzhou Yang, Michael K. Wendt. *Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN*

Metastatic breast cancer (MBC) is the most advanced stage of breast cancer. Our understanding of the molecular mechanisms which drive MBC remain

incomplete. Epithelial to mesenchymal transition (EMT) and mesenchymal to epithelial transition (MET) promote drug resistance and metastasis. It has been reported that fibroblast growth factor receptor 1 (FGFR1) plays a key role during the EMT:MET cycle. Furthermore, FGFR1 is amplified in 13% of primary and 20% of metastatic breast cancer patients. Therefore, optimizing inhibition of FGFR1 is crucial for the therapeutic targeting of the late stage breast cancer. First, we examined the efficacies of FGFR kinase inhibitors in the murine based dormant 4T07 tumor model. Inhibition of FGFR kinase activity leads to tumor growth inhibition but fail to eradicate dormant breast cancer cells. Therefore, we explored broader approaches to inhibit FGFR1 expression in addition to blockade of its kinase activity. G-quadruplex (G4) structures are secondary DNA structures commonly found upstream of transcriptional start sites (TSS) of oncogenes restricting their expression. Consequently, pharmacological stabilization of G4 structures within the promoters of cancer-related genes via use of small molecules has emerged as a promising therapeutic approach in cancer. Results herein demonstrate that the proximal promoter of FGFR1 contains sequences that form G4. Circular dichroism was used to verify formation of G4 in the FGFR1 proximal promoter. Importantly, use of the G4-binding compound CX-5461 stabilized the FGFR1 G4 structure, blocked the transcriptional activity of the FGFR1 proximal promoter and decreased FGFR1 expression. Therefore, we implemented the G4 stabilizers in FGFR1 expressing and metastatic drug-resistant cell lines. This approach results in dramatic downregulation of FGFR1 in the protein level after treatment with the G4 stabilizer. G4 stabilizing agents also interfere with constitutive FGFR1 and EMT-driven FGFR1 expression. Importantly, use of the G4-targeting compound CX5461 effectively blocked FGFR1 expression and inhibited FGFR1 downstream signaling, resulting in eradication of dormant breast cancer cells using a 3D culture model system. Finally, *in vivo* application of CX5461 reduced pulmonary tumor growth and prolonged animal survival in an FGFR1-driven model of metastasis. In conclusion, our evaluation of FGFR kinase inhibitors validates clinically observed resistance to this approach in MBC. Moreover, our findings suggest that G4 stabilization may be a potential therapeutic strategy for FGFR1 expressing MBC.

Discovery of novel heterobifunctional degraders of mutant EGFR proteins for NSCLCs harboring various EGFR mutations

Dong Hyuk Ki[1], Min Sung Joo[1], Joonwoo Nam[1], Hunmi Choi[1], Kyoungwan Seo[1], Eun-Jung Kim[1], Jiyeon Kim[2], Chulwon Kim[2], Jimmy Taiguang Jin[3], Wooseok Han[1]. *[1]Cyrus Therapeutics, Seoul, Korea, Republic of,[2]Bridge Biotherapeutics, Seongnam, Korea, Republic of,[3]Bridge Biotherapeutics, Cambridge, MA*

Abnormal expression and activation of Epidermal Growth Factor Receptor (EGFR) contribute to malignancy development, especially in non-small cell lung cancers (NSCLCs). Although the first- to third-generation EGFR small molecule inhibitors have made significant progress in the treatment of EGFR mutant NSCLC patients, acquired mutations have been developed rapidly, resulting in drug resistance. Targeted protein degradation (TPD) technologies including PROteolysis Targeting Chimeras (PROTACs) have recently emerged as a promising alternative modality to address the confronting issues of small molecule inhibitors such as drug resistance. Recently, we have developed a series of heterobifunctional degraders of EGFR mutant proteins, which showed strong degradation ability against a variety of mutant EGFRs including triple mutants with C797S. DC_{50} (half-maximal degradation concentrations) values of the degraders were obtained using HiBiT assay in NCI-H1975 (EGFR $^{L858R/T790M}$), HCC827 (EGFR ^{Del19}), and H1299 (EGFR ^{WT}) cells. Our lead compounds demonstrated excellent EGFR degradation potency with high selectivity against EGFR wild type. Moreover, C-09045, C-09066, and C-13951 strongly inhibited the cell growth of Ba/F3 cells harboring one of the EGFR mutations including L858R/C797S, Del19/C797S, L858R/T790M/C797S, Del19/T790M/C797S, and Exon20 NPH insertion. By contrast, these compounds showed much weaker potency in normal lung fibroblast (HFL-1) and Ba/F3 cells harboring EGFR wild-type. In PK analysis, C-09066 showed good oral bioavailability in mice (F%=41.4) with desirable pharmacokinetic parameters and robust tumor growth inhibition efficacy in the NCI-H1975 EGFR $^{L858R/T790M/C797S}$ xenograft and the Ba/F3 $^{Del19/C797S}$ allograft mouse models. In summary, we have identified selective, potent, and orally bioavailable degraders of various EGFR mutant proteins with broad spectrum anti-tumor efficacy both *in vitro* and *in vivo*.

Targeting Protein Kinases and Phosphatases for Therapy 2

#5009
Inhibition of TGFBR2 signaling re-sensitizes TMZ-resistant glioblastoma cells to therapy

Maya K. Johnson, Jack Korleski, Amanda Johnson, Sophie Sall, John Laterra, Hernando Lopez-Bertoni. *Neurology, Neuroscience, Oncology, Kennedy Krieger Research Institute, Baltimore, MD*

Glioblastoma (GBM), the most aggressive and lethal form of brain tumors, recurs in 90% of cases and the standard protocol of care—temozolomide (TMZ)—is an ineffective method to combat chemo-resistant GBM. It is therefore imperative that we identify, develop, and design novel therapeutics to effectively combat recurrent GBM (rGBM). Multi-potent stem-like cell subpopulations within GBM (also referred to as glioma stem cells or GSCs) play important roles in tumor propagation, therapeutic resistance, and recurrence following treatment. Understanding the molecular mechanisms that drive resistance in GSCs can lead to novel therapeutic approaches for rGBM. Bioinformatics analyses of transcriptome data sets from rGBM clinical specimens identified transforming growth factor-beta receptor type 2 (TGFBR2) as a putative driver of resistance and recurrence in GBM. We show that TMZ-resistant cells become more stem-like concurrent with higher expression of TGFBR2 protein and mRNA. Importantly, shRNA-mediated inhibition of TGFBR2 decreases proliferation of TMZ-resistant cells and enhances the effects of TMZ. We hypothesize that by developing targeted therapeutics to reduce TGFBR2 expression we will inhibit the growth capacity and/or re-sensitize rGBM cells to ionizing radiation (IR) or TMZ treatment by simultaneously targeting multiple putative oncogenes implicated in the induction of stem-like resistant GBM cell subsets. Future directions include inhibiting TGFBR2 signaling in clinical specimens derived from rGBM patients using two translatable approaches: (1) ITD1, a small molecule TGFBR2 inhibitor predicted to cross the blood-brain-barrier and (2) microRNAs to target multiple TGFBR2 target genes up-regulated in rGBM.

#5010

Inhibition of discoidin domain receptor 1 (DDR1) as a new therapeutic strategy for osteosarcoma

Jinglu Wang, Robert Walker, Francis Hornicek, Zhenfeng Duan. *University of Miami, Miami, FL*

Osteosarcoma is the most common type of bone cancer. Current management for osteosarcoma includes neoadjuvant chemotherapy and surgery. Unfortunately, some patients eventually develop recurrent or metastatic diseases and treatment options are extremely limited. Discoidin domain receptor 1 (DDR1) is a unique collagen-activated tyrosine kinase that participates in various human diseases, including cancer. DDR1 promotes the adhesion, proliferation, differentiation, migration, and metastasis of cancer cells. However, the expression and function of DDR1 remain unknown in osteosarcoma. The purpose of this study is to assess the expression, clinical prognostic relationship, and functional roles of DDR1 in osteosarcoma. The correlation between DDR1 expression in tumor tissues and clinicopathological features and prognosis was assessed via immunohistochemical staining of a unique tissue microarray (TMA) constructed from osteosarcoma specimens. Furthermore, DDR1 expression in osteosarcoma cell lines was determined by Western blot. DDR1-specific siRNA and a highly selective DDR1 inhibitor, 7rh, were applied to determine the impact of DDR1 expression on osteosarcoma cell growth and proliferation. In addition, the effect of DDR1 inhibition on clonogenicity was evaluated using a clonogenic assay, and a 3D cell culture model was used to mimic DDR1 effects in an *in vivo* environment. The results demonstrate that higher DDR1 expression significantly correlates with recurrence, metastasis, and shorter overall survival in osteosarcoma patients. The expression of DDR1 is also inversely correlated to the response to neoadjuvant chemotherapy. Therapeutically, DDR1 knockdown with siRNA or selective inhibition with 7rh decreases the proliferation and growth of osteosarcoma cells. In conclusion, our study supports DDR1 expression as an independent predictor of poor prognosis and a promising therapeutic target for osteosarcoma.

Targeting kinome reprogramming in ESR1 fusion-driven breast cancer

Xuxu Gou[1], Beom-Jun Kim[1], Meenakshi Anurag[1], Jonathan T. Lei[1], Meggie N. Young[1], Matthew V. Holt[1], Diana Fandino[1], Craig T. Vollert[1], Purba Singh[1], Mohammad A. Alzubi[1], Anna Malovannaya[1], Lacey E. Dobrolecki[1], Michael T. Lewis[1], Shunqiang Li[2], Matthew J. Ellis[3], Charles E. Foulds[1]. *[1]Baylor College of Medicine, Houston, TX,[2]Washington University, Saint Louis, MO,[3]AstraZeneca, Gaithersburg, MD*

Background: Transcriptionally active ESR1 gene fusions (ESR1-TAF) are a potent cause of estrogen receptor alpha-positive (ERα+) breast cancer endocrine therapy (ET) resistance. These ESR1-TAF are gain-of-function mutations, exhibiting estrogen-independent cell growth, motility and ET resistance. They are not directly druggable because the ERα C-terminal ligand binding domain (LBD) encoding sequence is replaced with a translocated in-frame partner gene sequence. Herein we utilized proteomic approaches to develop novel targeted therapies against ESR1-TAF driven tumorigenesis.

Methods: *ESR1* fusion cDNA constructs were expressed in ERα+ breast cancer cell lines (T47D and MCF7). Cell growth was assayed by an Alamar blue assay. A mass spectrometry (MS)-based Kinase Inhibitor Pulldown Assay (KIPA) was employed to identify druggable kinases that are commonly upregulated by diverse ESR1-TAFs. A panel of 22 ERα+ patient-derived xenograft (PDX) models were profiled using proteomics and phosphoproteomics to identify models with sensitivity to RET kinase inhibition.

Results: KIPA detected an increased abundance of a receptor tyrosine kinase, RET, in T47D cells expressing ESR1-TAFs in an estrogen-independent manner, compared to stable cell lines expressing transcriptionally inactive fusions as well as wild-type ERα protein. Interestingly, RET was also increased when constitutive activating ERα LBD point mutants, Y537S and D538G, were expressed in breast cancer cells. Inhibition of the RET kinase *in vitro* by repurposing pralsetinib, an FDA-approved RET inhibitor for advanced thyroid and non-small-cell lung cancers, demonstrated a significant reduction in the growth of cells expressing ESR1-TAFs and ERα LBD mutants. These data nominate RET kinase as a common therapeutic vulnerability for ESR1-TAF expressing breast cancers. Proteomic profiling of 22 biologically heterogenous ERα+ PDX tumors defined targetable pathways and predicted tumor subsets that

were responsive to RET inhibition therapy. Organoids and xenografts from the pan-ET resistant WHIM18 PDX (that expresses the ESR1-YAP1 TAF) were inhibited by pralsetinib to a similar extent as the CDK4/6 inhibitor palbociclib. These data provide key preclinical rationale for the consideration of RET inhibition for the treatment of ESR1-TAF-driven ET-resistant breast cancer. Interestingly, the growth of WHIM37 PDX (that expresses ERα D538G) that had low level of RET and high level of GFRα-1, the co-receptor of RET, was also suppressed by pralsetinib. This data suggests that either RET or GFRα-1 is a predictive biomarker for RET inhibitor efficacy.
Conclusions: Kinome analysis of *ESR1* translocated breast tumors using KIPA followed by drug sensitivity studies nominated RET as a new therapeutic target for ET-resistant ERα+ breast cancer.

#5012

Characterizing the functional significance of PDGFRA^{K385I} and PDGFRA^{K385L} extracellular domain mutations in the newly defined myxoid glioneuronal tumor

Catherine Z. Beach[1], Romel Somwar[2], Matthew D. Wood[3], Monika A. Davare[4]. *[1]Oregon Health & Science University, Portland, OR,[2]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Pathology, Oregon Health & Science University, Portland, OR,[4]Pediatrics, Oregon Health & Science University, Portland, OR*

In 2021, the World Health Organization (WHO) approved new diagnostic guidelines that stratify central nervous system (CNS) tumors based on molecular, transcriptomic, and epigenetic analysis instead of relying solely on phenotypic characterization and added twenty-two new CNS tumor entities based on these guidelines. Our focus is on one of these newly defined entities—myxoid glioneuronal tumors—a slow growing, mucinous glial tumor defined by a pathognomonic dinucleotide substitution in the extracellular domain of PDGFRA p.K385I/L. PDGFRA p.K385I/L remains a variant of unknown significance, however, constitutive activation of PDGFRA is well established as a pharmacologically actionable, oncogenic driver present in a variety of tumor types. Here we report the functional

characterization of PDGFRA^{K385I} and PDGFRA^{K385L} by assessing transforming potential using Ba/F3 cells and immortalized human astrocytes. Our results demonstrate that both p.K385I and K385L substitutions are oncogenic, driving cytokine-independent Ba/F3 cell growth and anchorage-independent colony formation. Western blot analysis of downstream cellular signaling pathways in the absence of PDGF-ligand further confirm the activating nature of these mutations, showing robust phosphorylation of PDGFRA and constitutive phosphorylation of downstream signaling effectors ERK1/2, SHP2, and STAT3. To assess whether PDGFRA^{K385I} and PDGFRA^{K385L} are pharmacologically actionable, we tested multiple tyrosine kinase inhibitors with known activity against PDGFRA aberrant cancers using our mutant-transformed PDGFRA Ba/F3 cells. We found that the PDGFRA^{K385I} and PDGFRA^{K385L} mutants were sensitive to inhibitors axitinib, AZD-3229, and avapritinib at therapeutically relevant concentrations. Further, these mutants showed resistance to imatinib, nilotinib, and crenolanib underscoring the importance of pharmacogenomic investigation. No appreciable difference in sensitivity or resistance profiles was observed between the two mutants. In summary, our findings indicate that these previously uncharacterized p.K385I/L extracellular domain mutations in PDGFRA are oncogenic and represent a pharmacologically actionable target that could be harnessed to increase therapeutic options in the setting of myxoid glioneuronal tumors.

#5013

Effects of PP2A-activating drugs on FLT3 inhibitor resistance mediated by diverse mechanisms in acute myeloid leukemia with FLT3-ITD

Moaath Mustafa Ali, Aditi Chatterjee, Jonelle K. Lee, Mario Scarpa, Maria R. Baer. *Department of Medicine, University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD*

Internal tandem duplication (ITD) of the *fms*-like tyrosine kinase 3 (FLT3) receptor tyrosine kinase is present in AML cells in 25% of patients, causing constitutive activation and aberrant signaling. *FLT3*-ITD+ AML patients have a high relapse rate following chemotherapy and short disease-free and overall survival. Incorporation of FLT3 inhibitors (FLT3is) into therapy for *FLT3*-ITD+ AML has improved outcomes, but FLT3i efficacy is limited by

onset of resistance, which occurs by diverse mechanisms. The tumor suppressor protein phosphatase 2A (PP2A) is inactivated in *FLT3*-ITD+ AML, and we previously showed that PP2A-activating drugs (PADs), including DT-061 and FTY720, enhance FLT3i efficacy through enhanced proteasomal degradation of c-Myc and Pim-1, mediated by activation of the serine/threonine kinase GSK-3β (Mol Cancer Ther 20:676, 2021). Here we sought to determine whether concurrent treatment with PADs overcomes resistance to FLT3is. We studied MOLM-14 human AML cells, with heterozygous *FLT3*-ITD, and FLT3i-resistant MOLM-14 cells with D835Y tyrosine kinase domain and F691L gatekeeper *FLT*3 mutations and M14(R)701 MOLM-14 cells (from Dr. Donald Small, Johns Hopkins) with a G12D *NRAS* activating mutation. IC_{50}s, determined by WST-1 cytotoxicity assays, of Type 1 FLT3i gilteritinib in MOLM-14, D835Y, F691L and M14(R)701 cells were 9.2, 18.6, 56 and 57.5 nM, and the Type II FLT3i quizartinib, 2.8, 211, 659 and >4,000 nM. Both DT-061 and FTY720 sensitized MOLM-14 D835Y cells to quizartinib (IC_{50}s <10 nM) but not to gilteritinib in cytotoxicity assays and showed synergy with quizartinib (combination indexes 0.6, 0.5), but not with gilteritinib in drug combination studies using Chou-Talalay analysis. In contrast, DT-061 and FTY720 did not sensitize to or synergize with quizartinib or gilteritinib in MOLM-14 F691L cells. Finally, FTY720 markedly sensitized M14(R)701 cells to both quizartinib and gilteritinib and showed substantial synergy (combination indexes <0.1), while DT-061 did not. In mechanistic studies, quizartinib alone did not decrease phospho-FLT3 expression by western blot analysis in MOLM-14 D835Y cells, but DT-061 or FTY720 and quizartinib co-treatment markedly decreased phospho-FLT3, but not FLT3, expression. Thus PADs resensitize cells with D835Y to quizartinib by inactivating FLT3-ITD, thereby enabling the binding of quizartinib to FLT3-ITD. Additionally, while FTY720, but not DT-061, markedly sensitized M14(R)701 cells to quizartinib and gilteritinib, FTY720 and DT-061 increased phosphatase activity similarly in a PP2A immunoprecipitation phosphatase assay, indicating that sensitization by FTY720 likely occurs by a mechanism other than PP2A activation. Potential induction of ceramide accumulation by FTY720, a sphingolipid analog, in M14(R)701 cells is being studied.

HPK1 gene knockout reporter cell line: an efficient drug screening system

Yunpeng Zhai, Lidan Li, Jianyu Hao, Yuqing Hu, Jinying Ning, Feng Hao.
Kyinno Biotechnology Co., Ltd, Beijing, China

Immunotherapy is the stimulation of the immune system, improving on the ability of immune system to treat cancer. It is expected to be the most effective therapy for patients with tumor metastasis. Checkpoint inhibitor (CPI) therapy is a form of cancer immunotherapy which can block inhibitory checkpoints, restoring immune system function. Tumor cells could recruit immunomodulatory cells and induce inhibitory signals, resulting in losing immunomodulatory. Therefore, there is an urgent need to develop new therapeutic agents that work in concert with CPI. HPK1, also known as MAP4K1, can act as a negative regulator of activation signals generated by T cell receptor (TCR). The development and screening of HPK1 inhibitors have great potential in the cancer immunotherapy. Herein, we constructed a HPK1 knockout reporter cell line Jurkat-NFAT-Luc2-HPK1-Knockout-Cell-Line by CRISPR/Cas9 which can be used in high-throughput HPK1 inhibitors screening. Wild type cells were incubated with HPK1 inhibitors and luciferase signals were compared in HPK1-knockout cells. Our HPK1 knockout reporter cell line has high sensitivity and specificity. The reporter system can achieve high-throughput compound library screening. After selected the compound with selective inhibitory activity, further validation and optimization would be performed. Moreover, we constructed a Jurkat-HPK1-HiBiT reporter cell line by CRISPR/Cas9. It can be used in the screening of HPK1 degradants. We believe that HPK1 gene editing cell lines play an important role in the high-throughput screening of drugs. It could facilitate the development of drugs in tumor immunotherapy.

#5015

Wee1 inhibition and its synthetic lethal combination with Chk1 inhibition in mouse model of neuroendocrine prostate cancer

Yapeng Chao, Yuzhou Chen, Yu Liu, Jaclyn A. Connelly, Hong Wang, Qiming Jane Wang. *University of Pittsburgh, Pittsburgh, PA*

The mitotic regulator Wee1 is a critical regulator of G2/M cell cycle checkpoint and DNA damage response pathways. Wee1-targeted agents are under active clinical investigation in multiple cancer types. However, Wee1 and its inhibitors have not been well studied in prostate cancer, particularly neuroendocrine prostate cancer (NEPC). In this study, we investigated the therapeutic potential of Wee1 inhibitor AZD1775 and its synthetic lethal combination with Chk1 inhibitor in the context of NEPC. Our data demonstrated increased Wee1 expression in NEPC cells and tumors. Treatment of NEPC cells with AZD1775 inhibited NEPC tumor cell survival with greater potency as compared to other prostate cancer cells, demonstrating increased vulnerability of NEPC cells to Wee1 inhibition. We further identified synthetic lethality between the inhibition of Wee1 and several protein kinases, particularly Chk1, another key G2/M checkpoint kinase. Using an autochthonous adenocarcinoma mouse prostate (TRAMP) model that gives rise to NEPC tumors, we assessed the efficacy of AZD1775 and a highly selective Chk1 inhibitor SRA737 as single agents and in combination on the progression, survival, and metastatic spread of NEPC tumors *in vivo*. AZD1775 and SRA737 when used as single agents significantly suppressed tumor growth, improved overall survival, and incidence of distant metastases of mice with NEPC tumors. The combination of AZD1775 and SRA737 on a sequential 2-wk treatment schedule was more efficacious in suppressing tumor growth and metastasis than each drug alone in castrated TRAMP NEPC tumors. Mechanistically, the combination of Chk1 and Wee1 inhibitors synergized to reduce the inhibitory phosphorylation of CDK1 at Y15 and Cdc25c at S216, resulting in enhanced activation of CDK1/cyclin B complex, abrogation of G2/M checkpoint, and consequent premature mitotic entry, which ultimately led to mitotic catastrophe and apoptosis. Our findings provide promising preclinical evidence supporting the therapeutic values of Wee1 and Chk1 inhibitors as single agents and in combination for the treatment of NEPC.

IL-6 influences PIM1 expression in renal cell carcinoma
Kimberly S. Meza, Sheldon L. Holder. *Brown University, Providence, RI*

Renal cell carcinoma (RCC) is the most common kidney neoplasm, accounting for over 430,000 new cases worldwide and 179,000 deaths

annually. The overexpression of the proviral integration site for moloney murine leukemia virus 1 (PIM1) kinase is associated with poor clinical outcomes in patients with RCC. PIM1 is a constitutively active effector serine/threonine kinase with roles in tumor progression including cell proliferation, apoptosis, invasion, and migration. Yet, the mechanisms underlying PIM1 expression and its function in RCC are not fully delineated. IL-6 is a pleiotropic cytokine involved in the activation of the JAK/STAT signaling cascade. High serum IL-6 levels are implicated in the poor prognosis of RCC patients and are hypothesized to contribute to RCC invasion and metastasis. PIM1 is shown to be transcriptionally regulated downstream of JAK/STAT signaling and an IL-6/STAT3/PIM1 axis exists in pancreatic cancer. We thus hypothesize that this pathway also regulates expression of PIM1 in RCC. Here, we explore the levels of PIM1 in RCC and identify potential signaling pathways influencing PIM1 expression. Our results show five RCC cell lines, 769-P, 786-O, ACHN, CAKI-1, and RCC-4 cells overexpress PIM1 relative to normal renal proximal tubule epithelial cells. In RCC cell lines, IL-6 secretion correlates with PIM1 protein levels. Treatment with ruxolitinib, a JAK1/2 inhibitor, leads to a dose and concentration dependent decrease in PIM1 levels. We then tested whether incubation with an IL-6 neutralizing antibody is sufficient to regulate PIM1 protein levels. Indeed, use of an IL-6 antibody resulted in decreased pJAK2 protein and PIM1 protein. Our initial studies suggest that differential expression of PIM1 among RCC cell lines may be linked to autocrine IL-6 signaling. Interestingly, 769-P cells demonstrate increased PIM1 levels but do not secrete IL-6 and neither ruxolitinib treatment nor incubation with an IL-6 neutralizing antibody appear to affect PIM1 levels. Therefore, an IL-6/JAK-independent pathway resulting in increased PIM1 protein levels likely exists in 769-P cells. Further investigation is required to elucidate the contexts of PIM1 regulatory pathways in order to develop novel targeted anti-cancer strategies in RCC.

#5017

Simultaneous targeting of EphA3 on glioblastoma and tumor microenvironment to overcome resistance to CART cell therapy in brain cancer

Ekene J. N. Ogbodo[1], Michael W. Ruff[2], Reona L. Sakemura[1], Claudia ManriquezRoman[3], Truc Huynh[1], James H. Girsch[4], Olivia L. Sirpilla[1],

Kun Yun[3], Carli M. Stewart[3], Ismail Can[3], Lionel K. Fonkoua[3], Mehrdad Hefazi[3], Elizabeth L. Siegler[3], Saad S. Kenderian[3]. *[1]Department of Immunology, Mayo Clinic, Rochester, MN,[2]Department of Neurology, Mayo Clinic, Rochester, MN,[3]Department of Hematology, Mayo Clinic, Rochester, MN,[4]Division of Hematology, Mayo Clinic, Rochester, MN*

Glioblastoma multiforme (GBM) is the most aggressive and common form of brain tumor, and it is characterized by an immunosuppressive tumor microenvironment (TME) that supports tumor growth and pathology. An integral part of the GBM stroma is the mesenchymal stem cells (MSC), which promote GBM growth. Receptor tyrosine kinase EphA3, a member of the Eph family, is overexpressed in GBM tumors and in MSCs within TME, making it an attractive target for Chimeric antigen receptor T-cell (CART) therapy. CART has proven incredible promise in certain hematological malignancies therapy but remained short in solid tumors, particularly GBM. We hypothesize that concurrent targeting of cancers and TME by EphA3-CART can be a potential therapeutic option in GBM. We first showed the expression of the EphA3 receptor by Immunohistochemistry and western blot on GBM patient-derived xenograft (PDX), as well as on the SNB-19 and U87 human GBM cell lines and adipose-derived MSCs using flow cytometry. We then generated EphA3-CAR construct derived from a clinically validated anti-EphA3 scFv cloned in a lentiviral vector containing CD28 and CD3ζ, and generated EphA3 CART cells with over 90% efficiency. EphA3 CART cells demonstrated potent antigen specific effector functions. To demonstrate the antitumor activity *in vivo*, we subcutaneously grafted 1 x 10^6 GBM cells per NOD-SCID-γ-/- mice and at ~150-300 mm^3 tumor volume, mice were then treated with 5 x 10^6 EphA3-CART or un-transduced (UTD) T cells control. Tumors were monitored by bioluminescence imaging (BLI) and caliper measurements, and mice were followed for survival. Mice treated with EphA3 CART cells exhibited a significant reduction in tumor volume ($p<0.005$), and prolonged overall survival ($p=0.0015$). Finally, we tested the ability of EphA3-CART cells to overcome MSC induced CART cell suppression by co-culturing EphA3-CART cells with MSC and $EphA3^+$ GBM target cells while using the $CD19^+$ mantle cell lymphoma cell line JeKo-1 and CART19 as control. MSC conditioned coculture of GBM and

CART showed significant suppression of CAR19 in the CART19 - JeKo-1 system (p=000.3), but no significant suppression of EphA3-CART cells. In summary, our results indicate that EphA3 CART cells exhibited potent and specific antitumor activity in vitro and in vivo and ameliorated MSC induced inhibition of CART cell functions, representing a potentially promising therapeutic option in GBM.

PROTAC degraders of CDK8/CDK19 Mediator kinases potently suppress multiple myeloma proliferation

Li Zhang[1], Jing Li[1], Charles E. Dowling[1], Eugenia V. Broude[1], Igor B. Roninson[1], Campbell McInnes[1], Mengqian Chen[2]. *[1]Drug Discovery and Biomedical Sciences, University of South Carolina, Columbia, SC,[2]Senex Biotechnology, Columbia, SC*

CDK8 and CDK19 are kinase components of the CDK module that comprises CDK8 or CDK19 together with their binding partner cyclin C (CCNC) and two other proteins; the CDK module is associated with transcriptional Mediator complex. CDK8/19 Mediator kinases potentiate transcription induced by different signals, regulate protein levels of Mediator complex components and protect CCNC from proteolytic degradation; the latter activity is exerted in a kinase-independent manner. CDK8/19 kinase inhibitors have entered clinical trials for solid tumors and leukemias. To extend the effects of CDK8/19 inhibition and to suppress their kinase-independent activities, we have developed three series of PROteolysis TArgeting Chimeras (PROTACs) based on different selective inhibitors of CDK8/19 kinases, connected via different linkers to a moiety binding cereblon (CRBN) E3 ligase. The most potent PROTACs degraded both CDK8 and CDK19 in different cell types with DC50s of 10-20 nM. RNA-Seq analysis of 293 cells treated with a CDK8/19 kinase inhibitor or PROTAC showed that the bulk of the PROTAC's transcriptomic effects matched the effects of the kinase inhibitor. In contrast to the kinase inhibitors, CDK8/19-degrading PROTACs also induced CCNC degradation. Cancer Dependency Map (DepMap) analysis revealed that multiple myelomas (MM), where CRBN is an established therapeutic target, show greater dependency on CCNC than most of the tumor cell lines. We have tested two strongly CCNC-dependent MM cell lines and one CCNC-

independent MM line for sensitivity to different CDK8/19 kinase inhibitors and PROTACs. Kinase inhibitors showed low to moderate anti-proliferative activity in all three MM lines, whereas CDK8/19 PROTACs were an order of magnitude more potent than the kinase inhibitors in the two CCNC-dependent MM lines (IC50s of 20-30 nM) but not in the CCNC-independent line. The effects of CDK8/19-degrading PROTACs were stronger than those of the CRBN-targeting drug pomalidomide (approved for MM), a CRBN-binding PROTAC acting on androgen receptor or a CDK8 degradation-inactive PROTAC analog containing CDK8/19- and CRBN-binding moieties. These results suggest the potential of CDK8/CDK19-degrading PROTACs for the treatment of MM.

Next-generation DYRK1A inhibitors as a new therapeutic approach for the treatment of hematological malignancies

Matthew C. Jarvis, Gopi Mittapalli, Emily Creger, Chelsea Nora, Maureen Ibanez, Deepti Bhat, Brian Hofilena, Josh Stewart, Elizabeth A. McMillan, Hadi Falahatpisheh, Chi-Ching Mak, Michael White, John S. Hill, Carine Bossard. *Biosplice Therapeutics, Inc., San Diego, CA*

Background: The dual-specificity tyrosine-regulated kinase 1A (DYRK1A) can phosphorylate multiple targets involved in key cellular processes that have been associated with the hallmarks of cancer, including proliferation, survival, cell cycle regulation and the DNA damage response[1]. In addition, compounds that inhibit DYRK1A have demonstrated anti-tumor activity both in vitro and in vivo. However, until recently, there was a paucity of potent, specific, and bioavailable DYRK1A inhibitors that did not target the related cdc2-like kinases (CLKs) and glycogen synthase kinase 3β. In this study, we describe a set of next-generation DYRK1A inhibitors and used them to evaluate the specific contribution of DYRK1A activity to tumor biology and evaluate the therapeutic potential of DYRK1A inhibition in cancer.

Methods: *DYRK1A* expression was analyzed in The Cancer Genome Atlas and Cancer Cell Line Encyclopedia databases. Cancer cell growth dependencies were evaluated by DepMap analysis. Cell-based target engagement (TE) was assessed by NanoBRET™. Cell viability was assayed with CellTiter-Glo® following 4-day treatment with DYRK1A

inhibitors. Synergy was calculated using Chalice software. Pharmacokinetics (PK) were evaluated in rodents and Tumor Growth Inhibition (TGI) in nude mice. Preliminary toxicology was assessed in a 14 day rat study.
Results: *DYRK1A* expression and a systematic DYRK dependencies analysis in human cancers revealed that hematological malignancies, Small Cell Lung and Ovarian cancers rely on *DYRK1A* expression for their proliferation. A series of potent (biochemical IC_{50}s 3nM to 10nM, TE 19 nM to 134 nM) and highly selective ATP-competitive DYRK1A inhibitors were designed with minimal inhibition of the rest of the kinome (1%-2.3% of kinases inhibited $\geq$ 90%) Cancer cell lines (n=160) were treated with DYRK1A inhibitors and those belonging to hematological lineages were among the most sensitive ($P<0.01$). In vitro combination of DYRK1A inhibitors with the anti-leukemia agent venetoclax revealed high synergy in 3 out of the 5 AML cell lines tested (synergy score >20). Compounds that showed good oral bioavailability and plasma exposures in rodents were selected for further characterization in vivo. In the MV-4-11 xenograft model, mice treated daily with 25mg/kg, or 50mg/kg of 2 different DYRK1A showed 72-99% TGI compared to vehicle. Preclinical toxicity profile in rats showed next generation DYRK1A inhibitors were well tolerated.
Concluding Remarks: these studies support further evaluation of DYRK1A inhibitors as a therapeutic strategy for some cancers, especially hematological malignancies including AML.

IRAK1 is a critical mediator of hyaluronic acid induced stemness

David Standing[1], Prasad Dandawate[1], Jaimie Johnson[1], Sumedha Gunewardena[1], Michele T. Pritchard[1], Harsh Pathak[1], Dineo Khabele[2], Katherine Roby[1], Andrew Godwin[1], Roy Jensen[1], Scott Weir[1], Shrikant Anant[1]. *[1]University of Kansas Medical Center, Kansas City, KS,[2]Washington University in St. Louis, St. Louis, MO*

Ovarian cancer (OvCa) is the leading cause of gynecologic cancer-related deaths, due in part to late-stage diagnoses. While the overall response rate to first line therapy is encouraging (~80%), the majority of women develop recurrent disease, characterized by resistance to standard chemotherapy. There is convincing evidence that cancer stem cells (CSCs) have implications in resistance and recurrence of OvCa. To understand the pathways involved in enhancing this stem-like phenotype, we performed RNA sequencing and identified TLR-ILR1 (TIR) pathways as highly activated in cisplatin resistant OvCa and stem-cell populations. Subsequently, using a tumor microarray, we observed that interleukin receptor-associated kinase 1 (IRAK1), a critical mediator of TIR signaling, is upregulated in OvCa patient tissues compared to normal. This expression further correlated with younger diagnosis age and shorter overall survival, suggesting a role in OvCa tumorigenesis. Knockdown of IRAK1 by specific shRNA in OvCa cells, significantly impaired CSC enriched spheroid growth and orthotopic tumor growth in mouse models replicating advanced peritoneal OvCa. RNA sequencing of IRAK1 knocked down cells identified downregulation of CSC related genes including STAT3, MYC, NOTCH1, and NOTCH3. In addition, there was a reduction in the cisplatin efflux transporter ABCC1 and stemness marker gene CD44. Advanced OvCa is often associated (~90% in stage III and IV) with the development of malignant ascites. We demonstrate for the first time that significant amounts of low molecular weight hyaluronic acid fragments (LMW HA) are present in ascites. LMW HA induced IRAK1 dependent activation of non-canonical signaling through PKC-β leading to induction of STAT3 phosphorylation and MYC. This was further accompanied by increased spheroid formation, demonstrating a critical role for IRAK1 in HA-induced stemness. We have further identified a selective IRAK1 inhibitor, TCS2210 (1,2-Dihydro-N-hydroxy-2-oxo-3-(3-phenylpropyl)-6-quinoxalinecarboxamide). TCS2210 abrogated LMW HA induced activation of IRAK1 and expression of stemness genes MYC, NOTCH1, and NOTCH3. Lastly, we found that TCS2210 effectively suppresses OvCa cell growth *in vitro* and *in vivo*, synergizing with standard-of-care cisplatin. Our data suggests a role of IRAK1 in OvCa, by enhancing cancer cell growth and stemness. It further suggests that IRAK1 is a putative target for advanced OvCa.

Preclinical evaluation of immunomodulatory effects of aurora kinase inhibition in HPV+ cancers

Pragya Sinha, Soma Ghosh, Faye M. Johnson, Jagannadha K. Sastry.
Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Human papillomavirus (HPV) is the causative agent of cervical cancer and some cancers of the penis, vulva, vagina, anus, and oropharynx. In an earlier study, we identified Aurora Kinase (AK) inhibitors from a large-scale drug screening as a unique class of reagents to induce selective apoptosis in HPV+ human tumor cells in vitro and in vivo (using HPV+ PDX mouse models). We tested the in vivo efficacy of alisertib, an Aurora Kinase A inhibitor, in an immunocompetent mouse model (mEER) for HPV+ oropharyngeal cancers. In preparation for this, we first tested 300 nM alisertib on 3 HPV+ murine cancer cell lines: TC-1, C3.43, and mEER for 48h. We observed that when compared to the vehicle (DMSO) control group, the level of phospho Aurora Kinase A was completely inhibited. Furthermore, in multiple HPV+ murine tumor cell lines we observed significant apoptosis as measured by annexin V 7-AAD staining along with higher cell surface expression of calreticulin (CRT), and high mobility group box 1 protein (HMGB1) which are markers for immunogenic cell death (ICD). Both CRT and HMGB1 serve as “eat me” signals that in turn trigger APC-mediated dead-cell antigen uptake, a crucial event for priming the responses from the innate immune system. In support of this, we observed that in a co-culture setting, the conditioned medium from alisertib-treated tumor cells increased the frequencies of CD8+ cells expressing GnzB as well as a significant decrease in the population of T regulatory cells (Tregs) (CD4+ FoxP3+). Additionally, we observed an increase in the innate immune natural killer cell subset. Future studies will explore the in vivo efficacy of Aurora Kinase inhibition along with immune checkpoint blockade and/or therapeutic vaccination. Our proposed research will have a positive impact because we will gain insight into the immune responses underlying the co-dependency of HPV+ cancers on Aurora kinase. Our research may lead to an increase in the rates of long-term, durable clinical responses or may allow for therapy de-escalation.

Atypical protein kinase C inhibitors abrogate malignant breast cancer

Nuzhat Nowshin Oishee, Khandker Mohammad Khalid, Dr. Mildred Acevedo-Duncan. *Chemistry, University of South Florida, Tampa, FL*

Breast cancer is the most common cancer type with expected cases of approximately 284,200 according to the National Cancer Institute. Atypical Protein Kinase C (aPKC) plays a significant role in many cancer types. A positive correlation between elevated PKC levels and both the invasive and chemotactic potential of human breast cancer cell lines has been suggested in *in-vitro* studies. In addition, the atypical protein kinase C isoforms (aPKC), PKC- and PKC- are involved in the increased proliferation of several cancer types, including breast cancer and ovarian cancer. Hence, this project focused on utilizing aPKC inhibitors, ICA-1S (5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide and - Stat (8-hydroxy-1,3,6- naphthalenetrisulfonic acid), on two malignant breast cancer cell lines (T47D and BT549) to observe the effect on cell proliferation. To observe the effects of the aPKC inhibitors on the malignant breast cancer cells, cell proliferation assays were conducted, where cells were treated with ICA-1S, and - Stat for 72 hours (about 3 days). Furthermore, to observe if ICA-1S induces apoptosis in the malignant breast cancer cells, both the cell lines were treated with ICA-1S for 120 hours (about 5 days), and western blotting techniques were utilized. The results indicated that in T47D cell line, treatment with ICA-1S (50uM) and - Stat (10uM) caused 52% and 75% reduction in cell proliferation, respectively. Moreover, with BT549 cell line, treatment with - Stat (1uM) decreased the cell proliferation by 40%. Additionally, it was observed by western blotting that ICA-1S induces apoptosis in BT549 cell line. This was shown by an increase in the cleavage of caspase 3 and PARP, along with a decrease in survivin, and phospho-BAD. However, ICA-1S did not induce apoptosis in T47D cell line. Further investigation will be conducted on determining the effect of aPKC inhibitors on the proliferation, invasion, and migration of the malignant breast cancer cell lines. In addition, siRNA treatment will be applied to knockdown PKC- and PKC- and subsequent effect will be observed. In conclusion, PKC- and PKC- plays a significant role on breast cancer, and further investigation will be conducted to analyze these roles, which will lead to the determination of a signaling

pathway via which atypical protein Kinase C functions in breast cancer.

PFKP contributes to ovarian cancer metastasis, stemness and anchorage-independent growth via α5 integrin and ERK/MMP9 signaling

Ruiqian Zhang[1], Michelle K.Y. Siu[1], Xuetang Mo[1], Mingo M.H. Yung[1], Jingjing Wang[1], Yuxin Jiang[1], Annie N.Y. Cheung[2], Hextan Y.S. Ngan[1], Karen K.L. Chan[1]. *[1]Departments of Obstetrics and Gynaecology, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Pok Fu Lam, Hong Kong,[2]Departments of pathology, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Pok Fu Lam, Hong Kong*

Background: Ovarian cancer is one of the most aggressive malignancies threatening women's health worldwide. Its high mortality rate is largely due to symptoms not appearing until late in the disease, usually after the cancer has metastasized. Despite current state-of-the-art treatments, the prognosis for patients remains poor. New effective treatments are urgently needed to improve patient survival. High lactate production and low glucose oxidation, independent of oxygen availability, is known as the Warburg effect and is common in cancer. Phosphofructokinase 1 (PFK-1) irreversibly converts fructose 6-phosphate to fructose 1,6-bisphosphate, the first step in the Warburg effect. The platelet isoform of PFK (PFKP) regulates glycolysis and plays roles in tumorigenesis in other human cancers, the precise mechanisms has yet to be defined. Moreover, PFKP in ovarian cancer remain unknown. We hypothesize that PFKP modulates metastasis and stemness in ovarian cancer.
Methods: Expression of PFKP in clinical samples, ascites-derived tumor cells, normal ovarian epithelial cells (HOSEs) and ovarian cancer cell lines was determined by immunohistochemistry/immunofluorescence and qPCR/immunoblotting, respectively. The correlation between PFKP and clinicopathological parameters was analyzed. Ectopic expression or knockdown of PFKP followed by migration, invasion, sphere formation and soft agar assays were performed in ascites-derived tumor cells and ovarian cancer cell lines to investigate the effects on metastasis, stemness and malignant transformation respectively. Additionally, the related signaling pathway was explored by qPCR and immuoblotting.

Results: Up-regulation of PFKP in clinical samples, ascites-derived tumor cells and ovarian cancer cell lines was found when compared to HOSEs. Higher PFKP was correlated to shorter overall and disease-free survival. Functionally, knockdown of PFKP by siRNA/shRNA approaches in ascites-derived tumor cells, ES-2 and HeyA8 cells decreased migration, invasion, sphere formation and colony formation in soft agar, which was accompanied by decreased expression α5 integrin, pERK and MMP9. Ectopic expression of PFKP in SKOV-3 cells showed opposite effects. Intriguingly, we found that MEK-1 inhibitor (U0126) or an anti-MMP9 neutralizing antibody could block PFKP-mediated migration/sphere formation abilities.
Conclusion: PFKP was overexpressed in ovarian cancer and regulates metastasis, stemness and anchorage-independent growth. α5 integrin and ERK/MMP9 signaling were involved in such functional effects. PFKP could be a potential prognostic marker and therapeutic target for ovarian cancer.

Role of protein kinase C ζ and ι inhibitors on ovarian cancer cell lines in combination with cisplatin

Mahfuza Marzan, Nuzhat Nowshin Oishee, Khandker Mohammad Khalid, Mildred Acevedo-Duncan. *Chemistry, University of South Florida, Tampa, FL*

Ovarian cancer causes more death than any other cancers of the female reproductive system. Current treatment strategies are surgical removal of cancerous parts and chemotherapy with platinum drugs (e.g. cisplatin, carboplatin) or taxols. However, recurrence of cancer with drug resistance is frequent. Previously two inhibitors; ICA-1S (5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide and ζ-stat (8-hydroxy-1,3,6- naphthalenetrisulfonic acid) specific for two atypical protein kinases, PKC-ι and PKC-ζ respectively have been reported. These inhibitors have an anticancer effect in different cancers, including clear-cell ovarian cancer. Our aim was to find if cisplatin has any synergistic effect with ICA-1S and ζ-stat on ovarian cancer cell proliferation, migration, and apoptosis. Ovarian cancer cell line ES-2, which has mutation in p53 gene was used in this study. After 72 hours of

treatment with ICA-1S (10 μM) and ζ-stat (10 μM), proliferation of ES-2 cell line was inhibited by 42.5% and 23.5% respectively compared to control. When combined with cisplatin (0.5 μM), the inhibition of cell proliferation increased to 67% for ζ-stat and 65.8% for ICA-1S (N=3 trials) which is synergistic. Wound healing assay with ES-2 cells showed that ICA-1S and cisplatin inhibited the migration of ES-2 cells separately as well as in combination. SDS-PAGE and subsequent western blotting showed that ICA-1S monotherapy and combination with cisplatin reduced the expression mutant p53, PI3K, AKT, Bcl2, and phopho-BAD. IP with PKC ζ beads showed the association of PKC ζ with PKC-ι and p53 in ES-2 cell line. As mutation in p53 is quite frequent in ovarian cancer with gain of function, ICA-1S may have an advantageous role in inhibiting mutated p53 regulated pathway. Inhibition of ES-2 cell line with ICA-1S and ζ-stat also suggested that PKC-ι and PKC ζ play important roles in ovarian cancer and may augment traditional chemotherapy. Further study on the pathway affected by aPKC inhibitors combined with cisplatin would be investigated through WST, western blotting and immunoprecipitation assay.

#5025

Reduced level of protein kinase C iota renders human glioblastoma less invasive and induces apoptosis via modulating Tak1/NF-κB pathway

Khandker Mohammad Khalid, Wishrawana S. Ratnayake, Avijit Dey, Nuzhat N. Oishee, Mahfuza Marzan, Mildred Acevedo-Duncan. *University of South Florida, Tampa, FL*

Glioblastoma (GBM) is characterized by poor therapeutic response and overall survival. It is the most aggressive form of primary brain tumor with a tendency to invade surrounding healthy brain tissues, rendering them largely incurable. In this study, small-interference RNA was used to knock down the expression of protein kinase C PKC-ι. The reduced PKC-ι expression impaired the phosphorylation of LIM kinase 1/2 (LIMK), which is a critical step in cofilin recycling and actin polymerization. Additionally, there was a down-regulation of matrix metalloprotease-9 expression in LN-229 and U87G cells, which coincided with decreased invasion. Therefore, PKC-ι regulates both cytoskeleton rearrangement and cell adhesion, which contributed to cell migration. Silencing of PKC-ι also dampened Transforming growth factor-β (TGF-β)-activated kinase 1 (Tak1) level.

TAK1 is an essential component in genotoxic stresses-induced NF-κB-activation and mitogen-activated protein kinase (MAPK)-pathways in GBM. TAK1, when activated, forms a complex with TAB1-3 (Tak1 binding proteins). Our data reveal, reduced Tak1 level after silencing PKC-ι interferes with complex formation and reduces NF-κB-activation. Diminished PKC-ι level also reduces activation of Tak1/JNK axis. This deactivation exerts an anti-oncogenic effect on glioblastoma via suppression of Akt1, c-Myc, and STAT3. This implies PKC-ι may have a crucial role in the activation of Tak1. Reduced migration and invasion in glioblastoma cells upon inhibition of PKC-ι was further confirmed by Scratch assay and Boyden assay. These results indicate that PKC-ι is involved in the control of glioblastoma cell migration and invasion. PKC-ι is a central component of multiple converging and bifurcating pathways and is a potential therapeutic target against GBM survival and infiltration.

Protein tyrosine phosphatase Ptpn1 knockout in mouse models drives B-cell hematological malignancies

Toshihiro Matsukawa[1], Nupur Nigam[1], Ryan Bertoli[1], Michel L. Tremblay[2], Mianmian Yin[1], Peter D. Aplan[1]. *[1]NIH-NCI, Bethesda, MD,[2]McGill University, Montreal, QC, Canada*

Background: Ptpn1 is a member of Protein Tyrosine Phosphatase family that dephosphorylates tyrosine residues. We previously reported that an Mcm2 hypomorphic mouse (designated Mcm Cre/Cre) develops T cell acute lymphoblastic leukemia (T-ALL), due to acquisition of 100-1000 kb interstitial deletions involving tumor suppressor genes. When crossed to mice that express a NUP98-HOXD13 (NHD13) fusion gene, NHD13+;Mcm2Cre/Cre mice develop B-cell precursor ALL (BCP-ALL). Sparse whole genome sequencing revealed somatic copy number variants (CNV) involving Pax5 and Ptpn1. The role of Pax5 in B-cell development, differentiation, and leukemia has been widely studied. However, little is known about deletions of Ptpn1 and its role in BCP-ALL.
Objective: The principal objective is to investigate how deletion of Ptpn1 impacts BCP-ALL development in mouse models.
Methods: Mice expressing NHD13 fusion (NHD13+) were crossed with Ptpn1 knockout mice. The F2 cross generated 6 genotypes that were

positive or negative for NHD13 and wild type/heterozygous/homozygous for Ptpn1. Mice were studied for incidence of BCP-ALL, which was characterized by whole-exome sequencing, molecular pathway analysis and transcriptome-sequencing.
Results: NHD13+;Ptpn1-/- mice developed BCP-ALL, characterized by hyperleukocytosis, variable anemia and thrombocytopenia, expression of B220 and/or CD19, and invasion of non-hematopoietic tissues (liver, kidney, lung). In addition, NHD13+;Ptpn1+/- mice that developed BCP-ALL lost the wild-type (WT) Ptpn1 allele in the leukemic cells. Similar to human BCP-ALL, NHD13+;Ptpn1-/- mice that developed BCP-ALL showed presence of clonal TCR-delta rearrangements as well as IGH rearrangements in the leukemic cells. Whole exome sequencing showed presence of acquired mutations in genes known to be involved in B-cell differentiation, such as Pax5 or Bcor, as well as genes involved in B cell signaling pathways, such as Jak3, Jak1 and Flt3 and Western blots demonstrated accumulation of phosphorylated STAT3 protein.
Conclusion: This study demonstrates that Ptpn1 loss along with expression of an NHD13 fusion gene leads to a highly penetrant BCP ALL in mice, suggesting a role for Ptpn1 in preventing malignant transformation. Taken together, these findings are consistent with a collaborative model for BCP ALL in which the NHD13 transgene leads to increased stem cell self-renewal, somatic Bcor or Pax5 mutations block normal B cell differentiation, and somatic signaling mutations (Jak1/3, Flt3) lead to hyperproliferation, which is potentiated by Ptpn1 deficiency.

#5027

Targeting *ARAF* p.S214C mutation with sorafenib in non-small cell lung cancer

Carol Lee, Sze Man Chan, Sai Fung Yeung, Stephen Kwok-Wing Tsui.
School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Sorafenib is an FDA-approved multi-kinase inhibitor for the treatment of several cancer types, but is still under investigation for non-small cell lung cancer (NSCLC). Although sorafenib has not shown significant survival benefit in clinical trials for NSCLC patients, one study identified a patient with advanced lung adenocarcinoma harboring *ARAF* p.S214C mutation as

an exceptional sorafenib responder. As NSCLC lacks clinically validated predictive biomarkers for drug responses, we aim to evaluate the potential of *ARAF* p.S214C mutation as a biomarker for sorafenib sensitivity and its mechanism of action. Constructs with *ARAF* p.S214C mutation, *ARAF*-wild type (WT) and EGFR-vector control were ectopically expressed in a lung adenocarcinoma cell line, H2023, by retroviral transduction. Western blot confirmed stable overexpression of ARAF proteins over time. MTT assay showed that sorafenib inhibited growth of cells expressing *ARAF* p.S214C more pronouncedly than cells expressing *ARAF*-WT or vector control. In addition, spheroids formed by cells expressing *ARAF* p.S214C were more sensitive to sorafenib inhibition, indicating sorafenib sensitivity of *ARAF* p.S214C in NSCLC *in vitro*. To evaluate whether such sorafenib sensitivity is dependent on the kinase activity of ARAF, phospho-MEK and MAPK levels in mutant cells will be determined. As ARAF belongs to the Raf protein family which also includes BRAF and RAF1, knockdown studies and co-immunoprecipitation will be performed to determine whether BRAF and RAF1 are essential for *ARAF* p.S214C activity. The *in vivo* sorafenib sensitivity of *ARAF* p.S214C will be validated in tumor xenografts established from cells expressing the above constructs upon sorafenib treatment. Tumor volume will be assessed and expression of the tumor marker cytokeratin will be evaluated by immunohistochemistry. This study may reveal *ARAF* p.S214C as a potential biomarker for sorafenib sensitivity and a new target for precision medicine in NSCLC.

#5028

The regulation of inflammatory signaling in cancer via A20 phosphorylation

Tania Lopez Palacios, Tsz-Yin Chan, Christina Egbert, Jacob Truman, Spencer Ashworth, Alec Vaughan, Joshua L. Andersen. *Chemistry and Biochemistry, Fritz B. Burns Cancer Research Laboratory at Brigham Young University, Provo, UT*

A20 is an anti-inflammatory protein with a dual ubiquitin-editing activity. Through its N-terminal ovarian tumor (OTU) domain, A20 negatively regulates NF-κB by removing the K63-linked ubiquitin chains on RIP1 that act as platforms for NF-κB activation downstream of tumor necrosis factor alpha (TNFα). On the other hand, A20 also catalyzes the addition of K48-

linked ubiquitin chains on RIP1 via its C-terminal zinc finger domain 4 (ZnF4) to promote its proteasomal degradation. Through both mechanisms, A20 is a means of negative feedback on TNFα-induced NF-κB activity. Importantly, inactivation of A20 is frequently found in B-cell lymphomas, where loss-of-function A20 truncations promote cell proliferation and upregulation of NF-κB signaling. Among the post-translational modifications (PTMs) reported in A20, there are several phosphorylation events in its C-terminus, including within the ZnF4 domain. Besides its known E3 ubiquitin ligase activity, previous reports show that the C-terminal region of A20 is important for ubiquitin binding, having preference for K63-linked poly-ubiquitin. However, a little is known about the effects of phosphorylation at this region on A20 activity as well as its consequences in downstream signaling. Our current work suggests that phosphorylation in the C-terminus of A20 inhibits its E3 ubiquitin ligase activity and disrupts its interaction with ubiquitin, which may also affect its deubiquitinase activity by preventing its recruitment to ubiquitinated proteins in the TNFα receptor (TNFR) complex. We also propose that the C-terminal region is important for the formation of the A20 ubiquitin-editing complex, necessary to downregulate NF-κB-activated inflammatory signals. Based on these observations, we hypothesize that not only gene-inactivating mutations, but also post-translational mechanisms, such as phosphorylation, inhibit A20 to promote cancer development. Our research is now focused on understanding the upstream signaling that regulates A20 phosphorylation.

Determining the biological function of TNK1

Emmalee Kohler, Tania Lopez-Palacios, Tsz-Yin Chan, Christina Egbert, Jacob Truman, Spencer Ashworth, Alec Vaughan, Joshua Andersen, D. Madhusanka. *Chemistry and Biochemistry, Fritz B. Burns Cancer Research Laboratory at Brigham Young University, Provo, UT*

Thirty-eight-negative kinase 1 (TNK1) is a poorly characterized member of the ACK family of non-receptor tyrosine kinases, which we recently identified as a driver of cell survival in a subset of primary hematological malignancies. However, the biological function of TNK1 is not well understood. We also found that TNK1 is unusual among kinases for the

presence of a functional ubiquitin association (UBA) domain on its C-terminus. We discovered that the TNK1 UBA domain binds to poly-ubiquitin with high affinity and has no apparent preference for ubiquitin chain length or linkage type. Interestingly, the UBA domain is important for TNK1 function, given that deletion of the UBA domain (TNK1 ΔUBA) alters its localization and phospho-substrate network, while also weakening the oncogenic activity of TNK1 in cell transformation assays. Based on these data, we hypothesized that the UBA domain tethers TNK1 to its substrates. To test this hypothesis, we performed quantitative phospho-tyrosine proteomics using murine pro-B cells transformed with either TNK1 full length or TNK1 ΔUBA and identified TANK-binding kinase 1 (TBK1) as a putative UBA-dependent TNK1 substrate. TBK1 is a serine/threonine kinase involved in the regulation of inflammation, autophagy, and NF-κB signaling. During the selective autophagic degradation of misfolded proteins (aggrephagy), TBK1 phosphorylates p62 at S403 to increase its affinity to ubiquitin, and thereby increases p62-mediated recruitment of misfolded proteins into the condensate. Unchecked growth of ubiquitin condensates can overwhelm the size capacity of autophagosomes, potentially causing misfolded proteins to become proteotoxic aggregates. Our preliminary data suggest a model in which active TNK1 accumulates at ubiquitin condensates to phosphorylate and inhibit TBK1. Based on these data, we propose that TNK1 acts as a kinase sensor of poly-ubiquitin to control the TBK1-mediated growth of ubiquitin condensates.

Treatment of aromatase inhibitor-resistant cells with polyisoprenylated cysteinyl amide inhibitors stimulates the mitogen-activated protein kinase pathway enzymes, impedes cell proliferation and causes cell death

Jassy Mary S. Lazarte, Syreeta L. Tilghman, Nazarius S. Lamango. *Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL*

Overexpression and hyperactivity of the estrogen receptor drives 67-80% and 90% of breast cancer in women and men, respectively. Resistance to aromatase inhibitor (AI) therapies necessitates the continuous search for novel therapies. Previous studies demonstrate AI-resistance is associated

with hormone-independence, enhanced motility, and increased growth factor signaling. Here, long-term letrozole-treated (LTLT-Ca) breast cancer cells were used to evaluate polyisoprenylated cysteinyl amide inhibitors (PCAIs) as potential alternative therapies for the treatment of aromatase inhibitor-resistant breast cancer. We determined the potency of PCAIs as anticancer agents by evaluating their effects on cell viability, phosphorylation of MAPK pathway enzymes, G-proteins levels, cell migration and apoptosis. Among the PCAIs tested, NSL-YHJ-2-27 showed significant potency against cell viability with an EC_{50} of 3.6 μM. MEK (p-MEK1/2), ERK (p-ERK1/2), and p90RSK (p-p90RSK) phosphorylation were significantly increased by 178, 119 and 125%, respectively, over controls. In addition, of the seven G-proteins evaluated, only KRAS and NRAS showed significant increases of 49% and 97%, respectively. Cell proliferation and colony formation were impeded by 82% and 74%, respectively, after PCAIs treatment. Migration of the LTLT-Ca cells was inhibited by 80% following treatment with 5 μM of NSL-YHJ-2-27. Lastly, the PCAIs also caused the degeneration of the spheroids after 10 μM PCAIs treatment, dead cells were very apparent after AO/EB staining. Our findings suggest that the PCAIs' suppression of cell viability and activation of the MAPK pathway causes apoptosis possibly through the activation of the proapoptotic p-p90RSK isoforms. The results reveal the ability of the PCAIs to effectively cause a negative impact on several cancer hallmarks suggesting their potency as anticancer agents. These findings also support a potential role for PCAIs' use in treating breast cancers that have become resistant to aromatase inhibitor therapies.

Targeting CXCR4 and thioredoxin reductase in high grade neuroendocrine tumors and neuroendocrine carcinomas

Melissa A. Fath, Dijie Liu, Claudia Robles-Planells, Jordan T. Ewald, Keegan A. Christensen, Spenser S. Johnson, Stephen A. Graves, Douglas R. Spitz, Yusuf Menda, M. Sue O'Dorisio. *University of Iowa, Iowa City, IA*

Introduction/Background: Atypical lung carcinoids and lung neuroendocrine carcinomas (NECs) are currently incurable. Most of these

cancers express the C-X-C chemokine receptor 4 (CXCR4), making CXCR4 an attractive target for cancer diagnosis and treatment using radioligand therapy (RLT) with nuclides such as alpha emitter Pb^{212} conjugated to Pentixather (Pent). Alpha particles produce dense ionization tracks and damage cytosolic structures such as mitochondria, leading to the generation of reactive oxygen species such as superoxide ($O_2^{\bullet -}$) and hydroperoxides (H_2O_2 and ROOH) in targeted cancer cells. The FDA approved thioredoxin reductase inhibitor, auranofin (Aur), inhibits peroxiredoxin-mediated hydroperoxide metabolism increasing cell killing in targeted cancer cells.
Hypothesis: Inhibition of hydroperoxide metabolism using Aur can enhance therapeutic efficacy of alpha particle emitting ^{212}Pb-Pent in preclinical models of lung carcinoids and NECs.
Results: Clinically, IHC revealed greater than 75% of atypical carcinoids and NECs tested had moderate to high CXCR4. qRT-PCR, flow cytometry and immunohistochemistry performed on different lung carcinoid and NEC lung cell lines, determined that the majority moderately or highly express CXCR4. The minimal non-toxic dose of Aur that inhibits 50-70% of thioredoxin reductase activity was 4 mg/kg (intraperitoneal once a day) in DMS273 (small cell lung cancer) xenografts. ^{212}Pb-Pent given IV (1 and 3 μCu/g) was effective at increasing the survival of mice with DMS273 xenografts. Mice were then treated with 1.5, 3 or 6 μCu/g ^{212}Pb-Pent w/wo Aur 4 mg/kg/day. A trend test showed that both increasing dose of ^{212}Pb-Pent and the addition of Aur, caused a significant ($p<0.01$) delay in tumor growth. There were no significant changes in body weights, complete blood counts, and serum alanine aminotransferase indicating the combination treatments were well tolerated. Radiation dosimetry estimates using quantitative SPECT/CT imaging with Pb^{203}-Pent demonstrated average absorbed doses of 0.133 Gy/μCi (liver), 0.098 Gy/μCi (kidneys), 0.013 Gy/μCi (H292 xenografts), 0.028 Gy/μCi (DMS53 xenografts), 0.057 Gy/μCi (DMS273 xenografts), and 0.096 Gy/μCi (H69AR xenografts). Xenograft absorbed dose levels were positively correlated with CXCR4 expression.
Conclusion: The use of ^{212}Pb-Pent therapy to target CXCR4 on NECs showed pre-clinical efficacy in a dose dependent manner that was enhanced by Aur without significant normal tissue toxicity supporting the hypothesis

that CXCR4 can be successfully targeted with the radionuclide theragnostic pair, Pb^{212}/Pb^{203}-pentixather.

#5035

Preclinical development of a ^{89}Zr-labeled human antibody as a novel immuno-PET agent for noninvasive cancer detection and monitoring response to treatment

Abhay Kumar Singh, Calvin D. Lewis, Cristian AWV Boas, Philipp Diebolder, Prashant N. Jethva, Aaron Rhee, Jong Hee Song, Young Ah Goo, Shunqiang Li, Yongjian Liu, Buck Rogers, Vaishali Kapoor, Dennis E. Hallahan. *Washington University School of Medicine in St. Louis, Saint Louis, MO*

Lung cancer is the leading cause of cancer death worldwide. There is an unmet need for therapies to improve lung cancer outcomes without causing additional toxicities. Tax-interacting protein 1 (TIP1) is a radiation-inducible antigen that plays a role in lung cancer progression and resistance to therapy. TIP1 is a targetable cell surface protein. We developed human antibodies (Ab) that bind specifically to lung cancer. This study aimed to evaluate our lead anti-TIP1 human antibody targeting lung cancer *in vitro* and *in vivo*. Anti-TIP1 IgG1 Ab was developed by biopanning phage display human antibody library. The purified Ab was characterized by size-exclusion chromatography-HPLC (SEC-HPLC), mass spectrometry, ELISA, BIAcore and flow cytometry. Ab was labeled with ^{89}Zr using desferrioxamine chelator. The surface binding of ^{89}Zr-Ab was evaluated in the A549 and H460 lung cancer cells. Stability of the ^{89}Zr-Ab was assessed in human serum. Mice bearing 3 patient-derived xenografts (PDX) lung tumors or A549 tumors were injected with 50 μCi of ^{89}Zr-Ab. Small animal PET imaging and biodistribution were conducted over 7 days. Specific tumor uptake was evaluated in biodistribution studies on day 5 by injecting cold Ab before ^{89}Zr-Ab. We obtained 95% pure anti-TIP1 Ab by SEC-HPLC. Mass spectrometry confirmed the intact mass and glycosylation pattern of the anti-TIP1 IgG1. The Ab is bound to recombinant TIP1 protein and cancer cell surface with high affinity. The radiochemical purity of the ^{89}Zr-Ab was 99.9%, and the molar activity was 11.54 MBq/nmol with a radiolabeling yield of 91.4%. Both A549 and H460 cell lines demonstrated

specific binding as >70% inhibition was observed when the cold Ab was added. The ratio of SUV tumor to SUV muscle increased from 5.8 at 2 days to 6.3 at 7 days in PDX. In biodistribution studies, we found significantly higher ($p<0.05$) tumor uptake of the anti-TIP1 Ab (9.15±3.13 %ID/gm) vs. isotype control (5.72±1.02 %ID/gm). Cold anti-TIP1 Ab significantly blocked ($p<0.0001$) binding of the ^{89}Zr-Ab in A549 tumors. The anti-TIP1 Ab targets lung cancer cells *in vitro* and *in vivo*. The Ab retained antigen-binding potential following labeling with ^{89}Zr. This Ab can detect TIP1 positive tumors for therapy when conjugated with therapeutic radionuclides. IND enabling studies with the lead anti-TIP1 Ab are underway.

Single dose treatment with a novel Yttrium-90-labeled high affinity anti-B7-H3 antibody selective for the 4Ig-B7-H3 isoform provides long term survivors for established radioresistant colorectal carcinoma

Sarah Glazer, Margie Sutton, Ping Yang, Federica Pisaneschi, Seth Gammon, David Piwnica-Worms. *UT MD Anderson Cancer Center, Houston, TX*

The immune checkpoint antigen B7-H3 (CD276), expressed on cell surfaces of a variety of epithelial solid tumors, is a type 1 transmembrane protein consisting of an extracellular domain of repeating immunoglobulin constant and immunoglobulin variable domains (IgV, IgC, IgV, IgC), known as the 4Ig-B7-H3 isoform. 4Ig-B7-H3 is the dominant isoform in human cancers and is expressed at much lower levels on normal tissues. Humans also express a sheddable 2Ig-B7-H3 isoform containing only one immunoglobulin variable and constant extracellular domain (IgV, IgC) that is found in circulation (soluble 2Ig-B7-H3) and presents a challenge for systemic targeting of solid tumors. To develop an antibody suitable for fulfilling the promise of B7-H3 as a systemic therapeutic target, herein we report a murine antibody (MIL33B) that demonstrates mid-picomolar affinity to human 4Ig-B7-H3 (Kd, 72 pM) with 8-fold selectivity over 2Ig-B7-H3 (Kd, 580 pM) extracellular domains. Furthermore, MIL33B maintains high affinity to porcine 4Ig-B7-H3 (Kd, 102 pM), selectivity over murine 2Ig-B7-H3 (Kd, 41 nM), facilitating pre-clinical testing, and low cross-reactivity to other B7 family members (Kd, >1 μM). MIL33B-AF495 conjugates showed selective binding by live cell fluorescence microscopy

to HeLa and HCT116 cells with high endogenous 4Ig-B7-H3 expression and 4T1, B16F10 and CT26 cells induced to express human 4Ig-B7-H3 compared to HeLa 4Ig-B7-H3 KO cells or murine cell lines with endogenous 2Ig-B7-H3 expression. Compared to uptake in respective KO or vector control tumors, quantitative analysis *in vivo* with ^{89}Zr-DFO-MIL33B and PET imaging of tumor models demonstrated significantly higher normalized tumor-specific uptake in tumors with high endogenous expression of 4Ig-B7-H3 (HeLa) (3.25 ± 0.65 vs. 0.79 ± 0.13 SUV ratio, * $p = 0.02$) or those induced to express human 4Ig-B7-H3 (B16F10 and CT26) (3.16 ± 0.30 vs. 1.20 ± 0.69 SUV ratio, ** $p = 0.0032$; and 3.62 ± 1.62 vs. 1.89 ± 0.85 SUV ratio, *** $p < 0.0001$, respectively). As a first radio-theranostic treatment application, MIL33B labeled with yttrium-90 (^{90}Y-DOTA-MIL33B), a therapeutic beta-emitter, administered as a single dose I.V. (100 mCi, 3700 kBq), induced complete tumor regression and long-term survival of > 50% of mice harboring established syngeneic radioresistant colorectal CT26 tumors expressing human 4Ig-B7-H3 compared to vector control tumors (* $p = 0.0376$, log-rank test). ^{90}Y-DOTA-MIL33B-responsive mice developed immunologic memory and depletion assays *in vivo* demonstrated that CD8b+ cells contributed to the therapeutic efficacy of ^{90}Y-DOTA-MIL33B. These results point to the promise of ^{90}Y-DOTA-MIL33B as a selectively-targeted immune priming agent for radioligand therapy of 4Ig-B7-H3-expressing solid tumors.

DARPins as powerful targeting agents for radioligand therapeutics

Andreas Bosshart[1], Stephan Wullschleger[1], Martin Behe[2], Alain Blanc[2], Stefan Imobersteg[2], Alexandra Neculcea[1], Jacqueline Blunschi[1], Liridon Abduli[1], Sarah Schütz[1], Julia Wolter[1], Christian Reichen[1], Amelie Croset[1], Alessandra Villa[1], Christian Lizak[1], Anne Goubier[1], Roger Schibli[2], Daniel Steiner[1]. *[1]Molecular Partners AG, Schlieren, Switzerland,[2]Paul Scherrer Institute, Villigen, Switzerland*

The development of effective radioligand therapeutics (RLTs) is frequently hampered by the lack of high-quality targeting agents that selectively deliver radioactive payloads to the site of disease while sparing healthy tissues. Antibodies can have high affinity and specificity to tumor targets,

but their large size results in limited tumor penetration and long systemic half-life is frequently causing haematological toxicities. Alternatively, targeting agents with low molecular weight such as small molecules and peptides often suffer from limited affinity and specificity to the tumor target, resulting in off-target effects and limited tumor retention. DARPins (Designed Ankyrin Repeat Proteins) developed by Molecular Partners combine small size (15 kDa) and ideal binding properties. Due to their rigid-body target binding mode DARPins combine very high affinity and specificity and unless engineered accordingly, DARPins have very short systemic half-lives. Thanks to a simple and robust architecture, DARPins can be efficiently coupled with radioactive payloads, even at elevated temperatures; and they can tolerate sequence-engineering approaches, which are not compatible with other protein scaffolds. To establish the DARPin platform for RLT, we have used DARPin candidates against different tumor targets. We have previously shown that increasing affinity to the tumor target correlates with elevated tumor uptake and long tumor residence in preclinical mouse models. We now also show that DARPins exhibit a homogeneous and deep tumor penetration *in vivo* that is highly superior to antibody benchmarks. Globular proteins below 60 kDa in size are typically cleared from the bloodstream via the renal pathway. This generally results in a strong kidney accumulation of small sized, protein-based targeting agents and their coupled residualizing radionuclides, leading to dose-limiting kidney toxicities. To overcome this limitation, we have undertaken an extensive engineering approach of the DARPin scaffold. Our results show that sequence engineering strongly reduces kidney uptake of DARPins without affecting their tumor uptake. This effect was confirmed with independent DARPin candidates suggesting a general applicability of the approach. Combined with other orthogonal strategies, we are able obtain favourable tumor to kidney ratios in preclinical mouse models. These results show that our proprietary optimized DARPin platform offers an attractive solution to the limitations of protein-based targeting agents for RLT applications. Together with the fact that high-affinity DARPins can be generated against a large variety of tumor targets, we conclude that our platform provides a powerful basis for the development of next-generation RLTs. Several DARPin-RLT programs in indications with high unmet medical need are currently in development.

Evaluation of anti-tumor immunity in response to [^{177}Lu]Lu-PSMA in a mouse model of prostate cancer

Gemma Dias, Sarah Able, Irini Skaripa-Koukelli, Rachel Anderson, Gracie Wilson, Katherine A. Vallis. *Oncology, University of Oxford, Oxford, United Kingdom*

[^{177}Lu]Lu-PSMA improves progression-free and overall survival in metastatic castration resistant prostate cancer. However, the role of immune stimulation by molecularly targeted radionuclide therapy (MRT) is poorly understood. The aim of this study was to evaluate the anti-tumor immune response induced by [^{177}Lu]Lu-PSMA. The markers of immunogenic cell death (ICD), translocation of calreticulin (CRT) to the cell membrane, HMGB1 release and ATP release, were evaluated in the RM1 cell line (PSMA-negative murine prostate carcinoma) and its derivative, RM1-PGLS (stably transduced with human PSMA and SFG-EGFp/Luc), using flow cytometry, ELISA and a luminescence detection assay respectively. The *in vivo* biodistribution of [^{177}Lu]Lu-PSMA in RM1-PGLS tumor-bearing C57BL/6 mice was investigated using microSPECT-CT imaging, and the *in vivo* efficacy of [^{177}Lu]Lu-PSMA was tested in RM1-PGLS tumor growth inhibition studies. Vaccination/rechallenge experiments were performed to elucidate whether [^{177}Lu]Lu-PSMA elicits ICD *in vivo*. The Nanostring Pan Cancer Immune Profiling Platform was used to assess changes in the tumor immune microenvironment (TIME) in response to [^{177}Lu]Lu-PSMA. External radiation (EBRT; ^{137}Cs γ-radiation; 6-10 Gy) was used as a comparator treatment in most experiments. We observed a dose-dependent increase in cell surface CRT following [^{177}Lu]Lu-PSMA and EBRT at 24 and 72 h and of HMGB1 release in response to [^{177}Lu]Lu-PSMA and EBRT at 96 and 144 h. At 24 h following [^{177}Lu]Lu-PSMA (60 MBq) there was a significant increase in ATP release compared to untreated samples. Collectively these data indicate [^{177}Lu]Lu-PSMA causes ICD. A high RM1-PGLS tumor:muscle uptake ratio (210 ± 59) was noted in biodistribution experiments confirming highly specific tumor accumulation of [^{177}Lu]Lu-PSMA. In tumor growth inhibition studies the time for tumors to reach a volume of 400 mm^3 was delayed in mice treated with [^{177}Lu]Lu-PSMA (60 MBq) compared to no treatment (30 versus 21 days; $P<0.01$).

We showed that a subcutaneous inoculum of [^{177}Lu]Lu-PSMA (60 MBq)-treated RM1-PGLS cells prevents tumor growth in approximately 50% of cases on rechallenge with viable RM1-PGLS cells one week later. This indicates that [^{177}Lu]Lu-PSMA induces ICD *in vivo*. We observed a significant reduction in most tumor infiltrating lymphocyte (TIL) types at 2 days after *in vivo* exposure to [^{177}Lu]Lu-PSMA (80 MBq), followed by an increase in TILs by Day 7. The observed pattern is similar to that after EBRT (6 Gy). There was overlap in the top 10 differentially expressed genes (treatment versus no treatment) for the [^{177}Lu]Lu-PSMA and EBRT groups. The gene showing the greatest level of upregulation at day 7 in [^{177}Lu]Lu-PSMA-treated tumors, IDO1, is known to be involved in immune tolerance and radioresistance. In conclusion, [^{177}Lu]Lu-PSMA induces ICD *in vitro* and *in vivo* and modulates the TIME.

#5039

Development of a prostate cancer PDX model radioresistant to PSMA targeted radionuclide therapy

Maria Thaysen[1], Esben Christensen[1], Rikke N. Nielsen[1], Michael Wick[2], Mette M. Wessel[1], Lotte K. Kristensen[1], Sebastian Gnosa[1], Carsten H. Nielsen[1]. *[1]Minerva Imaging, Oelstykke, Denmark,[2]XenoSTART, San Antonio, TX*

Prostate cancer is the second most common cancer diagnosis worldwide and the fifth leading cause of cancer related death among men. Lutetium Lu 177 vivivotide tetraxetetan was recently approved by the FDA for treatment of prostate-specific membrane antigen (PSMA)-positive metastatic castration-resistant prostate cancer. However, not all patients respond to treatment and combination therapies may improve outcomes. One approach is to combine targeted radionuclide therapy with inhibitors targeting DNA damage response pathways such as ATM/ATR inhibitors to enhance the radiosensitivity of the cancer cells. Currently, models used to study radioresistance in prostate cancer are based on cancer cell lines or cell-line derived xenograft models, but these models do not account for the heterogenous and complex biology of the disease.
To overcome this issue, we aimed at developing a radioresistant PSMA positive prostate cancer patient-derived xenograft (PDX) model based on

the ST1273 model (XenoSTART). ST1273 originates from a sixty-five-year-old Hispanic male that did not receive treatment prior to sampling. The model is characterized by overexpression of androgen receptor and PSMA. Tumors were implanted in nude mice and radioresistance was induced by external beam radiation therapy (3x2Gy per cycle) until tumor growth was unresponsive to the treatment. Flow cytometry were applied to evaluate if altered proliferation rate or changes in the tumor microenvironment (TME) convers the resistance.
Out of five initially treated tumors, one tumor re-occurred after 19 days. Repeating the treatment led to an initial decrease in tumor volume but the growth delay was reduced to 12 days. A third treatment rendered the tumor resistant as tumor growth was unaffected. Current evidence confirms that radioresistance was maintained when passaging, and PSMA expression was unaffected. Next, we tested whether the tumor would also withstand targeted radionuclide therapy. Animals implanted with parental or radioresistant ST1273 tumors were treated with Lu177-PSMA-617 (5MBq, QW x2). The treatment reduced tumor size in both tumor types, but significantly less in the resistant model. Moreover, parental tumors had a significantly slower recurrence of 45 days compared to the resistant tumors that relapsed 24 days after the first dosing. Flow cytometry analysis of control and treated tumors (parental and radioresistant) showed that the radioresistance might be attributed to alterations in the cell cycle control. Altogether, we developed a PDX prostate cancer model that is resistance to external beam radiation and PSMA targeted radionuclide therapy. This model will allow us to further characterize radioresistance and evaluate combinatorial therapy in a clinically relevant model.

Novel HER3 targeting antibody radioconjugates, ^{225}Ac-HER3 ARC and ^{177}Lu-HER3 ARC, exhibit potent antitumor efficacy in HER3-positive solid tumors

Denis Beckford-Vera, Megan McCloskey, Jason Li, Caroline Jennings, Le-Cun Xu, Debbie Lewis, Patrik Brodin, Amanda Chin, Monideepa Roy, Mary Chen, Helen Kotanides. *Actinium Pharmaceutical, Inc., New York, NY*

Background: HER3 is a unique member of the EGFR family that collaborates with other EGFR receptors to induce tumorigenesis and drug resistance. Moreover, HER3 expression is linked to poor survival for patients with solid tumors. Despite HER3 being a rational cancer therapeutic target, no HER3-directed therapies have been approved for clinical use. However, new therapeutic strategies such as antibody drug conjugates (ADCs) are being investigated. Targeted radiotherapy, including radiolabeled antibodies (ARCs), is unique mechanistically by inducing cell death independent of biologic pathway inhibition, and can be efficacious with less toxicity relative to other therapeutic modalities. Therefore, we hypothesized that the cytotoxic effects of alpha (^{225}Ac) or beta (^{177}Lu) emitting radionuclides combined with the specificity of anti-HER3 antibody targeting is a compelling therapeutic approach for HER3-expressing tumors. Here we evaluated the antitumor effects of ^{225}Ac or ^{177}Lu armed HER3 ARCs across multiple HER3-expressing cancer models such as ovarian, colorectal, prostate, and renal cancer.
Methods: ARCs were prepared by radiolabeling AT-02, an anti-HER3 antibody, with ^{225}Ac or ^{177}Lu using *p*-SCN-Bn-DOTA to yield ^{225}Ac or ^{177}Lu-HER3 ARC. The binding activity and tumor cell cytotoxicity of HER3 ARCs were assessed by ELISA using human recombinant HER3, flow cytometry on HER3-expressing cells, and colony forming assays. To evaluate the antitumor growth effects of ^{225}Ac-HER3 and ^{177}Lu-HER3 ARCs in vivo, preclinical human tumor xenograft models were developed. Mice bearing HER3-positive tumors were dosed with ^{225}Ac-HER3 ARC (0.2 or 0.4 μCi), or ^{177}Lu-HER3 ARC (200 or 400 μCi) and tumor growth and body weight was monitored.
Results: The pharmacological binding properties of HER3 antibody radiolabeled with ^{225}Ac or ^{177}Lu were similar to that of unmodified antibody as demonstrated by HER3 binding ELISA and flow cytometry. HER3 ARCs induced cytotoxicity and inhibited colony formation of HER3-positive tumor cell lines. Significant in vivo human tumor xenograft growth inhibition was observed in response to ^{225}Ac or ^{177}Lu HER3 ARCs compared to control groups (unmodified AT02 or IgG ARCs) in the models studied. No significant loss of body weight was observed in mice treated with HER3 ARCs suggesting that all treatments were well tolerated.

Conclusions: In this study, both ^{225}Ac-HER3 ARC and ^{177}Lu-HER3 ARC demonstrated significant antitumor activity against HER3-expressing tumors in a dose-dependent manner. The HER3 targeted radiotherapy approach that we have undertaken could potentially overcome the limitations of current solid tumor therapies in resistance settings and warrants further evaluation in patients with HER3-expressing tumors.

TEM-1 targeted alpha therapeutic [Ac-225]-FPI-1848 induces regression in pre-clinical sarcoma xenograft models

Sean Collens, Nicole Robinson, Matt Moran, Ryan Simms, Yarina Storozhuk, Meiduo Hu, Natalie Grinshtein, John Forbes, Christopher P. Leamon, John Valliant. *Fusion Pharmaceuticals Inc. (Canada), Hamilton, ON, Canada*

Background**:** Tumor endothelial marker 1 (TEM-1 or CD248) is a cell surface receptor belonging to a family of C-type lectin transmembrane proteins. Identified as a fetal antigen, expression peaks during embryogenesis but is minimally detected in adulthood. In pathological conditions TEM-1 has been shown to be overexpressed in cancer and fibrosis. In sarcomas, expression occurs throughout the tumor environment in malignant cells, stromal cells and perivascular cells. The first line of treatment for sarcomas is surgical removal; however, many sarcomas arise in inoperable sites prompting a need for novel therapies. Herein, we describe the development of a novel TEM-1 targeting radiotherapeutic, [^{225}Ac]-FPI-1848, in mouse xenograft models of sarcoma.
Methods: [^{225}Ac]-FPI-1848 is a radioimmunoconjugate consisting of a humanized anti-TEM-1 monoclonal antibody conjugated to a proprietary DOTA-based chelate (FPI-1397) and radiolabeled with actinium-225 **[**^{225}Ac]. [^{177}Lu]-FPI-1835 is the lutetium-177 radiolabeled analogue. The biodistribution and therapeutic efficacy of these radioimmunoconjugates were evaluated in human sarcoma xenograft models using *nu/nu* mice of Balb/c background. For biodistribution studies, approximately 37 MBq/kg of [^{177}Lu]-FPI-1835 was injected intravenously into mice and tumor/organ radioactivity was quantified *ex vivo* at timepoints between 4 and 196 h. For therapeutic studies, a single intravenous dose of [^{225}Ac]-FPI-1848 was

administered over a dose range of 18.5 to 740 kBq/kg. Tumor size and body weight were monitored for 28 days.
Results: Biodistribution studies with [^{177}Lu]-FPI-1835 confirmed robust tumor uptake with minimal normal tissue uptake in three sarcoma models expressing high (SJSA-1), moderate (SK-N-AS) or low (A673) levels of TEM-1. Furthermore, the degree of uptake trended with TEM-1 expression levels across these models (SJSA1> SK-N-AS> A673). In corresponding therapeutic studies, [^{225}Ac]-FPI-1848 demonstrated dose-dependent efficacy consistent with tumor uptake. In the SJSA-1 model, tumor regression was observed at doses of 92.5 kBq/kg or greater. Tumor regression was observed at doses of 185 kBq/kg or greater in the SK-N-AS model. In the low TEM-1 expressing A673 model, significant tumor regression was only observed at the highest radionuclide dose level (740 kBq/kg). Overall, therapy was well tolerated with no significant loss of body weight or clinical signs of poor health.
Conclusions: [^{177}Lu]-FPI-1835 demonstrated target-dependent uptake consistent with the degree of TEM-1 expression in human sarcoma xenograft models. In turn, corresponding efficacy studies with [^{225}Ac]-FPI-1848 demonstrated strong dose-dependent, and target level-dependent efficacy with no apparent toxicity. These results suggest [^{225}Ac]-FPI-1848 could be a promising therapy for TEM-1 expressing sarcomas.

Anti-tumor activity of RYZ101 (Ac-225 DOTATATE) in somatostatin receptor-expressing preclinical models of small-cell lung cancer
Guangzhou Han, Eunmi Hwang, Fanching Lin, Renee Clift, Daniel Kim, Eric Bischoff, Susan Moran, Gary Li. *RayzeBio, Inc, San Diego, CA*

Introduction: Overexpression of somatostatin receptors (SSTRs), particularly SSTR2, is found in gastroenteropancreatic neuroendocrine tumors (GEP-NETs), and subsets of other solid tumors such as small-cell lung cancer (SCLC). β-emitting radiopharmaceutical therapy Lu-177 DOTATATE has been approved for SSTR-expressing (SSTR+) GEP-NETs, but the relatively low objective response rate and frequent post-treatment progression represent an unmet medical need. Based on preliminary clinical anti-tumor efficacy, RYZ101 (Ac-225 DOTATATE) is being developed for inoperable SSTR+ well-differentiated GEP-NETs with disease progression following Lu-177-somatostatin analogue (SSA) therapy (ACTION-1, NCT05477576). SCLC accounts for approx. 13% of lung cancer and lacks effective therapeutic options. Immunohistochemistry analysis indicates that ~50% of SCLC tumors are SSTR2+, with a substantial subset showing high and homogenous expression. The goal of this study was to provide preclinical support for RYZ101, as a single-agent or in combination with carboplatin and etoposide, for SSTR+ SCLC.
Methods: RYZ101 is comprised of the α-emitting radioisotope actinium-225, chemical chelator DOTA, and SSA octreotate (TATE). Binding affinity to human SSTR1-5 was determined using a competitive radioligand binding assay in engineered cell lines expressing individual SSTR. Internalization was measured by PathHunter SSTR2 Activated GPCR Internalization Assay. The preclinical biodistribution of RYZ101 was carried out in non-tumor-bearing BALB/c mice of both sexes. The efficacy studies were performed in cell line-derived and patient-derived xenograft (PDX) models of SCLC.
Results: In preclinical studies where Lanthanum (La^{3+}) was used as a surrogate for Ac-225, RAYZ-10001-La (La-DOTATATE) had high binding affinity (K_i=0.057nM) to human SSTR2 (>600-fold more potent than other SSTR subtypes) and exhibited efficient internalization. In a preclinical biodistribution study, RYZ101 performed similarly to Lu-177 DOTATATE. In multiple SCLC xenograft models, RYZ101 significantly inhibited tumor growth and prolonged survival, with deeper responses, including sustained regression, observed in the models with higher SSTR2 level. The anti-tumor effect was further enhanced when combining RYZ101 with carboplatin and etoposide at clinically relevant doses.

Conclusions: In summary, RYZ101 is a first-in-class, highly potent, α-emitting radiopharmaceutical therapy being developed for the treatment of SSTR+ solid tumors. Preclinical data demonstrate the potential of RYZ101 for the treatment of patients with SSTR+ SCLC.

Radium-223 demonstrates increased antitumor activity in combination with ^{177}Lu-PSMA-617 in the intratibial LNCaP xenograft model of bone metastatic prostate cancer

Arne Scholz[1], Matias Knuuttila[2], Justyna Zdrojewska[3], Mari I. Suominen[3], Esa Alhoniemi[4], Christoph A. Schatz[1], Sabine Zitzmann-Kolbe[1], Sanna-Maria Käkönen[2], Urs B. Hagemann[1]. *[1]Research & Development, Pharmaceuticals, Bayer AG, Berlin, Germany,[2]Aurexel Life Sciences Ltd., Askainen, Finland,[3]Pharmatest Ltd., Turku, Finland,[4]Inoi Oy, Turku, Finland*

Radium-223, a bone-specific alpha particle therapy, increased survival of patients with metastatic castration-resistant prostate cancer (mCRPC) and bone metastases (Parker *et al.,* NEJM 2013). ^{177}Lu-PSMA-617 is a small molecule radioligand that delivers beta-particle radiation to cancer cells expressing prostate-specific membrane antigen (PSMA). Despite improving overall survival of patients with heavily pretreated mCRPC (Sator *et al.,* NEJM 2021), responses to ^{177}Lu-PSMA-617 are often not durable and many patients develop progressive disease presumably due to microscopic osseous lesions. Compared to beta-particle radiation, alpha particles have a shorter range and higher linear energy transfer, making them more suitable for treating microscopic lesions. In this study, we evaluated preclinical antitumor efficacy and potential beneficial combination effects of radium-223 combined with ^{177}Lu-PSMA-617 in the intratibial LNCaP xenograft model mimicking progressive prostate cancer micrometastases in bone. LNCaP prostate cancer cells were inoculated into the right tibiae of male NOD.scid mice. Six weeks after inoculation, the mice were randomized to treatment groups based on serum prostate-specific antigen (PSA) and treated with two injections (Q4Wx2, i.v.) of vehicle, radium-223 (330 kBq/kg), ^{177}Lu-PSMA-617 (10 MBq) or their combination. ^{177}Lu-PSMA-617 was given 24 hours after radium-223. PSA and bone formation marker

procollagen type I intact N-terminal propeptide (PINP) were measured from blood samples and tumor-induced abnormal bone growth was determined by radiography. Terminal blood samples were analyzed for hematologic status at sacrifice.
The combination treatment of radium-223 and ^{177}Lu-PSMA-617 demonstrated robust antitumor efficacy, as indicated by lower serum PSA (mean change relative to pretreatment levels: 63.9 % vs 631 % (vehicle control), $p=0.026$), decreased tumor-induced abnormal bone area in tumor-bearing tibiae ($p<0.001$) and suppression of abnormal bone metabolic activity as evidenced by a reduced level of the bone formation marker PINP ($p<0.001$), compared with vehicle. Tolerability of the combination treatment was evidenced by the lack of significant body weight loss and the absence of cumulative hematological toxicity.
In conclusion, these preclinical results show that the combination of radium-223 and ^{177}Lu-PSMA-617 is well-tolerated and efficacious in inhibiting osseous tumor growth and improving response. The combination of radium-223 and ^{177}Lu-PSMA-I&T is currently being investigated in patients with mCRPC in a phase 1/2 trial (AlphaBet, NCT05383079).

Antitumor activity comparison of two somatostatin receptor ligands radiolabeled with Lutetium-177 (SSO110 and DOTA-TATE) alone or combined with chemotherapy in mice bearing AR42J SST2-positive tumors

Olivier Raguin[1], Marcel Krüger[2], Peggy Provent[1], Funda Cay[2], Elodie Marie dit chatel[1], Marie Lux[1], Stéphane Lezmi[3], Florence Meyer-Losic[3], Pascale Plas[3], Ben Pais[4], Cyril Berthet[1]. *[1]Oncodesign Services, Dijon Cedex, France,[2]Werner Siemens Imaging Center, Tübingen, France,[3]IPSEN, Les Ulis, France,[4]Ariceum Therapeutics, Berlin, Netherlands*

Only a limited number of studies have compared the therapeutic effects of repetitive cycles of radiolabeled somatostatin (SST) analogues or assessed potential synergy of these analogues with chemotherapy agents.
Hence, a comparison was conducted in an in vivo AR42J tumor model with an SST2 antagonist, [^{177}Lu]Lu-satoreotide tetraxetan ([^{177}Lu]LuSSO110),

and a SST2 agonist, [^{177}Lu]Lu-DOTA-TATE. The efficacy of treatment combining [^{177}Lu]Lu-satoreotide tetraxetan with capecitabine plus temozolomide was also assessed.
Swiss Nude mice were xenografted with AR42J tumor cells. For the evaluation of the tumor response to radiation therapy, animals received one weekly dose of [^{177}Lu]LuSSO110 or [^{177}Lu]Lu-DOTA-TATE for four consecutive weeks. For combined treatments, animals received one weekly dose of [^{177}Lu]LuSSO110 at 20 MBq for four consecutive weeks in association with daily doses of capecitabine and temozolomide (CAPTEM). Weekly treatment for four consecutive weeks with [^{177}Lu]LuSSO110 at 15 MBq revealed a significantly reduced tumor growth, with 68 days to reach a tumor volume of 850 mm^3, compared to [^{177}Lu]Lu-DOTA-TATE at 15 MBq or 30 MBq, with, respectively, 43 days and 48 days. This was associated with a 3.5 fold higher tumor uptake of [^{177}Lu]LuSSO110 (15 MBq) compared to [^{177}Lu]Lu-DOTA-TATE, with no or mild effects on body weight, hematological toxicity, or renal toxicity.
In AR42J tumor-bearing mice treated once a week for four consecutive weeks, [^{177}Lu]LuSSO110 (15 MBq) associated with CAPTEM regimen did not significantly increase the median time to reach a tumor volume of 1000 mm^3 as compared to treatment with [^{177}Lu]Lu-satoreotide alone: 50.7 vs 42.2 days, respectively. The association of the two treatments only led to mild weight losses.
Repeated administrations of [^{177}Lu]LuSSO110 were able to potentiate peptide receptor radionuclide therapy with a higher tumor uptake and longer median survival compared to [^{177}Lu]Lu-DOTA-TATE. The The combination of [^{177}Lu]Lu-satoreotide with capecitabine and temozolomide did not show any synergy, but no antagonism was observed either.

#5045
NTSR1-targeted alpha therapeutic [Ac-225]-FPI-2059 induces growth inhibition in a preclinical colorectal tumor model
Saleemulla Mahammad, Jaline Broqueza, Brigitte L. Theriault, John Forbes, Christopher P. Leamon, John Valliant. *Fusion Pharmaceuticals Inc. (Canada), Hamilton, ON, Canada*

Background: Neurotensin receptor 1 (NTSR1) is overexpressed in multiple cancer indications that include pancreatic, colorectal and prostate cancers, all of which have limited therapeutic treatment options and unmet medical need. Fusion is developing novel targeted alpha therapeutics (TATs) that enable the specific delivery of high energy alpha particles (actinium-225; [^{225}Ac]) to tumor cells while sparing surrounding normal tissues. The alpha radiation released by TATs causes cell damage through the induction of multiple double-stranded DNA breaks leading to tumor cell death. Here, we describe the therapeutic efficacy of an [^{225}Ac]-conjugated, NTSR1 targeting small molecule in a colorectal cancer tumor model.
Materials and Methods: CT26 colorectal cancer cells overexpressing murine NTSR1 (mNTSR1) were generated by lentiviral transduction. Selected cells were evaluated for stable mNTSR1 expression by an *in vitro* radioligand binding assay and subsequently implanted subcutaneously into Balb/c mice for *in vivo* evaluations. FPI-2056 (parent compound) was radiolabeled with either lutetium-177 ([^{177}Lu]-FPI-2057) or actinium-225 ([^{225}Ac]-FPI-2059). Biodistribution assessment studies were conducted in mice bearing CT26-mNTSR1 tumors dosed intravenously with [^{177}Lu]-FPI-2057. Therapeutic efficacy studies were conducted by intravenous administration of single doses of 0.185 - 5.55 MBq/kg of [^{225}Ac]-FPI-2059 (0.1-3 μCi) to animals bearing CT26-mNTSR1 tumors, followed by tumor growth monitoring for 50 days. Study endpoints included tumor volume measurements and impact on animal health status.
Results: Evaluation of [^{177}Lu]-FPI-2057 biodistribution and excretion revealed rapid renal clearance via urine with a clearance from the blood by 24 h. Uptake of [^{177}Lu]-FPI-2057 was detected in the CT26-mNTSR1 tumors with a maximum concentration of 7.0 %ID/g at 6 h post-injection, dropping to 4.6 and 2.8 %ID/g at 24 and 48 h post-injection, with 20-fold higher uptake in the tumor vs. blood levels at both 24 and 48h time points. Therapeutic administration of a single dose of [^{225}Ac]-FPI-2059 resulted in dose-dependent tumor growth inhibition at doses above 1.85 MBq/kg of [^{225}Ac]-FPI-2059 (1 μCi), which translated into increased survival compared to control animals.
Conclusion: These results demonstrate that targeted delivery of [^{225}Ac]-FPI-2059 to NTSR1 expressing tumors results in significant growth

inhibition and enhanced survival, thereby providing promising preclinical evidence to support the clinical development of [^{225}Ac]-FPI-2059.

Cerenkov luminescence imaging of interscapular brown adipose tissue using TSPO-targeting probe to overcome off-target effect of [^{18}F]FDG

Seok-Yong Lee[1], Ho Rim Oh[1], Young-Hwa Kim[2], Sung-Hwan Bae[2], Yongseok Lee[3], Yun-Sang Lee[4], Byung Chul Lee[5], Gi Jeong Cheon[6], Keon Wook Kang[7], Hyewon Youn[3]. *[1]Seoul National University College of Medicine, Seoul National University of Graduate School, Cancer Research Institute, Seoul, Korea, Republic of,[2]Seoul National University College of Medicine, Cancer Research Institute, Seoul, Korea, Republic of,[3]Seoul National University Hospital, Seoul, Korea, Republic of,[4]Seoul National University College of Medicine, Seoul National University of Graduate School, Seoul, Korea, Republic of,[5]Seoul National University Bundang Hospital, Seoul National University, Seongnam, Korea, Republic of,[6]Seoul National University College of Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[7]Seoul National University College of Medicine, Seoul National University of Graduate School, Seoul National University Hospital, Seoul, Korea, Republic of*

Aim/Introd**uction**: [^{18}F]fluorodeoxyglucose-positron emission tomography ([^{18}F]FDG-PET) has been used as an imaging methods for measuring interscapular brown adipose tissue (iBAT) activity. However, [^{18}F]FDG-PET has limitations for obtaining iBAT-specific images due to off-target effects with high uptake in skeletal muscle, tumors, and inflamed tissue. Uncoupling protein 1 (UCP1), a well-known biomarker for BAT, located in mitochondria also has been suggested as BAT imaging marker. Recently, UCP1 ThermoMouse was established as a reporter mouse for monitoring UCP1 expression. Translocator protein-18 kDa (TSPO) located in the mitochondria outer membrane along with UCP1 is overexpressed in BAT. TSPO targeting probe has been proposed as a potential imaging marker for iBAT imaging. To date, there have been no studies for BAT imaging using TSPO-targeting probe in UCP1 ThermoMouse reflecting UCP1 expression. Moreover, Cerenkov luminescence imaging (CLI) which captures Cerenkov radiation emitted from PET probes has been suggested as an alternative

option for PET. In this study, we aim to evaluate [^{18}F]fm-PBR28-d_2 as a TSPO-targeting probe for iBAT imaging using PET and CLI in the UCP1 ThermoMouse.
Materials and Methods: UCP1 ThermoMouse with insertion of a Luc2-T2A-tdTomato cassette into the initiation of codon of the Ucp1-coding sequence exon 1 were used to monitor UCP1 expression. UCP1 ThermoMouse were characterized with Western blotting and immunohistochemistry to measure the levels of UCP1 expression. PET images were acquired with SimPET, and optical images such as bioluminescence imaging (BLI), fluorescence imaging (FLI) and Cerenkov luminescence imaging (CLI) were acquired with IVIS 100.
Results: BLI or FLI reflecting UCP1 expression were clearly showed iBAT in UCP1 ThermoMouse. Also, UCP1 and TSPO expression were correlated in iBAT. TSPO-targeting PET probe with [^{18}F]fm-PBR28-d_2 showed iBAT-specific signals without off-target effect in brain or heart. In addition, [^{18}F]fm-PBR28-d_2 better reflected individual variation in different UCP1 expression than [^{18}F]FDG. In particular, higher molar activity of [^{18}F]fm-PBR28-d_2 was required to obtain better imaging quality of CLI as well as PET. In physiological changes such as cold stimulation and isoflurane exposure, we observed increased imaging signals with cold exposure and decreased imaging signals with prolonged isoflurane exposure.
Conclusions: We showed that the TSPO-targeting probe is superior to [^{18}F]FDG as a reliable imaging probe reflecting UCP1 expression in iBAT imaging. Probes with higher molar activity provide better images and are required for quantitative analysis of TSPO-CLI and PET. Our data suggest that CLI with TSPO-targeting probe could be an alternative option for PET.

PSMA-targeted actinium-225 conjugate (^{225}Ac-pelgifatamab) potentiates the antitumor efficacy of darolutamide in androgen-dependent and -independent prostate cancer models

Christoph A. Schatz[1], Bernard Haendler[1], Sabine Zitzmann-Kolbe[1], Aasmund Larsen[2], Hartwig Hennekes[1], Carsten H. Nielsen[3], Maria Z. Alfsen[3], Alan Cuthbertson[2], Stefanie Hammer[1], Arne Scholz[1], Urs B. Hagemann[1]. [1]*Research & Development, Pharmaceuticals, Bayer AG,*

Berlin, Germany,[2]Bayer AS, Oslo, Norway,[3]Minerva Imaging, Copenhagen, Denmark

Patients with advanced prostate cancer have few treatment options. While androgen receptor (AR) inhibitors are the standard of care for the systemic treatment, patients often develop resistance despite an initial response. Thus, novel therapeutic approaches are required. Prostate-specific membrane antigen (PSMA; *FOLH1*) is highly expressed in prostate cancer with limited expression in normal tissues. Therefore, PSMA presents an attractive target for radionuclide therapy and PSMA-targeted therapies have already shown efficacy in the clinical setting. Here, we evaluated the efficacy of ^{225}Ac-pelgifatamab, a PSMA-targeted actinium-225 conjugate, in combination with the AR inhibitor darolutamide in androgen-dependent and -independent prostate cancer models. AR inhibitors are known to upregulate PSMA expression, therefore providing a rationale for combining ^{225}Ac-pelgifatamab with darolutamide and potentially resulting in an enhanced treatment effect.

In vitro, darolutamide induced the expression of PSMA in androgen-dependent VCaP and androgen-independent 22Rv1 cells by more than 10-fold and 2-fold, respectively. The efficacy of darolutamide in combination with ^{225}Ac-pelgifatamab was synergistic in these cells with combination indexes of 0.12 and 0.47, respectively. In the androgen-dependent, patient-derived ST1273 model, a single i.v. injection of ^{225}Ac-pelgifatamab at 75 kBq/kg resulted in a treatment/control (T/C) ratio of 0.22 on day 30, while twice daily (BID) oral (p.o.) treatment with 100 mg/kg darolutamide showed a T/C ratio of 0.29. However, the combination of darolutamide and ^{225}Ac-pelgifatamab resulted in enhanced antitumor efficacy with a T/C ratio of 0.008. Furthermore, 5/10 mice remained tumor-free 86 days after the ^{225}Ac-pelgifatamab injection. In the androgen-independent cell line-derived 22Rv1 model, darolutamide (100 mg/kg, p.o., BID) monotherapy was not efficacious with a T/C of 0.84 on day 16 but a single i.v. dose of ^{225}Ac-pelgifatamab at 150 kBq/kg resulted in a T/C ratio of 0.69. Remarkably, the combination of darolutamide and ^{225}Ac-pelgifatamab resulted in further enhanced efficacy with a T/C ratio of 0.34. Flow cytometric analysis of isolated 22Rv1 tumors showed a 50-fold increase in PSMA expression upon darolutamide treatment compared with vehicle. Taken together, these

results suggest that upregulation of PSMA expression contributes to the higher efficacy observed when darolutamide is combined with ^{225}Ac-pelgifatamab.
In conclusion, our results provide a proof of concept for investigating the combination of ^{225}Ac-pelgifatamab with darolutamide in the clinical setting.

Combatting pancreatic cancer stem cells by novel titanium peroxides nanoparticles combined with X-ray radiation
Mohammed Salah[1], Hiroki Kawaguchi[2], Hiroaki Akasaka[3], Yasuyuki Shimizu[3], Kenta Morita[4], Yuya Nishimura[5], Hikaru Kubota[3], Tomomi Sogawa[3], Naritoshi Mukumoto[3], Chiaki Ogino[6], Ryohei Sasaki[3]. *[1]South Valley University, Qena, Egypt,[2]Division of Radiation oncology, Kobe University Graduate School of Medicine, Kobe City, Japan,[3]Division of Radiation Oncology, Kobe University Graduate School of Medicine, Kobe City, Japan,[4]Graduate School of Engineering, Kobe University Graduate School of Engineering,, Kobe City, Japan,[5]Kobe University Graduate School of Science, Technology and Innovation,, Kobe City, Japan,[6]Graduate School of Engineering, Kobe University Graduate School of Engineering, Kobe City, Japan*

Background: Radiotherapy is widely used as the main treatment for multiple malignancies. However, several types of cancers, including pancreatic cancer, show resistance to radiation therapy. The presence of cancer stem cells (CSCs) are the major cause of radiation resistance in pancreatic cancer. Whereas, titanium peroxides nanoparticles (TiOxNPs) which are a modified form of titanium oxide nanoparticles promote enhanced remarkable efficacy of radiation therapy. Therefore, we examined the efficacy of TiOxNPs as radiosensitizers to eradicate pancreatic cancer stem cells.
Methods and materials: In vitro, Sphere-forming assay, survival assay, migration, and invasion assay were evaluated after using TiOxNPs prior to radiation exposure to pancreatic cancer cell line. In vivo, tumor-bearing nude mice were injected by TiOxNPs either intratumoral or intravenous one hour prior to radiation treatment, and the tumor volume, body weight, and

mice survival was calculated. In addition, proteins-related stemness were measured in vitro and in vivo to evaluate the usage of TiOxNPs as radiosensitizers to pancreatic CSCs. Moreover, we planned to evaluate the mechanism beyond the efficacy of TiOxNPs as radiosensitizers to CSCs by detecting reactive oxygen species (ROS) production, mitochondrial function, and the phosphorylation of some signaling proteins. We found that TiOxNPs combined with ionizing radiation showed anti-cancer effects on radioresistant CSCs both in vitro and in vivo.
Results: In vitro, a marked reduction in growth was detected after exposing the TiOxNPs-treated cells to radiation therapy, specifically with a 5Gy dose compared with 2Gy dose. TiOxNPs exhibited a synergistic effect with radiation on pancreatic CSC-enriched spheres by downregulating self-renewal regulatory factors and CSC surface markers. In vivo, we first established an aggressive xenograft by injecting MIA PaCa-2 sphere cells into the flank region of BALB/c nude mice, and found that animals treated with combined TiOxNPs and irradiation showed a dramatic reduction in tumor volume and weight compared to the untreated group. Moreover, combined treatment suppressed epithelial-mesenchymal transition, migration, and invasion properties in primary and aggressive pancreatic cancer cells by reducing the expression of proteins relevant to these processes. Radiosensitizing TiOxNPs suppressed pancreatic xenograft outgrowth after primary or dissociating sphere MIA PaCa-2 cell implantation. It is assumed that synergy is created by inactivating the AKT signaling pathway and producing unbearable amounts of ROS.
Conclusion: Our findings showed that using TiOxNPs in combination with radiation might be a favorable therapeutic approach to eradicate pancreatic CSCs.

Pb-203 image guided Pb-212 receptor targeted alpha particle therapy for cancer - a powerful emerging paradigm

Michael King Schultz[1], Yusuf Menda[2], Dijie Liu[3], Mengshi Li[3], Frances Johnson[3], Brianna Cagle[3], Nicholas Baumhover[3], Ivy Vance[3]. *[1]University of Iowa, Hills, IA,[2]University of Iowa, Iowa City, IA,[3]Viewpoint Molecular Targeting, Inc., Coralville, IA*

Objective: Pb-203 and Pb-212 have emerged as a promising elementally-matched theranostic pair for imaging-guided alpha-particle radiotherapy for cancer. A somatostatin receptor 2 (SSTR2)-targeted peptide coupled with novel Pb specific chelator (PSC) has been developed (PSC-PEG2-TOC). Here, preclinical *in vitro* and *in vivo* evaluation of ^{203}Pb/^{212}Pb-labeled PSC-PEG2-TOC was conducted including head to head therapy of SSTR2+ tumors in mice vs standard of care beta particle therapy and first in humans clinical imaging of SSTR2+ tumors.
Method: [^{203}Pb]PSC-PEG2-TOC and [^{212}Pb]PSC-PEG2-TOC was prepared by published methods. Radiochemical stability of [^{203}Pb]PSC-PEG2-TOC, [^{212}Pb]PSC-PEG2-TOC and [^{212}Bi]PSC-PEG2-TOC in human serum was determined. Binding affinity of [^{203}Pb]PSC-PEG2-TOC was determined by binding assays in AR42J cells. *In vivo* SSTR2-mediated tumor targeting of [^{203}Pb]PSC-PEG2-TOC was determined by SPECT imaging in athymic nude mice bearing AR42J xenografts. *In vivo* biodistribution of [^{212}Pb]PSC-PEG2-TOC in normal organs and potential redistribution of ^{212}Bi daughter were determined in CD-1 Elite mice. Clinical imaging was conducted under appropriate regulations to determine the biodistribution of the agent in patients bearing SSTR2+ tumors as determined by gold standard 68Ga-DOTATOC PET imaging.
Results: Rapid incorporation of ^{203}Pb and ^{212}Pb in PSC-PEG2-TOC was observed after reactions at temperatures as low as 4ºC within 15 min. Greater than 95% radiochemical stability was observed for both [^{203}Pb]PSC-PEG2-TOC and [^{212}Pb]PSC-PEG2-TOC after incubation in human serum for up to 55 hours. Stable decay product [^{212}Bi]PSC-PEG2-TOC with minimal free ^{212}Bi was observed. Agents demonstrated superior binding affinity to SSTR2 with K_d=0.59 nM. In *in vivo* studies, rapid tumor uptake and renal clearance of [^{203}Pb]PSC-PEG2-TOC were observed in athymic nude mice bearing AR42J xenografts. In the biodistribution study, nearly identical biodistribution profiles of [^{212}Pb]PSC-PEG2-TOC and progeny [^{212}Bi]PSC-PEG2-TOC were found. No redistribution of ^{212}Bi activity was identified, indicating that ^{212}Bi remained co-localized with parent [^{212}Pb]PSC-PEG2-TOC *in vivo*. Therapeutic studies in this same mouse model resulted in 100% complete responses for both a single dose 4.4 MBq administration of [^{212}Pb]PSC-PEG2-TOC or a fractionated

regimen of 4 x 1.1 MBq. First in humans clinical imaging showed PK properties that included rapid tumor accumulation and retention at over 20 h post administration, coupled with fast renal clearance of residual agent. Conclusion: [^{203}Pb]PSC-PEG2-TOC and [^{212}Pb]PSC-PEG2-TOC have promising potential for image-guide alpha-particle therapy for SSTR2 positive tumors. Agents have received a Fastrack designation by the US FDA and a safe to proceed for a Phase 1 trial.

Case report: A 17-year-old patient developed glioblastoma secondary to intracranial germ cell tumor and was stabilized with chemoradiotherapy combined with Tumor Treating Fields

Shaoqun Li, Mingyao Lai, Hainan Li, Juan Li, Jiangfen Zhou, Qingjun Hu, Minting Ye, Ruyu Ai, Junqiao Zhu, Lijun Huang, Linbo Cai. *Guangdong Sanjiu Brain Hospital, Guangzhou, China*

Background: Germ Cell Tumor (GCT) is a rare intracranial tumor occurring in children and young adults. Some patients with GCT are curable with radiotherapy and chemotherapy. Due to long-term survival, the tumor secondary to radiotherapy is of concern. The treatment of the secondary tumor is less elaborated and worth exploring.
Case Presentation: Here we report a patient with GCT who developed radiotherapy-induced glioblastoma. He was diagnosed as pineal gland GCT at the age of 12. Afterwards, he underwent a set of treatments, including chemotherapy, radiotherapy, and surgery. Unfortunately, after 5 years of tumor-free survival, he developed an intracranial mass involved the right thalamus and brainstem, around pineal region. The GCT recurrence was firstly considered, however, the failure of 7 cycles of chemotherapy drew attention. Then brain biopsy underwent by ROSA robot showed high-grade glioma. Next Generation Sequencing showed *IDH*-wildtype, *MGMT* methylation, *CDKN2A/B* homozygous deletion, *EGFR* amplification, the +7/−10 signature, which supported the diagnosis of glioblastoma. Resection operation is not applicable for this patient as the involvement of thalamus and brainstem. Considering the difficulty of treatment and poor prognosis of glioblastoma, re-radiotherapy is a feasible choice. Chemoradiotherapy with Tumor Treating Fields (TTFields) is a innovative try for secondary glioblastoma in a 17-year-old patient. After the combination therapy, the

intracranial mass went regression and the patient has lived for more than 1 years.
Conclusions: For the patients with brain tumor who anticipate long-term survival, the secondary tumor after radiotherapy is of concern. Secondary Glioblastoma is rare and difficult to treat. Chemoradiotherapy with TTFields is a feasible and safe treatment option for some patients, but we need more evidence to support.

Assessment of boron delivery peptides with angiopep-2 for boron neutron capture therapy
Qi Liu, Jing Xiang, Lin Ma, Qiushi Ren. *Shenzhen Bay Laboratory, Shenzhen, China*

Boron neutron capture therapy (BNCT) induces intracellular nuclear reactions that release heavy charged particles to destroy cancer cells during thermal neutron radiation. In order to selectively eliminate cancer cells but avoid harmful effects to normal tissues, targeted delivery of boron-10 in cancer cells is required, whereas the conventional boron delivery agent phenylalanine (BPA) is unsatisfactory. Angiopep-2 is a cell-penetrating peptide that can trigger transcytosis and traverse the blood-brain barrier by recognizing low density lipoprotein-related protein 1. In this study, we developed angiopep-2 for boron delivery in BNCT. Angiopep-2 was labeled with boron-10 using solid-phase peptide synthesis with 4-carboxyphenylboronic acid and fluorenylmethyloxycarbonyl (Fmoc)-protected amino acids, namely ANG-B. Molecular mass of the synthesized ANG-B were validated by mass spectrometry. In a cell proliferation assay, little toxicity of ANG-B was detected. Boron concentrations in 6 cell lines from different cancer types and an intracranial glioblastoma mouse model after treatment with ANG-B or BPA were analyzed by ICP-AES. The in vivo distribution of ANG-B showed that the ratio of boron content of tumor tissue to that of blood (T/B ratio) was 9.42±2.47 at 4h post treatment, while the ratio of boron content of tumor tissue to that of normal brain tissue (T/N ratio) was 5.61±1.0, demonstrated an optimal tumor targeting ability of ANG-B. We further measured the effects of ANG-B in BNCT by clonogenic cell survival assay in vitro or by PET/CT imaging on a glioblastoma mouse model in vivo. Radiation for BNCT was given with

neutron flux at $3.0\pm0.4\times10^{11}$ n/cm^2. BNCT with 5 mM ANG-B resulted in 86.5%±5.3% clonogenic cell death, while the number was 72.9%±5.1% for BPA. The effect of ANG-B based BNCT in vivo was also better than BPA. The glioblastoma tumors in ANG-B treated group at 31 days after BNCT were shrank by 62.9% in average, while the BPA treated tumors shrank by only 23.0% ($P<0.05$). Therefore, we concluded that ANG-B is an efficient boron delivery agent, which may improve BNCT performance in clinical trials.

IB-DNQ enhances radiation induced ferroptosis in NQO1-positive cancer cells

Xiumei Huang[1], Xiaolin Su[1], Matthew W. Boudreau[2], Paul J. Hergenrother[2]. *[1]Indiana University School of Medicine, Indianapolis, IN,[2]University of Illinois at Urbana-Champaign, Urbana, IL*

Cancer is the second leading cause of death worldwide. Current treatments for solid cancers are associated with inherent resistance mechanisms and are ineffective against non-cycling cancer cells. Thus, there is a critical need to develop novel tumor-selective combination therapies to overcome resistance while optimally spare normal tissues. In this study, we investigate the mechanistic basis for tumor-selective potentiation of ionizing radiation (IR) in combination with IB-DNQ, a novel NQO1-bioactivatable agent. We found that combination of a low dose of ionizing radiation (IR, 2 Gy) with a sublethal dose of IB-DNQ dramatically increased Fe^{2+} leakage and induced elevated lipid peroxidation and ferroptosis in NQO1-positive cancer cells via upregulating the expression of ACSL4, a lipid metabolism enzyme required for ferroptosis. Knockdown of endogenous ACSL4 significantly inhibited lipid peroxidation via downregulating the expression of PTGS2 and dramatically inhibited the cell death that induced by IR or IB-DNQ alone or combination treatment. We further found that this combination treatment significantly decreased IR or IB-DNQ alone mediated upregulation of the expression of GPX4 that led to the accumulation of lipid peroxides, which suggests that IR or IB-DNQ-induced expression of GPX4 may function as a negative feedback loop to restore cell survival upon a sublethal dose of IR or IB-DNQ treatment. Finally, we demonstrated that this combination therapy synergistically suppressed tumor growth and

dramatically extended mouse lifespan in orthotopic pancreatic and non-small-cell lung cancer xenograft models. Together, our study provides novel preclinical evidence for new combination therapy in NQO1-positive solid tumors that may overcome IR-induced resistance.

A critical role for copper in enhanced radioirdide uptake in thyroid cancer cells

Katie Brookes[1], Ling Zha[1], Jana Kim[2], Vinodh Kannappans[3], Weiguang Wang[3], Kavitha Sunassee[2], Philip J. Blower[2], Vicki E. Smith[1], Martin L. Read[1], Christopher J. McCabe[1]. *[1]Institute of Metabolism & Systems Research, University of Birmingham (UK), Birmingham, United Kingdom,[2]School of Biomedical Engineering & Imaging Sciences, King's College London, London, United Kingdom,[3]Research Institute in Healthcare Science, University of Wolverhampton, Wolverhampton, United Kingdom*

New drug approaches are urgently required to improve radioiodide (RAI) uptake for efficient ablation of thyroid cancer cells in RAI-refractory disease. Employing high-throughput screening of FDA-approved compounds we recently identified drugs capable of robust induction of sodium iodide symporter (NIS) activity to promote RAI uptake[1]. In particular, a leading drug candidate - the well-established anti-alcoholism drug disulfiram (DSF) - had not been previously implicated in regulating NIS. Here, we demonstrate that the ability of DSF to increase RAI-uptake in thyroid TPC-1 (3.1-fold; $p<0.01$) and 8505C (4.9-fold; $p<0.001$) cells can be significantly potentiated by combination with Cu^{2+} to 5.1-fold and 18.9-fold increases respectively. Despite promising data, DSF is known to have poor bioavailability *in vivo* due to its rapid metabolism to diethyldithiocarbamate (DDC) within the stomach and circulation with subsequent methylation in the liver. Whilst methylated-DDC did not have any effect on NIS function, DDC chelated to divalent copper ions [$Cu(DDC)_2$] was highly effective at increasing RAI uptake (up to 8-fold; $P<0.001$) in multiple thyroid cell types and induced significant NIS protein expression (up to 36.2-fold; 250nM; $P<0.001$). Importantly, $Cu(DDC)_2$ retained the ability to enhance NIS function in thyroid cells ablated for

expression of either VCP or its co-factor NPL4, indicating its effect on NIS was via VCP-independent pathways. Instead, a transcriptional effect of $Cu(DDC)_2$ was revealed by significant induction of NIS mRNA levels in TPC-1 (8.5-fold; $P<0.001$) and 8505C (104.8-fold; $P<0.001$) cells. In wild-type Balb/c mice the intraperitoneal administration of albumin nano-encapsulated $Cu(DDC)_2$ significantly induced thyroidal uptake of technetium-99m (^{99m}Tc) after 30 min (~40% increase; n=11 per group; 3 mg/kg dose; $P<0.001$). Thus, our study demonstrates a promising drug strategy utilizing copper to significantly enhance NIS function with clinical potential to improve treatment effectiveness in RAI-refractory thyroid cancer patients.

The study of synergy mechanism between surufatinib and vinorelbine in the treatment of non-small cell lung cancer

Xiaoran wu[1], Yanfang Zheng[1], Lingyu qin[1], Ying li[1], Zhongjian yu[1], Xiongjie zhu[1], Rui cai[1], Feiyu niu[1], Yan yuan[1], Peng jiang[1], Shaoshi wen[2], Xing lv[2], Jiancai zhou[2]. *[1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China,[2]Hutchison MediPharma Ltd, Shanghai, China*

Background: The incidence and mortality rate of lung cancer ranks first among malignant tumors. Non-small cell lung cancer (NSCLC) is the most common pathological type of lung cancer. Combined use of targeted therapy can enhance the efficacy of chemotherapy drugs while reduce the related side effects in clinical practice. Surufatinib is a potent, small-molecule tyrosine kinase inhibitor (TKI), selectively targeting VEGF receptors (VEGFR) 1, 2, and 3, Fibroblast growth factor receptor 1 (FGFR1), and CSF-1R, which simultaneously prevents tumor angiogenesis and tumor immune evasion. Our clinical study (NCT04922658) has showed the promising effect and safety of surufatinib plus vinorelbine in NSCLC

patients, but the potential mechanism is still to be revealed. Herein, tumor-bearing models and cancer cell culture platform would be established for further studying, which may shed light on the synergy mechanism between surufatinib and vinorelbine, and guide the clinical treatment ultimately. Methods: Subcutaneous tumorigenesis in nude mice were successfully established, and then treated with related experimental drugs. The tumor size was observed and CD31 expression of tumor tissue was measured using immunohistochemical analysis. In vitro study, the A549 and PC9 cell multiplication capacities were measured by CCK8 assay and plate cloning assay. The abilities of cancer cell migration and apoptosis were detected using cell scratch assay and flow cytometry kit, respectively. Results: Monotherapy with surufatinib or vinorelbine showed a moderate tumor suppression, whereas the combination therapy of surufatinib and vinorelbine showed the remarkable inhibition of tumor growth in vivo. Surufatinib and the combination therapy obviously decreased the expression of CD31 in tumor issue which might cause the anti-angiogenesis. Monotherapy with surufatinib or vinorelbine significantly inhibited the proliferation of lung cancer cells (A549 cells and PC9 cells) in a concentration-dependent manner, and surufatinib could memorably promote the anti-proliferation activity of vinorelbine. As a result, combination therapy of surufatinib and vinorelbine distinctly inhibited lung cancer cell proliferation when compared with monotherapy with vinorelbine. Consistently, the synergistic effects of surufatinib plus vinorelbine were also observed in cell migration and apoptosis analysis. Conclusions: Synergistic effect of surufatinib and vinorelbine resulted in a conspicuous tumor regression, which is consistent with the clinical observation. In a depth data analysis, surufatinib enhanced the antitumor activity of vinorelbine probably by inhibiting tumor cell proliferation and migration, suppressing tumor angiogenesis and promoting tumor apoptosis in NSCLC patients.

Targeting $BRAF^{V600E}$/$NRAS^{Q61K}$-melanoma brain metastases by pharmacological intervention modulating ER/redox stress and EMT

Jana Jandova, Sophia L. Park, Jeremy A. Snell, Georg T. Wondrak.
Pharmacology and Toxicology, R Ken Coit College of Pharmacy and UA Cancer Center, The University of Arizona, Tucson, AZ

Intracranial melanoma metastases originating from peripheral malignancy remain a frequent clinical condition with unsatisfactory pharmacological options. After screening a focused library of clinical artemisinin-combination therapeutic (ACT) antimalarials with established brain availability, we report here that an oral antimalarial regimen {(*R*,*S*)/(*S*,*R*)-[2,8-bis(trifluoromethyl)quinolin-4-yl]-piperidin-2-ylmethanol; BQPM} blocks (*i*) melanoma cell invasiveness and EMT-related gene expression and (*ii*) tumor growth in a bioluminescent murine model of BRAFi-resistant intracranial melanoma. First, we examined apoptotic elimination of cultured malignant melanoma cell lines, also examining feasibility of overcoming BRAFi-resistance comparing isogenic melanoma cells that differ only by NRAS mutational status (BRAFi-sensitive A375-$BRAF^{V600E}$/$NRAS^{Q61}$ versus BRAFi-resistant A375-$BRAF^{V600E}$/$NRAS^{Q61K}$). Among ACT antimalarials tested, BQPM was the only apoptogenic agent causing melanoma cell death at low micromolar concentrations. Comparative gene expression-array analysis (A375-$BRAF^{V600E}$/$NRAS^{Q61}$ versus A375-$BRAF^{V600E}$/$NRAS^{Q61K}$) revealed that BQPM is a dual inducer of endoplasmic reticulum (ER) and redox stress responses that precede BQPM-induced loss of viability. Moreover, we observed that BQPM treatment blocked EMT-related gene expression and phenotypic invasiveness in both BRAFi-sensitive and -resistant human cell lines, observable also in murine CNS-tropic Ret-melanoma cells. These data (combined with clinical evidence that documents brain availability of BQPM) suggest that blockade of brain metastasis and inhibition of intracranial tumor growth, even if BRAFi-resistant, can be achieved using BQPM as a repurposed ACT-antimalarial.

ABN401 demonstrates robust anti-tumor efficacy in orthotopic PDX models of MET-driven NSCLC brain metastases in a pre-clinical study

Nirmal Rajasekaran[1], Kyung Eui Park[1], Saehyung Lee[1], Na Young Kim[1], Suk-Jae Chung[2], Young Kee Shin[3], Jun Young Choi[1]. *[1]ABION INC., Seoul, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of,[3]Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of*

Background Brain metastases (BM) are manifested in approximately 30-50% of patients with non-small cell lung cancer (NSCLC) and are associated with catastrophic implications on prognosis and survival. The development of blood-brain barrier-penetrant therapies for brain metastases of NSCLC is imperative and is a major clinical hurdle. ABN401, a highly potent and selective c-MET inhibitor, shows promising anti-tumor activity without significant safety concerns in patients with advanced NSCLC. Here, we report that ABN401 exhibits potent anti-tumor efficacy in pre-clinical orthotopic patient-derived xenografts (PDXs) derived from MET-driven NSCLC brain metastases.
Methods Anti-tumor efficacy of ABN401 was assessed in two lung cancer PDXs (LU5349 and LU5406) from BM models harboring high-level MET amplification grown in NOD/SCID mice. Subcutaneous PDXs (n=14/group) were treated with ABN401 (60 mg/kg QD, 125 mg/kg QD, and 165 mg/kg QD) or control groups. Established PDXs were orthotopically implanted into the brain (n=14/group) and were treated with ABN401 (125mg/kg QD), or control groups. The tumor volume of orthotopic model was monitored using magnetic resonance imaging (MRI). Brain, plasma, and tumor samples were collected for pharmacokinetics (PK) and pharmacodynamics (PD) correlation analysis.
Results The efficacy of ABN401(125 mg/kg QD) was confirmed in the subcutaneous PDX models (LU5349 and LU5406). Treatment with ABN401 showed up to 95% and 99% tumor growth inhibition in the LU5349 and LU5406 models, respectively. ABN401 (125 mg/kg QD) treatment induced complete or near-complete tumor growth regressions in the orthotopic tumor model. ABN401 also showed a desirable PK and safety profile with no significant changes in body weight.
Conclusions ABN401 treatment showed robust anti-tumor efficacy in PDX models of MET-driven NSCLC brain metastases. Our findings suggest that ABN401 has excellent potential for treating NSCLC patients with BM and supports its ongoing clinical development.

Impact of dexamethasone on chemotherapy response in ovarian cancer

Annapoorna Venkatachalam[1], Cristina Correia[1], Cordelia D. Mcgehee[2], Sarah Finstuen-Magro[3], Jamison VanBlaricom[3], Paula A. Schneider[4],

Kevin L. Peterson[4], Ethan P. Heinzen[5], Melissa C. Larson[6], Xiaonon Hou[3], Ann L. Oberg[7], Saravut John Weroha[8], Scott H. Kaufmann[9]. *[1]Molecular Pharmacology and Experimental Therapeutics, Division of Oncology Research, Mayo Clinic, Rochester, MN,[2]Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic, Rochester, MN,[3]Oncology Research, Mayo Clinic, Rochester, MN,[4]oncology Research, Mayo Clinic, Rochester, MN,[5]4Division of Computational Biology, Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[6]Division of Computational Biology, Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[7]4Division of Computational Biology, Department of Quantitative Health Sciences, Research, Mayo Clinic, Rochester, MN,[8]Medical Oncology, Mayo Clinic, Rochester, MN,[9]Department of Molecular Pharmacology and Experimental Therapeutics; Oncology Research;Hematology, Mayo Clinic, Rochester, MN*

Background: Ovarian cancer ranks fifth in cancer deaths among women. The gold standard of care for advanced disease includes cytoreductive surgery along with adjuvant or neoadjuvant platinum/taxane-based chemotherapy. Although response to this treatment is high, chemotherapy-induced nausea and vomiting due to platinum agents and allergic reactions due to both agents are common. For nearly half a century, the glucocorticoid (GC) dexamethasone (DEX) has been administered as part of supportive care. However, there have periodically been questions about the possible deleterious effects of DEX on chemotherapy response, especially in solid tumors.
Methods: Platinum-sensitive, glucocorticoid receptor (GRα) expressing ovarian cancer cells were exposed to DEX prior to chemotherapy and clonogenic survival was assessed. The effects of DEX on cell cycle and apoptosis were assessed by flow cytometry. Changes in the tumor cell transcriptome after acute DEX treatment were determined by RNA sequencing. Mice bearing orthotopic ovarian cancer patient-derived xenografts (PDXs) were treated with chemotherapy ± DEX to assess changes in chemotherapy response *in vivo.*
Findings: DEX pre-treatment decreased platinum cytotoxicity in ovarian cancer cell lines *in vitro* and diminished platinum response in some PDXs analyzed for chemotherapy response *ex vivo*. RNA-seq analysis revealed

changes in transcripts encoding proteins involved in platinum detoxification and TNFα pro-survival signaling. In ovarian cancer PDXs, DEX decreased platinum response in one model and had limited impact on both platinum and platinum/taxane chemotherapy in three distinct studies.
Interpretation: DEX appears to modulate chemotherapy response in some settings *in vitro* and *ex-vivo*. The impact of DEX on chemotherapy response *in vivo* appears to be limited. However, further investigation of this question *in vivo* in non-immunosuppressed murine models appears warranted.

High-throughput monitoring of proteoforms and pathways through multiplexed and customizable mass spectrometry assay panels
Sebastian Müller, Véronique Laforte, Simonas Savickas, Maik Müller, Yuehan Feng, Lukas Reiter. *Biognosys AG, Schlieren, Switzerland*

Proteins represent a key class of analytes in pharmacodynamic (PD) analysis, an essential component in preclinical and clinical studies which inform about a biological system's response to drug treatment. Pharmacodynamic signatures typically comprise target engagement marker and downstream pathway markers. With recent development in targeted therapies and novel therapeutic modalities such as protein degraders, the scope of PD has widened to cover predictive and stratification biomarkers which can inform patient selection and contribute to further understanding of potential drug resistance.
Using peptides as surrogate for proteins of interest, mass spectrometry (MS)-based approach alleviates the barriers of reagent specificity of antibody-based methods which can be affected by species and matrices used in preclinical drug development. Moreover, the use of stable-isotope labeled standard (SIS) reference peptides grants targeted MS assays unraveled specificity and the ability to determine absolute quantity of a given analyte. Harnessing the power of targeted MS, we present an oncology-focused assay repository which contains 804 peptides corresponding to 582 proteins. All 804 peptide surrogates were chosen under strict selection criteria such as uniqueness/proteotypicity and stability. Off-the-shelf availability (PQ500 kit) of SIS reference peptides for all 582 proteins facilitates the deployment of any of these assays in a plug-and-play manner. The collection of 582 protein targets cover > 180 cellular pathways

(Reactome pathways e.g. cytokine signaling, cell-cell communication, activation of matrix metalloproteinases) together with 49 FDA-approved drug targets. To further evaluate the performance of these assays, we carried out a case control study comprising plasma samples from 5 patient groups (lung, colorectal, pancreatic, breast and prostate cancer) and age and gender-matched healthy subjects. In total, we measured absolute quantities of 582 proteins across 180 plasma samples while validating the expression profiles of well-characterized biomarkers in patient plasma.
To conclude, we've demonstrated the application of targeted MS approach for the routine analysis of pharmacodynamic biomarkers. Its multiplexing capability, together with the adaptability to various species allow this method to maneuver through preclinical and clinical scenarios.

Tucatinib does not alter oxaliplatin PK or associated renal function: An OCT2 and MATE transport inhibition study

Ariel R. Topletz-Erickson[1], Anthony Lee[2], Vineet Kumar[2], Michelle Ubowski[3], JoAl G. Mayor[3], Layth I. Abdulrasool[3], Clark M. Henderson[2], Joseph A. Ware[4], Christopher J. Endres[1]. *[1]Clinical Pharmacology and Pharmacometrics, Seagen, Bothell, WA,[2]Translational ADME and PKPD, Seagen, Bothell, WA,[3]Clinical Development, Seagen, Bothell, WA,[4]Clinical Pharmacology and Pharmacometrics, Seagen, South San Francisco, CA*

Background**:** Oxaliplatin (OX)-containing regimens are frequently utilized to treat gastrointestinal (GI) cancers. OX is eliminated predominately via urinary excretion (GFR and active tubular secretion). The contribution of active transport via OCT2 and MATE1/2-K to OX clearance is not fully understood. Tyrosine kinase inhibitors (TKIs) are frequently found to interact with OCT2/MATE transporters; however, a gap in knowledge remains between their clinical potential to impact OX pharmacokinetics (PK) and in turn, impact renal function. Tucatinib (TUC) is a highly selective human epidermal growth factor receptor 2 (HER2)-directed TKI approved in multiple regions in combination with trastuzumab and capecitabine for adult patients with metastatic HER2+ breast cancer and is currently being investigated in other HER2+ tumors. TUC inhibits OCT2/MATE-mediated transport of metformin and creatinine in vitro and

in vivo. In this study, we investigated the impact of TUC on OX plasma PK, OX renal clearance (Clr), and renal function.
Methods: In vitro inhibition of OCT2/MATE-mediated transport of OX by TUC was assessed in OCT2, MATE1, or MATE2-K-expressing MDCK-II cells. SGNTUC-024 (NCT04430738) is a Ph1b/2 clinical study in patients with HER2+ GI cancers evaluating the impact of TUC on the safety and PK of OX. Patients received TUC 150 mg (Cohort 1A) or 300 mg (Cohort 1B) BID starting on C1D8 of a 2-week cycle in combination with modified FOLFOX6/7. Intensive PK was collected in plasma and urine for OX alone (C1D1) or with steady-state TUC (C2D1). Total plasma platinum (Pt, analyzed as a surrogate for OX and catabolites), plasma Pt ultrafiltrate (PUF, unbound), and urine Pt were quantitatively analyzed via ICP-MS. Serum Cystatin C (CysC) was measured as a pharmacodynamic (PD) renal function marker in Cohorts 1A and 1B.
Results: TUC inhibited in vitro OX transport by MATE1 (IC_{50} = 0.0639 μM), MATE2-K (IC_{50} = 0.0382 μM), and OCT2 (IC_{50} = 0.491 μM). In 11 patients, total Pt and PUF $AUC_{0\text{-}8h}$ geometric mean ratio (GMR) and 90% confidence intervals (CI) between patients who received OX alone compared to in combination were 1.1 (0.98, 1.3) and 1.0 (0.78, 1.4) in Cohort 1A (n=4) and 1.1 (0.96, 1.2) and 1.0 (0.98, 1.1) in Cohort 1B (n=7), respectively. OX GM (%CV) renal clearance ($Cl_{r,0\text{-}8h}$ in mL/min) and fraction excreted 24h post-dose ($f_{e,0\text{-}24h}$) were similar with and without TUC in both Cohort 1A (C1D1 $Cl_{r0\text{-}8h}$ = 277 (33), $f_{e,0\text{-}24h}$ = 22% (17); C2D1 $Cl_{r0\text{-}8h}$ = 249 (78), $f_{e,0\text{-}24h}$ = 21% (15)) and Cohort 1B (C1D1 $Cl_{r0\text{-}8h}$ = 189 (37), $f_{e,0\text{-}24h}$ = 17.7% (16); C2D1 $Cl_{r0\text{-}8h}$ = 177 (40), $f_{e,0\text{-}24h}$ = 16.6% (35)). Reversible slight increases in CysC (normalized to baseline) on day 3 of each cycle, irrespective of tucatinib, were observed.
Conclusions: This investigation of in vitro and in vivo determinants of OX PK demonstrates that TUC does not alter the renal clearance of oxaliplatin nor renal function when OX is administered in combination with TUC.

Toxicological characterization and comparison of ATR inhibitors in mice
Joshua J. Deppas[1], Brian F. Kiesel[1], Jianxia Guo[2], Lora H. Rigatti[3], Joseph Latoche[4], Anthony Green[5], Paul Knizner[5], Christopher J. Bakkenist[6], Jan

H. Beumer[1]. *[1]Pharmaceutical Sciences, University of Pittsburgh, Pittsburgh, PA,[2]Cancer Therapeutics Program, UPMC Hillman Cancer Center, Pittsburgh, PA,[3]Division of Laboratory Animal Resources, University of Pittsburgh, Pittsburgh, PA,[4]Medicine, University of Pittsburgh, Pittsburgh, PA,[5]Biospecimen Core Research Histology, University of Pittsburgh, Pittsburgh, PA,[6]Radiation Oncology, University of Pittsburgh, Pittsburgh, PA*

Cancer is often treated with DNA-damaging cytotoxic and ionizing radiation (IR) therapies. However, anticancer efficacy is limited by activation of DNA damage response (DDR) pathways that support DNA repair resulting in cancer cell survival. Disruption of DDR pathways may enhance cancer cell sensitivity to DNA-damaging therapies. Ataxia telangiectasia and Rad3 related (ATR) protein kinase, an apical initiator of DDR, is highly relied on by tumor cells and is critical for survival. Pharmacological ATR inhibitors (ATRi) can sensitize cancer cells to DNA damaging therapies. Although combining radiation therapies with ATRi may enhance anticancer efficacy, the resultant toxicity to normal organs is largely unknown. The ATRi furthest in development are the orally administered AZD6738 (ceralasertib), BAY-1895344 (elimusertib) and the intravenously administered M6620 (berzosertib, VX-970). We aimed to characterize and compare the preclinical toxicity of ATRi with and without total body irradiation (TBI) by pathology and complete blood counts (CBC). To determine the appropriate TBI dose for combination with ATRi, female balb/c mice (n=6) were grouped to receive 2, 4, 6 or 8 Gy. Within these cohorts, mice (n=2) were subdivided for euthanization times of 48, 72 and 96 h post TBI. Next, mice (N=5) were treated with a single dose of ATRi, 6 Gy TBI, the combination (TBI within 30 min of ATRi), or control. Mice were euthanized 48 h post treatment and blood was collected for analysis of CBC. Changes to body weight were documented and tissues with known sensitivities to radiation-related toxicity were collected for histopathology. Statistical analyses were performed using ANOVA with Tukey's multiple comparisons test. A 6 Gy TBI dose and 48 h euthanasia time point were selected for investigation in combination studies with ATRi. TBI alone resulted in ~5% decreased body weight compared to vehicle controls. The addition of any ATRi appeared to ameliorate this loss,

but not to a significant extent. TBI caused leukocytopenia and lymphocytopenia, which was not exacerbated by the addition of any ATRi. Neutrophilia was observed after ATRi alone and abolished by addition of TBI. TBI caused moderate toxicity in spleen, small intestine and bone marrow, and the addition of ATRi did not exacerbate these findings. AZD6738 caused moderate pericarditis and myocarditis, which was abrogated by the addition of IR. Collectively, ATRi administered alone are associated with neutrophilia at 48 h. AZD6738 appeared to be associated with cardiac toxicity, consistent with clinical observations of related CHK1 inhibitors. M6620 alone is associated with a significant decrease in lymphocytes compared to vehicle control, however in the setting of TBI, M6620 appears to ameliorate TBI-induced lymphocytopenia. This study demonstrated that the addition of ATRi did not increase toxicity associated with TBI in mice.

Small molecule superoxide dismutase mimetic avasopasem manganese for the mitigation of cisplatin induced ototoxicity

Keegan A. Christensen[1], Osama Tarabichi[1], Sei Sho[1], Hidaly Hernández[2], Bryce Hunger[1], Melissa A. Fath[1], Jeffery Keene[3], Robert Beardsley[3], Marlan Hansen[1], Douglas R. Spitz[1]. *[1]Carver College of Medicine, University of Iowa, Iowa City, IA,[2]Wartburg College, Waverly, IA,[3]Galera Therapeutics, Malvern, PA*

Introducti**on**: Avasopasem manganese (GC4419) is a selective superoxide dismutase mimetic which has recently completed a Phase 3 clinical trial (NCT03689712) demonstrating a significant reduction in the severity of oral mucositis in patients receiving standard cisplatin and radiotherapy for head and neck squamous cell carcinoma (HNSCC). Up to 66% of HNSCC patients experience ototoxicity from platinum-based chemotherapy, resulting in tinnitus and hearing loss. The analysis of clinical trial data also revealed that patients treated with GC4419 in addition to cisplatin (cis) and radiotherapy reported less tinnitus than those treated with standard therapy alone. The generation of reactive oxygen species has long been recognized as an important contributor to cis-induced hearing loss; therefore, we hypothesize that administration of GC4419 with cisplatin can prevent ototoxicity by scavenging superoxide.

Results: Organotypic cultures using postnatal day 2 or 3 mouse cochlea were treated with cis 4 μM and 0.5, 2, or 4 μM GC4419 for 24 hours. The explants were then stained for anti-myosin-VIIa. Hair cells were counted, and it was determined that 4 μM cis was sufficient to cause a decrease in hair cell numbers and GC4419 dose as low as 2 μM protected against this biological endpoint. To assess the effects of GC4419 on hearing loss *in vivo*, CBA/CaJ mice were treated as follows: 5 mice (1 female, 4 males) received 3 mg/kg cis IP, 4 mice (2 males and 2 females) received vehicle, 3 mice (2 females, 1 males) received 10 mg/kg IP GC4419, and 5 mice (2 females, 3 males) were treated with GC4419 10 minutes prior to cisplatin injection. Cis and GC4419 were administered for four consecutive days followed by two days of GC4419. The animals were allowed 8 recovery days, with Normosol SQ and high calorie food administered, prior to a second repetition of the treatment cycle. This protocol for cis dosing was found to be lethal in three mice in the cisplatin only group. Auditory brainstem response testing was performed before and after treatment, revealing elevated hearing thresholds in cis treated mice but not in mice treated with GC4419 and cis. Additionally, the cis treatment group experienced greater weight loss than the mice treated with GC4419 and cis Separately, in an H1299 tumor xenograft model in nu/nu mice, GC4419 5 mg/kg IP BID over 14 days was shown not to interfere with, and in fact somewhat increased, the tumor growth delay with cis 5 mg/kg IP QW x 3. **Conclusion**: These results support the hypothesis that treatment with the SOD mimetic GC4419 can reduce cis induced ototoxicity by scavenging superoxide and justify further studies to determine if this mechanism based approach can be implemented in cancer therapy. (Supported by a sponsored research agreement between the University of Iowa and Galera Therapeutics, Inc.)

Optimizing benefit/risk in oncology: Review of post marketing dose optimization

Pooneh Soltantabar, Hoi-Kei Lon, Kourosh Parivar, Diane Wang, Mohamed Elmeliegy. *Pfizer, Inc., San Diego, CA*

Introducti**on:** Molecularly targeted (MTAs) and immune-oncology (IO) agents are more selective with wider therapeutic window than cytotoxic

agents resulting in maximal activity at doses < MTD. However, these agents commonly selected the MTD (or highest tested dose) which is assessed using dose-limiting toxicities in escalating doses in limited number of patients/dose. This led to several post-marketing requirement (PMR) studies to evaluate alternative dosing regimens to optimize the benefit-risk.
Methods: Post-marketing dose optimization studies (required by FDA or sponsor initiated) for oncology MTAs/IO agents were reviewed. These studies/analyses were classified in to attempts to improve efficacy, safety, or 'life cycle management' (ie, fixed vs body size-based dosing, favorable route of administration, or extending the dosing interval). Approvals 1999-April/2022 were evaluated using FDA review documents and published literature. PMR studies for organ impairment, DDI, or food effect were excluded.
Results: Overall, 27 (16 MTAs and 9 IO) out 126 FDA oncology approvals reviewed were identified to have conducted post-approval dose optimization studies (27/126, 21.4%). Dose optimization studies were either efficacy-driven (n = 4), safety-driven (n = 13), or to improve method of administration (ie, IV to SC route; body-weight to fixed dosing; less dosing frequency) (N = 14). Efficacy-driven PMRs evaluated a higher dose either for the overall population (1/4) or for a subgroup with lower exposure (3/4); the latter cases showed no clear benefit in this subgroup vs case-matched subgroup from the control arm. No changes of label dosing recommendations resulted from efficacy-driven PMRs. All safety-driven PMRs which evaluated lower doses were for drugs with a positive exposure-safety relationship and most had a flat exposure-efficacy relationship (9/13, 69%) suggesting that a lower dose might improve safety without compromising efficacy. Completed safety-driven PMR studies resulted in changing the approved dose in 2/7 cases (29%). Lower doses were commonly associated with better safety profiles, however, establishing efficacy non-inferiority vs approved doses was typically not successful except in 1 case where non-inferiority was met for the primary endpoint of overall survival; this did not lead to label change as secondary endpoints, eg, PFS, favored the higher dose.Attempts to improve method of administration tended to be feasible and resulted in a successful change of the label dose for drugs with relatively flat exposure-efficacy and safety profiles and with adequate efficacy/safety data at multiple dose levels.

Conclusion: Our results suggest that safety or efficacy-driven post-marketing dose optimization studies were rarely successful in changing the label dose. Dose optimization could be more important for drugs with a steep exposure-safety relationship and a flat exposure-efficacy relationship.

Tyrosine Kinase and Phosphatase Inhibitors 1

Targeting drug-resistant acute myeloid leukemia (AML) cells using novel casein kinase II (CK2) inhibitor

Koby Duke[1], Katherine Mercer[2], Rajesh Rajaiah[1], Muhammad Daniyal[1], Yi Qiu[1], Ashok Purandare[3], Yasin Uzun[1], Lijun Zhang[4], Morgann Klink[4], Chandrika Gowda[1]. *[1]Pediatrics, Penn State Hershey - College of Medicine, Hershey, PA,[2]Penn State Health Milton S. Hershey Medical Center, Hershey, PA,[3]Bristol-Myers Squibb, Princeton, NJ,[4]Penn State Hershey - College of Medicine, Hershey, PA*

Introduction: Protein Kinase CK2 level and activity are high in Acute Myeloid Leukemia (AML) stem cells. Genetic inhibition of CK2 promotes apoptosis and shows synergistic cytotoxic activity with cytotoxic therapy. Here we report the anti-leukemia efficacy of a novel and potent small molecule inhibitor of CK2, BMS-135, in AML mouse models.
Methods: AML cell lines (n=8) and primary AML cells (n=3) representing various AML genetic subtypes (MLL rearranged, FLT3-ITD, TP53 mutation) were tested in vitro. Cells were treated with serial dilution of BMS-135 for 24 to 48hrs, and cell viability was measured using calorimetric cell viability (WST) assay. Similarly, treated cells were analyzed for cell cycle distribution, apoptosis, and colony formation. We measured the mRNA and protein levels of known CK2 targets. RNA sequencing and gene expression analysis was done to evaluate gene expression changes following treatment with BMS-135. Cell line-derived xenograft and patient-derived xenograft of AML were treated with BMS-135 at a dose of 7.5mg/kg oral gavage twice daily for 21 days or vehicle.
Results: Combined *in vitro* and *in vivo* experiments establish the efficacy of BMS-135. Cytotoxicity at inhibitory concentrations of 30-800nM, G0-G1 cell cycle arrest, increased apoptosis, and poor colony formation following treatment were noted consistently in all cells. Single-drug treatment with

BMS-135 achieved 50-80% leukemia inhibition and significantly prolonged survival in treated mice after 3 weeks of therapy. Following in vivo treatment with BMS-135, we confirmed the inhibition of known CK2 targets (AKT, PI3K, Bcl-xL) in the bone marrow and spleen AML cells. No significant myelosuppression or organ toxicity was noted in tumor-bearing mice following 3 weeks of treatment when compared to vehicle-treated mice. BMS-135 shows synergistic cytotoxic activity with daunorubicin and cytarabine.
Conclusions: Selective inhibitor of CK2 is well tolerated and shows superior in vivo efficacy and target inhibition in a series of AML cells and xenografts. BMS-135 works synergistically with cytotoxic agents like daunorubicin and cytarabine. These results support further pre-clinical characterization and clinical development of BMS-135 for treating AML in combination with cytotoxic therapy.

#4005

PH009-1, a highly potent and selective fourth-generation EGFR-TKI overcoming EGFR common mutations and T790M/C797S-mediated resistance in NSCLC

Feng Gao[1], Bin Liu[1], YongYong Wu[1], Liandong Jing[1], Pengzhi Zhang[1], Jing Wang[1], Shuai Yuan[1], Hui Zhao[1], Yu Gao[1], Zhizhong Li[2], Xiaofan Wang[3], Yongqi Guo[1]. *[1]Puhe Biopharma, Beijing, China,[2]Shiyu Children Foundation, Beijing, China,[3]Duke University Medical Center, Durham, NC*

Background: Epidermal growth factor receptor (EGFR) activating mutations have been reported in 10-50% of patients with non-small cell lung cancer (NSCLC). The common mutations, ex19del (D) and L858R (L) substitution, are sensitive to first- and second-generation EGFR-TKIs. However, acquired on-target resistance, especially T790M (T) mutation, comprises the anti-tumor effects of these inhibitors. Though the third-generation EGFR-TKI Osimertinib potently inhibits both EGFR common mutations and T790M mutation, 10-24% of patients acquire C797S (C) resistant mutation. Here, we report a highly potent and selective fourth-generation EGFR-TKI, PH009-1, designed to overcome both EGFR common mutations and T790M/C797S-mediated resistance in NSCLC.
Methods: Kinase selectivity of Ph009-1 was assessed by KINOMEscan against 468 human kinases. A functional safety panel including 47 targets

contributing to clinical adverse drug reactions was used to evaluate pharmacological profiling of PH009-1. Biochemical enzyme activities were detected with kinase assays and anti-proliferative activities were measured in various tumor and engineered Ba/F3 cell lines. The *in vivo* anti-tumor efficacy was tested in four cell derived xenograft (CDX) mouse cancer models with tumor harboring single, double or triple mutant EGFR. The *in vitro* and *in vivo* pharmacokinetic (microsome metabolic stability, hepatocyte metabolic stability, plasma protein binding, drug-drug interaction, oral absorption, et al) and safety properties (hERG potassium channel assay, Ames assay, repeated dosing study, et al) of PH009-1 were assessed in various species with corresponding assay methods.
Results: High kinase selectivity and very low off-target effects were observed in KINOMEscan and safety panel assays, respectively. PH009-1 inhibited kinase activity of all tested EGFR mutants with IC_{50}<4 nM. Furthermore, PH009-1 displayed potent anti-proliferation activity against Ba/F3 (EGFR L, D, LC, DC, DT, LTC, DTC) with IC_{50} of 3.6, 3.1, 1.6, 1.7, 0.3, 3.9, 3.1 nM, respectively. Excellent selectivity of PH009-1 was observed when compared the above values to IC_{50} against Ba/F3 (WT, 93.3 nM), A431 (WT, 2415 nM), LoVo (WT, 3700 nM) and NCI-H23 (WT, 2359 nM). In all four CDX cancer models including HCC827 (D), Ba/F3 (DC), Ba/F3 (LC) and Ba/F3 (DTC), PH009-1 at a dose of 40 mg/kg BID induced tumor regression or eradication without significant effect on mouse body weight. Favorable pharmacokinetic and safety profiles were suggested in *in vitro* and *in vivo* pharmacokinetic and safety evaluations.
Conclusion: The present data suggest that PH009-1 is a promising and highly selective fourth-generation EGFR TKI with potent *in vitro* and *in vivo* activity against single, double and triple EGFR mutations including T790M and C797S.

#4006

TRX-221, a novel 4th-generation EGFR inhibitor for overcoming C797S mutation-mediated acquired resistance in NSCLC

Sumin Lim[1], Seulgi Choi[1], Ju-Kyung Lee[1], Eunhyun Choi[1], Sungwon Lee[1], Kwangwoo Chun[1], Myoungki Baek[1], Jiyeon Park[1], Jihyun Kim[1], Areum Kang[1], Younghoon Kim[2], Namkyoung Kim[2], Byoungchul Cho[3], Taebo Sim[2], Koo Lee[1]. *[1]Therapex Co., Ltd, Seoul, Korea, Republic of,[2]Sevrance*

Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Targeting mutated EGFR is a clinically validated approach for tackling non-small cell lung cancer (NSCLC). Approximately 20% of patients with advanced NSCLC harbor an EGFR mutation. Osimertinib is a 3rd-generation oral EGFR-TKI targeting the EGFR sensitizing mutations Del19 and L858R, as well as an acquired mutation, T790M. Despite osimertinib's efficacy in NSCLC, resistance develops and the mechanisms of resistance to osimertinib are complex. Development of another mutation, C797S is the most common mechanism of acquired resistance following osimertinib treatment. This mutation occurs with about 12% frequency after a 1L therapy of osimertinib, and with approximately 17% frequency after a 2L therapy. Here, we report TRX-221 as a novel 4th-generation EGFR-TKI that can overcome C797S-mediated acquired resistance in NSCLC models in vitro and in vivo. TRX-221 exhibited potent inhibitory activity against multiple EGFR mutant kinases, including Del19/T790M/C797S, L858R/T790M/C797S, Del19/C797S, L858R/C797S, Del19/T790M, L858R/T790M, Del19, and L858R. Likewise, TRX-221 potently inhibited the proliferation of Ba/F3 cells stably overexpressing these eight EGFR mutants. TRX-221 however showed sparing activity against EGFR wild-type kinase and cell lines. TRX-221 also demonstrated marked anti-proliferative activity against osimertinib-resistant patient-derived cancer cell lines (PDCs). With favorable DMPK profiles, once-daily oral dosing of TRX-221 induced strong anti-tumor effects in a dose-dependent manner in a variety of osimertinib-resistant CDX and PDX models. As a reversible, selective, and broad-spectrum 4th-generation EGFR-TKI, TRX-221 is currently undergoing IND-enabling studies and shows strong potential as a therapeutic solution to treat advanced NSCLC patients harboring EGFR mutations.

#4007

Efficacy of vepafestinib in preclinical models of *RET* fusion-driven sarcoma models

Igor Odintsov[1], Ryan C. Cheng[2], Allan J. W. Lui[3], Tom Zhang[4], Yue C. Lu[4], Renate I. Kurth[4], Morana Vojnic[5], Inna Khodos[4], Qing Chang[4], Kevin

Chen[4], Claudio Giuliano[6], Annalisa Bonifacio[6], Isao Miyazaki[7], Elisa de Stanchina[4], Emanuela Lovati[6], Marc Ladanyi[4], Romel Somwar[4].
[1]Pathology, Brigham and Women's Hospital, Boston, MA,[2]Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Cancer Research UK, Cambridge, United Kingdom,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]Northwell Health, New York, NY,[6]Helsinn Healthcare, Lugano, Switzerland,[7]Taiho Pharmaceutical Co. Ltd, Ibaraki, Japan

Background: Vepafestinib (TAS0953/HM06, Vepa) is a 2nd generation RET-selective inhibitor that effectively penetrates the brain, and inhibits the wildtype RET kinase domain (KD) and RET KD mutants (G810, V804, Y806, L730) (presented at AACR-NCI-EROTC 2021 meeting). *RET* rearrangements are found in an increasing number of soft tissue sarcomas, including infantile fibrosarcoma (IFS). Here we investigated the efficacy of Vepa in comparison to other RET-selective inhibitors in preclinical models of pediatric sarcomas harboring *RET* fusions.
Methods: Multiple preclinical models of *SPECC1L::RET*-driven sarcomas were established: 1) Paired patient-derived xenograft (PDX) and cell line models from a brain metastasis (BM) of an IFS tumor (SR-Sarc-0001); 2) A human mesenchymal stem cell line with RET fusion introduced with CRISPR-Cas9 (HMSC-RET); 3) A murine BM model produced by injection of luciferase-expressing HMSC-RET into the cerebellum. CNS penetration of Vepa was assessed by pharmacokinetic profiling in the prefrontal cortex (PFC), cerebrospinal fluid (CSF), and plasma in freely-moving male Han Wistar rats after oral administration of 3, 10, or 50 mg/kg single doses.
Results: Exposure of SR-Sarc-0001 and HMSC-RET cells to Vepa resulted in dose- and time-dependent decreases in phosphorylation of RET, ERK1/2, AKT, STAT3 and S6, expression changes in cell cycle regulators (p27 up, cyclin D1 down), induction of pro-apoptosis proteins (c-PARP, BIM), and loss of MYC expression. Growth of SR-Sarc-0001 (IC_{50}: 0.09 μM, 95% CI: 0.03-0.2) and HMSC-RET cells (IC_{50}: 0.2 μM, 95% CI: 0.09-0.5), but not parental HMSC cells (IC_{50} > 1 μM), was suppressed by Vepa, with concomitant elevation of caspase 3/7 activity. Vepa was more effective than vandetanib and similar to the FDA-approved RET inhibitors, selpercatinib

(Selp) and pralsetinib (Pral), in all *in vitro* assays. Significant regression of SR-Sarc-0001 PDX tumors was seen after Vepa treatment (64.8 ± 0.5%). Notably, no regrowth was observed up to 46 days after cessation of Vepa treatment, whereas 25 days after stopping Selp (10 mg/kg BID) and Pral (15 mg/kg BID) treatment, 1/5 and 3/5 tumors started to regrow, respectively. Similar efficacy was observed in the HMSC-RET xenograft model. Vepa was more effective than Selp at blocking HMSC-RET brain xenograft tumor growth (p=0.001) and increasing survival (p=0.0001). CNS penetration of Vepa was excellent, with near-equivalent concentrations detected in the PFC, CSF, and plasma-free fraction after equilibration between body fluid compartments.
Conclusions: Our preclinical results suggest that vepafestinib has the potential to more effectively manage CNS metastasis compared to selpercatinib, representing a promising new therapeutic option for patients with RET-driven sarcomas. Vepafestinib is currently in a phase 1/2 trial for adult patients with advanced solid tumors harboring *RET* alterations (margaRET, NCT04683250).

#4008

TAS2940, a novel brain-penetrable pan-ERBB inhibitor, exhibits tumor regression and prolongs survival in intracranial models bearing ERBB aberrations

Kei Oguchi, Hikari Araki, Shingo Tsuji, Masayuki Nakamura, Akihiro Miura, Kaoru Funabashi, Akiko Osada, Sakiho Tanaka, Takamasa Suzuki, Shinji Mizuarai. *Discovery and Preclinical Research Division, Taiho Pharmaceutical Co., Ltd, Tsukuba, Japan*

Background: Primary and metastatic brain tumors have significant unmet medical needs as few drugs can penetrate the blood-brain barrier (BBB). Brain metastasis is more common in non-small cell lung cancer (NSCLC) and breast cancer than in other cancers. Genetic alterations in *ERBB* family genes are frequently observed in those cancers, with about half of *HER2/EGFR* aberrations metastasizing in the brain. *EGFR* aberrations have been also observed in glioblastoma. Several pan-ERBB inhibitors are clinically available or under clinical development, such as afatinib, neratinib, and poziotinib. However, none are highly brain-penetrable as they are pumped out via the BBB. Here, we report TAS2940 as a novel potent

pan-ERBB inhibitor that elicits brain penetrability and anti-tumor effects in brain metastasis models.
Methods: The kinase selectivity of TAS2940 was evaluated in a panel of 257 kinases. Autophosphorylation of wild-type and mutant ERBB in stably expressing cell lines was evaluated using a quantitative immunofluorescence assay. The growth inhibitory effect on cell lines expressing HER2/EGFR aberrations was evaluated based on quantitation of the cellular ATP concentration. Cell lines were transplanted subcutaneously or intracranially in BALB/cAJcl-nu/nu mice. HER2 tyrosine kinase inhibitors, including TAS2940, were then orally administered once daily followed by evaluation of tumor volume and body weight.
Results: TAS2940 showed potent and selective inhibition against ERBB family proteins over more than 250 kinases on enzymatic assay. TAS2940 also showed preferential cytotoxicity in cells harboring *HER2/EGFR* genetic alterations *in vitro*, while sparing cells without *ERBB* genetic aberrations. TAS2940 showed potent anti-proliferative activity in cells containing *HER2* genetic alterations or *EGFR* exon 20 insertions, commonly found in NSCLC or breast cancer, as well as EGFRvIII alterations, frequently observed in glioblastoma. *In vivo* xenograft tumor models with various *EGFR* genetic alterations showed that TAS2940 exerted anti-tumor effects, such as growth retardation or regression. We further examined brain penetration by assessing the brain to blood concentration of TAS2940 in mice with intact BBBs, showing higher brain penetrability compared to other ERBB inhibitors. Evaluation of TAS2940 in intracranial brain metastasis mouse models resulted in tumor regression and prolonged survival.
Conclusion: TAS2940 is a novel potent and selective pan-ERBB inhibitor with high brain penetrability *in vivo*. These results support the clinical development of TAS2940 in primary and metastatic brain tumors driven by *ERBB* genetic aberrations.

#4009

Discovery of PLM-102, a highly potent 3rd generation FLT3 inhibitor, in drug-resistant FLT3-ITD-TKD mutated acute myeloid leukemia

Jin-Hee Park[1], Jae-Seon Lee[1], Su-jin Oh[1], So-Deok Lee[1], Yong June Choi[2], Keon Wook Kang[2], Miran Moon[1], Soo Yeon Jang[1], Myung Jin Kim[1], Yong-

Chul Kim[1]. *[1]PeLeMed, Seoul, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of*

Mutations of the FMS-like tyrosine kinase 3 (FLT3) gene occur in approximately 25 ~ 30% of all acute myeloid leukemia (AML) cases and FLT3-ITD mutations are associated with a particularly unfavorable prognosis, with an increased risk of relapse and shorter overall survival (OS) compared with AML patients without the mutation. Even though multiple FLT3 inhibitors are in various stages of clinical evaluation, resistance to FLT3 inhibitors resulting from acquired point mutations in tyrosine kinase domain (TKD) have limited the sustained efficacy of treatments. Among them, a “gatekeeper” mutation (F691L) is resistant to most available FLT3 inhibitors. Here, we show the efficacy and mechanism of PLM-102, developed an orally available and highly selective small molecule, in overcoming drug-resistant FLT3-ITD-TKD mutations as a strong candidate of the 3rd generation of FLT3 inhibitor.

PLM-102 displays extraordinary potency of enzyme inhibitory activities of all FLT3 WT/mutants including F691L with IC_{50} values of <1 nM. In FLT3-ITD-positive cell lines (MV4-11, MOLM-13, MOLM-14, Ba/F3-ITD-D835Y, Ba/F3-ITD-F691L), PLM-102 shows about 18~25-fold higher anti-proliferative activities than Gilteritinib. Also, PLM-102 potently inhibited the phosphorylation of FLT3 and its downstream signaling pathways, and induced apoptosis as evidenced by PARP-cleavage and caspase-3 activation.

Moreover, in AML-related xenograft mouse models (MV4-11, MOLM-14, Ba/F3-ITD-D835Y, Ba/F3-ITD-F691L), once-daily oral dose of PLM-102 significantly suppressed the tumor growth and achieved complete tumor regression. In addition, the outstanding efficacy of our compound has been confirmed in large tumor xenograft models. These results are very encouraging because large tumors have a limited blood supply and high interstitial fluid pressure, leading to a poor absorption of anticancer drugs. Pharmacokinetics of PLM-102 displayed higher bone-marrow exposure indicating better target engagement and benefits in the clinical translation in AML.

In conclusion, PLM-102 is a promising therapeutic candidate for the FLT3-ITD-mutated AML as well as the acquired resistance to current FLT3 inhibitors.

#4010

Inhibition of PERK by HC-5404 sensitizes clear cell renal cell carcinoma tumor models to anti-angiogenic tyrosine kinase inhibitors

Michael E. Stokes, Veronica Calvo, Crissy Dudgeon, Sho Fujisawa, Sharon Huang, Leyi Shen, Nupur Ballal, Joe McGinley, David Liu, Mark J. Mulvihill, Alan C. Rigby, Nandita Bose, Eric S. Lightcap, David Surguladze. *HiberCell, New York City, NY*

Anti-angiogenic agents form the backbone of standard of care for advanced clear cell renal cell carcinoma (ccRCC), but their clinical impact is limited by primary and secondary resistance mechanisms that remain a critical problem. Furthermore, the approvals for VEGFR-targeting receptor tyrosine kinase inhibitors (VEGFR-TKIs), cabozantinib in second-line, and tivozanib in third-line RCC patients were based on modest objective response rates and median progression-free survival. There is an urgent need for novel mechanisms that target adaptive tumor responses that drive resistance to these agents, as well as combination drug partners that improve outcomes for patients.

As part of their mechanism, VEGFR-TKIs induce oxygen- and nutrient-deprivation that drives ER stress. Tumors can evade deleterious ER stress by activating PERK branch of the integrated stress response, which arrests global translation and restores homeostasis. We hypothesized that inhibiting PERK would enhance the anti-tumor activity of VEGFR-TKIs *in vivo* and tested this using HC-5404, a potent and selective PERK inhibitor currently in Ph1 clinical testing (NCT04834778). Here, we present preclinical evidence that supports combining HC-5404 with VEGFR-TKIs in ccRCC. We demonstrate that axitinib, cabozantinib, lenvatinib, and sunitinib all activate PERK in 786-O ccRCC xenografts in a dose-responsive manner. The addition of HC-5404 significantly enhanced the tumor growth inhibition (TGI) of VEGFR-TKIs across multiple ccRCC tumor models, resulting in tumor stasis or regression in combination groups. Expression profiling and IHC analysis of tumor sections revealed that HC-5404 enhanced the anti-angiogenic effects of axitinib and lenvatinib in 786-O tumors, highlighting the protective role of PERK in response to anti-angiogenics.

To evaluate whether the combination treatments could benefit a diverse patient population, sensitivity to HC-5404 and axitinib was evaluated across a panel of patient-derived xenograft (PDX) models. This experiment confirmed widespread responsiveness to the combination treatment that in some cases achieved ≥50% tumor regression. As tumor progression on VEGFR-TKIs limits the success of these agents in the clinic, we evaluated the effect of adding HC-5404 to tumors that have previously progressed on axitinib. In this study, 786-O xenografts were treated with axitinib for 2-weeks and non-responders were rerandomized into groups of either single agent or combination of HC-5404 and axitinib. The combination treatment significantly improved TGI relative to either monotherapy, resulting in tumor regression of ~20%. Taken together, these findings highlight that by disrupting an adaptive stress response evoked by VEGFR-TKIs, HC-5404 presents a clinical opportunity to enhance the anti-tumor effects of well-established standard of care therapies in ccRCC.

Preferential cytotoxicity of ESK981 in neuroendocrine prostate cancer

Yang Zheng[1], Kyle J. Garcia-Rogers[2], Yi Bao[1], Rahul Mannan[1], Tongchen He[1], Sarah N. Yee[2], Caleb Cheng[1], Xia Jiang[1], Isabella E. Taylor[2], Xuhong Cao[1], Yuzhuo Wang[3], Yuanyuan Qiao[4], Arul M. Chinnaiyan[4]. *[1]Michigan Center for Translation Pathology; Department of Pathology, University of Michigan, Ann Arbor, MI,[2]Michigan Center for Translation Pathology, University of Michigan, Ann Arbor, MI,[3]Vancouver General Hospital and Department of Urologic Sciences; The Vancouver Prostate Centre, University of British Columbia, Vancouver, BC, Canada,[4]Michigan Center for Translation Pathology; Department of Pathology; Rogel Cancer Center, University of Michigan, Ann Arbor, MI*

Introduction: Despite advances in the understanding of neuroendocrine prostate cancer (NEPC) development, effective therapeutic options remain limited. We previously reported that ESK981, a phase I-cleared multi-tyrosine kinase inhibitor (MTKI), exhibited tumor growth inhibitory abilities in multiple preclinical castration resistant prostate cancer (CRPC) and androgen-negative models by blocking the PIKfyve activity and disrupting autophagy. The results suggested that AR-negative prostate

cancer have better response to ESK981 induced tumor inhibition than AR+ prostate cancer (Qiao et al, *Nature Cancer* 2022).
Methods: In order to examine the tumor growth efficacy of ESK981 in NEPC, we assessed the efficacy of ESK981 monotherapy in six NEPC (LTL-352, LTL-331R, LTL-545, and LTL-610 patient-derived xenografts (PDXs); and NCI-H660 cell line-derived xenograft) *in vivo* models. PDXs were maintained in CB17 SCID male mice and passaged by subcutaneous implantation. When the tumors reached ~100mm^3, mice were randomized and treated with either vehicle (Ora-plus) or 30mg/kg ESK981 administered by oral gavage once a day in a five-day per week schedule. Mouse body weight and tumor volume was monitored throughout the treatment schedule. Subcutaneous tumors were collected post five days of treatment for early assessment and long-term treatment for efficacy evaluation, respectively. H&E staining, TUNEL *in situ* cell death assay, and western blotting were performed to determine the morphology changes and apoptosis after ESK981 treatment. Single cells were isolated from tumors and stained with Zombie live/dead dye, CD45, CD11b and Ly6G fluorescently conjugated antibodies to assess neutrophil population by flow cytometry.
Conclusions: We demonstrated that ESK981 monotherapy is well tolerated in all *in vivo* models and ESK981 exerted greater cytotoxicity in NEPC than previous evaluated prostate adenocarcinoma by percent tumor growth inhibition. ESK981 also induced dramatic cell deaths in NEPC preclinical models, determined by H&E staining, TUNEL-positive apoptotic tumor cells, and increased protein level of PARP cleavage via western blotting. Moreover, flow cytometry analysis revealed a dramatic increase in the intratumoral neutrophil infiltration after ESK981 treatment in the NEPC preclinical models in a time-dependent manner. NEPC tumors are sensitive to ESK981 monotherapy *in vivo*, suggesting NEPC patients may be the right population to target with ESK981. Together, ESK981 monotherapy is safe and effective therapy in NEPC preclinical models, and these results will warrant the clinical trial of ESK981 on NEPC patients.

#4012
Preclinical development of SHP2 allosteric inhibitor ICP-189
Ruixia Liang, Yingxiang Gao, Fangfang Yang, Yingrui Han, Zuopeng Wang, Richard Liu, Charles Ying Wang, Jason Bin Zhang, Xiangyang

Chen, Davy Xuesong Ouyang. *InnoCare Pharma Tech co. Ltd, Beijing, China*

Background: SHP2 is a non-receptor protein tyrosine phosphatase which functions as a convergent signaling node downstream of multiple receptor tyrosine kinases (RTKs), and upstream of RAS to promote oncogenic signaling and tumor growth. SHP2 also mediates PD-1 immune blockade of T cells by binding to the immune receptor tyrosine-based inhibitory motif (ITIM) and immune receptor tyrosine-based switch motif (ITSM) of PD-1. SHP2 has long been considered as a plausible oncology drug target not only as an oncoprotein, but also as an important immune modulator. However, for decades, SHP2 was thought to be "undruggable" due to difficulties in targeting its catalytic site. Recent discovery of allosteric site of SHP2 has inspired a novel approach for SHP2 targeting. Here we report the development of ICP-189, which is a potent, highly selective, and orally bioavailable allosteric inhibitor of SHP2, demonstrated robust efficacies in various *in vitro* and *in vivo* RAS/MAPK pathway-driven models as mono-therapeutic agent or in combination with other anti-cancer drugs.
Results: ICP-189 inhibits phosphatase activity of SHP2 with IC_{50} values < 5 nM. In a phosphatase profiling assay, ICP-189 efficiently inhibits the catalytic activity of SHP2, with no significant effects on 21 other tested tyrosine and serine/threonine phosphatases, indicating its high selectivity for SHP2. ICP-189 has demonstrated robust *in vitro* efficacies in a panel of tumor cell lines bearing activated RTK, RAS, NF1 loss-of-function, or BRAF class III mutations. It has also exhibited synergistic tumor killing effects in combination with EGFR, $KRAS^{G12C}$, MEK and CDK4/6 inhibitors. In a series of *in vivo* efficacy studies, ICP-189 treatment results in robust tumor growth control of MIA-PaCa-2, KYSE-520 and NCI-H358 xenografts. ICP-189 has also shown strong synergies in tumor killing when combined with MEK inhibitor trametinib, $KRAS^{G12C}$ inhibitor sotorasib, EGFR inhibitor osimertinib in xenograft models; and when combined with anti-PD-1 antibody in EMT6 syngeneic tumors. The *in vivo* efficacy of ICP-189 is well accompanied by pharmacodynamic modulations, where ICP-189 exposure levels correlate with the inhibition of p-ERK and *DUSP6* mRNA level in tumors. The pharmacokinetic parameters of ICP-189 are overall favorable, with high oral bioavailability. Nonclinical safety

evaluations also exhibit acceptable drug tolerability in SD rats and Beagle dogs.
Conclusions: ICP-189 is a novel allosteric inhibitor of SHP2 with broad-spectrum anti-tumor activities as a single agent or in combination with other targeted or immune modulating anti-cancer therapeutics. ICP-189 is now in phase I clinical trial in China and United States.

#4013

Combination of BTK inhibitor orelabrutinib, anti-CD19 antibody tafasitamab, and IMiD lenalidomide for the treatment of B cell malignancies

Hongjuan Zhang, Ruixia Liang, Haipeng Xu, Xiaorong Li, Renbin Zhao, Jason Bin Zhang, Davy Xuesong Ouyang. *InnoCare Pharma Tech co. Ltd, Beijing, China*

Background: R-CHOP has been widely recognized as effective first-line treatment for DLBCL. However, 30-50% of the patients are either refractory or eventually develop relapsed diseases (r/r DLBCL). The CD19-targeted cytolytic antibody tafasitamab, in combination with immunomodulating drug (IMiD) lenalidomide, has been approved as one of the very few treatment options for transplant-ineligible patients with r/r DLBCL. Tafasitamab is a Fc-enhanced anti-CD19 monoclonal antibody, mediating B cell tumor lysis through ADCC/ADCP activities and direct cytotoxicity. Bruton's tyrosine kinase (BTK) is a key oncogenic driver in many B cell malignancies. Orelabrutinib is a highly selective BTK inhibitor approved for r/r CLL/SLL and r/r MCL in China. In addition, multiple clinical trials of orelabrutinib are being carried out for the treatment of other B cell lymphomas including the MCD subtype of DLBCL. In this study, we have investigated the potential benefit of combining orelabrutinib with tafasitamab and lenalidomide in pre-clinical B cell tumor models.
Results: ADCC activity of tafasitamab alone or in combination with lenalidomide and orelabrutinib/ ibrutinib was measured by co-culturing $CD19^+$ B cell tumor cells TMD8 or RS4;11 with Jurkat-CD16a(V158)-NFAT reporter cells or PBMC. In both assays, orelabrutinib slightly enhances, or well retains the ADCC activity of tafasitamab, while ibrutinib consistently suppresses the ADCC function of tafasitamab. Mechanistically, our data indicate that ibrutinib has an off-target effect on ITK, a key kinase

regulating FcR signaling in NK cells, which in turn may lead to compromised ADCC activity of tafasitamab. In contrast, orelabrutinib is a highly selective BTK inhibitor with no effect on ITK, which confers its ability to enhance or retain the ADCC activity of tafasitamab. Combination of orelabrutinib with tafasitamab and/or lenalidomide also leads to synergistic tumor lysis activity, with or without the presence of immune effector cells. *In vivo* efficacy study of REC-1 xenografts has further demonstrated much improved tumor growth inhibition with combinatory treatment of orelabrutinib, tafasitamab and lenalidomide compared to single agents.
Conclusions: The highly selective BTK inhibitor orelabrutinib offers an alternative to ibrutinib as a combinatory partner with antibody therapeutics whose mechanism of action is highly dependent on ADCC. Confirmation of the synergistic effects of orelabrutinib with tafasitamab and lenalidomide in various preclinical models has provided scientific rationales for testing the combinatory treatment in clinical studies. An open-label, single-arm, multi-cohort phase I study to evaluate the safety and efficacy of orelabrutinib, tafasitamab and lenalidomide combinations in patients with relapsed/refractory non-Hodgkin's lymphoma (NHL) is ongoing.

#4014

Comparative biochemical kinase activity analysis identifies rivoceranib as the most selective VEGFR-2 inhibitor compared with other TKIs with known activity against VEGFR-2

Seong Jang[1], Bill Strickland[1], Lynda Finis[1], Jeffrey J. Koojiman[2], Janneke J. T. Melis[2], Guido J. R. Zaman[2], Jan V. Tornout[1]. *[1]Elevar Therapeutics, Salt Lake City, UT,[2]Oncolines B.V., Oss, Netherlands*

Introduction: Vascular endothelial growth factor receptor 2 (VEGFR-2) is a key regulator of tumor angiogenesis that is highly expressed in several tumor types and is a known target for anti-cancer therapy. Yet the clinical use of VEGFR-2 inhibitors has been challenged by limited efficacy and various side effects, potentially due to the low selectivity of these TKIs for VEGFR-2. Thus, potent VEGFR-2 inhibitors with improved selectivity are needed. Rivoceranib is an oral tyrosine kinase inhibitor (TKI) that potently and selectively inhibits VEGFR-2. A comparison of the potency and

selectivity of VEGFR-2 inhibitors can provide a rationale for selecting a specific TKI for anticancer therapy in the clinic.
Methods: Binding of rivoceranib to VEGFR-2 was determined on a Biacore T200. The affinity constant (K_D) was derived from the association and dissociation rate constants. Inhibitory potency of rivoceranib and 10 FDA-approved reference inhibitors on kinase enzyme activity was determined using mobility shift assays (MSA) or immobilized metal ion affinity particle (IMAP) assays. The half-maximum inhibitory activity (IC_{50}) of the 11 inhibitors on VEGFR-2 was determined in 10-point dose-response curves. The selectivity of the inhibitors was determined on 270 wild-type kinases at a fixed concentration of each inhibitor. Rivoceranib was tested at 10- and 100-times IC_{50} (160 nmol/L and 1.6 μmol/L). Reference inhibitors were tested at 1 μmol/L (35 to 1056-times IC_{50}).
Results: Rivoceranib had a K_D of 3 nmol/L on VEGFR-2. In enzyme activity assays, rivoceranib had intermediate potency compared with the 10 reference inhibitors, with a VEGFR-2 kinase inhibition IC_{50} value of 16 nmol/L. Analysis of the residual activity of the panel of 270 kinases in the presence of rivoceranib or the reference inhibitors showed wide variation in selectivity for VEGFR-2, with rivoceranib identified as the most selective inhibitor (activity of 16 additional kinases inhibited by >50% at 1.6 μmol/L). Tivozanib, the most potent VEGFR-2 inhibitor, displayed greater than 50% inhibitory activity against more than 70 additional kinases. Sunitinib was identified as the least selective inhibitor included in this study, inhibiting 125 additional kinases by >50%.
Conclusion: Variations in selectivity among TKIs with similar anti-VEGFR-2 potency can help explain differences in their clinical toxicity profiles, which may be partially due to variant inhibitory effects against TKIs other than VEGFR-2. This comparative biochemical analysis highlights the potential for rivoceranib to address clinical limitations associated with the poor selectivity of currently available VEGFR-2 inhibitors. Rivoceranib is under ongoing investigation as monotherapy and in combination with chemotherapy in various tumor types.

#4015
EGFR activation via c-Jun axis promotes adaptive resistance to third generation ALK-TKI lorlatinib in ALK-rearranged non-small cell lung

cancer cells

Yuki Katayama[1], Tadaaki Yamada[1], Kenji Morimoto[1], Hiroaki Ozasa[2], Shinsaku Tokuda[1], Koichi Takayama[1]. *[1]Kyoto Prefectural University of Medicine, Kyoto, Japan,[2]Kyoto University, Kyoto, Japan*

Anaplastic lymphoma kinase-tyrosine kinase inhibitors (ALK-TKIs), including lorlatinib have shown dramatic efficacy in patients with ALK-rearranged lung cancer; however, complete response in these patients is rare, as a small population of tumor cells survives due to adaptive resistance. In this preclinical study, we investigated the adaptive resistant mechanisms to lorlatinib and its therapeutic strategies to overcome, using in vitro and in vivo experiments. We have identified EGFR as an adaptive resistance mechanism of lorlatinib using phospho-RTK array and siRNA library. Cell line-based assay showed that exposure of lorlatinib accelerated EGFR signal activation as an adaptive response via activation of JNK cascade in ALK-rearranged lung cancer cells. Knockdown for EGFR suppressed the survival signal of ALK lung cancer cells when treated with lorlatinib. The combination of lorlatinib and erlotinib, a first-generation EGFR-TKI, was shown to enhance cell growth inhibition by inducing cell apoptosis via suppressing the anti-apoptotic factor Bcl-xl compared with lorlatinib monotherapy. Moreover, cell line-derived xenograft model indicated that the combination of lorlatinib plus erlotinib enhanced anti-tumor effects compared with lorlatinib monotherapy. Taken together, our results displayed that EGFR activation plays an important role in the initial adaptive resistance to lorlatinib for ALK-rearranged lung cancer. The combination of lorlatinib and erlotinib is expected as the promising strategy for those tumors.

Discovery of a small-molecule EGFR inhibitor that can potently target various EGFR mutants, including C797S mutant, in vitro and in vivo

Yeejin Jeon, Kiram Lee, Anna Jang, Miyeon Kim, Kyeong Jin Yoon, Yeri Lee, Dongsu Kim, Donggeon Kim, Dohyun Park, Sang Kyun Lim, Sung Pil Choi. *Kanaph Therapeutics Inc, Seoul, Korea, Republic of*

EGFR is one of receptor tyrosine kinases (RTKs) and, upon ligand binding, turns on the downstream signals that include oncogenic RAS/MEK/ERK,

PI3K/AKT/mTOR, and JAK/STAT pathways. EGFR gene mutations, such as Exon 19 deletion (Del19) and L858R mutations, induce abnormal activation of the EGFR protein even in the absence of the ligand leading to various cancers. EGFR mutations are found in non-small cell lung cancer (NSCLC) patients with 10-15% frequency (approximately 50% in Asian patients).
Starting from Del19 and L8585R mutations, additional mutations in the EGFR gene occur during the treatment with 1st/2nd/3rd generation EGFR inhibitors, resulting in Del19/T790M, L858R/T790M, Del19/T790M/C797S, L858R/T790M/C797S, Del19/C797S, and L858R/C797S mutations. While double mutations that include the T790M mutation have been efficaciously treated with Osimertinib, there are currently no approved therapies that can effectively target the C797S-containing mutants.
Here we present preclinical data showing a small-molecule inhibitor that effectively disables EGFR mutants, including Del19/T790M/C797S, L858R/T790M/C797S, Del19/C797S, and L858R/C797S mutants. High potency and selectivity were confirmed by in vitro kinase assays and cellular assays. Outstanding anti-cancer activity was observed in mouse xenograft models with various EGFR mutations and, importantly, it was inactive in the EGFR wild-type model. With confirmed brain penetrance through in vivo studies, our potent EGFR inhibitor may provide a great therapeutic potential for patients with EGFR mutation-driven NSCLC.

TAS2940 inhibits intracranial tumor growth and prolongs survival in HER2-aberrant and EGFR-amplified patient-derived xenograft models

Jing Han[1], Mikhila Mahendra[1], Poojabahen Gandhi[1], Joseph R. Daniele[1], Caroline C. Carrillo[1], Benjamin J. Bivona[1], Ningping Feng[1], John V. Heymach[2], Funda Meric-Bernstam[3], Kei Oguchi[4], Shinji Mizuarai[4], Timothy P. Heffernan[1], Christopher P. Vellano[1], Joseph R. Marszalek[1].
[1]TRACTION Platform, Therapeutics Discovery Division, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Thoracic, Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Investigational Cancer Therapeutics, UT MD Anderson

Cancer Center, Houston, TX,[4]Discovery and Preclinical Research Division, Taiho Pharmaceutical Co, Tsukuba, Japan

Patients with brain tumors and metastases have poor prognosis and overall survival rates despite the advancements in neurosurgery, radiotherapy, and chemotherapy. Genomic alterations in HER2 are present in brain metastases of breast cancer (BC; ~20%) and non-small cell lung cancer (NSCLC; 13-20%), and EGFR alterations occur frequently in glioblastoma multiforme (GBM; >50%). Despite the advancements in standard of care options, optimal treatment management for these patients remains an unmet medical need. Recent evidence suggests activity of systemic therapy for immune and targeted therapies in the brain, including agents targeting HER2/EGFR. HER2-targeted tyrosine kinase inhibitors lapatinib, neratinib, and tucatinib and the HER2-targeted antibodies trastuzumab and pertuzumab, in combination with chemotherapy, have been shown to improve survival of patients with HER2 overexpressing BC in the presence of brain metastases. The limited penetration of these compounds into the CNS, however, limits their efficacy. TAS2940 is an irreversible pan-ErbB inhibitor with greater brain-penetrability than poziotinib, tucatinib, and neratinib. Here, we demonstrate that TAS2940 induces downregulation of phosphorylated HER2/EGFR, reduces tumor burden, and promotes a significant increase in survival in intracranial xenograft mouse models with HER2-amplification (BC), HER2-Exon20 insertion mutation (NSCLC), and EGFR-amplification (GBM). These promising preclinical data highlight potential novel therapeutic strategies for patients with EGFR-aberrant GBM and brain metastases harboring HER2/EGFR alterations, and may help support the advancement of the ongoing first-in-human clinical trial (NCT04982926) for TAS2940 in solid tumors with EGFR and/or HER2 alterations.

#4018

BBT-207 is a broad-spectrum, highly potent, 4th generation EGFR TKI with enhanced activity to both sensitizing and treatment-emergent EGFR mutations including T790M and C797S

Chulwon Kim[1], Youn Hee Jung[1], Naeun Jeon[1], Yong-Hee Lee[2], Sang-Yoon Lee[3], Jimmy Taiguang Jin[2]. *[1]Research Center, Bridge Biotherapeutics, INC., Seongnam-si, Korea, Republic of,[2]Bridge Biotherapeutics, INC.,*

Cambridge, MA,[3]Bridge Biotherapeutics, INC., Seongnam-si, Korea, Republic of

Background: *EGFR* mutation in non-small cell lung cancer (NSCLC) presents a viable therapeutic target for which tyrosine kinase inhibitor (TKI) therapy has shown impressive clinical benefit over the past 20 years. Unfortunately, most patients inevitably progress on earlier-generation EGFR TKIs due to various mechanisms after a period of therapy. The most commonly acquired on-target resistance mutations are T790M and C797S, often appearing after progression on 1st-, 2nd-generation, and 3rd-generation EGFR TKIs, respectively. To prevent the emergence of drug-resistant subclones, a next-generation EGFR TKI must have activity against both treatment-emergent and drug-naïve mutants. Further preclinical studies were conducted to evaluate the activity of BBT-207 in delaying tumor regrowth or prolonging survival in NSCLC tumor models driven by the *EGFR* T790M and C797S mutation.
Method: We evaluated the inhibitory potency of BBT-207 against wild-type (WT) and mutated EGFR proteins. In vivo anti-tumor activity was evaluated in Ba/F3 *EGFR* ex19del/T790M (DT), L858R/T790M (LT), ex19del/C797S (DC), L858R/C797S (LC), ex19del/T790M/C797S (DTC) or L858R/T790M/C797S (LTC), H1975 *EGFR* LTC cell line-derived xenograft (CDX), and *EGFR* DTC-patient-derived xenograft (PDX) models. In vivo inhibition of brain metastases (BM) was evaluated in a luciferase-expressing PC-9 *EGFR* DTC BM model through direct intracranial implantation.
Results: BBT-207 is broadly active against activating and acquired resistance *EGFR* mutants and displayed potent anti-proliferation activity against Ba/F3 *EGFR* DT, LT, DC, LC, DTC, LTC with 4, 4, 1, 16, 5 and 8nM, respectively while being highly selective against Ba/F3 *EGFR* WT (184 nM). BBT-207 also showed IC_{50} values <5 nM against Osimertinib-resistant *EGFR* L792H triple mutants, DTL and LTL in cell-free *in vitro* kinase assay. QD administration as a single agent resulted in significant tumor regression in the Ba/F3 *EGFR* DT, LT, DC, LC, DTC, LTC CDX models and *EGFR* DTC PDX model. Indeed, BBT-207 showed sustained anti-tumor efficacy in Ba/F3 *EGFR* DC CDX model. Furthermore, BBT-207 exerted dose-dependent intracranial anti-tumor activity and enhanced

survival rate of mice in the PC-9/*EGFR* DTC_Luc BM model. PK studies revealed CNS penetration with good B/P ratios in animals.
Conclusion: BBT-207 is a reversible, mutant-specific, broad-spectrum TKI, active to clinically observed mutations of *EGFR* and is expected to be compatible with monotherapy of QD schedule in humans. BBT-207 is well-positioned to augment the treatment of *EGFR* mutated NSCLC, either for acquired drug resistance or in earlier line, with potential to treat or prevent CNS metastasis. PK/TK evaluation justify exploration in humans. First-in-human study in patients harboring *EGFRm* and previously treated with EGFR TKI, is to begin enrollment in USA 1H 2023.

#4019

Preclinical Activity of ELVN-002: A Potent, Selective, Irreversible and CNS Penetrant HER2 and pan-HER2 Mutant Small-Molecule Inhibitor for the Treatment of HER2-Driven Malignancies

Monette Aujay, Amanda J. Broad, Stefan D. Gross, Li Ren, Joseph P. Lyssikatos, Samuel Kintz, Qi Wang, Helen Collins. *Enliven Therapeutics, Boulder, CO*

Mutation or amplification of the human epidermal growth factor receptor 2 (HER2) gene has been identified in numerous solid tumor types, including non-small cell lung cancer (NSCLC), breast, and colorectal cancer. These genetic alterations are believed to confer elevated HER2 activity resulting in oncogenic transformation. In NSCLC, an estimated 3% of patients harbor activating mutations in the HER2 gene. Enhertu (T-DXd), a HER2-specific antibody-drug conjugate was recently approved as an important therapy for this patient population. However, for patients who are not candidates for T-DXd or have discontinued treatment due to an adverse event or disease progression, there exist few therapeutic options. Accordingly, HER2 inhibitors have the potential to provide meaningful therapeutic benefit to these patients. Due to significant structural homology between EGFR and HER2, most investigational small molecule HER2 kinase inhibitors are dual EGFR/HER2 inhibitors and are substantially dose-limited by EGFR-related toxicities in patients. These toxicities likely limit their clinical activity. Currently, tucatinib is the only HER2-selective small molecule inhibitor approved for metastatic breast cancer in combination with trastuzumab and capecitabine. However, it lacks sufficient potency against several of the key

clinically relevant mutations, including HER2 YVMA, the most common exon 20 insertion mutation, prevalent in HER2 mutant NSCLC. ELVN-002 is a potent, irreversible inhibitor of HER2 with a >100-fold selectivity over EGFR. ELVN-002 potently inhibits the phosphorylation of HER2 in cell lines endogenously expressing HER2 or in those engineered to express specific clinically relevant HER2 mutants. This activity readily translates into marked anti-proliferative activity against cell lines dependent upon HER2 for their growth and survival. In addition, ELVN-002 is highly selective for HER2 and HER2 mutants versus wild-type EGFR as demonstrated via assessment of both EGFR-driven proliferation and EGFR phosphorylation in cells. Furthermore, ELVN-002 is highly active in mouse models of HER2-driven cancers, including subcutaneous models driven by wild type or mutant HER2. ELVN-002 is also active in an NCI-N87 wild-type HER2 intracranial model. In all models tested, ELVN-002 treatment is well tolerated and resulted in tumor regressions at exposures believed to be clinically achievable. Due to its selectivity and breadth of activity versus the clinically relevant HER2 mutants, ELVN-002 has the potential to be an effective treatment for HER2 mutant NSCLC as well as other HER2 mutant amplified solid tumors, including metastatic HER2 positive breast cancer. Additionally, ELVN-002 could provide a meaningful therapeutic option for patients with CNS metastases. ELVN-002 has been selected for clinical development.

#4020

HMPL-760 is a highly potent and selective reversible BTK inhibitor, targeting BTK and BTK^{C481S} in B-cell malignancies

Linfang Wang, Junqing Liang, Zhihu Gao, Jia Hu, Weigang He, Xianwen Yang, Fangfang Mao, Wei Zhang, Ying Yu, Qihang Zhang, Na Yang, Chun Zhang, Jian Wang, Yu Cai, Xiong Li, Weiguo Qing, Guangxiu Dai, Yongxin Ren, Michael Shi, Weiguo Su. *HUTCHMED Limited, Shanghai, China*

Introduction: Bruton's tyrosine kinase (BTK), a member of the Tec family, plays a crucial role in signaling through B-cell receptor (BCR). BTK inhibition blocks BCR signals and prevents B-cell activation and growth. First-generation BTK inhibitors such as ibrutinib covalently binds to a cysteine residue (C481) of BTK. Their most frequent acquired resistance is the development of a serine mutation in the binding site (C481S). Next

generation BTK inhibitors such as LOXO-305 and ARQ 531 are being developed to overcome this resistance to first-generation inhibitors.
Methods: HMPL-760 was tested in biochemical assays using recombinant human wild type (WT) and C481S mutant BTKs. Its selectivity was carried out using Eurofins Cerep KinaseProfiler^{TM} panel. Cellular activity of HMPL-760 was evaluated in HEK293 cells stably transfected with BTK^{WT} or BTK^{C481S}, and other tumor cell lines, which are either human diffuse large B cell lymphoma (DLBCL) or mantle cell lymphoma (MCL) cell lines. The in vivo antitumor activity and PKPD correlation of HMPL-760 was studied in HBL-1 xenograft mouse models bearing BTK^{WT} or BTK^{C481S} respectively.
Results: In biochemical assays, HMPL-760 strongly inhibits BTK kinase activities towards wild-type BTK (BTK^{WT}) and C481S mutant (BTK^{C481S}), and binds to BTK in a reversible way. HMPL-760 demonstrates high selectivity in a panel containing 413 kinases. In cellular assays, HMPL-760 displays strong anti-proliferative activities in B-cell lymphoma cells (TMD-8, OCI-LY10, REC-1, HBL-1 and HBL-1-BTK^{C481S}) harboring either BTK^{WT} or BTK^{C481S} (GI_{50}: 0.0015-0.046 μM). In human whole blood assay, HMPL-760 inhibits activation of B-cells at nanomolar concentrations measured by inhibition of immunoglobulin-induced CD69 expression in $CD19^{+}$cells. HMPL-760 shows ≥ 10-fold inhibitory potency than ARQ 531 in both BTK^{WT} and BTK^{C481S} cells, and ~3-fold higher inhibitory potency than that of LOXO-305 in BTK^{C481S} cells. In cellular assay by detecting p-BTK after compound washout, HMPL-760 maintains a longer duration of target inhibition than LOXO-305 in both BTK wild type (HBL-1) and BTK mutant (HBL-1-BTK^{C481S}) cell lines. HMPL-760 displays dose-dependent antitumor efficacy in multiple human B cell lymphoma xenograft models in mice when orally administered at 3~50 mg/kg once daily. Complete tumor regression occurs in most of the tested models at the high dose levels. HMPL-760 shows much stronger antitumor efficacy than LOXO-305 and ARQ 531 at similar dose level, which may be associated with HMPL-760's higher drug exposures and more sustainable inhibition on BTK phosphorylation in the tumor tissues.
Conclusion: HMPL-760 is a reversible, selective, highly potent, BTK inhibitor targeting both BTK^{WT} and BTK^{C481S}. The first-in-human Phase 1

clinical trials of HMPL-760 are under way in patients with r/r B-NHL (NCT05190068, NCT05176691).

#4021

CTS2016, a novel AXL/FLT3 inhibitor for targeting AML/MDS and solid tumors

Hui Shi, Meng Wang, Jiaxin Huang, Qiugeng Ouyang, Jiannan Guo, Youzhen Wang, Yuan Mi, Haiping Wu. *CytosinLab Therapeutics Co., Ltd., Shanghai, China*

We identified CTS2016 as a novel, selective, orally bioavailable small molecule inhibitor with single-digit nanomolar enzymatic activity to AXL and FLT3. Overexpression of AXL is associated with metastasis, drug resistance, and poor prognosis of various hematological and solid tumors, which are all broadly modulated with epigenetic regulation. In addition, inhibition of AXL phosphorylation may overcome drug resistance to current FLT3 inhibitors in *FLT3-ITD*+ Acute Myeloid Leukemia (AML) (Park *et al*., 2015). We tested CTS2016 as a single agent or in combination with either venetoclax, a Bcl-2 inhibitor, or azacitidine, a hypomethylating agent (HMA) and an epigenetic modulation drug, in a series of *in vitro* and *in vivo* studies using various AML models. CTS2016 resulted in a potent growth inhibitory effect with strong induction of cell death in a spectrum of AML cell lines carrying *FLT3* mutations (*FLT3-ITD* and/or *FLT3-TKD*). CTS2016 orally administered once daily, demonstrated potent and dose-dependent antitumor responses in a variety of AML xenograft mouse models. The anti-tumor activity was correlated with the inhibition of receptor tyrosine kinase signaling, as measured by decreased phosphorylation of key downstream signaling targets of FLT3. In a tail vein injection of mouse LLC-Luciferase model, CTS2016 treatment could significantly reduce tumor metastasis. A combination of CTS2016 with venetoclax or azacitidine provides a therapeutic benefit over monotherapy and supports a rationale for testing these combination therapies in patients with relapsed or refractory (R/R) AML and myelodysplastic syndromes (MDS). In addition, CTS2016 significantly reduced the tumor burden of a leukemia model harboring *FLT3-ITD-F691L*, a drug-resistant mutation of *FLT3*. Notably, the selectivity of CTS2016 over other kinases (such as c-KIT) mitigates the off-target toxicity effects on normal hematological

differentiation which is common in clinics for other FLT3 inhibitors. These data demonstrate that CTS2016 could be a promising therapy for treating patients diagnosed with AML and MDS harboring *FLT3* mutations and solid tumors such as NSCLC and TNBC with high-expression of AXL. More proof-of-concept data would come from the ongoing clinical trial.

#4022

Preclinical intracranial activity of NVL-655 in an alectinib-resistant patient-derived model harboring EML4-ALK fusion with G1202R mutation

Jii Bum Lee[1], Mi Ra Yu[1], Mi Ran Yun[1], You Won Lee[1], Seung Yeon Oh[1], Eun Ji Lee[1], Anupong Tangpeerachaikul[2], Henry E. Pelish[2], Byoung Chul Cho[1]. *[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Nuvalent Inc, Cambridge, MA*

Introduction: NVL-655 is a brain-penetrant, ALK-selective tyrosine kinase inhibitor (TKI) designed to maintain activity against ALK and ALK mutations that confer resistance to currently approved therapies, and to avoid neurological adverse events and dose-limiting toxicities associated with TRK inhibition. Brain metastases are common in ALK-positive non-small cell lung cancer (NSCLC), with an incidence of ~40% at diagnosis and ~60% after progressive disease on the first-generation ALK TKI (crizotinib) due to its limited brain penetration. Second- (ceritinib, alectinib, brigatinib, and ensartinib) and third-generation (lorlatinib) ALK TKIs have higher intracranial responses than crizotinib but are still limited by emergence of resistance mutations, most commonly G1202R-containing single and compound mutations. We previously reported that NVL-655 has intracranial activity in a preclinical model of Ba/F3 EML4-ALK v1 G1202R/L1196M. Here we further demonstrate the intracranial activity of NVL-655 in a preclinical patient-derived model harboring EML4-ALK v3 G1202R.

Methods: The YU-1077 cell line was established from a patient with ALK-positive NSCLC after relapse on alectinib and was confirmed to harbor EML4-ALK v3 G1202R alteration. ALK TKIs (crizotinib, ceritinib, alectinib, brigatinib, ensartinib, lorlatinib, and NVL-655) were profiled against YU-1077 cells in 3-day viability assays and signaling assays. YU-1077 cells were intracranially implanted in Balb/c nude mice and treated

with NVL-655 orally twice daily. Brain tumor burden was monitored weekly using magnetic resonance imaging (MRI).
Results: NVL-655 suppressed the viability of YU-1077 cells bearing EML4-ALK v3 G1202R (IC_{50} < 1 nM) with potency >10-fold that of lorlatinib. NVL-655 at ≤10 nM fully inhibited ALK signaling as measured by ALK, ERK, and S6 phosphorylation, compared to ≥100 nM of lorlatinib required to achieve similar inhibition. Other ALK TKIs tested had limited activity against YU-1077 cells in viability and signaling assays, consistent with the G1202R mutation conferring resistance to first- and second-generation ALK TKIs. In mice intracranially implanted with YU-1077 cells, MRI scans confirmed rapid tumor regression upon treatment with 0.5 and 1.5 mg/kg NVL-655.
Conclusion: Patient-derived models are widely viewed as among the most disease-relevant models for evaluating new therapies and drug resistance. Using a xenograft model derived from an alectinib-relapsed patient, we showed that NVL-655 had high intracranial activity against brain tumors bearing the ALK G1202R mutation that confers resistance to multiple ALK TKIs. NVL-655 is being evaluated in a Phase 1/2 clinical trial for patients with advanced NSCLC and other solid tumors harboring ALK rearrangement or activating ALK mutation (ALKOVE-1): NCT05384626.
[J. Lee and M. Yu contributed equally.]

#4023
Inhibiting GRP78 in non-small cell lung cancer with acquired resistance to EGFR-TKI
Jaewoo Park, Baskaran Purushothaman, Sera Hong, Munkyung Choi, Joon Myong Song, Keon Wook Kang. *Seoul National University College of Pharmacy, Seoul, Korea, Republic of*

Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) have improved the survival of non small cell lung cancer (NSCLC) patients with active mutation of EGFR. However, some of the patients who received EGFR-TKIs showed the acquired resistance, and eventually relapsed within several months. In the TCGA data sets, gene expression of glucose-related protein 78 (GRP78), an ER chaperone, was upregulated in NSCLC tissues. We also confirmed that protein level of GRP78 was increased in HCC827-GR, H1993-GR and H1993-ER NSCLC cell lines with acquired resistance

to EGFR-TKIs. Since GRP78 modulates ER stress level which induces ROS and apoptosis, Ru(II) complex 1 and HA15, both the known GRP78 inhibitors induced higher ER stress and ROS generation accompanying more remarkable anti-proliferative and apoptotic effects in EGFR-TKI-resistant NSCLC cell lines. GRP78 level was also found to be higher in H1975, EGFR-TKI-resistant T790M-mutant cell line than other NSCLC cell lines. Blockade of GRP78 also led to apoptosis in H1975, which is consistent with the results found in the acquired EGFR-TKI-resistant cell lines. In summary, we suggest GRP78 targeting as a potential therapeutic strategy for the acquired EGFR-TKI-resistant NSCLC patients.

Overcoming ALK resistance with covalent cysteine-reactive inhibitors in lung cancer

Diane Yang[1], Stefan Harry[2], Edwin Zhang[1], Zavontae Oppong-Holmes[1], Alexander Daniel Carlin[1], Wenxin Yang[1], Abigail Smith[1], Maristela Onozato[1], Liron Bar-Peled[1], Anthony J. Iafrate[1]. *[1]Massachusetts General Hospital, Boston, MA,[2]Massachusetts General Hospital/Harvard University, Boston, MA*

The EML4-ALK fusion gene is the main oncogenic driver in 5% of non-small cell lung cancer and has been effectively targeted using ALK-specific tyrosine kinase inhibitors. While survival rates have improved steadily with each new generation of ALK TKI, resistance generally develops, including second site ALK kinase mutations as well as by-pass track activation. Since almost all anti-ALK approaches have focused on kinase domain inhibition, we sought to develop novel inhibitors with alternative mechanisms of action against ALK to overcome current drug resistance. Cysteine-reactive small molecule drugs may enable new mechanisms of target inhibition, and clinically successful examples of recent FDA-approved drugs in NSCLC include afatinib, osimertinib, sotorasib, and adagrasib.We aimed to explore and uncover novel cysteine-reactive covalent inhibitors of EML4-ALK. Using cysteine druggability mapping (CDM), a proteome-wide mass spectrometry target engagement assay, we first determined the landscape of reactive cysteines in ALK-positive cell lines and identified various targetable cysteines within the MAPK pathway and within the EML4-ALK fusion protein itself. To identify small molecules that modulate ALK

activation, degradation, and downstream signaling, we conducted a high-content phosphorylated protein screen by testing 4,400 reactive cysteine compounds and found 20 potential hits that impacted ALK phosphorylation or expression. Using proteomic analysis, we have determined the comparative specificity of these compounds, and have ranked them based on p-ALK reduction efficiency and on their off-target binding patterns. We have initiated hit-to-lead development on a compound that binds to the EML4 portion of the fusion and we are performing a detailed analysis of its mechanism of action. To further optimize the potency of the compound, we designed, synthesized, and are testing several hundred analog compounds. By applying the hit compounds from the screen in ALK TKI-resistant models, we will be able to evaluate the ability of these compounds to overcome ALK resistance. To our knowledge, we have identified the first EML4-ALK covalent binder targeting the EML4 domain. Using the unique mechanism of action of the current ALK kinase inhibitor, we have uncovered a potential compound to overcome ALK resistance.

Tyrosine Kinase and Phosphatase Inhibitors 2

#4027
TSN084, a multi-kinase inhibitor, overcomes acquired drug-resistant mutations of cMet, Trks, and Flt3, and displays broad activities against kinase oncotargets Axl, DDRs, and CDK8/19
Boyu Zhong, Tony Zhang, Chunlan Dong, Shengtang Mark Ma, Ziyang Jia, Guangming Chen, Renjuan Zheng, Jing Cindy Li, Han Fu. *Tyligand Bioscience (Shanghai), Ltd., Shanghai, China*

Background: Up to date, over 80 small molecule kinase inhibitors have been approved for the treatment of cancers worldwide. This class of targeted therapy benefits millions of patients by improving their disease management and quality of life. However, acquired drug resistance can develop quickly after treatment in most of the patients. Herein, we disclose TSN084, a unique small molecule multi-kinase inhibitor, which can overcome many common acquired drug-resistant mutations of cMet, Trks, and Flt3, etc. It also inhibits other oncotargets including Axl, DDRs, and CDK8/19.

Method: The primary screen of TSN084 against 468 kinases at a single concentration was carried out by Eurofins DiscoverX Corporation. Its inhibitory activity on interested kinases and relevant cellular proliferation were determined separately. A series of cell-derived xenograft (CDX) models were used to evaluate its *in vivo* antitumor effect. Both *in vitro* and *in vivo* PK study was performed in mouse, rat, dog, and monkey. An *in vitro* safety panel and *in vivo* GLP animal studies were carried out to assess its preliminary toxicity profile in preparation for human clinical trials.
Results: Kinase activity profiling assay revealed that TSN084 is a multi-kinase inhibitor. Among the 468 kinases tested, 33 showed >50% inhibition at 0.1 uM, including many oncotargets and their mutants such as Met, Met-Y1235D, Met-M1250T, Flt3, Flt3-N841I, Flt3-ITD, Flt3-K663Q, Flt3-D835Y, Flt3-D835V, Axl, TrkA, DDR1, and CDK8/19. It demonstrated potent anti-proliferation activity against many tumor cell lines, e.g. KM12, MKN45, MV-4-11, and HS746T. It also effectively inhibited tumor growth in several CDX drug-resistant models like NTRK-G667C and NTRK3-G696C and showed outstanding survival advantage. TSN084 is an orally bioavailable small molecule agent in mouse, rat, dog, and monkey. It is clean in a safety panel assessment of 44 concerning targets and considered safe enough to advance into clinical study.
Conclusion: TSN084 targets several oncogenic kinases and their drug-resistant mutants. It demonstrated potent antitumor effects in both *in vitro* and *in vivo* studies. It showed excellent PK properties and acceptable preclinical safety profile. A phase I clinical trial of TSN084 in patients with advanced or metastatic malignancies is currently ongoing (NCT05300438). As of Oct 30, 2022, 6 patients have been enrolled into the trial, and no DLTs or treatment-related AEs were observed. It is a promising agent for the potential treatment of resistant cancers in the clinic.

High-dose short-exposure of osimertinib robustly inhibits growth of patient-derived metastatic colorectal cancer organoids

Kirti K. Iyer, Dennis Poel, Anne Miggelenbrink, Wouter Kerkhof, Erik van den Hombergh, Loek A. W. de Jong, Nielka P. van Erp, Daniele V. F. Tauriello, Henk M. W. Verheul. *Radboudumc, Nijmegen, Netherlands*

Despite major interest in tyrosine kinase inhibitors (TKIs) as a treatment option for metastatic colorectal cancer (mCRC), almost all TKIs tested for mCRC fail in early-phase clinical trials. Although showing specific target inhibition at low concentrations, TKIs have a much broader kinase inhibitory potency at higher concentrations. Alternative high dose regimens have been proposed to explore if efficacy can be improved with acceptable toxicity. We used 3D matrix-embedded tumor organoids as a preclinical platform to determine optimal drug exposure, i.e. *preclinical pharmacology*, and to dissect the mechanisms of action to potentially convert the dismal translational success rate of TKIs for mCRC. We established patient-derived tumor organoids (PDTOs) from mCRC biopsies and, based on favorable physicochemical and pharmacokinetic properties, selected 3 TKIs (sunitinib, cediranib and osimertinib). Following standard IC50 assessment using continuous dosing with a concentration range, we investigated the cytotoxic antitumor effect of high-dose, short-exposure (HDSE) treatment. Five PDTOs were exposed to 20 μM TKI for 1-24h, washed and given normal medium, and PDTO-outgrowth was determined 1 week later. At exposures of 1, 3 and 6h, we measured intra-tumoroid TKI concentrations using a clinically validated LC/MS-MS method. PDTO cell death was observed using live-cell microscopy, and quantified by both caspase 3/7 enzyme activity assay and cleaved caspase-3 immunofluorescent staining. While PDTOs could be categorized for their sensitivity across tested TKIs, all were highly sensitive for osimertinib (IC50 values 0.40-3.8 μM). Lower sensitivity was observed for sunitinib (2.0-10.5 μM) and cediranib (2.5-7.1 μM). Only for osimertinib exposure to 20 μM for 3h was sufficient to block proliferation in all PDTOs. Interestingly, peak intra-tumoroid TKI concentration measurements across PDTOs revealed marked cellular accumulation, indicating an expanded potential for target inhibition. The concentrations correlated with sensitivity: for sunitinib from 1.5 mM for the most sensitive PDTO to 0.72 mM for the least sensitive PDTO. Likewise, the corresponding cediranib concentrations were 0.15 mM *vs* 0.062 mM. All PDTOs had high intra-tumoroid osimertinib concentrations (0.90-1.6 mM). Lastly, we detected a significant increase in apoptosis after 3h of HDSE with osimertinib. Whereas our HDSE regimen shows promising results for all 3 TKIs, very short exposure with high-dose osimertinib effectively reduces proliferation and induces cell death in all mCRC PDTOs. While this is likely due to high intra-tumoroid concentrations

reached by osimertinib—the mechanism of action at these concentrations remains unknown and is subject to further studies. In parallel, we propose that a HDSE osimertinib regimen warrants clinical exploration as a potential new treatment option for mCRC.

JIN-A04, highly effective tyrosine kinase inhibitor targeting HER2 exon 20 insertion mutations in NSCLC

Mi Ra Yu[1], Mi Ran Yun[1], Jii Bum Lee[2], Ji Yun Lee[3], So Won Aum[4], Su Jin Choi[4], Ju Yeon Park[4], Seung Yeon Oh[5], Eun Ji Lee[5], Krishna Babu Duggirala[6], Kwangho Lee[6], Min Hee Hong[7], Sun Min Lim[7], Anna Jo[8], Ethan Seah[8], Choonok Kim[8], Byoung Chul Cho[2]. *[1]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Lung Cancer Center, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[5]Department of Medical Science, Graduate School of Medical Science, Brain Korea 21 Project, Yonsei University College of Medicine, Seoul, Korea, Republic of,[6]Bio & Drug Discovery Division, Korea Research Institute of Chemical Technology, Daejeon, Korea, Republic of,[7]Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[8]J INTS BIO, Seoul, Korea, Republic of*

Introduction: Non-small cell lung cancer (NSCLC) is the most common type of lung cancer, accounting for about 85% of lung cancer patients. 2% - 4% of patients with NSCLC harbor human epidermal growth factor receptor 2 gene (HER2) mutations, being the 90 % of them exon 20 insertions. The most common HER2 mutations in NSCLC are exon 20 mutation A775_G776insYVMA (YVMA) mutation in the kinase domain. Currently, treatment options for this subset of patients are limited. JIN-A04 is an orally available tyrosine kinase inhibitor (TKI) targeting HER2 exon20 insertion mutations and has the potential to be a best-in-class drug candidate to address this unmet clinical need.

Method: The inhibitory activity of JIN-A04 was evaluated by cell viability assay in both Ba/F3 cell lines expressed HER2 YVMA and HER2 P780_Y781insGSP (GSP) mutations. Also, Ba/F3 HER2 wild-type (WT) and normal cell lines for HUVEC (endothelial cells) and BEAS-2B (human bronchial epithelial cells) were used to assess cellular activity. In addition, to confirm mechanism action, western blotting analysis was performed on Ba/F3 YVMA and Ba/F3 GSP cell lines.
Results: In cell viability assay, JIN-A04 strongly inhibited cellular activity against Ba/F3 cell lines engineering to express the mutants HER2 YVMA (IC_{50} = 11.1 nM) and GSP (IC_{50} = 1.4 nM). It was superior to Mobocertinib (IC_{50} = 27.1 nM for YVMA and IC_{50} = 3.3 nM for GSP) and comparable with Poziotinib (IC_{50} = 3.4 nM for YVMA and IC_{50} = 0.4 nM for GSP). In normal cell lines, JIN-A04 did not inhibit the activity of HUVEC (IC_{50} = > 1000 nM) and BEAS-2B (IC_{50} = > 1000 nM) cell lines, largely sparing HER2 WT activity (IC_{50} = > 1000 nM). In protein expression analysis, JIN-A04 was effectively inhibited in all signaling pathway of p-EGFR, p-AKT, p-ERK1/2, and p-S6 on Ba/F3 YVMA and Ba/F3 GSP cell lines at a low dose level.
Conclusion: JIN-A04 is highly potent against HER2 exon 20 insertion mutations including YVMA and GSP, while largely sparing HER2 WT activity. Also, JIN-A04 demonstrated effective HER2 pathway inhibition. Based on these robust activities for HER2 exon 20 insertion, JIN-A04 is expected to provide a potent therapeutic opportunity for NSCLC patients with HER2 exon20 insertion mutations.

#4030

Generation of profound anti-tumor immunity by AUR-109, a spectrum-selective tyrosine kinase inhibitor, either as a single agent or in combination with immune checkpoint inhibitors

Girish Daginakatte, Saravanan Thiyagarajan, Kiran Aithal, Mamon Dey, Reshma Reghu, Monalisha Mandal, Kavitha Nellore, Susanta Samajdar, Murali Ramachandra. *Aurigene Discovery Technologies Limited, Bengaluru, India*

AUR-109 is an orally bioavailable clinical stage receptor tyrosine kinase inhibitor (RTK) that inhibits the activity of proangiogenic and oncogenic

pathway-related RTKs including DDR1, FGFR, VEGFR, PDGFR, and RET. DDR1 instigates immune exclusion by promoting collagen fiber alignment thereby altering extracellular matrix (ECM) components in tumor immune microenvironment (TIME). DDR1 expression inversely correlated with reduced immune cell infiltration in TIME leading to exhaustion of tumor-fighting immune cells, tumor escape, EMT and metastasis. FGFRs induce the expression the PD-L1 and VEGFRs promote the proliferation of regulatory T cells (Treg), inhibit T-cell development and maturation of dendritic cells. These findings suggest that the spectrum-selective inhibition of these RTKs by AUR-109 has the potential to strongly modulate the anti-tumor immune response. Clinically successful immune checkpoint inhibitors (ICI) (anti-PD1, anti-PD-L1, and anti-CTLA4 antibodies) block the pathways that inhibit immune cell activation thus stimulating immune responses against the tumor cells. Although ICIs show improved survival in patients with many types of cancers, they suffer from the lack of response in majority of patients along with the development of resistance to therapy. To overcome the resistance and improve the efficacy, a number of combinations of PD-1 blockade with other anticancer therapies are being evaluated. We have undertaken a detailed characterization of the anti-tumor immune response by AUR-109 either as a single agent or in combination with anti-PD1 antibodies. The effect of AUR-109 on CD4 T cells and Treg cells was evaluated in the Renca subcutaneous tumor model. Immune cell population in the blood and tumor microenvironment were analyzed by FACS. Anti-tumor efficacy was analyzed in both subcutaneous and orthotopic Renca syngeneic tumor models. AUR-109 treatment resulted in an increase of total and CD4 T cells. Higher ratio of total T cells to regulatory T cells was observed indicating that there is an increase in effector T cells. In the TILs, there was decrease in the expression of PD-1 and PD-L1 with a concomitant increase in IFN-γ expression on CD8 T cells and NK cells indicating a profound immune activation caused by AUR-109 within the tumor. These results demonstrate the therapeutic potential of AUR-109 in combination with PD-1 blockade in preclinical models and the results from the ongoing combination studies will be presented.

#4031

***In vivo* studies demonstrate differences in target inhibition and anticancer efficacy between NXP900 and dasatinib in ovarian clear cell**

carcinoma model

Saúl Navarro-Marchal[1], Carolin Temps[1], Iñigo Lanzagorta-Calvillo[1], John C. Dawson[1], Enrique Poradosu[2], Neil O. Carragher[1], Valerie G. Brunton[1], Asier Unciti-Broceta[1]. *[1]Edinburgh Cancer Research, University of Edinburgh, Edinburgh, United Kingdom,[2]Nuvectis Pharma, Fort Lee, NJ*

Background: NXP900 (formerly known as eCF506) is a novel SRC/YES1 family kinase (SFK) inhibitor that locks SRC into its native closed conformation (= type 1.5), thereby inhibiting both kinase activity and complex formation with protein partners including FAK (Temps et al. Cancer Res. 2021, 81, 5438-5450). This mode of inhibition differentiates it from dasatinib, which blocks SRC into an open conformation (type 1) that promotes SRC-FAK interactions and increases FAK autophosphorylation. According to Watanabe and coworkers (Higuchi et al. Cell Rep 2021, 34, 108876), the enhancement of SRC-protein complex formation makes type 1 SFK inhibitors allosteric facilitators of conformational protein activation. Although dasatinib is a potent inhibitor of kinase activity, because of its allosteric effects, an in vivo decrease in tumor drug exposure below the active threshold could lead to fast activation of SFK-mediated signaling, temporarily promoting cancer growth until the next dose is administered. In contrast, the capacity of NXP900 to inhibit SRC in its inactive conformation should result in a more durable blockade of SFK-induced signaling; a critical advantage to prolong on-target inhibition and improve antitumor efficacy.
Materials and Methods: Mice strain: CD1 Nude. Cell line: TOV-21G. Xenograft: bilateral SC implantation of 0.1M cells with matrigel.
Groups: Vehicle PO QD; dasatinib 30 mpk PO QD; NXP900 20 mpk PO QD; NXP900 40 mpk PO QD; NXP900 80 mpk PO QD. PD study (n=3): 3 d treatment, tumors retrieved 3 and 24 h after last dose. H&E, IHC. Efficacy (n=5): 28 d treatment.
Results: An ovarian clear cell carcinoma (OCCC) cell model, TOV-21G, was implanted subcutaneously in mice to study SRC and FAK phosphorylation (Y419 and Y397, respectively) after oral administration of NXP900 and dasatinib. Tumors were excised 3 and 24 h post-treatment and analyzed by IHC. NXP900 showed lower phosphorylated SRC levels compared to the vehicle control for all doses. Dose response correlation was clearly observed for NXP900 in tumors analyzed 24 h after the last dose,

with complete inhibition achieved at 40 mg/Kg. Importantly, comparison between vehicle and dasatinib groups showed that the tumors from the dasatinib-treated group exhibited higher levels of phospho-SRC 24 h after the last dose, evidence of the paradoxical activation of SRC proposed by Watanabe as a consequence of blocking SRC in an open conformation. Analysis of tumor growth showed that treatment with NXP900 resulted in higher anticancer effect than that of dasatinib.
Conclusions: NXP900 induces superior target inhibition and anticancer activity than dasatinib in an OCCC xenograft model. The PD study suggests that the conformation selective mode of inhibition of NXP900 is more favorable for clinical development against SFK-driven cancers.

Discovery of a potent, selective, and orally available SHP2 inhibitor that can penetrate blood-brain barrier

Miyeon Kim[1], Dongsu Kim[1], Kyeong Jin Yoon[1], Yeejin Jeon[1], Dohyun Park[1], Mijung Lee[2], Dahye Jeon[2], Soyeon Jang[2], Jinhwan Kim[2], Eunji Kim[2], Jihoon Park[3], Victor Hong[3], Sang Kyun Lim[1], Sungpil Choi[1].
[1]Kanaph Therapeutics, Seoul, Korea, Republic of,[2]Yungjin Pharm, Suwon, Korea, Republic of,[3]Keimyung University, Daegu, Korea, Republic of

Src homology region 2-containing protein tyrosine phosphatase 2 (SHP2/PTPN11) is one of the key signaling proteins in many oncogenic receptor tyrosine kinase (RTK) pathways. It mediates RAS-driven downstream signaling and activates gene expression for tumorigenesis. Importantly, a critical role of SHP2 has been found during the process of temporal adaptation and ERK re-activation after the treatment of RAS/RAF/MEK/ERK inhibitors, which means that SHP2 could be a promising therapeutic target to shut down the oncogenic RAS pathway, especially in combination with RAS/RAF/MEK/ERK inhibitors. Here we present preclinical data of an allosteric small-molecule SHP2 inhibitor that is highly potent, selective, and brain-permeable. In vitro biochemical and cellular assays showed excellent potency against SHP2 protein. In addition, we confirmed exceptional in vivo activity in mouse xenograft models, and demonstrated combination effects with a KRAS G12C inhibitor. Most importantly, the BBB penetration and anti-tumor activity in brain was confirmed both in vitro and in vivo, supporting the great potential in

treating brain-metastasized tumors. In summary, we have successfully discovered and developed a potent and blood-brain barrier permeable SHP2 inhibitor that provides a novel therapeutic option for diverse cancers associated in the RAS pathway.

Pan-exon mutant KIT inhibitor DCC-3009 demonstrates tumor regressions in preclinical gastrointestinal stromal tumor models

Bryan D. Smith, Subha Vogeti, Timothy M. Caldwell, Hanumaiah Telikepalli, Yu Mi Ahn, Gada Al-Ani, Stacie L. Bulfer, Andrew Greenwood, Cale L. Heiniger, Joshua W. Large, Cynthia B. Leary, Wei-Ping Lu, Kylie Luther, William C. Patt, Max D. Petty, Yeni K. Romero, Forrest A. Stanley, Kristen L. Stoltz, Daniel C. Tanner, Sihyung Yang, Yu Zhan, Bertrand Le Bourdonnec, Daniel L. Flynn. *Deciphera Pharmaceuticals, LLC, Lawrence, KS*

Introduction: Gastrointestinal stromal tumors (GISTs) are typically driven by primary mutations in KIT exons 9 or 11. Heterogeneous drug-resistant secondary mutations arise in patients treated with FDA approved KIT inhibitors, including imatinib and sunitinib. Drug resistant secondary mutations are found at multiple regions in the ATP pocket (encoded by exons 13 and 14) or activation switch (encoded by exons 17 and 18) of KIT kinase. In addition, multiple drug-resistant clones can arise within a tumor or in metastatic tumor sites. An inhibitor that can broadly and potently inhibit the spectrum of KIT mutations is highly sought. Ripretinib has been FDA approved as a 4^{th} line treatment for GIST and has broad activity against KIT mutations, including clinical potency in patients with mutations in KIT exons 11, 17, or 18. DCC-3009 was designed as a next generation KIT inhibitor that broadly and potently inhibits primary KIT mutations in exons 9 and 11 and secondary drug-resistant mutations across exons 13, 14, 17, and 18. DCC-3009 is a potent and selective inhibitor in enzyme and cell-based assays, and has demonstrated efficacy in xenograft models driven by drug resistant KIT mutations.

Methods: DCC-3009 was tested for inhibition of KIT mutants using standard enzyme and cell-based assays. Levels of phosphorylated KIT were determined by Western blot or ELISA. Proliferation was measured using the fluorescent dye resazurin. KIT mutant xenograft or patient-derived

xenograft models were performed at Crown Biosciences or Labcorp, AAALAC accredited facilities, with the approval of Animal Care and Use Committees.
Results: In BaF3 cells transfected with KIT mutants, DCC-3009 was shown to potently inhibit the spectrum of known primary and secondary drug-resistant mutations in GIST. The pan-mutant KIT profile of DCC-3009 was shown *in vitro* to be superior to 2nd and 3rd line standard of care therapies sunitinib and regorafenib. DCC-3009 was selective for KIT when screened against a large panel of kinases. DCC-3009 has optimized pharmaceutical properties for oral administration. In pharmacokinetic/pharmacodynamic studies DCC-3009 achieved sufficient free drug levels to significantly inhibit drug-resistant KIT mutants for 12 hr post dose. In xenograft studies, treatment with DCC-3009 twice daily led to tumor regression in drug-resistant models with KIT exon 9/13, 11/13 or 11/17 mutations.
Conclusions: DCC-3009 is a pan-exon mutant KIT inhibitor exhibiting high potency in KIT mutants in pre-clinical models spanning exons 9, 11, 13, 14, 17 and 18. *In vivo,* DCC-3009 exhibited efficacy in drug-resistant models with KIT exon 9/13, 11/13 or 11/17 mutations. Based on this profile, DCC-3009 has entered formal preclinical development.

#4034

A potent and highly selective irreversible HER2 inhibitor for treating HER2-driven cancers

Chunmei Zhao, Lana Kulyk, Iriny Botrous, Kelly Chen, Chang Zhao, Afsheen Banisadr, Mary L. Anderson, Fred Manby, Tom Miller, Chao Zhang, Laurent Gomez, Zhongdong Huang. *Entos, Inc, La Jolla, CA*

HER2 amplification and mutations occur frequently in multiple human cancers, including breast, ovarian, gastric and lung cancers. Despite HER2 being one of the earliest oncogenic drivers discovered, HER2 inhibitors have had limited clinical success compared to inhibitors of other kinase oncogenes. This has been attributed to a compensatory mechanism present in HER2-driven cancers that significantly raises the exposure threshold for durable pharmacological inactivation of HER2 signaling in vivo. This requires a therapeutic index far exceeding that of available pan-ERBB and HER2 inhibitors, all of which are hampered by dose-limiting side effects from collateral or residual EGFR inhibition.To address this critical unmet

need, we present a novel irreversible HER2 inhibitor, ENT-H1, discovered via artificial intelligence-enabled chemistry. ENT-H1 potently inhibits wild-type and mutated HER2, including the recalcitrant exon 20 insertion mutations, while sparing wild-type EGFR. In a panel of Ba/F3 cells whose growth is driven by HER2 or EGFR expression, ENT-H1 displayed low nanomolar potency across 23 representative HER2 mutations, while showing minimum effect on the growth of Ba/F3 EGFR cells. This exquisite selectivity was confirmed by comparing the sensitivity of cancer cell lines that over-express HER2 (e.g. BT-474 and Calu-3) and EGFR (e.g. A431), and translated into a high in vitro therapeutic index when ENT-H1 was evaluated in a gastrointestinal toxicity assay. In vivo, ENT-H1 demonstrated strong efficacy and better tolerability than benchmark HER2 inhibitors in multiple HER2-amplified or -mutated tumor models, including those bearing HER2 exon 20 insertion mutations (e.g. A775G776insYVMA and G776VC). Treatment with ENT-H1 led to significant tumor regression without causing body-weight loss. In these models, ENT-H1 showed robust and rapid pharmacodynamic effect in reducing phosphorylated HER2 and downstream phosphorylated AKT and ERK levels, confirming that the antitumor effect was a result of targeted inhibition of HER2 oncogenic signaling. Further analysis showed that ENT-H1 concentrations were significantly higher in xenograft tumors than in plasma; this distribution profile has the potential to maximize target engagement in the tumor while minimizing untoward systemic side effects. These data establish that ENT-H1 is a safe and effective HER2 small-molecule inhibitor. With 100-fold selectivity against the highly homologous EGFR and a desirable pharmacokinetic profile, ENT-H1 represents a promising drug candidate to realize the full therapeutic potential of a HER2-targeting agent while avoiding side effects associated with EGFR inhibition.

#4035

Preclinical activity of BAY 2927088 in HER2 mutant non-small cell lung cancer

Franziska Siegel[1], Gizem Karsli-Uzunbas[2], Kristyna Kotynkova[2], Quinn McVeigh[2], Stephan Siegel[3], Daniel Korr[4], Volker Schulze[3], Markus Berger[3], Georg Beckmann[5], Andrew Cherniack[2], Matthew Meyerson[6], Heidi Greulich[2]. *[1]Research & Early Development Oncology, Bayer AG, Berlin, Germany,[2]Broad Institute of MIT and Harvard, Cambridge,*

MA,[3]Synthetic Modalities, Bayer AG, Research & Development, Pharmaceuticals, Berlin, Germany,[4]Therapeutic Compound Research, Nuvisan ICB GmbH, Berlin, Germany,[5]Biomedical Data Science, Bayer AG, Research & Development, Pharmaceuticals, Berlin, Germany,[6]Dana-Farber Cancer Institute, Boston, MA

HER2 mutations are potent oncogenic drivers in various cancer indications. In NSCLC, about 2% of patients carry either a HER2 exon20 insertion mutation or a HER2 point mutation. With the recent approval of fam-trastuzumab deruxtecan-nxki, the first targeted treatment option became available for HER2 mutant NSCLC patients. However, there remains a high unmet need for more effective and better tolerated therapies with the potential to improve response rates and response durability.
BAY 2927088 is a reversible small molecule inhibitor that is currently being evaluated in a first-in-human, phase I clinical trial in patients with EGFR mutant NSCLC (NCT05099172).
Here, we present the preclinical activity profile of BAY 2927088 in HER2 mutant NSCLC. BAY 2927088 shows strong antiproliferative activity in an isogenic Ba/F3 cell line panel of HER2 exon20 insertion mutations as well as HER2 point mutations. BAY 2927088 is highly potent on the most frequent HER2 exon20 insertion mutations A775insYVMA and G776del insVC, as well as in the HER2 point mutations S310F, S335C, and L755S, among others. In addition, the compound was active in a subset of endogenously HER2 mutant cancer cell lines. The *in vitro* activity of BAY 2927088 was validated *in vivo* in a patient-derived xenograft model carrying the HER2 exon20 insertion mutation A775insYVMA.
The strong preclinical activity of BAY 2927088 in HER2 mutant NSCLC supports clinical evaluation in this indication and might offer a novel targeted therapy option for NSCLC patients that carry HER2 mutations.

#4036

NMS-0963 is a novel potent, selective and orally available Syk inhibitor with promising preclinical activity in diffuse large B-cell lymphoma

Grazia Saturno, Michele Modugno, Paolo Orsini, Giovanni Cervi, Laura Buffa, Ilaria Motto, Nilla Avanzi, Marisa Montemartini, Fabio Gasparri, Gemma Texido, Arturo Galvani, Antonella Isacchi. *Nerviano Medical Sciences, Nerviano, Italy*

The B-cell receptor (BCR) is a key survival molecule for normal B cells and for most B-cell malignancies, such as Chronic Lymphocytic Leukaemia (CLL) and Non-Hodgkin's Lymphomas (NHL) including Diffuse Large B-cell Lymphomas (DLBCL). Small molecule inhibitors of key signaling kinases involved in the BCR pathway, such as the Btk inhibitor ibrutinib and the PI3Kdelta inhibitor idelalisib, have already demonstrated significant clinical activity. Spleen tyrosine kinase (Syk) is a non-receptor cytoplasmic tyrosine kinase that plays a fundamental role in BCR signaling initiation thus representing an additional potential therapeutic target for the inhibition of the BCR pathway. Here, we report the discovery and characterization of NMS-0963, a novel potent, selective and orally available Syk inhibitor, identified through an integrated medicinal chemistry and rational design approach. NMS-0963 showed potent inhibitory effect on Syk in an in vitro biochemical assay and displayed a good selectivity profile on a broad panel of kinases. On-target potency was confirmed in a cell-based assay using BaF3 cells engineered to express constitutively activated Syk, showing potent inhibition of Syk activity resulting in antiproliferative effect with IC50s in the low nanomolar range. Effective inhibition of BCR-mediated signaling pathway was observed in DLBCL-derived cell lines. NMS-0963 showed favourable ADME profile and good in vivo pharmacokinetic profiles after oral administration in mouse, rat and dog. Furthermore, NMS-963 demonstrated striking in vivo efficacy in tumor models of CD79/Myd88 mutated DLBCL, superior to competitors. Together with a permissive preclinical safety profile, these results support a rational for clinical development of NMS-0963 in DLBCL.

#4037

Doxazosin exerts anti-metastatic potential in triple-negative breast cancer via impairment of cancer stem-like features

Seongjae Kim, Dongmi Ko, Juyeon Seo, Soeun Park, Minsu Park, Kee Dal Nam, Yong koo Kang, So Ra Seock, Jaeyoun Park, Eunhye Oh, Eunsun Jung, Yoon-Jae Kim, Ji Young Kim, Jae Hong Seo. *Korea University Guro Hospital, Seoul, Korea, Republic of*

Background **and Purpose:** Triple-negative breast cancer (TNBC) tumors typically harbor a high cancer stem-like population leading to chemo-

resistance, recurrence, and metastasis. Tumor metastasis is associated with 90% of cancer-related deaths, highlighting the urgent clinical unmet need. Doxazosin is known to inhibit cell migration and invasion in several cancer cell types; however, the precise mechanisms underlying doxazosin's anticancer effects in TNBC have not been fully elucidated. In the present study, we sought to investigate the mechanism of action of doxazosin responsible for its effects on apoptosis, cancer stem cell (CSC)-like properties, cell migration, and metastasis in TNBC.
Experimental designs: Doxazosin on TNBC cell lines [MDA-MB-231, BT549, and 4T1] in vitro was evaluated in cell viability, apoptosis, cell migration, CD44/CD24 staining, ALDH1 activity, and mammosphere formation. The effect of doxazosin on tumor growth, angiogenesis, and metastasis was evaluated in an orthotopic allograft mice model with CSC-enriched population.
Results: Doxazosin significantly reduced cell viability and induced apoptosis in MDA-MB-231 and BT549 cells via activation of caspase-3/-7 and cleavage of PARP. Doxazosin significantly suppressed cell migratory capability, concomitant with disrupting cytoskeletal proteins, including vimentin and F-actin expression in TNBC cells. An impairment of BCSC-like properties was associated with reduction of ALDH1 activity and the CD44+/CD24- population, concomitant with suppression of mammosphere-forming ability. Doxazosin administration reduced tumor growth and lung metastasis, as evidenced by a sharp decline in bioluminescence signal intensity. Inhibitory effect of tumor growth was accompanied by a significant decrease of Ki-67 and enhancement of apoptosis with DNA fragmentation and increased cleaved-caspase-3 expression. The latter phenomenon was associated with the impediment of JAK2/STAT3 signaling pathway and CSC-like properties. Furthermore, no toxic effects of doxazosin were found in liver and kidney function in animals.
Conclusion: Taken together, our findings highlight doxazosin as a promising candidate for drug repurposing in suppressing metastatic TNBC.

#4038
Discovery of potent and selective inhibitors of the protein tyrosine phosphatases PTPN2 and PTPN1 to trigger anti-tumor immunity through sensitization of tumor cells and activation of immune cells

Kalliopi Pervolaraki[1], Egle Katkeviciute[2], Dominique Lambin[1], Sandro Boland[1], Amuri Kilonda[1], Vincent Pericolle[1], Marnik Nijs[1], Wanda Haeck[1], Kristine Metzger[1], Hugo Klaassen[1], Arnaud Marchand[1], Patrick Chaltin[1], Matthias Versele[1], Marianne Spalinger[2], Michael Scharl[2]. *[1]CD3 (Centre for Drug Design and Discovery), Leuven, Belgium,[2]Department of Gastroenterology and Hepatology, University of Zurich, Zurich, Switzerland*

Protein tyrosine phosphatase nonreceptor type 2 (PTPN2) has emerged as a promising cancer immunotherapy target. Previously, we reported on the functional role of PTPN2 in the pathogenesis of colorectal carcinoma (CRC). We demonstrated increased PTPN2 phosphatase activity correlates with disease progression and decreased immune responses in tumor tissues, while loss of PTPN2 in T-cells or in dendritic cells (DCs) reduces tumor burden in several CRC models and potentiates anti-PD1 efficacy (Katkeviciute et al., 2021). Others reported that loss of PTPN2 in tumor cells sensitizes to immune-mediated tumor killing (Manguso et al., 2017; Goh et al., 2022). Thus, PTPN2 was proposed as a critical node to modulate anti-tumor immunity, and PTPN2 inhibition is expected to enhance anti-tumor immunity by sensitizing tumor cells and by activating immune cells. Recently, also the closely related phosphatase PTPN1 (PTP1B) was demonstrated to restrain T-cell mediated tumor killing (Wiede et al., 2022). Inhibition of Protein Tyrosine Phosphatases has historically been a demanding area for drug discovery. However, both allosteric PTP inhibitors (*eg* targeting SHP2/PTPN11) and catalytic-site inhibitors (targeting PTPN2/N1) have recently progressed to clinical studies. We now identified a chemical series of novel dual PTPN2/N1 inhibitors. These inhibitors bind to the catalytic site of PTPN2, as confirmed by crystallography. The best molecules of the series are low nM inhibitors of PTPN2 and PTPN1 enzymes with excellent selectivity across other phosphatases. As an immediate consequence of PTPN2/N1 inhibition, these compounds augment phosphorylation of STAT1 and/or STAT5 isoforms in myeloid and T-cell lines, and in primary T-cells, macrophages and DCs. This results in immune-cell activation as evidenced by increased production of effector cytokines (e.g. IFNγ), immune-activation, levels of cytotoxicity markers in T-cells (e.g. granzyme B) as well as upregulation of antigen presentation and co-stimulatory markers in macrophages and DCs. Furthermore,

inhibition of PTPN2/N1 sensitizes murine and human cancer cell lines to IFNγ, and enhances immune-mediated tumor killing in co-culture assays *in vitro*. *In vivo* evaluation of selected examples is in progress and results will be presented at the conference. Our data indicate that inhibition of PTPN2/N1 phosphatase activity is a powerful pharmacologic strategy to promote anti-tumor immunity, with strong potential to be exploited for cancer immunotherapy both as a single agent treatment in anti-PD1 refractory cancers, and in combination with anti-PD1 therapy.

RET overexpression is frequent in lung neuroendocrine tumors (NET) and associates with response to RET tyrosine kinase inhibitors (RET TKIs) in NET cell lines

Jaume Roca-Arias[1], Jordi Bertran-Alamillo[1], Ruth Román[1], Cristina Aguado[1], Laura López[2], Leticia Ferro-Leal[3], Beatriz Garcia-Pelaez[1], Rodrigo de Oliveira Cavagna[3], Silvia Teixeira[3], Rafael Rosell[4], Rui Manuel Reis[3], Miguel A. Molina-Vila[1], Ivana Sullivan[5]. *[1]Laboratory of Oncology, Pangaea Oncology, Dexeus University Hospital, Barcelona, Spain,[2]Pathology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,[3]Molecular Oncology Research Center, Hospital de Amor, Barretos, Brazil,[4]Hospital Dexeus, Barcelona, Spain,[5]Medical Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Background**:** *RET* (rearranged during transfection) is a proto-oncogene encoding for a tyrosine kinase membrane receptor that promotes protein synthesis and cell proliferation. A small percentage of human tumors harbor *RET* fusions or mutations as oncogenic drivers and RET-TKIs have been developed. Two of them, selpercatinib and pralsetinib, have recently been approved. However, their effect on tumors overexpressing wild-type RET (wt-RET) has not been investigated. A large-scale mRNA analysis performed by our group revealed that ~2% of lung tumors present high expression of wt-RET in absence of fusions. Interestingly, ~60% of high wt-RET tumors presented neuroendocrine characteristics.

Methods: Twenty large cell neuroendocrine (LCNEC) and 19 small cell (SCLC) lung carcinomas from two additional institutions were analyzed by nCounter® to validate the previous results. For *in vitro* experiments, a panel

of cell lines derived from lung NETs (DMS-53, NCI-H82, NCI-H727) was used, together with a lung adenocarcinoma cell line (LC2/ad, a positive control harboring the *CDCC6-RET* translocation). *RET* fusions and mRNA expression were analyzed by nCounter®, RET protein expression by Western blotting and immunohistochemistry (IHC) and *RET* mutations by next generation sequencing. The inhibitory effects of selpercatinib and pralsetinib were analyzed *in vitro* by MTT in 2D and spheroid/3D cultures. Finally, *in vivo* experiments implanting tumor cells into athymic nude mice are ongoing.
Results: Among the 20 LCNECs and 19 SCLCs analyzed, 3 (15%) and 3 (15%) presented very high levels of wt-RET mRNA by nCounter, respectively. Fusions were absent in all cases. The NCI-H82 and NCI-H727 NET cell lines showed very low RET mRNA and protein expression by nCounter, Western blotting and IHC. In contrast, DMS-53 cells presented levels of RET mRNA and protein higher than the observed in the *RET*-fusion positive LC2/ad. In 2D models, the three NET cell lines tested showed moderate resistance to pralsetinib and selpercatinib, with IC50s of 1.5 - 9.7 μM for pralsetinib and 4.6 - 6.1 μM for selpercatinib; while the RET-fusion positive LC2/ad cells showed an IC50 in the nM range, as expected. In 3D cultures, DMS-53 was found to be sensitive to RET TKIs, with IC50s of and 0.3 μM for praseltinib and 2.5 μM for selpercatinib. In contrast, spheroids of the two RET low cell lines showed complete resistance to both drugs (IC50>10 μM). Experiments in animal models are currently ongoing, final results will be presented at the meeting.
Conclusions: Overexpression of RET is frequent in lung tumors with neuroendocrine features (LCNEC, SCLC). Selpercatinib and Pralsetinib show antitumor activity in lung NETs cells expressing high levels of wt-RET.

Asciminib activates erythroid differentiation in K562 cell line
Hammad Hassan, Sarah Yousuf, Syed Muhammad Areeb Ahmed, Karim Ruknuddin, Hadiqa Raees, Sadia Habib, Fizza Iftikhar, Afsar Ali Mian, Elnasir Lalani. *Centre for Regenerative Medicine and Stem Cell Research, Aga Khan University, Aga Khan University, Pakistan*

Background**:** Asciminib an allosteric tyrosine kinase inhibitor (TKI) was recently approved by the FDA for managing Philadelphia positive chronic myeloid leukemia (CML) patients in chronic phase who had failed to respond to previous TKIs. In this study, we used human erythroleukemic K562 cell line to investigate the role of asciminib as an inducer of erythroid differentiation. Additionally, imatinib, which has previously been reported as a potential inducer of erythroid differentiation, was also tested on these cells, both independently as well as in combination, in order to investigate the degree of erythroid differentiation in a K562 cell line.
Methodology: In this study, we investigated the effect of asciminib (5-20nM) with and without imatinib (50-200nM) in differentiating the erythroleukemic cell line K562 towards erythroid lineage. K562 cells were cultured over a 12-day period in basic (IMDM) media and an EPO-based differentiation media to select optimal medium conditions. In addition, an *in-vitro* drug cytotoxicity experiment (XTT) was used to determine the preliminary toxicity of asciminib with IMDM media and EPO-based differentiation media. CD235a and CD71 surface marker expressions were analyzed by flow cytometry at all time-points to determine the degree of differentiation achieved by each of the conditions. Moreover, to analyze and identify hemoglobin producing cells ensuing differentiation, benzidine staining was performed at indicated time points.
Results: Our results suggest that asciminib, imatinib or a combination of both drugs in EPO-based differentiation media results in efficient erythroid differentiation with high levels of GPA expression (approx. 90%) and significant upregulation of globin genes (p value = 0.0001). These results were further confirmed by benzidine staining, where drug addition and dose escalation significantly increased benzidine-positive cells. Our results also demonstrated that asciminib was able to achieve maximum differentiation at a much earlier time point as compared to imatinib. Moreover, asciminib, when combined with another TKI such as imatinib, can also aid in lowering the drug concentrations being used, hence resulting in lessening the toxicity of the drug when used alone required at high doses.
Conclusion: The results from this study highlighted the novel role of asciminib in erythroid differentiation using an *in-vitro* K562 model that can give high-levels of surface markers and globin expression. Potential clinical application of asciminib in hematological diseases that are associated

specifically with a failure in the expression of globin genes should be evaluated.
Keywords:K562, erythroid differentiation, asciminib, imatinib, glycophorin A, transferrin receptor, hemoglobin

The EML4-ALK fusion protein mediates reduced sensitivity to the combination of neratinib and dasatinib

Myra E. Castel[1], Neil T. Conlon[1], Lisa D. Eli[2], Alvin Wong[2], John Crown[3], Denis M. Collins[1]. *[1]NICB, Dublin City University, Dublin 9, Ireland,[2]PUMA Biotechnology, Inc, Los Angeles, CA,[3]St. Vincent's University Hospital, Dublin, Ireland*

Introducti**on:** The anaplastic lymphoma kinase (ALK) gene encodes a receptor tyrosine kinase involved in cellular proliferation, differentiation, and cell death. ALK becomes oncogenic when it forms a fusion gene. The EML4-ALK fusion gene has been identified mainly in non-small cell lung cancer (NSCLC). It is unknown whether neratinib, an irreversible pan-HER tyrosine kinase inhibitor (TKI) targeting EGFR, HER2 and HER4, is effective in cancers harboring EML4-ALK gene fusion. The objective of this study was to assess *in vitro* efficacy of neratinib in combination with dasatinib (Src/Abl TKI) or crizotinib (ALK TKI) in EML4-ALK+ NSCLC.
Methods: The antiproliferative effects of neratinib, dasatinib and crizotinib were assessed in the CRISPR/Cas9-modified EML4-ALK fusion-A549 (EML4-ALK+) and parental A459 (A549-Par) NSCLC cell lines by 5-day acid phosphatase assay. IC_{50} values were calculated using CalcuSyn software. To assess the synergy between neratinib and dasatinib, and neratinib and crizotinib, matrix assays were performed and analyzed using Combenefit software. To further assess the efficacy of the TKIs, changes in signaling pathways were assessed by Western blotting, and apoptosis induction and cell migration were measured with the Incucyte® S3 imaging system.
Results: Neratinib, crizotinib, and dasatinib displayed nanomolar IC_{50} values in both cell lines. As expected, EML4-ALK+ cells were more sensitive to crizotinib than A549-Par cells (IC_{50} = 595 nM vs 1 μM, $p \leq 0.05$). EML4-ALK expression led to numerical increases in neratinib IC_{50}

value (326.37 ± 44.34 nM in EML4-ALK+ vs 247 ± 32.65 nM in A549-Par) and dasatinib IC_{50} value (39.95 ± 5.67 nM in EML4-ALK+ vs 27.75 ± 18.53 nM in A549-Par) but these changes were not statistically significant. Matrix assays showed that neratinib-crizotinib (NC) was more effective than crizotinib alone in both cell lines, with more potent sensitivity in EML4-ALK+ cells. The neratinib-dasatinib (ND) combination was synergistic in the A549-Par cell line but only additive in the EML4-ALK+ cell line, suggesting a reduced sensitivity to the ND combination. EML4-ALK+ cells had sustained pERK1/2 levels after treatment with all TKIs, except NC, compared to A549-Par cells. Neratinib alone was significantly less effective at inhibiting pAkt (99.2 ± 5.3 % in EML4-ALK+ vs 64.9 ± 19.0 %, $p \leq 0.05$) and pERK1/2 (91.3 ± 4.6 % in EML4-ALK+ vs 54.9 ± 15.9 %, $p \leq 0.01$) in EML4-ALK+ cells than in A549-Par cells at 24h. In A549-Par cells, ND caused the highest apoptotic induction, followed by NC. Apoptosis levels induced by ND in EML4-ALK+ cells were 4-fold lower at 72hr than in A549-Par cells ($p \leq 0.0001$). Dasatinib and ND were more effective than crizotinib or NC at preventing cell migration in both cell lines.

Conclusion: EML4-ALK potentially decreases sensitivity to the neratinib-dasatinib combination. This warrants further investigation in other EML4-ALK+ models.

#4042

Role of individual HER family members and pan-HER targeting treatment strategy in NRG1 fusion positive cancer

Hibiki Udagawa, Monique Nilsson, Junqin He, Alissa Poteete, John Victor Heymach. *Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Huston, TX*

NRG1 gene fusions are rare, clinically actionable somatic alterations identified in 0.1% of all tumors. Previous studies have demonstrated that NRG1 fusions signal through *ERBB*/HER family members and that HER2 inhibition has anti-tumor activity in *NRG1* fusion-driven cancers. However, NRG1 can also bind to HER4 in addition to HER3, and the contribution of individual HER family members in tumor cells with NRG1 fusions has not been fully elucidated. To determine the role of individual HER family members in NRG1 fusion positive cancer cells, we engineered Ba/F3 cells

to express various HER family members along with NRG1 fusions. Expression of NRG1 fusions in combination with EGFR/HER3, HER2/HER4 or HER4 induced cellular transformation as measured by IL-3 independent growth. These results indicated that in addition to HER2/HER3 signaling, EGFR/HER3, HER4, and to a greater extent, HER2/HER4 signaling, may activate key oncogenic signaling pathways in cells expressing NRG1 fusions. We next assessed whether targeted inhibition of HER family members could inhibit the growth of NRG1 fusion positive cancer cells using our panel of engineered Ba/F3 cells, human tumor cell lines, and xenograft models. Our data indicated that pan-HER tyrosine kinase inhibitors (TKIs), such as poziotinib, were more effective at blocking HER2/HER3, EGFR/HER3 and HER4 signaling in NRG1-fusion expressing cells as compared to TKIs with greater relative specificity for EGFR (erlotinib, lapatinib), HER2 (pyrotinib), EGFR/HER2 (afatinib, dacomitinib, neratinib) or HER2/HER4 (TAS0728,tucatinib). In NRG1 fusion-positive cancer cell lines, poziotinib showed potent anti-tumor cell activity with IC_{50} values of 0.2 - 0.4 nM. The IC_{50} values of EGFR/HER2 TKIs were 0.3 - 23 nM, and HER2/HER4 TKIs showed modest activity with IC_{50} values of 11 - 560 nM. Next, we assessed whether inhibition of HER family dimerization also had activity against tumor cells harboring NRG1 fusions. We observed that pertuzumab, a HER2 antibody which inhibits HER2 dimerization with other HER family members, had improved single agent activity as compared to trastuzumab, a HER2 antibody that inhibits HER2 activation, suggesting crosstalk between HER family members. Moreover, an additive effect was observed when tumor cells were treated with trastuzumab in combination with pertuzumab. Treatment with cetuximab, an antibody that targets EGFR, in combination with trastuzumab and pertuzumab yielded a synergistic effect on tumor cell killing. These data indicate that HER4 and EGFR can play a role in NRG1 fusion-driven signaling through crosstalk with HER2/HER3 and thus, pan-HER/EGFR inhibitors are more effective than EGFR/HER2 or HER2/HER4-selective inhibitors, highlighting the therapeutic potential of targeting multiple members of the HER family in NRG1 fusion driven cancers.

Stimulation of the mapk and pi3k/akt pathways in pancreatic cancer cells by polyisoprenylated cysteinyl amide inhibitors

Kweku Ofosu-Asante, Jassy M. Lazarte, Amarendar G. Burra, Nazarius S. Lamango. *Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL*

Pancreatic cancer is the third deadliest cancer with a 5-year survival rate of less than 10%. Over 90% of reported cases are driven by *KRAS* mutations. KRAS signals through the MAPK and PI3K pathways. Targeting mutant KRAS has been a decades-long challenge until recently whereby drugs that react with specific mutant proteins have been developed. Polyisoprenylated cysteinyl amide inhibitors (PCAIs) are potential anticancer agents with an alternative design strategy targeting polyisoprenylation-dependent processes of hyperactive mutant or overexpressed G-proteins. The effect of PCAIs on the viability and downstream mediators of KRAS signaling was determined on PANC-1 and MIAPaCa-2 cells. Of the 16 different analogs tested, NSL-YHJ-2-45 and NSL-YHJ-2-27 were the most potent with EC_{50} values of 3.6 and 3.8 against PANC-1 cells, respectively. For MIAPaCa-2 cells, NSL-YHJ-2-27 was the most potent with an EC_{50} value of 2.2. Western blotting analysis of PCAIs-treated PANC-1 cells revealed that phosphorylated BRAF, MEK 1/2, ERK 1/2 and p90RSK increased by 64, 129, 152 and 79%, respectively, while phosphorylated CRAF levels decreased by 27%. Moreover, monomeric G-proteins, CDC42, RHOA and RAC 1/2/3 protein levels decreased by 20, 58 and 13%, respectively. NSL-YHJ-2-27 (5 μM) also increased the levels of pAKT (Ser 473) and pAKT (Thr 308) by 72 and 192%, respectively. When MIAPaCa-2 cells were treated with 0-5 μM NSL-YHJ-2-27, MEK 1/2, ERK 1/2 and p90RSK phosphorylation increased by 78, 270 and 260%, respectively. However, at 5 μM NSL-YHJ-2-27, there were no significant changes in protein levels of the monomeric G proteins RAC 1/2/3 and RHOA, but protein levels of CDC42 increased by 132%. NSL-YHJ-2-27 (5 μM) increased the levels of pAKT (Ser 473) and pAKT (Thr 308) of MIAPaCa-2 cells by 97 and 82%, respectively. The results indicate the effect of PCAIs on the phosphorylation of important kinases involved in MAPK and AKT pathways. These effects on these signaling pathways strongly indicate the potential of the PCAIs against RAS-driven cancers.

Development of UCT-01-097, a novel orally available ERK1/2 inhibitor for the treatment of ERK1/2 dependent cancers

Neil A. O'Brien[1], Martina S. J. McDermott[1], Brendan M. O'Boyle[2], Corey M. Reeves[2], Michael Bartberger[2], Oliver Loson[2], Kevin Chau[1], Jenny J. Hong[1], Weiping Jia[1], Naeimeh Kamranpour[1], Tong Luo[1], Raul Ayala[1], Athena M. Madrid[1], John A. Glaspy[1], Brian M. Stoltz[3], Dennis J. Slamon[1].
[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]1200 Pharma, Culver City, CA,[3]Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, CA

The MAPK signaling pathway is the most commonly mutated and/or dysregulated pathway in cancer. Strategies to target it have yielded some success with inhibitors against $KRAS^{G12C}$ and BRAF, and to a lesser extent, MEK1/2. However, the impact of these molecules is often limited by toxicity and rapid and diverse mechanisms of resistance; both adaptive and/or acquired. For example, treatment with MAPK pathway targeting agents results in compensatory activation of the downstream mediator ERK1/2 and enables tumors to subvert the targeted therapy. Thus, targeting ERK1/2 provides promising potential advantages in overcoming and/or preventing adaptive and acquired resistance. We evaluated multiple preclinical and clinically staged ERK1/2 inhibitors—including ERAS-007 and BVD-523—in a 500+ cell line screening platform and identified cancers with subpopulations that are sensitive to this class of inhibitor. KiNativ analyses helped to inform the differences in sensitivity/selectivity that we observed between each ERK1/2 inhibitor. Comprehensive molecular profiling of the cell lines at baseline allowed us to screen for potential molecular markers of sensitivity/resistance to these compounds. Using this platform, we have developed a novel, potent ERK1/2 small molecule inhibitor, UCT-01-097, with improved selectivity over other clinically staged inhibitors. These data, coupled with the broad spectrum of in vitro responses, suggests an improved therapeutic index with this molecule. UCT-01-097 shows kinase selectivity in both cell free and in-cell assays and robust efficacy in panel of pancreatic PDX models. Inhibition of xenograft tumor growth was achieved using both daily dosing and intermittent dosing schedules. We have successfully submitted a regulatory

IND and are currently enrolling a Phase 1 clinical trial in advanced solid tumors for treatment with UCT-01-097 (NCT04761601).

DCC-3084, a RAF dimer inhibitor, broadly inhibits BRAF class I, II, III, BRAF fusions, and RAS-driven solid tumors leading to tumor regression in preclinical models

Stacie L. Bulfer, Bertrand Le Bourdonnec, Jeffery D. Zwicker, Yu Mi Ahn, Gada Al-Ani, Hikmat Al-Hashimi, Chase K. Crawley, Kristin M. Elliott, Saqib Faisal, Andrew M. Harned, Cale L. Heiniger, Molly M. Hood, Salim Javed, Michael Kennedy, Joshua W. Large, Cynthia B. Leary, Wei-Ping Lu, Kylie Luther, Max D. Petty, Hunter R. Picard, Justin T. Proto, Yeni K. Romero, Forrest A. Stanley, Kristen L. Stoltz, Daniel C. Tanner, Hanumaiah Telikepalli, Mary J. Timson, Lakshminarayana Vogeti, Subha Vogeti, Sihyung Yang, Lexy H. Zhong, Bryan D. Smith, Daniel L. Flynn.
Deciphera Pharmaceuticals, LLC, Waltham, MA

Background**:** Mutations in the RAS/MAPK pathway are a frequent driver of cancer, with oncogenic RAS or RAF mutations occurring in >30% of all cancers. First generation BRAF inhibitors are approved for use for tumors with Class I BRAF mutations (V600X). However, these drugs are not efficacious in RAF dimer mutant and RAS mutant cancers due to paradoxical activation of RAF dimers. Herein, we describe DCC-3084, a potent and selective investigational Switch Control inhibitor of BRAF and CRAF kinase dimers that targets Class I, II and III BRAF mutations, BRAF fusions, and BRAF/CRAF heterodimers. DCC-3084 combines with inhibitors of additional nodes in the MAPK pathway to potentially target a large unmet medical need in RAS and RAF mutant cancers.
Methods: Inhibition of RAF kinases, including off-rate analysis, was measured using recombinant enzymes. X-ray crystallography was used for structure-based drug design. Cellular proliferation was measured using resazurin to monitor cell viability. Synergy in cells was measured using BLISS scores and curve shift analysis. Inhibition of ERK or RSK phosphorylation was measured by AlphaLISA or ELISA. Pharmacokinetics (PK) in the plasma, brain and CSF compartments were measured following oral dosing in Wistar rats. RAF and RAS mutant mouse xenograft models were used to assess PK, pharmacodynamics (PD), and efficacy.

Results: DCC-3084 is a potent and selective Switch Control inhibitor of RAF dimers that was designed to target Class I, II, III BRAF mutants, BRAF fusions, and BRAF/CRAF heterodimers. DCC-3084 inhibits BRAF and CRAF, exhibiting slow off-rates ($t_{1/2}$ >20 hr). Potent single-agent inhibition of MAPK pathway signaling and cellular proliferation was observed in a wide range of Class I, II, III BRAF and BRAF fusion altered cell lines. Synergy was observed in combination with inhibitors of other nodes in the RAS/MAPK pathway in RAS mutant cell lines. DCC-3084 was demonstrated to be CNS penetrable and exhibited dose dependent oral exposure with robust inhibition of the RAS/MAPK pathway in PK/PD models. DCC-3084 accumulated in tumor tissue relative to plasma, further demonstrating a favorable pharmaceutical profile. Oral treatment of DCC-3084 as a single agent resulted in tumor regression in BRAF mutant and KRAS Q61K mutant mouse xenograft models and tumor growth inhibition in KRAS G12C/D mutant models. Additionally, DCC-3084 in combination with a MEKi resulted in tumor regression in KRAS mutant models.
Conclusions: The Switch Control inhibitor DCC-3084 broadly inhibits Class I, II and III BRAF mutations, BRAF fusions, and BRAF/CRAF heterodimers leading to tumor regression in preclinical models. The overall preclinical profile of DCC-3084 supports IND-enabling activities towards clinical development in a key area of unmet medical need in RAS and RAF mutant cancers.

TIDAL-01: A selected TIL process that enriches for neoantigen reactive TIL in solid tumors

Larissa A. Pikor[1], Antoine Bernard[2], Nathalie Brassard[2], Anna Fritzsche[1], Anna Kluew[1], Zachary K. Jilesen[1], Jake Nikota[3], Rohan Bareja[4], Christian Laing[4], David F. Stojdl[1], TJ Langer[4], Stewart Abbot[4], Barbara Sennino[4], Simon Turcotte[2]. *[1]Turnstone Biologics, Ottawa, ON, Canada,[2]CHUM, Montreal, QC, Canada,[3]Turnstone Biologics, Hamilton, ON, Canada,[4]Turnstone Biologics, San Diego, CA*

Background**:** Tumor infiltrating lymphocyte (TIL) therapy is capable of mediating durable complete responses in melanoma. While solid tumors such as colorectal cancer (CRC), non-small cell lung cancer (NSCLC), ovarian and breast have been shown to contain neoantigen reactive TIL, the success of bulk TIL therapy in these tumors has been limited. Enhancing tumor reactivity through the selective expansion of neoantigen-reactive subpopulations, has demonstrated success in cancers outside of melanoma underscoring the potential of a neoantigen selected TIL approach in indications with lower tumor mutational burdens. Here we demonstrate that the TIDAL-01 process, which utilizes tumor-specific mutation containing peptides to select neoantigen reactive TIL produces TIL products significantly enriched in neoantigen reactivity.
Methods: Fresh tumors were cut into fragments or dissociated and cultured in a primary expansion (preREP). Antigen presenting cells (APCs) were isolated and expanded from patient matched blood. Whole exome and RNA sequencing was performed on tumor tissue and autologous PBMCs and used to predict and prioritize neoantigen mutations. Peptides encoding the mutations were synthesized, loaded onto APCs and co-cultured with autologous TIL. Neoantigen reactive TIL were selected by fluorescence activated cell sorting (FACS), based on the upregulation of the activation markers CD134 and CD137 and expanded with a rapid expansion protocol (REP). Bulk and unselected TIL were expanded alongside for comparison. Neoantigen reactivity was quantified and deconvoluted by cytokine secretion, degranulation, upregulation of CD134/CD137 by flow and when practical, killing of autologous tumor cell lines or organoids.
Results: Successful TIL expansion was achieved in 31/34 (91%) tumors (14/17 CRC, 10/10 NSCLC, 3/3 ovarian and 3/3 melanoma) using both tumor fragments and dissociated tumors. CRC tumors accounted for half of the samples (17/34), and the tumor mutational burden within these samples varied substantially, ranging from 229 to 5436 mutations. Upregulation of CD134 and CD137 and increased IFN-γ production was observed in all samples upon co-culture with peptide loaded APCs. Peptide restimulation and deconvolution revealed that the TIDAL-01 process is capable of enriching for both CD4 and CD8 reactivities. Selected TIL products produced up to 50x more IFN-γ, TNF-α and Granzyme B than bulk TIL and

at least 2x higher levels of degranulation, indicative of greater killing potential.
Conclusions: TIL from metastatic CRC, melanoma, NSCLC and ovarian tumors were successfully expanded from the majority of patients. Co-culture of TIL and peptide loaded APCs followed by FACS significantly enriched for neoantigen reactivity compared to bulk TIL, demonstrating the potential of the TIDAL-01 process to produce selected TIL products for the treatment of non-melanoma tumors.

Microfluidic incubation of patient derived tumor and immune cells boosts lymphocyte cytotoxic phenotype

Damian C. Hutchins[1], Cecilia R. Schaaf[1], Nicholas P. Edenhoffer[1], Mitra Kooshki[2], Robyn Greissenger[3], Steven D. Forsythe[1], Adam R. Hall[4], Lance D. Miller[5], Shay Soker[6], Pierre L. Triozzi[7], Konstantinos Votanopoulos[8].
[1]Wake Forest Organoid Research Center (WFORCE), Wake Forest University School of Medicine, Winston Salem, NC,[2]Hematology and Oncology, Wake Forest University School of Medicine, Winston Salem, NC,[3]Wake Forest Organoid Research Center (WFORCE), Virginia Tech-Wake Forest School of Biomedical Engineering and Sciences, Winston Salem, NC,[4]Biomedical Engineering, Virginia Tech-Wake Forest School of Biomedical Engineering and Sciences, Winston Salem, NC,[5]Cancer Biology, Wake Forest University School of Medicine, Winston Salem, NC,[6]Wake Forest Institute of Regenerative Medicine, Wake Forest University School of Medicine, Winston Salem, NC,[7]Division of Medical Oncology, Wake Forest University School of Medicine, Winston Salem, NC,[8]Division of Surgical Oncology, Department of Surgery, Wake Forest University School of Medicine, Winston Salem, NC

Introducti**on:** Tumor infiltrating lymphocytes (TILs), hold promise in advancing adoptive cell therapy for patients with otherwise limited treatment options. However, many tumors do not attract TILs, or the TILs themselves are exhausted which limits treatment availability and efficacy. Consequently, there is a need for alternative sources of tumor reactive T cells. Here, we address this need through the *ex vivo* 3D cell culture biofabrication of immune competent patient tumor organoids (iPTOs).

These constructs, composed of patient-matched cancer cells, antigen presenting cells (APCs), and stromal cells encapsulated in extracellular matrix (ECM)-like hydrogel, closely mimic the *in vivo* tumor microenvironment. We demonstrate that constant circulation of peripheral blood mononuclear cells (PBMCs) through a microfluidic device housing iPTOs can emulate lymph node activation of immune cells to the tumor, yielding organoid interacting lymphocytes (OILs) that possess increased markers of activation, cytotoxicity, proliferation, homing markers, and inflammatory cytokine production relative to uncirculated PBMCs.
Methods: Tumor tissue, APCs (from lymph nodes or spleen), and peripheral blood were collected from 8 patients with mesothelioma (3), melanoma (2), and appendiceal cancer (3). Chips were built from a glass slide and laser cut Polymethyl methacrylate. IPTOs were made such that a concentration of 3 APCs for every 1 tumor cell were added to a collagen and hyaluronic acid mixture that was then photocrosslinked in the chip chamber. PBMCs were circulated through chips housing the photocrosslinked iPTOs for 7 days and then expanded. Following expansion, a subpopulation of these cells were cocultured with tumor only organoids for a 7 day period. Single and secondary tumor exposure populations of effector, memory, and reactive T cells were analyzed via flow cytometry, immunohistochemistry, and cell culture medium proteomic analysis, and compared with both uncirculated PBMCs and patient TILs.
Results: Data collected from patients with appendiceal, melanoma, and mesothelioma tumors shows generation of OILS with increase in cytotoxic T lymphocyte, effector memory, and central memory phenotypes when compared to uncirculated PBMCs, greater than or comparable to TILs and with similar effector cytokine and enzyme expression. OILs were also found to express less immunosuppressive signals (i.e., Tim3, PD1, and IL 10). Critically, chip-based T cell activation resulted in 10x more viable OILs than were typically observed with TILs following parallel growth period of 14 days.
Conclusions: This data suggests that microfluidic incubation of lymphocytes with lymph node and tumor cells can generate large amounts of viable tumor-specific T cells on-demand with characteristics similar to TILs but with increased viability, cell expansion propensity, and cytotoxic responsiveness.

#4052

Direct selection of PD1$^+$ CD39$^+$ tumor infiltrating lymphocytes (TIL) from tumor dissociates enrich for functional tumor-reactive cells

Christophe Pedros[1], Larissa Pikor[2], Anna Fritzsche[2], Zachary K. Jilesen[2], Bethany Macleod[2], Niloufar Khojandi[1], Bryant Thompson[1], Matthew Thayer[1], Nikolas Bryan[1], Emily Carron[1], Sowbarnika S Ratliff[1], April Fraley[1], Jake Nikota[2], Robert Fisher[2], Sebastien Delpeut[2], Anna Kluew[2], Madysson Scott[2], Christian Laing[1], Leo He[1], Antoine Bernard[3], Nathalie Brassard[3], Simon Turcotte[3], Timothy J Langer[1], David Stojdl[2], Stewart Abbot[1], Barbara Sennino[1]. *[1]Turnstone Biologics, San Diego, CA,[2]Turnstone Biologics, Ottawa, ON, Canada,[3]Centre Hospitalier de l'Universite de Montreal (CHUM), Montreal, QC, Canada*

Background**:** The autologous cell therapy field has investigated numerous novel strategies and processes to improve response rates and expand the use of adoptive cell therapies (ACT) to patient suffering from a broad range of cancers. Tumor infiltrating lymphocytes (TIL) can be harvested from tumors, expanded *in vitro,* and infused to patients leading to substantial clinical benefits in some patient populations. Tumor reactivity of TIL can vary greatly, representing a key limiting factor of bulk TIL therapies. The ability to generate an autologous cell product enriched in tumor reactive cells while limiting the presence of potentially detrimental and/or competitive non-reactive cells is highly desirable for next generation TIL products. Here we demonstrate that direct selection of antigen experienced TIL from tumor dissociates is feasible and allows to obtain functional cells enriched for tumor reactivity from various tumor indications.

Methods: Patient-derived tumor material from various indications, including ovarian, kidney, colorectal cancer and lung tumors were first processed into single cell suspensions, maximizing TIL recovery and viability. Antigen experienced TIL were immediately selected based on the co-expression of PD-1 and CD39, using fluorescence-activated single cell sorting (FACS). The sorted cells or the unselected counterparts were expanded in a rapid expansion protocol (REP), then analyzed for phenotypic and functional characteristics and reactivity against autologous tumor cells.

Results: The PD-1$^+$ CD39$^+$ selection strategy consistently allowed sorting of a population of viable TIL that was amenable to *in vitro* culture from tumors of various cancer indications. The selected TIL successfully expanded in a rapid expansion protocol. TCR sequencing analysis revealed that the PD-1$^+$ CD39$^+$ sorted populations were enriched in unique clones compared to the unselected populations. Expanded PD-1$^+$ CD39$^+$ selected cells demonstrated the ability to produce key effector cytokines upon restimulation in polyclonal assays. Importantly, the PD-1$^+$ CD39$^+$ expanded TIL were enriched for tumor reactive T cells and showed improved cytotoxic activity against autologous tumors.
Conclusions: PD-1$^+$ CD39$^+$ selected TIL can be successfully isolated and expanded *in vitro*, generating a TIL product of superior reactivity in multiple cancer indications. PD-1$^+$ CD39$^+$ selected TIL showed increased cytokine secretion and cytotoxic activity against autologous material, indicating that this selection strategy enriches for functional tumor-reactive lymphocytes, which is likely to be a key feature of successful ACT.

A mesothelin targeting chimeric antigen receptor macrophage (CAR-M) for solid tumor immunotherapy: pre-clinical development of CT-1119

Nicholas R. Anderson, Brinda Shah, Alison Worth, Rashid Gabbasov, Brett Menchel, Kerri Ciccaglione, Daniel Blumenthal, Stefano Pierini, Sabrina Ceeraz DeLong, Sascha Abramson, Thomas Condamine, Michael Klichinsky. *Carisma Therapeutics, Philadelphia, PA*

While adoptive cell therapies have seen significant success in the treatment of hematological malignancies, solid tumors remain challenging for the field. A significant obstacle is the exclusion of T cells from the tumor microenvironment (TME). In contrast, monocytes/macrophages are naturally recruited to the TME. These cells then have the potential to phagocytose tumor cells, activate the TME, and prime a broad anti-tumor adaptive immune response via T cell recruitment and activation. We have previously developed CT-0508, a chimeric antigen receptor macrophage (CAR-M) targeting HER2 which showed efficacy in a variety of pre-clinical models and is currently in a Phase I clinical trial for patients with HER2+ solid tumors. Mesothelin is overexpressed in a variety of solid

tumors, including mesothelioma, lung, pancreatic, and ovarian cancers. To leverage tumor biology with myeloid cells, we engineered primary human macrophages using the chimeric adenoviral vector Ad5f35 to express a CAR containing a human scFv against human mesothelin. We used both *in vitro* cell based assays and *in vivo* xenograft models to assess the activity of CT-1119. CAR-M engineered with an Ad5f35 vector demonstrated high CAR expression, high viability, upregulated M1 (anti-tumor) macrophage markers, and downregulated M2 (pro-tumor) macrophage markers. CT-1119 specifically phagocytosed multiple mesothelin expressing tumor cell lines in a CAR-dependent and antigen-dependent manner. CT-1119 demonstrated robust *in vitro* killing of the relevant tumor cell lines A549 and MES-OV expressing mesothelin. CAR engagement also induced the release of pro-inflammatory cytokines such as TNFα following stimulation with mesothelin in both cell-free and cell-based contexts in a dose-dependent manner. *In vivo*, CT-1119 significantly reduced tumor burden in a murine xenograft model of lung cancer. Similarly, human monocytes targeting mesothelin were successfully generated using the same Ad5f35 vector and demonstrated specific activity against mesothelin positive tumor cells. The presented results demonstrate that CT-1119, an autologous human anti-mesothelin CAR-M, can cause phagocytosis, tumor cell killing, and pro-inflammatory cytokine release in response to stimulation with mesothelin. These results show that CAR-M is a feasible approach for the treatment of mesothelin expressing sold tumors via the potential for induction of a systemic anti-tumor response.

Macrophages engineered with cytokine switch receptors: Development of a modular platform for rebalancing inflammation in microenvironments

Chris Sloas, Yuhao Huangfu, Rehman Qureshi, Michael Ball, Thomas Condamine, Michael Klichinsky, Yumi Ohtani. *Carisma Therapeutics, Philadelphia, PA*

Motivation: Cytokines in tissue microenvironments regulate the balance between pro- and anti-inflammatory signals. Dysregulated cytokines cause deleterious immunosuppression or inflammation, which underpins the pathophysiology of solid tumors, chronic kidney disease, and more.

Rebalancing inflammation/immunosuppression by rectifying cytokine signals offers a generalizable approach for treating numerous diseases. While doing so through cytokine blockade carries risks due to systemic administration, cellular immunotherapies offer a localized approach that could detect pathogenic cytokines then proportionately rebalance inflammation as needed. Specifically, macrophages are homeostatic regulators responsible for initiating and resolving inflammation. Here, we leveraged macrophages' ability to regulate inflammation by equipping them with synthetic cytokine switch receptors (SR) that convert immunosuppressive M2 signals into pro-inflammatory M1 responses for solid tumor microenvironment conversion, or *vice versa* for inflammatory disease. We termed this platform "Engineered Microenvironment Converters" (EM-C) and evaluated its modular ability to target disease-associated cytokines.

Methods: EM-Cs targeting IL10, TGFβ, IFNγ and IL17A were generated by expressing SR in primary human macrophages. M2-to-M1 SR were designed to convert IL10 or TGF-β into pro-inflammatory stimuli, and M1-to-M2 SR were designed to IFNγ or IL17A into immunosuppressive signals. The *in vitro* response of EM-Cs to their target cytokine was monitored using phenotypic characterization of surface molecules, measurement of cytokine production, mRNA sequencing, and biochemical analysis of downstream signaling. Co-culture assays with bystander cells were used to assess the ability of EM-Cs to alter their microenvironment.

Results: Pro-inflammatory EM-Cs converted IL10 and TGFβ, two prevalent immunosuppressive cytokines in the TME, into pro-inflammatory signals. Unlike wildtype macrophages, these EM-Cs responded to IL10 or TGFβ with upregulated M1 markers and cytokines in a dose-dependent manner. Furthermore, EM-Cs repolarized bystander M2 macrophages towards a pro-inflammatory phenotype following co-culture. Similarly, anti-inflammatory EM-Cs responded IFNγ and IL17A, two cytokines canonically overexpressed in inflammatory disease, by upregulating M2 markers and inducing an anti-inflammatory environment.

Conclusion: We present for the first time a novel immunotherapy platform that harnesses macrophages as "living converters" to locally regulate inflammation for oncology and inflammatory applications. By demonstrating EM-Cs in the M2-to-M1 and M1-to-M2 direction, this

platform offers modularity in controlling the inflammatory status of tissue microenvironments without systemic cytokine antagonism.

CD40L stimulates melanoma infiltrating B cells and enhances *ex vivo* TIL expansion

Renata Ariza Marques Rossetti[1], Leticia Tordesillas[1], Matthew Beatty[1], Dongliang Du[2], Yian Ann Chen[2], Amod Sarnaik[3], Shari Pilon-Thomas[1], Daniel Abate-Daga[1]. *[1]Immunology, H. Lee Moffitt Cancer Center, Tampa, FL,[2]Biostatistics and Bioinformatics, H. Lee Moffitt Cancer Center, Tampa, FL,[3]Cutaneous Oncology, H. Lee Moffitt Cancer Center, Tampa, FL*

Adoptive transfer of tumor infiltrating lymphocytes (TIL) is a feasible and effective therapy for melanoma and lung cancer[1,2]. Multiple factors may determine the quality of the TIL product including components of the tumor microenvironment. In this work, we analyzed the role of melanoma infiltrating B cells in the context of TIL expansion based on their documented association with response to other types of immunotherapies[3]. We stimulated melanoma infiltrating B cells using human recombinant CD40L on the first day of *ex-vivo* TIL expansion. Samples were expanded from cryopreserved melanoma tumor single cell suspensions, in high dose IL-2 alone (standard protocol), or in high dose IL-2 plus CD40L. After 48h, analysis of activation markers on the CD40-expressing cells by flow cytometry was performed. For further investigation of the changes induced by CD40L stimulation, TIL expansion cultures (+/- CD40L) were analyzed using scRNA-seq (10X Genomics Chromium NextGEM Single Cell 5' v2 and V(D)J Reagent kits; Illumina NovaSeq 6000 instrument with S4 sequencing flow cell) at 48h of culture (n=7 patients). The TIL expansion success rate was 68% with the CD40L treatment condition compared to 36% with the standard protocol. TILs cultured in the presence of CD40L expanded to on average three times more than with the standard protocol ($P \leq 0.01$). Treatment with CD40L increased the percentage of CD39- CD69- T cells ($P \leq 0.05$). Within the tumor digests, a higher percentage of B cells, including switched memory B cells ($CD27^+$ IgD^-), was associated with successful TIL expansion (P=0.04). scRNA-seq analysis demonstrated different clustering patterns within the B cell compartment based on culture

conditions. No clear partition was observed for other cell types, including the myeloid compartment. B cells displayed 126 DEGs associated to CD40L addition, CCL22, CD83, EBI3 and CD58 were among the upregulated genes in the CD40L-treated B cells. Other cell types experienced minimal to no change in transcriptomic profiles. B cell clusters were sub-classified based on CD27 and IgD expression[4], showing a predominance of naïve and switched memory B cells. Our results show that higher presence of B cells within tumors is associated with better TIL expansion, suggesting an interplay between T and B cells, and providing rationale for the design of improved TIL expansion protocols based on B cell stimulation with CD40L. This work has been supported in part by the Flow Cytometry, Genomics and Biostatistics and Bioinformatics Core Facilities at Moffitt Cancer Center, an NCI designated Comprehensive Cancer Center (P30-CA076292). We acknowledge Moffitt's Melanoma Center of Excellence and the Mark Foundation for the financial support. [1] Sarnaik, A.A. et al. JCO 39, 2656-2666 (2021). [2] Creelan, B. et al. Intratumoral delivery of autologous tumor antigen specific CD4 Th1 cells combined with dendritic cells eradicates HER2 mammary carcinoma

Ganesan Ramamoorthi, Amy Aldrich, Colin Snyder, Brian Czerniecki.
Clinical Science & Immunology Program, Moffitt Cancer Center, Tampa, FL

Human epidermal growth factor receptor 2 (HER2) overexpression accounts for 30% of invasive breast cancer (BC) and is critically associated with aggressive disease, recurrence and metastasis. Adoptive cell therapy approaches using cytotoxic CD8 T cells and natural killer cells have been shown to trigger anti-tumor immunity in BC. However, the immunosuppressive tumor microenvironment (TME) can inhibit response to these therapies and diminish the presence and function of tumor-infiltrating lymphocytes. Recently, we have shown a critical role for anti-tumor CD4 Th1 cells in dendritic cells (DC) intratumoral (i.t.) delivery in combination with anti-HER2 therapy. This combination therapy enhanced

systemic and local anti-tumor immunity and eradicated tumors in HER2 positive BC with a requirement for CD4 Th1 cells. Here we investigated the efficacy of i.t. delivery of both autologous anti-tumor CD4 Th1 cells and tumor antigen pulsed type 1 polarized dendritic cells (HER2-DC1) in a HER2 mammary carcinoma model. CD4 T cells were isolated from BALB/c mice that had completely regressed (pCR) from orthotopic TUBO tumors following HER2-DC1 i.t. or combination therapy with anti-HER2 antibody. CD4 Th1 cells were then expanded by co-culturing with HER2-DC1 in the presence of interleukin (IL)-2 and IL-7 cytokines. BALB/c mice bearing orthotopic TUBO tumors were treated weekly for six weeks with anti-tumor CD4 Th1 cells i.t., non-specific CD4 Th1 cells i.t., HER2-DC1 i.t. or combination therapy. The i.t. delivery of anti-tumor CD4 Th1 cells combined with HER2-DC1 induced a strong anti-tumor response with survival benefit and complete tumor eradication in 50% of treated mice. Importantly, the i.t. delivery of anti-tumor CD4 Th1 cells were critical for providing priming signals to HER2-DC1 within the TME via CD40/CD40L engagement (licensing). This was supported by a strong anti-tumor response and complete tumor regression in 60% of orthotopic TUBO tumor bearing mice treated with CD40/CD40L licensed HER2-DC1 i.t. therapy compared to un-licensed HER2-DC1 i.t. therapy. Additionally, enhanced survival and functionality of human and mouse HER2-DC1 was observed following activation of CD40/CD40L signaling using anti-CD40 agonistic antibody *in vitro*. Collectively, these results suggest a new promising therapeutic strategy using DC1-anti-tumor CD4 Th1 adoptive cell therapy intratumoral delivery to induce DC1 priming and create robust anti-tumor immunity within the TME in BC.

T cells co-expressing a highly potent NY-ESO-1-specific TCR and a chimeric PD1-41BB co-stimulatory switch receptor show a favorable polyfunctional profile for the treatment of solid tumors

Andrea Coluccio[1], Stefanie Tippmer[1], Petra Prinz[1], Maja Buerdek[1], Kathrin Mutze[1], Barbara Loesch[1], Kathrin Davari[1], Giulia Longinotti[1], Dolores J. Schendel[2]. *[1]Medigene Immunotherapies GmbH, Munich, Germany,[2]Medigene AG, Munich, Germany*

T cell receptor (TCR)-based immunotherapies have shown great potential for the safe and efficacious treatment of patients suffering from various solid malignancies. However, novel strategies are needed to overcome the immunosuppressive tumor microenvironment (TME) and to enhance the efficacy of TCR-T cell (TCR-T) therapies in solid tumors. NY-ESO-1 is a cancer/testis antigen that is highly expressed in various solid tumor indications while its expression in healthy tissues is restricted to male germ cells. Our HLA-A2-restricted, NY-ESO-1-specific TCR used here was selected from a non-tolerized T cell repertoire of a healthy donor using Medigene's proprietary Allo-HLA TCR priming technology and high-throughput TCR isolation and characterization processes. To prevent inhibition of TCR-T cell function via the PD1-PDL1 axis within the TME, the NY-ESO-1-TCR was co-expressed with a chimeric PD1-41BB co-stimulatory switch receptor, consisting of the extracellular domain of PD1 and the intracellular domain of the 41BB co-stimulatory receptor. Thereby, an inhibitory signal from the PD1-PD-L1 axis is turned into a co-stimulatory one, which results in a dual mechanistic benefit, and superior TCR-T cells with respect to tumor cell killing, cell proliferation and poly-cytokine secretion. Co-expression of PD1-41BB on NY-ESO-1 TCR-T cells led to a 3-fold increase in IFN-γ release and a higher proliferation index (~1.5 fold) (after antigen encounter. Under conditions of repeated antigen exposure *in vitro* using HLA-A2/NY-ESO-1/PDL1-positive tumor spheroids, TCR-T cells co-expressing PD1-41BB showed enhanced functional activities compared to TCR-T cells carrying the TCR alone. *In vitro* single-cell secretome analyses demonstrated up to a 5-fold increase in polyfunctional T cells and a higher polyfunctional strength index (PSI) for NY-ESO-1 TCR-T cells expressing PD1-41BB compared to "naked" NY-ESO-1 TCR-T cells lacking PD1-41BB. Typical Th1 cytokines/proteins like IFN-γ, TNF-α and Granzyme B mainly contributed to the superior PSI of NY-ESO-1-TCR-T cells co-expressing PD1-41BB. Importantly, our data indicate that transgenic PD1-41BB has the capacity to provide a co-stimulatory signal despite the presence of endogenous PD1 which is upregulated in stimulated "naked" NY-ESO-1 TCR-T cells. In summary, we find that co-expression of a chimeric PD1-41BB co-stimulatory switch receptor significantly enhances *in vitro* NY-ESO-1 TCR-T cell proliferation, functionality and anti-tumor activity. Analyses of single-cell T cell cytokine polyfunctionality helped us to unravel the mode of action of

NY-ESO-1 TCR-T cells co-expressing PD1-41BB and point to their complex display of effector, stimulatory and chemoattractant cytokines as a potential driver for superior recognition of tumor cells.

In vitro binding, efficacy and safety studies to support engineered T cell therapies

Sophie Vermond[1], Benita Quist[1], Monique Hazenoot[1], Rene McLaughlin[1], David Cobeta Lopez[1], Namrata Jayanth[1], Folkert Verkaar[1], Omar Aziz[2], Maria LH Vlaming[1], Sabrina de Munnik[1], Gemma Moiset[1]. *[1]Charles River Laboratories, Inc., Leiden, Netherlands,[2]Charles River Laboratories, Inc., Portishead, United Kingdom*

Engineered T cell therapies such as Chimeric Antigen Receptor (CAR) T cells and T cell receptor (TCR)-engineered T cells have emerged as a promising cancer therapy. To date, four anti-CD19 CAR-T and two anti-BCMA CAR-T products have been approved by the FDA for the treatment of hematological malignancies. Many more T cell therapy products are currently being explored, directed towards both liquid and solid tumors as well as for other clinical indications. High-quality and robust *in vitro* and *in vivo* assays are essential for the discovery and characterization of lead T cell therapy products. Furthermore, despite demonstrating therapeutically successful, the further development of T cell immunotherapies has been hindered by safety concerns. Selected target antigens might be expressed in healthy tissues or engineered T cells may non-specifically bind to antigens in healthy tissues, potentially resulting in severe side effects. In addition, the random integration of the CAR- or TCR-encoding DNA cassettes in the host cell genome has the potential risk of causing insertional mutagenesis and may contribute to oncogenic transformation of the T cells. The aim of this study was to develop several *in vitro* assays for the assessment of target cell binding, efficacy and safety of T cell therapies using CAR-T cells targeting the Human Epidermal growth factor Receptor 2 (HER2) as a model system. The z-Movi cell avidity analyzer was used to study the binding strength between the CAR-T cells and target tumor cells. Cytotoxicity co-culture assays were developed using increasing effector:target cells ratios and an impedance-based readout to quantify the viability of HER2-positive and -negative cancer cell lines in real-time, to

confirm the activity and selectivity of the HER2-CAR-T cells. Furthermore, co-culture assays were also developed for a variety of primary or iPSC-derived healthy human cells (representing various tissues) to assess potential off-tumor effects of the HER2-CAR-T cells against healthy cells. In addition, an oncogenicity assay was developed to quantify the survival and proliferation of the HER2-CAR-T cells in the absence and presence of cytokines by flow cytometry, to determine whether the genomic editing of the T cells affected their cytokine-dependency. In conclusion, Charles River Laboratories developed several *in vitro* assays for the preclinical assessment of T cell therapy binding, efficacy, potency, specificity and safety to aid early-stage lead discovery, optimization and development, and to support Investigational New Drug (IND) applications. Charles River has the capabilities to support a full CAR/TCR program from inception to IND filing.

Developing an allogeneic iPSC derived macrophage cell therapy for oncology

Huafeng Wang[1], May Sumi[1], Christine Huh[1], Fereshteh Parviz[1], Jessica Mastroianni[1], Jane Healy[1], Nicole Stevens[1], Leah Mitchell[1], Susanne Lang[1], Dan Kaufman[2], Robert Hollingsworth[1], David T. Rodgers[1].
[1]Shoreline Biosciences, Inc., San Diego, CA,[2]UCSD, San Diego, CA

The full potential of cell therapy has yet to be realized in solid tumor indications and new approaches are urgently required. Macrophages are innate immune cells that can kill tumor cells and orchestrate the anti-tumor immune response. Macrophage cell therapy is an exciting new approach to treat cancer with the aim to harness the powerful activity of macrophages to reignite the immune system. Patient derived macrophages, however, are difficult to genetically engineer and do not proliferate, which makes generating high-quality cells at clinically relevant scales challenging. To address this, we have developed an induced pluripotent stem cell (iPSC) approach to macrophage cell therapy. These cells can be genetically engineered at the iPSC stage and then differentiated into billions of highly functional iPSC derived macrophages (iMACs). This allogenic cell therapy product can then be cryopreserved and stored for immediate use in the clinic when the patient is ready.

Here we show that iMACs function like normal macrophages. They migrate towards tumor cells, respond to challenges through innate immune receptors, and produce immune recruiting and activating cytokines and chemokines. iMACs also express high levels of antibody receptors and we show that these cells can be directed to kill tumors *in vitro* and *in vivo* via antibody dependent cellular phagocytosis. Furthermore, we have conducted a robust screen to develop a novel CAR that is optimized for use in iMACs. These receptors can be engineered into iMACs at the iPSC stage and trigger robust tumor cell killing. In summary, these data highlight the therapeutic potential of iMACs in oncology and support the further development of this technology for clinical use.

Selective Neoantigens Peptide TILs (snapTILs): A next generation tumor infiltrating lymphocytes (TIL) therapy platform

Tithi Ghosh Halder[1], Shelby Rheinschmidt[1], Sydney Adamson[1], Anna Larson[2], Taylor Bargenquast[2], Ryan Rodriguez del Villar[1], Serina Ng[1], Kate Gutowsky[1], Alexis Weston[1], Trason Thode[1], Mohan Kaadige[1], Erin Kelley[1], Jorge Soria-Bustos[1], Jorge Giron[1], John Altin[1], Raffaella Soldi[1], Sunil Sharma[1]. *[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ,[2]HonorHealth Clinical Research Institute, Scottsdale, AZ*

Background**:** Immunotherapies using autologous tumor infiltrating lymphocytes (TILs) have become effective treatment modalities for several patients with solid tumors, yielding a response rate of around 49% in patients with metastatic melanoma. Most clinical centers utilize bulk, randomly isolated TILs from the tumor tissue for *ex vivo* expansion and infusion. Only a minor fraction of these administered TILs recognize tumor antigens and most are non-mutated public antigens. Moreover, expression of these antigens on normal cells can trigger central and peripheral tolerance mechanisms. Against this background, cancer neoantigens derived from private mutations represent an ideal class of cancer antigens to target because they are highly tumor specific by nature, therefore reducing the potential induction of central and peripheral tolerance. We recently developed a new technology to enrich TILs with predefined neoantigen specificities, which we termed Selective Neo Antigens Peptides TILs (snapTILs). Here we describe the efficacy studies of a melanoma and

pancreatic cancer patient's snapTILs done in autologous settings both *ex vivo* and *in vivo*.

Methods: Our workflow consisted of a multistep process performed on a patient-specific basis. Briefly, mutations were called by whole-exome sequencing of tumor vs. normal DNA to generate a peptide library. The peptides were further filtered using an in-silico prediction algorithm and our proprietary peptide-MHC binding assay. Selected peptides were then incubated with TILs isolated from the patient's tumor biopsy, resulting in TIL population enriched of T cells that recognize the neopeptides (snapTILs). After rapid expansion, snapTIL efficacy was tested by checking their ability to infiltrate in patient-derived tumor organoids, their activation status (IFNγ), cytotoxicity (Granzyme B), and T-cell exhaustion markers. Lastly, snapTILs *in vivo* efficacy was tested in human melanoma and pancreatic cancer xenograft models using hIL-2 transgenic mice.

Results: Our initial data showed that the levels of infiltration of snapTILs into tumor organoids was significantly higher compared to IL2-stimulated TILs in both cancer models. Also, snapTILs recognized tumors with great specificity as they showed significantly less infiltration in organoids generated from generally uninvolved tissues from the same patients. Moreover, snapTILs were found to be more cytotoxic in nature than the IL2-stimulated TILs in terms of IFNγ and Granzyme B secretion after coculture with autologous tumor cells. Our *in vivo* data confirmed these observations by showing 70% tumor growth inhibition in highly immunogenic melanoma and 50% tumor growth restriction in a poorly immunogenic pancreatic tumor model. In conclusion, our approach proves the potential for personally tailored immunotherapies to yield more effective and safer cancer treatments using snapTILs.

#4061

Systemic autologous lymphocyte transfer can enhance tumor-infiltrating lymphocyte infiltration in glioblastoma and license co-stimulatory immunotherapy

Kirit Singh, Kelly M. Hotchkiss, Eliese Moelker, Gary E. Archer, John H. Sampson, Mustafa Khasraw. *Duke Brain Tumor Immunotherapy Program, Duke University Medical Center, Durham, NC*

Glioblastoma is an immunologically 'cold' malignancy where few tumor infiltrating lymphocytes (TILs) are present. We sought to overcome this by 'seeding' the tumor with TILs via administration of autologous lymphocytes (ALT). We hypothesized that prior administration of ALT will enhance subsequent immunomodulatory therapies (e.g. immune checkpoint blockade (ICB) or co-stimulation). To evaluate this, we initially generated a pro-infiltrative TIL phenotype. CD45.1 splenocytes (C57/Bl6 background) were co-cultured with either IL2 and Concanavalin A (Con A) or IL7 and Con A for 5 days. Flow cytometric analysis found that both conditions resulted in similar CD4:CD8 ratios (20:80%) but IL7 co-culture upregulated expression of VLA-4, a pro migratory integrin. We then compared the entry of TILs into tumor bearing CNS when co-cultured with either IL2 or IL7. 8–10-week-old C57/Bl6 mice (n=5-6 per group) were implanted orthotopically with 30,000 CT2AvIII cells (syngeneic glioma) which established for 14 days. Mice received (1) CD45.1 lymphocytes activated with IL-7 and Con A (single intravenous (IV) injection, 1 x 10^7 cells) or (2) CD45.1 lymphocytes activated with IL2 and serial Con-A stimulation. Mice were sacrificed 3- and 48-hours following ALT and brains analysed for CD45.1+CD3+ populations. Groups were compared using a Mann-Whitney U test. Mice in Group 1 demonstrated significantly enhanced entry of CD8+ effector and memory T cells into tumor bearing hemispheres at both time points following administration compared to Group 2 ($p = 0.005$, $p = 0.0159$ respectively). By 48 hours post ALT, IL7 co-culture resulted in an average 810.1% expansion of CD8 T cell numbers in tumor bearing CNS compared to counts at Day 0. We then evaluated if mice with a TIL enriched CNS might be more responsive to ICB or co-stimulatory therapy. 8–10-week-old C57/Bl6 mice (n=5-7 per group) were implanted with 30,000 CT2AvIII cells that established over 10 days. On day 10, mice

received IV ALT of either IL7 T cells only, or IL-7 and treatment courses of IP ICB (anti-PD1, anti-CTLA 4 or anti-41BB). Mice given ICB following IL7 ALT demonstrated a median survival (aPD1: 27 days, aCTLA-4: 25 days) similar to mice given IL7 ALT alone (25 days). However, 4/7 mice who received IL7 ALT and anti-41BB were still alive 45 days post tumor implantation (p=0.0004). Taken together, we demonstrated that certain *ex vivo* autologous lymphocyte co-culture conditions can generate a T cell population which infiltrates tumor bearing CNS in significant numbers. Further, we found that seeding a tumor with TILs prior to stimulatory therapy yields long term survival *in vivo*. Future work will focus on optimizing *ex vivo* culturing approaches for ALT and determine whether therapeutic efficacy is due to expansion of resident TILs at the tumor site, or ongoing recruitment of endogenous T cells from the periphery.

#4062

The discovery and development of a CRISPR/Cas9-engineered tumor-infiltrating lymphocytes product (GT316) as a next-generation TIL therapy

Yarong Liu, Jingwei Sun, Yao Sheng, Jingman Wang, Jiahui Jin, Fei Li, Lingyun Chen, Di Zhou, Yongchao Tan, Quanwei Wang, Zhao Xu, Haibao Li, Pin Wang, Jun Cui. *Grit Biotechnology, Shanghai, China*

Adoptive cell therapy by tumor-infiltrating lymphocytes (TILs) has demonstrated promising therapeutic effects in multiple types of solid tumors and significantly prolonged the survival of late-stage patients. However, the “prone-to-exhaustion” phenotype of the final TIL product after rapid expansion during manufacture and the presence of various immunosuppressive mechanisms in tumor microenvironment (TME) compromises the persistence and anti-tumor efficacy of TIL post infusion. To discover potential immunoregulatory targets that could maximize the function of TIL, we established a genome-wide CRISPR/Cas9 screening platform, ImmuT Finder®, to unbiasedly identify functional gene targets in primary T cells. Notably, this platform employed T cells bearing a tumor-antigen specific TCR-T that were repeatedly stimulated by tumor cells with cognate tumor antigen and demonstrated similar exhaustion profile as TIL. We selected top 30 targets after several rounds of screening and quickly validated their function in a 96-well array. Then, the top targets that showed

significantly enhancement in proliferation and function of TCR-T were further selected, and their combinational effects on TIL were tested both in vitro and in vivo. Finally, double KO of GT304 and GT312 (GT316) stands out as the most potent combination, which significantly improves TIL proliferation and cytokine release, eradicates tumor growth in both CDX and PDX mouse models and promotes long-term in vivo persistence with low-dependence on IL-2. Specific and potent sgRNAs targeting both targets have been selected, and manufacturing process of GT316 TIL product has been developed (KOReTIL®). In summary, these data demonstrated that our ImmuT Finder® platform enables unbiased discovery of potent and novel targets for the development of T cell therapy and support the clinical assessment of GT316 as a next-generation TIL therapy. Currently, an investigator-initiated trial of GT316 is ongoing in China.

Adoptive transfer of NF-kB p50 knockout immature myeloid cells shows a trend towards slower glioblastoma tumor growth in an orthotopic mouse model

Patrick J. Beck[1], Theresa Barberi[2], Alan D. Friedman[2]. *[1]Virginia Tech Carilion School of Medicine, Roanoke, VA,[2]Division of Pediatric Oncology, Johns Hopkins University, Baltimore, MD*

Background: Glioblastoma (GBM) is a universally fatal brain tumor. Tumor-associated macrophages (TAMs) comprise up to 40% of GBM tumors and predominantly demonstrate an M2 phenotype, favoring tumor growth while suppressing host immune response. Previously, we showed that in p50-/- mice lacking the repressive NF-κB subunit, GBM TAMs are biased toward the pro-inflammatory M1 phenotype, limiting GBM tumor growth by increasing activated tumor T cells. The present study aims to determine whether adoptively transferred immature myeloid cells lacking p50 (p50-IMC) localize to mouse GBM tumors and slow tumor growth. Methods: Lineage-negative bone marrow (BM) cells were isolated from C57BL/6 (B6) p50-/- mice, expanded, and treated with Macrophage-Colony Stimulating Factor (M-CSF) for 24h to produce p50-IMC. BM-derived myeloid cells from both wild-type (WT) and p50-/- mice were subjected to analysis of M1 (TNFα, IL-12b) and M2 (Fizz1, Mannose Receptor) markers via quantitative PCR after exposure to M-CSF for 24h or after M2-

polarization via five days in M-CSF and then two days in IL-4. B6-derived GL261-Luc GBM cells were inoculated intracranially into wild-type B6 mice, and four days post-implantation, mice were given 5-fluorouracil to deplete endogenous leukocytes. Mice then received either no additional treatment or three doses of ten million p50-IMCs 9-, 11-, and 14-days post-implantation, and tumor growth was monitored via bioluminescence, measured following luciferin injection using the Spectrum in vivo imaging system. The number of p50-IMCs localizing to the GBM-containing brain was determined by CFSE-dye-labeling of IMC followed by flow cytometry analysis 24h after injection.
Results: Both TNFα and IL-12b were increased in p50-/- cells after 5 days M-CSF, and increased IL-12b expression was maintained even after M2-polarization with IL-4. Of the 10 million injected p50-IMCs, 0.07% of those cells were found in the brain. Despite such a small number of p50-IMCs localizing to the tissue of interest, inhibition of GBM growth was observed. Mice receiving the p50-IMC treatments (n = 4) demonstrated a 2.3- and 2.4-fold reduction in tumor growth at 15 ($p = 0.13$) and 18 ($p = 0.14$) days post-implantation, respectively, compared to control mice (n = 5). At 21 days post-implantation, tumor size was effectively equivalent between the two groups ($p=0.76$). p50-IMC treatment did not correlate with improved survival.
Conclusion: Loss of p50 skews myeloid cells toward a proinflammatory phenotype, even under M2-polarizing conditions. Adoptive transfer of p50-IMC transiently impairs GBM growth in an orthotopic mouse model. Although statistical significance was not attained, this may be due to the small number of animals used in this experiment. Further investigation is needed to evaluate the full potential of p50-IMC as an immunotherapy option for GBM patients.

PD-1 blockade therapy enhances the antitumor effects of lymphodepletion and adoptive T cell transfer

Satoshi Watanabe[1], Miho Takahashi[2], Ryo Suzuki[1], Masashi Arita[1], Ko Sato[3], Toshiya Fujisaki[4], Aya Ohtsubo[1], Satoshi Shoji[1], Kunihiro Shono[1], Takaaki Masuda[1], Tomoki Sekiya[1], Koichiro Nozaki[1], Tomohiro Tanaka[1], Rie Kondo[1], Yu Saida[1], Satoshi Hokari[1], Toshiyuki Koya[1], Toshiaki Kikuchi[1]. *[1]Niigata University Medical & Dental Hospital, Niigata,*

Japan,[2]Saiseikai Niigata Hospital, Niigata, Japan,[3]Joetsu General Hospital, Joetsu, Japan,[4]Tachikawa Medical Center, Nagaoka, Japan

Background: Lymphodepleting cytotoxic regimens, such as chemotherapy and radiotherapy, have shown the ability to enhance antitumor immunity. Although the mechanisms of antitumor effects augmentation in tumor-bearing hosts after lymphodepletion and T cell transfer have been intensively investigated, the influence of lymphodepletion followed by T cell transfer on immune checkpoint molecules (ICMs) expressed on tumor cells and immune cells remains to be elucidated. In the current study, we evaluated the effects of lymphodepletion and adoptive T cell transfer on ICMs in the tumor microenvironment. In addition, we investigated whether lymphodepletion and adoptive transfer of T cells augments antitumor effects of anti-PD-1 blockade therapy.
Methods: B6 mice were inoculated subcutaneously with the MCA205 murine fibrosarcoma. On day 7, mice were lymphodepleted by sublethal irradiation with 500 cGy and were reconstituted intravenously with spleen cells from normal mice as a source of naïve T cells. These mice were injected intraperitoneally with anti-PD-1 mAb on days 7 and 14. On day 21, tumor tissues were harvested, and single cell suspensions were labeled with fluorophore-conjugated antibodies for FACS analyses.
Results: The expressions of ICMs, including PD-L1, PD-1, TIGIT, TIM-3 and LAG-3, were upregulated on recipient $CD4^+$ and $CD8^+$ T cells in the tumor microenvironment. In contrast, these ICMs were significantly reduced in transferred donor T cells. Administration of anti-PD-1 antibodies after lymphodepletion and adoptive transfer of T cells significantly inhibited tumor progression. Furthermore, transfer of both donor $CD4^+$ and $CD8^+$ T cells was responsible for this augmentation of antitumor effects.
Conclusions: Our observations suggest that a possible mechanism of the antitumor effect augmentation mediated by lymphodepletion followed by T cell transfer is the prevention of donor T cell exhaustion and dysfunction. Blockade of PD-1 significantly enhanced the antitumor effects of lymphodepletion and T cell transfer.

Modulation of Trastuzumab antitumoral activity by co-culture with different T cell subtypes in 2D and 3D T cell killing assays targeting

HER2+ breast cancer

Ina Rohleff, Matthias Bleisch, Kanstantsin Lashuk, Julia Schueler. *Charles River Laboratories, Inc., Freiburg, Germany*

Breast cancer is one of the leading causes of death in women worldwide. Hence, it is important to develop and improve (immuno)therapies for breast cancer patients. Adoptive T-cell therapy with autologous $CD8^+$T cells is a promising method that has already succeeded in melanoma patients. A possible combination with antibody-dependent cell-mediated cytotoxicity dependent (ADCC) antibodies such as Trastuzumab might be beneficial for relapsed late-stage patients. We developed an in vitro protocol to generate antigen-specific $CD8^+$T cells by priming on the HER2+ breast cancer cell line JIMT-1. Subsequently, these primed $CD8^+$T cells were tested in a 2D and a 3D immune cell killing assay in a life cell imaging device in combination with an endpoint viability assay. The activity was compared with unspecific $CD8^+$T cells activated by phytohemagglutinin (PHA) or αCD2/αCD3/αCD28 beads. All T cells were tested as monotherapy and in combination with trastuzumab in JIMT-1 and SKBR-3. The antigen specific CD8+T cells displayed a significantly improved killing potential of JIMT-1 cells compared to unspecific activated or non-activated CD8+T cells. Along these lines, those cells showed the highest TNF-alpha secretion and expression of CD69 (determined by flow cytometry) among all T cell lines. Antigen-specific CD8+T cells from different settings displayed a significantly improved killing potential towards JIMT-1 than non-antigen-specific activated or non-activated CD8+T cells. The use of peripheral blood monocytes (PBMC) instead of isolated CD8+T cells did not influence the activity against JIMT-1 significantly. Interestingly, antigen-specific CD8+T cells activated as PBMC increased the activity of Trastuzumab significantly as compared to unspecific activated CD8+T cells. Testing of different donors revealed a donor dependent degree of killing, however in all donors the activity pattern was the same with antigen specific CD8+T cells being the most active. A direct comparison of fresh vs frozen immune cells from the same donors indicated no significant differences in the killing activity of unspecific activated CD8+T cells. Yet, there were substantial differences in antigen-specific immune cells: the killing potential of the freshly isolated immune cells was significantly higher than of the frozen. In summary, we have developed a protocol to produce antigen-specific tumor-

infiltrating $CD8^+$T cells primed to the heterologous JIMT-1 breast cancer cell line. The antigen-specific $CD8^+$T cells showed an increased killing potential over non-specific $CD8^+$T cells. In addition, they were able to increase ADCC-mediated antitumoral activity of trastuzumab. The 2D as well as the 3D immune cell killing assay proved to be robust and amendable for mid throughput screening. The impact of donor variability and fresh vs frozen immune cells must be further evaluated.

Lipid nanoparticle library towards development next generation genomic medicines

Nikita Jain, Sedigheh Nazaripour, Rehan Higgins, Zhengyu Chen, Suraj Abraham, Leanna Yee, Srinivas Abbina, Gayatri Mehar Namala, Helena Son, Sams Sadat, Sijo Chemmannur, Malathi Anantha, Ruchi Sharma, Kobe Tickner, Eve Boyer, Shannon Tsai, Seetalakshmi Thambatti, Vinay Mayya, Emily Soon, Jay Paquette, Samuel Clarke, Anitha Thomas.
Precision NanoSystems ULC, Vancouver, BC, Canada

Ionizable amino lipids are a major constituent of the lipid nanoparticles for delivering nucleic acid therapeutics (e.g., DLin-MC3-DMA in ONPATTRO®, ALC-0315 in Comirnaty®, SM-102 in Spikevax®). Scarcity of lipids that are suitable for cell therapy, vaccination, and gene therapies continue to be a problem in advancing many potential diagnostic/therapeutic/vaccine candidates to the clinic.
Herein, we describe the development of novel ionizable lipids to be used as functional excipients for designing vehicles for nucleic acid therapeutics/vaccines in vivo or ex vivo use in cell therapy applications. We first studied the transfection efficiency (TE) of LNP-based mRNA formulations of these ionizable lipid candidates in primary human T cells and established a workflow for engineering of primary immune T cells. We then adapted this workflow towards bioengineering of CAR constructs to T cells towards non-viral CAR T therapy. Lipids were also tested in rodents for vaccine applications using self-amplifying RNA (saRNA) encoding various antigens. We have then evaluated various ionizable lipid candidates and their biodistribution along with the mRNA/DNA translation exploration using various LNP compositions. Further, using ionizable lipids from the library, we have shown gene editing of various targets in rodents.

We believe that these studies will pave the path to the advancement in nucleic acid based therapeutics and vaccines, or cell & gene therapy agents for early diagnosis and detection of cancer, and for targeted genomic medicines towards cancer treatment and diagnosis.

RNA primed SMAR-T^{TM}cells against multiple driver mutations, all HLA's, designed for first line therapy

Benjamin A. Schwarz, Farzonai Muzaffar, Ryan G. Campbell, David Ryan, Walter Barry, Abenezer Abera, Alfred E. Slanetz. *Geneius Biotechnology, Inc., Natick, MA*

Immune checkpoint inhibitors, such as anti-PD1 antibodies, have revolutionized cancer immunotherapy. Their success demonstrates that a patient's own T cells recognize and treat cancer. However, anti-PD1 therapy is most effective in the treatment of cancers with high mutational burden, ~5% of all malignancies. Therefore, an alternative strategy is necessary to target cancer with lower mutational burden (the other ~95%). Importantly, the efficacy of PD-1 blockade is associated with the recruitment of new T cells from the blood rather than the activation of pre-existing tumor infiltrating lymphocytes (Yost K.E., *et al*. Nat. Med. 2019). Our approach is to use RNA to prime and expand T cells from the blood to cancer-specific mutations *ex vivo*. We can generate T cell populations reactive to as few as 8 and as many as 40 cancer-specific mutant proteins in a single production run. *In vitro*, these T cells have mutation-specific cytotoxicity and do not kill the normal cells. These T cells express homing receptors that allow them to infiltrate the tumor and express high levels of TNFα and IFNγ, both of which are associated with effective tumor cytotoxicity and pro-inflammatory modification of the tumor microenvironment (TME). The predominant immunophenotype of these cells is consistent with central and effector memory, CD4+ and CD8+ T cells, with almost no regulatory or exhausted T cells. We believe these T cells can be used as a cellular therapy in conjunction with, or as an alternative to, immune checkpoint inhibitors to treat lower mutational burden cancers that comprise most patients' tumors.

Ganglioside SSEA4 in Ewing sarcoma: A marker of tumor cells with highly aggressive features and a potential immune target

Silke Jamitzky[1], Bianca Altvater[1], Carolin Krekeler[1], Laura Hoen[1], Caroline Brandes[1], Lisa Richter[1], Julia Ebbinghaus[1], Laurin Ochs[1], Nicole Farwick[1], Katja Urban[1], Dennis Görlich[2], Ian Johnston[3], Rita Pfeifer[3], Claudia Rossig[1], Wolfgang Hartmann[4], Sareetha Kailayangiri[1]. *[1]University Children's Hospital Münster, Muenster, Germany,[2]Institute of Biostatistics and Clinical Research, University Hospital Muenster, Muenster, Germany,[3]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany,[4]Division of Translational Pathology Gerhard-Domagk-Institute of Pathology, University of Muenster, Muenster, Germany*

Cancers can aberrantly express carbohydrate antigens restricted to immature cells during prenatal human development, and these may be exploited for selective immune targeting. We studied expression and functional associations of the globo-series ganglioside stage-specific embryonic antigen 4 (SSEA4), a cell surface marker of human embryonic stem cells, in Ewing sarcoma (EwS). Flow cytometry revealed SSEA4 expression on the cell surface of each of 13 EwS cell lines, with moderate to high expression densities in 6 of 13 (46%) cell lines. Of 31 primary EwS tumor biopsies, 21 (68%) were SSEA4 positive by immunofluorescence staining. No associations of SSEA4 positivity with molecular or clinical disease parameters were found. Comparisons of paired tumor cell subpopulations with high and low/negative SSEA4 expression selected by cell sorting from 8 EwS cell lines revealed increased cell proliferation and colony formation of SSEA4^{high} tumor cells, along with higher doxocrubicin chemoresistance and a higher propensity to migrate in transwell assays. SSEA4 negative cells selected from bulk populations of EwS cells regained SSEA4 expression during continued *in vitro* culture as well as after in vivo xenografting into immunodeficient mice. SSEA4^{high} expression in EwS cells was not dependent on expression levels of the EWSR1-FLI1 fusion transcript or its direct targets, nor associated with markers of epithelial/mesenchymal plasticity. To retarget human T cells to SSEA4, we generated a second-generation, 41BBζ CAR using the antigen-binding domains of a murine anti-SSEA4 monoclonal antibody. SSEA4-specific CAR T cells specifically interacted with SSEA4 positive EwS cells in a

strictly antigen-dependent manner, resulting in effective tumor cell lysis in vitro. We conclude that targeting of SSEA4 with CAR T cells or alternative immune therapeutics could be an attractive strategy to eliminate tumor cell subsets with high propensity to drive disease progression in EwS and therefore deserves further evaluation towards clinical translation.

Engineering TRAIL-expressing immune cells to target GI malignancies

Praveen R. Srinivasan, Shengliang Zhang, Wafik S. El-Deiry. *Pathology and Laboratory Medicine, Legorreta Cancer Center at Brown University, Providence, RI*

While adoptive cell therapies, such as chimeric antigen receptor (CAR) T cells, have had promising results in hematologic malignancies, their translation to solid tumors has been mostly unsuccessful. A significant limitation to use of adoptive cell therapy in solid tumors has been life-threatening off-target toxicities, including acute respiratory toxicity and cytokine release syndrome. The native T cell program releases a diverse range of toxic proteins upon activation, including interferons, interleukins, perforins, and granzymes. Rather than activate the native T-cell program, selective expression of tumor-targeting agents may be advantageous. TNF-related apoptosis-inducing ligand (TRAIL) is known to selectively target tumor cells with minimal toxicity to normal tissues. We therefore engineered Jurkat (a human CD4+ T cell leukemia cell line) and THP-1 (a human monocytic leukemia cell line) cells to constitutively express wild-type TRAIL using a third-generation lentivirus system. These cells killed multiple cell lines across colorectal and pancreatic cancer, thus representing a possible therapeutic strategy to target GI malignancies. Furthermore, the addition of the ferroptosis induced erastin enhanced cytotoxicity of TRAIL-engineered cells, suggesting that targeting ferroptosis in addition to apoptosis is a promising strategy for enhancing immune killing. Future work will focus on overcoming TRAIL resistance, tumor trafficking, and alteration of the tumor microenvironment.

Identification of myeloma-specific T cell receptors by functional single cell interaction analyses

Tim R. Wagner[1], Eren Boğa[2], Patrick Schmidt[2], Wolfram Osen[1], Michael Platten[3], Hartmut Goldschmidt[4], Marc S. Raab[4], Mirco J. Friedrich[4], Stefan B. Eichmüller[1]. *[1]Research Group GMP & T Cell Therapy, German Cancer Research Center, Heidelberg, Germany,[2]Medical Oncology, National Center for Tumor Diseases, Heidelberg, Germany,[3]Clinical Cooperation Unit Neuroimmunology and Brain Tumor Immunology, German Cancer Research Center, Heidelberg, Germany,[4]Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany*

Innovative immunotherapy approaches such as adoptive transfer of chimeric antigen receptor (CAR) T cells or tumor infiltrating lymphocytes (TILs) have shown great success in the treatment of solid tumors and hematological malignancies. Although treatment of multiple myeloma with CAR T cells can induce deep responses, relapses frequently occur due to antigen escape and limited CAR T cell persistence. TCR-engineered T cells may mediate sustained antitumor effects upon recognition of intracellular targets, thereby significantly increasing the range of relevant target antigens. In our project, we propose to identify T cell receptors (TCRs) specifically targeting autologous myeloma cells. Tumor-reactive T cells were identified using the Berkeley Lights Lightning platform, allowing simultaneous functional analysis of up to 1500 individual T cell/target cell interactions per run. Reactive T cells have been identified upon detection of secreted chemokines (IFNγ, TNFα, IL-2) and by measurement of CD137 surface expression. Tumor-reactive T cells showing various cytokine secretion patterns and CD137 expression profiles could be detected in each myeloma patient (7 to 26 of approx.1200 cells tested per patient). Individual tumor reactive T cells have been isolated for TCR sequencing. Recovered TCR genes will be cloned and overexpressed in autologous T cells for functional validation and analysis of tumor derived neoepitope specificity. In summary, we present a pipeline allowing identification of myeloma-recognizing T cells and recovery of bona fide tumor-reactive TCRs eligible for patient-individualized T cell therapy.

Class I HLA-independent lysis of immunotherapy-resistant melanoma by CD8 T cells

Hongyan Xie[1], Aiping Jiang[2], Anne Jenney[3], Yi Sun[1], Tatyana Sharova[1], Moshe Sade-Feldman[1], Or-yam Revach[1], Angelina Cicerchia[1], Martin Q. Rasmussen[1], Nir Hacohen[1], Robert T. Manguso[2], Russell W. Jenkins[1].
[1]Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA,[2]Broad Institute of MIT and Harvard, Cambridge, MA,[3]Laboratory of Systems Pharmacology, Harvard Program in Therapeutic Sciences, Harvard Medical School, Boston, MA

Cancer immunotherapy with immune checkpoint blockade (ICB) has transformed the treatment of melanoma, although intrinsic or acquired resistance develops in nearly half of patients. Tumor-infiltrating CD8+ T lymphocytes (TILs) are key determinants of anti-tumor immunity in melanoma and other cancers, and single-cell RNA-sequencing has identified T cell states associated with improved clinical response to ICB, as well as adoptive T cell therapy (ACT). Despite these advances, strategies to identify and analyze tumor-reactive TILs in ICB-resistant patients remain limited. Here, we demonstrate that TILs from ICB-resistant melanoma patients can recognize and eliminate autologous tumor cells independent of class I HLA-TCR interactions. TILs eliminated matched melanoma cells in a time and dose-dependent fashion associated with secretion of effector cytokines. Strikingly, the deletion of B2M (resulting in loss of class I HLA surface expression) did not alter the activity of these TILs. Immunophenotyping studies confirmed that TILs are largely (>95%) effector memory (Tem) CD8 T cells (CD45RA-CD45RO+CCR7-) and give rise to terminal effector cells after co-culture with matched melanoma cells. Further, the elimination of melanoma cells by TILs required intact JAK1/2 signaling, although interferon-gamma (IFNγ) was neither necessary nor sufficient for tumor cell elimination. Together, these findings demonstrate that expanded TILs from ICB-resistant melanoma patients are capable of eliminating melanoma cells via a novel, class I MHC-independent mechanism.

Tunable STAT activation by synthetic pathway activators (SPAs) increases engineered T-cell potency and persistence

Thomas J. Gardner, Beatriz Millare, Anzhi Yao, Ashley Cass, Suchismita Mohanty, Jeremy Chen, Alma Gomez, David DeTomaso, Manching Ku,

Lionel Berthoin, Meng Lim, Azalea Ong, Vince Thomas, Nicholas Quant, Brian Hsu, Amy-Jo Casbon, Natalie Bezman, Aaron Cooper, Levi Gray-Rupp, Angela C. Boroughs, W. Nicholas Haining. *Arsenal Biosciences, South San Francisco, CA*

Clinically effective adoptive T cell therapy for the treatment of solid tumors will require robust T cell expansion, persistence, and potency. The Janus-kinase signal transducer and activator of transcription (JAK-STAT) pathway governs T cell activation and differentiation, and can thereby serve as a critical regulator of these properties. To take advantage of the benefits of STAT signaling in programming an antitumor T-cell response, we used synthetic biology to create a library of proteins, termed Synthetic Pathway Activators (SPAs) which constitutively drive STAT signaling without the need for external cytokine input. SPAs can be designed to engage activity of multiple STAT family transcription factors at variable levels through rational design. We have developed several classes of SPAs, including but not limited to Class I SPAs, which primarily increase pSTAT3 activity, and Class II SPAs, which increase pSTAT5 activity. When constitutively expressed in ArsenalBio Integrated Circuit T (ICT) cells, SPAs result in significant enhancements in T-cell potency and expansion. Repetitive stimulation assays, wherein T cells are challenged with tumor cells every 2 days, reveal that Class I SPAs result in 6-log or higher improved tumor cell clearance over a 2-week assay period. Across various mouse xenograft models, SPA-expressing ICTs reach at least 6-fold improved tumor growth inhibition. RNAseq and ATACseq analysis indicate dramatic changes to gene expression profiles in T cells expressing Class I SPAs, with maintenance of T cell stem-like phenotypes, and restricted accessibility of various exhaustion marker genes. Importantly, despite significantly increased levels of expansion, ICTs equipped with SPAs are not immortalized, showing no signs of cytokine-independent outgrowth. In addition, SPA-expressing ICT cells rapidly contract following tumor clearance in-vivo. The SPA platform represents a novel, tunable, and T cell intrinsic approach for engineering cell fates that result in potent anti-tumor properties.

#4074

Cellular immunotherapy targeting kappa myeloma antigen for the treatment of multiple myeloma

Jessica Li[1], Nicole Haynes[1], Katherine Cummins[1], Kavitha Gowrishankar[2], Kenneth Micklewaithe[2], Halley Hilton[3], Rosanne Dunn[3], Jane Oliaro[1], Simon Harrison[1]. *[1]Peter MacCallum Cancer Centre, Melbourne, Australia,[2]University of Sydney, Sydney, Australia,[3]Haemalogix, Sydney, Australia*

Multiple myeloma (MM), the second most common blood cancer, is characterized by the accumulation of malignant plasma cells in the bone marrow. Chimeric Antigen Receptor (CAR)-T cell therapy has recently entered the standard of care for relapsed and refractory MM, following the recent FDA-approval of two CAR-T cell products, ide-cel® and cilta-cel®, which target the B cell maturation antigen (BCMA). However, despite impressive response rates, most patients relapse within 1-3 years. Kappa (κ) myeloma antigen (KMA) is a tumour specific membrane associated protein expressed on malignant plasma cells in patients with kappa light-chain restricted (κ-type) MM. KMA is absent on normal plasma cells and haematopoietic stem cells, making it an attractive and alternative target antigen for CAR-T cell therapy for MM. The monoclonal antibody, KappaMab (MDX-1097), binds to a conformational epitope on KMA, and has been assessed in phase I, IIa and IIb clinical trials in relapse refractory myeloma patients (1). Here, we have engineered a lentiviral vector encoding a second-generation CAR expressing a scFv from MDX-1097, fused to a 4-1BB co-stimulatory domain and CD3 zeta chain. We successfully generated human anti-KMA CAR-T cells with high and stable CAR expression and a predominately memory T cell phenotype. The CAR-T cells selectively killed KMA-expressing tumour lines, secreted interferon-gamma upon target recognition, and demonstrated potent anti-tumour activity in a xenograft model. Anti-KMA CAR-T cell therapy therefore represents a novel and potent treatment ready to enter a phase I clinical trial for patients with myeloma. (1) Spencer et al. Blood Cancer Journal (2019) 9:58

#4075

A modified FcγRI expressing-T cell, SolidT, enables antibody-mediated cytotoxicity to overcome the limitations of CAR-T cell therapy against

solid tumors

Diana Rasoulouniriana[1], Nadine Santana-Magal[2], Amit Gutwillig[2], Leen Farhat-Younis[2], Hana Shpilt[1], Shahar Dotan[1], Noam Pilpel[1], Peleg Rider[1], Yaron Carmi[2]. *[1]Gilboa Therapeutics Inc., Rehovot, Israel,[2]Department of Pathology, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel*

The pioneering design of chimeric antigen receptor T-cell (CAR-T) therapy demonstrated the potential of reprogramming the immune system. Nonetheless, T-cell exhaustion, toxicity, and suppressive microenvironment limit their efficacy in solid tumors. Recently, we characterized a novel subset of tumor-infiltrating $CD4^+$ T-cells expressing the FcγRI receptor (Rasoulouniriana et al, 2019). Herein we detail the engineering of a novel receptor, based on the FcγRI structure, which is retrovirally transduced into PBMCs (both CD4 and CD8 T-cells). These cells, named SolidT cells, can target tumor cells using antibody intermediates. They show effective and specific cytotoxicity only when an appropriate antibody is added. Only target-bound antibodies activate these cells, while free antibodies are internalized without activation. Their cytotoxic activity is correlated to target protein density, therefore targeting tumor cells with high antigen density while sparing normal cells with low or no expression. This activation mechanism prevents premature exhaustion. Furthermore, during ADCC these cells secrete attenuated cytokine levels compared to CAR-T, thereby enhancing their safety profile. These cells eradicate established melanoma tumors, infiltrate the tumor microenvironment and facilitate host immune cell recruitment in immunocompetent mice. In NSG mice, they infiltrate, persist, and eradicate tumors. As opposed to CAR therapies, which require changing the receptor across different types of cancer, our engineered T-cells remain the same throughout tumor types, while only the injected antibody changes. As such, can be adapted to treat a wide range of solid cancers without changing the manufacturing program. Overall, SolidT cells are capable of binding tumor cells with high affinity, while preserving the cytotoxic specificity only to cells expressing a high density of tumor-associated antigens.

#4076

4-1bb selection augments DC/AML fusion vaccine-educated T cells for adoptive cell therapy

Kathrine S. Rallis*[1], Jessica Liegel*[1], Giulia Cheloni[1], Dina Stroopinsky[1], Poorva Bindal[1], Kenel Dufort[1], Daniela Torres[1], Isabella Saldarriaga[1], Samuel Herzlinger[1], Abigael Morin[1], Raphael Kesselman[1], Jeremy Rosenbaum[1], Georges Chedid[1], Sophia Adamia[1], Donald Kufe[2], Jacalyn Rosenblatt[1], David Avigan[1]. *[1]Hematology-Oncology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA,[2]Dana Farber Cancer Institute, Harvard Medical School, Boston, MA*

Introducti**on:** Our group has pioneered a novel vaccine by fusion of patient-derived tumor with autologous dendritic cells (DCs) that presents an array of tumor antigens generating a polyclonal immune response. DC/AML vaccination led to expansion of leukemia-specific T cells with survival benefit in a phase II clinical trial. We postulated that ex vivo generation of vaccine-educated T cells would provide a powerful platform for adoptive immunotherapy with opportunity to augment T-cell functional potency prior to infusion. We report on an ex vivo system in which vaccine-educated T cells are further enriched for activated antigen-specific effector cells via an agonistic 4-1bb antibody. We report phenotypic and functional characteristics of 4-1bb-enriched vaccine-educated T cells.
Methods: DC/AML fusion vaccines were generated from C57BL/6J mice DCs and syngeneic C1498 mCh/luc$^+$ AML cells. Splenic T cells were co-cultured with autologous irradiated DC/AML fusions in presence of IL-2/7/15. Selection with biotinylated agonistic 4-1bb (3H3) was performed on vaccine-educated T cells followed by expansion with anti-CD3/CD28 activation beads. T cells were phenotyped for activation (CD25/CD69), immune checkpoints (PD1/LAG3/TIM3), memory (CD44+CD62L-) and enrichment (anti-rat H&L). Cytotoxicity was evaluated by luminescence. Mice were inoculated with C1498 and injected with T cells 7 days later. BLI imaging was performed and 100-day survival measured.
Results: Vaccine-educated T cells demonstrated evidence of immune activation and memory phenotype compared to unstimulated naïve T-cell controls (TN) (7.24-fold, CD4+CD25+CD69+; 1.7-fold, CD3+CD44+CD62L-). Vaccine-educated T cells selected based on 4-1bb expression showed enhanced markers of activation (15.3-fold, CD4+CD25+CD69+) and memory phenotype (5-fold, CD3+CD44+CD62L-) compared to TN. Selection enriched for 4-1bb$^+$

vaccine-educated T cells resulting in enhanced antigen-specific recognition as measured by tumor lysate induction of IFNg expression. Tumor specificity and activation was maintained following CD3/CD28-mediated expansion. The 4-1bb+ vaccine-educated T cells showed enhanced cytotoxicity (1.9-fold increase/TN at 10:1 E/T, $P<0.0001$). Phenotypic and functional analysis support 3-5 days as the optimal duration of time for T-cell vaccine education. In vivo, 60% of mice treated with 4-1bb^{+} vaccine-educated cells were alive at 60 days vs. 20% treated with unselected vaccine-educated cells.

Conclusion: We demonstrate that vaccine-educated T cells subject to selection via an agonist 4-1bb antibody confer enhanced tumor selectivity and potency. Optimal duration for T-cell education was 3-5 days. T-cell stimulation and enrichment by agonistic 4-1bb selection enhanced cytotoxicity and memory phenotype. Thus, 4-1bb selection is a novel approach for antigen-specific T-cell enrichment for superior adoptive immunotherapy in AML.

#4077

Dual-targeted CAR-NK cell therapy: optimized CAR design to prevent antigen escape and elicit a deep and durable response in multiple myeloma

Cuiqing Yang[1], Yifang Wang[1], Tingting Liu[1], Chao Wang[1], Huanyu Wang[1], Qingyang Wang[1], Qin Wang[1], Gang Ye[1], Renhong Tang[2], Zhuoxiao Cao[1].
[1]Shanghai Simnova Biotechnology Co., Ltd., Shanghai, China,[2]Jiangsu Simcere Pharmaceuticals Co. Ltd, Shanghai, China

Introduction: Multiple myeloma (MM) is an incurable hematologic malignancy and new strategies that offer a chance of obtaining long-term progression free survival are urgently needed. MM is associated with profound immune alterations and dysfunction of natural killer (NK) cells have been demonstrated to be crucial factors in MM progression. Myeloma cells are susceptible to killing by natural killer (NK) cells but acquire the ability to elude NK cell surveillance by avoiding recognition and suppressing NK cell function. Given the role of NK cells in the pathogenesis of MM, interest in harnessing NK cells to treat the cancer has been energized by the remarkable success of other adoptive cell therapies such as chimeric antigen receptor (CAR)-T cells. However, relapses

associated with residual low-to-negative BCMA-expressing MM cells have been reported, necessitating the identification of additional targets. GPRC5D, expressed on MM cells from primary marrow samples with a distribution independent of BCMA.
Methods: To prevent BCMA-antigen escape and elicit a deeper and more durable response in MM, we developed a new multiplexed edited NK cell configuration to restore anti-myeloma NK cell immunity, consisting of anti-BCMA VHH and anti-GPRC5D VHH antibodies, NKG2D and 2B4 co-stimulation signaling domains, and IL-15.
Results: Dual targeting BCMA/GPRC5D CAR-NK showed potent in vitro killing of both BCMA+ and GPRC5D+ myeloma cells. Utilizing a repeated rounds of cancer cell clearance assay, BCMA/GPRC5D CAR NK cells showed remarkable persistence and antigen-mediated expansion of CAR-NK cells after more than 4 rounds of tumor cell re-challenges. Moreover, in comparison with single targeted BCMA CAR-NK cells, Dual targeting BCMA/GPRC5D CAR-NK cells effectively lysed BCMA negative target cells. In addition, in BCMA-antigenic escape model, it achieved more sustained tumor control than single targeting BCMA CAR-NK cells. PD-1/PD-L1 axis inhibition has been reported to enhance NK cell activity against MM cells by augmenting NK cell trafficking, immune complex formation, and cytotoxicity against PD-L1-expressing MM cells. We also demonstrated that combination of BCMA/GPRC5D CAR-NK with anti-PDL1-IL15 also showed more persistent tumor control.
Conclusions: Our studies demonstrate the development of dual targeting BCMA/GPRC5D CAR NK cells may represent a highly effective off-the-shelf therapeutic product as a monotherapy or in combinations with other immune-regulating agents.

#4078

Optimized chimeric antigen receptors (CARs) for CAR-NK cell therapies

Cuiqing Yang[1], Yifang Wang[1], Tingting Liu[1], Fuwei Jiang[1], Qingyang Wang[1], Qin Wang[1], Gang Ye[1], Renhong Tang[2], Zhouxiao Cao[1]. *[1]Shanghai Simnova Biotechnology Co., Ltd., Shanghai, China,[2]Jiangsu Simcere Pharmaceuticals Co. Ltd, Nanjing, China*

Introduction: CAR-T-cell therapy has shown great success in treating hematopoietic malignancies. Allogenic NK cell-based therapies have also been shown to mount potent responses against hematopoietic malignancies. Unlike T-cell therapies, allogeneic NK cells do not cause toxicities such as serious cytokine release syndrome, neurotoxicity, or graft-vs-host-disease. Several groups have demonstrated the clinical efficacy of allogeneic CAR-expressing NK cells that utilize CARs developed for T-cells. However, activating receptor signaling in NK cells is different from T cells. NK cell-mediated cytotoxicity is regulated by a repertoire of activating and inhibitory receptors. Activating receptors include natural cytotoxic receptors (NCRs) such as NKG2D, CD16, LFA-1, CD244 (2B4), and CD137 (4-1BB) and so on. These activating cell surface receptors have the capacity to trigger cytolytic programs as well as cytokine and chemokine secretion via intra-cytoplasmic immunoreceptor tyrosine-based activation motifs (ITAMs) such as in 2B4 and 4-1BB and/or via other transmembrane signaling adaptors. Recent studies using NK cell-based activating receptor signaling modules such as NKG2D and 2B4 as CAR co-stimulatory domains proved increased anti-tumor activity compared to T-cell CARs.
Methods: The goal of this study is to develop next-generation NK cell-optimized CARs to improve targeting and potency of NK cell treatment. To achieve this, we constructed a library of CARs containing signaling modules from diverse T cell signaling receptors and NK cell specific signaling receptors, and then screened for CAR activity using short-term and long-term NK cell cytotoxicity assays. In comparison with T cell signaling receptors, CAR-NK cells with NK cell signaling receptors showed more potent cytotoxicity. Using a repeated rounds of cancer cell clearance assay, serial re-stimulation by fresh cancer target cells was tested. CAR-NK cells with NK cell signaling receptors showed remarkable persistence and antigen-mediated expansion of CAR-NK cells compared with T cell signaling receptors.
Results: We identified a NK cell-CAR containing two NK cell co-stimulatory domain and CD3z signaling domain,showing better persistence than T-cell CAR (CD28-CD28-zeta) and 2 previously described NK cell-CARs (NKG2D-2B4-zeta and 2B4).
Conclusions: We have successfully identified an optimized CAR suitable for NK cells that enable increased potency of NK cells compared to other CAR designs. The most potent CARs identified in our screen are being

engineered into a highly effective dual targeting BCMA-GPRC5D CAR-NK cell product as a next-generation “off-shelf” cell therapy.

CAR T-cell Therapy 2

Impact of immunosuppressive monocytes on CART19 cell effector functions and outcomes

Kun Yun[1], Reona Leo Sakemura[1], Michelle J. Cox[1], Truc Huynh[1], Claudia Manriquez-Roman[1], Olivia Sirpilla[1], Carli M. Stewart[1], James H. Girsch[1], Ekene J. Ogbodo[1], Ismail Can[1], Brooke Kimball[1], Lionel A. Kankeu Fonkoua[1], Mehrdad Hefazi[1], Michael W. Ruff[1], Elizabeth L. Siegler[1], Mike Mattie[2], Sao-Mai Nguyen-Mau[2], Simone Filosto[2], Saad S. Kenderian[1].
[1]Mayo Clinic, Rochester, MN,[2]Kite, a Gilead company, Santa Monica, CA

CD19 directed chimeric antigen receptor T (CART19) cell therapy has resulted in remarkable outcomes in B cell malignancies and was FDA approved in multiple indications. However, durable remissions are limited to 40% of treated patients. Inhibitory myeloid cells in tumor microenvironment have been found to suppress T cell expansion and contribute to failure of CART19 cell therapy. In this study, we aimed to unravel the interactions between monocytes, CART19 cells and tumor cells to understand how monocytes-CART19 cell interactions impact CART19 cell effector functions and clinical outcomes. Two sets of experiments were conducted, 1) use of healthy CART19 cells, CD19+ tumor cells, and healthy monocytes; 2) use of brexu-cel products from ZUMA-2 clinical trial treating mantle cell lymphoma (MCL), patient-matched monocytes and circulating MCL tumor cells (n = 11; 6 durable responders, 2 relapsed after initial response and 3 non-responders).
CD28 costimulated CART19 (CART19-28ζ) cells generated in the lab from healthy donors were co-cultured with donor freshly isolated monocytes in the presence of Jeko-1 cells (a CD19+ MCL cell line). CART19 antigen specific proliferation was not inhibited by freshly isolated monocytes . When monocytes were co-cultured with CART19 and tumor cells, higher levels of eotaxin, GRO, MCP-3 and IL-7 were detected. When CART19 cells were co-cultured with the CD19+ JeKo-1 cells in the presence of ex vivo M2 polarized macrophages, CART19 antigen specific proliferation

was inhibited (p=0.0045). Transwell experiments demonstrate that M2-induced CART19 inhibition is not contact dependent. Cytokine profile analysis indicated increased level of IL-1ra, IP-10 and MCP-1 and decreased level of IL-17A, sCD40L, IL-9 and MIP-1α when M2 macrophages were co-cultured with CART19 and tumor cells compared to co-cultures of tumor cells and CART19.
Then we conducted ex vivo co-cultures of brexu-cel products, autologous monocytes and circulating MCL tumor cells from MCL patients (ZUMA-2) collected prior to CART19 cell infusion. Here we observed trends of elevation of IL-13 and IL-5 and reduction of GRO, MCP-3, MIP-1β and IL-8 in non-responders, compared to responders (durable responses or relapsed patients).
Our results support that monocyte- and macrophage-dependent cytokine release could modulate CART19 effector and trafficking functions, and thus CART19 clinical outcomes. This warrants further investigation around strategies to improve durable responses to CART cell therapy.

In vivo efficacy of LGR5-targeting CAR-T cell therapies developed for the treatment of colorectal cancer

Dylan McPeake[1], Timona Tyllis[1], Caitlin Abbott[1], Jade Foeng[1], Veronika Bandara[2], Batjargal Gundsambuu[2], Elaheh Rohani-Rad[1], Silvana Napoli[2], Timothy Sadlon[3], Simon Barry[4], Shaun McColl[1]. *[1]Department of Molecular & Biomedical Science, The University of Adelaide, Adelaide, Australia,[2]The Robinson Research Institute, Adelaide, Australia,[3]The Robinson Research Institute/Women and Childrens' Health Network, Adelaide, Australia,[4]The Robinson Research Institute/Women and Childrens' Health Netwok, Adelaide, Australia*

While CAR-T cells have demonstrated significant efficacy in the treatment of haematological malignancies, there are many challenges to overcome in developing CAR-T cell therapies against solid tumours. In particular, the scarcity of recognised effective target antigens in solid tumours remains a significant hurdle. Leucine-rich repeat-containing G-protein coupled receptor (LGR5) is a cancer stem cell marker, which mediates important roles in tumor initiation and metastasis. Upregulated LGR5 expression in malignant cell contexts highlights this surface receptor as a promising target

for CAR-T cell therapy. In this study, we evaluated the efficacy of LGR5-targeting CAR-T cells against a range of human cancers. We demonstrate that LGR5 is expressed, both *in vitro* and *in vivo*, by numerous human cancers, including colorectal, ovarian, hepatic, brain, and pancreatic cancer. LGR5-targeting CAR-T cells effectively kill LGR5-expressing cancer cells in *in vitro* cytotoxicity assays and display significant anti-tumor activity *in vivo* when administered at 1, 2 or 3 weeks post-tumor inoculation in a subcutaneous human colorectal cancer xenograft mouse model. Furthermore, LGR5-targeting CAR-T cells that induce primary tumor rejection confer complete protection against a secondary tumor challenge 5 weeks post-T cell transfer. *In vivo* spatiotemporal distribution and repeated dosing studies demonstrate that LGR5-targeting CAR-T cells accumulate at the tumor site until tumor elimination, do not persist in off-target organs by d28 post-tumor inoculation and are safe and well-tolerated under the conditions tested. Together, these results provide the foundation for furthering the development of LGR5-targeting CAR-T cells for use in the clinic against colorectal cancers and other solid tumours.

Development and *in vitro* validation of an LGR-5 targeting CAR-T against colorectal cancer

Veronika Bandara[1], Batjargal Gundsambuu[2], Silvana Napoli[2], Stuart Mills[3], Emma Thompson[4], Lih Tan[4], Jade Foeng[5], Dylan McPeake[5], Timona Tylis[5], Caitlin Abbott[5], Allison Cowin[3], Claudine Bonder[6], Timothy Sadlon[7], Shaun McColl[8], Simon C. Barry[9]. *[1]Molecular Immunology, Robinson Research Institute, Adelaide, Australia,[2]Robinson Research Institute, Adelaide, Australia,[3]Future Industries Institute, University of South Australia, Adelaide, Australia,[4]Centre for Cancer Biology, Adelaide, Australia,[5]Chemokine Biology, University of Adelaide, Adelaide, Australia,[6]Centre for Cancer Biology, University of South Australia, Adelaide, Australia,[7]Molecular immunology, Robinson Research Institute, Adelaide, Australia,[8]Chemokine Biology, Carina Biotech Pty and University of Adelaide, Adelaide, Australia,[9]Robinson Research Institute and Carina Biotech Pty Ltd, Adelaide, Australia*

Chimeric antigen receptor (CAR) T cells have demonstrated robust clinical efficacy against B-cell malignancies, and rapid translation to approval for use in man has inspired the search for CAR-T cells against solid tumours. Cancer stem cells are a small population of cells within a tumour that have the capacity to self-renew, differentiate, and initiate new tumours. Cancer stem cells are known to be resistant to chemotherapy and radiotherapy and are enriched in residual disease, which allows relapse. Targeting cancer stem cells is desirable as it will reduce a tumours' ability to generate new cells, resulting in tumour remission. Leucine-rich G protein-coupled receptor 5 (LGR5) expression is restricted to stem cell populations in several tissues in adults. In addition, LGR5 is a marker of cancer stem cells and $LGR5^{+}$ cancer cells are implicated in tumour progression and metastasis. We have designed and tested a CAR targeting the extracellular domain of LGR5, and optimised gene delivery to purified human CD3+ T cells showed robust CAR expression. Having confirmed on target specificity and cytotoxicity we show antigen-specific IFNγ release against colorectal cancer (CRC) and neuroblastoma cell lines *in vitro.* We confirmed the specificity and safety of the LGR5 targeting CAR-T cells by testing against normal human tissues from colon, liver, kidney, lung and heart. Using optimised gene delivery and CAR-T manufacturing protocols, we generated clinical scale batches to evaluate their potency in a preclinical CRC xenograft mouse model. A protocol for clinical scale manufacture of LGR5-targeting CAR-T cells has been developed using CD3+ T cells from healthy donors and now we have successfully tested this protocol using CRC patient-derived CD3+ T cells. This protocol is GMP ready and has been tested in a GMP manufacturing facility. Using T cells from healthy donors and CRC patients we were able to generate optimal cell numbers (80-fold expansion) with high CAR expression. These CAR-T cells showed high *in vitro* cytotoxicity and IFNγ release when co-cultured with LGR5 expressing CRC cell line. Post expansion, CAR-T cell products expressed markers of self-renewing naïve-like and central memory phenotype and showed very low percentage of cells that were triple-positive for PD1, TIM3 and LAG3. These results suggest a CAR-T targeting LGR5 may provide long-term protection against tumour growth. Our data positions LGR5-targeting CAR-T therapy as a viable therapeutic for human metastatic colorectal cancer types with minimal off-target effects, which we now aim to test in human clinical trials.

#4084

Globo H-targeted CAR T cell cancer immunotherapy

Jiann-Shiun Lai, Shiou-Ling Jian, Woan-Eng Chan, Ming-Tain Lai. *OBI Pharma, Inc, Taipei, Taiwan*

Background: Globo H (GH), a Globo-series glycosphingolipid (GSL), is highly expressed in epithelial tumors, such as colon, endometrial, gastric, pancreatic, lung, prostate, and breast cancers. Aberrant expression of Globo H has been reported to be associated with the metastatic potential and poor prognosis of these cancers. However, in normal tissues, GH expression is limited to the secretory borders of apical epithelial cells, making it difficult to access by the immune system. GH is therefore a promising target for anticancer therapeutics. Clinical studies with the Globo H vaccines (OBI-822 and OBI-833) and the humanized anti-Globo H antibody (OBI-888) demonstrating an excellent safety profile. In recent years, cell therapy using chimeric antigen receptor T (CAR T) cells have shown impressive clinical outcomes. As a result, development of CAR T targeting GH may offer a novel anticancer therapeutic agent.

Aim: The aim of this study was to develop a CAR T cell therapy targeted against Globo H (obi-R007) using lentivirus-mediated genetic engineering with a proprietary Globo H-specific antibody. Methods: We conducted *in vitro* and *in vivo* studies to determine the characteristics of GH CAR T obi-R007.

Results: *Ex vivo* expansion of obi-R007 from healthy donors ranged from 40- to 200-fold post-activation for 10 days. Previous studies have suggested that less differentiation and fewer exhaustion markers of CAR T cells are beneficial for therapeutic persistence. In our study, there was less differentiation in the $CD62L^+$ population (T_{SCM} and T_{CM}) in greater than 80% of obi-R007 cells, and no significant exhaustion markers (PD-1, LAG-3, etc.) were detected. obi-R007 showed specific cytotoxicity against Globo H-positive tumor cells with an E/T ratio of 0.5:1~2:1 and exhibited Globo H-specific activation through the expression of CD69, CD25, and Granzyme B as well as the release of Interferon γ and IL-2. Moreover, the activation and proliferation of obi-R007 were dependent on the presence of target cells. All the *in vitro* results indicate the specific targeting of obi-R007 to Globo H resulting in cytotoxic T cell responses. In the *in vivo*

study, the efficacy of obi-R007 was demonstrated by adoptive cell transfer in several xenograft models and obi-R007 was shown to be persistent under multiple tumor challenges in the NCI-N87 gastric cancer model. Luminance labelling of CAR T cells showed that the distribution of CAR T cells in mice was specific to the tumor site and lymphoid organs suggesting a homing activity of the CAR T cells. Furthermore, no obviously physiological toxicity was observed *in vivo*.
Conclusion: In conclusion, our *in vitro* and *in vivo* pharmacology and preliminary toxicology studies support clinical development of Globo H CAR T immunotherapy for patients with cancer.

#4086
Mitigating the CD5 CAR-CD5 interaction enhances the functionality of CD5 CAR-T cells by alleviating the T-cell fratricide
Lee Young Ho, Seung Rok Yu, Jeong Hoon Jeong, Hyeong Ji Lee, Hyeon Jeong Cho, Hyung Cheol Kim. *Curocell Inc., Daejeon, Korea, Republic of*

Chimeric antigen receptor (CAR) T-cell therapy has been used with unprecedented clinical responses in relapsed/refractory B-ALL or B-NHL, MM patients. However, CAR-T therapy has not yet been proven effective in other hematological malignancies, such as T cell lymphoma and leukemia (T-NHL/T-ALL) and acute myeloid leukemia (AML). Developing CAR-T cells for patients with T-cell malignancies remains challenging as most CARs targeting T-lineage antigens, such as CD5, CD7, and CD3, target themselves, potentially resulting in fratricide of CAR-T cells. Thus, there is a need for technical approaches to alleviate the fratricide of CAR-T to treat T-cell malignancies successfully. As part of the approach, we studied whether the affinity of CAR and cognate antigen expression of CAR-T cells influence the intensity of CAR-T`s fratricide and hypothesized that if a single chain Fragment variable (scFv) with a low intensity of fratricide is applied to T-lineage antigen-downregulated CAR-T cells, the effector function of CAR-T cell targeting T cell antigen can be maximized. For this, we screened full human scFvs targeting CD5, a pan T-cell marker, tested the affinity of scFvs for CD5 antigen, and generated anti-CD5 CAR-T cells (CAR5). We evaluated the intensity of *in vitro* fratricide in CAR5 based on cell expansion and cytokine secretion *in vitro* and tested their anti-tumor activity in a CD5+ T-ALL xenograft model (Jurkat). In addition, to

minimize CAR recognition to a cognate antigen expressed in CAR-T cells, we also generated CD5-downregulated CAR5s (CD5-KD CAR5) using a short hairpin RNA cassette integrated into an anti-CD5 CAR vector to test if the downregulation of CD5 in CAR5s can reduce the fratricide. We found that a CAR5 clone (C7CAR5) with the lowest level of fratricide in vitro, showed superior anti-tumor activity compared to other CAR5s *in vivo* and that CD5-downregulated C7 CAR5 (CD5-KD C7CAR5) further reduced the fratricide, maximizing the anti-tumor activity. In conclusion, we demonstrate that high-affinity CAR may not always show superior functionality in T cell malignancy CAR-T therapy, explaining one or more strategies to alleviate the fratricide are required. These studies provide the foundation for developing CD5 CART products to treat relapsed T-cell malignancies.

Co-expression of membrane bound IL-15 enhanced anti-tumor response of CAR-T

Cuiqing Yang[1], Fuwei Jiang[1], Yifang Wang[1], Tingting Liu[1], Chao Wang[1], Qingyang Wang[1], Qin Wang[1], Gang Ye[1], Renhong Tang[2], Zhuoxiao Cao[1].
[1]Shanghai Simnova Biotechnology Co., Ltd., Shanghai, China,[2]Jiangsu Simcere Pharmaceuticals Co. Ltd, Nanjing, China

Introduction: Chimeric antigen receptors (CARs) T cells have been used successfully to treat patients with hematologic malignancies, but showed less effective in solid tumors. We investigated multiple approaches to engineer and enhance CAR-T activity in solid tumors. It has been previously reported that improvement in the quality of CAR-T cells, through CAR design or manufacturing optimization, could enhance the therapeutic potential of CAR-T cells. One parameter influencing the effectiveness of CAR-T cell therapy is the differentiation status of the final product: CAR-T cells that are less-differentiated and less exhausted are more therapeutically potent. It is well known that IL-2 is the main cytokine used to culture cells for adoptive cell therapy, as it plays an important role in the proliferation and functional effect of T cells. However, it has been noted T cells cultured with IL-2 are phenotypically heterogeneous, being predominantly composed of effector memory cells. In comparison with IL2, IL-15 can induce a memory stem-like T cell phenotype, which is less

differentiated and with a superior capacity for cell expansion and survival. Several groups reported that compared with cells cultured with IL-2, CAR-T cells expanded with IL-15 preserve a less-differentiated stem cell memory (Tscm) phenotype and exhibited reduced expression of exhaustion markers, higher antiapoptotic properties, increased proliferative capacity upon antigen challenge, and promoted superior anti-tumor responses in vivo.
Method: To provide localized IL-15 mediated signaling to T cells, we constructed a version of IL-15 as a membrane-bound molecule (mIL-15) designed to stimulate T cells in cis and in trans, and mIL-15 is tethered to the cell surface and functions locally to enhance the functionality of the CAR-T cell without systemic delivery of IL-15.
Result: Expression of mbIL-15 is shown to enhance T cell expansion, preserve a less-differentiated Tscm phenotype and prevent CAR-T cell exhaustion, leading to longer persistence and an enduring anti-tumor response over the conventional CAR-T cells.
Conclusion: We demonstrate that CAR-T activity and persistence can be enhanced by simultaneous expression of mIL-15, which preserves the CAR-T cell Tscm phenotype and improves their metabolic fitness, resulting in superior antitumor activity. These preclinical data support the notion that CAR-T cells are designed and optimized to persist in the hostile tumor microenvironment and potentially improve efficacy against solid tumors.

#4088

A neovasculature-inducible CA9 CAR resistant to FASL and TGFb mediated suppression for the treatment of ccRCC

Angela C. Boroughs, Irene Scarfo, Nickolas Attanasio, Thomas Gardner, Jenessa B. Smith, Jennifer McDevitt, Laura Lim, Nishant Mehta, Suchismita Mohanty, James Zhang, Eric Cui, Vibhavari Sail, Amanda Fearon, Samuel Williams, Stephen Santoro, W. Nicholas Haining, Levi Gray-Rupp. *Arsenal Biosciences, South San Fransisco, CA*

Clinically effective CAR-T cell therapy for solid tumors, such as clear cell renal cell carcinoma (ccRCC), will require substantial T cell engineering to increase their specificity and potency. We have developed an Integrated Circuit T cell (ICT) that encodes multiple synthetic “modules” in order to overcome diverse barriers to efficacy in ccRCC; ICT cells are generated via CRISPR-mediated, targeted knock-in of a single large transgene into the

novel GS94 safe-harbor locus. Both primary and metastatic sites of ccRCC are highly vascularized, with the majority of tumor cells expressing elevated levels of carbonic anhydrase IX (CA9), suggesting CA9 may be an excellent CAR target. However, CA9 is also expressed in healthy bile ducts and stomach tissue which has led to on-target, off-tumor toxicities in patients treated with constitutive CA9 CAR T cells. To improve the therapeutic index of CA9 CAR T cells, we developed an "AND" logic gated ICT cell that requires the presence of two antigens to trigger tumor cell killing, thereby enhancing tumor specificity. Induction of the CA9 CAR is gated on the expression of PSMA found on the tumor neovasculature of ccRCC. Importantly, PSMA and CA9 are not co-expressed in normal tissues. When the anti-PSMA priming receptor (PrimeR^{TM}) binds PSMA, PrimeR^{TM} engagement triggers proteolytic release of a chimeric, fully human transcription factor that induces expression of a CA9 CAR. We confirmed the feasibility of vascular priming using a transwell assay where ICTs were primed by a PSMA expressing endothelial cell line and then migrated across the transwell membrane to kill CA9 expressing RCC cells. In addition, a dual flank xenograft model was used to show logic gated circuits selectively kill tumors that express both CA9 and PSMA, and not tumors that express CA9 alone.
Transforming growth factor beta (TGFb) is an immunosuppressive cytokine known to be highly expressed in ccRCC. To further increase the potency and persistence of the ICT cells an shRNA cassette was developed targeting both FAS and TGFBR2, a receptor required for TGFB signaling in T cells. Addition of FAS/TGFBR2 shRNA enhanced antitumor activity of PSMAxCA9 logic gate expressing T cells during in vitro chronic stimulation assays conducted in the presence of exogenous TGFb. Furthermore, FAS/TGFBR shRNA containing ICTs demonstrated enhanced antitumor activity in multiple xenograft RCC models. Collectively, these results demonstrate that PSMAxCA9 ICT cells can (i) selectively target antigens that cannot be safely targeted by conventional CARs and (ii) overcome multiple suppressive mechanisms in the tumor microenvironment.

#4089
PanCAR-specific antibody-cytokine fusion proteins

John T. Keane, Avery D. Posey. *Perelman School of Med. Univ. of Pennsylvania, Philadelphia, PA*

CAR-T cells are a potent immunotherapy that redirect T cell specificity towards cell surface tumor-associated antigens. While this therapy has been effective in hematological malignancies, therapies against solid tumors not achieved the same efficacy due to a multitude of additional challenges, including a lack of tumor specific antigens and an immunosuppressive tumor microenvironment. One strategy to increase T cell potency is to use fourth generation CAR-T cells that also secrete an immunostimulatory factor, such as a cytokine. We have created CAR-T cells targeting Tn-MUC1 utilizing a scFv from the 5E5 antibody that also secrete interleukin-12 (IL-12), interleukin-18 (IL-18), and interleukin-23 (IL-23). These cytokine-secreting CAR-T cells have shown an increase in efficacy against multiple epithelial based tumors in impedance-based killing assays. In a xenograft model of human breast cancer, CAR-T cells secreting IL-12 and IL-23 were able to significantly delay tumor growth compared to non-transduced T cells, CAR-T cells alone, and CAR-T cells secreting IL-18. While these cells showed good efficacy *in vivo*, clinical translation is difficult due to concerns over cytokine storm due to the constitutive secretion of cytokines. To overcome this, we created a fusion protein utilizing an antibody specific to an invariant region found in majority of CAR molecules, including those utilized commercially available therapies and under pre-clinical development, fused to the three immunostimulatory cytokines. In impedance-based killing assays, antibody-cytokine fusions stimulated non-cytokine secreting CAR-T cells to completely clear the tumor at an E:T ratio in which the CAR-T cells incubated with only the antibody alone were unable to control the tumor growth. Interestingly, combination therapy of CAR-T cells and antibody-cytokine fusions outperformed CAR-T cells constitutively secreting the same cytokines in *in vitro* assays. This work highlights the use of a single reagent capable of increasing the efficacy of the majority of CAR-T cell therapies and may be an important contribution towards treating solid tumor malignancies with CAR-T cell therapies.

#4090

Regional administration of IL-12 endowed CAR T cells effectively targets systemic disease

Hee Jun Lee[1], Yuki Yamaguchi[1], Jackson Gibson[1], Cody Cullen[1], John P. Murad[1], Anthony K. Park[1], Isabel Monroy[1], Cari Young[2], Lea Christian[1], Lauren Adkins[1], Lawrence Stern[1], Wen-Chung Chang[1], Catalina Martinez[1], Stephen J. Forman[1], Saul J. Priceman[1]. *[1]City of Hope National Medical Center, Duarte, CA,[2]Irell and Manella Graduate School of Biological Sciences, City of Hope, Duarte, CA*

While chimeric antigen receptor (CAR) T cells have received FDA approvals in treating hematological malignancies, clinical responses of CAR T cells for solid tumors have been underwhelming. Intense investigation is underway to improve CAR T cells trafficking, persistence and efficacy. Interleukin-12 (IL-12) is a potent inflammatory cytokine that recruits and activates various endogenous and adoptively transferred immune cells, but development of its clinical applications is hindered by toxicity of systemic IL-12 signaling. In this study, we engineered and expressed membrane-bound IL-12 (mbIL12) in CAR T cells to overcome current limitations in CAR T cell and IL-12 therapies.

We evaluated CAR T cell function using co-culture assays and preclinical murine models bearing human tumor xenografts. We modeled systemic metastasis of ovarian and breast cancer and assessed the impact of mbIL12 in CAR T cells on targeting regional and systemic diseases. Syngeneic mouse models were used to evaluate toxicity induced by mbIL12 in CAR T cells.

We observed a greater number of CAR T cells in the peripheral blood of mice receiving locoregionally delivered CAR T cells engineered with mbIL12, suggesting that mbIL12 improves CAR T cell trafficking and persistence. Furthermore, mice bearing regional and systemic diseases experienced more potent and durable anti-tumor activity when treated with mbIL12 endowed CAR T cells. These results were mirrored in vitro where mbIL12 improved CAR T cells activation, proliferation and IFNg secretion when co-cultured with tumor cells, recapitulating our findings in vivo. Toxicities observed in immune-competent mice receiving systemic IL-12 delivery were not detected in those administered CAR T cells with mbIL12. We demonstrated that mbIL12 enhances anti-tumor function of CAR T cells for treatment of solid tumors. This study also showed that mbIL12 is safe,

providing a translatable engineering strategy to improve CAR T cell therapy. IL-12 signaling is well known to modulate function of various immune cells, but the impact of CAR T cells with mbIL12 on immune tumor microenvironments remains to be elucidated. We are currently investigating changes in the immune landscape that CAR T cells with mbIL12 induce.

#4091

Engineered hypoimmune CAR T cells provide lasting tumor control in immunocompetent allogeneic humanized mice even with re-challenge

Xiaomeng Hu, Pascal Beauchesne, Karl Manner, Corie Gattis, Priscilla Ngo, Rowena De Jesus, Ramya Ankala, Chi Young, Frank Wells, Lindong Weng, Kathy White, William E. Dowdle, Aaron Foster, Terry J. Fry, Sonja Schrepfer. *Sana Biotechnology, South San Francisco, CA*

Off-the-shelf CAR T cells potentially offer advantages over autologous strategies such as ease of manufacturing, quality control, off-the-shelf availability, and lack of T cell dysfunction, as well as the ability to generate a more consistent CAR T product from healthy T cells. However, the vigorous host-versus-graft immune response against histoincompatible T cells prevents expansion and persistence of allogeneic CAR T cells and mitigates the efficacy of this approach. A major challenge is that, while HLA deletion can result in adaptive immune evasion, innate reactivity is enhanced with this approach. CD47 overexpression can block both NK cell and macrophage killing (J Exp Med 2021;218(3):e20200839), and we hypothesized that T cells would lose their immunogenicity when human leukocyte antigen (HLA) class I and II genes are disrupted and CD47 is over-expressed. We describe here the engineering of human immune evasive CAR T cells building on our previously described hypoimmune technology (Nat Biotechnol 2019;37(3):252-258 and Proc Natl Acad Sci U S A 2021;118(28):e2022091118).Human T cells from healthy donors were obtained by leukapheresis. CRISPR/Cas12b technology was used to disrupt the B2M, CIITA, and TCR genes, and lentiviral transduction was used to overexpress CD47 and to express a CD19 CAR to generate hypoimmune (HIP) CD19 CAR T cells. Control T cells were unmanipulated except for overexpression of the CD19 CAR (unmodified).For 3 months persistence studies, allogeneic SGM3 humanized mice were injected with 1×10^6 Luc^+

Nalm6 cells and received 7×10^6 control CD19 CAR T cells or HIP CD19 CAR T cells.In the mice treated with either unmodified CD19 CAR T cells and HIP CD19 CAR T cells, tumor control was initially rapidly achieved. However, unmodified CD19 CAR T cells were eventually rejected by the host and the loss of these cells resulted in re-growth of tumor. By contrast, in HIP CD19 CAR T injected mice, tumor control was maintained throughout the study, including following a rechallenge at day 83 with NALM6 cells without further administration of HIP CD19 CAR T cell. Flow cytometry at endpoint from bone marrow and spleen confirmed persistence of HIP CD19 CAR T cells.These findings show that HIP CD19 CAR T cells are immune evasive in allogeneic recipients and data suggest that HIP CD19 CAR T cells are able to persist and maintain efficacy without immunosuppression.

Development of nucleotide metabolic reprogrammed CAR T cell therapy suitable for solid tumors

Yue Hu[1], Abhijit Sarkar[1], Kevin Song[1], Magnus Hook[1], Andras Heczey[2], Xiaotong Song[1]. *[1]Texas A&M University, Houston, TX,[2]Baylor College of Medicine, Houston, TX*

CAR T cell therapy has represented an exciting breakthrough in the treatment of patients with hematologic malignancies. In contrast, the antitumor activity of CAR T cell therapy in solid tumors has been modest so far in clinical studies. The suboptimal clinical efficacy is a result of multiple factors including limited T cell trafficking, persistence, and the immunosuppressive tumor microenvironment (TME). While current strategies utilize costimulatory molecules and cytokines to activate CAR T cells, a key but largely overlooked problem of CAR T cell therapy is nutrient competition between tumor cells and T cells in the nutrient-poor TME. In our previous studies, a metabolic screen identified inosine as an alternative fuel for T cells which can support T cell growth and function in the absence of glucose. T cells could metabolize inosine into hypoxanthine and phosphorylated ribose by purine nucleoside phosphorylase. Moreover, we demonstrated that T cells have advantage over cancer cells in utilizing inosine, and supplementation with inosine enhances the antitumor efficacy of PD-1 mAb and adoptive T cell transfer in mouse models. In this study,

we therefore engineered CAR T cells to express CD26 on the cell surface and a secreted adenosine deaminase (ADA) fused with an anchor. These metabolic reprogrammed CAR (designated as $_{MR}$CAR) T cells exerts their activities through different mechanisms. ADA irreversibly converts adenosine to inosine, overcoming adenosine-mediated immunosuppression and providing inosine for CAR T cell growth, while CD26 induces a rich chemokine receptor profile enabling CAR T cells to traffic to solid tumors. We demonstrated that CD26-overexpressed CAR T cells displayed superior migration capacity and resisted TGF-beta suppression, while the CD26 expression on unmodified CAR T cells was significantly down-regulated by TGF-beta. We further proved that ADA is conditionally secreted in stress condition (i.e., low pH, lack of nutrient and oxygen) based on ADA's biological characteristics, suggesting that ADA activates CAR T cells as a trans-signaling to the CAR construct in a tumor specific manner. Remarkably, we observed that the $_{MR}$CAR T cells inhibit tumor growth more effectively than unmodified CAR T cells in both Huh7 human hepatocellular carcinoma (GPC3-$_{MR}$CAR) and A549 human non-small cell lung cancer (HER2-$_{MR}$CAR) mouse models. Thus, MR-CAR T cell therapy represents a promising approach to improve CAR T cell therapy against solid tumors.

#4093

Dual targeted CAR immunotherapy for neuroblastoma using γδ T cells

Hunter C. Jonus, Jasmine Y. Lee, Jordan A. Silva, H. Trent Spencer, Kelly C. Goldsmith. *Emory University, Atlanta, GA*

Cellular immunotherapy for aggressive pediatric solid tumors like neuroblastoma (NB) has focused on autologous products of αβ T cells, that so far, have been uniformly unsuccessful. γδ T cells offer a potentially superior, off-the-shelf therapy that is directly cytotoxic towards tumors without alloreactivity. Furthermore, γδ T cell infiltration of the hostile, solid tumor microenvironment is a prognostic marker of favorable disease outcome. Our team recently opened a first-in-child evaluation of unengineered allogeneic γδ T cells in combination with dinutuximab, an anti-GD2 antibody, and chemotherapy (NCT05400603). Our focus now is to optimize a second-generation γδ T-cell therapy by engineering the

expression of tumor targeting chimeric antigen receptors (CAR). We hypothesize that CAR-targeting will further enhance γδ T-cell homing and antitumor potency. While anti-GD2 antibodies have been clinically successful immunotherapies for NB, GD2-targeted cell therapies need improvement. Our team recently validated a novel immunotherapy target for NB, protein tyrosine kinase 7 (PTK7), an inactive tyrosine kinase expressed highly amongst all NBs with low to no normal pediatric tissue expression.

We designed a dual-targeting platform directed against both GD2 *and* PTK7 using γδ T cells, where CARs are separately encoded and dually expressed. Previously optimized transgenes containing GD2 or PTK7 scFv targeting domains followed by a CD8 hinge region, CD28 co-stim/trans-membrane domain, and CD3ζ signalling domain were inserted under the T7 promoter for mRNA production. Purified mRNA was electroporated into γδ T cells following their thaw from cryopreservation. Electroporation titrations were performed to optimize CAR expression to be detected up to 72 hours post-modification, which is compatible with the approximate *in vivo* lifespan γδ T cells in mice. Simultaneous expression of both CARs appears highest 24 h after electroporation, with ~70% of the target γδ T cell population modified. Anti-GD2/PTK7 γδ T cells are potent against the NB cell line IMR5 (GD2+PTK7+) in a 4 h cytotoxicity assay at effector:target ratios as low as 0.5:1. Importantly, specificity is also shown against NB cell lines genetically engineered to represent the clinical heterogeneity of GD2 and PTK7 expression that may be observed, where the dual CAR therapy is effective against $GD2^{+}PTK7^{+}$, $GD2^{+}PTK7^{-}$, and $GD2^{-}PTK7^{+}$, but not $GD2^{-}PTK7^{-}$ NBs.

In conclusion, we developed a dual CAR-based cellular therapy for NB using γδ T cells as an effector population in place of classical αβ T cells. Early studies demonstrate feasibility for innovative dual CAR expression and show promise for strong anti-NB potency. Future work will optimize CAR signaling domains for maximal efficacy in solid tumors, as well as confirm efficacy and safety *in vivo* with results rapidly translatable into our established γδ T cell clinical trial pipeline.

Enhanced CRISPR-Cas9 edited CAR-T cells through simultaneous inactivation of multiple T cell exhaustion pathways

Oksana Sergeeva, Amber Fearnley, Shu Shien Chin, Xingyue An, Nana Adjoa Pels, Kristen Metzler, Kyla Joinville, Lizet Aquino Calderon, Abudukadier Abulizi, Hayden Karp, Julio Rodriguez, Louis Matis, Jay Fine, Jeremy Myers. *EvolveImmune Therapeutics, Inc, Branford, CT*

T cell exhaustion is a hallmark of tumor-infiltrating T cells and a major therapeutic challenge for immunotherapy which is not sufficiently understood. To identify T cell exhaustion promoting genes which may be targeted by new therapies, we combined highly efficient CRISPR/Cas9 gene knockouts in primary human T cells with functional assessment of effector function under exhaustion-inducing chronic T cell activation conditions. We conducted an initial CRISPR/Cas9 T cell exhaustion screen focused on previously identified genes reported as enhancers of anti-tumor T cell response in mouse tumor models, published exhaustion genes, and genes associated with CD8 T cell activation. Based on these results, we constructed gene networks from these screen hits and performed a secondary CRISPR-Cas9-based screen. We found that eight genes, when efficiently knocked out, limited T cell exhaustion, as measured by increased proliferation under chronic activation, reduced expression of T cell exhaustion markers, and improved tumor cell killing in CD3-bispecific antibody-mediated tumor/T cell co-culture assays. Prioritized T cell exhaustion gene hits were also evaluated in assays assessing anti-CD19 CAR-T cell function. The CRISPR-mediated ablation of five T cell exhaustion gene hits resulted in significantly more effective CD19-positive human tumor cell killing, compared to the non-targeting control CAR-T cells. These five genes included a transcriptional regulator, a member of a CD28-independent costimulatory pathway, and a series of ligand/receptor pairs that have been previously associated with T cell exhaustion and dysfunction. Interestingly, knockdown of combinations of the top three T cell exhaustion gene hits resulted in CAR-T cells that were more effective in tumor killing than any of the single gene knockouts, suggesting a non-redundant role for each gene, most likely comprising independent pathways. Furthermore, enhanced tumor cell killing was observed when each T cell exhaustion gene hit was ablated in combination with PDCD1 (PD-1) in double knockout CAR-T cells, suggesting that the T cell exhaustion pathways we identified were complementary to the PD1-PDL1 immune checkpoint pathway in regulating effector T cell function. By using

a multidimensional, functional CRISPR-Cas9-based T cell exhaustion screen, we have uncovered genes that are involved in T cell exhaustion. These gene knockouts can be universally applied individually or in combination to create CAR-T cells with more durable effector activity, with the potential to achieve superior patient outcomes in a variety of tumor indications.

Preclinical characterization of switchable allogeneic chimeric antigen receptor T cells to support first in human clinical study in CD123-positive hematologic and lymphatic malignancies

Armin Ehninger[1], Johannes Spehr[1], Simon Loff[1], Anika Langer[1], Julia Riewaldt[1], Julia Reinhardt[1], Jan-Erik Meyer[1], Josephine Dietrich[1], Gabriel Jurado[1], Reynald Lescarbeau[2], Marc Cartellieri[1]. *[1]AvenCell Europe GmbH, Dresden, Germany,[2]AvenCell Therapeutics, Inc., Cambridge, MA*

Approximately 80% of AML patients express CD123 on their leukemic blasts and CD123 is frequently expressed on other hematologic and lymphatic malignancies. Chimeric antigen receptor (CAR) T-cell therapy has demonstrated significant efficacy in B cell malignancies. Breakthrough of conventional CAR-T technology in AML has been hampered by expression of suitable target antigens on normal hematopoietic progenitor cells posing a risk for continued aplasia. Thus, innovative approaches putting the power of CAR-T technology under the control of reliable and fast-acting on/off switches to avoid and/or abrogate acute and long-term side effects are required. We have recently reported clinical proof-of-concept for autologous switchable CAR-T cell therapy in AML (Wermke et al. *Blood* 2021). However, manufacturing of autologous products is very costly and rrAML patients are often in urgent need for a product and multiple prior lines of treatment may be detrimental for product quality. While current clinical allogeneic approaches successfully prevent graft-versus-host disease, observed persistence has been limited due to rejection of the grafted T cells by host immune cells. Here, we report preclinical development of a donor-derived allogeneic switchable CAR-T therapy for CD123-positive hematologic and lymphatic malignancies (AVC-201). The reverse universal chimeric antigen receptor platform (RevCAR) is a 2-component CAR-T platform. The first component is a universal CAR-T

cell. Its binding domain is a short, non-immunogenic peptide that by itself does not recognize any human cell surface antigen but is specifically bound by an scFv included in the second component, a soluble adaptor called targeting module (TM). To target CD123, a TM with a short half-life was selected (R-TM123), enabling a rapid switch-off of the RevCAR system by TM withdrawal to avoid acute and long-term toxicity usually associated with continuous activation of CAR-T cells. The allogeneic cells are generated by three edits with CRISPR-Cas9, which is meant to fully overcome graft-versus-host disease as well as graft rejection by host T and NK cells. Therefore, we expect a persistent T cell product that can be re-expanded with additional TM cycles. A summary of preclinical characterization of AVC-201 will be presented at the meeting including *in vitro* and *in vivo* pharmacology and toxicology experiments. Activation of Allo-RevCAR-T cells is strictly dependent on the presence of CD123-positive target cells and R-TM123. Allo-RevCAR-T cells redirected by R-TM123 efficiently lyse CD123-positive AML cells *in vitro* and *in vivo,* and *in vitro* EC_{50} values are in the low picomolar range of R-TM123 concentrations. In conclusion, preclinical data support the clinical exploration of AVC-201 in a first in human study.

#4096

Assessing individual variability in efficacy and toxicity of autologous and allogeneic chimeric antigen receptor T-cell immunotherapy using a PBMC-humanized mouse model

Won Lee[1], Destanie Rose[1], Katelyn Burleigh[2], Blair Armstrong[2], Heather Gustafson[2], Rebecca Gardner[3], James G. Keck[1], Jiwon Yang[1]. *[1]Innovation & Product Development, The Jackson Laboratory, Sacramento, CA,[2]Ben Towne Center for Childhood Cancer Research, Seattle, WA,[3]Division of Hematology-Oncology, Seattle Children's Hospital, Seattle, WA*

Chimeric antigen receptor T-cell (CAR-T) therapy has emerged as a revolutionary therapeutic to fight cancer. However, side effects such as cytokine-release syndrome and neurotoxicity often accompany and remain unpredictable. While autologous CAR-Ts are FDA-approved, allogeneic CAR-Ts are in active development in pursuit of “off-the-shelf” availability and reduced manufacturing costs. However, the same concern for adverse events applies. Importantly, how the immune characteristics of the patient

may predispose towards toxicity is not well modeled. Further, it is unclear how autologous versus allogeneic products interact with the patient immune system. Toxicity does not correlate with in vitro characterization of the CAR-Ts, adding unpredictability to the toxicity and efficacy. These highlight the need for in vivo mouse models to explore biological variation, predictive biomarkers, and therapeutic intervention. Therefore, we developed a humanized mouse model using NSG™-MHC Class I/II double knock-out (DKO) mice engrafted with human PBMCs to access individual variability in CAR-T-induced toxicity and efficacy. DKO mice are optimal for assessing human cytokine induction from CAR-Ts as they show delayed onset of GvHD and low baseline cytokine levels. To test donor variation in autologous CAR-T toxicity, we humanized mice and treated with autologous CD19 CAR-Ts containing the CD28 costimulatory domain and CD3z chain from two human PBMC donors (Donor A and B). CAR-T successfully eliminated human B cells from both PBMC donors in vivo. We observed drastic body weight loss and 83% of Donor A mice (engrafted with 17M PBMCs) reached the humane endpoint. In contrast, Donor B mice did not experience body weight loss. CAR-T induced human cytokines such as IFN-γ, IL-2, IL-4, IL-6, IL-10, TNFα, MIG, MIP-1a, and IP-10, recapturing clinical data. To test donor variation in allogeneic CAR-T toxicity, we engrafted mice with 10M PBMCs from 6 healthy donors and treated with allogeneic CAR-Ts from Donor A or B. Allogenic efficacy was greater in Donor B CAR- than Donor A CAR-Ts. Donor-specific variability was observed; mice humanized with one of the six donors, experienced significant body weight loss only from the Donor B CAR-Ts but not from Donor A CAR-Ts. Principal component analysis of cytokine data revealed that Donor B CAR-Ts induced more distinguished cytokine responses than Donor A CAR-Ts, driven by IFN-γ and IL-10. Lastly, the data indicates that the CAR-T cells show poor expansion in allogeneic treatment, corresponding to the current literature. PBMC-humanized mice provide an in vivo platform to assess the toxicity and efficacy of autologous and allogeneic CAR-T treatment. This platform can be used to preclinically assess cytokine induction from the interaction between the patient immune system and allogeneic CAR-Ts from healthy donors.

Functional and translatable efficacy of CAR-T cells targeting B cell lymphomas

Lauren Kelsey[1], Karin Latta[2], Joey Kolb[2], Bincy John[2], Ilona Aylott[1], Daniel Rocca[1], Alexandru Bacita[1], Christopher Kirkham[1], Patrick Walters[1], Charlotte Humphery[1], Lorena Sueiro Ballesteros[1], Jezrom Self-Fordham[1], Louise Brackenbury[1], Chassidy Hall[2], Harris David[2], Julia Schueler[3], Robert Nunan[1]. *[1]Charles River Laboratories, Inc., Bristol, United Kingdom,[2]Charles River Laboratories, Inc., Morrisville, NC,[3]Charles River Laboratories, Inc., Freiburg, Germany*

Chimeric Antigen Receptor (CAR)-T cell therapy has achieved great success in treating a variety of liquid tumors, in particular CD19+ lymphomas. CAR technology is advancing rapidly, with notable improvements in efficacy, safety and complexity as human ingenuity seeks solid tumor applicability. Here we describe how to efficiently generate, expand and validate *in-vitro* and *in-vivo* efficacy of a clinically tested CD19-specific CAR. HLA-A*02:01+ CD3+ T-cells were transduced to express a CD19-CAR to >80% efficiency (in 5 donors) and reproducibly expanded to >68 fold over a 19 day period. *In-vitro* studies were used to assess tumor killing ability, utilizing a HLA-A*02:01+ patient derived xenograft (PDX) CD19+ cell line, alongside human cancer cell lines RAJI (CD19+) and K562 (CD19-). Analysis revealed the potent ability of CD19-CAR-T cells to specifically target CD19+ cells in a dose dependent manner. Supernatant analysis showed highly elevated IFNγ concentrations, identifying enhanced activation of CAR-T cells in the presence of CD19+ target cells only. *In-vivo* survival studies were completed to identify translatability & efficacy in both systems. Mice were inoculated with CD19+ cells to produce multiple tumor burdened models (RAJI, JEKO-1 & PDX4009). This demonstrated high efficacy of CAR-T at targeting both tumor cell line RAJI or PDX *in vivo*, with almost complete tumor regression seen in both models. JEKO-1 tumors saw progression slowed in comparison to non-transduced or no treatment controls however due to the nature of this cell line (highly tumorigenic) the level of tumor regression was not matched to the other models. Cell bio-distribution was assessed with CAR-T cells tracking successfully to the tumors as well as the highly vascularized tissues, which was expected and consistent with previous data. These assays can be translated to any CAR construct aimed at targeting

either solid or hematological tumors and demonstrates an integrated platform for translating CAR research that can be utilized end to end.

Chimeric antigen receptor (CAR) T cells overexpressing Bcl-xL increase proliferation and antitumor activity alone and in combination with BH3 mimetics

Felix Korell[1], Michael Olson[2], Diego Salas-Benito[1], Mark B. Leick[1], Rebecca C. Larson[1], Harrison Silva[1], Alessandro Gasparetto[1], Trisha R. Berger[1], Amanda Bouffard[1], Michael C. Kann[1], Markus Mergen[1], Tamina Kienka[1], Marc Wehrli[1], Stefanie R. Bailey[1], Anthony Letai[2], Marcela V. Maus[1]. *[1]Cellular Immunotherapy Program, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background**:** Chimeric antigen receptor (CAR) T cells have become a well-established treatment option for patients, with six products approved for different hematologic diseases and new approvals allowing for their therapeutic use as early as second line. However, relapse rates of around 50% have been observed in all patient subsets, with one major mechanism associated with CAR T failure being cancer cell resistance to apoptosis. A form of cancer therapeutic named BH3-mimetics has been designed to inhibit members of the anti-apoptotic B cell lymphoma-2 (Bcl-2) family and, therefore, directly activate the apoptotic machinery in malignant cells. We hypothesized that integration of these anti-apoptotic molecules into CAR T cells would induce resistance towards the BH3 mimetics and allow combinational therapeutic approaches.

Methods: 4-1BB and CD28 CAR constructs were designed to overexpress one of four anti-apoptotic proteins: wildtype Bcl-2, a Venetoclax-resistant Bcl-2 variant (G101V), B cell extra-large (Bcl-xL), or myeloid cell leukemia-1 (Mcl-1). CAR T cells made from these constructs were tested against leukemia (Nalm6) and lymphoma (JeKo-1) cell lines in combination with three different BH-3 mimetics: Venetoclax (ABT-199, an FDA-approved Bcl-2 inhibitor), Navitoclax (ABT-263, a Bcl-2/Bcl-xL inhibitor), and AZD5991 (an Mcl-1 inhibitor).

Results: CAR T cells with a 4-1BB costimulatory domain tended to have increased killing over CARs with CD28 and were less susceptible to

apoptosis; therefore, 4-1BB CARs were used for all further testing. Integration of Bcl-2 family proteins into CAR T cells didn't impair or even increase tumor cell clearance *in vitro*; however, in combination with Venetoclax, Navitoclax, or AZD5991, killing capacity significantly increased compared to control CAR T cells. Even without combination with drugs, CAR T cells overexpressing Bcl-xL and Bcl-2 (both wildtype and mutant) provided higher anti-tumor activity and prolonged survival against JeKo-1 cells *in vivo*, whereas only Bcl-xL overexpression showed increased tumor control compared to regular 4-1BB CARs against Nalm6 cells. **Conclusion:** Of the tested antiapoptotic proteins, Bcl-xL overexpressing CAR T cells proved superior, having higher proliferation and increased anti-tumor activity in combination with or without BH3 mimetics, providing a new strategy to optimize CAR T cell function for the treatment of leukemia and lymphoma.

Dual targeting of tumor cells and cancer associated fibroblasts enhances CAR T efficacy in solid tumors

Bo Huang[1], Suilan Zheng[1], Haiyan Chu[2], Ramesh Mukkamala[1], Suresh K. Bowroju[1], Yashapal Singh[1], Sudarsan R. Kasireddy[1], Md Sazzadul Bari[1], Madduri Srinivasarao[1], Laurie Beitz[2], Byoung Ryu[2], Michael Jensen[3], Andrew M. Scharenberg[2], Philip S. Low[1]. *[1]Purdue University, West Lafayette, IN,[2]Umoja Biopharma, Seattle, WA,[3]Seattle Children's Hospital, Seattle, WA*

CAR T cell therapies have demonstrated considerable potency in treating hematologic cancers, but only limited efficacy in eliminating solid tumors. One reason for this discrepancy may derive from the immunologic and physical barriers created by infiltration of cancer associated fibroblasts (CAFs) into solid tumors. These CAFs, which can comprise 15-85% of the stromal cells in a tumor mass, are correlated with poor patient survival and can reduce CAR T cell efficacies by secreting immunosuppressive cytokines, stimulating tumor cell proliferation, and depositing fibrotic barriers to CAR T cell penetration. Here, we are pursuing a method to suppress or eliminate CAF activities in the tumor microenvironment (TME).

A potential CAR T cell target that is uniquely expressed on CAF surfaces is fibroblast activation protein (FAP). In this study, we have employed a novel, highly specific FAP targeting small molecule to direct our universal CAR T cells to CAFs. For this purpose, we have designed a CAR that contains an otherwise classical CAR except the extracellular scFv specifically binds fluorescein. Upon addition of a bispecific adaptor comprised of fluorescein linked via a short spacer to our FAP ligand, a bridge is formed between the anti-fluorescein CAR on the T cell and FAP on the CAF, resulting in formation of an immunologic synapse between the CAR T cell and CAF that triggers CAF destruction and CAR T cell proliferation. Importantly, this CAR T cell design also permits simultaneous administration of a second bispecific adaptor (i.e. fluorescein linked via a short spacer to a cancer-specific ligand) that can enable the same CAR T cell to concurrently kill adjacent cancer cells.
To test whether this universal CAR T cell can eliminate both cancer cells and CAFs, we have implanted KB cells (i.e. a cell line that creates an immunologically “cold” folate receptor (FR) expressing solid tumor) into NSG mice and quantitated the CAR T cell’s toxicity in the presence of one or both bispecific adapters. While administration of the universal CAR T cells followed by intravenous injection of an FR-targeting bispecific adaptor achieved significant anti-tumor efficacy, co-injection of a FAP-targeted bispecific adaptor enhanced this efficacy without apparent toxicity. Analyses of tumor masses from the therapy further revealed that co-administration of the FAP-targeted bispecific adaptor not only promoted CAF elimination but also enhanced CAR T infiltration and activation. Importantly, a similar improvement in anti-tumor efficacy could be readily demonstrated in a second immunologically “cold” PSMA-expressing solid tumor model. Taken together, we conclude that the bispecific adaptor/universal CAR T approach offers a unique opportunity to concurrently eradicate cancer cells and tumor-supporting CAFs in a manner that can improve the overall performance of the CAR T cells in solid tumors.

Co-stimulatory signaling boosts CAR T cell efficacy against chronic lymphocytic leukemia

Ziran Zhao[1], McKensie Collins[2], Clare Sun[3], Adrian Wiestner[3], J. Joseph Melenhorst[1]. *[1]Center for ImmunoTherapy & PrecisionImmuno-Oncology, Lerner Research Institute, Cleveland Clinic, Cleveland, OH,[2]Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA,[3]Hematology Branch, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD*

Chimeric antigen receptor (CAR) T cell therapy has been promising in chronic lymphocytic leukemia (CLL) treatment showing durable remission. However, only a third of CLL patients can achieve complete remission with persistent effect featured by early memory T cells. This disparity is attributed to T cell-intrinsic defects or tumor-mediated immunosuppression. The mechanism how CLL cells impact CAR T cell potency still remains poorly understood. Here we used second-generation CD19- and ROR1-directed CAR T cells with a 4-1BB intracellular signaling domain. To recapitulate CLL-derived T cell defects, we developed an *in vitro* model of chronic antigen stimulation using CAR T cells recursively exposed to primary CLL cells. Upon each round of CLL stimulation, both types of CAR T cells were lack of proliferation and differentiation, accompanied with cytokine production failure in IL-2, suggesting hypofunction of CAR T cell induced by CLL. We next found that this lack of CAR T cell response is not permanent but can be rescued by strong antigen stimulus or IL-2 administration. On the other hand, IL-2 affects phenotype of CLL cells by enhancing expression of co-stimulatory molecules CD80 and CD86, suggesting that IL-2 supplementation or auxiliary co-stimulation via CD80/CD86 can rescue CAR T cell reactivity against these tumor cells. To test this hypothesis, we employed the immunomodulatory drugs (IMiDs) lenalidomide and pomalidomide that have previously been demonstrated to upregulate co-stimulatory molecules on CLL and restore T-cell function via IL-2 upregulation. We sought to test if IMiDs can improve CAR T cell response to CLL. CAR T cells repeatedly exposed to primary CLL cells were co-treated with IMiDs at each round, showing significantly increased proliferation compared to the group without drug treatment. Furthermore, IMiDs can enhance the functions of these CLL stimulated CAR T cells, including differentiation (higher frequency of effector memory T cells), activation (HLA-DR, CTLA-4), proliferation (Ki67), and effector function (Granzyme B). In addition, IMiDs can increase cytotoxic efficacy of CD8+

CAR19 T cells on CLL cells. Overall, our study unveiled that in CLL, activation defect of 4-1BB, CD3-signaling anti-CD19 CAR T cells was attributable to low levels of co-stimulatory molecules on CLL cells and can be effectively overcome via upregulation of co-stimulation. Our data suggested that CLL resistance to CAR T cell can be successfully rescued by concurrent treatment with IMiDs. This study provides a potential translational approach to overcome the bottleneck of CLL treatment by CAR T cells.

Control of orthotopic melanoma and breast tumor growth and metastases is achieved by alpha$_v$ beta$_3$ CAR T cells and is augmented via PD-1 blockade

Dustin A. Cobb, Philip Mollica, Lixia Liu, Barbara Dziegielewska, Daniel W. Lee. *Pediatrics, University of Virginia, Charlottesville, VA*

Purpose: The purpose of this study was to determine the efficacy of $\alpha_v\beta_3$ CAR T cells deployed against melanoma and triple-negative breast cancer tumors, two malignancies recognized for harnessing the $\alpha_v\beta_3$ pathway for angiogenic and invasion purposes.

Procedures: CAR T cells expressing an anti-$\alpha_v\beta_3$ scFv containing either a CD28 or 4-1BB co-stimulatory domain and CD3zeta were generated by retroviral transduction. *In vitro* cytotoxicity of $\alpha_v\beta_3$ CAR T cells was assessed by co-culture with melanoma or breast tumor cells and evaluated by impedance-based real-time cell analysis and effector cytokine production by ELISA. Xenograft studies, including melanoma and orthotopic breast tumors, were carried out in NSG mice to evaluate *in vivo* efficacy of systemically administered $\alpha_v\beta_3$ CAR T cells. Immunohistochemistry was performed to evaluate T cell infiltration of tumors and changes in the microenvironment. NSG mice implanted with orthotopic tumors were monitored for disease progression and development of metastases using bioluminescent imaging.

Results: $\alpha_v\beta_3$ CAR T cells exert rapid cytotoxicity and prominent cytokine production against all melanoma and triple-negative breast tumor lines tested. Systemic administration of $\alpha_v\beta_3$ CAR T cells potently inhibited growth of SK-MEL-28 melanoma xenografts as demonstrated by

significant differences in tumor volume relative to control CARs. In orthotopic MD-AMB-231 breast tumors, $\alpha_v\beta_3$ CAR T cells were able to control tumor growth, prevent the formation of spontaneous lung metastases from the primary tumor, and resulted in improved survival. $\alpha_v\beta_3$ CAR T cells also mediated control and clearance of established lung metastases established via intravenous injection of breast tumor cells. Histological analysis of tumors at endpoint revealed striking infiltration of residual tumors by T cells in mice administered $\alpha_v\beta_3$.28z CARs, but to a lesser extent in $\alpha_v\beta_3$.BBz CAR-treated xenografts. Infiltration was accompanied by tumors up-regulating PD-L1 expression in response to treatment. Coadministration of $\alpha_v\beta_3$ CAR T cells with anti-PD-1 treatment led to augmentation of the therapeutic response against melanoma tumors. **Conclusions:** These studies highlight a renewed potential for targeting integrins, specifically $\alpha_v\beta_3$, for the treatment of solid tumors. These data suggest that $\alpha_v\beta_3$ CAR T cell therapy for melanoma can be further improved by combination therapy with checkpoint inhibition. Together with our prior work demonstrating robust efficacy of $\alpha_v\beta_3$ CAR T cells to treat orthotopic glioblastoma and DIPG, these results highlight the broad applicability of utilizing CAR T cells targeting $\alpha_v\beta_3$ for treatment of multiple cancer types with reduced risk of on-target, off-tumor toxicity due to the restricted expression of $\alpha_v\beta_3$ in normal tissues. Results of these studies warrant further development of $\alpha_v\beta_3$ CAR T cells for clinical use.

attIL12-T cell therapy destructs cancer-associated fibroblasts and extracellular matrix in heterogenous osteosarcoma xenograft models

Jiemiao Hu, Alexander Lazar, Davis Ingram, Wei-Lien Wang, Wendong Zhang, Zhiliang Jia, Dristhi Ragoonanan, Jian Wang, Xueqing Xia, Kris Mahadeo, Richard Gorlick, Shulin Li. *UT MD Anderson Cancer Center, Houston, TX*

The extracellular matrix (ECM) and cancer-associated fibroblasts (CAFs) play major roles in tumor progression, metastasis, and the poor response of many solid tumors to immunotherapy. CAF-targeted CAR-T cell therapy does not impair ECM components such as collagen. In this study, we

investigated whether the recently invented attIL12-T cells could destroy CAFs to disrupt the ECM and uncovered the underlying mechanism by which attIL12-T cells penetrate stroma-enriched osteosarcoma tumors. RNA sequencing demonstrated that attIL12-T cell treatment altered ECM-related gene expression. Immunohistochemistry staining revealed disruption or elimination of high-density CAFs and ECM in osteosarcoma xenograft tumors following attIL12-T cell treatment and that CAF/ECM density was inversely correlated with T-cell infiltration. Other IL12-armed T cells, such as wild-type IL12-T or ttIL12-T cells, did not disrupt the ECM because this effect depended on the engagement between cell-surface vimentin (CSV) on the tumor cell surface and its ligand on the attIL12 -T cells. Mechanistic studies found that attIL12-T cell treatment elevated IFNγ production upon interacting with CSV^+ tumor cells to suppress TGFβ secretion and in turn upregulate FAS-mediated CAF apoptosis. CAF destruction reshaped the tumor stroma to favor T cell infiltration and tumor destruction. Thus, this study unveiled a novel therapy—attIL12-T cells—for targeting CAFs/ECM. These findings are highly relevant to humans because CAFs are abundant in human osteosarcoma.

The IgG4 hinge with CD28 transmembrane domain improves V_HH-based CAR T cells targeting a membrane-distal epitope of GPC1 in pancreatic cancer

Nan Li[1], Alex Quan[1], Dan Li[1], Hua Ren[1], Weiming Ni[2], Jing Zhou[2], Raul Cachau[1], Mitchell Ho[1]. *[1]National Insts. of Health, Bethesda, MD,[2]Isoplexis, Branford, CT*

Heterogeneous antigen expression is a key barrier influencing the activity of chimeric antigen receptor (CAR) T cells in solid tumors. Here, we developed CAR T cells targeting glypican-1 (GPC1), an oncofetal antigen expressed in pancreatic cancer. We report the generation of dromedary camel V_HH nanobody (D4) based-CAR T cells targeting GPC1 and the optimization of the hinge (H) and transmembrane domain (TM) to improve activity. We found that a structurally rigid IgG4H and CD28TM domain making the two D4 fragments in proximity drove CAR dimerization, which led to enhanced T cell signaling and tumor regression in orthotopic

pancreatic cancer models with low antigen density. Furthermore, single-cell-based proteomic and transcriptomic analysis of D4-IgG4H-CD28TM CAR-T cells revealed specific genes (e.g., *ID1*) associated with high T cell polyfunctionality. This study demonstrates the potential of V_HH-based CAR-T for pancreatic cancer therapy and provides an engineering strategy for developing potent CAR T cells targeting membrane-distal epitopes.

#4104

Development of adoptive T-cell therapies to target heterogeneity of mCRPC

Lupita S. Lopez[1], Nathanael Bangayan[2], Owen Witte[2], Saul J. Priceman[1].
[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]University of California, Los Angeles, Los Angeles, CA

Metastatic castration resistant prostate cancer (mCRPC) remains a significant challenge with limited durable therapeutic responses, and innovative and effective treatment strategies are needed. Advanced mCRPC often comprises a heterogeneous population of prostate adenocarcinoma (PrAd) and neuroendocrine prostate cancer (NEPC), and current targeted therapies often result in transient anti-tumor responses. Chimeric antigen receptor (CAR) T-cell therapies are being actively investigated to target mCRPC, including CARs targeting antigens that are overexpressed in PrAd. Our group has developed a CAR T cell targeting the PrAd antigen, prostate stem cell antigen (PSCA), and have an ongoing phase 1 trial at City of Hope in patients with mCRPC. However, we anticipate that targeting NEPC in addition to PrAd will be required to achieve durable anti-tumor responses in patients. Here, we have developed novel dual-targeting approaches for the simultaneous treatment of both PrAd and NEPC. Our first approach optimizes a tandem CAR T-cell approach capable of targeting distinct antigens found on both PrAd and NEPC. Additionally, we are actively developing combinations of PSCA-CAR T-cells with secretable T-cell bispecific antibodies to target NEPC antigens. Our studies encompass the *in vitro* and *in vivo* safety and efficacy of CAR T-cells engineered to co-target PrAd and NEPC for the treatment of heterogeneous mCRPC.

#4105

Improvement of CD133-specific chimeric antigen receptor T cells by secreting anti-PD-L1 single-chain variable fragment against cholangiocarcinoma

Thanich Sangsuwannukul, Kamonlapat Supimon, Thaweesak Chieochansin, Kornkan Choomee, Jatuporn Sujjitjoon, Mutita Junking, Pathai Yenchitsomanus. *Division of Molecular Medicine, Research Department, Siriraj Center of Research Excellence for Cancer Immunotherapy (SiCORE-CIT), Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand*

Cholangiocarcinoma (CCA) is rare but hard-to-treat solid cancer affecting people worldwide. Cancer stem cells (CSCs) in CCA contribute to tumor heterogeneity and resistance to conventional therapies. Thus, CSCs are notable targets for cancer immunotherapy. CD133 is a potential CSC surface marker overexpressed in various cancers. T cell-based immunotherapy, namely chimeric antigen receptor (CAR) T-cell targeting CD133 has shown potential in eradication of some solid tumors including CCA. Nevertheless, anti-tumor function of CAR T cell could be decreased under immunosuppressive tumor microenvironment (TME). Thus, to improve its function under TME, the next-generation of CD133-specific CAR T-cell is required. We therefore constructed two lentiviral vectors containing: (i) anti-CD133 single-chain variable fragment (scFv), 4-1BB costimulatory molecule, and CD3ζ (133CAR), and (ii) anti-CD133 scFv, 4-1BB, and CD3ζ in tandem with anti-PD-L1 scFv (133CARsL). The lentiviruses were transduced to generate CD133-specific CAR T cells expressing the second-generation (133CART) or anti-CD133 CAR with self-secreting anti-PD-L1 scFv (133CARTsL). The latter was able to simultaneously target CD133 and PD-L1 molecules on CCA cells. CCA cells endogenously expressing CD133 and PD-L1 were cocultured with either 133CART or 133CARTsL. In short-term coculture, the antitumor effects of 133CARTsL were not different from that of 133CART. However, in long-term coculture and after tumor re-challenge, 133CARTsL showed lower expression of programmed cell death protein (PD-1) and better cytotoxic function against high CD133 and PD-L1 CCA cells. The higher potential of 133CARTsL with reduced exhaustion profile would offer great promise for application of CD133-targeting CAR T cells in solid tumors.

Non-autonomous enhancement of gPDL1 CAR-T annihilates TNBC development

Chia-Wei Li[1], Shih-Han Wang[1], Yun-Ju Lai[2], Jyun Wang[3], Chun-Tse Kuo[1], Shih-Duo Hsu Hung[1], Shou-Hou Liu[1]. *[1]Academia Sinica - Institute of Biomedical Sciences (IBMS), Taipei, Taiwan,[2]Solomont School of Nursing,, University of Massachusetts Lowell, Lowell, MA,[3]Topmunnity Therapeutics, Taipei, Taiwan*

Triple-negative breast cancer (TNBC) is the most aggressive and challenging breast cancer subtype, which does not respond to traditional endocrine and anti-HER2-targeted therapies. PD-L1 is highly enriched in TNBC and has been considered a therapeutic target. Despite the excellent anti-cancer activity, the atezolizumab-based chimeric antigen receptor (CAR) T cells showed a robust off-target effect. In addition, the treatment of solid tumors with CAR-T is limited by abnormal glycosylation in malignant tumors. Targeting glycosylated PD-L1 (gPD-L1) provided tissue specificity against TNBC, implying it can prevent antigen escape and off-target effect. In this study, we generated gPD-L1 CAR-T cells using lentiviral vectors expressing the scFv regions of the anti-gPD-L1 antibody. The gPD-L1 CAR-T cells exhibited antigen-specific activation, cytokine production, and cytolytic activity against TNBCs *in vitro* and in the xenograft tumors model. CyTOF and single-cell RNA sequencing (scRNA-seq) showed distinct IFNγ-positive cell types. Mechanistically, IFNγ crosstalked with EGFR signaling through Src activation and, in turn, triggered B3GNT3-mediated PD-L1 glycosylation. Inhibition of Src resulted in reduced gPD-L1 expression in TNBC. CRISPR/Cas9 knockout of B3GNT3 in TNBC cells impaired gPD-L1 CAR-T response. As a result of nonautonomous gPDL1 amplification in TNBCs, gPD-L1 CAR-T cells continued to annihilate TNBCs. Additionally, since gPD-L1 CAR-T cells provided higher specificity on TNBC, they had lower normal tissue toxicity. Overall, gPD-L1 CAR-T exhibits excellent anti-tumor activity against TNBCs, and it could be a promising immunotherapy tool to treat TNBCs in clinic. Furthermore, targeting glycosylation moiety on the tumor antigen is a novel approach to lessen CAR-T toxicity in patients.

Cytotoxic T cells armed with IL-4 receptor-targeting and PD-L1-blocking peptides inhibits lung tumor growth

Dong Gyun Jo, Gunassekaran Gowri Rangaswamy, Poongkavithai Vadevoo Sri Murugan, Byungheon Lee. *Kyungpook National Univ. School of Med, Daegu, Korea, Republic of*

Tumor homing of adoptively transferred cytotoxic T cells (CTLs) to solid tumors is still inefficient. In addition, CTLs that arrive at tumor tissues meet the immune-suppressive tumor microenvironment. To reduce these limitations in adoptive T-cell therapy against solid tumors, we here exploited CTLs dual-labeled with IL-4 receptor (IL4R)-targeting peptide and programmed cell death-ligand 1 (PD-L1)-blocking peptide. IL4R is commonly upregulated in many solid tumors including lung tumor. PD-L1, an immune checkpoint, is frequently upregulated in tumor cells and contributes to the suppression of CTLs in the tumor microenvironment. CTLs were isolated from the splenocytes of LLC lung tumor-bearing mice and non-genetically labeled with IL4RPep-1, an IL4R-targeting peptide, and PD-L1Pep2, a PD-L1-blocking peptide, using a sulfhydryl-reactive cross linker. Compared to unlabeled CTLs, IL4R-targeted, PD-L1-blocking CTLs showed more robust cytokine secretion and tumor cell lysis during co-culture with LLC tumor cells. The CTLs armed with the dual-acting peptides exerted higher levels of tumor homing and anti-tumor growth activity in LLC lung tumor-bearing mice, which was accompanied by decrease of immune-suppressive cells in the tumor tissues. These results suggest that the IL4R-targeted, PD-L1-blocking CTLs can be a promising strategy in adoptive T-cell therapy against solid tumors.
Key words: Adoptive T-cell therapy, CTLs, IL-4 receptor, lung tumor, PD-L1

Transient epigenetic reprogramming enhances T-cell proliferation and tumor clearance

Alec McQuiston, Junbao Yang, Jason Romero, Naveen Bojjireddy, Travis McQuiston, Vittorio Sebastiano, Mustafa Turkoz. *Immunology, Turn Biotechnologies, Inc., Mountain View, CA*

Manufacturing-induced differentiation and accelerated T-cell exhaustion prevent CAR-T therapies from reaching their full therapeutic potential and broader application in the treatment of cancer. To combat these inherent

challenges, Turn Biotechnologies is developing its novel and proprietary mRNA-based technology, Epigenetic Reprogramming of Aging (ERA^{TM}), to i) preserve a less differentiated status; ii) diminish (or even eliminate) exhaustion; and iii) improve the cytotoxicity and efficacy of CAR-T cell cells. Prolonged CAR-T cell manufacturing process leads to a more differentiated and effector-like phenotype, which is susceptible to accelerated exhaustion *in vivo*. Unfortunately, clinical evidence suggests that less differentiated and stem-cell like CAR-T products have increased proliferative capacity, reduced exhaustion, and greater efficacy. Additionally, aging is known to compromise T-cell function, reducing chances of CAR-T therapy candidacy for older patients. These compounded effects of manufacturing and aging severely limit CAR-T cell functionality in terms of proliferation, perdurance, and cytotoxic capacity, as well as precluding wider patient access. Leveraging our previous work with other aged human cells, we hypothesized that the transient expression of ERA^{TM} factors could impact manufacturing of CAR-T cells by mitigating their differentiation, promoting T stem cell memory (Tscm) phenotype, reducing/eliminating exhaustion, and resetting the epigenetic clock in CAR-T cells. Here, we present preclinical data showing that ERA^{TM} treatment of T cells delivered using our proprietary eTurna^{TM} platform can restore youthful functionality, reducing exhaustion and effects of aging, improving their ability to fight cancer while safely maintaining cellular identity. ERA^{TM} -treated T cells have higher proliferation capacity and cytotoxicity upon tumor cell engagement *in vitro* compared to control cells. Treatment of ERA^{TM} -treated T-cells also increases the production of beneficial cytokines to support their survival and cytotoxic activity. Importantly, ERA^{TM} treatment preserves T-cell identity and T-cell repertoire, while avoiding unwanted hyperproliferation or clonal expansion. In murine models of hematological cancers, these effects of ERA^{TM} treatment on T-cells results in superior cancer cell killing and clearance. These benefits of ERA^{TM} technology to current CAR-T manufacturing processes have the potential to translate into the clinic as improved patient outcomes and survival with reduced side effects, thereby expanding patient access and enabling immunotherapies to serve as a first-in-line lifesaving solution.

Inhibition of CD47-SIRPα axis to enhance immunity against different molecular subtypes of breast cancer

Xingru Ma, Zachary Hartman, Li-Chung Tsao, Tao Wang, Cong-Xiao Liu, Xiao Yang, Gangjun Lei, Junping Wei. *Duke University, Durham, NC*

Background: The CD47-SIRPα axis is an innate immune checkpoint that primarily regulates myeloid cells. In the context of cancer, tumor cells upregulate CD47 to engage SIRPα inhibitory signaling to block phagocytosis. Thus, inhibition of this axis may enhance myeloid cell phagocytosis and adaptive immune responses against cancer. While our previous studies identified that CD47 mAbs enhance HER2-specific mAb therapy (Tsao et al., 2019), clinical trials have revealed that CD47-targeting mAbs are associated with severe side effects of anemia and thrombocytopenia in patients. We thus hypothesized that targeting SIRPα, which is more restrictively expressed on myeloid cells, may achieve similar but less toxic treatment effects.

Methods: To ascertain the impact of SIRPα inhibition against different molecular subtypes of breast cancer, we utilized and validated a novel SIRPα KO mouse, along with SIRPα mAbs in our previously utilized models of Triple-Negative Breast Cancer (TNBC) and HER2+ Breast Cancer (Crosby et al., 2018; Tsao et al., 2019). Using both in vitro and in vivo tumor models, we tested the therapeutic impact of SIRPα inhibition/blockade combined with immunogenic chemotherapy (doxorubicin) in TNBC or combined with HER2-specific mAbs in HER2+ Breast Cancer (HER2+ BC).

Results: After validating the loss of SIRPα in KO mice, we found that E0771 TNBC cells had reduced rates of engraftment in SIRPα KO mice compared to controls, but comparable rates of growth once tumors were established. We then treated E0771 engrafted SIRPα KO and wildtype mice with doxorubicin. This treatment elicited tumor rejection in the majority of SIRPα KO mice (70% of injected tumors), compared to only 10% rejection in SIRPα WT mice. To study tumor antigen-specific immunity, we expressed different forms of OVA (secreted, cytoplasmic, membrane) in tumor cells. We found that membrane expressed OVA led to universal tumor rejection (10/10 mice) with high levels of OVA-specific Abs, in

contrast to non-membrane expressed forms of OVA. This suggested the importance of tumor-specific Abs in eliciting tumor rejection. To specifically test the antitumor effect of tumor-specific antibodies in the context of SIRPα blockade, we evaluated the impact of a HER2 mAb (Trastuzumab) on HER2+ BC cells. We found enhanced phagocytosis and antitumor effects by SIRPα KO macrophages in comparison to wild-type macrophages, suggesting the potential of targeting SIRPα along with the use of standard-of-care mAb.
Conclusion: Our study demonstrates that SIRPα loss can prevent tumor engraftment but may not have a strong effect against established tumors without secondary immune stimulation. However, addition of immunogenic cell death-eliciting chemotherapy or tumor-specific Abs promote tumor phagocytosis and stimulate anti-tumor immunity. These results support further investigation of SIRPα-targeting combination therapies for cancer.

Nintedanib enhances antitumor effects of anti-PD-1 therapies through inhibition of immunosuppressive cells in tumor microenvironment

Ryo Suzuki[1], Satoshi Watanabe[1], Kunihiro Shono[1], Takaaki Masuda[1], Tomoki Sekiya[1], Yuka Goto[1], Toshiya Fujisaki[1], Masashi Arita[1], Aya Ohtsubo[1], Satoshi Shoji[1], Tomohiro Tanaka[1], Koichiro Nozaki[1], Rie Kondo[1], Yu Saida[1], Satoshi Hokari[1], Riuko Ohashi[2], Kenjiro Shima[1], Yosuke Kimura[1], Nobumasa Aoki[1], Yasuyoshi Ohshima[1], Toshiyuki Koya[1], Toshiaki Kikuchi[1]. *[1]Department of Respiratory Medicine and Infectious Diseases, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan,[2]Division of Molecular and Diagnostic Pathology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*

Background: Although programmed cell death-1 (PD-1) inhibitors have achieved promising and durable responses in patients with several types of cancer, many patients show intrinsic resistance to PD-1 inhibitors. Extensive studies have demonstrated that immunosuppressive cells are induced in tumor microenvironment and inhibit antitumor effects of PD-1 inhibitors. The aim of current study is to investigate whether nintedanib, which targets multi-tyrosine kinase including vascular endothelial growth

factor, fibroblast growth factor, and platelet-derived growth factor, reduced immunosuppressive cells in tumor microenvironment and augments antitumor effects of PD-1 inhibitors.
Method: Mice were inoculated subcutaneously with CT26 murine colon carcinoma or MC38 murine colon carcinoma and were treated with nintedanib (50 mg/kg), αPD-1mAbs (10 mg/kg) or nintedanib plus αPD-1mAbs. The tumor size was measured in 2 perpendicular dimensions 3 times per week. Types of cells infiltrating into tumors and immune status of tumor-draining lymph nodes were assessed using flow cytometry and immunohistochemistry (IHC).
Results: RNA sequencing data revealed that nintedanib decreased gene expression related to endothelial mesenchymal transition, angiogenesis and coagulation. Flow cytometry showed that nintedanib significantly decreased the percentage of myeloid-derived suppressor cells and cancer-associated fibroblast in tumor tissues. Both of flow cytometry and IHC analysis showed that nintedanib significantly increased IFN-$\Upsilon^{+}CD4^{+}$ and $CD8^{+}$ T cells infiltrating in tumors. In addition, nintedanib plus αPD-1mAbs significantly retarded tumor progression.
Conclusion: Nintedanib decreased immunosuppressive cells, increased effector T cells, and enhanced anti-tumor effects of αPD-1mAbs. Based on these findings, there are possibility that nintedanib improves clinical outcomes of cancer patients treated with PD-1 inhibitors.

Cancer immunotherapy based on the RNAi-based PD-L1 inhibitor, MN-siPDL1, demonstrates efficacy in preclinical pancreatic adenocarcinoma

Byunghee Yoo[1], Mozhdeh Sojoodi[1], Veronica Clavijo Jordan[2], Pamela Pantazopoulos[1], Subrata Ghosh[3], Peter Caravan[1], Zdravka Medarova[3].
[1]Harvard Medical School, Boston, MA,[2]Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Harvard Medical School, Lexington, MA,[3]TransCode Therapeutics Inc, Boston, MA

The recent past has seen impressive progress in the treatment of various malignancies using immunotherapy. One of the most promising approaches involves immune checkpoint inhibition, mainly relying on monoclonal antibodies or small molecules. With specific relevance to pancreatic cancer,

however, checkpoint inhibitors are largely ineffective, in part because of poor T cell infiltration, low tumor mutational burden, an immunosuppressive tumor microenvironment, and the presence of a dense desmoplastic stroma. To overcome these challenges, here we describe the preclinical testing of a new checkpoint inhibitor named MN-siPDL1 in combination with gemcitabine in an aggressive model of PDAC. MN-siPDL1 utilizes the RNA interference mechanism (siRNA) to block the synthesis of the critical immune checkpoint mediator, PD-L1 by tumor cells. The siRNA is delivered by a nanoparticle carrier (MN) that is optimized for oligonucleotide delivery to solid tumors. The efficacy and preliminary safety of MN-siPDL1 were tested in an orthotopic syngeneic model of pancreatic ductal adenocarcinoma generated by implanting Hy15549 murine PDAC cells into the pancreas of C57BL/6J mice. Our studies demonstrated that MN-siPDL1 was successfully delivered and effective even in the highly desmoplastic and hypovascular Hy15549 murine model of PDAC, which has been deemed nonresponsive to antibody-based immune checkpoint blockade. Anatomic MRI showed that in the animals treated with MN-siPDL1 plus gemcitabine, tumor growth rates were lower than in the vehicle control. After two weekly treatments with MN-siPDL1 plus gemcitabine, tumor volumes were four times smaller than in untreated animals. Importantly, animal survival was improved dramatically in animals treated with MN-siPDL1 plus gemcitabine compared to all other groups. Among the animals treated with MN-siPDL1 plus gemcitabine, the hazard ratio for overall survival (OS) relative to PBS was 0.08. Interestingly, even in the absence of gemcitabine, MN-siPDL1 as monotherapy improved survival more dramatically than gemcitabine (HR, 0.24 for MN-siPDL1 vs. 0.42 for gemcitabine). Immunohistology on the tumor tissues post-necropsy indicated that the treatment inhibited PD-L1 and induced a cytotoxic immune response. Finally, as an initial measurement of tissue damage due to the treatment, we analyzed major organs by histopathology and saw no differences from the vehicle-treated controls. Considering the aggressive and fibrous nature of the Hy15549 model and its resistance to traditional checkpoint inhibitors, the described RNAi-based therapeutic approach could be promising against PDAC and could make an impact on one of the most intractable cancers which has long evaded the power of modern medicine to deliver long-term survival.

#5070

Anti-tumor activity of HPN328, a DLL3-targeting tri-specific, half-life extended T cell engager, is enhanced by combining with an anti-PD-L1 antibody in an immunocompetent mouse model

Laura B. Valenzuela[1], Chi-Heng Wu[2], Wade Aaron[2], Raphalea R. Banzon[1], Mabel Bush[1], S. Jack Lin[1], Sony S. Rocha[1], Subramanian Thothathri[1], Holger Wesche[1], Mary Ellen Molloy[2], Banmeet S. Anand[2]. *[1]Translational Medicine, Harpoon Therapeutics, Inc., South San Francisco, CA,[2]Harpoon Therapeutics, Inc., South San Francisco, CA*

TriTAC® is a T cell engager platform comprised of three binding domains: a target binder for tumor cell engagement, an albumin binder for half-life extension, and a CD3 binder for T cell engagement. HPN328 is a Delta-like ligand 3 (DLL3)-targeting TriTAC currently being evaluated in a Phase 1/2 clinical trial enrolling patients with advanced cancers associated with DLL3 expression, including small cell lung cancer (SCLC) and other neuroendocrine malignancies (NCT04471727). While HPN328 has demonstrated single agent clinical activity in relapsed/refractory SCLC patients, combinations with other immunotherapeutic agents could further potentiate HPN328 anti-tumor activity and enable the testing of HPN328 in earlier lines of therapy. To test this hypothesis, we developed a human CD3ε (hCD3ε) immunocompetent mouse model that has the epitope of human CD3ε, as recognized by TriTAC molecules, specifically knocked-in (KI) to the mouse CD3ε gene. hCD3ε KI mice have comparable immune cell repertoire as wild-type mice. However, unlike wild-type mice, TriTAC molecules bind to the T cells in hCD3ε KI mice. In a MC38 tumor model, an EGFR-targeting TriTAC was able to exert the expected anti-tumor activity and EGFR-dependent toxicity, thereby confirming TriTACs can engage and activate endogenous T cells in this immunocompetent hCD3ε KI mouse model. Next, we tested HPN328 in hCD3ε KI mice with MC38 tumors that have been engineered to express human DLL3. As expected, HPN328 inhibited tumor growth in a dose-dependent manner. HPN328 also resulted in a notable upregulation of PD-L1 in these tumors, suggesting that HPN328 in combination with an anti-PD-L1 antibody could potentially drive deeper anti-tumor responses. Indeed, sub-therapeutic doses of HPN328 in combination with an anti-PD-L1 antibody enhanced the anti-tumor activity of HPN328 when compared to either treatment alone.

Atezolizumab and durvalumab, anti-PD-L1 antibodies, are approved in combination with platinum-doublet chemotherapy as part of front-line therapy for extensive-stage SCLC. These results demonstrate the utility of combining anti-PD-L1 antibodies to enhance the anti-tumor activity of HPN328 and further supports investigation of this combinatorial approach in patients. Clinical studies of HPN328 in combination with atezolizumab are planned.

Olverembatinib (HQP1351) enhances antitumor effects of immunotherapy in renal cell carcinoma (RCC)

Guangfeng Wang[1], Eric Liang[2], Ping Min[1], Huidan Yu[3], Bingxing Wu[3], Dajun Yang[3], Yifan Zhai[2]. *[1]Ascentage Pharma Co., Ltd., Shanghai, China,[2]Ascentage Pharma Group Inc., Rockville, MD,[3]Ascentage Pharma Co., Ltd., Suzhou, Jiangsu Province, China*

In solid tumors, resistance to checkpoint inhibitors (CPIs) is frequently observed, partially due to upregulation of vascular endothelial growth factor A (VEGFA) and programmed death-ligand 1 (PD-L1). This culminates in an immunosuppressive tumor microenvironment and immune escape. Inhibitors against VEGF and the VEGF receptor (VEGFR) foster tumor vessel normalization and immunostimulatory reprogramming, in turn promoting treatment effects of immunotherapies. In recent years, TKIs, including axitinib, lenvatinib, and cabozantinib, plus immunotherapy have been approved to treat advanced RCC. Currently under clinical development for relapsed or refractory chronic myeloid leukemia and gastrointestinal tumor, olverembatinib (HQP1351) is a new-generation multikinase inhibitor with targets including VEGFR, fibroblast growth factor receptor (FGFR), SRC, BCR-ABL1, c-KIT, and platelet-derived growth factor receptor. The aim of this study was to assess whether olverembatinib combined with immunotherapy can promote inhibitory effects on RCC. In cell-free kinase assays, olverembatinib inhibited VEGFR1, -2, and -3 with IC_{50} values of 4.2, 6.1, and 4.1 nM, respectively. Compared to lenvatinib, olverembatinib had more potent antiproliferative effects on human umbilical vein endothelial cells. Olverembatinib also had antiproliferative activity in murine RCC lines RANCA and RAG, with IC_{50}

values of 141 and 53 nM, respectively. When olverembatinib was coadministered with an anti-PD-1 antibody in a RANCA-derived syngeneic model, both agents exerted synergistic effects, with tumor growth inhibition rates reaching 60.6%. Mechanistically, olverembatinib influenced cancer cell proliferation directly by inhibiting phosphorylation of FGFR and downstream proteins. Increased cleavage of caspase-3 and poly (ADP-ribose) polymerase 1 were observed, suggesting induction of apoptosis. Olverembatinib also influenced proliferation of vascular endothelial cells by inhibiting phosphorylation of VEGFR, SRC, and downstream proteins Akt and extracellular signal-regulated kinases. Olverembatinib also reduced expression of PD-L1 in RCC cells. In tumor-infiltrating lymphocyte assays, olverembatinib increased numbers of cytotoxic T cells (CTL, $CD8^+$) and natural-killer cells (NK, $CD3^-/CD49B^+$) in RANCA tumor tissues. Combined with an anti-PD-1 antibody, olverembatinib increased CTLs, NK cells, dendritic cells (DCs, $MHC\text{-}II^+/CD11C^+$), and M1 macrophages ($F4/80^+/CD11B^+/CD86^+$) in RANCA tumor tissues, indicating an immunoregulatory effect of olverembatinib. Taken together, these data suggest that combining olverembatinib with a CPI confers synergistic antitumor effects in an RCC cancer mouse model by targeting tumor growth, angiogenesis, and immune regulation. This novel combination may provide an alternative approach to enhance treatment effects with CPIs in renal cancers.

"Armed" oncolytic herpes simplex virus enables CD19 CAR-T for solid tumor cell treatment as a combination therapy

Yanxin Zheng[1], Yuanyuan Liu[1], Tianyi Deng[1], Yue Huang[1], Ziwen Liu[1], Borui Zhan[1], Xusha Zhou[1], Runbin Yan[1], Jiangtao Ren[2], Yun Xing[2], Guixing Wu[2], Yonghong Liu[1], Jing Zhao[1], Xiaoqing Chen[1], Grace Zhou[1].
[1]ImmVira Co., Limited, Shenzhen, China,[2]Nanjing Bioheng Biotech Co., Ltd., Nanjing, China

Background: Chimeric antigen receptor (CAR) T cell therapy has achieved unprecedented success in treating hematologic malignancies but still struggles in the context of solid tumors. The challenges of effective CAR-T cell therapy for solid tumors are multifaceted including 1) physical barriers

that limit T cell infiltration; 2) tumor heterogeneity and antigen escape leading to resistance to therapy; 3) immunosuppressive tumor microenvironment (TME) dampening T cell function. As a novel modality for cancer therapy, oncolytic virus (OV) can be engineered to overcome the limitations of CAR-T therapy in solid tumor. Here we developed a new-generation of oncolytic herpes simplex virus (oHSV) to enable clinically approved CD19 CAR-T for solid tumor therapy.
Methods: oHSV MVR-T7011 (T7011) was genetically engineered to drive ectopic expression of the extracellular domain of CD19, the blood tumor antigen, on solid tumor cell surface upon viral infection. In addition, multiple payloads, CCL5, IL-12, and anti-PD-1 antibody were introduced into T7011 to modulate the TME. Payload expression was detected both *in vitro* and *in vivo*. Co-culture studies were performed to test the cell-killing activity of CD19 CAR-T combined with T7011. Antitumor activities of T7011 administrated via intratumoral (IT) or intraperitoneal (IP) in combination with CD19 CAR-T cells were assessed in immunodeficient and immunocompetent mice.
Results: The *in vitro* studies indicated that the expression of CD19 on tumor cell surface was detected as early as 4 hours post infection (hpi) and retained for at least 96 hours in the T7011-infected cells. In mouse study showed that the CD19 expression on tumor cells was detected as early as 8 hpi and lasted for 20 days when T7011 was injected via IT in immunodeficient mice. The payload of CCL5, IL-12, and anti-PD-1 antibody showed a similar expression pattern as CD19. Co-culture studies showed that T7011 infection enhanced cell-killing activity of CD19 CAR-T but the virus had no effect on viability and proliferation of CAR-T cell itself, which concludes that T7011 does not dampen the CAR-T function as its combination treatment. The *in vivo* efficacy studies demonstrated that IT and IP administration of T7011, rather than MVR-T3011 virus which lacks CD19, specifically promoted CD19 CAR-T anti-solid tumor activities in both immunodeficient and immunocompetent mice.
Conclusions: The new-generation of HSV oncolytic virus T7011 expressing the targetable CD19 antigen on tumor surface enables the CD19 CAR-T for solid tumor cell treatment as a combination therapy. In addition, T7011 also carries multi-immunomodulators further to enhance antitumor efficacy by reinvigorating the infiltrated CAR-T cells and reversing the immunosuppressive TME. T7011 is expected to be a promising

combinational therapy with CD19-specific CAR-T cells enabling effective cell therapy against multiple solid tumors.

NT219 induces tumor PD-L1 expression and potentiates anti-PD-1 efficacy

Ricardo Alexandre de Azevedo[1], Hadas Reuveni[2], Menashe Bar-Eli[3], Michael Curran[1]. *[1]Department of Immunology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Purple Biotech, Rehovot, Israel,[3]Department of Cancer Biology, The University of Texas MD Anderson Cancer Center, Houston, TX*

While the advent of immune checkpoint blockade (ICB) has dramatically improved the prognosis of many immune-infiltrated cancers, for others, unfortunately, these benefits have yet to be realized. The major challenge before the field, then, is to identify combination therapies that act both to combat evolved resistance. NT219 is a novel dual inhibitor of insulin receptor substrates 1 and 2 (IRS) and STAT3. NT219 demonstrated antitumor effects against both in situ and metastatic human melanoma models in mice as a stand-alone treatment and in combination with mutated BRAF and MEK inhibitors. The potential of NT219 to overcome resistance and increase efficacy was demonstrated in PDX models with multiple drug classes. Collectively, these findings provided preclinical proof-of-concept NT219 as a promising novel cancer therapy. Given this data, the goal of our study was to assess the efficacy of combining NT219 with anti-PD-1 and anti-CTLA-4 ICB, and test capacity of the combination to overcome immune resistance. To that end, we have examined PD-L1 expression levels in vitro following NT219 treatment in two different strains of melanoma cells, B16-tdTomato (TMT) and B16 3I-F4, ICB sensitive and ICB resistant derivative lines, respectively. In addition, to evaluate the combination effect of NT219 with ICB therapy in ICB-resistant PDX model, we used a humanized PDX model of pembrolizumab-resistant gastroesophageal tumor (GEJ). These mice were injected with PBMCs from the same patient. Using multiple syngeneic immunocompetent models of melanoma (TMT and 3I-F4 cells) and the humanized PDX model, we investigated the potential of each ICB with NT219. Our findings showed that NT219 increased PD-L1 expression levels on both melanoma cell lines in vitro, however, the PD-L1

expression levels were much more elevated 3I-F4 than TMT cells. Interestingly, the levels of both IRS and activated pSTAT3, the targets of NT219, which consist well known resistance mechanisms, were higher in the resistant cells as compared to the sensitive line. In accordance we found that NT219 was able to restore anti-PD-1 sensitivity in 3I-F4 model (TGI = 58%) in the syngeneic model, promoting tumor rejection and increasing survival rates. The combined approach between NT219 and anti-CTLA-4 displayed a moderate effect (TGI = 37%). In the TMT, NT219 combined with anti-PD-1 showed greater efficacy compared to anti-PD-1 alone (TGI = 63% and TGI = 47%, respectively). These results were confirmed using the humanized ICB-resistant PDX model, where impressive synergy between NT219 and the anti-PD-1 (TGI = 98%) was demonstrated. To summarize, we found a significant synergistic effect of NT219 combined with anti-PD-1 therapy, supported by a mechanism of PDL-1 induction making ICB resistant tumors amenable to ICB treatment. Collectively, these findings demonstrated that NT219 has the potential to reverse ICB resistance in both human PDX and murine syngeneic tumor model systems

Kenderian[4]. *[1]Mayo Clinic, Rochester, MN,[2]Molecular Pharmacology and Experimental Therapeuthics, Mayo Clinic, Rochester, MN,[3]Cancer Biology Departmetn, Mayo Clinic, Jacksonville, FL,[4]T cell Engineering, Mayo Clinic, Rochester, MN,[5]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN,[6]Business Development, Mayo Clinic, Rochester, MN,[7]Cancer Biology Department, Mayo Clinic, Jacksonville, FL,[8]Endocrine Division, Internal Medicine Department, Mayo Clinic,*

Jacksonville, FL,[9]Internal Medicine Department, Mayo Clinic, Jacksonville, FL,[10]Cancer Biology, Mayo Clinic, Jacksonville, FL

Thyroid cancer is the most common endocrine cancer in the US, and its incidence is rising. Most thyroid cancer deaths are attributed to treatment-refractory, metastatic tumors. Thyroid stimulating hormone receptor (TSRH) expression is largely limited to the thyroid gland and is abundantly expressed on thyroid tumor cells, making TSRH a compelling target for advanced thyroid cancer diagnostics and therapeutics. Therefore, we developed a novel TSHR-targeted chimeric antigen receptor (CAR) T cell therapy to treat aggressive thyroid cancers. TSHR-CAR constructs were cloned into a lentiviral CAR construct containing 4-1BB and CD3ζ. First, we demonstrated potent TSHR-CART antigen-specific anti-tumor activity in vitro. Then, NOD-SCID-γ-/- (NSG) mice were inoculated subcutaneously with TSHR+ tumor cells and randomized by tumor volume to treatment with TSHR-CART cells or control Untransduced T cells (UTD). Treatment with TSHR-CART cells resulted in dose-dependent antitumor activity and prolonged survival. De-differentiated anaplastic thyroid cancers (ATC) downregulate TSHR. Our TSHR immunohistochemistry results corroborated these findings and displayed minimal TSHR protein expression, precluding successful TSHR-CART treatment. We therefore sought to sensitize these tumors with MAPK inhibitors, as a strategy to upregulate TSHR expression in patients with metastatic thyroid cancer. TSHR expression was upregulated in patient-derived xenograft (PDX) ATC models after one week of daily administration of the MAPK inhibitors ($p=0.0024$). After confirming that MAPK inhibition does not dampen TSHR-CART effector functions, we tested sequential and combination therapy of TSHR-CART with MEK and BRAF inhibition in vivo. NSG mice were engrafted with ATC BRAF-mutant PDX tumors and randomized by tumor volume to daily oral treatment with placebo or trametinib (MEK inhibitor) plus dabrafenib (BRAF inhibitor). One week later, mice received either UTD or TSHR-CART. Mice conditioned with trametinib plus dabrafenib ($p=0.0018$) and subsequently treated with TSHR-CART showed superior antitumor activity. However, the improved antitumor activity in this setting was transient. We therefore tested the durability of TSHR upregulation following MEK/BRAF inhibition and demonstrated that TSHR upregulation lasts less than 48-72

hours after discontinuation. Finally, we tested the combination of TSHR CART cells with MEK/BRAF inhibitors in ATC BRAF-mutant PDX tumors. Here, combining TSHR-CART cells with MEK/BRAF inhibitors result in durable control of the tumors. Collectively, our findings indicate that MEK/BRAF inhibition of de-differentiated thyroid cancers upregulated TSHR expression and enhanced TSHR-CART antitumor activity. This work represents a viable strategy to improve outcomes of patients with aggressive, metastatic thyroid cancers.

Antitumor activity of liposomal formulation of eribulin combined with anti-human PD-1 antibody using hPBMC-humanized mouse models

Yuki Niwa, Taro Semba. *Molecular Profiling Department, Discovery Concept Validation Function, Eisai Co., Ltd., Tsukuba-shi, Japan*

Eribulin (ERI) has been reported a microtubule dynamics inhibitor with unique tumor microenvironment modulations such as vascular remodeling and reversal of epithelial-mesenchymal transition activities. In the previous meeting (AACR2022), we reported that ERI and liposomal formulation of ERI (ERI-LF) have immunomodulatory activity that induces CD8+ T cells via its vascular remodeling activity and ERI-LF has greater immunomodulatory activity than ERI. Furthermore, we also reported that these immunomodulatory activities contribute combination antitumor activity of ERI and ERI-LF with anti-PD-1 antibody (Ab) using a P-glycoprotein-knockout 4T1 mouse breast cancer syngeneic model; however, evaluation of antitumor activity of immune-checkpoint inhibitor (ICI) using mouse cancer syngeneic model has limitation because numbers and cancer types of mouse cancer cell lines are limited. In this study, we developed humanized mouse model bearing both human cancer cell lines and human peripheral blood mononuclear cells (hPBMC) to evaluate antitumor activity of ICI for various cancer types. Furthermore, we also evaluated combination antitumor activity of ERI-LF with anti-human PD-1 Ab using this hPBMC-humanized mouse models to verify generality of this combination. We first isolated hPBMC from healthy volunteers and the obtained hPBMC was intravenously injected into NOG mice. To confirm transplantation of hPBMC in the mice, we performed flow cytometric analysis of peripheral blood of mice in a time course manner. In the

peripheral blood of humanized mice, chimera ratio of hCD45+ cells gradually increased until 5 weeks after hPBMC-injection and then decreased after 6 weeks after hPBMC-injection. Because tumor growth of some cancer cell lines was rejected by hPBMC transplantation, we evaluated some human cancer cell lines that are able to grow in hPBMC-humanized condition and selected MKN45 and NCI-H526 cell lines for human gastric cancer and small cell lung cancer models, respectively. Finally, we verified combination antitumor activity of ERI-LF with anti-human PD-1 Ab in hPBMC-humanized MKN45 and NCI-H526 models. In both models, combination of ERI-LF with anti-human PD-1 Ab showed significantly stronger antitumor activity compared with each monotherapy. In summary, we demonstrated that combination of ERI-LF with anti-PD-1 Ab is effective for gastric and small cell lung cancers, suggesting that this combination therapy is effective for various cancer types. Currently, Phase 1b/2 clinical trial of ERI-LF plus nivolumab in patients with selected solid cancers including gastric and small cell lung cancers (NCT04078295) is underway.

Combination PancVAX neo-epitope vaccine with anti-CTLA-4 and anti-PD-1 antibodies enhances infiltration of cytotoxic T cells and mitigates T cell exhaustion in a murine model of pancreatic ductal adenocarcinoma

Jacob T. Mitchell, Amanda Huff, Emily Davis-Marcisak, Fangluo Chen, Todd D. Armstrong, Luciane T. Kagohara, James Leatherman, Rulin Wang, Srinivasan Yegnasubramanian, Elizabeth M. Jaffee, Elana J. Fertig, Neeha Zaidi. *Oncology, Johns Hopkins University School of Medicine, Baltimore, MD*

Pancreatic ductal adenocarcinoma (PDAC) is a deadly cancer with a low tumor mutational burden and therefore few neoantigen targets that can be recognized by cytotoxic T cells. Most PDACs are thus insensitive to either single or dual immune checkpoint inhibitor (ICI) therapy. Personalized neoantigen vaccines can expand the number and repertoire of anti-tumor T cells that infiltrate the tumor and mediate cytotoxicity. To model a personalized neoantigen vaccine treatment strategy in PDAC, we previously developed PancVAX, a peptide-based vaccine targeting 12 neoantigens

expressed in the murine pancreatic cell line Panc02 (Kinkead et al, *JCI Insight* 2018). Although we observed increased T cell infiltration present in the tumor post-vaccination, these cells expressed high levels of exhaustion markers. We therefore hypothesized that sequential administration of anti-CTLA-4 and anti-PD-1 would enhance the pool of T cells primed by the neoantigen vaccine and maintain activation of antigen-experienced T cells, respectively, to yield optimal and durable neoantigen-specific anti-tumor immunity in PDAC. To address this, mice bearing subcutaneous Panc02 tumors were vaccinated with two rounds of the PancVAX neoantigen vaccine followed by anti-CTLA-4 and anti-PD-1 3 days later. Anti-PD-1 maintenance was given twice weekly beginning at the first vaccine dose. Twelve days after the last peptide vaccine dose, tumors were harvested and dissociated into single-cell suspensions for paired single-cell RNA-sequencing and TCR-sequencing. Mice that were untreated or given ICIs without PancVAX had the highest proportions of CD8+ T cells expressing exhaustion markers. PancVAX-treated mice had more intratumoral cycling CD8 T cells and effector CD8+ T cells with high cytotoxic gene expression. Among mice treated with PancVAX, tumors from mice treated with PancVAX + anti-PD1 or PancVAX + anti-PD1 + anti-CTLA-4 had the highest proportions of effector CD8+ T cells. Ongoing analyses include differential gene expression and pathway analysis between treatment conditions in the T cell compartment in mice treated with combination ICI and PancVAX. Additionally, we will assess changes in T cell clonality and diversity within the tumors when mice are treated with single or combination therapy. These results will define a transcriptional signature associated with the generation of a productive anti-tumor immune response when neoantigen vaccines and ICI are used in combination. This work demonstrates how the addition of ICIs to personalized neo-epitope vaccines for PDAC can further enhance the quality of vaccine-induced T cell effector function in an otherwise immunologically cold tumor type and supports their inclusion in neoantigen vaccination strategies for patients with PDAC.

Engineering dendritic cell-derived exosomes forbrain metastases immunotherapy

Hao-Nien Chen[1], Xiangliang Yuan[1], Yimin Duan[1], Yi Xiao[1], Shao-Ping Yang[1], DIhua Yu[2]. *[1]Department of Molecular and Cellular Oncology, UT*

MD Anderson Cancer Center, Houston, TX,[2]Department of Molecular and Cellular Oncology, DIhua Yu, Houston, TX

Brain metastases (BrMs) represent an unmet challenge for the therapy of most aggressive cancers owing to the extremely poor survival and the limited efficacy of available therapies. Currently, NO curative therapy for breast cancer BrM (BCBrM) is available and we urgently need to develop new and effective therapies. Immune checkpoint therapies (ICT) have revolutionized cancer treatment, but are generally unsuccessful in treating BrMs, including BCBrM. A crucial reason for this is the unique brain immune microenvironment with low antigen exposure/presentation in BrMs and fewer antigen-specific T cells in the brain parenchyma. The priming and activation of antigen-specific T cells require professional antigen-presenting dendritic cells (DCs) for effective antigen presentation through multifaceted communication between DCs and T cells by direct intercellular contact and indirect distant communication via exosomes and other means. DC-derived exosomes (DCEXs) carry functional MHC-I/peptide complexes (pMHC-I) and costimulatory molecules, hence facilitating systemic T cell immune responses. DCEXs have been developed as immunotherapies which exhibit advantages over DC-based immunotherapies. However, DCEXs in ongoing clinical trials showed limited efficacy. We found that increased non-receptor protein tyrosine phosphatase SHP1, a DC-intrinsic inhibitory checkpoint, in monocyte-derived DCs (MoDCs) ex vivo led to DC exhaustion that limits DCEXs function resulting in poor systemic T cells stimulation in vivo. To improve DCEXs functions, we developed next-generation DCEXs by genetic knockout of SHP1 in DCs from which DCEXs (iSHP1-DCEXs) were isolated. Remarkably, the modified iSHP1-DCEXs exhibited significantly increased pMHC-I expression and more effectively improved T cell proliferation compared to control DCEXs, indicating a greater capacity of antigen presentation of engineered iSHP1-DCEXs. In the EO771-OVA mammary tumor cells-bearing mouse model, iSHP1-DCEXs treatment greatly increased tumor infiltration of OVA antigen-specific CD8+ T (OT-1) cells resulting in tumor inhibition and prolonged mouse survival, indicating that iSHP1-DCEXs elicited an effective and specific antitumor immunity in vivo. Moreover, combining iSHP1-DCEXs with anti-PD1 Ab yielded a strong syngenetic therapeutic response in mice bearing the anti-PD1-

resistant EO771 tumors, as indicated by delayed tumor growth and prolonged survival. importantly, iSHP1-DCEXs also significantly increased tumor-infiltrating antigen-specific T cells and synergized with PD-1 Ab leading to tumors clearance in mice bearing the B16-GMCSF melanoma. To further test the iSHP1-DCEXs effect in BCBrM, we co-injected EO771-OVA and iSHP1-DCEXs into mice and found that iSHP1-DCEXs inhibited BrM. Together, the engineered iSHP1-DCEXs offer a promising option to generate a potent antigen-specific T cell immune response for BCBrM inhibition.

Immune response markers following combination treatment with oncolytic adenovirus AMUN-003 and immune checkpoint inhibitors in a murine model of triple negative breast cancer

Soon Cheon Shin[1], Beniamin Filimon[1], Yuefeng Yang[2], Zebin Hu[3], Vijayakrishna K Gadi[4], Weidong Xu[1]. *[1]NorthShore University HealthSystem, Evanston, IL,[2]Department of Experimental Medical Science, Key Laboratory of Diagnosis and Treatment of Digestive System Tumors of Zhejiang Province, Ningbo, China,[3]National Institutes for Food and Drug Control, Beijing, China,[4]Translational Oncology Program, University of Illinois Cancer Center, Chicago, IL*

Background: Accounting for about 10-15% of all breast cancer diagnoses, triple negative breast cancer (TNBC) has the highest mortality rate partly attributable to few effective treatment options. We evaluated a novel oncolytic adenovirus (rAd.sT.GM; named as AMUN-003 by AmunBio, Inc) encoding sTGFβRIIFc (a TGF-β protein decoy) and GM-CSF transgenes in combination with ICI treatments in the mouse TNBC 4T1 subcutaneous model. We previously reported that infection of target cancer cells with AMUN-003 and co-treatment with ICI led to potent inhibition of tumor progression and lung metastasis without off-target organ or systemic toxicity. Here, we provide details on the specific immune markers associated with responses.
Methods: Immune competent BALB/C mice harboring 4T1 tumors were treated with combinations of anti-PD1 antibody, anti-CTLA antibody, AMUN-003 or sham injections. We measured inflammatory serum

cytokines/chemokine levels by Meso Scale immunoassays and immune modulator gene expression in lung, spleen and tumor by qRT-PCR.
Results: The "Triplet" combination of AMUN-003, anti-PD1 and anti-CTLA-4 antibodies was associated with decrease of poor prognosis biomarkers in serum: **TGF-β1**: Triplet $p< 0.001$, ICIs $p<0.01$, AMUN-003 $p< 0.05$; **IL-27p28/IL-30**: Triplet and ICIs $p< 0.05$; **IL-1β**: Triplet, AMUN-003, ICIs, and AMUN-003+anti-CTLA-4 $p< 0.05$; **TNF-α**: Triplet $p< 0.01$, ICIs $p<0.05$, and increase of immune stimulatory IFN-γ: Triplet $p<0.01$ (all compared to the buffer). In lung tissue, no significant changes in cytokine/chemokine expression were detected, however **Granzyme B** levels were significantly increased in Triplet: $p< 0.05$. In spleen, we detected increased cytokine expression (**IL-2**: Triplet, anti-CTLA-4, AMUN-003+anti-PD-1 $p< 0.05$; **IL-4**: Triplet $p< 0.001$, AMUN-003+anti-PD-1, AMUN-003+anti-CTLA-4: $p< 0.01$). In tumor, expression of TGF-β1 was significantly decreased by triplet and ICIs treatments (both $p<0.05$), but increases in IFN-γ, **IL-4**, **CXCR4**, and **Perforin** were observed in several treatment groups.
Conclusions and Summary: Our data support the interpretation that the most potent intratumoral and systemic anti-tumor response took place with triplet therapy. Specifically, triplet therapy led to reduction of markers of systemic pathogenic inflammation but activation of anti-tumor cellular immunity (e.g., IFN-γ). In lung (site of 4T1 metastases), Granzyme B expression indicated activated NK cell and cytotoxic T cell infiltration was greatest in Triplet. Tumor expression data for IFN-γ, IL-4, CXCR4, and Perforin have limited interpretability because several animals had complete remissions at the primary tumor. Collectively, quantitative protein and expression immune response data presented here further support advancement of combination testing of AMUN-003 and ICIs in human clinical trials.

Intratumoral CD40 agonist enhances the antitumor effect of anti-PD1 immunotherapy by activation of antigen-presenting cells and selective expansion of effector CD8+ T cells

Barbara Pazdrak, Heather M. Sonnemann, Salah-Eddine Bentebibel, Barbara M. Nassif, Greg Lizee, Adi Diab. *UT MD Anderson Cancer Center, Houston, TX*

Agonistic CD40 antibodies have shown promise when used in combination with checkpoint inhibitors in clinical trials for the treatment of malignancies. However, the mechanisms driving antitumor immune responses in patients are not well understood. The aim of this study was to use a preclinical melanoma model to evaluate the impact of intratumoral anti-CD40 administration on treatment efficacy and the tumor immune landscape in the context of systemic anti-PD1 therapy. Mice bearing 8-day established B16 melanoma tumors were injected with CD40 agonist intratumorally, either alone or in combination with anti-PD1 Ab, every 3 days for a total 4 doses. All mice treated with the combination therapy exhibited tumor growth arrest while progressive tumor growth was observed in control mice and mice treated with anti-PD1 alone. At day 15, tumor weights were 7- and 3-fold reduced in mice treated with the combination therapy as compared to control IgG or PD1 monotherapy, respectively. CyTOF analysis showed a 4-fold increase in the frequency of tumor-infiltrating immune cells in mice treated with either CD40 agonist alone or the combination therapy. Interestingly, CD40 agonistic Ab selectively expanded CD8+ T cells and the combination therapy exhibited a more pronounced effect compared to treatment with anti-PD1 Ab alone. Moreover, CD39+ CD8 T cells, representing tumor antigen-specific cytotoxic T cells, were 14- and 3-fold higher in tumors from mice treated with the combination therapy as compared to control or PD1-treated mice, respectively. This effect correlated with increases in the frequency of antigen-presenting cells, including cDC1 (6-fold) and B cells expressing CD40 (3-fold) in response to the combination therapy. In addition, the combination therapy significantly decreased myeloid cell population resulting in an 8-fold reduction in the ratio of myeloid cells to T cells. Amongst myeloid cells, the density of the monocytic population was diminished, with a selective 10-fold reduction of CD206+ M2-macrophages in tumors from mice treated with both Abs. Our findings provide evidence that combining systemic anti-PD1 therapy with intratumoral CD40 agonist enhanced antitumor immune responses by selectively expanding tumor antigen-specific effector CD8+ T cells, which was associated with increased infiltration of antigen-presenting cells and attenuation of immunosuppressive myeloid cells.

TU2218, a novel ALK5/VEGFR2 dual inhibitor, overcomes tumor endothelial cell anergy and enhances anti-PD1 immunotherapy efficacy

Jihyun Lee, Nam-hoon Kim, Hun-Taek Kim. *Discovery2, TiumBio, Seongnam-si, Korea, Republic of*

Immune tolerance by TGF-β and VEGF is inextricably related with poor outcomes of approved anti-PD-(L)1 therapy. Accordingly, a dual target for ALK5 and VEGFR2 via single or combination treatments can be an unequivocal tactic to tune tumor-microenvironment (TME) favorable to ICI, and to essentially overcome immune evasion against TGF-β- and VEGF-enriched tumors. Specifically, several reports from clinical data suggest that VEGF-induced endothelial cell anergy (ECA) acts as a vascular immune checkpoint in TME immune response, and the activation of ECA is associated with worse outcomes. Herein, we demonstrate that TU2218, a *first-in-class*, orally available inhibitor against ALK5 and VEGFR2 can recover the downregulated endothelial adhesion molecules, i.e., ICAM-1 and VCAM-1, and suppress ECA. In this work, TU2218 completely recovered the expression of ICAM-1 and VCAM-1 on VEGF-induced ECA in HUVECs. The restored level of ICAM-1 and VCAM-1 at 1 μM TU2218 was equivalent to the activity of combined treatment of 1 μM Vactosertib (ALK5 inhibitor) and 25 μg/ml Ramucirumab (VEGFR2 inhibitor). 1 μM of Vactosertib alone, however, did not show such restoration. These results indicate that VEGF-induced ECA is mediated by both VEGFR2 and TGF-β signal, thereby validating the superiority of dual target strategy for ALK5 and VEGFR2 over a single target in overcoming ECA. We further tested if TU2218 could restore VEGF-induced decrease of Jurkat adhesion to HUVECs, considering the close relationship between the expression of adhesion-molecules of endothelial cell surface and the adhesion of lymphocytes to endothelium. TU2218 recovered the number of Jurkat adhering to VEGF-elicited HUVEC monolayer in a dose-dependent manner, but Vactosertib did not. Furthermore, the activity of TU2218 on Jurkat adhesion was reversed by VCAM-1 neutralizing antibody. Therefore, our results demonstrate that TU2218 improves Jurkat adhesion by restoring VCAM-1 expression. Finally, the *in vivo* translatability of TU2218 in overcoming ECA was confirmed with B16F10-bearing mice, a well-defined immune desert model, after treatments of anti-PD1 antibody, TU2218, or

combined regimen for 15 days. TU2218 combined with an anti-PD1 antibody significantly suppressed tumor growth by c.a. 74 % compared to vehicle, thus being superior to a single treatment (e.g., tumor growth inhibition (TGI) 44% for TU2218, TGI 45% for anti-PD1). In this combination, TU2218 increased the number of both $CD31^{+}VCAM\text{-}1^{+}$ and $IFN\gamma^{+}CD8^{+}$ T cells in the tumor. We conclude that TU2218 leads not only to the enhancement of T cell-traffic toward TME, but also to the conversion of immune balance favorable to anti-PD1 therapy. The Phase 1b trial of TU2218 combined with pembrolizumab is underway for advanced solid cancers (NCT05204862).

#5081

Anti-tumor activity of HPN217, a BCMA-targeting tri-specific T cell engager, is enhanced by γ-secretase inhibitors in preclinical models

Payton C. Laurie, Mary Ellen Molloy, Patrick P. Ng, Banmeet S. Anand.
Translational Medicine, Harpoon Therapeutics, Inc., South San Francisco, CA

HPN217 is a Tri-specific T Cell-Activating Construct (TriTAC) currently being evaluated in a phase 1 clinical trial for relapsed or refractory multiple myeloma (MM) (NCT04184050). It consists of a single domain antibody (sdAb) specific for B-cell maturation antigen (BCMA), a serum albumin-specific sdAb for half-life extension, and a single chain Fv (scFv) specific for the CD3ε subunit of the T cell receptor (TCR) complex for T cell engagement. BCMA is a cell surface receptor highly expressed on malignant plasma cells in MM patients and plays an important role in B-cell proliferation and survival. Soluble BCMA (sBCMA) is produced when the extracellular domain of BCMA is cleaved by γ-secretase and enters circulation. sBCMA may act as a sink for BCMA targeted therapies, potentially decreasing anti-tumor efficacy. Previous studies have shown γ-secretase inhibitors (GSIs) can increase membrane bound BCMA expression on MM cells and decrease sBCMA concentrations, providing a rationale for combining GSIs with HPN217. Here we describe preclinical studies evaluating that combination *in vitro* and *in vivo*. To evaluate the effects of GSIs on BCMA expression, MM cell lines MOLP8, KMS-12-BM, and MM.1S were incubated with GSIs LY3039478, PF03084014, or RO4929097overnight. GSI treatment led to a 3-7-fold increase in BCMA

expression on MM cell surface. To determine the effects of increased BCMA expression mediated by GSIs on the activity of HPN217, an *in vitro* T cell dependent cell cytotoxicity assay (TDCC) was conducted. GSIs enhanced the activity of HPN217, in some cases leading to a 3.5-fold increase in potency compared to HPN217 alone. Next, the impact of the combination was tested *in vivo* using a disseminated MOLP-8 xenograft model engrafted with T cells from a healthy human donor. Vehicle treated mice succumbed to disease burden with a median survival of 23 days as assessed by body weight loss and clinical observations. A suboptimal dose of 4 ug/kg HPN217 protected mice from disease burden for an additional 3 days. By contrast, the combination of HPN217 and LY3039478 led to a significant increase in survival compared to vehicle or either monotherapy, with a median survival of 43 days. Taken together these results demonstrate the potential utility of GSIs to enhance the anti-tumor activity of HPN217 and supports further investigation of this combinatorial approach in patients.

Heterodimeric IL-15 (hetIL-15) immunotherapy synergizes with Fatty Acid Metabolism Modulator (FAMM) to eradicate TNBC EO771 murine tumors

Sevasti Karaliota[1], Dimitris Stellas[2], Vasiliki Stravokefalou[2], Breana Myers[1], Barbara K. Felber[2], George N. Pavlakis[2]. *[1]Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Frederick, MD,[2]National Cancer Institute at Frederick, Frederick, MD*

Introducti**on:** Metabolic fitness and T cell survival are crucial in anti-tumor responses because nutrients are often scarce and other regulatory molecules may be unfavorable in the tumor microenvironment leading to T cell dysfunction, stress, and apoptosis. Tumor-infiltrating cytotoxic $CD8^+$T cells frequently acquire an altered state of differentiation referred to as "exhaustion" and, as a result, they fail to control tumor outgrowth. IL-15 cytokine stimulates the generation, proliferation and cytotoxic function of tumor specific $CD8^+$ T cells and NK cells. The objective of this study was to assess the effects of hetIL-15 immunotherapy in triple negative breast cancer tumors (TNBC), to evaluate the metabolic profile of the tumor-

infiltrating T cells and to study any potential synergy using a Fatty Acid Metabolism Modulator (FAMM) to enhance T cell metabolism.
Study design and methods: We used the murine EO771 orthotopic breast cancer model to study the efficacy of locoregional administration of hetIL-15 immunotherapy in combination with a FAMM. We monitored the effect of treatment on number, metabolism and mitochondrial function of the tumor-infiltrating immune cells by flow cytometry, Seahorse flux analysis and Mitotracker, 2-NBDG and/or Bodipy staining.
Results: hetIL-15 locoregional administration, as as single agent, resulted in complete regression in 40% of the treated animals and increased survival. Tumor-infiltrating cytotoxic $CD8^+$T and NK cells increased in hetIL-15 treated tumors and showed enhanced activation and proliferation. Metabolic flux analysis of the tumor-infiltrating cytotoxic $CD8^+$T cells from hetIL-15-treated mice confirmed a rise in oxygen consumption rate (OCR) with substantial increase of spare respiratory capacity, which supports an activated/non exhausted phenotype of these hetIL-15 treated effector cells. Since, further promoting fatty acid (FA) catabolism improves the tumor-infiltrated $CD8^+$T cells's ability to slow tumor progression, we combined hetIL-15 immunotherapy with a FAMM. Combination therapy resulted in increased mitochondrial function, FA uptake and OCR, revealing a more metabolically active phenotype compared to the tumor-infiltrating $CD8^+$T cells from hetIL-15 monotherapy group. In addition, combined treatment of IL-15 immunotherapy and FAMM resulted in statistically significant EO771 tumor growth delay and complete eradication of the tumors in 85% of mice.
Conclusions: Our results indicate that hetIL-15 synergizes with metabolic reprogramming of T cells to achieve superior antitumor efficacy and complete cures. We suggest that metabolic reprogramming of tumor-specific $CD8^+$Tcells might represent a strategy to promote survival in the metabolically hostile TME as part of an approach to enhance the clinical efficacy of immunotherapy.

Investigating the development and therapeutic potential of intra-tumoral $CXCR6^+$ effector/effector memory T cells ($T_{EFF/EM}$) in triple-negative breast cancer

Bryan Jian Wei Lim[1], Xiao-Fan Wang[2], Qi-Jing Li[3]. *[1]Duke University, Durham, NC,[2]Pharmacology and Cancer Biology, Duke University, Durham, NC,[3]Institute of Molecular and Cell Biology, Agency of Science and Technology (A*STAR), Singapore, Singapore*

Triple-negative breast cancer (TNBC) is an aggressive subtype that makes up 10-20% of all breast cancer cases. Because of the higher risk of metastasis and recurrence post-treatment, there is a need to develop novel therapeutics to address these challenges. In previously published work, we demonstrated that CXCL16 traps $CXCR6^{+}PD\text{-}1^{+}$ effector/effector memory ($T_{EFF/EM}$) within the primary tumor and that these T cells have anti-metastatic function that can be harnessed when released into peripheral sites with intra-tumoral administration of anti-CXCL16 prior to surgical resection. However, whether CXCL16 blockade can be used in combination with conventional checkpoint targets and the developmental route of this $CXCR6^{+}$ $T_{EFF/EM}$ is not known. To develop a novel neoadjuvant therapy, we use the spontaneously metastasizing murine TNBC model, 4T1. Here, we report that anti-4-1BB, and not anti-PD-1, when used in combination with blockade of CXCL16 can prolong survival post-surgical resection. Using anti-4-1BB in combination with CRISPR-generated *Cxcl16*-KO 4T1 model, we show that both deficiency of CXCL16 within the tumor microenvironment (TME) and anti-4-1BB contribute synergistically to survival advantage. To study the development of this population of T cells, we use the Py8119 murine TNBC model. We definitively show that $CXCR6^{+}PD\text{-}1^{+}$ $T_{EFF/EM}$ is uniquely generated within the primary tumor. Co-expression of CXCR6 and PD-1 indicates that T cell receptor (TCR) signaling is a potential regulator of the development of this $T_{EFF/EM}$ sub-population. Analyses of our previously published scRNA-seq dataset reveals *Lat2* to be the top gene involved in TCR signaling. Tumors growing on *Lat2*-KO animals show a significant increase in tumor size accompanied by significant reduction of $CD44^{high/mid}$ $CXCR6^{+}PD\text{-}1^{+}$ $T_{EFF/EM}$. However, competitive transfer of naïve WT and *Lat2*-KO T cells into *Tcra*-KO recipients led to comparable levels of $CXCR6^{+}$ $T_{EFF/EM}$. Surprisingly, transferred *Lat2*-KO T cells failed to engraft within the primary tumor relative to WT T cells. Future work will address if this engraftment defect is

due to expansion/survival defects. Therefore, regulation of TCR signaling within the TME via LAT2 potentially represents a mechanism in which primary tumors trap T cells, promoting their exhaustion. Importantly, this can be harnessed through combinatorial activation and blockade of 4-1BB and CXCL16 respectively.

Targeted delivery of low-dose radiation alleviates tumor resistance to CAR-T cell therapy

Yanping Yang[1], Yago Alcaina[1], Yogindra Vedvyas[1], Maria Cristina Riascos[1], Edward K. Fung[2], Brett Vaughn[1], Sarah M. Cheal[1], Irene M. Min[1], Claire Vanpouille-Box[2], Moonsoo M. Jin[1]. *[1]Radiology, Weill Cornell Medicine, New York, NY,[2]Weill Cornell Medicine, New York, NY*

Purpose: Current understanding of resistance to CAR-T cell therapy in solid tumors implicates inadequate CAR-T cell potency in the immunosuppressive tumor microenvironment (TME). We have previously developed a platform using somatostatin receptor 2 (SSTR2) as a positron emission tomography (PET) reporter to detect CAR-T cell expansion and trafficking. The current study aimed to leverage SSTR2 for low-dose targeted radionuclide therapy (^{177}Lu-DOTATATE, Lutathera), which under dosimetry guidance might enhance antitumor immunity by reprograming the TME and promoting T-cell reinvigoration.
Methods: Using intercellular adhesion molecule 1 (ICAM-1) as a model antigen, we evaluated the immunomodulatory effects of low-dose radiation in a gastric cancer animal model. NSG mice were inoculated subcutaneously with firefly luciferase-expressing Hs 746T cells (0.1×10^6 per mouse) and treated 5 days later with 10×10^6 SSTR2-expressing ICAM-1 CAR-T cells. CAR-T cell expansion was monitored weekly by PET scan using ^{18}F-NOTA-Octreotide, a radiotracer targeting SSTR2. Three weeks post-T cell infusion, a cohort of mice were injected with 7.4 MBq of ^{177}Lu-DOTATATE via the tail vein. SPECT imaging was performed for dosimetry analysis. Tumor growth was monitored by bioluminescence imaging and tumor size measurement. Serum cytokines were analyzed.

Results: Single dose ^{177}Lu-DOTATATE treatment (delivering 1-6 Gy to tumor) improved response of established gastric cancer tumor (>1,000 mm^3) that was not responsive to CAR-T cell treatment alone and significantly prolonged survival. All mice receiving CAR-T cells plus ^{177}Lu-DOTATATE displayed rapid tumor shrinkage, with 83% of mice achieving complete remission within 3 weeks of ^{177}Lu-DOTATATE treatment. SPECT imaging confirmed specific delivery of ^{177}Lu-DOTATATE by tumor-infiltrating CAR-T cells, with tumor uptake of 0.43 ± 0.24 and 0.19 ± 0.08 MBq/g at 24 and 144 hours post ^{177}Lu-DOTATATE injection, respectively. Most radioactivity reduction over time (73%) is explained by physical decay of ^{177}Lu, indicating persistent tumor retention of ^{177}Lu-DOTATATE. In contrast, rapid clearance of ^{177}Lu-DOTATATE was observed in liver and kidneys. Importantly, longitudinal CAR-T cell imaging using ^{18}F-NOTA-Octreotide revealed increased CAR-T cell expansion induced by low-dose radiation. Furthermore, we detected high levels of IFN-γ and perforin in serum after ^{177}Lu-DOTATATE treatment, which were >10 folds higher than that in control mice receiving CAR-T cell only, indicating activation of T cells by low-dose radiation.
Conclusions: We developed a translatable radioimmunotherapy platform that incorporates a FDA-approved theranostic endoradiotherapy (Lutathera) to improve tumor response to CAR-T cell therapy. The next steps would be to explore the immunomodulatory effects of low-dose radiation systematically and elucidate the mechanism of action.

#5085
Blockade of tumor derived CSF1 promotes an immune-permissive tumor microenvironment
Maria Del Mar Maldonado, Duane H. Hamilton, Jeffrey Schlom. *Center for Immuno-Oncology, NIH-NCI, Bethesda, MD*

The macrophage colony stimulating factor 1 (CSF1) is a chemokine essential for the survival, proliferation, and differentiation of especially mononuclear phagocytes, such as macrophages and monocytes. However, within the tumor microenvironment (TME), CSF1 regulates the production, survival, and recruitment of tumor associated macrophages (TAMs), further promoting a protumorigenic and immunosuppressive M2-like phenotype.

Overexpression of CSF1 in breast, prostate, and ovarian cancers has been shown to promote tumorgenicity, invasiveness, and accelerate tumor metastasis. In this study, we demonstrate for the first time, that treating established murine MC38 colon and 4T1 breast carcinoma tumors with a CSF1R blocking antibody promotes the expansion of neoepitope-specific T cells. To assess the role of tumor derived CSF1 in these model systems, we generated and characterized CSF1 CRISPR-Cas9 knockouts. In both models, elimination of tumor-derived CSF1 results in a decreased tumor growth in both syngeneic and immune-compromised mice as compared to the parental cell lines. Inhibition of CSF1/CSF1R signaling axis generated enhanced immunity against 4T1 and MC38 tumor neoepitopes, potentially promoting an immune permissive TME in tumor bearing mice. Combination of a neoepitope targeting cancer vaccine with anti-PDL1 in the MC38 CSF1-/- tumor model significantly decreased tumor growth *in vivo*. Furthermore, combining CSF1R blockade with adeno-TWIST1 vaccine decreased tumor volume, lung metastasis, and synergistically increased in CD8 T cell infiltration in 4T1 mammary tumors. Analysis of the tumor microenvironment demonstrated increased infiltration in CD8 T cells accompanied by a reduction in tumor associated macrophages following CSF1R inhibition in both tumor models. Our findings confirm the therapeutic potential of combining CSF1 targeting agents with vaccine agents to further modulate anti-tumor immune responses in the tumor microenvironment.

Transcriptomic analysis in a renal cancer PDX model enables the deconvolution of additive and synergistic effects of six different standard of care compounds with anti-PD-1 treatment

Kanstantsin Lashuk[1], Eva Oswald[1], Oliver Jonas[2], Julia Schueler[1]. *[1]Charles River Laboratories, Inc., Freiburg, Germany,[2]Kibur Medical Inc, Boston, MA*

Identifying how to optimally combine immunotherapies with other available anti-cancer therapies is a major challenge in oncology. We have utilized an implantable microdevice performing cassette (IMD) microdosing that measures intratumor drug responses and anti-tumor immunity for six agents in parallel. This approach was combined with the

systemic administration of anti-PD1 treatment to examine whether immunogenic cell death (ICD) induced by a given drug potentiates the immunotherapy's anti-tumor effect. Local tumor response was measured by multiplex immunohistochemistry (IHC) and transcriptomic analyses. The study was performed in a humanized mouse model of a clear cell renal cancer, patient derived xenograft (PDX) RXF488. RXF488 was implanted subcutaneously in 30 NSG mice. Animals were stratified into 6 groups with n= 4-6. Humanization was performed by the intravenous injection of 5x10e6 human peripheral blood mononuclear cells prior to the first treatment. Systemic aPD1 treatment was applied in the presence and absence of the microdevice loaded with six different drugs. Control groups received the empty IMD in the presence or absence of PBMC. Several agents showed a significant increase in apoptosis induction when aPD1 was added: The largest increase was observed for the panRAF inhibitor LXH254, Sorafenib, Oxaliplatin and Doxorubicin. The increased efficacy from immunotherapy administration has a strong positive correlation with increased induction of ICD in the tumor microenvironment determined by CD11b, ICAM-1 and MHC-II expression: drugs that showed the highest increase in apoptosis when combined with aPD-1 showed an increased likelihood for markers associated with ICD, namely Oxaliplatin and LXH254. A transcriptomic analysis on the tumor tissue revealed nine different clusters. The implantation of the empty device modulated the expression data in a way that these samples clustered together and separate from the untreated tumor samples. Other clusters were defined by presence of absence of aPD1 and the different local treatments. A more focused analysis using a subset of 19 genes described to be predictive for ICD in solid cancer confirmed the activity of LXH254 but identified Sunitinib in combination with anti PD1 as another potential inducer of ICD. An induction of ICD by Oxaliplatin as indicated by the IHC results could not be confirmed by the expression data. Overall treatment arms the systemic treatment with anti-PD1 led to an increased expression of the above mentioned 19 genes. Our results demonstrate that local tumor response signatures of ICD can be used to systemically identify synergistic combinations of a range of drugs with immunotherapy on a tumor specific basis. A deeper dive into the transcriptomic data will help to identify other predictive biomarker for efficacy beyond ICD.

Combination therapy of immune checkpoint inhibitor and HIF1α/c-MET peptide vaccine suppresses metastasis by modulating tumor microenvironment in triple-negative breast cancer

JinHwa Hong, Jimin Lee, Soon Young Lim, Ju Won Kim, Ah Reum Lim, Kyong Hwa Park. *Korea University, Seoul, Korea, Republic of*

Triple-negative breast cancer (TNBC) accounts for 20% of all breast cancer and has limited therapeutic option except for immunotherapy because ER, PR, and HER2 targeted for treatment are absent. It also tends to be more aggressive meaning more likely to metastasize faster to other organs such as lungs, liver, and bone, and its recurrence rate is high which leads to a poor prognosis. Immunotherapy is an option to treat TNBC such as programmed death ligand 1 (PD-L1) antibody. However, tumor cells use various immune evasion mechanisms in addition to PD-1/PD-L1 pathway to interrupt the effect of immunotherapy. Moreover, tumor microenvironment (TME) is one of the important factors for the effective anti-tumor immune responses from immunotherapy. Hypoxia is a typical event in TNBC. Hypoxia inducible factor 1-alpha (HIF1α) is a transcription factor that regulates angiogenesis by expressing VEGF, and in addition, upregulates the c-MET which increases the proliferation, migration, and survival of tumor cells. Moreover, HIF1α directly regulates the expression of CD47. CD47 is a transmembrane protein that binds to SIRPα of macrophages to inhibit the phagocytosis of macrophages. Therefore, the efficacy of immune checkpoint inhibitors decreases even if there is a higher degree of tumor-infiltrating lymphocytes (TILs). Combination therapy with immune checkpoint and tumor associated antigens (TAAs) derived peptide vaccine could inhibit metastasis. In present study, we found that HIF1α/c-MET peptide vaccination delayed metastasis in C3(1)Tag mouse. We also investigated whether combination therapy with immune checkpoint inhibitors and peptide vaccine inhibited metastasis. Next, we observed that combination strategy of HIF1α/c-MET peptide vaccine and treated anti-PD-L1 antibody or/and anti-CD47 antibody was more effective in systemically inoculated M6 cells growth in C3(1)Tag mice. Immunohistochemical analysis of the tumors showed that the protein expression of CD47, HIF1α, and c-MET were significantly decreased. On the other hand, $CD4^+$ T cells, $CD8^+$ T cells and M1 macrophages increased, but M2 macrophages

decreased, resulting in delayed metastasis in combination therapy group compared to single therapy and control group. In addition, IFNγ ELISPOT showed that peptide vaccination significantly increased the HIF1α/c-MET specific IFNγ-secreting T cell response in splenocytes. We also assessed osteoclastogenesis in bones, which showed reduction of osteoclast in combination therapy group compared to single therapy and control group.Taken together, combination therapy with immune checkpoint inhibitor targeting PD-L1 and CD47 and peptide vaccine appears to be a promising strategy that inhibit metastasis by modulating tumor microenvironment in triple negative breast cancer.

MDSC-targeted TFF2-MSA synergizes with PD-1 blockade therapy in diffuse-type gastric cancer

Jin Qian[1], Sandra Ryeom[1], Bruce Daugherty[2], Seth Lederman[2], Timothy C. Wang[1]. *[1]Columbia University Irving Medical Center, New York, NY,[2]Tonix Pharmaceuticals, Inc., New York, NY*

Aims: Recent studies revealed myeloid-derived suppressor cell (MDSC) in the tumor microenvironment as an appealing therapeutic target to sensitize intestinal-type gastric cancer (GC) to PD-1 blockade therapy. However, whether MDSC inhibition can improve survival in the more aggressive diffuse-type GC is unknown. Trefoil factor family 2 (TFF2), a secreted anti-inflammatory peptide, suppresses MDSC expansion partly via CXCR4 receptor. Here, we developed a novel MDSC-targeted peptide TFF2-MSA and investigated whether it can synergize with anti-PD1 to prolong survival in syngeneic diffuse GC mouse models.
Methods: Murine serum albumin (MSA) was appended to the murine TFF2 to generate TFF2-MSA peptide with an extended serum half-life. ACKP (Atp4b-Cre; Cdh1-/-; LSL-KrasG12D; Trp53-/-) GC cells developed from a highly malignant diffuse GC mouse model were grafted subcutaneously into HDC-GFP transgenic mice in which the more immunosuppressive histidine decarboxylase (HDC)-expressing myeloid cells were traced with GFP. These recipient mice subsequently received either TFF2-MSA or anti-PD-1 antibody or both. Further, to assess treatment efficacy in inhibiting spontaneous lung metastasis, subcutaneous flank tumors were resected in ACKP cell-grafted mice once tumors reached 500 mm^3, and mice then

received treatment with TFF2-MSA or anti-PD-1 or the combination. At the endpoint, flow cytometry and histopathological analyses were performed to examine immune profiles and tumor metastasis. In another model, ACKP-luc cells were implanted orthotopically to stomach submucosa, and recipient mice received the same treatments started from 1 week later to assess their efficacy.
Results: While either TFF2-MSA or PD-1 antibody showed little benefit as a single agent (TGI 15% and 25% respectively, $p>0.05$), their combination dramatically suppressed ACKP s.c. tumor growth (TGI 78%, $p<0.0001$) and markedly prolonged median survival (64 days vs. 32.5 days in control) of host mice in a synergistic manner. The combination therapy efficiently reduced HDC-GFP$^+$ MDSCs (by 67% vs. control, $p<0.01$), and profoundly increased tumor-infiltrating cytotoxic CD8$^+$ T cells (by 18 fold, $p<0.001$). Further, while standard chemotherapy (5-fluorouracil and oxaliplatin) showed limited efficacy in this model, addition of chemotherapy to the TFF2-MSA/PD-1 antibody combination further improved treatment efficacy (TGI 91%) and extended median survival to 73 days. In addition, combination of TFF2-MSA/PD-1 antibody significantly reduced 80% lung metastasis (vs. control, $p<0.0001$), in contrast to minimal inhibition observed with either monotherapy ($p>0.05$). Finally, in the orthotopic model, the combo regimen eradicated GC in 50% mice compared to 0% in either monotherapy treatment.
Conclusion: Targeting MDSCs using TFF2-MSA synergizes with PD-1 blockade therapy in advanced and metastatic syngeneic mouse models of diffuse-type GC.

Small molecule Bax activator enhances immunotherapy against lung cancer
Abu Syed Md Anisuzzaman, Muhammad Waliul Talukdar, Xingming Deng.
Emory University, Atlanta, GA

Induction of apoptosis is a critical mechanism underlying the durable efficacy of cancer treatment agents. Bax is a major proapoptotic protein whose activation is required for apoptotic cell death. We have recently discovered that small molecule Bax activator CYD-2-11 targets the S184 structural pocket in the c-terminal tail of Bax, directly activates its

proapoptotic activity via conformational change and formation of Bax homo-oligomers in mitochondrial membranes. CYD-2-11 has potent anti-tumor activity against lung cancer in various animal models. Here we found that CYD-2-11 in combination with radiation, cisplatin or BH3 mimetic Bcl2 inhibitor venetoclax (ABT-199) synergistically suppressed tumor growth in non-small cell lung cancer (NSCLC) xenograft models. It is known that LKB1 mutations or deficiency are associated with therapeutic resistance to PD-1/PD-L1 checkpoint blockade immunotherapy. To test whether Bax activator CYD-2-11 reverses resistance to immunotherapy in immunologically "cold" genetically engineered LSL-KRAS^{G12D} LKB1 $^{fl/fl}$ (KL) mouse model, KL mice were treated with CYD-2-11, PD-L1 antibody or in combination. Results indicate that PD-L1 antibody alone has no significant anti-tumor effect in KL mice. CYD-2-11 alone can reduce tumor burden, but combination of CYD-2-11 with PD-L1 antibody has very strong synergistic effect and produces maximum efficacy in tumor burden reduction and significantly prolongs survival of KL mice. Mechanistically, combined treatment with CYD-2-11 and PD-L1 antibody enhances T cell infiltration in tumor tissues. These findings provide preclinical evidence for pharmacologic combinations of small molecule Bax activator with chemoradiotherapy, Bcl-2 inhibitor or PD-L1 antibody as novel strategies to treat lung cancer more effectively.

TU2218, a dual inhibitor against ALK5/VEGFR2, increases anti-CTLA4 antitumor efficacy in syngeneic tumor models

Nam-Hoon Kim, Jihyun Lee, Hun-Taek Kim. *TiumBio, Seongnam-si, Korea, Republic of*

The combination of pembrolizumab with low-dose ipilimumab shows substantial antitumor activity and manageable profile of toxicity in anti-PD-(L)1 antibody failure-setting (NCT02743819). This suggests a breakthrough for the absence of treatment option after relapsed/refractory anti-PD-(L)1 therapy. Accordingly, the anti-CTLA4 drug-based combination can be considered as a promising strategy for beneficial outcomes against resistance acquired from immunotherapy. Herein, we demonstrate that TU2218, a *first-in-class*, orally available inhibitor against ALK5 and VEGFR2, showed synergistic antitumor efficacy when combined with an

anti-CTLA4 antibody in preclinical tumor models which is being accompanied by increasing ratio of CD8 T cell to regulatory T cell and enhanced immunological memory. In this work, antitumor efficacy of TU2218 combination with an anti-CTLA4 antibody was assessed with CT26-, 4T1-, B16F10- and WEHI-164-bearing mice. In the CT26 model, the combination of TU2218 with an anti-CTLA4 antibody significantly inhibited tumor growth up to 92% compared to vehicle, thus being superior to single treatments (e.g., tumor growth inhibition (TGI) 46% for TU2218, TGI 74% for anti-CTLA4). In this combination group, the complete regression (CR) rate was 75 % (i.e., six cases among eight mice), while single treatments showed lower CR rates (e.g., CR 10% (1/10) for TU2218, CR 30% (3/10) for anti-CTLA4). Meanwhile, the role of CD8+ T cell in antitumor activity was elucidated by *in vivo* depleting CD8+ T cell in mice treated with combination therapy. The depletion of CD8+ T cells reduced the antitumor response, which suggests the indispensable role of CD8+ T cells in the antitumor efficacy of TU2218 and anti-CTLA-4 antibody combination. In addition, the long-term immune-memory was evaluated by re-implanting tumor cells into both mice cured by combination therapy and age-matched tumor-naïve mice. In this case, 6 mice cured of original implantation with CT26 tumors showed complete resistance to the re-implantation of CT26 cells during an untreated period for 21 days, whereas all age-matched tumor-naïve mice have developed tumors after 10 days from cell-transplants. Importantly, we could confirm the positive correlation between the immunological memory-response of combination therapy and the increasing rate of effector memory CD4+ and CD8+ T cells in spleens compared to those of age-matched group. In 4T1-, B16F10- and WEHI-164-bearing mice, combination of TU2218 with an anti-CTLA4 antibody led to higher CR rate as well as enhanced inhibition of tumor growth. Overall, our findings showed that TU2218 plays multifaceted roles in inducing immune activation under combination with an anti-CTLA4 antibody, which may be attributed to the increased ratio of cytotoxic CD8 T cell to regulatory T cell and improvement of adaptive immunity with long-term immunological memory.

Potentiating immunogenicity of PD1 blockage with metronomic Oral CAPOX for local and liver metastasized colorectal cancer

Seong Jin Park, Seho Kweon, Moyo Knowledge Mudhibadhi, Ha Rin Kim, Youngro Byun. *Seoul National University College of Pharmacy, Seoul, Korea, Republic of*

Since the appearance of oxaliplatin, FOLFOX therapy is positioned as the standard of care for colorectal cancer (CRC). And after the advent of capecitabine, an oral prodrug of 5-FU, both FOLFOX and CAPOX remain the first-line treatment for local and advanced CRC. Even though oral 5-FU prodrug has approved more than two decades ago, orally available oxaliplatin has not been developed yet. Oral chemotherapy has garnered attention in the era of cancer immunotherapy because oral form of the therapy makes metronomic therapy feasible. In this regard, we invented orally absorbable oxaliplatin exploiting complexation with bile acid moiety. The invention encouraged to expand the dosing of combination treatment of 5-FU and oxaliplatin, the most established chemotherapy combination of CRC, into metronomic scheduling. Oral CAPOX therapy is developed to administrate 5-FU and oxaliplatin combination (FOX) metronomically for chemo-immunotherapy. Metronomic dosage successfully induced immunogenic cancer cell death in colorectal cancer xenograft mouse model not exerting toxicity to other organs abolishing immune suppressive effect of chemotherapy. Oral CAPOX boosted tumor immunity translating immune microenvironment. Immune cell population and activation was analyzed using flow cytometry. Suppressive immune cell population decreased after Oral CAPOX treatment. Especially, immune-suppressive macrophage population diminished. Macrophages became immunogenic and presented antigen more frequently. Improved tumor microenvironment combined with anti-PD1 treatment activated and proliferated T cells locally and systemically. Oral CAPOX and anti-PD1 combination therapy activated cytotoxic T cell in tumor tissue and tumor draining lymph node. This therapy also activated NK cells systemically. Oral CAPOX and anti-PD1 combination treatment regressed established tumor completely in more than 90% of the mouse showing its capacity for clinical usage. Liver is the region which makes CRC least immunogenic among metastatic site and the organ CRC is metastasized most abundantly. Immuno-suppresive macrophage in liver is known for the factor discriminating liver metastasized CRC from other organs metastasized one suppressing T cells. Because Oral CAPOX therapy converts macrophage more immunogenic,

Oral CAPOX therapy could reverse immunosuppressive tumor microenvironment of liver metastasized colorectal cancer. Oral CAPOX and anti-PD1 combination is treated liver metastasized CRC model and showed standing out antitumor efficacy, and T cell activation.

#5092

Non-IL-2 blocking Treg-depleting anti-human CD25 mAb primes potent anti-tumor immunity and synergizes anti-tumor effects of anti-PD-1 in a novel hIL-2RA knockin model

Daniel He. *Shanghai Model Organisms Center, Inc., Shanghai, China*

The therapeutic effects for cancer immunotherapy are largely hampered by intratumoral $CD4^+CD25^+$ regulatory T cells (Tregs) which leads to poor outcome in many cancer patients upon treatment of immune checkpoint inhibitors. Moreover, the balance between effector T (Teff) cells and Treg cells in the tumor microenvironment (TME) impacts on tumor progression and anti-tumor immunity. Depleting tumor-infiltrating Tregs by selectively targeting CD25 to reduce the ratios of regulatory to effector T cells (Treg/Teff) without disturbing IL-2 signalling is a promising strategy to advance anti-tumor immunity. Hence, we evaluated the in vivo anti-tumor effects of Non-IL-2 blocking Treg-depleting anti-hCD25 mAb versus IL-2-blocking anti-hCD25 mAb (Basiliximab) in an engineered hCD25 (IL-2RA) knockin mouse model.Firstly, we developed the genetically engineered CD25 (IL-2RA) humanized mouse model by ES cell targeting, in which mouse Cd25 exons 2-6 are replaced by human counterparts corresponding to the extracellular domain leaving the intracellular regions intact. Then, we performed flow cytometry analysis to confirm the surface expression of hCD25 on naive Treg cell from peripheral blood and spleen in homozygous hCD25 knockin mice. In addition, we found the hCD25 expression is upregulated on activated Treg cell derived from splenocytes for both heterozygous and homozygous hCD25 knockin mice. Furthermore, the female homozygous hCD25 knockin mice subcutaneously engrafted with MC38 syngeneic tumors received two different therapeutic anti-CD25 mAb treatment in parallel and we found the Non-IL-2 blocking Treg-depleting anti-human CD25 mAb (anti-$hCD25^{NB}$) displayed more potent anti-tumor response compared to IL-2-blocking Treg-depleting anti-human CD25 mAb (anti-$hCD25^{BL}$), supporting that keeping IL-2 signaling on

effector T cells are required to enhance effector activation and anti-tumor immunity. Notably, the study groups treated with anti-hCD25^{NB} plus anti-mPD-1 showed synergistic therapeutic effects as expected. As a matter of fact, both CD4$^+$CD25$^+$ T cells and CD4$^+$CD25$^+$FoxP3$^+$ Treg cells reduced significantly upon treatment of anti-hCD25^{NB} and anti-hCD25^{BL} in spleen and tumors, but no big change in the number of CD4$^+$FoxP3$^+$ Treg cells.Likewise, anti-hCD25^{NB} in combination with anti-mPD-1 leads to more significant CD4$^+$CD25$^+$ Treg depletion in spleen and tumors along with increased CD8$^+$Granzyme B$^+$ cytotoxic T cells.Collectively, our CD25 (IL-2RA) humanized mouse provides a powerful model to assess the in vivo preclinical therapeutic effects of CD25$^+$ Treg-depleting antibodies for cancer immunotherapy.

Chemically inducible splice-neoantigens for cancer immunotherapy

Shingo Matsushima[1], Masahiko Ajiro[1], Kei Iida[2], Kenji Chamoto[1], Tasuku Honjo[1], Masatoshi Hagiwara[1]. *[1]Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[2]Kindai Univ. Faculty of Science and Engineering, Osaka, Japan*

Although immune checkpoint blockade therapies have dramatically improved the survival rate of patients with cancer compared with other treatment approaches, a substantial number of patients show poor response or resistance to these therapies. Meta-analyses for programmed cell death 1 (PD-1) blockade responses highlight the importance of neoantigens, derived from non-synonymous mutations in cancer cells, for antitumor immune responses. Intriguingly, recent transcriptome and genomics studies predict the presence of putative neoantigens as a result of an irregular pre-mRNA splicing regulation in cancer cells, indicating that alterations in RNA splicing in cancer cells might induce antitumor immune responses. Here, we report that induction of serine/arginine-rich splicing factor (SRSF)-dependent splicing boosts the production of splicing-associated neoantigens (splice-neoantigens) and potentiates the response to PD-1 blockade. Administration of a synthetic SRSF activator RECTAS suppressed tumor growth in a host CD8$^+$ T cell- and tumor major histocompatibility complex class I-dependent manner and promoted the antitumor effect of anti-PD-L1

antibody without detectable autoimmunity. Subsequent transcriptome analysis and validation for immunogenicity identified six splice-neoantigen candidates whose expression was induced by RECTAS treatment. Importantly, vaccination of the identified neoepitopes elicited T cell responses capable of killing cancer cells in vitro, in addition to suppression of tumor growth in vivo upon sensitization with RECTAS. Collectively, these results provide support for the further development of splice variant-inducing treatments for cancer immunotherapy.

B7-H3 blockade in combination with natural killer cell activity enhancers including NKTR-255 and venetoclax synergistically induces cytotoxicity in B7-H3+ AML cells

Anudishi Tyagi[1], A. Mario Marcondes[2], Willem Overwijk[2], Venkata Lokesh Battula[3]. *[1]Department of Leukemia, UT MD Anderson Cancer Center, Houston, TX,[2]Nektar Therapeutics, San Francisco, CA,[3]UT MD Anderson Cancer Center, Houston, TX*

Background: Acute myeloid leukemia (AML) is characterized by clonal proliferation of malignant myeloid blasts in the bone marrow. We have recently reported that blocking B7-H3 using a novel monoclonal antibody (mAB), T-1A5 enhances natural killer (NK) cell mediated cytotoxicity against AML cells. IL-15 is an essential component for NK cell activity. Recombinant human IL-15 (rIL-15), however, degrades rapidly and therefore may provide a suboptimal stimulus to NK cells. Studies have shown that BCL2 inhibitor, venetoclax (ABT-199), enhances NK cell induced antibody dependent cellular cytotoxicity (ADCC) against cancer cells. However, the combined effect of B7-H3 blocking and BCL2 inhibition remains unexplored in AML. We hypothesized that blocking B7-H3 using T-1A5 in the presence of novel investigational polymer-engineered IL-15 receptor agonist, NKTR-255, and the BCL2 inhibitor synergistically induces NK cell mediated ADCC in AML cells.
Methods: CD16 and NKG2D activation markers measured by flow cytometry in AML patient and healthy donor derived NK cells. The NKTR-255 was used to generate NK cells, and their cytotoxicity was compared to

that of NK cells generated with rIL-15 using IncuCyte. To investigate these NK cells' cytotoxic activity against AML cells, we treated B7-H3$^+$ AML cell lines (OCI-AML3 and MV4-11) with anti-B7-H3 chimeric mAb ChT-1A5 in the presence and absence of NK cells generated using NKTR-255 or rIL-15. To assess the potential synergy of BCL2 and B7-H3 in NK cell mediated anti-leukemic activity against AML cells, we treated B7-H3$^+$ cells with T-1A5 with or without ABT-199in the presence or absence of NK cells.
Results: The expression of NK cell activation markers were significantly lower in NK cells derived from AML patients than healthy donors. To assess the effect of NKTR-255 on NK cell activity, we generated NK cells using NKTR-255 and compared them with NK cells generated using rIL-15 using the standard 14-day culture protocol. We observed similar proliferation and NK cell numbers between NKTR-255 and rIL-15. However, NK cells stimulated with NKTR-255 showed significantly enhanced (more than 2-fold) cytolytic activity against B7-H3$^+$ AML cell lines compared with NK cells stimulated with rIL-15. Moreover, when combined with ChT-1A5, NKTR-255 significantly enhanced NK cell mediated ADCC activity in B7-H3$^+$ AML cells compared to rIL-15. Interestingly, we observed that the combination of T-1A5 and venetoclax synergistically induced an anti-leukemic effect in B7-H3$^+$ AML cell lines when compared with either drug alone or isotype IgG1 in a dose-dependent manner.
Conclusion: Our data demonstrate that blockade of the immune checkpoint protein, B7-H3 with the IL-15 receptor agonist, NKTR-255, or the BCL2 inhibitor, ABT-199, synergistically induces NK cell mediated cytotoxicity against B7-H3$^+$ AML cells.

#5099

Anti-tumor effect of DA-4505, a novel AhR antagonist as an immunotherapy in the tumor microenvironment

Daewon Cha, Dajeong Kim, Jongho Cho, Chaelim Ryu, Hyeon Uk Jeong, Dae Young Lee, Kyu-Hwan Kim, Sunghwa Kim, Jee-Heun Kim, Taedong Han, Hyounmie Doh. *Dong-A ST, Yongin-si, Korea, Republic of*

Aryl hydrocarbon receptor(AhR) is a ligand-dependent transcription factor that regulates the activity of innate and adaptive immune cells subsequent to

binding of numerous endogenous and exogenous ligands. Recently, kynurenine (Kyn), a tryptophan metabolite, has been identified as the most prominent endogenous ligand of AhR, which is constantly secreted into the tumor microenvironment by cancer cells via IDO1 and TDO2. As this secretion is known to cause a broad immunosuppression, AhR is considered to be a central mediator of suppressing immune responses, thereof, a novel target for cancer immunotherapy. In this study, we have discovered a novel small molecule AhR antagonist, DA-4505, and investigated whether it can pursue the restoration of functionally suppressed immune cells in the tumor microenvironment, then, achieve a consequent anti-tumor effect specifically via altering various aspects of tumor microenvironment. DA-4505, AhR antagonist, exhibited high potency (IC50=3 nM) and showed comparable antagonism to Compound B (an AhR antagonist drug candidate being studied in the clinical phase) in both human and mouse hepatocytes. Furthermore, DA-4505 showed superior alleviating activity on benzo[a]pyrene and 2,3,7,8-tetrachlordibenzodioxin (TCDD, an AhR ligand) induced CYP1A1 mRNA level compared to Compound B in mouse livers. Similarly, DA-4505 treatment presented comparable or even better recovery effect on TNF production under Kyn-induced immunosuppressive condition in monocytes of mouse and human compared to Compound B. DA-4505 dose-dependently enhanced activation of human CD8+ T cells comparable to Compound B and rescued IL-2 and IFNγ production under Kyn treated condition. Moreover, DA-4505 specifically polarized macrophages towards inflammatory macrophage phenotype (M1).Oral administration of DA-4505 induced a significant tumor growth inhibition in several murine syngeneic mouse models and was synergistic in combination with anti-PD1 antibody. DA-4505 enhanced the infiltration of M1-macrophage and CD8+ T cells while suppressed the infiltration of M2-macrophage and Treg, thus, presenting anti-tumor effect. Specifically, we confirmed that the anti-tumor effect of DA-4505 is CD8+ T cell-dependent by CD8+ T cell depleted MC38 mouse model. Taken together, our result showed that DA-4505, AhR antagonist, presented its anti-tumor effects in two distinctive but cooperative way into some extent. Firstly, DA-4505 activated stimulatory immune cells such as monocytes, dendritic cells (DC) and effector T cells. Secondly, DA-4505 reduced the immunosuppressive mechanisms by regulating Treg and M2-macrophage. Thus, our data demonstrate the potential of AhR as a promising therapeutic target for

cancer immunotherapy as well as proposing DA-4505 as a novel therapeutic agent for both mono and aPD-1 combinatory therapeutic scheme.

#5100

Combination of κλ bispecific antibodies targeting innate (CEAxCD47, NILK-2401) and adaptive immunity (CEAxCD3, NILK-2301 and CEAxCD28, NILK-3301) for next generation immunotherapy of CEA-expressing cancers

Anja Seckinger[1], Lise Nouveau[2], Sara Majocchi[2], Valéry Moine[2], Vanessa Buatois[2], Bruno Daubeuf[2], Franck Gueneau[2], Ulla Ravn[2], Krzysztof Masternak[2], Yves Poitevin[2], Emeline Rousset[2], Giovanni Magistrelli[2], Pauline Malinge[2], Limin Shang[2], Nicolas Fischer[2], Klaus Strein[1], Walter Ferlin[2], Dirk Hose[1]. *[1]LamKap Bio Group, Pfäffikon, Switzerland,[2]Light Chain Bioscience - Novimmune SA, Geneva, Switzerland*

Background: The CEAxCD3 bispecific antibody (bsAb) NILK-2301 couples CEA (CEACAM5) on cancer cells and CD3 on T-cells inducing T-cell activation (signal 1) and tumor cell killing (TDCC). T-cell activation can be boosted by CEA-targeted CD28-costimulation (NILK-3301; signal 2). NILK-2401, carrying a fully effective IgG1 Fc, induces antibody-dependent phagocytosis (ADCP) and antibody-dependent cytotoxicity (ADCC) of tumor cells by co-targeting CEA and the innate immune checkpoint CD47 (“don’t eat me” signal). We present here next generation immunotherapy to overcome limited single class activity in CEA-expressing solid cancers.

Methods: BsAbs were generated using LCB’s fully human κλ body platform. TDCC, ADCP, and ADCC with human PBMC or monocyte-derived macrophages were assessed using CEA+ colorectal (n=3), lung (n=2), and gastric (n=2) cancer lines. Combination activity of NILK-2401 + NILK-2301 (± NILK-3301) was assessed by flow cytometry. In vivo activity was tested in xenograft NOG or NSG/human PMBC-, HIS-, and hSIRPα/hCD47/hCD3/hCD28 transgenic mice. Safety data include binding to other CEACAMs, cytokine release in whole blood, erythrophagocytosis, platelet activation, exclusion of superagonism (NILK-3301), as well as PK- and tolerability in cynomolgus monkeys and Tg32-mice.

Results: NILK-2301 induced dose-dependent killing of all tested cell lines, which was also visualized by live cell imaging. Combination of NILK-2301 (1 nM) + NILK-3301 vs. NILK-2301 alone (10 nM) increased TDCC (3-8-fold), T-cell activation (CD25, CD69, HLA-DR), cytokine secretion (interferon-γ, granzyme B, perforin), and CD4+/CD8+ T-cell proliferation. NILK-2401 blocked CD47-SIRPα interaction and induced ADCP/ADCC-mediated elimination of all cell lines. NILK-2301 + NILK-2401 treatment increased maximum activity (Emax) and reduced necessary dose of the T-cell bsAb to reach Emax. E.g., Emax of 30% killing (NILK-2301 alone) was increased in combination with NILK-2401 at 0.1/1/10 µg/mL to 40%, 80%, and 80%. *In vivo,* NILK-2301 (10 mg/kg IV, BIW) decreased tumor progression. NILK-2301/-3301 combination induced tumor regression in 8/8 mice. NILK-2401 delayed tumor growth vs. mean of control in 100% (15/15) of mice and prevented establishment of detectable tumors (>50mm^3) in 53% (8/15). Results of double and quadruple transgenic mice, including triple bsAb combinations, will be presented at the meeting. No relevant safety signals were detected.
Conclusions: NILK-2301 and NILK-2401 are active as single agents. Addition of NILK-2401 or NILK-3301 to NILK-2301 significantly increases activity, already at 10 -100x lower CEAxCD3 doses. GMP drug substance has been produced for NILK-2301 and NILK-2401. Generation of the clonal cell line for NILK-3301 clinical material production is ongoing.

Inhibition of Notch reverses immunosuppression in basal-like breast cancer
Qiang Shen, Kiichi Murakami, Pamela Ohashi, Michael Reedijk. *UHN Princess Margaret Cancer Centre, Toronto, ON, Canada*

Aberrant Notch activation is a defining feature of basal-like breast cancer (BLBC), which has poor prognosis compared to other breast cancer molecular subtypes. Despite the clinical success of immune checkpoint blockade (ICB) in many malignancies including melanoma and small cell lung cancer, ICB has failed to demonstrate similar response in BLBCs, where most cases are highly infiltrated by tumor-associated macrophages (TAMs). There is increasing evidence that Notch is decisive in regulating

intercellular communication in the tumor immune microenvironment (TIME). This includes the recruitment of TAMs which contribute to an immunosuppressive TIME, illuminating the potential of Notch-inhibition as adjuvant immunotherapy in BLBC. To examine the immune phenotype and therapeutic response of BLBC to combined Notch-inhibition and ICB, we employed an *in vivo* tumorgraft model using murine basal-like mammary tumor 4T1 cells. Briefly, tumor cells were orthotopically injected into the mammary fat pads of BALB/c mice. Using a crossover design, mice were randomly allocated to treatment with either Notch inhibitor (γ-secretase inhibitor, LY411575), anti-PD1 (RMP1-14), or control treatment for 12-days (stage-1), followed by randomization to a second 12-day period (stage 2) with the same, or one of the other treatments. Results: Despite the low response rate of BLBC to ICB alone, Notch inhibition reduced TAMs and induced responsiveness to sequential ICB. This response was characterized by increased cytotoxic T lymphocytes (GrB+, CTL) infiltration of the primary tumor. Similar results were observed when Notch-regulated cytokines (IL-1β and CCL2), crucial to TAM recruitment, were inhibited. Moreover, a more impressive therapeutic effect of sequential treatment was observed in lung metastasis, whereby TAM depletion and increased CTL infiltration were accompanied with near-complete abolition of metastases. Mechanistically, tumor cell Notch signaling upregulates a group of circulating cytokines including IL-1β and CCL2, which prime the lung for metastases. Additionally, compared to primary tumor cells, PD ligand 1 is up-regulated in lung metastases, rendering them profoundly sensitive to sequential ICB treatment. These findings highlight the potential of sequential Notch inhibition and ICB as a novel immunotherapeutic strategy in BLBC.

Developing CYNK-001-derived exosomes to deliver TGF-β siRNA for GBM immunotherapy enhancement

Marina Gergues, Veronica Farag, Alex Hariri, Qian Ye, Yuechao Zhao, Lin Kang, Robert Hariri, Shawn He. *Celularity Inc., Florham Park, NJ*

Introduction: Glioblastoma Multiforme (GBM) is the most aggressive brain malignancy in adults, where the 5-year survival rate is less than 10%. Celularity Inc. has developed an allogenic, off-the-shelf and cryopreserved

human placental $CD34^+$ derived natural killer (CYNK-001) cell therapy as potential treatment for GBM. NK cell-derived exosomes are notable for their anti-tumor activity. Exosomes have been demonstrated their ability to pass through blood-brain barrier in vivo. We hypothesized that engineering exosomes to deliver TGF-β short interfering RNA (siRNA) would reduce TFG-β expression, thus enhance the anti-tumor activity of CYNK-001 against GBM cells. This study aims to investigate if (i) CYNK-001-derived exosomes (CYNK-Exo) have anti-tumor effects against GBM, (ii) CYNK-Exo loaded with TGF-β siRNA (siCYNK-Exo) can effectively knockdown TGF-β expression in tumor cells, and (iii) siCYNK-Exo and CYNK-001 have a synergistic effect against GBM cells.
Methods: CYNK-Exo were isolated from CYNK-001 conditioned media by one-step sucrose cushion ultracentrifugation and characterized by nano-tracking analysis (NTA) and on-bead flow cytometry. Cytotoxicity of CYNK-Exo against tumor cells was measured by real-time impedance-based xCELLigence assay. To measure uptake of siRNA, Cy3-tagged siRNA was loaded into CYNK-Exo and quantified by flow cytometry. Knockdown of TGF-β was measured by RT-qPCR and ELISA.
Results: CYNK-Exo showed a median size of 117.4 nm by NTA and expressed the exosomal-characteristic CD9 and CD81, as well as NK cell-characteristic CD56, CD226 and CD11a biomarkers. CYNK-Exo displayed cytotoxicity against GBM cell line U251 in a time- and dose- dependent manner. U251 cells treated with siCYNK-Exo showed efficient uptake with 97.7% $Cy3^+$ cells. RT-qPCR results demonstrated 78.6% reduction in TGF-β mRNA expression and ELISA results demonstrated 71.8% reduction in TGF-β secretion. Similar findings were demonstrated on LN-229 GBM cell line. To test if knocking down TGF-β could reduce tumor immunosuppression, U251 cells were treated with siCYNK-Exo followed by CYNK-001. Enhanced cytotoxicity against U251 was demonstrated with combination treatment when compared to that with CYNK-001 alone: 73.9% vs. 36.5% respectively. Compared to CYNK-001 alone, combination siCYNK-Exo and CYNK-001 treatment not only increased the secretion of the proinflammatory cytokines GM-CSF, IFN-γ, and TNF-α by CYNK-001 cells, but also enhanced the production of perforin, granzyme A and granzyme B, which are typically inhibited in NK cells by TGF-β.
Conclusion: Our results demonstrated anti-tumor activity of CYNK-Exo against GBM cells; efficient TGF-β knockdown in GBM cells by siCYNK-

Exo; and synergistic anti-tumor activity of
TGF-β siCYNK-Exo in combination with CYNK-001 against GBM cells. Our data support a potential combination therapy using CYNK-001 and TGF-β siCYNK-Exo for GBM treatment.

Targeting IL-1B synergizes with PD-1 blockade for enhanced T and B cell immune responses and inhibition of early lung cancer development

Warapen Treekitkarnmongkol[1], Guangchun Han[1], Zahraa Rahal[1], Jiping Feng[1], Ansam Sinjab[1], Tina Cascone[1], Christopher S. Stevenson[2], Cheryl Sweeney[2], Matt Edwards[2], Avrum Spira[2], Junya Fujimoto[1], Seyed Javad Moghaddam[1], Linghua Wang[1], Humam Kadara[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Lung Cancer Initiative at Johnson and Johnson, Boston, MA*

Early immunotherapy with inhibitors of immune checkpoints such as PD-1 has revolutionized lung adenocarcinoma (LUAD) treatment. Still, many patients do not respond or relapse following PD-1 blockade. Tumor-promoting inflammation, such as that mediated by the pleiotropic cytokine interleukin 1 beta (IL-1B), fosters immunosuppression in the tumor immune microenvironment (TIME). Our group and others showed that IL-1B blockade inhibits lung cancer development. We thus hypothesized that addition of IL-1B blockade to anti-PD-1 treatment may enhance outcomes against LUAD. Using a human-relevant, tobacco-associated, mouse model of LUAD development, we compared the effects of combined PD-1 and IL-1B blockade relative to treatment with single-agents (anti-IL-1B or anti-PD-1) and control antibody on early lung tumor development and the TIME. Drugs (anti-PD-1 + anti-IL-1B, anti-PD-1, anti-IL-1B, control IgG) were administered at end of exposure to the tobacco-specific carcinogen NNK, to evaluate effects on formation of early lesions (preventive), or at 3 months post-NNK (prophylactic) to interrogate LUAD development (8 groups). Comprehensive interrogation of the lung ecosystem and the TIME was performed using deep single-cell RNA-sequencing (scRNA-seq) analysis in a subset of the mice (n = 3 to 4) from each of the 8 groups (n = 31 total; 143,897 cells after stringent quality control). Mice treated with combined PD-1 and IL-1B blockade displayed reduced development of lung tumors when compared to animals treated with anti-IL-1B, anti-PD-1, or control

antibodies. Fractions of cytotoxic *Cd8*+ T cells were conspicuously higher and those of tumor cells and exhausted *Cd8*+ T cells evidently lower in lungs of mice treated with combined PD-1 and IL-1B blockade relative to monotherapy- or control antibody-treated animals. *Igha*+ plasma cells were strikingly highest in lungs of mice treated with combined PD-1 and IL-1B blockade and nearly absent in monotherapy- and control-treated groups. Lungs of mice treated with combined PD-1 and IL-1B blockade showed higher fractions of *Cd80+/Cd86*+ memory B cells and, consistently, T follicular helper T cells, while exhibiting reduced fractions of naïve B and *Cd24a+/Tgfb1*+ B cells suggestive of enhanced activation of B cell responses by the combinatorial treatment. These effects were, overall, present, or much more pronounced, in animals that were prophylactically treated. Flow cytometry analysis of lung tissues and immune profiling of bronchioalveolar lavage fluid overall confirmed augmented immune cell responses by combined PD-1 and IL-1B blockade. Our findings show that blocking IL-1B synergizes with anti-PD-1 in regression of early tumor cells and reversal of immunosuppression. Combined blockade of PD-1 and IL-1B may be a promising strategy for early treatment of lung cancer that warrants further clinical studies.

TIMP1 mediates astrocyte-dependent local immunosuppression in brain metastasis

Neibla Priego[1], Pedro García-Gómez[1], Ana de Pablos-Aragoneses[1], María Perea-García[1], Laura Álvaro-Espinosa[1], Carolina Hernández-Oliver[1], Elena Martínez-Saez[2], Ángel Pérez-Núñez[3], Aurelio Hernández-Laín[3], Rebeca Sanz-Pamplona[4], Marc Schmitz[5], Stephen J. Crocker[6], Diego Serrano[7], Asís Palazón[8], RENACER Red Nacional de Metástasis Cerebral[1], Manuel Valiente[1]. *[1]Spanish National Cancer Research Ctr. (CNIO), Madrid, Spain,[2]Vall d´Hebron Hospital, Barcelona, Spain,[3]Hospital Universitario 12 de Octubre Research Institute, Madrid, Spain,[4]Aragon Health Research Institute (IISA), Zaragoza, Spain,[5]Faculty of Medicine Carl Gustav Carus, TU Dresden, Dresden, Germany,[6]University of Connecticut School of Medicine, Farmington, CT,[7]Applied Clinical Research (CIMA)-Navarra University, Navarra, Spain,[8]Cooperative Research in Biosciences (CIC BioGUNE) and Ikerbasque Basque Foundation for Science, Bilbao, Spain*

Brain metastasis is an unmet clinical need, affecting between 10-30% of cancer patients with 200000 to 400000 newly diagnosis per annum in the US. Recently, several clinical trials have reported benefits using immunotherapy to treat brain metastasis. However, variability of the responses is broad and high benefit is found mainly in asymptomatic brain metastasis, while the benefit is dramatically reduced in the clinically relevant stage. Thus, it is currently unknown how to effectively target symptomatic brain metastases with immunotherapy. We previously reported a clinically relevant protumoral program driven by STAT3 activation in a subpopulation of reactive astrocytes in these advanced stages of the disease. Our current study further exploited the heterogeneity within the metastasis-associated microenvironment as a resource to identify novel therapeutic vulnerabilities to improve the benefits of immunotherapies based on immune checkpoint blocking antibodies (ICB) in symptomatic brain metastasis.

Our results demonstrate that reactive astrocytes are strong immunomodulatory cells in brain tumors. We have identified the molecular profile of disease-associated glial cells and defined its connection to modulatory activities on specific lymphocyte populations in experimental brain metastasis as well as human-derived samples. scRNASeq and high content multiplex immunofluorescence allowed us to report a novel local immunomodulatory axis dependent on TIMP1 (astrocytes)/CD63 (CD8 T cells), which is present in brain metastasis patients with high immunoscore and would imply an additional immunosuppressive signal for potential ICB responders in brain metastasis.

Genetic and pharmacologic approaches targeting this STAT3-dependent local immunomodulatory axis have allowed us to define the rationale to combine immune checkpoint blockade with a STAT3 inhibitor, which we previously used in patients. We proved that such combined immunotherapy boost the systemic activation of T cells while also preventing the local blockade. Additionally, our comprehensive strategy includes the possibility to stratify patients that are best qualified to benefit from this therapy by measuring TIMP1 in liquid biopsies from CSF. Even more, our data using Patient Derived Organotypic Cultures (PDOC) from fresh brain metastasis neurosurgeries confirms that our therapeutic strategy might benefit brain metastases generated from any primary source.

In conclusion, we describe an immunosuppressive mechanism in the brain microenvironment that could explain the lack of response to ICB in patients with advanced brain metastasis. Our finding provides the rationale to implement complementary approaches targeting local immunosuppression to increase the benefit of immunotherapy in symptomatic brain metastasis.

Although IL-2 has been shown to critically mediate NK and T cell effector functions, when used in clinical trials this cytokine has failed due to toxicity and severe side effects of the systemic treatment. Our lab has investigated the use of a next-generation IL-2 compound, murine PD1-IL2v, which consists of an anti-PD-1 antibody fused to a IL2-variant with abolished binding to IL2Rα. Previous work shows this molecule results in tumor-antigen specific T cell expansion and differentiation towards immune effectors. Here, we report for the first time that radiation therapy amplifies the anti-tumor effect observed with PD1-IL2v treatment of murine orthotopic models of local tumor growth and metastasis. This anti-tumor effect is correlated with increases in proliferative and polyfunctional CD8 T cells across tumor, lymph node, and blood compartments. Furthermore, using an OVA-antigen specific orthotopic model, we found that radiation in combination with PD1-IL2v treatment enhances infiltration and activation of antigen-specific CD8 T cells, which have been shown to be critical for immunotherapy clinical success. A portion of tumor-bearing mice treated with radiation and PD1-IL2v fully eradicated their primary tumors and tumor rechallenges, which we show correlates with increased markers of memory in CD8 T cells of these mice. To demonstrate the clinical relevance of these preclinical findings, we performed RNA sequencing on paired

pancreatic adenocarcinoma (PDAC) patient tumor tissue samples prior to and following radiation. We observed enhanced IL2Rβ and IL2Rγ expression as well as IL2R signaling in PDAC-patient responders to radiation therapy compared to non-responders. In conclusion, the antigen-specific, lasting memory response to preclinical PDAC models demonstrated here provides rationale for the treatment of PDAC with a radiation and PD1-IL2v combination.

A novel AhR inhibitor 'DA-4505' improved the anti-cancer efficacy of surgical and chemotherapy via synergistic anti-tumor effects of aPD-1

DongKwon Kim[1], Sujeong Baek[2], Seung Min Yang[2], Yu Jin Han[2], Seong-san Kang[3], Chun-Bong Synn[1], Mi Hyun Kim[2], Heekyung Han[2], Kwangmin Na[2], Young Taek Kim[2], Sungwoo Lee[3], Taedong Han[4], Hyounmie Doh[4], Jongho Cho[4], Dajeong Kim[4], Daewon Cha[4], Jae Hwan Kim[2], Youngseon Byeon[2], Young Seob Kim[2], Mi Ran Yun[5], Ji Yun Lee[6], Jii Bum Lee[6], Chang Gon Kim[6], Min Hee Hong[6], Sun Min Lim[6], Byoung Chul Cho[6], Kyoung-Ho Pyo[5]. *[1]Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicinei University Inst. for Cancer Research, Seoul, Korea, Republic of,[2]Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]JEUK Institute for Cancer Research, JEUK Co., Ltd, Gumi, Korea, Republic of,[4]Dong-A ST Research Institute, Yongin, Korea, Republic of,[5]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[6]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of*

Background: The Aryl hydrocarbon receptor (AhR) is one of the most predominant regulators of cancer metabolism. The AhR exerts important immunosuppressive functions by activating Treg cells and myeloid-derived suppressor cells and repressing $CD8^+$ effector T cells. Here, we propose that a best-in-class AhR inhibitor, DA-4505, improves anti-tumor efficacy via modulation of tumor immune surveillance compared to BAY2416964, an AHR antagonist drug candidate being studied in the clinical phase.

Methods: To evaluate anti-tumor effects of DA-4505 and BAY2416964, the two AhR inhibitors were dosed at 10 mg/kg once daily alone or in combination with aPD-1 (10 mg/kg) in surgical and chemotherapy models, and a PDX model (YHIM2004). Tumor volume, relapse, and survival were evaluated, and immune profiles were analyzed with IHC, flow cytometry, and scRNAseq.
Results: A significant tumor reduction appeared in the CT26 and 4T1 tumor models after the DA-4505 treatment compared to vehicle group ($P<0.05$). In contrast, DA-4505 treatment did not induce significant tumor regression compared to vehicle group in tumor-bearing NOG mice, suggesting that anti-tumor effects of DA-4505 were driven by immunologic mechanisms. To evaluate the role of DA-4505 in conjunction with surgery, DA-4505 alone or in combination with anti-PD-1 was given prior to and following resection of the tumors in 4T1 tumor-bearing mice. Survival of mice treated with DA-4505 alone or DA-4505 combined with anti-PD-1 was significantly prolonged after resection compared to aPD-1 treatment group ($P<0.05$). In addition, there were four mice that did not have a relapse by treating DA-4505 with or without aPD-1 after surgery (4/5). A tumor regression also appeared in the YHIM2004-engrafted humanized mouse study. A tumor reduction was shown by treating DA-4505 alone or in combination with pembrolizumab compared to vehicle group ($P<0.05$). Next, we co-administered an AhR inhibitor and aPD-1 as a partner to improve the antitumor effects of chemotherapy. The DA-4505 add-on group showed tumor regression when compared with the combination therapy group treated with aPD-1 and chemotherapy ($P<0.0001$). In addition, a significant increase in survival rate was shown in the group treated with a DA-4505 add-on compared to vehicle group ($P<0.001$). Analysis of scRNAseq showed that M1 macrophage expressing CCL7 and CCL8 were increased in DA-4505 treated group compared to the vehicle and aPD-1 groups. This suggests that immune modulatory effect of DA-4505 may be due to enhanced recruitment of immune cells into the tumor site by macrophages with high chemotactic activity.
Conclusion: The AhR inhibitor DA-4505 demonstrated an improvement in anti-tumor efficacy. In addition, it has shown a synergistic effect when combined with aPD-1. Discoveries from this study provide a preclinical rationale for future clinical implications in solid tumor.

#5108

Overcoming roadblocks of immunotherapy in non-small cell lung cancer

Tanmoy Saha, Shiladitya Sengupta. *Harvard Medical School, Brigham and Women's Hoapital, Cambridge, MA*

Non-small cell lung cancer (NSCLC) is one of the major causes of cancer-related death worldwide. Immunotherapy has helped to increase the survival of NSCLC patients, but the therapeutic response is limited to 23-26% of patients. While many factors impact immunotherapy failure, we have focused on a few, (**a**) heterogeneous expression of immune checkpoints (ICs) limiting the use of single immune checkpoint inhibitor (ICI) for everyone, (**b**) additional ICs responsible for blocking innate immune system and lack of antigen presentation to the T cells, and (**c**) lack of rationally designed combination therapies.Commonly used immunotherapies for NSCLC block PD1-PDL1 interaction, but the majority of the NSCLC patient does not have high PDL1 expression indicating PD1-PDL1 as a subsidiary mode of immune evasion. So, it is necessary to include additional ICIs in order to achieve adequate objective response in all NSCLC patients. In order to investigate the immune checkpoint expression, we screened several NSCLC patient-derived tumor tissues, and only 33% of them showed high expression of PDL1, whereas 64.6% of patients had high CD47 expression. CD47, an innate immune regulator, is overexpressed in lung cancer cells and delivers an "*eat-me-not*" signal by binding to signal regulatory protein alpha (SIRPα) in macrophage resulting in diminishing phagocytosis and antigen presentation to the T cells.Combining anticancer drugs with immunotherapy agents has become a popular approach to achieve a less toxic and long-acting objective therapeutic response. Here, we introduce antibody conjugated drug loaded nanotherapeutics (ADNs) consisting of a targeted therapy drug, phosphatidylinositol 3-kinase (PI3K) inhibitor PI103, and decorated with two ICIs for CD47 and PDL1. The ADN particles have been designed based on classical liposomal supramolecular nanoparticles followed by surface functionalization by the specific antibody. The anti-CD47-PDL1-ADN has shown increased cellular internalization and delivery of PI103 than IgG-ADN and anti-PDL1-ADN. The anti-CD47-PDL1-ADN showed low hematotoxicity and higher cell-killing potency for the cancer cells. The bispecific anti-CD47-PDL1-ADNs can block PD1-PDL1 and SIRPα-CD47 immune checkpoint interaction, activating both the innate (macrophage) and adaptive (T cells) immune responses. Reduced tumor growth and higher survival probability have been observed in the syngeneic LLC tumor model for anti-CD47-PDL1-ADN than monotherapy and traditional immunotherapy.*In summary,* we have introduced a lung cancer treatment

strategy that can be an effective therapy for NSCLC patients, irrespective of the PDL1 expression level. The strategy combining bispecific immunotherapy and targeted therapy for activating the innate and adaptive immune systems and delivering targeted therapy drugs can emerge as a significant advance in the treatment of NSCLC patients.

The anti-PD1+anti-LAG3 and anti-CTLA4+anti-PD1 combinations have non-overlapping mechanisms of action in melanoma cranial and extra cranial metastases

Manali S. Phadke, Jiannong Li, Jessica Mandula, Ann Chen, Paulo C. Rodriguez, Keiran S. M. Smalley. *Moffitt Cancer Center, Tampa, FL*

Around 40-60% of patients with advanced melanoma develop brain metastases. Recent clinical studies have demonstrated that the efficacy of anti-PD1+anti-LAG3 may be equivalent to anti-PD1+anti-CTLA4. The goal of our project is to understand the mechanisms of action and resistance to anti-PD1+anti-LAG3 in mouse model of melanoma brain metastases. We used orthotopic syngeneic mouse model in which SM1 and B16100kVII2 cells are injected stereotactically into the brain and into the flank. The mice were treated with anti-PD1+anti-LAG3 and anti-PD1+anti-CTLA4 every 5 days. Single cell RNA-seq platform was used to determine the impact of both the combination therapies upon each individual cell type. Flow cytometry experiments were carried out to assess the percentage of immune cells recruitment. The *in vivo* studies demonstrated that the anti-PD1+anti-CTLA4 had similar efficacy to anti-PD1+anti-LAG3 at both cranial and extracranial sites over a period of 80 days in the SM1 model. In the less responsive B16100kVII2 model, anti-PD1+anti-LAG3 was initially less effective, but similar numbers of mice failed both each combination. scRNA-seq and IHC analysis of responding tumors showed that the anti-PD1+anti-LAG3 led to a greater accumulation of B cells, DCs, CD4+ T cells and different subsets of CD8+ T cells. Of note, the anti-PD1+anti-CTLA4 was associated with infiltration of Tregs, whereas the anti-PD1+anti-LAG3 was associated with CD4+ Th1 helper cells. Depletion of CD4+ T cells decreased responses to anti-PD1+anti-LAG3 in both the cranial and extracranial tumors, with no change in the magnitude of response to the anti-PD1+ anti-CTLA4. By contrast, depletion of CD8+ T

cells suppressed responses to both combinations. Depletion of CD4+ T cells decreased activated CD8+ T cells by 30% in anti-PD1+anti-LAG3 treated tumors and conversely increased numbers of activated CD8+ T cells by 40 % in anti-PD1+anti-CTLA4 tumors. In anti-PD1+ anti-LAG3 treated tumors, T helper function was directed towards CD8+ T cells and not B cells, with B cell depletion impacting responses to both combination immunotherapies in a similar manner. Analysis of relapsing brain tumors from both anti-PD1+anti-LAG3 treated mice showed an increased association of MDSCs and loss of tumor reactive CD8+ T cells. The anti-PD1+anti-LAG3+anti-CTLA4 triplet had a good efficacy and suppressed the growth of both flank and brain tumors over a period of 35 days, an effect associated with increased CD8+ T cell infiltration and reduced numbers of MDSCs and Tregs.We show that anti-PD1+anti-LAG3 can drive CD4+ Th1 T helper cell responses hence increasing the accumulation of effector CD8+ T cells and B cells in melanoma and melanoma brain metastases, improving the durability of response. The triplet combination maximizes the efficacy and duration of response in treatment of melanoma brain metastases.

Locally administered Interleukin-15 combined with cancer cell-targeted near-infrared photoimmunotherapy in a syngeneic mouse cancer model

Hiroshi Fukushima, Aki Furusawa, Takuya Kato, Seiichiro Takao, Shuhei Okuyama, Peter L. Choyke, Hisataka Kobayashi. *Molecular Imaging Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health (NIH), Bethesda, MD*

Near-infrared photoimmunotherapy (NIR-PIT) is a new anti-cancer treatment by NIR light-induced photochemical reactions within antibody-IRdye700DX conjugates, leading to significant immunogenic cell death. The efficacy of NIR-PIT is synergistically enhanced by combining immune activating agents including immune checkpoint inhibitors and cytokines. However, there are still needs for improving the efficacy of NIR-PIT. A recent study showed that cytokines could exert strong anti-cancer effects when administered locally. Interleukin-15 (IL-15) elicits immune responses that include the generation and persistence of cytotoxic T cells and natural

killer (NK) cells. Based on these findings, we hypothesized that local IL-15 administration combined with cancer cell-targeted NIR-PIT could be a highly effective therapy. The efficacy of IL-15 was evaluated by intratumorally or intraperitoneally injecting 5 μg of human IL-15 in C57BL/6 mice inoculated s.c. with murine colon cancer MC38 cells. Human IL-15-secreting MC38 (hIL-15-MC38) was constructed by introducing human IL-15-coding plasmids into MC38 cells and the efficacy of CD44-targeted NIR-PIT was compared in vitro and in vivo. The efficacy of intratumoral IL-15 injection combined with CD44-targeted NIR-PIT was also evaluated in MC38 tumor models. Moreover, bilateral tumor models were used to analyze whether local IL-15 administration combined with CD44-targeted NIT-PIT could induce abscopal effects in untreated tumors. Intratumoral IL-15 injection significantly suppressed tumor growth and induced immune activities compared with intraperitoneal injection. Both hIL-15-MC38 and parental MC38 cells had high CD44 expression on their cell surface and in vitro NIR-PIT induced rapid cell death in both two cell lines. When hIL-15-MC38 or MC38 tumor-bearing mice were treated with or without NIR-PIT, hIL-15-MC38 tumor-bearing mice treated with NIR-PIT showed the best tumor growth inhibition and survival. The hIL-15-MC38 tumors treated with NIR-PIT showed significant increases in the cell number/g tumor of CD8+ T cells, NK cells, and natural killer T cells, and significantly higher Granzyme B expression in these cells compared with the control MC38 tumors. Similar results were observed in vivo by intratumoral IL-15 injection combined with NIR-PIT. Moreover, in bilateral tumor models with right hIL-15-MC38 and left MC38 tumors, NIR-PIT against right hIL-15-MC38 tumors significantly suppressed the growth of left untreated MC38 tumors. In conclusion, local IL-15 administration combined with CD44-targeted NIR-PIT promoted anti-cancer immune responses, resulting in the inhibition of growth of treated tumors, longer survival of mice, and abscopal effects in untreated tumors. Thus, locally administered IL-15 is a promising anti-cancer therapy in combination with cancer cell-targeted NIR-PIT.

#5111

VentX-modulated tumor associated macrophages revert immune suppression in tumor microenvironment and promote efficacy of gemcitabine against pancreatic cancer

Joanna Le[1], Hong Gao[2], Yi Le[3], William Richards[4], Scott Radig[5], Ronald Bleday[4], Thomas Clancy[4], Zhenglun Zhu[3]. *[1]Obstetrics and Gynecology, University of Massachusetts Medical Center, Worcester, MA,[2]Medicine, Tufts Medical Center, Boston, MA,[3]Medicine, Brigham and Women's Hospital, Boston, MA,[4]Surgery, Brigham and Women's Hospital, Boston, MA,[5]Pathology, Brigham and Women's Hospital, Boston, MA*

Pancreatic ductal adenocarcinoma (PDA) is a lethal malignancy with median survival of less than one year and overall 5-year survival less than 5%. Gemcitabine has been the cornerstone in PDA treatment, yet its efficacy remains limited. Over the past decades, extensive investigations suggested a role of tumor microenvironment (TME) in rendering PDA resistance to gemcitabine, however, its underlying mechanism remained largely unknown. Cellular profiling has revealed the macrophages as a major immune cell component of PDA-TME. Our recent study showed that the expression of the homeobox protein VentX, a master regulator of macrophage plasticity, is significantly down-regulated in tumor associated macrophages (TAMs) of PDA. We demonstrated that restoration of VentX expression in PDA-TAMs polarizes the TAMs from a pro-tumor M2-like phenotype to an anti-tumor M1-like phenotype. We showed further that VentX-regulated-TAMs (VentX-TAMs) revert immune suppression of PDA-TME by inhibiting CD4 Treg differentiation and by promoting CD8 proliferation and activation. Using a newly developed tumor immune microenvironment-enabling model system (TIME-EMS), we showed that VentX-TAMs drastically promote efficacy of gemcitabine against PDA for about 4-fold but not cytotoxicity on normal pancreatic tissue. As such, our data suggested a function of VentX-TAMs to promote chemosensitivity of gemcitabine and to improve PDA prognosis.

Immune biomarkers of clinical response after NSAID treatment in combination with vaccination targeting EGFR-COX2-CDC25B in the APC(Min/+) mouse model

Denise L. Cecil, Ying Liu, Lauren Corulli, Mary L. Disis. *University of Washington, Seattle, WA*

Studies from our group have shown that administration of NSAIDs in mouse models of Familial Adenomatous Polyposis (FAP) results in a decrease in the development in small intestinal polyps with a significant increase in CD8 tumor infiltrating lymphocytes (TIL) and downregulation of PD-L1 on tumors. Furthermore, we have demonstrated that NSAIDs could be used in combination with vaccination to even further reduce the development of intestinal polyps. We questioned what tissue specific biomarkers could define the efficacy of response with the combination treatment. APC(Min/+) male and female mice (4-6 weeks old) were immunized with a multi-antigen (EGFR, COX2, CDC25B) peptide vaccine with CFA/IFA as an adjuvant. Control mice received immune adjuvant alone. Regular chow or chow containing 400 ppm naproxen was provided intermittently (3 weeks on, 3 weeks off for 3 cycles) or continuously (18 weeks on) at the initiation of the vaccine regimen. Animals were euthanized at 22 weeks and tumors quantified. TIL were evaluated by flow cytometry. Since intermittent naproxen treatment was just as effective at inhibiting tumor development as continuous naproxen treatment, with or without vaccine, we did not differentiate between NSAID regimens. We observed an increase in CD8+ (83%; $p<0.0001$), Tbet+CD4+ (94%; $p<0.001$), effector memory (EM) CD4+ (76%; $p<0.0001$) and EM CD8+ (94%; $p<0.0001$) TIL in the tumors that did develop in the mice treated with the combination NSAID and vaccination as compared to control. There was increased CD8+ (Pearson correlation coefficient: −0.506, $p<0001$), Tbet+CD4+ (Pearson correlation coefficient: -0.6222, $p<0.001$), EM CD4+ (Pearson correlation coefficient: 0.-6074, $p<0.001$) and EM CD8+ (Pearson correlation coefficient: -0.7155, $p<0.001$) in mice with greater tumor inhibition than those with less protection. Receiver operator curves revealed that CD8+ (AUC: 0.7623; $p=0.002$), Tbet+CD4+ (AUC 0.7273; $p=0.008$), EM CD4+ (AUC 0.6782; $p=0.04$) and EM CD8 (AUC 0.7897; $p<0.001$) TIL can differentiate mice receiving the combination of NSAID and vaccination as compared to either monotherapy alone. These data define potential biomarkers of response that can guide human clinical trials of NSAIDs +/- vaccination in patients with FAP.

INTASYL self-delivering RNAi therapeutic dual targeting PD-1 and CTLA-4 provides synergistic antitumor efficacy in the treatment of

murine colon cancer *in vivo*

Benjamin G. Cuiffo, Andrew Boone, Dingxue Yan, Melissa Maxwell, Brianna Rivest, James Cardia, Simon P. Fricker. *Phio Pharmaceuticals, Marlborough, MA*

Combination immune checkpoint inhibition (ICI) with antibodies targeting PD-1 and CTLA-4 provides superior outcomes compared to either monotherapy alone. This combination has been approved for advanced melanoma, metastatic colon cancer and others. However, combination therapy with anti-PD-1/CTLA-4 antibodies results in serious immune related adverse events (irAEs), presenting an obstacle for effective treatment with combination systemic anti-PD-1/CTLA-4. Intratumoral (IT) immunotherapy is a strategy to enhance local activity while decreasing systemic irAEs. While clinical testing of IT antibodies is underway, antibodies' high molecular weight may limit their local diffusion and retention time within tumors. RNAi is an emerging therapeutic modality well-suited for local clinical application of ICI. We have demonstrated that self-delivering RNAi therapeutics built on proprietary INTASYL™ technology specifically silence their targets in tissues without need for specialized formulations or delivery systems, and convey robust antitumor efficacy in vivo. Furthermore, multiple INTASYL compounds can be easily co-formulated into a multi-targeting therapeutic, providing specific silencing of multiple therapeutic targets in a single injection. Here, we present proof-of-concept (POC) in vivo data demonstrating synergistic efficacy of a novel INTASYL dual-targeting murine PD-1 (mPH-762) and CTLA-4 (27790) coformulation in PBS in a syngeneic CT26 model of murine colon cancer. Dual on-target silencing was first validated in murine T cells in vitro. In vivo, CT26 cells were implanted subcutaneously into female BALB/c mice. Vehicle (PBS) or INTASYL IT treatment commenced when tumors reached a mean threshold volume (150 mm^3; Day 1) with doses given on Days 1, 4, 7, 10, and 13. Mice received a total 1 mg/dose with the dual-targeting INTASYL, comprised of 0.5 mg of each compound. Another group received the dual-targeting INTASYL at 2 mg/dose. Tumor volumes and body weights were recorded longitudinally and analyzed by area under the curve (AUC). Tumors were isolated on Day 15 and mechanistic immunomodulation of the tumor microenvironment (TME) was assessed by flow cytometry. IT INTASYL dual-targeting PD-1

and CTLA-4 elicited robust dose-associated antitumor efficacy that was superior to the identical total dose of either single-targeting INTASYL, when comparing mean tumor volume AUC, demonstrating antitumor synergy by the dual-targeting coformulation. On-target mechanistic immunomodulatory effects were observed in the TME. These data demonstrate POC synergistic efficacy of IT INTASYL dual-targeting CTLA-4/PD-1 in vivo, supporting further development to maximize efficacy and minimize irAEs. PH-762 is currently under clinical investigation in a Phase 1b study for advanced melanoma.

Development of personalized RNA-based immunotherapeutics for glioblastom

Vrunda Trivedi, Changlin Yang, Oleg Yegorov, Kelena Klippel, Graeme Fenton, Christina von Roemeling, Lan Hoang-Minh, Elizabeth Ogando-Rivas, Paul Castillo, Kyle Dyson, Ginger Moore, Duane Mitchell.
Neurological Surgery, University of Florida, Gainesville, FL

Background: The development of successful immunotherapy targeting antigens in glioblastoma multiforme (GBM) remains a challenge owing to antigen heterogeneity and the low mutation burden in GBM. Cancer immunogenomics represents a complementary approach to the application of genomics in developing novel immunotherapies for GBM. Our goal is to develop a personalized RNA-based therapeutic vaccine that simultaneously targets a selected pool of tumor rejection antigens including all neoantigens and tumor-associated antigens (TAAs) as identified using cancer immunogenomics. We evaluated the treatment efficacy of these RNA therapeutics in combination with adoptive cellular therapy and checkpoint inhibitors.
Methods: We identified immunogenic neoantigens and TAAs that are aberrantly overexpressed in KR158-luc and GL261 murine GBM tumors using our cancer immunogenomics pipeline called the Open Reading Frame Antigen Network (O.R.A.N.). A tumor antigen-specific RNA library was created for each tumor using a novel gene enrichment strategy and validated by RNAseq. Tumor-bearing animals were treated with adoptively transferred ex vivo expanded lymphocytes and dendritic cells loaded with the tumor antigen-specific RNA as vaccines. Additionally, we treated

animals with the tumor antigen-specific RNA vaccines in combination with anti-PD-1 checkpoint-blockade therapy. Tumor progression and survival outcomes were analyzed to evaluate the treatment efficacies. We determined the peripheral and tumor-infiltrating lymphocyte responses using flow cytometry, TCR sequencing, and single cell RNAseq.
Results: The tumor antigen-specific RNA vaccines were significantly effective in slowing the progression of murine GBM tumors in combination with both the adoptive cellular therapy and the checkpoint blockade therapy and improved the outcome of these therapies as compared to monotherapy alone. Additionally, we identified antigen-specific T cells targeting several of our predicted antigens and an increase in tumor-infiltrating lymphocytes and memory T cells in the treated animals.
Conclusion: Here, we developed an RNA-based immunotherapy that simultaneously targets numerous tumor-specific antigens and demonstrated its therapeutic efficacy in preclinical models of GBM.

Novel humanized anti-GD2 antibody inhibits GD2-mediated immunosuppression by targeting GD2+ breast cancer stem-like cells

Vivek Anand[1], Venkatesh Hegde[1], Maryam Siddiqui[1], Anudishi Tyagi[1], Bolutyfe Oderinde[1], Mario Marcondes[2], Willem Overwijk[2], Venkata Lokesh Battula[3]. *[1]Department of Leukemia, UT MD Anderson Cancer Center, Houston, TX,[2]Nektar Therapeutics, San Francisco, CA,[3]UT MD Anderson Cancer Center, Houston, TX*

Background: Breast cancer stem-like cells (BCSCs) are reported to be a major contributing factor for tumor growth and chemotherapy resistance in triple-negative breast cancer (TNBC). We reported that the disialoganglioside GD2 is highly expressed on BCSCs and that targeting GD2 with dinutuximab (chimeric anti-GD2 antibody) in combination with NK cells synergistically reduced tumor volumes in TNBC animal models. Here, we hypothesize that naxitamab targets $GD2^+$ BCSCs and inhibits breast cancer (BC) growth by enhancing macrophage mediated phagocytosis and T cell mediated cytotoxicity. In addition, we explore whether addition of an investigational polymer-engineered IL-15 receptor-agonist, NKTR-255 treated NK cells, can further enhance this anti-GD2 mediated anti-cancer activity.

Methods: Naxitamab is a US FDA approved fully humanized anti-GD2 (hu3F8) monoclonal antibody for the treatment of pediatric neuroblastoma. We evaluated the effects of naxitamab treatment on macrophage mediated phagocytosis of BC cells using the live cell imaging system, IncuCyte®. Next, we compared the effects of NKTR-255 treated NK cells with recombinant human IL-15 (rIL-15) treated NK cells in naxitamab induced ADCC in $GD2^+$ BC cells. We also performed immunohistochemistry (IHC) to examine GD2 expression and correlate it with T cell infiltration in primary TNBC patient samples with high and low GD2 levels. The effect of naxitamab treatment on T cell mediated cytotoxicity in BC cells was also observed.
Results: When compared to control, naxitamab treatment promoted macrophage mediated phagocytosis of Hs578T and HCC1395 cells in a dose dependent manner *($p < 0.001$)*. Additionally, when co-cultured with healthy donor derived macrophages, we found a significant reduction in Hs578T spheroids treated with naxitamab in comparison to IgG control *($p<0.001$)*. Furthermore, we observed a significantly higher rate of apoptosis in $GD2^+$ Hs578T and HCC1395 breast cancer cells treated with naxitamab and NK cells generated using NKTR-255, compared to rIL-15 treated NK cells (*$p<0.0001$*). Interestingly, IHC analysis showed that TNBC patients with high GD2 expression have significantly lower $CD3^+$ T cell infiltration than patients with low GD2 expression *($p<0.05$)*. We also observed increased T cell mediated killing of BT549 and T47D cells treated with naxitamab in comparison to IgG control *($p<0.001$)*.
Conclusion: TNBC with high GD2 expression inhibits immune cell infiltration and naxitamab can inhibit BCSC growth by targeting GD2. Combination of naxitamab with macrophages induced macrophage mediated phagocytosis TNBC cells. NK cells were more stable and cytotoxic when generated with NKTR-255 vs. native IL-15, and naxitamab further enhanced NK cell mediated ADCC of $GD2^+$ BCSCs. The increased T cell mediated killing of breast cancer cells treated with naxitamab further supports the immunomodulatory role of GD2.

Inflammasome unleashing during anti-PD-1 therapy modulates $CD8^+$ T cell exhaustion through Th17 cells

Sofia Russo, Mateo Malcuori, David Charbonnier, Mercedes Segovia, Marcelo Hill. *Institut Pasteur De Montevideo, Montevideo, Uruguay*

PD-1/PD-L1 blockade has greatly improved overall and progression free survival in a variety of cancers. However, only a minority of patients with advanced disease benefit from this approach. We have recently showed that inflammasome unleashing by inhibition of the intracellular cation channel TMEM176B with Boritinib (BayK8644) augments anti-PD-1 efficacy. However, the mechanisms involved were not completely understood. We hypothesized that inflammasome activation triggered by Boritinib may recruit Th17 cells to modulate $CD8^+$ T cell exhaustion. To test this hypothesis, we have analyzed Th17 cells and subsets of exhausted $CD8^+$ T cells in the tumor microenvironment of WT mice treated with anti-PD1 ± Boritinib. Combining Boritinib with anti-PD-1 led to an increased frequency of Th17 cells in the tumor microenvironment compared to anti-PD-1 alone. Furthermore, CD73 expression was down-regulated whereas IFN-γ was up-regulated in Th17 cells in the tumor microenvironment of Boritinib + anti-PD-1 treated mice, suggesting an effector phenotype of these cells. In addition, combination of anti-PD-1 with Boritinib results in an increased frequency of progenitor exhausted $CD8^+$ T cells ($CD44^+PD\text{-}1^+TCF1^+TOX^+$) and transitory exhausted $CD8^+$ T cells ($CD44^+PD\text{-}1^+TCF1^-TOX^-CX3CR1^+$) in the tumor microenvironment compared to anti-PD-1 alone. Similar results were obtained using *Tmem176b*$^{-/-}$ mice treated with anti-PD-1, suggesting an on-target effect of Boritinib. To assess a potential role of Th17 cells in the anti-tumor immunity triggered by Boritinib + anti-PD-1, we treated WT and *Il17a*$^{-/-}$ mice. We found that *Il17* is necessary for the anti-tumor effect of Boritinib + anti-PD-1, since *Il17a*$^{-/-}$ mice showed a reduced overall survival compared to WT mice. Under this combined therapy, IL-17 may impact on exhausted $CD8^+$ T cells subsets since we found that transitory and terminally exhausted $CD8^+$ T cells in the tumor microenvironment of *Il17a*$^{-/-}$ mice had less granzyme B than in WT mice. To directly show the role of Th17 cells in the anti-PD-1 anti-tumor immunity we adoptively transferred *in vitro* differentiated effector Th17 cells. Adoptive transfer of effector Th17 cells into tumor-bearing mice treated with anti-PD-1 resulted in better survival than mice treated with anti-PD-1 alone. To characterize the downstream mechanisms, we

performed an *in vivo* cytotoxicity assay. We found that mice adoptively transferred with effector Th17 cells exhibited greater cytotoxicity by $CD8^+$ T cells than mice treated with anti-PD-1 alone. Furthermore, this could be explained by an increased frequency in progenitor exhausted $CD8^+$ T cells. Thus, effector Th17 cells potentiate $CD8^+$ T cells on anti-PD-1 treatment. In conclusion, combination of anti-PD-1 with Boritinib augments the efficacy of the former by unleashing the inflammasome which results in an increased frequency of Th17 cells leading to modulation of exhausted $CD8^+$ T cells.

Combined treatment with the epigenetic drug CM272 and an anti-BCL-XL proapoptotic drug sensitizes solid tumors to immune checkpoint blockade

Yaiza Senent[1], Vicente Fresquet[1], Victoria Jimenez[1], Karmele Valencia[1], Ana Remirez[1], Francisco Exposito[2], Marisol Gonzalez-Huarriz[1], Borja Ruiz-Fernandez de Cordoba[1], Haritz Moreno[1], Daniel Ajona[1], Marta M Alonso[1], Fernando Lecanda[1], Antonio Pineda-Lucena[1], Felipe Prosper[1], Alfonso Calvo[1], Jose Angel Martinez-Climent[1], Ruben Pio[1]. *[1]Center for Applied Medical Research (CIMA)-University of Navarra, Pamplona, Spain,[2]Yale School of Medicine, Yale Cancer Center, New Haven, CT*

Epigenetic modulators in combination with proapoptotic drugs have become a standard of treatment for acute myeloid leukemia. However, the clinical efficacy of these combinations in solid tumors has shown to be negligible. Our group has demonstrated that the epigenetic drug CM272, which targets DNMT and G9a, induces synergistic responses in combination with proapoptotic drugs in hematological malignancies (Cancer Discovery 2021). We have also reported that CM272 induces an immunogenic cell death that sensitizes tumor cells to immune checkpoint blockade (ICB) (Nature Medicine 2020). Here, we hypothesized that CM272 in combination with proapoptotic drugs may sensitize tumor cells to ICB, resulting in profound anti-tumor responses. To test this hypothesis, we evaluated *in vitro* the sensitivity of cancer cells to different combinations of epigenetic and proapoptotic drugs. The most efficient combination was tested in various immunocompetent mouse models,

followed by an immunophenotypic characterization of the tumor microenvironment. We found that CM272 in combination with inhibitors of BCL-XL, BCL2 or MCL1, yielded synergistic *in vitro* responses in a large collection of human and mouse cell lines derived from solid tumors. Mechanistically, the treatments induced the expression of endogenous retroelements/retroviruses, which led to the activation of RIG-1 and MDA5 viral sensors, ATP hydrolysis and tumor cell death. Remarkably, we found that CM272 in combination with BCL-XL inhibition had more potent anti-tumor effects than that found with BCL2 or MCL1 inhibitors. *In vivo*, the triple combination CM272, A1331852 (BCL-XL inhibitor) and an anti-PD-1 moAb significantly reduced tumor growth and increased overall survival in three subcutaneous lung cancer models (LLC, 393P, Lacun-3) in comparison to double treatments. Moreover, this triple combination also induced significant anti-tumor responses in subcutaneous mouse models of colon cancer (MC38) and melanoma (B16), as well as in orthotopic models of lung cancer (LLC), glioblastoma (CT-2A) and breast cancer (ANV5), leading to prolonged survival and cure in a fraction of animals. The triple therapy was associated with a significant increase in the ratio of CD8 T versus immunosuppressive Treg cells, and M1 versus M2 macrophages. In conclusion, we report a novel regimen combining a dual epigenetic inhibitor, an anti-BCL-XL, and an anti-PD-1 moAb that results in potent responses in multiple pre-clinical models of solid tumors. The mechanisms underneath the antitumor responses include the modulation of the energy metabolism in tumor cells, leading to cell death boosted by an anti-BCL-XL pro-apoptotic drug, along with fostering the immune system to generate an efficient anti-tumor response assisted by ICB. This study reveals the potential of epigenetic therapeutics to treat and cure patients with solid tumors.

STING agonist and TLR7/8 agonist overcome anti-PD-1 resistance mediated by loss of β2M

Li Hua, Chenpan Nie, Jie Lin, Annie Xiaoyu An, Ludovic Bourre, Jingjing Wang. *Crown Bioscience, Inc., San Diego, CA*

Introduction: PD-1 blockade has achieved great success in the clinic. However, only a small subset of patients benefits from the treatment and

most responders develop acquired resistance thereafter. One of the resistance mechanisms is beta-2-microglobulin (β2M) mutation mediated dysfunction of MHC-I antigen presentation, which contributes to attenuation of cellular cytotoxicity triggered by adaptive $CD8^+$ T cells. Activating innate immunity, such as natural killer (NK) cells, can be used as a strategy to circumvent the attenuation. Immune-stimulating agents like Stimulator of interferon genes (STING) agonists and Toll-like receptor (TLR) 7/8 agonists can elicit NK cell-mediated tumor rejection in preclinical tumor models, independent of $CD8^+$ T cells. Thus, to evaluate novel therapeutic strategies overcoming anti-PD-1 resistance, we established a MC38-OVA-β2M KO tumor model.
Methods: We knocked out β2M genes in a murine MC38-OVA colorectal cancer cell line using CRISPR/Cas9 to generate MC38-OVA-β2M KO cells. β2M knockout was verified by western blot and flow cytometry. For *in vitro* testing, both MC38-OVA and MC38-OVA-β2M KO cells were treated with IFN-α, IFN-β and IFN-γ for 24h, and then MHC-I and OVA peptide SIINFEKL expression were analyzed by flow cytometry. For *in vivo* testing, 1×10^6 MC38-OVA cells and MC38-OVA-β2M KO cells were subcutaneously injected into C57BL/6 mice and the models were treated with anti-PD-1. Finally, the MC38-OVA-β2M KO tumor model was treated with anti-PD-1, cyclic nucleotides (CDN), R-848 and anti-PD-1 combined with either CDN or R-848. At the endpoint, the composition of immune cells in spleens were analyzed by flow cytometry.
Results: Following confirmation of β2M knockout, MHC-I expression and MHC-I-OVA peptide presentation were also diminished on MC38-OVA-β2M KO cells, even after treatment of IFN- α, IFN-β, or IFN-γ. *In vivo*, anti-tumor efficacy of PD-1 blockade was significantly diminished in MC38-OVA-β2M KO model (TGI=31%, $p<0.001$), compared to MC38-OVA model (TGI=91%). To overcome the resistance, CDN, a STING agonist or R-848, a TLR7/8 agonist was administered alone or combined with anti-PD-1 in the MC38-OVA-β2M KO model. Single treatment of either CDN (TGI=73%) or R-848 (TGI=89%) markedly impeded tumor growth, and combination with anti-PD1 greatly enhanced their anti-tumor effects (TGI of 98% and 99%, respectively). Additionally, flow cytometry analysis showed a decrease of Myeloid-derived suppressor cells (MDSCs) and an increase of NK cells in spleens of the mice treated with CDN and

anti-PD-1. In parallel, a decrease of MDSCs was also observed in the mice with combined treatment of R-848 and anti-PD-1.
Conclusion: The successfully established MC38-OVA-β2M KO model is a useful tool for investigating therapeutic strategies to overcome MHC-I down-regulation mediated immunotherapy resistance. Moreover, STING agonists and TLR7/8 agonists may be potential candidates.

Nano-immunotherapy targeting PD-L1, PLK1, and TLR9 for treatment of non-small cell lung cancer

Moataz Reda[1], Worapol Ngamcherdtrakul[1], Ruijie Wang[2], Noah Crumrine[1], Cole Baker[1], Alyssa Wallstrum[1], Jeremy Saito[1], Natalie White[1], Wassana Yantasee[2]. *[1]Pdx Pharmaceuticals, Inc., Portland, OR,[2]Oregon Health & Science University, Portland, OR*

Given the complexity of cancer, it is becoming apparent that combination therapy - in which complementary biological pathways are simultaneously targeted - is required to achieve clinically meaningful responses. To that end, PDX Pharma, in collaboration with Oregon Health & Science University, has developed a proprietary nanoparticle platform (Pdx-NP™) that can effectively co-deliver a plethora of therapeutic modalities while maintaining a small size in saline (100 nm), suitable for infusion and tumor accumulation. This enables the targeting of complementary cancer and immune pathways, leading to synergistic clinical benefits. Herein, we report on the second generation ARAC-02 (Antigen Release Agent and Checkpoint Inhibitor) which is designed to improve the efficacy of immune checkpoint inhibitors (ICIs) in non-small cell lung cancer (NSCLC). While ICIs have improved survival in a subset of patients with advanced NSCLC, only a minority of patients respond to ICIs, highlighting the need for combination immunotherapy. ARAC-02 co-delivers a polo-like kinase 1 (PLK1)-targeted therapy (volasertib), a PD-L1 antibody, and the immune-stimulant CpG. These three agents were carefully selected based on their roles in cancer and immune pathways. Volasertib 1) selectively kills cancer cells, 2) modulates the immune-suppressive tumor microenvironment, and 3) upregulates PD-L1 expression in cancer cells, providing opportunity for targeted delivery with PD-L1 antibody on the nanoparticles. CpG is a TLR9 agonist that enhances antigen presentation to generate tumor-specific T

cells. PD-L1 antibodies serve as tumor targeting agent for nanoparticle delivery as well as an ICI (i.e., PD-L1 degradation upon internalization with the nanoparticles), releasing the brakes and allowing T cells to attack the cancer. We found that the optimized ARAC-02 is preferentially internalized in PD-L1 expressing NSCLC cells, demonstrating a 10-fold greater uptake to PD-L1(high) NSCLC cells than PD-L1(low) normal cells. ARAC-02 effectively kills NSCLC cells regardless of their mutational status, while sparing normal cells. In a metastatic lung tumor model, ARAC-02 treatments reduced the tumor burden by 30-fold vs. saline control and 8-fold vs. the first generation ARAC (not containing CpG), whose effect was mainly mediated by CD8+ T cells. ARAC-02 was found to be safe to mice as assessed by body weight, serum biomarkers, and histology. Importantly, intravenous infusions of the platform was also found to be safe in a preliminary toxicology study in non-human primates. Due to its unique ability to catalyze various steps of the adaptive immune response, ARAC-02 is anticipated to provide superior outcomes in NSCLC and a broad range of tumor types regardless of baseline PD-L1 expression.

NPRL2 gene therapy induces effective antitumor immunity in KRAS/STK11 mutant anti-PD1 resistant metastatic human NSCLC in a humanized mouse model

Ismail M. Meraz[1], Mourad Majidi[1], Renduo Song[1], Feng Meng[1], Gao Lihui[1], Qi Wang[2], Jing Wang[2], Elizabeth Shpall[3], Jack A. Roth[1]. *[1]Thoracic and Cardiovascular Surgery, UT MD Anderson Cancer Center, Houston, TX,[2]Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Stem Cell Transplantation, UT MD Anderson Cancer Center, Houston, TX*

NPRL2/TUSC4 is a potent tumor suppressor gene whose expression is reduced in many cancers including NSCLC. Restoration of NPRL2 expression in cancer cells induces DNA damages which leads to cell cycle arrest and apoptosis. We investigated the antitumor immune responses to NPRL2 gene therapy on anti-PD1 resistant KRAS/STK11 mutant NSCLC in a humanized mouse model. H1299 cells transfected with NPRL2 showed significant inhibition of colony formation after NPRL2 transfection. Humanized mice were generated by transplanting fresh human cord blood

derived CD34 stem cells into sub-lethally irradiated NSG mice. The level of engraftment of human CD45, CD3 T, CD19 B, NK cells was verified before tumor implantation. Mice harboring > 25% human CD45 cells were considered humanized. KRAS/STK11 mutant anti-PD1 resistant A549 NSCLC cells were injected intravenously into humanized NSG mice and developed lung metastasis. Metastases were treated with intravenous injection of NPRL2 gene loaded cationic lipid nanoparticles with or without pembrolizumab (anti-PD1). A dramatic antitumor effect was mediated by NPRL2 treatment, whereas pembrolizumab was ineffective. A significant antitumor effect was also found in non-humanized NSG mice, although the effect was greater in humanized mice suggesting that the possible role of antitumor immunity. The antitumor effect of NPRL2 was associated with increased infiltration of human CD45, CD3 T, cytotoxic T, NK cells, and a decreased number of human regulatory T cells (Treg) in tumors. PD1 expressing exhausted CD8 T cells were downregulated in both the NPRL2 and pembrolizumab groups. The number of activated T cells ($CD69^+CD8^+T$), effector (EM) and central memory (CM) CD8 T cells were significantly increased by NPRL2 treatment. NPRL2 induced antigen presenting HLA-DR^+ dendritic cells. When NPRL2 was combined with pembrolizumab, no synergistic antitumor effect was found in the KRAS/STK11 mutant anti-PD1 insensitive tumors. However, a robust and synergistic antitumor effect was observed in the KRAS wild type, anti-PD1 sensitive H1299 tumors grown in humanized mice treated with NPRL2 + pembrolizumab. Cytotoxic T cells, NK cells, and HLA-DR^+ DC were associated with the antitumor effect. DOTAP-NPRL2 was tested in a syngeneic mouse model with LLC2 tumors that are KRAS mutant and anti-PD1 resistant. Consistent with the A549 humanized mouse model, NPRL2 showed a significantly strong antitumor effect whereas anti-PD1 was not effective in this model. The antitumor effect of NPRL2 was again correlated with the upregulation of HLA-DR^+ DC, CD11c DC, TILs, NK and downregulation of Treg and myeloid cells in the tumor microenvironment. Taken together, these data suggest that NPRL2 gene therapy induces antitumor activity on KRAS/STK11 mutant anti-PD1 resistant tumors through DC mediated antigen presentation and cytotoxic immune cell activation.

TriTCE Co-stim, next generation costimulatory trispecific T cell engagers for the treatment of solid tumors

Lisa Newhook, Purva P. Bhojane, Peter W. Repenning, Diego Perez Escanda, Nichole K. Escalante, Patricia Zwierzchowski, Alec Robinson, Lauren Clifford, Harsh Pratap, David N. Douda, Chayne L. Piscitelli, Nicole J. Afacan, Thomas Spreter von Kreudenstein, Nina E. Weisser.
Zymeworks Inc., Vancouver, BC, Canada

Bispecific T cell engager (TCE) therapies have exhibited clinical utility against hematological cancers, but limited success in solid tumors. Treatment of solid tumors has additional challenges - including immunosuppressive environments and low T cell infiltration - limiting the antitumor activity of CD3-bispecific TCEs. Conventional T cell activation and sustained proliferation requires signaling via CD3 (signal 1) and costimulatory molecules (signal 2), such as CD28. The balance between signals 1 and 2 is critical for optimal T cell activation – signal 1 in the absence of signal 2 results in T cell anergy, while overactivation via signals 1 and 2 can lead to T cell dysfunction and cytokine release, as observed with toxicities associated with αCD28 superagonist antibodies (Abs). Optimal signal 2 costimulation via CD28 results in improved T cell fitness, activation and proliferation. To improve T cell responses in solid tumors, we developed costimulatory trispecific TCEs (TriTCE Co-stim) that engage CD3, CD28 and a tumor-associated antigen (TAA).

Our novel TriTCE Co-stim Abs were generated using the Azymetric^{TM} and EFECT^{TM} platforms to facilitate heterodimeric TriTCE Co-stim assembly and to knockout Fc gamma receptor interactions, respectively. To limit potential CD28-mediated toxicities, we evaluated a conventional αCD28 agonist paratope and generated a paratope library with varying affinities for CD28. TriTCE Co-stim Abs were engineered with various formats, geometries, paratope affinities, and TAA specificities. To understand the impact of TriTCE Co-stim Abs on T cell activation, we assessed *in vitro* cytotoxicity, cytokine production and proliferation of primary human CD3 T cells in co-culture with TAA-expressing cancer cell lines. A human PBMC-engrafted xenograft model was used to assess *in vivo* antitumor activity in a TAA^{high} tumor model.

TriTCE Co-stim Abs exhibited a range of cytotoxic potency, with several formats exhibiting greater potency than bispecific TCEs, and induced

greater cytotoxicity of tumor cells in long term co-cultures at low effector to target ratios. TriTCE Co-stim Abs exhibited TAA-dependent cytokine release and T cell proliferation, with enhanced IL-2 production and proliferation compared to that induced by bispecific TCEs. Tumor growth regression was observed *in vivo* following treatment with different TriTCE Co-stim Ab formats. In summary, we identified TriTCE Co-stim Ab formats that exhibit improved proliferation and antitumor activity against multiple TAA targets compared to bispecific TCE, which may translate to improved and more durable antitumor responses in solid tumors with low T cell infiltration. The evaluation of multiple formats, geometries and paratope affinities allowed optimization of activity and selectivity to promote maximal therapeutic index and efficacy, key factors that may contribute to improved clinical outcomes.

Electrochemotherapy and IL-12 gene electrotransfer in treatment of mast cell tumors in companion dogs

Maja Cemazar[1], Ursa Lampreht Tratar[1], Nina Milevoj[2], Katarina Znidar[1], Katja Ursic Valentinuzzi[1], Andreja Brozic[1], Gregor Sersa[1], Natasa Tozon[2].
[1]Institute of Oncology Ljubljana, Ljubljana, Slovenia,[2]Veterinary faculty, University of Ljubljana, Ljubljana, Slovenia

When cells or tissues are exposed to an electric field, structural changes can be induced in the cell membrane, allowing molecules to flow into the cells. This condition is useful for delivering cytotoxic drugs whose transport into cells is impeded, such as bleomycin and cisplatin. This is referred to as electrochemotherapy (ECT). When DNA or RNA molecules are transported into cells, the approach is called gene electrotransfer (GET). ECT is an effective local treatment for tumors, but it lacks the systemic component of treatment that is essential for fighting metastatic disease. Cancer progression and metastasis are closely related to an inadequate antitumor immune response. Therefore, the antitumor efficacy of interleukin 12 (IL -12), a cytokine that stimulates the innate and adaptive immune response, has been tested in preclinical studies using plasmid DNA encoding IL -12 delivered into the tumor by gene electrotransfer (IL -12 GET). In addition, the combined treatment of ECT and IL -12 GET has already been shown to be effective in the treatment of mouse tumors and has been used in clinical

trials in companion dogs to treat various histological types of spontaneous tumors. The results of these studies showed that the treatment is safe and effective. However, in these clinical trials, IL -12 GET was administered by different routes, either intratumorally (i.t.) or peritumorally (peri.t.). Therefore, the aim of this study was to compare the two IL -12 GET routes of administration in combination with ECT and to determine their contribution to the enhanced response to ECT. In the clinical trial, 59 dogs with spontaneous mast cell tumors (MCT) were divided into two groups: one group was treated with the combination of ECT and GET peri.t. (29 dogs) and the other with the combination of ECT + GET i.t. (30 dogs). The efficacy of the treatment was compared with the group of 18 dogs treated with ECT alone. In addition, immunohistochemical studies of tumor samples before treatment and flow cytometric studies of PMBC before and after treatment were performed to determine immunological aspects of the treatment. The results of this study showed that local tumor control was significantly better in the ECT + GET i.t. group ($p < 0.05$) than in the ECT + GET peri.t. and ECT groups. In addition, the disease-free interval (DFI) and progression-free survival (PFS) were significantly longer in the ECT + GET i.t. group than in the other two groups ($p < 0.05$). The data on local tumor response, DFI and PFS were consistent with immunological studies, as we detected increased infiltration of antitumor immune cells after treatment in the ECT + GET i.t. group, also suggesting a systemic effect.

The anti-tumor and anti-angiogenic effects of a lipid nanoparticle suspension of an AKT-1 anti-sense oligonucleotide

Fengyang Xie[1], Jia Wei[2], Lan Deng[2], Chao Wang[2], Ben Zhao[1], Robert J. Lee[1], Yuxin Angela Men[2]. *[1]Zhejiang Haichang Biotechnology Co., Ltd., Hangzhou, China,[2]The WhiteOak Group, Inc., Rockville, MD*

Background: AKT-1 is known to play a critical role in cancer progression by stimulating cell proliferation and inhibiting apoptosis. AKT inhibition has been shown to inhibit tumor growth as well as tumor angiogenesis. Archexin is a fully phosphorothioated 20-mer antisense oligonucleotide, which can specifically bind to AKT-1 mRNA resulting in RNase H-based AKT-1 downregulation. WGI-0301 is a proprietary lipid nanoparticle (LNP) formulation of Archexin designed for enhanced delivery. A phase I

clinical study has recently been initiated for WGI-0301 in patients with advanced solid tumors.
Methods: Anti-tumor efficacy of WGI-0301 was studied *in vivo* in a Hepa1-6 syngeneic murine tumor model for hepatocellular carcinoma (HCC). The mice were injected i.v. with vehicle control or WGI-0301 at 8 mg/kg once weekly for 4 doses (n=8). Tumor size and body weight changes were monitored. In addition, the anti-angiogenesis activity of WGI-0301 was investigated *in vitro* using human umbilical vein endothelial cells (HUVEC). In the study, combination of WGI-0301 with Lenvatinib or Sorafenib were investigated to determine possible synergism. Three experimental groups were set up, including WGI-0301(0, 0.2, 2 and 20 μM), WGI-0301+ 2 μM Sorafenib, and WGI-0301+ 5 μM Lenvatinib. The cells were plated at 1.5×10^4 per well. The cells were treated with 50% Matrigel and then cultured in the 24 well plate in triplicates and were incubated for an additional 6 hours.
Results: The *in vivo* study demonstrated anti-tumor efficacy of WGI-0301 in the Hepa1-6 model. The tumor growth inhibition % (TGI) for WGI-0301 was 46.16%, and the medium survival time (MST) of the treatment group was 55 days, which was significantly different from that of the control group (37 days). There was no severe adverse event observed during the study. In the *in vitro* anti-angiogenesis study, WGI-0301 alone or in combination with 2 μM Sorafenib and 5 μM Lenvatinib exhibited dose-dependent inhibition of angiogenesis. Compared with the control group, 20 μM WGI-0301 either alone or in combination with 2 μM Sorafenib and 5 μM Lenvatinib showed significantly inhibitory effect on angiogenesis. The 2 μM WGI-0301 in combination with 5 μM Lenvatinib also showed a significant inhibition effect on angiogenesis.
Conclusion: Data obtained demonstrated anti-tumor and anti-angiogenesis efficacy of WGI-0301. In addition, combining WGI-0301 with Sorafenib or Lenvatinib resulted in increased anti-angiogenetic activity relative to monotherapy. WGI-0301 warrants further investigation as a selective AKT-1 inhibitor.

The effect of lenvatinib in combination with chemotherapy plus immune checkpoint inhibitors on tumor microenvironments in the mouse syngeneic tumor model

Yu Kato[1], Yoichi Ozawa[1], Keito Adachi[1], Masahiko Kume[1], Yusuke Adachi[1], Yudai Narita[1], Megumi Kuronishi[1], Junji Matsui[2], Akira Yokoi[1], Yasuhiro Funahashi[2]. *[1]Eisai Co., Ltd., Tsukuba, Japan,[2]Eisai Inc., Nutley, NJ*

Introducti**on:** Lenvatinib (LEN) is an oral, multiple-receptor, tyrosine kinase inhibitor that mainly targets vascular endothelial growth factor and fibroblast growth factor receptors. Combination therapy with LEN and everolimus is approved for people with advanced renal cell carcinoma (RCC). Combination therapy with LEN and pembrolizumab, an anti human-programmed-cell-death-1 (PD-1) antibody, is also approved for the treatment of people with advanced endometrial cancer and advanced RCC. In this study, we investigated the antitumor activity of LEN in combination with chemotherapy and immune checkpoint inhibitors (ICIs), and explored the mechanism of action underlying these effects, in the mouse lung cancer syngeneic model.
Methods: In the LL/2 mouse Lewis lung carcinoma model, LEN was dosed at either 3 or 10 mg/kg (orally; once daily for 2 weeks) with or without cisplatin 4 mg/kg (intravenously; 3 or 4 times, twice weekly) and with or without anti-PD-1 200 ug/head + anti cytotoxic T-lymphocyte antigen 4 (CTLA4) antibodies 10mg/kg (intraperitoneally; twice weekly). Functional blood vessels were evaluated in tumor microenvironments by injections of Hoechst 33342 (Hoechst) into the tail veins of mice. The Hoechst-stained area and expressions of angiogenesis/immune-cell-related molecules were analyzed by immunohistochemistry (IHC) analysis.
Results: In this model, the combination treatment of LEN 3 mg/kg + cisplatin showed significant tumor growth inhibitory activity compared with each single agent without any marked body-weight loss. LEN 10 mg/kg + cisplatin did not show enhanced antitumor activity vs LEN 10 mg/kg as a single agent. IHC analysis using anti-CD31 antibody showed that LEN 3 mg/kg daily decreased microvessel density in tumors after 4 days. In addition, LEN 3 mg/kg daily for 4 days showed a trend toward an increase of the number of functional blood vessels stained with Hoechst in the tumor microenvironment compared with untreated controls. The combination of LEN 3 mg/kg + cisplatin + ICIs (anti-PD-1+anti-CTLA4) significantly inhibited tumor growth compared with combinations of cisplatin + ICIs.

Conclusion: Our findings show that LEN 3 mg/kg enhances the antitumor activity of cisplatin in the LL/2 mouse Lewis lung carcinoma tumor model; and LEN 3 mg/kg + cisplatin + ICIs shows greater antitumor activity compared with cisplatin + ICIs. The results of the IHC analysis suggest that LEN 3 mg/kg inhibits angiogenesis. Conversely, LEN 3 mg/kg increases functional vessels in tumor microenvironments. This situation could enhance combination antitumor activity of chemotherapy, and also chemotherapy + ICIs combination treatment. Further analysis of the mechanism of action of LEN 3 mg/kg in combination with chemotherapy + ICIs is warranted.

#5125

Depletion of CCR8+ tumor Treg cells with SRF114 or anti-CCR8 therapy promotes robust antitumor activity and reshapes the tumor microenvironment toward a more pro-inflammatory milieu

Marisella Panduro, Yue Ren, Ricard Masia, Yu Yang, Andrew C. Lake, Vito J. Palombella, Jonathan A. Hill, James F. Mohan. *Surface Oncology, Inc., Cambridge, MA*

$FOXP3^+$ regulatory T (Treg) cells play a crucial role in orchestrating immune responses across several tissues, including the tumor microenvironment (TME). The dominant immune regulatory activity of Treg cells is evidenced, both clinically and preclinically, by the profound inflammatory dysregulation that arises in their absence. Leveraging controlled depletion of Treg cells in tumor tissue while sparing Treg cells in healthy tissue may be achieved through antibody-mediated targeting of the C-C chemokine receptor 8 (CCR8). CCR8 is a seven transmembrane G-coupled chemokine receptor protein whose expression is predominantly upregulated on Treg cells in several types of tumors compared with peripheral blood. Importantly, depletion of CCR8-expressing Treg cells in tumors provides a novel pathway to immunotherapy that is mechanistically independent of checkpoint inhibition (CPI).
Using single-cell transcriptome and flow cytometry analyses, we evaluated the pharmacodynamic changes after treatment with anti-CCR8 antibodies to elucidate the effect of tumor Treg cell-targeting therapies on the downstream mechanisms of antitumor immunity within the TME.

SRF114, a highly selective human anti-CCR8 afucosylated antibody, and an anti-mouse CCR8 antibody were utilized to preferentially deplete $CCR8^+$ Treg cells in human CCR8 knock-in (hCCR8KI) or wild-type mice, respectively. Treatment with SRF114 or anti-mouse CCR8 antibody resulted in robust monotherapy activity in models susceptible to CPI. Moreover, pronounced monotherapy activity was also seen in checkpoint-resistant model(s), highlighting a mechanistically CPI-independent role for intratumoral Treg cell depletion to elicit potent antitumor activity. Treatment of tumor-bearing mice with anti-CCR8 antibodies resulted in a significant reduction of tumor-associated Treg cells, while peripheral Treg cells remained unchanged. Analysis of bulk tumor lysates showed that anti-CCR8 therapy elevated levels of pro-inflammatory cytokines and pro-angiogenic and chemoattracting factors. Evaluation of effector T cells demonstrated that anti-CCR8 therapy drives proliferation of $CD8^+$ T cells and an increase in intracellular cytokine production of IFNγ, TNFα, and granzyme A. Additionally, the tumor myeloid compartment was strongly affected by anti-CCR8 therapy. Multiple myeloid cell subsets had increased levels of co-stimulatory molecules and expression of PD-L1. Altogether, selective depletion of intratumoral $CCR8^+$ Treg cells results in robust antitumor activity by reshaping the TME toward a more pro-inflammatory milieu, providing an orthogonal approach to CPI for eliciting antitumor immunity and a strong rationale for evaluating SRF114 as a therapeutic agent for the treatment of cancer. SRF114 is currently in Phase 1 clinical studies.

Determinants of Immunotherapeutic Effectiveness

Evaluating the survival outcomes of an anti-isoaspELAVL4 response in a small cell lung cancer mouse model

Diego A. Velarde, Sarah A. Elmalh, Hannah Lee, Joseph Valdes, Matthew Gladstone, Ryan E. Dinigle, Martin Kast, Ite A. Offringa. *USC Norris Comprehensive Cancer Center, Los Angeles, CA*

Small cell lung cancer (SCLC) has a 95% mortality rate and a 5-year survival of 8%, resulting in the death of over 20,000 Americans each year. There has been marginal improvement in therapy over the past 30 years,

with the recent addition of immune checkpoint inhibition therapy modestly increasing overall SCLC patient survival from 10.3 to 12.3 months [PMID 30280641]. This highlights the need for additional SCLC therapies. Previous studies have identified a subset of SCLC patients (10-20%) exhibiting a naturally occurring immune response called 'anti-HuD'. It is associated with improved response to therapy and improved survival [PMID 9256130; 26606748]. Previous work identified the anti-HuD antigen to be ELAVL4. The Offringa lab and collaborators determined that the antigenic epitope consists of isoaspartylated ELAVL4 (isoAspELAVL4) [PMID 27725125]; the protein carries isoaspartylated residues in the N-terminal region (amino acids 1-36). All tested Anti-Hu-positive SCLC patient serum samples reacted with isoAspELAVL4, and all examined SCLC tissue samples stained positive for isoAspELAVL4 [PMID 27725125]. Here we used the Trp53fl/fl; Rb1fl/fl inducible SCLC mouse model [PMID 14522252] to examine 1) whether immunization with isoAspELAVL4 prior to SCLC induction is protective, and 2) whether immunization with isoAspELAVL4 following completion of 3 rounds of cisplatin+etoposide therapy increases survival. In both cases, mice were immunized with recombinant N-terminal fragment of ELAVL4 (amino acids 1-117) generated in *Clear Coli* and emulsified in incomplete Freund's adjuvant (IFA) or control (phosphate-buffered saline in IFA). The trajectories of mice have been monitored with a detailed body metric score and blood has been drawn every 2 weeks to monitor the anti-ELAVL4 antibody response. Kaplan-Meier analysis will be used to assess survival differences between the immunized and control groups and will be presented. The study will provide insight into interplay between SCLC and the immune response to isoAspELAVL4.

Classification of patient-specific sensitivity to immunotherapies by *ex vivo* tumor testing

Lieke Johanna Ceton[1], Marta Garcia Montero[1], Fanny Grillet[1], Dieudonné J. van der Meer[1], Willemijn Vader[1], Anne van Altena[2], Cor D. de Kroon[3], Nelleke Ottevanger[4], Judith Kroep[5]. *[1]VitroScan B.V., Leiden, Netherlands,[2]Gynecology, Radboud University Medical Centre (Radboudumc), Nijmegen, Netherlands,[3]Gynecology, Leiden University Medical Centre (LUMC), Leiden, Netherlands,[4]Radboud University*

Medical Centre (Radboudumc), Nijmegen, Netherlands,[5]Leiden University Medical Centre (LUMC), Leiden, Netherlands

Background: Immunotherapy has brought great progress with durable responses for cancers that were difficult to treat. However, it remains challenging to select sensitive patients upfront. PD-L1 expression, TMB and MSI/MSS status, do not optimally differentiate between the potential sensitivity to the individual immunotherapies.
Purpose: We aim to improve stratification of patients for immunotherapy through classification of patient-specific tumor sensitivity based on 3D ex vivo drug measurement.
Material: Our study includes 108 Patients with predominantly ovarian carcinoma (81/108). Tumor tissue was collected in ongoing clinical trials from biopsies, ascites or pleural fluid. Five immune checkpoint inhibitors and a STING pathway activator were tested.
Method: Fresh tumor clusters were seeded into 384 well plates and exposed to different immunotherapies, while preserving the TME. Tumor killing and immune cell proliferation were measured using 3D image analysis. Ex vivo tumor sensitivity was classified as no response (<10%), weak (10-20%), strong (20-50%), and very strong (>50%), based on percentage tumor killing and statistical significance (p-value: * < 0.05, ** < 3.33e-4).
Results: Differential patient response profiles were observed (Table 1). For the current cohort, we measured a highly significant immunotherapy response for ~30% of the samples. The assay has a technical success rate of 89%.
Conclusion: This study reports the development of a robust ex vivo tumor testing platform that classified patient-specific sensitivity to 6 immunotherapies for over 100 patients, demonstrating the potential of ex vivo tumor testing to optimize patient stratification for immunotherapy.
Discussion: The platform enables improved efficiency in clinical development of novel treatments and supports treatment decisions in the clinic. Clinical trials are ongoing to establish the correlation of our testing with patients' response to immunotherapy in lung cancer.

Overview of ex vivo immunotherapy response per category

Therapy	**# Samples tested**	**% Response**	**No response**	**Weak**	**Strong**	**Very strong**

Can exosomal cargoes predict checkpoint inhibitor response in melanoma, and can we overcome drug resistance?

Pablo Eduardo Puente[1], Dan Nguyen[1], Niramol Savaraj[1], Chunjing Wu[1], Medhi Wangpaichitr[1], Stephane Roche[2], Guangkuan Zhao[2], Alexis Richaud[2], Jose Lutzky[3], Leonel Hernandez Aya[3], Mecker Moller[3], Jessica Crystal[3], Neha Goel[3], Lynn Feun[3]. *[1]Miami VA Healthcare System, Miami, FL,[2]Florida Atlantic University Department of Chemistry and Biochemistry, Boca Raton, FL,[3]University of Miami Miller School of Medicine, Miami, FL*

Immune check point inhibitor(s) have become a main stay of treatment for melanoma regardless of its mutational status. However, not all patients respond to treatment. In fact, only 40-60% respond to treatment. Currently, only PD-L1/PD-1 expression and mutational burden can predict response to treatment. Published data have shown that exosomal PD-L1 is an important factor contributing to response/failure to checkpoint inhibitor treatment. Exosome is known to carry several types of cargoes and is one of the

important delivery systems in the body. We have begun to examine the role of exosomal PD-L1, PD-1 in predicting response, and as well as how to overcome drug resistance. We initiated an institutional study in metastatic melanoma patients who underwent immunotherapy treatment (anti-PD-1 + anti-CTLA 4 drugs). Blood samples were obtained at baseline and at subsequent treatment. Both serum and plasma exosomes were isolated. Eighteen patients were entered in the study. We have found that 1) Patients with PD-L1 negative tumor can have high exosomal PD-L1 expression, 2) all patients had exosomal PD-L1, and 3) all patients with decreased exosomal PD-L1 expression after treatment showed antitumor response [partial response (PR) or complete response (CR)]. In contrast, patients who had consistently high exosomal PD-L1 expression post-treatment showed no response, and this can be seen after the third cycle of treatment. Patients who achieved CR showed low exosomal PD-L1 and no exosomal PD-1 post-treatment. Importantly, we have also found that exosomes carry antiapoptotic protein and proapoptotic protein, as well as ATG family protein, which is related to autophagy. Whether these proteins also play a role in determining the cell fate in the metastatic sites is not known and will need future investigation. Interestingly, the two patients who showed no response also had high p-AKT. Since traditional anti PD-1 and anti-PD-L1 drugs do not have effect on exosomal PD-L1 and PD-1, we formed a collaboration with Dr. Stephane Roche at Florida Atlantic University, who has designed novel peptides by exploiting the innate plasticity of the PD-1 receptor (pembrolizumab H3 loop mimics). Thus far, we have screened many compounds and have selected 2 compounds for further testing. Together, we have also designed new PD-L1 peptides that can inhibit both PD-L1 and PI3K/AKT pathways simultaneously. Hence one can overcome checkpoint inhibitor resistance due to exosomal PD-L1/PD-1. Supported by grant from Sylvester Comprehensive Cancer Center and R21GM132754.

KLRG1 marks tumor-infiltrating CD4 T cell subsets associated with immune escape and immunotherapy response

Casey Ager, Matthew Chaimowitz, Shruti Bansal, Meri Rogava, Johannes Melms, Catherine Spina, Cory Abate-Shen, Charles G. Drake, Matthew Dallos, Benjamin Izar. *Columbia University, New York, NY*

Current methods for biomarker discovery and target identification in immuno-oncology rely on static snapshots of tumor immunity. To better capture the dynamic and compartmentalized nature of antitumor immune responses, we generated longitudinal “temporal atlases” of productive versus non-productive antitumor immune responses in murine tumor models. We utilized a 34-parameter full spectrum flow cytometry panel to comprehensively profile immune composition within tumors, draining and non-draining lymph nodes, and blood in and around key inflection points of tumor regression or progression. We leveraged two distinct preclinical models for this; the NPK-C1 ectopic prostate cancer model to map dynamics of spontaneous cancer immunoediting, and anti-PD-1 treated MC38 tumors to study response or non-response to immune checkpoint blockade (ICB). We utilized UMAP and FlowSOM algorithms for iterative dimensionality reduction and clustering, respectively, to reveal novel phenotypes associated with productive versus non-productive immunity across model systems, tissues, and time points. We discovered expression of KLRG1 within the intratumoral CD4 T cell compartment was highly associated with tumor progression and response to ICB. Specifically, both FoxP3+ Tregs and FoxP3- Tconv cells within tumors accumulated KLRG1 expression through disease progression, but this was not observed in CD4 T cell or other immune subsets residing in lymph nodes or circulating in blood. Among all intratumoral clusters, KLRG1+ Tconv were the only subset significantly correlated with tumor burden at each time point tested and across both models. KLRG1+ Tconv were significantly enriched in NPK-C1 tumors undergoing progression to escape versus those under immune-mediated equilibrium ($p=0.0004$) and were lost in animals undergoing curative responses to ICB ($p=0.003$). In the Treg compartment, unsupervised clustering revealed a KLRG1+Helios- tumor Treg subset that was positively correlated with transition from equilibrium to escape in the NPK-C1 model ($p=0.005$). Also indicating a potential functional significance, this phenotype was absent in tumors undergoing curative responses to ICB ($p=0.0002$). Systematic investigation of the functional characteristics, transcriptional programming, and translational significance of intratumoral KLRG1+ CD4 T cell subsets is ongoing. Together, these findings identify KLRG1+ CD4 T cell populations as subsets for further investigation in cancer and demonstrate the utility of longitudinal full

spectrum flow cytometry profiling as an engine of dynamic biomarker and/or target discovery in immuno-oncology.

Modulating gut microbiota to improve intrahepatic immunity against hepatocellular cancer

Xiaogiang Qi, Ming Yang, Lixin Ma, Jonathan Mitchem, Jussuf Kaifi, Shiyou Chen, Aaron Ericsson, Eric Kimchi, Kevin Staveley-O'Carroll, Guangfu Li. *University of Missouri - Columbia, Columbia, MO*

Gut microbiota plays a pivotal role in the pathogenesis of hepatocellular cancer (HCC), significantly affecting the HCC treatment. It has been reported that the HCC patients' response to the immunotherapy of PD-1/PD-L1 blockade was associated with their gut microbiota profiles. However, the impact of gut microbiota on anti-HCC immunity and its underlying mechanism are poorly understood. Treating HCC-bearing mice with a specific and non-hepatotoxic antibiotic cocktail caused the increased relative abundance of specific commensal bacteria such as *Bacteroides*, resulting in suppression of HCC growth and development which was involved in the activation of intrahepatic antitumor immune responses. Gut microbiota recolonization of *Bacteroides thetaiotaomicron (B. th)* in gut-sterilized HCC-bearing mice significantly improved the therapeutic efficacy of anti-PD-1 antibody (αPD-1 Ab) against HCC. Fecal microbiota transplantation (FMT) from HCC patients who received and responded to αPD-1 Ab treatment improved the efficacy of αPD-1 Ab treatment against HCC in mice model. Mechanistic studies demonstrated that the modulation of Krüppel-like factor 2 (KLF2) / Toll-like receptor 9 (TLR9) signaling and the accumulation of CpG-enriched genomic DNAs of *B. th* in livers/tumors activated the tumor antigen-specific $CD8^+$ T cells through the dendritic cell in a TLR9-dependent manner. In conclusion, gut microbiota as a causative factor can be targeted to improve anti-HCC immunotherapy.

Molecular insights into resistance mechanisms to therapy with T cell bispecific antibodies

Johannes Sam[1], Llucia Alberti Servera[1], Sina Nassiri[1], Atul Sethi[1], Alison Ribeiro[1], Gabrielle Leclercq-Cohen[1], Petra Schwalie[2], Tamara Hüsser[1],

Emilio Yangueez[1], Sylvia Herter[1], Christian Klein[1], Pablo Umana[1], Marina Bacac[1]. *[1]Roche Glycart AG, Schlieren, Switzerland,[2]Roche Innovation Center Basel, Basel, Switzerland*

T Cell Bispecific Antibodies (TCBs) are potent molecules that induce durable complete remissions with a favorable safety profile in Relapsed Refractory Non Hodgkin Lymphoma patients. Despite the promising clinical efficacy, a proportion of patients escape under treatment due to the occurrence of primary and acquired resistance mechanisms that may involve the modulation of target antigen expression, cancer cell intrinsic mechanisms, T cell functionality or treatment-induced changes in the tumor microenvironment (TME). Therefore, a better understanding of TCB-induced resistance mechanisms is of great importance to enable the design of novel therapeutic approaches and/or combination strategies to overcome resistance. We present the results of exploratory preclinical analysis using an aggressive lymphoma model in humanized mice and a syngeneic melanoma model in immunocompetent mice, focusing on the assessment of T cell functionality, TME reprogramming, and cancer cell intrinsic changes upon longitudinal TCB treatments, encompassing tumor regression and escape. Flow cytometry, IHC, scRNAseq and ex vivo functional analysis of T cell cytotoxicity and cytokine release demonstrate that intra-tumor T cell functionality is preserved over serial TCB treatments, including tumor escape. On the other hand, TCB treatment induced a reprogramming of the TME consisting of rapid myeloid cell infiltration, followed by the expansion of intra-tumor T cells at a later time point (favoring higher CD8:CD4 ratio). Cumulative evidence from in vitro and in vivo scRNAseq experiments provided insights into macrophage reaction to TCB-mediated T cell inflammation, consisting of a rapid (as early as 2 h) activation and upregulation of several pro-inflammatory molecules (IL-1b, CXCL8, CXCL9, CXCL10, CXCL1, CCL2, CCL3, CCL4, CCL5, IFN-g-induced genes: GBP2 -8 and BATF2). This was followed by a shift towards a more suppressive phenotype at later time points (20-96 h) as evidenced by the expression of PD-L1, INHBA, IDO, FLT1 genes. The analysis of cancer cells showed upregulation of Wnt/beta catenin, p53 and Hedgehog signaling pathways at tumor escape. In contrast, proliferation signatures including MYC, E2F target genes, MTORC signaling, and G2M checkpoint, along with metabolic pathways of oxidative phosphorylation

and glycolysis were enriched in cancer cells at regression. Taken together, our data show that T cell cytotoxicity and functional states are preserved during tumor regression and tumor escape phases, suggesting that T cell dysfunctionality is unlikely to be the sole cause of TCB resistance. TME reprogramming, consisting of a rapid myeloid cell infiltration and their acquisition of a suppressive phenotype over time, along with a selection of cancer cell clones that escape the TCB-mediated cytotoxicity and upregulate Wnt, p53 and Hedgehog pathways could contribute to TCB-mediated resistance, leading to tumor escape.

The role of microRNAs in the tumor immune microenvironment

Catherine T. Cronister, Robert S. Seitz, Brian Z. Ring, Douglas T. Ross, Brock Schweitzer. *Oncocyte Inc., Nashville, TN*

Background: miRNA have been shown to be central communicators between the immune system and cancer. They are attractive as candidate blood-based cancer detection targets because they are secreted in high copy number from cancer cells, are bound to circulating proteins and have secondary structures that prolong their half-life in blood. miRNAs that are thought to communicate between cancer associated fibroblasts and immune cells are of special interest for their potential involvement in transitions in the TIME from "hot" - an inflammatory state with a greater likelihood of sensitivity to immune checkpoint inhibitors - to "cold" - tumors with an immunosuppressive state or immune inert state or vice versa. We have previously described a gene expression signature that distinguishes immunomodulatory (IM, inflammatory cells), mesenchymal (M, EMT differentiated cells), and mesenchymal stem-like (MSL, cancer associated fibroblasts) features of the TIME, and when converted to a binary classifier, has been shown to be correlated with response to immune checkpoint inhibitors (ICI). Here we use TCGA microRNA data to identify a microRNA correlate of this classifier.
Methods: miRNA and RNA expression were collected from TCGA across five tissue types. Each tumor case was assigned a TIME phenotype as previously described [1]. Lung, breast, colon, and bladder data were used to identify miRNA’s whose expression pattern significantly correlated with at least one of three immune phenotypes identified by the previously defined

algorithm. Data from the IntAct database were used to identify putative gene targets of the candidate miRNA.
Results: Of the 151 miRNAs of interest, 147 known interactions were found in the IntAct database. Of these 147 interactions, 107 were between miRNA and genes of different TIME (or immune) phenotypes while 89 were interactions between miRNAs and genes implicated in regulating immune hot and cold phenotypes.
Conclusions: We identified miRNA whose expression patterns correlates with a classifier of the TIME that has been shown to identify likely responders to immune checkpoint inhibitors. This candidate gene list was significantly enriched for both miRNA targets of known immune mediators and or targets implicated in modulating the TIME. Next steps are to further narrow the list to those detectable in blood in cancer, and to train a blood-based diagnostic that might be able to predict response to ICI therapy for those patients where tissue is not available.

Anti-KRAS antibody aggregates KRAS in the cytoplasm of live *ex vivo* cultured human colorectal adenocarcinoma cells and prevents its trafficking to the plasma membrane

Peh Yean Cheah[1], Kuen Kuen Lam[1], Yee Syuen Low[1], Michelle Lo[1], Michelle Wong[1], Choong Leong Tang[1], Emile Tan[1], Aik Yong Chok[1], Issac Seow En[1], Siew Heng Wong[2]. *[1]Singapore General Hospital, Singapore, Singapore,[2]JW Bioscience, Singapore, Singapore*

Worldwide, colorectal cancer (CRC) is the third highest incidence cancer and a leading cause of cancer mortality. Metastasis to distal organ is the major cause of cancer mortality. However, chemotherapeutic treatment of metastatic CRC has a dismayed success rate of less than 30%. Patients who are resistant to chemotherapy and who are *KRAS* wildtype are sometimes offered anti-EGFR as a second line therapy. Nevertheless, only about ½ of these patients respond and those who do inevitably develop resistance within months due to selection for downstream *KRAS* mutations. Moreover,

most (80%) sporadic CRCs are microsatellite-stable and are refractory to immune checkpoint blockade therapy. Hence, there is an unmet need to identify novel therapeutics for CRC. KRAS is a gatekeeper gene in colorectal tumorigenesis but is 'undruggable' due to its structure not being easily amenable to inhibitor docking. Focus has been diverted to develop small molecule inhibitors for its downstream effectors such as ERK/MAPK and AKT. Despite intense research efforts for the past few decades, however, no small molecule inhibitor has been in clinical use for CRC. Recently developed Sotorasib inhibitor specific for *KRAS* G12C mutations (rare in CRC) is not effective for CRC. Antibodies have high affinity to their target proteins without having to bind to specific pocket and are fully human in nature and hence less toxic. Antibody targeting KRAS itself is thus an attractive alternative. We developed a transient *ex vivo* patient-derived matched mucosa-tumor primary culture to assess whether anti-KRAS antibody can be internalized to bind and inactivate KRAS. We showed that anti-KRAS antibody can enter live matched mucosa-tumor cells and specifically aggregate KRAS in the cytoplasm, thus hindering its trafficking to the inner plasma membrane. The mis-localization of KRAS reduces KRAS dwelling time at the site where it tethers to activate downstream effectors. We previously showed that expression of SOX9 was *KRAS*-mutation-dependent and possibly a better effector than ERK in CRC. In the present study, we showed that anti-KRAS antibody treated tumor cells have less intense SOX9 cytoplasmic and nuclear staining compared to untreated cells suggesting down-regulation of *KRAS* signaling. Our results demonstrated that anti-KRAS antibody can be internalized and specifically inhibits KRAS function in live tumor cells. With an efficient intracellular antibody delivery system, this can be further developed as combinatorial therapeutics for CRC and other KRAS-driven cancers.

Depletion of tissue-resident B cells by a CD20xCD3 IgM bispecific T cell engager in cynomolgus monkeys demonstrates effective tissue penetration and potent target cell killing

Miho Oyasu, Angus M. Sinclair, Haben Ghermazien, Genevive Hernandez, Thomas Manley, Maya K. Leabman, Stephen F. Carroll, Bruce A. Keyt, Maya F. Kotturi. *IGM Biosciences, Inc., Mountain View, CA*

Imvotamab (IGM-2323) is an engineered high-affinity, high-avidity bispecific anti-CD20 IgM antibody T cell engager (TCE) that is currently being studied as monotherapy in a Phase 1/2 clinical trial for relapsed/refractory non-Hodgkin's lymphoma (NHL) (NCT04082936). Imvotamab offers a novel treatment strategy in NHL by depleting CD20-expressing tumor cells through multiple mechanisms, including the recruitment of T cells to kill tumor cells through T cell dependent cellular cytotoxicity, complement-dependent cytotoxicity, and enhanced immune modulation via IFNγ-dominant cytokine stimulation. We evaluated the activity of a surrogate cynomolgus monkey cross-reactive CD20xCD3 IgM bispecific TCE, IGM-2324, in depleting CD20-expressing B cells in peripheral blood and lymphoid tissues of cynomolgus monkeys in vivo. We hypothesized that the high affinity and valency of IGM-2324 would enable potent B cell killing in blood and tissues even when B cells express low levels of CD20. Cynomolgus monkeys were administered vehicle or IGM-2324 at 5 mg/kg or 25 mg/kg through intravenous infusion twice weekly for a total of four doses on days 1, 4, 7, and 10. B cell depletion in peripheral blood was assessed by measuring the frequency of CD19+ B cells through flow cytometry. Administration of IGM-2324 at 5 and 25 mg/kg resulted in a nearly complete depletion in peripheral CD19+ B cells at 8 hours post the 1st dose through 24 hours post the last dose on day 11. Depletion of tissue-resident B cells was evaluated in the spleen, mesenteric lymph node (MLN) and bone marrow (BM) of monkeys at 24 hours post the last dose of vehicle or IGM-2324 on day 11. Immunohistochemistry studies were conducted on the formalin-fixed paraffin-embedded lymphoid tissues by staining for CD19 and CD20 expression. The number and intensity of CD19 or CD20 positive B cells were determined by quantitative imaging analysis. Compared to vehicle-treated animals, significant dose-dependent reductions in both CD19 and CD20-expressing B cells were observed in spleen, MLN and BM following treatment with 5 and 25 mg/kg of IGM-2324. Most importantly, IGM-2324 treatment led to the depletion of not only high and moderate tissue-resident CD20-expressing B cells, but also B cells that expressed low levels of CD20. Our preclinical data indicate that a CD20xCD3 IgM bispecific TCE can penetrate tissues and mediate direct killing of CD20-expressing target cells. B cell depletion in the periphery and tumors of relapsed/refractory NHL patients is currently being evaluated

as biomarker of pharmacodynamic activity and/or efficacy for imvotamab in a Phase 1/2 clinical study.

Heterogenous cellular responses to GITR and TIGIT immunotherapy in the human gastrointestinal tumor microenvironment

Anuja Sathe[1], Carlos Ayala[2], Xiangqi Bai[1], Sue M. Grimes[1], Andrew Shelton[2], Byrne Lee[2], Cindy Kin[2], George Poultsides[2], Hanlee P. Ji[1].
[1]Stanford University School of Medicine, Stanford, CA,[2]Department of Surgery, Stanford University, Stanford, CA

Many new immunotherapy agents fail in clinical trials. Major gaps remain in our understanding of their precise mechanism of action, with findings from preclinical studies that do not translate into the clinic. We identified the cellular and molecular responses to co-stimulatory GITR and co-inhibitory TIGIT immunotherapy by using an experimental approach that overcomes these challenges. We investigated these responses in a patient-derived *ex vivo* system that maintains the original tumor microenvironment (TME) in its near-native state. Using single-cell RNA sequencing (scRNA-seq) and paired single-cell TCR sequencing (scTCR-seq), we identified treatment induced transcriptional reprogramming in different cell lineages in the TME. We established *ex vivo* slice cultures from ten surgical resections of colorectal or gastric cancer. These cultures maintained all epithelial, stromal, and immune cell types and transcriptional cell states found in the original tissue sample. All tumors responded with activation of CD8, CD4 and T regulatory (Treg) cells following PMA/Ionomycin treatment, confirming the viable and functional status of the model system. GITR agonist led to a modest increase in cytotoxic gene expression in CD8 T cells in four out of nine patients. Transcriptional non-responders had significantly increased dysfunctional phenotype at baseline compared to responders. *Ex vivo* analysis confirmed that only cells with an effector non-exhausted cell state responded to GITR agonist, while exhausted cells did not. GITR agonist did not induce significant changes in expression in regulatory T (Treg) or T follicular helper-like (TFh-like) cells. TIGIT antagonist increased TCR signaling and activation in all five patients. These responses were observed in both effector and exhausted cells. A reduced transcriptional response to TIGIT in CD8 T cells correlated with the

increased expression of *GZMK*, *TXNIP* and *RGS1* together with reduced expression of metallothionine family genes. TIGIT antagonist also increased activation specifically in expanded TCR clonotypes, which are indicative of tumor antigen reactive cells. TIGIT antagonist further increased activation of TFh-like cells together with increased expression of B cell attracting chemokine *CXCL13*. Tregs responded with a reduced expression of *CTLA4* and *TNFRSF4* (OX40), indicative of modulation of immunosuppressive cell state.Our approach successfully identified heterogenous cellular and patient responses to GITR stimulation and TIGIT inhibition in gastrointestinal cancers. TIGIT antagonist led to a wider reprogramming of the TME compared to the limited effects of GITR agonist. Our strategy identified mechanisms of action of immunotherapy and factors associated with response or resistance, which can aid in prioritization of targets and their clinical translation.

TIL-containing patient-derived explant cultures reveal role of metformin on antigen presenting cell activation

Rita J. K. Turpin[1], Ruixian Liu[1], Pauliina Munne[1], Aino Peura[1], Jenna Rannikko[2], Gino Philips[3], Natasha Salmelin[1], Elina Hurskainen[1], Ilida Suleymanova[1], Minna Mutka[4], Tuomo Meretoja[5], Johanna Mattson[6], Satu Mustjoki[7], Päivi Saavalainen[8], Diether Lambrechts[3], Jeroen Pouwels[1], Maija Hollmén[2], Juha Klefström[9]. *[1]University of Helsinki, Helsinki, Finland,[2]Medicity Research Laboratories, University of Turku, Turku, Finland,[3]Human Genetics, VIB - KU Leuven Center for Cancer Biology, KU Leuven, Belgium,[4]Department of Pathology, HUSLAB and Haartman Institute, Helsinki, Finland,[5]Breast Surgery Unit, Helsinki University Central Hospital, Helsinki, Finland,[6]Department of Oncology, University of Helsinki & Helsinki University Hospital, Helsinki, Finland,[7]Clinical Chemistry and Hematology, University of Helsinki, Helsinki, Finland,[8]and Folkhälsan Research Center, University of Helsinki, Helsinki, Finland,[9]and FICAN Cancer Institute, and FICAN South Helsinki University Hospital, University of Helsinki, Helsinki, Finland*

Globally, breast cancer is among the most diagnosed cancer types for women. Current and upcoming breast cancer therapies are being

investigated in combination with compounds that stimulate an immune response, but whether the therapeutic agents themselves have unexpected immunomodulatory effects is often overlooked. Here, we have developed a method to grow 3D cultures of intact fragments of patient-derived tissue (Patient-Derived Explant Cultures; PDECs) to assess the preclinical potential of studying human tumor cells and immune cells simultaneously *ex vivo.* Single cell sequencing, flow cytometry, gene expression profiling and cytokine profiling data show that the tumor immunocontexture is conserved in PDECs and that these resident immune cells respond to distinct immune stimulus. We performed gene expression profiling, flow cytometry, and cytokine profiling of drug-treated human explants and found that metformin has antitumor potential through the activation of antigen presenting cells. We further validated *in vitr*o that metformin-mediated APC activation is largely through mitochondrial respiration inhibition irrespective of the presence of tumor cells. Our PDEC platform highlights the preclinical potential of *ex vivo* explants by simultaneously offering information of tumor and immune cell toxicity and mechanism.

Rhus verniciflua Stokes (RVS) inhibits PD-1 expression and induces anticancer effects via enhancing T-cell function

Seoyoung Kim[1], Young-Kwan Lee[1], Hyoun Jong Moon[1], Sunki Lim[1], Yujeong Gho[1], Wang Jun Lee[2], Sanghun Lee[3], Excelsisbio Inc.. *[1]New Horizon Cancer Institute, Myongji Hospital, Goyang-Si, Korea, Republic of,[2]Myongji Hospital, Goyang-Si, Korea, Republic of,[3]Dankook Univ. Hospital, Goyang-Si, Korea, Republic of*

Rhus verniciflua Stokes (RVS) has traditionally been used for centuries as a therapeutic herb and food supplement in East Asian countries. Over the last decade, the anticancer effects of RVS have been demonstrated in various preclinical and clinical studies. RVS contains major flavonoids such as fustin, fisetin, and sulfuretin, which were known to have apoptotic or anti-proliferative activities in various cancer cell lines. In clinical retrospective studies, RVS administration exclusively suggested more favorable outcomes with prolonged overall survival in solid cancer patients. However, the effect of RVS on immuno-oncology, especially the functional properties

of T cells and their phenotypes remain unclear. Dried RVS grown in Wonju (Korea) was extracted with sterile distilled water after removing the allergen (urushiol). Peripheral blood mononuclear cells (PBMCs) from breast cancer patients with HLA-A*02:01 were isolated using a vacutainer tube and cultured for T cell expansion in the presence of interleukin (IL)-2 for 14 days. Cells were enriched above 90% $CD3^+$ T cells after 14 days of expansion. Red fluorescent protein (RFP)-expressing HLA-A*02:01-matched breast cancer cell lines (MCF7 and MDA-MB-231), were used to determine the anticancer activity of T cells in the presence or absence of RVS. For *in vitro* killing assays, MCF7 and MDA-MB-231 cell lines expressing RFP were co-cultured with T cells with or without RVS treatment for 48 h, and cell viability was measured by the MTT assay. The phenotypic characteristics of the T cells were profiled by staining with various T cell surface markers, including CD3, CD4, CD8, PD-1, and CTLA4. RVS toxicity in the target cells (MCF7 and MDA-MB-231) was not observed at RVS concentrations up to 250 ug/mL. The anticancer activity of T cells against breast cancer cells was significantly increased by adding both 10 ug/mL and 100ug/mL of RVS. T cells co-cultured with MCF7 and MDA-MB-231 cells in the presence of 100 ug/mL of RVS showed 20.6% increases in cytotoxicity in MCF7 cells and 36.2% in MDA-MB-231 cells compared to no RVS treatment. Interestingly, relative reductions in programmed death-1 (PD-1) were found in T cells co-cultured with target cells by adding RVS, even though there was no significant difference in the other markers observed. Our findings showed that RVS could improve the function of T cells against cancer cells in the tumor microenvironment, as interpreted by reduced PD-1 expression in T cells after RVS treatment. Therefore, the components of RVS are candidates for restoring T cells exhausted against cancer. Active compounds should be identified for clinical efficacy, and further studies are necessary for combination strategies with conventional cancer treatments, such as chemotherapy and radiotherapy.

Targeting the clock pathway to modulate immune response in MSI-high colorectal cancer (CRC): evidence from a preclinical *in vivo* model

Shivani Soni[1], Francesca Battaglin[1], Sofi Castanon[1], Jae Ho Lo[1], Goar Smbatyan[1], Priscilla Chan[2], Meng Qu[2], Priya Jayachandran[1], Hiroyuki

Arai[1], Natsuko Kawanishi[1], Wu Zhang[1], Steve A. Kay[2], Heinz Josef Lenz[1], Evanthia T. Roussos Torres[1]. *[1]Medical Oncology, USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Neurology, University of Southern California, Los Angeles, CA*

Background**.** Immune checkpoint inhibitors have substantial clinical success in MSI-H/dMMR metastatic CRC. However, only a subset of patients exhibits durable responses, emphasizing the importance of identifying mechanism of innate and acquired resistance. The relation between the circadian clock and the immune system is well established. We used a syngeneic mouse model of MSI-H CRC to investigate whether a targeted enhancement of clock repressor proteins cryptochrome 1/2 (CRY 1/2) may affect tumor growth and response to anti-PD1 (aPD1).
Methods. $1X10^6$ MC38 cells were subcutaneously implanted into the right flank of 8 weeks old C57BL/6 mice. Mice were randomized into 1 control and 3 treatment arms (10 mice/group): A. CRY stabilizer SHP656(10 mg/kg PO, 5 days/week); B. aPD1 (100 μg/mouse IP, twice/week administered for 2 weeks); C**.** combination SHP656 + aPD1. Tumors from 4 mice/group were processed for tumor infiltration studies. Remaining 6 mice/group were kept for 3 weeks on maintenance aPD1 (twice/week) for survival studies. Treatment response was measured by tumor growth and survival. Treatment effects on immune cell infiltration in the tumor microenvironment (TME), functional myeloid derived suppressor cells (MDSCs) and T cells markers were investigated via flow cytometry.
Results. Single agent SHP656 significantly improved survival when compared with vehicle treated mice. Similarly, combination treatment with SHP656 + aPD1 improved survival, however no additional benefit was observed over treatment with aPD1 alone. All treatment groups had a response rate of 67% (4/6 mice/treatment group showed 2-fold decrease in tumor volume 24 days after tumor challenge vs vehicle). In responders, SHP656 as a single agent or in combination with aPD1 were more effective in suppressing tumor growth as compared to aPD1 alone. Flow cytometry of 14 tumor samples demonstrated that monocytic-MDSC infiltration was significantly decreased in the combination therapy and aPD1 alone treatment arms ($p = .016$) as compared to vehicle suggestive of a less suppressive TME. T cell analysis suggested a decrease in intratumoral exhausted $CD8^+$ T cells ($TIM3^-PD\text{-}1^+$, $p = .02$) in SHP656 + aPD1 vs

vehicle, while infiltration of $CD4^+$ T cells and T regulatory cells were not significantly affected by any treatment. Nanostring profiling on treated tumors also confirmed immune activation in responders.
Conclusions. Our results show for the first time that targeting the clock pathway through modulation of CRY affects TME and tumor progression in *in vivo* models of MSI-H CRC. A decrease in infiltration of mMDSCs and exhausted $CD8^+$ T cells seems to play a critical role in combination treatment efficacy but needs to be studied further. These results, suggests that pharmacological targeting of the circadian machinery holds great potential and could significantly impact the efficacy of immunotherapy in metastatic CRC.

#4125
Rencofilstat exerts a dominant role in synergistic anti-PD1-combination effects in a fatty liver model of hepatocellular carcinoma
Daren Ure[1], Jack Leslie[2], Lacey Haddon[1], Claude Fu[1], Jelena Mann[3], Derek Mann[4]. *[1]Hepion Pharmaceuticals, Edison, NJ,[2]Newcastle University, Newcastle, United Kingdom,[3]Fibrofind Ltd, Newcastle, United Kingdom,[4]Newcastle University and Fibrofind Ltd, Newcastle, United Kingdom*

Rencofilstat is a clinical-phase drug candidate that inhibits multiple cyclophilin isomerases and affects many cellular processes. The objectives of this study were to characterize rencofilstat's anti-tumor effects alone and in combination with anti-PD1 in a murine model of fatty liver-associated hepatocellular carcinoma (HCC). Murine Hep53.4 HCC cells were orthotopically implanted into livers of C57BL/6 mice fed either a normal diet or western diet. Treatments included rencofilstat and anti-PD1 IgG, alone or in combination, from Weeks 2-4 post-implantation. End-of-study analyses included tumor growth, survival, and tumor gene expression by bulk RNA sequencing. Hep53.4 tumors in fatty livers ("fatty tumors") were more resistant to treatments compared to tumors in nonfatty livers ("nonfatty tumors"). On the normal liver background, rencofilstat and anti-PD1 IgG as monotherapies or in combination decreased tumor volumes by 76-83%. In contrast, only combination treatment consistently decreased tumor volumes (84%) in fatty livers. Rencofilstat plus anti-PD1 IgG also extended mouse survival in the fatty liver model. Tumor transcriptomic

analyses revealed marked differences between treatments and tumor types. Rencofilstat altered the expression of 3-times more genes than anti-PD1 in fatty tumors (differentially expressed genes; DEGs), whereas the two treatments affected similar number of genes in nonfatty tumors. The same was true when analysis was restricted to only those genes whose expression correlated with tumor volume. The identities of the DEGs were very different between rencofilstat and anti-PD1 treatments in nonfatty tumors. In contrast, in fatty tumors, 40% of the anti-PD1 DEGs also occurred in rencofilstat-treated tumors, suggesting that rencofilstat can moderately mimic anti-PD1 in fatty tumors. Rencofilstat DEGs also overlapped significantly with combination-treatment DEGs (46%) in fatty tumors, whereas only 7% of the anti-PD1 DEGs were represented in the combination treatment tumors. DEG pathway mapping revealed that the biological pathways predicted to be affected by rencofilstat and anti-PD1 were highly dependent on the type of tumor. In nonfatty tumors both drug treatments predominantly affected cellular biology processes such as protein processing and metabolism, but in fatty tumors both drug treatments overwhelmingly affected immune-related processes such as T cell differentiation, natural killer cells, checkpoint pathways, and cytokine-chemokine signaling. These results highlight major differences in phenotype and treatment response of tumors in fatty livers compared to nonfatty livers. Furthermore, they suggest that a combination of a checkpoint inhibitor with rencofilstat may be especially efficacious for HCC in individuals with NAFLD or NASH, due in part to rencofilstat's multi-pathway targeting.

Anti-tumor immunity of M9657, a conditional CD137 immune agonist, is correlated with mesothelin expression on tumor cells

Chunxiao Xu[1], Xueyuan Zhou[1], Sireesha Yalavarthi[1], Rene Schweickhardt[1], Andree Blaukat[2], Laura Helming[1]. *[1]EMD Serono, Billerica, MA,[2]Merck KGaA, Darmstadt, Germany*

Background: In clinical trials, systemic administration of first-generation CD137 agonist monotherapies was suspended due to either low anti-tumor efficacy or hepatotoxicity mediated by the epitope recognized on CD137 and Fc gamma receptor (FcγR) ligand-dependent clustering. M9657 is a

bispecific conditional agonist that has been developed to bind simultaneously to mesothelin (MSLN) and CD137 to stimulate an anti-tumor immune response in the tumor microenvironment. M9657 was engineered in a tetravalent bispecific antibody (mAb^{2}™) format with a human IgG1 backbone with LALA mutations, which abrogates binding to FcγRs but retains FcRn binding for IgG-like pharmacokinetics. M9657 is expected to have enhanced anti-tumor efficacy while avoiding systemic immune activation.
Methods: MSLN surface copy number was quantified in a series of cancer cell lines with a broad range of MSLN expression. $CD8^+$ T cell-mediated tumor cell cytotoxicity and cytokine release from $CD8^+$ T cells were investigated in a series of in vitro functional assays. The receptor occupancy (RO) of MSLN on the tumor cell surface and of CD137 on $CD8^+$ T cells was determined by flow cytometry. MSLN in EMT-6 cells was knocked out using CRISPR and confirmed by immunohistochemistry. The anti-tumor efficacy of FS122m, a murine-reactive surrogate of M9657, was investigated in EMT-6 parental and MSLN knockout syngeneic tumor models.
Results: M9657 displayed MSLN-dependent cytokine release and tumor cell cytotoxicity. IFNγ release by $CD8^+$ T cells correlated with MSLN copy number on tumor cells. MSLN copy number of 3000 was found to be the minimum required to trigger CD137 agonism. CD137 RO by M9657 on activated human $CD8^+$ T cells and MSLN RO by M9657 on tumor cells increased with increasing concentrations of M9657. M9657 caused full agonism (EC_{100}) when CD137 RO on activated human $CD8^+$ T cells was approximately 30-38%. The mouse surrogate FS122m demonstrated potent dose-dependent anti-tumor efficacy in the EMT-6 tumor model, while no anti-tumor efficacy was observed in MSLN knockout tumors, which further confirmed that MSLN expression is required for M9657 anti-tumor immunity.
Conclusion: M9657 exhibits promising and potent MSLN-dependent conditional immune agonism, supporting its clinical investigation.

#4127
ANV600 is a potent, C*is*-signaling, non-alpha IL-2 agonist which efficiently expands intratumoral stem-like CD8 T cells

Patrizia Murer, Ulisse Salazar, Nicole Egli, Laetitia Petersen, Pia Neubert, Kirsten Richter, Christian Stocker, Alexander Rau, Andreas Katopodis, Christoph Huber. *Anaveon AG, Basel, Switzerland*

Non-alpha IL-2-based therapeutic modalities with preferential signaling through the IL-2 beta(CD122)/gamma(CD132) receptor are in clinical development and have the potential to substantially increase the therapeutic index of recombinant IL-2 (aldesleukin) for cancer therapy. ANV600 is a novel bispecific compound, which features an anti-IL-2 antibody/IL-2 fusion protein and a proprietary hPD-1 binding moiety for specific delivery of the non-alpha IL-2 to tumor antigen experienced PD-1+ T cells. Compared to the untargeted control, ANV600 has increased potency to induce STAT5 phosphorylation in human PD-1+CD8 T cells *in vitro*. At the same time, stimulation with ANV600 results in markedly reduced STAT5 phosphorylation on Treg cells compared to aldesleukin. In activated human PBMCs, ANV600 induces PD-1 co-internalization with the CD122-CD132 complex, reducing detectable PD-1 on CD8 and CD4 T-cells. Surface PD-1 levels decrease is not observed on cells incubated with untargeted bispecific compound. In transgenic human PD-1 mice ANV600 treatment leads to marked tumor growth retardation in the B16F10 and MC38 subcutaneous tumor models compared to untargeted compound and vehicle. Immunophenotyping of the tumor infiltrating lymphocytes revealed a dose-dependent increase of intratumoral stem-like PD-1+T cells and cytotoxic GrzB+PD-1+T cells in mice treated with ANV600. ANV600 has potent and selective effects on antigen-experienced CD8 T cells both in human PBMCs and mouse syngeneic tumor models. This agent may be a promising anti-tumor therapeutic against poorly immunogenic tumors and warrants further pharmaceutical development.

#4128

AJ17 potentiates agonist CD40 antibody efficacy and attenuates agonist CD40 induced PD-L1 expression and associated toxicity in murine tumor models

Vidit Gaur[1], Anjali Barnwal[1], Bushra Ateeq[2], Jayanta Bhattacharyya[1]. *[1]Center for Biomedical Engineering, Indian Institute of Technology Delhi (IIT Delhi), New Delhi, India,[2]Department of Biological Sciences and*

Bioengineering, Indian Institute of Technology Kanpur (IITK), Kanpur, India

Agonist CD40 antibody (αCD40) has shown excellent anti-tumor efficacy in both pre and early clinical studies. However, in clinics, αCD40 has failed to prove its potential as αCD40 is associated with dose-limiting toxicity due to cytokine release syndrome (CRS), grade 3 to 4 hematological and liver toxicities. In addition, αCD40 induces immune checkpoint proteins (PD-L1, CTLA-4) which makes the tumor microenvironment (TME) immunosuppressive. In this context, this study investigates the therapeutic efficacy of a novel combination of αCD40 and AJ17, a small molecule inhibitor of receptor tyrosine kinase. Combination treatment showed a significant delay in the tumor growth and improved overall survival in mice bearing B16-F10 melanoma and 4T1 orthotopic tumor by increasing the population of $CD8^+$ T cells and lowering the expression of PD-L1, $Foxp3^+$, and arginase in both tumor and spleen. Most interestingly, AJ17 lowered the *in vivo* toxicity associated with αCD40 monotherapy by lowering the levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), and IL-6 in serum. In conclusion, this combination can be further explored in clinics to improve the *in vivo* anti-tumor efficacy of αCD40 while lowering the associated toxicity.

Preclinical assessment of GlycoConnect™ ADCs with potency-modulated derivatives of PNU-159,682

Floris L. van Delft, Remon van Geel. *Synaffix, Nijmegen, Netherlands*

PNU-159,682 is an oxidized secondary metabolite of nemorubicin (MMDX), and substantially more potent (2100-6400-fold) than the commonly used chemotherapeutic anthracycline doxorubicin/adriamycin, but without the dose-limiting cardiotoxicity. Based on these beneficial features, PNU-159,682 is currently being clinically evaluated (phase 1) for solid tumor indications as a payload in various antibody-drug conjugates (NBE-002, SO-N102). It must be noted, however, that the HNSTD of current PNU-based ADCs in non-human primates (~1 mg/kg) may end up in a clinical dose that is sub-optimal to achieve high tumor uptake, due to putative target-mediated drug disposition in healthy tissue.

We embarked on a program to develop a set of 2nd-generation PNU-159,682 analogues with attenuated potency, to enable the generation of ADCs with a potentially improved pharmacokinetic profile. Moreover, we reasoned that the adaptation of the new PNU analogues to our proprietary best-in-class ADC technology (GlycoConnect™)[1], in combination with our polar spacer technology (HydraSpace™)[2] might enable PNU-based ADCs with significantly expanded therapeutic index (TI).
We here exhibit the chemical synthesis of a panel of PNU-analogues with attenuated potency and enhanced tolerability, based on specific tailoring of the aminosugar morpholino group. Homogeneous and stable GlycoConnect™/HydraSpace™ ADCs were subsequently generated and evaluated *in vitro* and *in vivo* to assess efficacy and tolerability. These studies demonstrate the potential of attenuated PNU derivatives for application in stable and site-specific ADCs with anticipated higher clinic dose and potentially improved therapeutic index.

[1] Wijdeven et al., Enzymatic glycan remodeling-metal free click (GlycoConnect™) provides homogenous antibody-drug conjugates with improved stability and therapeutic index without sequence engineering. *mAbs* **2022**, 14.

Genetically modified hematopoietic stem cells for improvement of immunotherapies against solid malignancies

Laura Falceto Font, Dan Jin, Connor P. Francis, Bayli DiVita Dean, John W. Figg, Brianna McDonald, Catherine Flores. *Neurosurgery, University of Florida, Gainesville, FL*

Hematopoietic stem cells (HSCs) are routinely used in the clinic to treat several diseases and their side effects, including cancers. Our group has previously shown that the combination of HSCs with two different immunotherapies improves survival in brain tumors, but it is still not curative. In this study, we wanted to explore whether modifying HSCs can drive them into a dendritic cell phenotype or suppress them from becoming immunosuppressive myeloid cells at the tumor microenvironment to

increase survival when combined with immunotherapy in a glioma model. HSCs have been historically challenging to grow *in vitro* for long-term culture due to the short periods of time they remain undifferentiated, which creates an extra challenge for the genetic modification of HSCs. Here, we test different *in vitro* conditions for expansion and modification of murine and human HSCs by employing the following methods for modulation of HSCs: shRNA lentiviral delivery, overexpression constructs, RNA electroporation, CRISPR, and AAV. This study describes the efficacy of each method as well as the observed limitations of each technique on HSCs. Furthermore, preliminary data shows IL6R downregulation as a candidate for driving HSCs into the dendritic cell lineage. Ultimately, these genetically modified cells will be used as an adjuvant therapy to improve the efficacy of various immunotherapeutic strategies against solid malignancies.

#4131

Long-term anti-tumor immunity induced by of HPN328, a DLL3-targeting trispecific, half-life extended T cell engager, in a preclinical immunocompetent mouse model

Mary Ellen Molloy[1], Laura B. Valenzuela[1], Chi-Heng Wu[1], Holger Wesche[1], Banmeet S. Anand[2]. *[1]Translational Medicine, Harpoon Therapeutics, Inc., South San Francisco, CA,[2]Harpoon Therapeutics, Inc., South San Francisco, CA*

Tri-specific T Cell-Activating Constructs (TriTACs) are T-cell engagers that have been developed to redirect T cells to kill tumor cells. HPN328 is a Delta-like ligand 3 (DLL3)-targeting TriTAC currently being evaluated in a Phase 1/2 clinical trial enrolling patients with advanced cancers associated with DLL3 expression, including small cell lung cancer (SCLC) and other neuroendocrine malignancies (NCT04471727). HPN328 consists of three binding domains: a CD3 binder for T cell engagement, an albumin binder for half-life extension, and a DLL3 binder for tumor cell engagement. We have previously reported that HPN328 induces potent dose-dependent killing of DLL3 expressing SCLC cell lines together with dose-dependent T cell activation and cytokine release in T cell co-cultures *in vitro*. Based on these data and the proposed mechanism of TriTAC induced tumor cell killing we hypothesized that HPN328 could induce epitope spreading and

long-term immunogenic effects. To test this hypothesis, we generated an immunocompetent mouse model in which six amino acid residues corresponding to the portion of human CD3ε which TriTAC molecules bind were added to the N terminus of the mouse CD3ε subunit. Homozygous knock-in mice (hCD3ε) were implanted subcutaneously with MC38 murine colon cancer cell line expressing human DLL3 and treated with HPN328 following tumor establishment. HPN328 treatment led to eradication of established tumors in mice. In addition, tumor infiltrating lymphocyte (TIL) analysis was performed on tumors harvested on day 4 post HPN328 treatment. Activation markers CD69 and CD25 were induced on both CD4+ and CD8+ TILs in this model. To evaluate if HPN328 can induce long-term immunity, mice whose tumors were cured by HPN328 were rechallenged on the opposite flank. As expected, tumors grew in treatment naïve mice, but no tumors were detected in mice previously treated with HPN328, demonstrating sustained and durable anti-tumor immunity induced by HPN328 treatment. Anti-tumor immunity is an indicator of T cell memory against tumor antigens. Concomitant with anti-tumor immune response, we detected increases in memory T cells in the spleens of mice previously treated with HPN328. Together these results indicate that HPN328 can induce epitope spreading and prolonged anti-tumor immunity, suggest a novel mechanism for its activity and efficacy *in vivo*.

Effect of mechanical cues on T cell killing of cancer cells

Hannah Dada[1], Kun Do[2], Alexander Cartagena-Rivera[2], Grégoire Altan-Bonnet[1]. *[1]NIH-NCI, Bethesda, MD,[2]NIH-NIBIB, Bethesda, MD*

Cancer immunotherapies have focused on strategies to strengthen immune cell activation and effector function. These treatment strategies enhance the effector function of immune cells, particularly cytotoxic T cells (CTL), driving tumor eradication. Methods to improve the killing mechanisms of CTLs are not well studied and largely focused on assessing/strengthening the antigenic responses of T cells. We hypothesize that the mechanical landscape of CTL-tumor interactions can also drastically impact CTL cytotoxicity. By altering the physical context for T cell recognition of tumors, we measured cytotoxicity changes and subsequently used these changes in killing capacities to train and generate a quantitative

parametrization of T cell killing. CTLs utilize cytokine expression to kill and shape the inflammatory milieu. Taking advantage of a robotic platform that enables the automatic collection of cytokines, we assembled datasets of T cell attacks of tumor cells grown on substrates with varying stiffness levels. The stiffness levels were altered using polyacrylamide (PAA) gels and ranged from 0.2kPa to approximately 113 kPa. Preliminary results from two different models (i.e., mouse and human TCR-transgenic T cells) suggest that there exists an optimal stiffness value for maximal response by T cells. These results suggest that CTLs utilize biophysical cues in addition to molecular cues (antigen) to properly elicit an immune response—modeling and fine-tuning these mechanical cues can be a novel and effective approach to improving cancer immunotherapies.

OncoTAM, a comprehensive preclinical platform to explore macrophages as key drivers of cancer progression and develop new therapies against tumor-associated-macrophages

Caroline Mignard, Damien France, Francis Bichat, Nicolas Legrand, Olivier Duchamp. *Oncodesign Services, Dijon Cedex, France*

Tumor-Associated Macrophages (TAMs) play an important role in the development of tumors, modulation of neoangiogenesis, immune suppression, and metastasis. A high infiltration of macrophages in the tumor is also correlated with a poor prognosis in several cancer types. Therefore, they became an attractive target for cancer immunotherapies. Several macrophage-targeting approaches in anticancer therapy are under development, including TAM depletion, inhibition of new TAM differentiation, or re-education of TAM activation for cancer cell phagocytosis. In this presentation, we will share different examples of in vitro assays and in vivo models we are implementing to support preclinical development of novel TAM-targeting strategies. Antibody-dependent cellular phagocytosis (ADCP) has been used to demonstrate one crucial mechanism of action of different antibody (Ab) therapies targeting macrophages. Some of these Ab (including anti-CSF1) have then been tested in syngeneic in vivo tumor models. To reach this goal, we demonstrated that the tumor implantation site in mice (subcutaneous vs orthotopic) could impact the polarization of macrophages (M1 vs M2).

Differences in the ratio of M1 and M2 subtypes infiltrating the PAN-02 pancreatic murine tumors were observed, and anti-CSF1 antibodies increased the survival of mice bearing orthotopic Renca murine kidney tumor by eliminating TAMs. Additionally, in xenograft models of human breast tumors in NOD-SCID mice, the eradication of TAMs by anti-CSF1R clearly demonstrated the importance of macrophages in the tumor progression and in the anti-tumor efficacy of Abs mediated by macrophages. By using an orthotopic Hepa1-6 murine liver cancer model, we showed high antitumor efficacy of compounds targeting the STAT6 pathway by reprogramming immunosuppressive TAMs into an M1 phenotype that promotes the induction of a cytotoxic immune response. For compounds displaying no cross-reactivity with murine target, we developed models and characterized the TAMs in breast, colon, melanoma and head & neck PDX and CDX tumors in different huCD34-engrafted mouse models. Altogether, the panel of in vitro assays and in vivo tumor models in OncoTAM should be useful to provide insights on the mechanism of action and antitumor efficacy of novel immune-oncology strategies targeting macrophages.

#4134

Boosting anti-tumor immunity by promoting high endothelial venule and tertiary lymphoid structure formation in solid tumors via LTBR agonism

Disi An, Guoying Chen, Wei Wang, Katja Mohrs, David DiLillo, Christopher Daly, Gavin Thurston, John Lin, Namita Gupta, Mickey Atwal, Frank Kuhnert. *Regeneron Pharmaceuticals, Inc., Tarrytown, NY*

High endothelial venules (HEV) are specialized blood vessels that mediate lymphocyte trafficking to lymph nodes. Tertiary lymphoid structures (TLS) are ectopic lymphoid formations that develop in inflamed, infected or tumoral tissues. TLS contain HEV and B cell follicles surrounded by a T-cell zone and are characterized by abundant chemokine expression. The presence of TLS and HEV in solid tumors is positively correlated with patient survival in many cancer types, and may even be predictive of better response to immune-checkpoint blockade. However, the molecular mechanisms underlying the intratumoral HEV and TLS formation remain unclear. Using murine syngeneic tumor models, we found that systemic

activation of lymphotoxin beta receptor (LTBR) with an agonistic antibody induced tumor-specific HEV formation, increased dendritic cell (DC) and T cell infiltration, and enhanced T cell activation in the tumor. *In vitro* assays revealed that LTBR agonism directly upregulated activation and maturation markers in bone marrow-derived DCs and promoted DC-mediated CD4 and CD8 T cell activation. Single agent LTBR agonist treatment attenuated Colon26 tumor growth in a CD8 T cell-dependent manner. In combination treatment studies, LTBR agonism further augmented anti-tumor efficacy of anti-PD1 and of CAR-T therapy. Notably, LTBR agonist mAb treatment upregulated the expression of TLS-related chemokines and induced TLS-like structures in approximately 20% of treated tumors. To enhance TLS induction, we generated syngeneic tumor models engineered to express several cytokines/chemokines and performed an *in vivo* screen for tumor-associated TLS formation. We identified some factors that in combination with LTBR agonism induced B cell enrichment and immature TLS formation, while others promoted robust TLS induction and anti-tumor effect. TLS formation induced by combined LTBR agonism and cytokine expression is associated with augmented anti-tumor responses to anti-CTLA-4 treatment. By studying anti-tumor mechanisms of LTBR agonism-mediated HEV and TLS formation, this work informs the future therapeutic strategies to boost T cell infiltration and activation in solid tumors.

#4135

A novel plasma cell-based mechanism of action of adenosine immunomodulation and A2AR antagonism

Chiara Martinoli[1], Paola Tieppo[1], Marjorie Mercier[1], Hussein Shehade[1], Noemie Wald[1], Anais Vezzu[1], Annelise Hermant[1], Boris Pirlot[1], Stephanie Ma[2], Maurizio Ceppi[1], Yvonne McGrath[1], Maura Rossetti[1]. *[1]iTeos Therapeutics, Charleroi, Belgium,[2]A4P Consulting Ltd, Sandwich, United Kingdom*

High levels of extracellular adenosine, often found in the tumor microenvironment (TME), promote immune suppression mainly through the A_{2A} receptor ($A_{2A}R$) expressed by tumor-infiltrating immune cells. Inupadenant (formerly known as EOS100850) is an oral, non-brain penetrant, potent and highly selective small molecule antagonist of $A_{2A}R$.

In a Phase I/Ib clinical trial (NCT03873883), inupadenant as monotherapy showed initial evidence of clinical benefit in subjects with advanced solid tumors. In this study, tumor biopsies with a high number of $A_{2A}R$-expressing immune cells at baseline were associated with response or stable disease.We now report that infiltration of $A_{2A}R^{+}$ cells was strongly correlated with the expression of B- and, more specifically, antibody-secreting cell (ASC)-related genes, as assessed by gene expression (Nanostring) and immunohistochemistry (IHC), hinting at a potential novel role for $A_{2A}R$ in B cell biology. Therefore, we explored the expression and function of $A_{2A}R$ in human B cells. Immunocytochemistry staining of $A_{2A}R$ on sorted tonsillar B cell subsets showed that $A_{2A}R$ was predominantly expressed on ASCs, including plasma cells and plasma blasts versus naïve or memory B cells. The preferential expression of $A_{2A}R$ by ASCs was confirmed on NSCLC tissues by multiplex immunofluorescence. In addition to $A_{2A}R$, ASCs expressed other adenosine pathway markers such as CD39, suggesting that the adenosine pathway is a key mechanism through which ASC functions may be modulated. Using B cells derived from peripheral blood, the $A_{2A}R$ agonist CGS-21680 was shown to inhibit the maturation of B cells into plasma cells, and that maturation could be fully restored by inupadenant. CGS-21680 did not affect B cell or plasma cell viability, indicating that the effect of $A_{2A}R$ signaling on plasma cell differentiation is not due to preferential plasma cell death in culture. Importantly, baseline expression of B cell- and ASC-related markers measured by Nanostring and IHC was associated with response or stable disease to inupadenant monotherapy, supporting the notion that these cells may be a novel target of inupadenant. This is in line with recent reports showing that B cells, plasma cells and tertiary lymphoid structures are associated with favorable responses to cancer immunotherapy. Interestingly, four out of the five non-progressors treated with inupadenant as monotherapy and with available biomarker data showed a reduction in ASC infiltration after inupadenant treatment, suggesting that inupadenant may promote terminal plasma cell differentiation and migration out of the tumor tissue and to the bone marrow.Altogether, these data support a novel plasma cell-centric

mechanism of action of inupadenant, which may complement its reported T cell-mediated anti-tumor activity.

Developments in Anticancer Immunotherapy

Functional human myeloid cells in BRGSF-HIS humanized mice enables myeloid-directed therapy assessment
Florence Renart-Depontieu[1], Gaëlle Martin[1], Valery Moine[2], Coline Burnet-Merlin[2], Florent Creusat[1], Alexis Gonon[1], Perrine Martin-Jeantet[1], Fabiane Sônego[1], Lise Nouveau[2], Yacine Cherifi[1], Kader Thiam[1].
[1]genOway, Lyon, France,[2]Light Chain Bioscience, Plan-Les-Ouates Genève, Switzerland

Translational preclinical assessment of myeloid-targeting therapies is considered challenging due to the reduced availability of humanized mouse models expressing both lymphoid and myeloid compartments. Most of the humanized models harboring myeloid compartment overexpress human cytokines, leading to body weight loss, anemia and a short life span. Recent report described the BRGSF-HIS as an alternative model displaying all major human hematopoietic cell subsets, such as B, T, natural killer (NK), dendritic cells (DCs), plasmacytoid cells (pDCs) and monocytes/macrophages. Human myeloid cells developed in the BRGSF-HIS mice without side effects and human immune system engraftment is stable for over a year (Labarthe et al., 2019), favoring long terms studies with agents requiring a wide therapeutic window. Here we report that myeloid compartment developed in BRGSF-HIS mice is recruited in the tumor microenvironment of tumor bearing mice, and are also capable of triggering effector mechanisms such as ADCP and ADCC. Myeloid cells developed in the BRGSF-HIS mice are functional as, *ex vivo* stimulation with TLR and STING agonists induce CD83 expression and pro-inflammatory cytokine secretion (TNF-α, IL-1β, CCL2, ⋯) by monocytes and bone marrow derived macrophages (BMDM). *In vivo*, myeloid cells are activated through LPS challenge, leading to increased CD83-expressing cDCs frequency and CD83 and CD86 expression levels. Furthermore, BMDM are efficiently skewed toward M1 and M2-like profiles in response to LPS and IL-4, respectively. Analyses of TME from MDA-MB-231, show

the recruitment of human immune cells, including T cells, NK cells, cDC and activated M2 macrophages (expressing both CD86 and CD206). Expression of FcγR, essential for antibody dependent cellular cytotoxicity (ADCC) and antibody dependent cellular phagocytosis (ADCP) activities, is found on human peritoneal macrophages and BMDM from BRGSF-HIS. ADCP activity mediated by macrophages was established as tumor cells are specifically phagocyted *ex vivo* in presence of a bispecific antibody (anti-human CD47 x tumor-associated antigen). Such findings were corroborated by B cell depletion *in vivo* induced by Rituximab (anti-CD20 mAb - hIgG1), which has been described to trigger CDC, ADCC and ADCP via FcγR (Teige *et al*., 2019). Finally, OKT3 induces cytokine release syndrome in these mice, evidenced by cytokine release, body weight and temperature drop. Treatment with Infliximab reduced these symptoms, suggesting that BRGSF-HIS mice enable assessment of safety and its clinical management. In summary, BRGSF-HIS mice develop myeloid cells without side effects and has a wide therapeutic window, enabling the assessment of effector mechanisms such as ADCP and ADCC, triggered by of myeloid-targeted therapies.

Oncogenic KRAS inhibition with ADT-007 primes T cell responses in pancreatic ductal adenocarcinoma

Jeremy B. Foote[1], Tyler E. Mattox[2], Adam B. Keeton[3], Ganji N. Purnachandra[1], Yulia Maxuitenko[3], Xi Chen[4], Jacob Valiyaveettil[3], Donald J. Buchsbaum[1], Gary A. Piazza[3], Bassel F. El-Rayes[1]. *[1]University of Alabama at Birmingham, Birmingham, AL,[2]University of South Alabama, Mobile, AL,[3]Auburn University, Auburn, AL,[4]Auburn Univeristy, Auburn, AL*

Background**:** Pancreatic ductal adenocarcinoma (PDAC) has low (<11%) 5-year survival due to the presence of advanced disease at diagnosis. Currently standard of care provides a median survival of 1 year in the majority of patients presenting with advanced disease. Targeting oncogenic KRAS, which is mutated in >90% of human PDAC tumors, provides an opportunity to inhibit a critical pathway and significantly impact standard of care in patients diagnosed with PDAC. Furthermore, evidence indicates that inhibiting-oncogenic KRAS signaling modulates anti-tumor immune

responses and demonstrates synergy with immune checkpoint blockade in pre-clinical models. The purpose of this study is to evaluate efficacy and impact on anti-tumor immunity of a novel inhibitor, ADT-007 that demonstrates pan-RAS inhibitory activity.
Methods: Female C57BL/6J, C57BL/6J. Ifng/Thy1.1 KI;Cg-Tg-IL2$^{tm1/eGFP/Weav}$ (IFNg-Thy1.1/IL-2-GFP reporter mice), or immune deficient (T/B cells) Rag 1 $^{-/-}$ mice (n=5-10/group) were implanted SQ with 10^6 mouse derived PDAC cell lines (7160c2 and 2838c3) bearing KRAS^{G12D} mutation, and then randomized (day 7), into vehicle (5% DMSO/5% Kolliphor/90% H_2O) or ADT-007 treatment, which was administered SQ (peritumoral), BID at 5 mg/kg for 2 - 3 weeks. Tumor growth *in vitro* (IC_{50}), KRAS-MAPK/AKT signaling, *in vivo* tumor volumes (tv = L x W^2/2), and tumor immune responses were assessed by CellTiter Glo, phosphoflow/western blotting, bi-weekly caliper measurements, and multi-parameter flow cytometry, respectively.
Results: ADT-007 inhibited KRAS-MAPK/AKT signaling in human and mouse PDAC cell lines inducing G2-M phase arrest and apoptosis at low nanomolar concentrations. Peritumoral administration of ADT-007 inhibited tumor cell growth *in vivo*, modulating T cells in the tumor microenvironment (TME), specifically, an increase in tumor infiltrating, $CD44^+$ $CD62L^-$ $CD4^+$ and $CD8^+$ T cells and increases in production of TNFα, IFN-γ, IL-2, and granzyme B upon stimulation with PMA/ionomycin.
Conclusion: The small molecule inhibitor, ADT-007 blocks oncogenic KRAS signaling and modulates T cell activation and function in the TiME of immune competent, syngeneic mouse models of PDAC. More broadly, these findings indicate that a pan-RAS inhibitor is capable of modulating anti-tumor immune responses extending previous observations that targeted inhibition of oncogenic KRAS^{G12C} modulates tumor immunity in animal models of colon and lung cancer.

Effects of exercise on tumorigenesis, immune system, and the gut microbiome in a bladder carcinogen mouse model
Joseph P. LaMorte, Brittany Tian, Rashida Ginwala, Laura Bukavina, Philip Abbosh. *Fox Chase Cancer Center, Philadelphia, PA*

Recent studies have begun to demonstrate the therapeutic capacity of physical exercise on cancer treatment outcomes. While this research suggests exercise may improve health in cancer patients, the specific mechanisms by which exercise influences tumor progression remain largely unknown. We hypothesized that exercise alters the gut microbiome and promotes immune cell activation in relevant immune sites. Therefore, we utilized BBN (N-butyl-N-(4-hydroxybutyl)-nitrosamine), a carcinogen that mimics human muscle invasive bladder cancer conditions, and voluntary exercise wheels to determine the effect of exercise on bladder carcinogenesis, gut microbiome, and the immune system. Ultrasound imaging revealed that the average tumor volume of female exercising mice was 11.9% of the total bladder volume at time of sacrifice, while the tumor volume of their non-exercising counterparts was 56.4%, a difference determined to be significant using a two-tailed t-test with p-value of 0.05. A similar trend was seen in male mice, though the difference between groups was not significant. Immune cell analysis did not show significant variation in cytotoxic T cell, helper T cell, macrophage, or dendritic cell populations between exercising and non-exercising mice in spleen, colon, or bladder tissues as measured by FACS. Standardization of the amount exercised, as evaluated by expression of myosin and actin levels in the tibialis anterior muscle, and sequencing of the gut microbiome are in progress and could better indicate the mechanism of exercise-induced tumor suppression.

CD4 T cell-driven response to immunotherapy against mouse melanoma tumors

Amy K. Erbe, Arika S. Feils, Alina Hampton, Dan Spiegelman, Noah Tsarovsky, Anna Hoefges, Peter M. Carlson, Alex Pieper, Callie Haertle, Mackenzie Heck, Sabrina VandenHeuvel, Lizzie Frankel, Lauren Zebertavage, Alexa Heaton, Zachary S. Morris, Ravi Patel, Alexander Rakhmilevich, Paul M. Sondel. *University of Wisconsin-Madison, Madison, WI*

Using an *in situ* vaccine (ISV) regimen that includes a combination therapy of radiation (given at D0) with hu14.18-IL2 immunocytokine [anti-GD2 linked to IL2, (Anyxis Immuno-Oncology GmbH (Austria)); given at D5-

D9], we can cure mice of large B78 melanoma tumors (B78s). GD2 is expressed on many solid tumors, including most melanomas, and is not often expressed on immune cells. Mice cured with ISV of B78 tumors demonstrate long-term immune memory, with mice rejecting tumor rechallenge >180 days post initial cure of tumor. Traditionally, immune effector memory is thought to be mediated via CD8 T cells, which require antigen presentation via MHC Class I (MHCI). However, B78s express little to no MHCI, but do express MHCII when stimulated with IFNγ. Expressed on 50-70% of melanomas in humans, the role of MHCII on response is unclear. We explored implications of MHCII and MHCI expression on response (initial response to ISV and memory response). Mice bearing B78s depleted of NK cells or CD8 T cells during ISV respond to therapy, but mice depleted of CD4 T cells fail to respond to ISV. Likewise, B78-cured mice depleted of NK and CD8 T cells during rechallenge are able to reject the B78 tumor rechallenge, whereas those depleted of CD4 T cells failed to reject their B78 rechallenge. Together these data suggest that CD4 T cells are required for the initial antitumor response to ISV as well as for immune memory formation and function. Tumors and tumor draining lymph nodes were harvested during ISV treatment in B78-bearing mice at D8 and assessed by scRNAseq, flow cytometry, IncuCyte and ImageStream (live-cell imaging assays), and IsoPlexis (cytokine profile). Though not required for initial or memory response, both CD8 and NK cells are activated and exhibit cytotoxic phenotypes in the tumor microenvironment (TME). Furthermore, a population of cells co-expressing both GD2 and CD45 was observed in the TME following ISV that was not observed in untreated mice. These GD2+/CD45+ cells were predominantly CD4+ T cells incorporate patchy GD2 expression on their surface via trogocytosis. We hypothesize that the interaction between MHCII on tumor cells and CD4 T cell receptors mediates the trogocytosis, activating CD4 T cells to function as helper T cells, initiating a cascade of antitumor immunity, as well as causing direct CD4 T cell-mediated cytotoxicity.

MHCII is expressed on some melanoma tumors, and its expression has been correlated with a positive response to immunotherapies. MHCII expression on tumors can directly engage CD4 cytotoxic T cells, suggesting an important role in the response to immunotherapy for CD4 T cells in melanoma tumors that express MHCII. Understanding the cellular and

molecular mechanisms involved in the ISV-induced immune recognition and destruction of B78 may guide future improvements of this clinically-relevant immunotherapy regimen.

#4143

Enhancing adaptive immune responses with telomerase-mediated telomere targeting therapeutics in hepatocellular carcinoma

Ann Marie Flusche[1], Jerry Shay[1], Ilgen Mender Ogunrinde[2]. *[1]UT Southwestern Medical Center, Dallas, TX,[2]MAIA Biotechnology, Chicago, IL*

Hepatocellular carcinoma (HCC) is the most common primary malignant tumor of the liver and is the third leading cause of cancer-related deaths. In recent years, immune checkpoint inhibitors (ICIs) have improved treatment of solid tumors including HCC. However, due to low response rates with current standard of care immunotherapy and angiogenic inhibitors, there is an urgent need to develop new therapeutic strategies to improve the efficacy of immunotherapy against HCC. Our lab has shown that 6-thio-2' deoxyguanosine (6-thio-dG), a telomerase-mediated telomere targeting agent, is incorporated into newly synthesized telomeres by telomerase and causes rapid telomere uncapping, thereby inducing telomere-associated DNA damage in cancer cells. These damaged DNA fragments can then lead to enhanced adaptive immune responses. In this study, we evaluated the therapeutic effects of 6-thio-dG *in vitro* and *in vivo* together with ICIs in liver tumors to determine whether combining immunotherapy with a telomere-targeting agent could serve as an effective strategy for HCC. To explore whether 6-thio-dG is effective in killing liver cancer cells, we ran cell viability and telomere dysfunction induced foci (TIF) assays to assess DNA damage on telomeres *in vitro* and compared tumor volumes of mice following 6-thio-dG monotherapy, immunotherapy, and sequential treatment of 6-thio-dG and immunotherapy in syngeneic mouse models. We observed that 6-thio-dG reduced cell viability and induced telomere dysfunction in a panel of human and mouse liver cancer cells. In addition, 6-thio-dG enhanced the therapeutic effect of immunotherapies in liver syngeneic mouse models. Overall, our findings show that the telomere-targeting anticancer agent 6-thio-dG inhibits HCC as a single monotherapy and/or sequential therapy together with immunotherapies. These results

provide an experimental rationale for a potentially new immunochemotherapy strategy based on the administration of a telomere-targeting agent.

Characterization of immune cell phenotypes in patient derived malignant pleural effusion treated with thiostrepton

Terri Messier[1], Roxana Del Rio Guerra[1], George Naumov[2], Brian Cunniff[1].
[1]Larner College of Medicine at The University of Vermont, Burlington, VT,[2]RS Oncology, LLC, Cambridge, MA

Tumor cells generate elevated levels of reactive oxygen species (ROS) and therefore exhibit increased expression, activity, and reliance on critical ROS scavenging pathways, including the mitochondrial peroxiredoxin 3 (PRX3) system. PRX3 is a critical reactive oxygen species (ROS) scavenging enzyme localized to the mitochondrial matrix. Our group has characterized the mechanism of action of the PRX3 inhibitor and pro-oxidant therapeutic thiostrepton (TS). TS covalently crosslinks the peroxidatic and resolving cysteines of PRX3, leading to increased levels of mitochondrial ROS, resulting in tumor cell death. We have characterized the cellular and chemical composition of malignant pleural effusion (MPE) from patients with advanced cancer and evaluated cellular responses to TS. TS targets PRX3 in both adherent tumor cells and in non-adherent immune cell populations in a dose-dependent manner. We further characterized MPE-infiltrated immune cells and cytokines released following TS-treatment. Together, these data provide the first evidence for the activity of TS in MPE and resulting changes to immune cell profiles. TS is the active pharmaceutical ingredient of RSO-021, a new covalent inhibitor of PRX3 currently being tested in the MITOPE phase 1/2 clinical trial in patients with malignant pleural effusion (MPE) due to advanced solid tumors or malignant mesothelioma (NCT05278975).

Frizzled-4 expression enhances hepatocellular carcinoma progression, sorafenib resistance and suppresses anti-tumor CD8 T cell immunity

Jie Luo, Lanqi Gong, Yuma Yang, Qin Liu, Jiao Huang, Xiaona Fang, Xin-Yuan Guan. *The University of Hong Kong, Pokfulam, Hong Kong*

Background**:** Hepatocellular carcinoma (HCC) is one of the most common and deadliest cancers. Sorafenib remains the globally accepted systemic first-line treatment for advanced HCC although acquired drug-resistance is becoming increasingly common. Hopefully, immune-checkpoint inhibitor therapy has recently revolutionized the treatment for advanced HCC that have poor response to sorafenib, but the durable response rate remains low in most patients for unknown reasons. This fuels a wave of research into the molecular mechanisms of tumor-intrinsic resistance to both chemotherapy and immune checkpoint blockade (ICB), which may provide potential systemic treatment options for advanced HCC patients.
Methods and Results: RNA sequencing of sorafenib-resistant HCC cell lines was performed to identify Frizzled-4 (FZD4) as a critical gene for drug resistance that was further validated in animal models. Clinical implication of FZD4 overexpression was studied in HCC patients. Using genetic and pharmacological approaches, we found that FZD4 was sufficient to increase clonogenicity, migration and invasion, and prevent sorafenib-induced apoptosis. In addition, FZD4 could reduce secretion of tumor necrosis factor-alpha (TNF-α) and interferon-gamma (IFN-γ), as well as intracellular levels of cytotoxic granzyme A and perforin in $CD8^+$ T cells, indicating significant suppression of $CD8^+$ T cell-mediated antitumor immunity in HCC tumors. *In vivo* studies also revealed that FZD4 expression promoted tumorigenesis and accelerated HCC cell metastatic lung colonization. Combination therapy of FZD4 inhibitor FzM1 with sorafenib in HCC of *MYC*/sg*p53*-induced model showed a tendency to significantly impede tumor growth and improve mice survival. Moreover, gene set enrichment analysis (GSEA) identified the cholesterol homeostasis and fatty acid metabolism signaling signatures as the top activated pathways in FZD4-high HCC cells. This evidence suggests a crucial role of FZD4-involved lipid metabolism linked to the development of therapeutic resistance.
Conclusion: Our study demonstrates that FZD4 expression plays a pivotal role in HCC progression and holds the potential for expanding the scope of targeted/ICB therapies to tumors that are currently unresponsive, especially in advanced HCC. The resistance mechanisms will be addressed in further work.

#4146

Unlocking IO drug potential by high content imaging of immune cell co-cultures with cancer organoids from diverse cancer indications

Saskia de Man, Chiara Foini, Tomas Veenendaal, Michelle Kop, Christos Santaris, Sergei Chavez Abiega, Nataliia Beztsinna, Daniel Okkes, Ashgard Weterings, Leo Price, Gera Goverse. *Crown Bioscience Netherlands B.V., Leiden, Netherlands*

Introduction

Immuno-oncology (IO) drugs have shown great results for specific cancer indications in the clinic, most notably for hematological cancers, as well as some solid cancers such as melanoma. However, the potential of many IO drugs as well as mechanisms of resistance in different indications remain to be uncovered. With the development of organoid technology, it is now possible to grow tumor objects in 3D scaffolds with a high resemblance to the original patient tumor in terms of genetics, transcriptomics and morphology. This technology is highly suited for pre-clinical screens and of great translational value. Here we present a high throughput platform using this organoid technology to study IO drug candidates in different indications.

Material and methods

Patient-derived organoids (PDOs) from different origins, including colorectal, lung, breast, melanoma and ovarian cancers, were cultured in protein hydrogels. Allogenic PBMCs were isolated from two healthy donors and were activated with superantigens or CD3/CD28 beads. PDOs and PBMCs were then co-cultured together in presence of IO drugs, such as monoclonal and bispecific antibodies, and analyzed for immune cell migration, infiltration and PDO killing. This was assessed by 3D high content imaging (HCI) and quantified with an automated image segmentation pipeline, which segments tumor objects and immune cells in the 3D reconstituted stack.

Results and discussion

Image-based analysis on PBMC numbers, migration and infiltration, and PDO volumes was performed. Data analysis showed that the activation status of the PBMCs induced different levels of infiltration and killing, as measured by the number of infiltrated immune cells and PDO volumes

respectively. In addition, different PDOs showed different sensitivities for immune cell-mediated killing and compound effects.
Conclusion
Our PDO - immune cell co-culture system in combination with HCI allows the detection and quantification of migration towards, infiltration into and killing effects of immune cells on PDOs in a single assay. This 3D assay allows the identification of IO drug mode of action, specificity, resistance and sensitivity and immune cell activation. Here, we observed a broad spectrum of responses based on the specific characteristics (e.g. morphology and gene expression) of different PDOs and differential activation of PBMCs. The broad range of PDOs available from our biobanks empowers IO drug developers to explore their candidates in multiple cancer indications or in multiple models of a single indication with a range of different genetics, target expression and morphology. Ultimately this allows for the testing of IO drugs, such as engineered T Cells, tumor targeting antibodies, bispecific T Cell engagers, and immune cell modulators in clinically relevant models, bringing the promise of IO therapies to more indications and patients.

#4147

Activated pyroptosis prior to treatment marks a potential response to immunotherapy in cancers

Yumo Xie, Xiaolin Wang, Meijin Huang, Yanxin Luo, Huichuan Yu. *The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Purpose: Immune checkpoint inhibitors (ICIs) have achieved remarkable survival improvement in multiple cancers by exerting anti-tumor effects through augmenting adaptive immunity. However, 60%-70% of patients showed primary resistance to ICIs, and the underlying mechanisms remained unclear. Pyroptosis is a programmed cell death accompanied by a robust inflammatory response with the secretion of pro-inflammatory molecules, and thus it has the potential to be a promising biomarker for immunotherapy.
Methods: A dataset with the clinical and transcriptomic profiles was derived from 16 randomized controlled trials and studies on ICIs treatment in multiple solid tumors, including melanoma, urothelial cancer, non-small cell lung cancer, renal cell cancer, breast cancer, and esophageal cancer. The

responder was defined as patients achieving complete or partial response, while the non-responder was defined as patients with stable or progressive disease. According to previous studies, we generated a cytotoxic pyroptosis-related gene set, including *CASP1, CASP3, CASP4, CASP5, CASP8, GSDMB, GSMDC, GSDMD, GSDME, GZMA, GZMB,* to explore the association of cytotoxic pyroptosis with response to ICIs. In addition, the previously defined gene set from the Gene Ontology working group that contains a pyroptosis-related gene set was also included to represent the level of total pyroptosis. Single sample Gene Set Enrichment Analysis (ssGSEA) was performed, and the fold-changes and p-values of gene sets were merged with the R package "MetaVolcanoR". Patients in each subset were split by the median of the ssGSEA score of pyroptosis-related genes and identified as with relatively activated and inhibited pyroptosis, respectively. A P-value < 0.05 was considered significant.
Results: A total of 1,407 patients were analyzed, including 475 responders and 932 non-responders. The ssGSEA revealed that both the pyroptosis and the cytotoxic pyroptosis gene sets were enriched in responders, while the cytotoxic pyroptosis-related gene set was one of the top five ones among the 545 enriched in responders. Moreover, the survival analysis showed that in urothelial and non-small cell lung cancer, patients with activated pyroptosis prior to treatment had better progression-free survival and overall survival after ICIs therapies. These results suggested that an activated status of pyroptosis, especially the pyroptotic process related to cytotoxic events, is a marker for better response to ICIs.
Conclusions: The transcriptomic analysis of universal immunotherapy biomarkers identifies an pre-existing activated status of pyroptosis within the tumor microenvironment was associated with a better ICIs response across different cancer types, and thus these pyroptosis-related genes may serve as valuable immunotherapy markers and in silico fundamental tool for exploring pyroptosis in tumor immunity.

#4148

Immunophenotyping of responses to immunotherapy in syngeneic tumor models using multiplex immunofluorescence compared to multiparametric flow cytometry

Philipp Metzger, Carla Castro, Cynthia Obodozie, Holger Weber. *Reaction Biology Europe GmbH, Freiburg, Germany*

In the last decades, several major breakthroughs in cancer treatment were achieved through a better understanding and therapeutic targeting of the immune system. Multiparametric flow cytometry is a robust and powerful tool to evaluate the frequency and activation status of a large variety of immune cells. However, for flow cytometric analysis tumor, tissue must be digested into a single cell suspension, and thereby the information on the tumor architecture as well as the spatial distribution of immune cells is lost. The distribution of immune cells in the tumor microenvironment is often heterogeneous and a favorable immune cell distribution is crucial for an efficacious anti-tumor immunotherapy. The recent advances in multiplex immunofluorescence (mIF) allows the analysis of multiple parameters simultaneously so that the frequency as well as the spatial distribution of multiple immune cells can be analyzed.
In this study, immunotherapy-responsive tumor cell lines (colon carcinoma cell lines MC38-CEA and CT26wt as well as melanoma cell line Clone M3) were implanted in the mammary fat pad (subQperiorTM), which leads to reduce ulceration rate and homogenous tumor growth compared to subcutaneous implantation. Anti-PD-1 immunotherapy reduced the tumor growth in all three tumor models significantly. Formalin-fixed paraffin-embedded tumor samples were collected from control and anti-PD-1 treated animals. Murine specific InSituPlex® (ISP) technology (Ultivue) was used to perform multiplex immune profiling of the markers CD3, CD4, CD8 and FOXP3 on mouse whole slide FFPE tumor serial sections. Slides were then imaged for high quality images of the four targets and downstream analysis performed. The evaluated T cell frequency and spatial distribution was compared to flow cytometric data of anti-PD-1 treatment in these models. In summary, flow cytometry and multiplex immunofluorescence (mIF) are valuable tools in the evaluation of immune responses in pre-clinical tumor models. Both technologies enable an improved understanding of treatment responses and facilitate the development of novel treatment modalities as well as the identification of potential predictive biomarkers.

Anti-CTLA-4 generates memory T-cells with greater expansion and functionality than anti-PD-1

Stephen Mok, Nana-Ama A.S. Anang, James J. Mancuso, James P. Allison.
UT MD Anderson Cancer Center, Houston, TX

Blocking either cytotoxic T-lymphocyte antigen-4 (CTLA-4) or programmed cell death-1 (PD-1) pathway relieves the negative regulation of T-cells resulting in durable tumor rejection in patients with cancer and improved survival rate. However, it remains unclear how these immunotherapies affect memory T-cell response. Here we address whether anti-CTLA-4 and anti-PD-1 have different effects on memory T-cells. We used anti-CTLA-4 or anti-PD-1 therapy in combination with irradiated cancer vaccine in mice. After re-challenge, we observed that in murine tumor models, anti-CTLA-4 generates a more robust memory antitumor response than anti-PD-1 as demonstrated by smaller tumor volumes at all time points. We have traced and profiled antigen-specific CD8 T-cells throughout priming, memory phase, and re-challenge. We observed the memory responses generated by anti-CTLA-4 and anti-PD-1 diverge at priming; where anti-CTLA-4 generates more TCF-1+ memory-like T-cells than anti-PD-1, and remains apparent throughout activation and expansion as anti-PD-1 results in a higher percentage of TOX1+ terminally-differentiated T cells. During re-challenge, the memory T-cells generated by anti-CTLA-4 1) expand in greater frequency, 2) have greater cytokine production and antitumor activity, and 3) more frequently differentiate into the population of KLRG1+ effector CD8 T-cells than those generated with anti-PD-1. We found each of these traits correlated with a more effective memory response.

Novel preclinical model for the evaluation of cytokine release syndrome in response to CD19xCD3 bispecific antibody in humanized mice

Deep S. Shah[1], Catalina Simion[2], Shuang Hu[2], Rhonda Chronis[2], Tre McClellan[2], Jae Hwang[2], Ryan Yang[2], Heather Baker[2], Danying Cai[2], James Keck[2], Lindsay Shopland[2]. *[1]The Jackson Laboratory, Sacramento, CA,[2]In Vivo, The Jackson Laboratory, Sacramento, CA*

Cytokine Release Syndrome (CRS) is a systemic inflammatory response that is caused by the large, rapid release of cytokines in the blood by immune cells affected by infection or immunotherapy and remains a

prominent challenge for T cell-based therapeutics. Bispecific T cell engagers (BiTEs) are fusion proteins that are generated by linking the targeting region of two antibodies: one arm binds to the tumor-associated antigen, and the other arm binds to T cells to promote T cell-mediated cytotoxicity in an MHC-independent manner. A CD19xCD3 BiTE has been approved by the FDA for the treatment of CD19-positive B-cell lymphoma. Despite having great clinical efficacy, CRS remains a major concern for BiTE therapy. This necessitates the development of a translational model that could predict CRS toxicity more accurately. Various *in-vitro* models proposed to assess BiTE-related CRS have several shortcomings as they do not provide details about the systemic immune response, off-target effects, neurotoxicity, tissue damage, and organ failure. Here we propose an *in-vivo* approach to concomitantly assess the efficacy and CRS toxicity of CD19xCD3 BiTE either alone or in combination with Rituximab (monoclonal antibody targeting CD20) in the Raji luciferase xenograft model of Burkitt's lymphoma in PBMC humanized NSG-MHC Class I/II knockout mice. Five days post human PBMC engraftment (Study Day- SD 5), the mice were injected with Raji-luciferase cells. On SD 6, the mice were treated with BiTE, Rituximab, or the combination of BiTE and Rituximab. Additional control groups included OKT3 and Anti-CD28, the anti-T cell antibodies that failed clinically due to severe CRS. Efficacy was assessed through in-vivo imaging on SD5, SD8, and SD11. We observed tumor growth inhibition with BiTE, Rituximab, and the combination treatment. Clinical observations were recorded daily post treatment. Following cytokines were measured 6 hours after dosing and at study termination - IL-2, IL-4, IL-6, IL-10, TNF-α, and IFN-γ. Elevated cytokine levels were observed in the BiTE/combination group 6 hours post dosing but not in the Rituximab alone group. Together, the data suggest that the model could be used to assess the preclinical efficacy and CRS toxicity of BiTE.

Anti-CEACAM5 immune stimulant TLR7/8 agonist antibody drug conjugate is a potent myeloid cell activator for the treatment of CEACAM5-expressing tumors

Stephanie Decary, Lydia Blot, Charlotte Lahoute, Sandrine Benoist, Anne Caron, Francesca Graziano, Marc Trombe, Loreley Calvet, Alexandra

Ferrier, Marc Frederic, Sukhvinder Sidhu, Marie-Priscille Brun, Marielle Chiron. *Oncology, Sanofi, Vitry-sur-Seine, France*

Toll Like Receptor 7 and 8 (TLR7/8) agonists are a promising approach to treat tumors by harnessing the innate immune system to trigger anti-tumor innate and adaptive immunity. One of the main obstacles to the use of this class of low molecular weight molecules in cancer treatment is the toxicity associated with systemic immune activation after intravenous administration. We developed a novel immune stimulant ADC by conjugating the anti-CEACAM5 (carcinoembryonic antigen related cell adhesion molecule 5) tusamitamab antibody with a resiquimod (R848) TLR7/8 agonist payload. This tumor-targeted compound administered systemically and locally active, is expected to eradicate CEACAM5-positive (+) tumors by recruiting and activating immune cells in tumor microenvironment to promote anti-tumor immune response. Tusamitamab R848 ADC, evaluated *in vitro*, binds to CEACAM5+ tumor cells via its Fab moiety, and to myeloid cells via its Fc part at nanomolar (nM) concentrations. TLR7/8 pathway activation was evaluated on myeloid THP1 reporter cells. The conjugate elicits a potent and FcyR-dependent activity at low nM concentration. In co-culture of human blood cells and human CEACAM5+ gastric cancer cells, it was shown to induce phagocytosis activity, associated with increased activation/maturation of both monocytes and dendritic cells. Tusamitamab R848 ADC evaluated *in vivo* in CEACAM5+ pancreatic human tumor model, HPAFII, leads to robust antitumor activity with complete regressions (CR) after single administration at 5 mg/kg. In a pharmacodynamic study using lung tumor patient-derived xenograft mouse model, this ADC triggers murine cytokine inductions, innate immune cell enrollment at tumor site, and tumor necrosis in a dose-dependent manner. Based on preclinical *in vitro* and *in vivo* data, the tusamitamab R848 ADC is an innovative ADC approach with the potential to eradicate CEACAM5+ tumors in patients.

Longitudinal local and peripheral immunologic changes associated with PD-L1 response in a murine breast cancer model

Ann Hanna[1], Xiaopeng Sun[2], Emily Tran[2], Quanhu Sheng[1], Brandie C. Taylor[2], Susan R. Opalenik[1], Justin M. Balko[1]. [1]*Vanderbilt University*

Medical Center, Nashville, TN,[2]Vanderbilt University, Nashville, TN

Immune checkpoint inhibitors (ICI) have significantly enhanced patient survival in many cancers but yield limited success in breast cancer. ICIs activate anti-tumor immunity by overriding the inhibition of tumor infiltrating lymphocytes (TILs). Clinical trials in triple negative breast cancer (TNBC) patients, who harbor TILs within tumor stroma, have demonstrated increased survival (IMpassion130) and pathologic complete response (KEYNOTE-522) to ICI leading to FDA-approval of ICI and chemotherapy combinations in metastatic TNBC. However, ICI benefit is heterogeneous among patients. We sought to model ICI response in vivo to evaluate therapeutic resistance and response heterogeneity and to ascertain predictive biomarkers for favorable ICI outcomes. An immunocompetent EMT6 orthotopic mammary tumor model was used to investigate the efficacy of anti-PD-L1. Matched longitudinal samples of the tumor microenvironment (TME) (collected by fine-needle aspiration) and peripheral blood (PBMC) from mice were profiled by bulk RNA and T-cell receptor sequencing.

Anti-PD-L1 robustly suppressed primary tumor growth and extended survival beyond the control group. The addition of chemotherapy demonstrated moderate therapeutic efficacy but failed to enhance ICI benefit. Phenotypic profiling of the TME revealed increased T cells, DCs, and NK cells in anti-PD-L1 only and chemotherapy combination groups. Despite using a genetically identical tumor model and host, PD-L1 blockade induced heterogeneous responses, like clinical outcomes in TNBC patients, ranging from complete response (CR) to intrinsic resistance (IR). The primary TME showed upregulated signatures of cytotoxic T cell response and activation, specifically inflammatory interferon signaling (both prior to and post ICI administration) that corresponded to favorable outcomes to anti-PD-L1 in individual mice. Longitudinal analysis of the peripheral blood identified modest changes among mice at baseline that progressively deviated by response type (IR-vs-CR). Mice harbored enriched myeloid signatures and clonal T cell expansion during therapy corresponding to ICI resistance and response, respectively. Further investigations of matched peripheral blood and the primary TME signatures may identify systemic biomarkers and tumor antigen-specific T cell clones

to accurately predict ICI response in patients and uncover mechanisms for sensitizing tumors refractory to ICI.
Thus, we identify an in vivo model that emulates TNBC patient heterogeneous outcomes to ICI combinatorial approaches. We describe host-specific signatures, specifically from myeloid cells, that correlate with differential responses to ICI, which may serve as a basis for peripheral blood tracking of breast cancer patient responses.

SETD2 loss and ATR inhibition synergistically promote cGAS signaling and immunotherapy response in renal cell carcinoma

Xiande Liu[1], Yanting Zhang[1], Xuesong Zhang[1], Daniel McGrail[2], Truong Lam[1], Anh Hoang[1], Elshad Hasanov[1], Ganiraju Manyam[1], Christine B. Peterson[1], Haifeng Zhu[1], Shwetha V. Kumar[1], Rehan Akbani[1], Nizar M. Tannir[1], Guang Peng[1], Eric Jonasch[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]Center for Immunotherapy and Precision Immuno-Oncology, Cleveland, OH*

Rationale: Immune checkpoint blockade (ICB) demonstrates durable clinical benefit only in a minority of renal cell carcinoma (RCC) patients. Identifying molecular features that determine response and developing approaches to enhance the response remain an urgent clinical need. Targeting S phase DNA damage repair (S-DDR) network has been reported to activate cGAS signaling and convert a non-immunogenic tumor microenvironment to an immunogenic tumor microenvironment, thus improving immunotherapy response in breast cancer and small cell lung cancer. SETD2 has been known to be required for ATM-mediated DNA damage response, and we hypothesize that *SETD2* loss confers greater dependence on ATR activity and provides vulnerability to ATR inhibitors, which may further potentiate the response to immunotherapy.
Methods: Applying molecular, cellular, and bioinformatic approaches, we comprehensively investigated the effects of *SEDT2*/*Setd2* loss on the cytosolic DNA damage response pathway, the cGAS-mediated cytosolic DNA sensing pathway, the tumor immune microenvironment, and immunotherapy response in RCC cell lines, in the Renca-BALB/c immune competent murine model, and in RCC patients cohorts with or without ICB therapy.

Results: We found that, in multiple RCC cell lines, pharmacological inhibition of the ATR-CHK1 axis activated the cGAS-IRF3-dependent cytosolic DNA sensing pathway, resulting in inflammatory cytokine expression. *SETD2* mutated RCC cell lines or tumor samples were associated with preferential ATR-CHK1 activation over ATM-CHK2 activation. *SETD2* knockdown promoted the cytosolic DNA sensing pathway and conferred greater sensitivity to ATR inhibition. In murine Renca tumors, *Setd2* knockdown and the ATR inhibitor VE822 synergistically activated the cytosolic DNA sensing pathway, immune cell infiltration, and immune checkpoint protein expression. *Setd2* deficient Renca tumors demonstrated greater vulnerability to ICB monotherapy or in combination with ATRi than *Setd2* proficient tumors. *SETD2* mutations were associated with a higher response rate and prolonged overall survival in ICB-treated RCC patients, but not in non-ICB-treated RCC patients. Conclusion: This study reveals that *SETD2*/*Setd2* loss and ATR inhibitor synergize to enhance cGAS signaling and RCC tumor immune responsiveness, and provides mechanism-based guidance to develop more personalized combination therapy regimens for RCC patients with *SETD2* mutations.

mRNA-based immunotherapies to treat women's cancers
Dan Tse. *Geneleap, Woburn, MA*

With its ability to potentially code for any given protein, peptide and fragments, synthetic mRNA has landed itself a broad range of cancer immunotherapy applications, including costimulatory receptors, therapeutic antibodies, vaccines, and cytokines able to change the tumor microenvironment.We have been able to leverage our mRNA platform to generate a vaccine for HPV-associated cervical cancer (CC), as well as an immune-stimulatory cytokine for triple negative breast cancer (TNBC), both diseases that disproportionately affects minorities who do not participate in routine medical screenings and contribute to disparity in mortality beyond individual risk factors.IL-12 is a potent pro-inflammatory type 1 cytokine with potential to enter the clinical practice as immunotherapy for cancer. Its use in the form of recombinant protein and/or DNA plasmid has been hampered by issues with systemic toxicity or

protein bioavailability within the tumor. To overcome these roadblocks, we developed a novel secreted single chain IL-12p70 mRNA. Intra-tumoral dosing of this mRNA induced tumor regression in a syngeneic and orthotopic mouse model of TNBC. Almost all cervical cancers are HPV (human papilloma virus) associated. We have developed a therapeutic vaccine, based on a single mRNA coding for two de-risked antigens, that is able to induce a T cell response against the oncogenic proteins E6 and E7 of the most common serotype (HPV16). When injected intramuscularly in mice bearing C3.43 masses, this vaccine suppressed tumor growth and generated immunological memory.Currently, these women's cancers do not have a cure or an effective standard of care. With an efficacy that relies on a few injections and non-invasive routes of administration, we believe our innovative RNA-based pharmaceuticals might close some treatment gaps.

The RAF/MEK clamp avutometinib (VS-6766) induces an immunogenic tumor microenvironment and potentiates the efficacy of anti-PD-1

Silvia Coma[1], Miriam Molina Arcas[2], Julian Downward[2], Jonathan A. Pachter[1]. *[1]Verastem Oncology, Needham, MA,[2]The Francis Crick Institute, London, United Kingdom*

The RAS/RAF/MEK/ERK (MAPK) pathway is one of the most commonly mutated oncogenic pathways in human cancers. Although RAS, RAF and MEK have been validated as anticancer targets with approval of KRAS G12C, BRAF and MEK inhibitors, combination strategies with chemotherapy, targeted therapies and/or immune checkpoint inhibitors may be optimal for deep and durable response. Avutometinib (avuto, VS-6766) is a unique RAF/MEK clamp that potently inhibits MEK kinase activity and induces a dominant negative RAF/MEK complex preventing phosphorylation of MEK by ARAF, BRAF and CRAF. Preclinically, avuto has shown strong anti-proliferative potency across tumor cell lines carrying various MAPK pathway alterations. Clinically, avuto monotherapy has shown responses in gynecological cancers and KRAS mutant non-small cell lung cancer. Here, we tested the immune modulatory effects of avuto on tumor cells and tumor-infiltrating immune cells and assessed anti-tumor efficacy in mice treated with avuto in combination with an anti-PD1

antibody. In a panel of KRAS and BRAF mutant human tumor cell lines, avuto treatment increased the expression of MHC-I complex genes, including B2M, HLA-A and TAP1. In the CT26 KRAS G12D syngeneic colorectal cancer model, upregulation of B2M and TAP1 by avuto was confirmed in vivo, suggesting that avuto may increase antigen presentation. Furthermore, avuto upregulated the expression of markers of T cells (CD8, PDCD1), NK cell activation (NCR1) and interferon response (IFNG, IRF7, IL12) in the CT26 model. Interestingly, all these pro-immune changes observed with avuto were stronger than those observed with an equivalent dose level of the MEK-only inhibitor trametinib. Avuto also increased expression of B2M, CD8A, PDCD1, NCR1 and IRF7 in a KPARG12C orthotopic lung cancer model. Flow cytometry analysis showed that avuto also significantly increased MHC-II expression by tumor cells and the numbers of CD8 T cells and M1 macrophages, and significantly decreased monocytic and granulocytic MDSCs. These immune changes indicate that avuto induces an immunogenic tumor microenvironment that may potentiate the efficacy of immuno-oncology agents such as anti-PD-1. Accordingly, in the CT26 model, whereas avuto and anti-PD-1 each delayed tumor growth, combination of avuto with anti-PD-1 increased antitumor efficacy and prolonged survival. Furthermore, all complete responders in the avuto + anti-PD-1 group were able to reject a re-challenge with CT26 tumor cells and showed increased CD8 and CD4 effector memory T cells relative to untreated naïve control mice, indicating that avuto + anti-PD-1 treatment induces durable immune memory. These results support clinical evaluation of avutometinib in combination with an anti-PD-1 antibody for treatment of patients with solid tumors harboring MAPK pathway alterations such as KRAS or BRAF mutations.

#4156

Site specific tumor response to combination chemotherapy and immune checkpoint inhibitor in the syngeneic Pan02 pancreatic ductal adenocarcinoma model

Andrew Wong, Patrick Fadden, Cara Clouse, Patrick Wood, Marianna Brown-Augustine, Fei Zhao, Elliot Ser, Joseph Kolb, Chassidy Hall, Elizabeth Rainbolt. *Charles River Laboratories, Inc., Durham, NC*

Syngeneic tumor models provide a platform to assess novel immune-oncology therapeutics in fully immuno-competent mice. A subcutaneous flank tumor implant provides a convenient and accessible location to monitor the tumor growth and response to therapy. However, the tumor microenvironment, and therefore, the responsiveness to immuno-oncology therapies, is greatly impacted by the location in which the tumor develops (Ho 2021, Oliver 2018). Given the potential of different immuno-suppressive features driven by the specific tumor location, we wanted to compare the tumor infiltrating leukocyte populations in the subcutaneous flank and orthotopic pancreatic Pan02 syngeneic models, as well as the response to standard of care therapies. Pan02 cells were either implanted orthotopically in the pancreas or subcutaneously in the flank and allowed to establish before dosing with either vehicle, oxaliplatin, anti-CTLA-4 or the combination of therapies. Established tumors from untreated orthotopic and flank models were sampled for flow cytometry to assess infiltration by a broad range of immune cell populations. Response to therapy was clearly dependent on tumor location with flank tumors being resistant to both monotherapy and combination therapy, while the orthotopic tumors responded modestly to monotherapy but displayed synergy with the combination therapy. The results suggest that for a given syngeneic tumor cell line with identical mutational load and antigenicity, we can generate unique tumor microenvironments dependent on implant location leading to different outcomes when testing novel immune-oncology therapies. These types of models can help define the context in which novel immune-oncology therapeutics can be expected to drive an effective immune response.

Tumor context dictates reliance on TCF1 for response to immunotherapy

Giulia Escobar[1], Katherine Tooley[1], Joan Pages Oliveras[1], Linglin Huang[1], Hanning Cheng[1], Chang Xue[1], Davide Mangani[1], Natanael Hazel[1], Carola Rutigliani[1], Luca Biasco[2], Ana C. Anderson[1]. *[1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Great Ormond Street Institute of Child Health, University College London, London, United Kingdom*

Stem-like CD8 T cells are regulated by the transcription factor TCF1 and are key players in the response to immune checkpoint blockade (ICB). However, recent findings indicate that the dependance on $TCF1^+$ stem-like T cells for ICB efficacy may not be equal across patients or in different tumor contexts. Here we leveraged TCF1 conditional knock-out (TCF1 cKO) mice to investigate how TCF1 instructs the early fate and functions of CD8 T cells upon ICB therapy in tumors that differ for immunogenicity and levels of tumor antigen expression. Strikingly, we discovered that TCF1 expression in CD8 T cells is required for ICB efficacy in poorly immunogenic B16OVA melanomas but is dispensable in highly immunogenic MC38OVA colorectal tumors. Single-cell RNA sequencing and immunophenotyping in the tumor draining lymph node (TDLN) revealed defective priming and expansion of tumor-specific TCF1 cKO T cells in B16OVA- but not MC38OVA-bearing mice treated with ICB. Conversely, ICB therapy efficiently expanded tumor-specific TCF1 WT T cells in the TDLN of both tumor models. In vitro, we found defective proliferation, reduced PD1 and CD28 up-regulation and reduced phosphorylation of key molecules downstream the T cell receptor pathway in TCF1 cKO T cells stimulated with low but not high TCR signals. These data indicate that TCF1 poises T cells for optimal responsiveness in suboptimal priming conditions such as those found in low antigen expressing tumors. Furthermore, in the absence of TCF1 we found the accumulation in the TDLN of a subset of tumor-specific naïve T cells poised to give rise to short-lived effectors, which are less suited to sustain anti-tumor responses in poorly immunogenic tumors where expansion of T cells retaining memory potential is required for durable responses. Single-cell RNA sequencing and immunophenotyping within the tumor microenvironment showed that in MC38OVA tumors both WT and TCF1 cKO mice expanded a CD8 subset sharing a signature with transitory effectors, which were shown to mediate ICB efficacy in chronic viral infection models. Expansion of cytotoxic CD8 T cells likely accounted for the strong anti-tumor response observed in both WT and TCF1 cKO mice. Conversely, B16OVA tumors failed to expand transitory effectors and accumulated Tox^+ dysfunctional CD8 T cells. Importantly, in the absence of TCF1 dysfunctional T cells became destabilized, failed to persist and shared features with CD8 T cells found in patients that fail ICB. Altogether, the reduced priming of stem-like T cells in the TDLN combined with a

destabilized dysfunctional T cell state in the tumor contributed to the failure of TCF1 cKO mice to sustain effective ICB responses in poorly immunogenic tumors. Our study highlights a role for TCF1 during the priming and early stages of the anti-tumor CD8 T cell response with important implications for guiding optimal therapeutic interventions in cancers with low frequency of $TCF1^+$ CD8 T cells and low neoantigen expression.

#4158

Selective targeting of CD122 combined with radiotherapy triggers CD8 and NK mediated immunity, abrogating metastasis in head and neck squamous cell carcinoma

Jacob Gadwa[1], Maria Amann[2], Thomas E. Bickett[1], Michael W. Knitz[1], Laurel B. Darragh[1], Miles Piper[1], Benjamin Van Court[1], Sanjana Bukkapatanam[1], Tiffany T. Pham[1], Xiao-Jing Wang[3], Laura Codarri Deak[2], Christian Klein[2], Pablo Umana[2], Angelo D'Alessandro[4], Sana D. Karam[1].
[1]Radiation Oncology, University of Colorado, Aurora, CO,[2]Roche Innovation Center Zurich, Zurich, Switzerland,[3]Pathology, University of Colorado, Aurora, CO,[4]Biochemistry and Molecular Genetics, University of Colorado, Aurora, CO

The implementation of cancer immunotherapies, while revolutionary in certain cancer types, has seen limited clinical success in head and neck squamous cell carcinomas (HNSCC). This revelation has prompted investigation in alternative targets to invigorate anti-tumor immunity. IL-2 signaling governs the survival and functionality of lymphocytes, thus making IL-2 receptor signaling an attractive target for new immunotherapies. However, therapies to enhance IL-2 signaling are often limited in their efficacy by modulating the activation of regulatory T cells (Tregs), which preferentially binds IL-2 via the high affinity receptor IL-2Rα (CD25). Selectively targeting IL2Rβ (CD122), the intermediate affinity receptor, can be leveraged to induce anti-tumor immune responses in effector T cells and natural killer (NK) cells while limiting negative regulation conferred by Tregs. The novel bispecific immunocytokine PD1-IL2v preferentially activates IL-2 signaling through CD122 on PD-1 expressing cells, activating immune effectors, and preventing immune

exhaustion by blockade of PD-1. However, PD-1 blockade can amplify immunosuppression by Tregs, necessitating their depletion using αCD25. Here, we observe that radiation therapy and combination of PD1-IL2v with an Fc-optimized αCD25 antibody induces systemic activation of effector CD4 and CD8 T cells, reducing overall tumor burden. Concordant with improved local tumor control, we also observed a decrease in metastatic spread using a newly developed Kras/smad4/p53 mutated metastatic tumor model. NK cells, which are known to play a central role in the control of tumor
cell dissemination though direct cytotoxicity, displayed a phenotypic shift towards an activated state upon treatment with PD1-IL2v, highlighted by enhanced cytotoxicity, NK receptor diversity, and metabolic activity. Although relatively uncommon in comparison to other cancer types, those patients who present with metastases display a substantially poorer outcome, demonstrating the need for therapies which target this axis of cancer disease progression. In summary, we find that radiation therapy and PD1-IL2v imparts potent anti-tumor immunity, reducing local tumor growth and distant tumor spread, which taken together contribute to increased overall survival.

#4159

The COX-2/PGE2 pathway as a mediator of resistance to anti-PD-1 therapy

Shuming Chen[1], Seoho Lee[2], Tracee L. McMiller[2], Isaac Morales[2], Preethi Sankaran[2], Brian Francica[3], Robert D. Leone[4], Tom W. Dubensky[3], Suzanne L. Topalian[2]. *[1]Surgery, Johns Hopkins University School of Medicine, The Sidney Kimmel Comprehensive Cancer Center, and The Bloomberg~Kimmel Institute for Cancer Immunotherapy, Baltimore, MD,[2]Surgery, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Tempest Therapeutics, South San Francisco, CA,[4]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: We previously found upregulation of the cyclooxygenase-2/prostaglandin E2 (COX-2/PGE2) pathway in the tumor microenvironment (TME) of cancer types that respond poorly to anti-PD-1 therapy, and showed that TME-resident cytokines such as IL-1B induce COX-2 expression in human tumor and myeloid cells. To investigate a potential

role for COX-2/PGE2 in anti-PD-1 resistance, we studied PGE2-mediated effects on human myeloid and T cells and their dependence on prostaglandin (EP) receptor signaling.
Methods: Monocytes (Monos) and T cells were enriched from normal donor peripheral blood by negative selection. PGE2 effects were tested on Monos activated with IFN-g (PD-L1 expression; FACS) or LPS (cytokine secretion; ELISA). PGE2 effects on monocytic dendritic cells (DCs) generated with GM-CSF+IL-4 and matured with CD40L were assessed by phenotyping for costimulatory molecules (CD80, CD86) and subpopulation markers (CD14, CD16, CD83). T cells activated with anti-CD3/CD28 +/- PGE2 for 2-6 days were assessed for expression of CD25, CD69, CD107a, CD137, OX40, GITR, LAG-3, PD-1, PD-1, PD-L1 and TIM3 (FACS); proliferation markers (Ki67, CFSE; FACS); cytokine secretion (IFN-g, IL-2, IL-10, TGF-b; ELISA); and metabolic function (Seahorse assay). In some experiments, cells were pre-incubated with inhibitors of EP2 (PF-04418948), EP4 (ONO-AE3-208), or the dual inhibitor TPST-1495 (Tempest Therapeutics).
Results: Myeloid cell functions were suppressed by PGE2, which reduced IFNg-induced PD-L1 expression and modulated LPS-induced cytokine secretion. Furthermore, PGE2 inhibited DC maturation, evidenced by persistent CD14 and CD16 expression and a decreased CD83+ subset. In CD4 and CD8 T cells activated with anti-CD3/CD28, PGE2 reduced expression of CD25 and CD69 (early activation markers), CD107a (cytolytic potential), Ki67 (cell proliferation), co-stimulatory molecules (CD137, OX40, GITR) and checkpoint molecules (LAG-3, PD-1, PD-L1, TIM3) in a dose-dependent manner. PGE2 also reduced the CFSE-low (proliferating) population in activated CD4, CD8 and Treg cells. Secretion of proinflammatory cytokines IFN-g and IL-2, and inhibitory cytokines IL-10 and TGF-b from activated T cells was also suppressed by PGE2. These effects were specifically reversed by chemical inhibitors of EP2 and/or EP4. PGE2 exposure at the time of T cell activation was associated with depressed mitochondrial oxidation and cellular glycolysis, suggesting global effects on T cell metabolism.
Conclusion: Understanding and preventing anti-PD-1 resistance is a critical goal in oncology. Our results suggest that the COX-2/PGE2 pathway exerts immunosuppressive effects on myeloid and T cells via the EP2 and EP4 receptors. COX-2 and PD-L1 are distinct immune checkpoints, providing a

rationale to test anti-PD-1 in conjunction with COX-2 pathway inhibitors such as IL-1B antagonists and highly specific EP2 and EP4 inhibitors in patients with cancer.

#4160

Characterization of cytotoxic resilient T cells in patients with advanced cancers in response to salvage radiation therapy or chemotherapy

Joanina K. Gicobi[1], Yiyi Yan[2], Hu Zeng[1], Sean Park[1], Haidong Dong[1].
[1]Mayo Clinic College of Medicine and Science, Rochester, MN,[2]Mayo Clinic College of Medicine and Science, Jacksonville, MN

Although cancer burden in patients with advanced diseases results in T cell exhaustion and failed prior therapies, some of them achieved durable clinical responses to salvage therapy (chemotherapy or radiation therapy) implying a presence of tumor-reactive resilient T cells in them. However, the phenotype and functional features of resilient T cells have not been clearly defined. We found that $CX3CR1^+$ $CD8^+$ T cells with low mitochondrial membrane potential demonstrated features of resilient T cells: (a) their cytotoxic T cell function (degranulation/CD107a expression) recovered quickly after tumor burden has been reduced by radiation therapy or chemotherapy; (b) they maintain a low profile of glycolysis but produce optimal levels of ATP; (c) they express lower levels of PD-1 and TOX; (4) they share a feature of stem-like T cells ($TCF1^+PD\text{-}1^+$) that can be responsive to immunotherapy; (5) they avoid accumulation of a harmful level of cytosolic reactive oxygen species (ROS) that may cause T cell exhaustion; (6) they upregulate malic enzyme 1 (ME1) to balance glycolysis and ROS, and to expand cytotoxic effector T cells. These unique features of resilient T cells may not only be used as T cell biomarker to design rational combination therapy to control advanced cancers but can also be used to convey a resilient functional state to T cells in patients who lack them.

#4162

T-cell metabolic profiling with bioluminescent assays

Maggie Bach, Natasha Karassina, Julia Gilden, Donna Leippe, Mike Valley, Kayla Sylvester, Jolanta Vidugiriene. *Promega, Fitchburg, WI*

Cellular energy metabolism is crucial for cell survival and the balance of metabolic pathways determines the health of the cell. Determining and understanding metabolic profiles of cells can aid in overall insight of cell health and improvement of cell therapeutics, especially for immune interventions. T-cells actively regulate their metabolic profile from quiescent to a highly metabolically active state after activation. Activation rewires the cell to drive glycolysis and oxidative phosphorylation for production of reducing power and ATP for cell growth and proliferation. A small population of these cells then transition to a more quiescent state and persist as memory cells to aid in secondary responses. Although the trend of T-cell metabolism after activation has been studied, the method of investigation is cumbersome and lacks depth of information of overall cell health. To address this, we developed a bioluminescence NAD(P)H core technology and applied it to build a set of cell-based assays covering diverse metabolic pathways including glucose, glycogen, and amino acid metabolism, and the TCA cycle. Here we utilize those assays to investigate changes in metabolic profiles of naïve, effector, and memory T-cells as they transition from a state of oxidative phosphorylation to increased glycolytic rates, dependence on different fuel consumption and storage, including an increase in fatty acid oxidation and glycogen accumulation. We demonstrate flexibility of the assays for detecting multiple metabolites from the same sample and monitoring metabolite changes over time by assaying multiple samples. We show that the assays are amenable to various volumes (96-,384-well plates) and low cell numbers. For example, activity of dehydrogenases involved in glycolysis, pentose phosphate and TCA cycles can be detected with less than 400 cells/well. In conclusion, understanding the processes governing dynamic metabolic changes of T-cells during their transition from naïve to activated to memory phenotypes is required for next-generation cell therapy development. The developed bioluminescence cell-based assays provide the sensitivity, throughput and robustness required for rapid evaluation of such changes.

Enhanced immune response according to different radiation fractionations in colorectal cancer cell lines

Sang Jun Byun[1], Shin Kim[2], Incheol Seo[3], Hye Won Lee[4], Sung Uk Bae[5], Seong Kyu Baek[5], Woon Kyung Jeong[5], Seung Gyu Park[1], Euncheol Choi[1].

[1]Department of Radiation Oncology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[2]Department of Immunology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[3]Department of Immunology, Kyungpook National University School of Medicine, Daegu, Korea, Republic of,[4]Department of Pathology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[5]Department of Surgery, Keimyung University School of Medicine, Daegu, Korea, Republic of

Background: Concurrent chemoradiation therapy is standard treatment in locally advanced rectal cancer. 5-FU is a commonly used chemotherapeutic agent, and radiotherapy is delivered with conventional or short-course fractionations. Immunotherapy is a new strategy with systemic effect, and several combinations with other treatments including surgery, chemotherapy, or radiotherapy in various sequences are evaluated. After irradiation, there is immunogenic changes in the tumor microenvironment, which is expected to improve the response of the added immunotherapy. The purpose of this study is to investigate the difference in immune response according to the radiation fractionation schedules after irradiation in various colon cancer cell lines.
Materials and Methods: The human colorectal cancer cell lines, DLD-1 and HCT116, were cultured and irradiated with total 1.8 Gy of X-rays in 10 fractions and 5 Gy of X-rays in 3 fractions using linear accelerator for 10 and 3 consecutive days. The mRNA expression levels of immune related genes including *CD274*, *TREX1*, *CD74*, *IFNG*, *CALR*, *HMGB1*, *TGFB1* were evaluated using real-time PCR in 0, 3, and 7 days after irradiation.
Result: The mRNA expression levels of *CD74*, *HMGB1* and *CD274* were increased in both DLD-1 and HCT116 cell lines, and *IFNG* increased only in DLD-1. However, there was a difference in the increasing patterns over time between the two radiation fractionations. According to the radiation fractionation, increasement of the mRNA expression levels was more prominent in 1.8 Gy in 10 fractions than 5 Gy in 3 fractions. In addition, the radiation-resistant DLD-1 cell line showed a more marked increase in the levels of CD274 mRNA as well as other genes associated with CD274 than the radiation-sensitive HCT116 cells. Moreover, DLD-1 cell line, which is more resistant to radiation, showed more prominent elevation in *CD274* mRNA level than HCT-116.

Conclusions: We could find that more fractionated irradiation schedule with smaller dose per fraction further increases the immune response. Even in radio-resistant tumor cells, better immune response could be expected after irradiation than radio-sensitive cells. It would be needed to verify the results in real tumor conditions, such as the tumor microenvironment containing immune cells and cancer-associate fibroblasts. It is also thought that studies on the appropriate time to use immunotherapeutic agent are needed.

Relieving immune suppressive pathways in breast cancer to improve outcomes

Amanda Poissonnier[1], Eivind Valen Egeland[2], Rossin Erbe[3], Wesley Horton[4], Ana Howells-Ferreira[4], Shamilene Sivagnanam[5], Nell Kirchberger[1], Dhaarini Murugan[1], Andrew Fields[6], Peter Ordentlich[7], Andrew C. Adey[8], Elana J. Fertig[9], Lisa M. Coussens[1]. *[1]Cell, Developmental and Cancer Biology, OHSU Knight Cancer Institute, Portland, OR,[2]Dept of Tumor Biology, Institute for Cancer Research, Oslo University Hospital, Norway,[3]Div. of Quantitative Sciences, Sidney Kimmel Comprehensive Cancer Center / Johns Hopkins University, Baltimore, MD,[4]Cell, Developmental and Cancer Biology / Computational Biology, OHSU Knight Cancer Institute, Portland, OR,[5]Cell, Developmental and Cancer Biology/ Computational biology, OHSU Knight Cancer Institute, Portland, OR,[6]Molecular and Medical Genetics, OHSU Knight Cancer Institute, Portland, OR,[7]Syndax Pharmaceuticals, Waltham, MA,[8]Molecular and Medical Genetics / CEDAR, OHSU Knight Cancer Institute, Portland, OR,[9]Div. of Quantitative Sciences, Sidney Kimmel Comprehensive Cancer Center / Johns Hopkins Univ, Baltimore, MD*

Triple negative breast cancer (TNBC)represents the most aggressive subset of breast cancer with limited treatment options leading to high mortality. While treatment of metastatic cancers with immune checkpoint inhibitors (ICIs) offers promise for many, early results from clinical trials evaluating ICIs in TNBC showed benefit for only a subset of patients. Preclinical data indicate that infiltrating macrophages foster tumor progression by limiting $CD8^+$ T cell infiltration, activation and cytotoxicity in tumor microenvironments. We hypothesized that response to ICI therapy could be

enhanced by sequentially combining a microtubule poison (paclitaxel; PTX) that enhances tumor immunogenicity, with a macrophage-depleting/reprograming agent, e.g. colony-stimulating factor 1 receptor blocking antibody (aCSF1R), in addition to an ICI targeting the PD-1/PD-L1 axis. Immune-competent mammary tumor-bearing MMTV-PyMT transgenic mice were randomized at day 80, and enrolled into experimental groups evaluating PTX, aCSF1R mAb, αPD-1 mAb, as monotherapy and in combinations. Cohorts were analyzed at distinct time points for primary and metastatic tumor burden, in addition to immunophenotyping (flow cytometry), transcriptional (RNA-Seq), epigenetic (sciATAC-Seq), and T cell receptor (TCR) changes correlating with outcomes. These studies revealed tumor regression and improved outcome for 60% of mice receiving PTX/aCSF1R/aPD-1, associated with localized $CD8^+$ T effector and resident memory cell expansion, increased antigen-specific clonal expansion at the primary tumor site. To address epigenetic plasticity as a limiting factor for long-term T cell memory, a class 1 benzamide histone deacetylase (HDAC) inhibitor (e.g., entinostat) was sequentially added to PTX/aCSF1R/aPD-1 triple therapy resulting in primary tumor stasis in 100% of mice, and significantly enhanced overall survival. Improved outcome and tumor stasis were associated with an increased presence of long-lived central and stem-like memory $CD8^+$ T cell infiltration, associated with increased intra-tumoral B memory cell and $CD4^+$ T follicular helper cell infiltration. Improved outcomes were $CD8^+$ T cell-dependent; depletion of $CD19^+/CD20^+$ B cells resulted in complete loss of granzyme B $^+$ $CD8^+$ T cell infiltration into primary tumors, and rapid tumor expansion. These preclinical studies indicate that therapies targeting myeloid-mediated T cell suppression can be leveraged to improve anti-tumor T cell memory, and that durable long-term T cell memory can be instated upon addition of an epigenetic modulator.

#4165

A systemically administered killed bacteria-based multiple immune receptor agonist for pulsed anti-tumor immunotherapy

Michael J. Newman. *Indaptus Therapeutics, San Diego, CA*

Systemic activation of multiple immune receptors, such as Toll-like (TLR), NOD-like (NLR) and Stimulator of Interferon Genes (STING) is essential

for efficient innate and adaptive immune responses. Attempts to use single receptor agonists for advanced cancers have not produced approved products. Limitations include insufficient immune activation and dose-limiting toxicities associated with continuous exposure. Gram-negative bacteria (G-NB) contain multiple TLR, NOD and STING agonists. Potential utility of G-NB for cancer immunotherapy is supported by observation of tumor regression in the setting of infection and Coley's Toxins. Coley reported that i.v. administration was likely most effective but produced toxicity. The discovery of TLRs, particularly the broad/potent activities of the TLR4 agonist lipopolysaccharide (LPS) suggest that it may be both a critical active ingredient and a dose-limiting feature of i.v. G-NB. Non-pathogenic *E. coli* were treated with polymyxin to achieve ~90% reduction of LPS activity without lysis and were then killed and stabilized with glutaraldehyde. The resulting product, Decoy10, was shown to contain multiple TLR, NOD and STING agonists and exhibited reduced i.v. toxicity (mice, rabbits) relative to unprocessed cells. Surprisingly, despite reduction in LPS activity and toxicity, Decoy10 induced secretion of similar or higher levels of most cytokines/chemokines by peripheral blood mononuclear cells, compared to unprocessed bacteria. Higher cytokine/chemokine induction was also observed compared to monospecific TLR agonists. Administration of 4 to 8 weekly or twice a week i.v. doses of Decoy10 to mice with established s.c., orthotopic or metastatic syngeneic breast, colorectal, hepatocellular, pancreatic carcinomas or syngeneic or human non-Hodgkin's lymphoma was well-tolerated and produced single agent anti-tumor activity and/or combination-mediated durable tumor regressions, with induction of immunological memory. Regressions were observed, without significantly increased toxicity, when Decoy10 was combined with chemotherapy, a non-steroidal anti-inflammatory drug, anti-PD-1 therapy or rituximab. Tumor regressions were associated with activation of innate and adaptive immune pathways in tumors after one dose of Decoy10 and were mediated by NK, $CD4^+$ and $CD8^+$ T cells.

Published studies have demonstrated that systemic bacteria are engulfed by and activate immune cells in the liver and spleen, with rapid clearance in mice, rabbits, and humans. Systemic bacteria have also been shown to accumulate in or around tumors. We have taken advantage of these phenomena to produce a detoxified but potent multiple immune agonist that induces systemic innate and adaptive anti-tumor immune activation without

requirement for continuous systemic exposure. A Decoy product has been cleared by the US FDA for a Phase 1 oncology trial.

#4166

Effects of cyproheptadine in eliciting natural killer cell-mediated immune response in bladder cancer

Himani Kumari[1], Guan-Ling Lin[1], Chih-Chieh Yeh[1], Ciao-Ni Chen[1], Yu-Ming Chuang[1], Wan-Hong Huang[1], Wen-Long Huang[1], Steven Lin[2], Michael W. Y. Chan[1]. *[1]Biomedical Science, National Chung Cheng Univ., Chiayi, Taiwan,[2]Institute of Biological Chemistry, Academia Sinica, Taipei, Taiwan*

Bladder cancer is one of the most common occurring cancers in urothelial carcinoma. The previous study suggested that cancer cells undergo immunoevasion due to epigenetic silencing of NKG2DL, in which NKG2D-NKG2DL interaction induced natural killer (NK) cell-mediated cytotoxicity. We hypothesized that NK-mediated cytotoxicity can be reactivated by restoring the expression of NKG2DL on tumor cells. Our previous studies demonstrated that cyproheptadine (CPH) is a novel HDAC inhibitor exhibiting antitumor activity by cell cycle arrest and apoptosis. To understand the mechanism behind, RNA-seq showed an upregulation of ULBP2, a NKG2DL, in bladder cancer cells treated with CPH. Interestingly, upregulation of ULBP2, was accompanied with the enrichment of H3K27Ac and H3K4me3 at ULBP2 promoter, was observed in cells treated with CPH. Increased NK-specific lysis was observed in CPH-treated cells co-cultured with NK-92 cells. More importantly, treatment of CPH enhanced the efficacy of immune checkpoint inhibitor in a syngeneic mice bladder cancer model. In conclusion, our results suggested that CPH may be a novel HDAC inhibitor which may elicit immune response in NK-cell dependent manner.

Translational control of T cell exhaustion in melanoma, perspectives in therapeutics

Samad Muhammadnejad[1], Biswendu Biswas[1], Ramdane Guemiri[1], Naima Benannoune[2], Jérémy Lavigne[1], Virginie Quidville[1], Jean-Yves Scoazec[3],

Stephan Vagner[4], Caroline Robert[5]. *[1]INSERM U981, Gustave Roussy, Villejuif, France,[2]INSERM U981 & Department of Cancer Medicine, Gustave Roussy, Villejuif, France,[3]INSERM U981, Gustave Roussy & University Paris Saclay, Villejuif, France,[4]CNRS UMR3348 & INSERM U1278, Curie Institute, Orsay, France,[5]INSERM U981 & Department of Cancer Medicine, Gustave Roussy & Paris Saclay University, Villejuif, France*

Background: Eukaryotic initiation factor 4F (eIF4F) complex plays a pivotal role in the selective translational control of protein expression in cancer. We previously showed that the inhibition of eIF4F had both a direct antitumor effect that could overcome resistance to BRAF inhibition in *BRAFV600* melanoma and an indirect immune-mediated antitumor effect via PD-L1 down regulation resulting from STAT1 decreased translation. We now explore further the translational control of immune checkpoints (ICs) on T cell and its link with lymphocyte exhaustion.
Methods: We performed polysome profiling (PP) on peripheral blood-derived activated and resting T lymphocytes as well as tumor-infiltrating lymphocytes (TILs) isolated from melanoma specimens in the presence or absence of silvestrol as an eIF4A (the helicase component of eIF4F) inhibitor. We studied the expression of ICs and exhaustion-associated transcription factors on lymphocytes at the various stages of exhaustion. The tumor cell lysing capacity of PBMC was evaluated with and without silvestrol. We also assessed the effect of silvestrol on tumor microenvironment in the BP syngeneic melanoma tumor model.
Results: Silvestrol decreased the translation of multiple ICs in activated CD4+ and CD8+ T cells, including TOX, NFAT1, NFAT2, LAG3, and TIM3 (the two latter being also transcriptionally regulated). FACS analysis confirmed the dose-dependent decrease of protein expression of exhaustion-associated transcription factors TOX, NFATc1, TCF1 and T-bet in activated lymphocytes. This effect was more prominent in more exhausted T cells. Silvestrol decreased T cell proliferation but, in co-culture experiments, it increased immune cell killing of melanoma cells by T-lymphocytes. In the BP murine model, the antitumor effect of silvestrol was associated with denser T cell infiltration and less exhausted TILs than control tumors.
Conclusion : Our findings demonstrate the role of eIF4F in the orchestrated regulation of functionally related proteins involved in T cell exhaustion.

They highlight the drugability of eIF4A for the cancer treatment and suggest that eIF4A inhibitors could be useful with IC inhibitors in combination or sequentially.

BALB/c-CD3EDG HuGEMM^{TM} mouse model for evaluation of CD3-targeted tumor immunotherapy

Demi Xiaojuan Liu, Kaixia Lian, Xuefei Yan, Jie Lin, Lei Zheng, Annie Xiaoyu An, Xiaoxi Xu, Ludovic Bourre, Jingjing Wang. *Crown Bioscience, Inc., San Diego, CA*

Introducti**on:** T cell immune response plays critical roles in cancer immunotherapy. CD3 complex, composed of CD3ε, CD3δ and CD3γ chains, is an essential component of TCR-CD3 complex mediating TCR signaling. Targeting CD3 complex has therefore become a popular strategy for manipulation of T cell function. Clinically relevant animal models for proper evaluation of human CD3 antibodies is in great demand in the field. Currently, adoptive transfer of human CD3+ T cells or transplantation of human hematopoietic stem/precursor cells to immunodeficient mice are usually employed. However, these mouse models are not fully immunocompetent. In this study we have evaluated in vitro CD3 EDG functionality and in vivo therapeutic efficacy, in BALB/c-hCD3EDG knock-in mouse in which all the three components of the CD3 complex — Cd3ε, Cd3δ, and Cd3γ— are replaced by their human counterparts, CD3E, CD3D, and CD3G.

Methods: A humanized CD3EDG mouse model (Hu**GEMM**) on BALB/c background was generated by replacing the entire mouse CD3EDG with its human counterpart through ES cell-based gene targeting. The cell surface expression of CD3E and intracellular expression of CD3D and CD3G were confirmed by FACS. Naïve CD3+ T cells were isolated from the splenocytes of homozygous CD3EDG Hu**GEMM** and activated by anti-hCD3 antibody. T cell proliferation was demonstrated by CFSE dilution assay. To validate the TCR functionality of humanized CD3EDG *in vivo*, we evaluated bispecific antibody anti-hCD3/hEpCAM5 in BALB/c-CD3EDG Hu**GEMM** bearing CT26-hEpCAM5.
Results: The expression of human CD3E, CD3D and CD3G were confirmed by flow cytometry. hEpCAM5 antigen expression was confirmed in CT26 cell line in vitro and tumor in vivo by flow cytometry. The TCR functionality was detected by *in vitro* T cell activation assays using anti-hCD3 antibody. *In vivo* efficacy was demonstrated using a bispecific antibody that simultaneously binds to human CD3 and human tumor associated antigen EpCAM5 in human *CD3 EDG* knock-in mice engrafted with CT26-hEpCAM5 tumor. The therapeutic efficacy of the bispecific antibody showed 32% tumor growth inhibition compared to control treatment. No significant body weight loss was recorded in any of the animals.
Conclusion: This study showed the successful establishment of humanized CD3 knock-in BALB/c mouse models providing a full immunocompetent model for human CD3-targeted tumor immunotherapies evaluation.

Inflammation and Immunity in the Tumor Microenvironment

#5129
Neutrophil extracellular traps induced by surgical stress regulate cancer metabolism leading to tumor growth

Tony Haykal, Ruiqi Yang, Celine Tohme, Ronghua Wang, David Geller, Christof Kaltenmeier, Hamza Yazdani, Samer Tohme. *University of Pittsburgh, Pittsburgh, PA*

Introducti**on:**
Surgery is a crucial intervention to cure malignancies. However, evidence shows that the surgical insult and its accompanying immune response can

enhance tumor growth and metastasis. Neutrophil Extracellular Traps (NETs) released systemically during surgical stress were previously shown to contribute to this process. In fact, to generate increased energy demands required for growth and metastasis, cancer cells in a stressful microenvironment need an adaptive mechanism where metabolic reprogramming to fatty acid (FA) oxidation has been emerging as an important process. Here, we aim to explore the direct effects of surgical NETs in regulating cancer cell metabolism leading to tumor growth and metastasis.

Methods:

For the indolent tumor model, C57BL/6 mice were injected with a small number of LLC-1 (Lewis Lung Cancer-1) cells subcutaneously (SQ) and a group was subjected to laparotomy for 30 mins, with or without intraperitoneal DNAse (NET inhibitor) injection perioperatively. Tumor growth was then followed for 4 weeks. For the tumor metastasis model, LLC-1 cells were injected SQ and allowed to grow for 3 weeks before resection with or without perioperative DNAse. Tumor metastasis to the lungs was assessed after 3 weeks. In vitro experiments on LLC-1 and MC-38 (murine colon adenocarcinoma) cancer cells were performed using NETs released from neutrophils freshly isolated from mice bone marrow and stimulated with Phorbol myristate acetate (PMA).

Results:

For the indolent tumor model, injection of cancer cells did not lead to any significant tumor growth after 4 weeks unless mice underwent surgical stress via laparotomy. Treatment with DNAse significantly reversed their growth. For the tumor metastasis model, tumor resection alone led to significant lung metastasis, but DNAse treatment during resection or resection in PAD-4 KO mice (unable to form NETs) led to significantly less metastatic burden. Furthermore, in vitro treatment of cancer cells with NETs lead to significant cell proliferation, relatively more under hypoxic and serum conditions. This was paralleled with a significant increase in fluorescently labeled FA uptake into cancer cells as detected by flow cytometry, as well as a significant upregulation of gene expression of FA transport proteins and oxidation enzymes.

Conclusion:

Surgical stress can promote tumor growth and metastasis through cancer cell metabolic reprogramming induced by systemically released NETs. We

hope that elucidating the molecular mechanism behind this process can help in finding therapeutics to prevent the protumorigenic effects of surgical stress.

Multi-plex cytokine profiling for mice on Bleomycin induced systemic sclerosis model

Yanping Yuan, Cheng Qian, Chuanzhi Yangmeng, Li Fang, Ruiqing Yan.
WuXi AppTec, Shanghai, China

Systemic sclerosis (SSc) is recognized as an autoimmune disorder characterized by immune dysregulation, obliterative vasculopathy, excessive accumulation of extracellular matrix, and fibrosis of the skin and other organs. It also ranks on the highest position of disease-related mortality and morbidity with an impaired quality of life among the rheumatologic illnesses. However, the immunological mechanism related to SSc remains to be elucidated systemically, which may lay for the novel therapeutic methodology. In the present study, we combined the MSD methodology and flow cytometry to landscape the chemokine or cytokine network, immunology response and signaling axis in mice on Blomycin induced SSc model. Our results provide the reference and path for the future direction of novel therapeutic reagents discovery.

Pulmonary influenza infection promotes the awakening of dormant metastatic breast cancer cells

Shi Biao Chia[1], Bryan Johnson[1], Julio A. Aguirre-Ghiso[2], Mercedes Rincon[3], James DeGregori[1]. *[1]Biochemistry and Molecular Genetics, University of Colorado Anschutz Medical Campus, Aurora, CO,[2]Cell Biology, Albert Einstein College of Medicine, New York, NY,[3]Immunology and Microbiology, University of Colorado Anschutz Medical Campus, Aurora, CO*

Breast cancer is the most common form of cancer and the second cancer-causing death in females. Although remission rates are high if detected early, survival rates drop substantially when breast cancer becomes metastatic. The most common sites of metastatic breast cancer are bone,

liver and lung. Respiratory viral infections inflict illnesses on countless people. The latest pandemic caused by the respiratory virus, SARS-CoV-2, has infected more than 600 million worldwide, with documented COVID-related death upward of 1 million in the United States alone. Respiratory viral infections result in increased inflammation with immune cell influx and expansion to facilitate viral clearance. Prior studies have shown that inflammation, including through neutrophils, can contribute to dormant cancer cells reawakening and outgrowth. Moreover, inhibition of IL6 has been shown to decrease breast cancer lung metastasis in mouse models. However, how respiratory viral infections contribute to breast cancer lung metastasis remains to be unraveled. Using MMTV/PyMT and MMTV/NEU mouse models of breast cancer lung metastasis and influenza A virus as a model respiratory virus, we demonstrated that acute influenza infection and the accompanying inflammation and immune cell influx awakens and dramatically increased proliferation and expansion of dormant disseminated cancer cells (DCC) in the lungs. Acute influenza infection leads to immune influx and expansion, including neutrophils and macrophages, with increased proportion of $MHCII^+$ macrophages in early time points, and a sustained decrease in $CD206^+$ macrophages starting 6 days post-infection until 28 days after the initial infection. Additionally, we observed a sustained accumulation of $CD4^+$ T cells around expanding tumor cells for as long as 28 days after the infection. Notably, neutrophil depletion or IL6 knockout reversed the flu-induced dormant cell expansion in the lung. Finally, awakened DCC exhibited downregulation of vimentin immunoreactivity, suggesting a role for phenotypic plasticity in DCC outgrowth following viral infection. In conclusion, we show that respiratory viral infections awaken and increase proliferation of dormant breast cancer cells in the lung, and that depletion of neutrophils or blocking IL6 reverses influenza-induced dormant cell awakening and proliferation.

The immunomodulatory role of paracrine signaling factor VSIG4 in peritoneal cancers

Yik Yan Chong[1], Sasinthiran Thiagarajan[1], Qiu Xuan Tan[1], Hui Jun Lim[1], Joey Wee-Shan Tan[1], Josephine Hendrikson[1], Gillian Ng[1], Ying Liu[1], Clara Yieh Lin Chong[1], Chin Jin Seo[2], Jolene Si Min Wong[2], Claramae Shulyn

Chia[2], Nicholas Brian Shannon[1], Chin-Ann Johnny Ong[1]. *[1]Laboratory of Applied Human Genetics, National Cancer Centre Singapore, Singapore, Singapore,[2]Department of Sarcoma, Peritoneal and Rare Tumours (SPRinT), National Cancer Centre Singapore, Singapore, Singapore*

Introduction: Colorectal cancer (CRC) is one of the most common cancers worldwide, often presenting with regional spread to the peritoneum. Peritoneal carcinomatosis (PC) has a significantly poorer prognosis compared to metastasis to the other regions of the body. Immunotherapy makes use of the memory and specificity of the adaptive immune system to achieve long lasting effective anti-tumor response. Tumor associated macrophages (TAMs) in the tumor microenvironment have been implicated in tumorigenesis by creating an anti-inflammatory environment suitable for the growth of cancer cells. Thus, our group sought to identify factors associated with immunomodulation in colorectal PC.
Methods: We interrogated publicly available colorectal cancer single cell database (n=5) to identify putative immune markers associated with macrophage activation in cancers. Validation was performed using V-set and immunoglobulin containing domain 4 (VSIG4) immunohistochemistry (IHC) staining on tumor microarrays (TMAs) of colorectal primary tumors (n=210). VSIG4 protein expression was assessed in cell-free ascites (n=39) derived from PC.
Results: Using publicly available single cell database, we shortlisted the top 100 genes from the expression data of CD136-positive TAMs cluster. Among these macrophage-associated genes, two putative markers, VSIG4 and NR1H3, were involved in the regulation of macrophage activation. NR1H3, also known as liver X receptor-alpha (LXR-α), is particularly associated with cholesterol metabolism and thus was excluded from our exploration of TAMs activity. Interestingly, our target of choice, VSIG4, is a membrane protein expressed by M2 macrophages, which is associated with the activation of anti-inflammatory macrophage subtype and the downregulation of pro-inflammatory macrophages. IHC staining of CRC TMA demonstrated that low VSIG4 expression in stroma of primary CRC is associated with poor prognosis (p=0.018). Moreover, enzyme-linked immunosorbent assay (ELISA) of the ascites from colorectal PC patients showed varying amounts of VSIG4, suggesting a possible biological role of VSIG4 amongst patients with upregulated VSIG4 levels in ascites. Taken

together, our studies suggest that VSIG4 plays a possible immunomodulatory role in colorectal PC and warrants further studies to assess its potential role as a therapeutic target in PC.
Conclusion: In view of its potential as a target for immunotherapy, further studies should be conducted to understand the role of VSIG4 in the progression of colorectal PC.

Oxazolone induced atopic dermatitis mouse model using hIL-4/hIL-4Ra double knock-in mice, a preclinical mouse model for evaluating Dupilumab biosimilars

Tao Yang[1], Rongfei Lu[1], Xiaofei Xu[1], Likun Zhang[1], Dawei Wang[1], Xinhe Feng[1], Xiaoyu An[1], Jessie (Jingjing) Wang[1], Xianfei He[2], Carl K. Edwards[1]. *[1]Crown Bioscience, Inc., San Diego, CA,[2]Shanghai Model Organisms Center, Inc, Shanghai, China*

Background. Th2 cytokines (e.g. IL-4, IL-5, IL13) drive defined allergic reactions and various autoimmune and inflammatory diseases including atopic dermatitis (AD), asthma and rhinitis. IL-4Ra is a receptor shared by both IL-4 and IL-13, thus blocking of IL-4Ra could prevent both IL-4 or IL-13 mediated Th2 inflammatory response. Dupilumab (Dupixent) is a humanized anti-IL-4Ra monoclonal antibody which binds to human IL-4Ra and attenuates IL-4/IL-13 mediated Th2 inflammation. It has been approved for treating moderate to severe AD and asthma. However, since Dupilumab isn't cross-reacting to mouse IL-4Ra, there is an unmet need for a robust mouse model to evaluate Dupilumab biosimilars at preclinical stages. In this study, we described an oxazolone induced AD model in hIL-4/hIL-4Ra double knock-in mice and its application to evaluate Dupilumab and its biosimilars.
Methods. The oxazolone induce AD mouse model was established in hIL-4/hIL-4Ra double knock-in mice by repeated topical applications of Oxazolone on ears. Oxazolone-induced mice received subcutaneous injection of Dupilumab at 25 mg/kg or 50 mg/kg. Dermatitis activity was assessed by measuring ear thickness, ear skin erosion, redness and scaling every other day. Serum were collected at the study end and IgE levels were measured by ELISA. In addition, spleens were also collected and their

weights were compared. Ear were collected at study end and proceeded with cytokine analysis and pathology evaluation.
Results. Repeated topical application of oxazolone on mouse ears induced AD-like phenotypes including ear skin swelling, erythema and scaling, drastic elevation of IgE in serum, excessive production of human IL-4 cytokine as well as excessive inflammatory cell infiltration in ear skin, which suggests oxazolone is able to induce AD in this hIL-4/hIL-4Ra double knock-in mice. Subcutaneous injection of Dupilumab at two different doses levels, 25 mg/kg and 50 mg/kg successfully ameliorated ear skin swelling, erythema and scaling at the study end. In addition, Dupilumab at both dose levels significantly reduced the IgE level in serum and mitigated the inflammatory cell infiltration, e.g. eosinophil infiltration, in mouse ear. Furthermore, Dupilumab treatment significantly reduced mouse IL-6 and mouse KC/GRO levels in mouse ear. However, Dupilumab at both dose levels did not change the serum levels of human IL-4 as well as some other Th1 cytokines such as IFN-γ, IL-1β, TNF-α, etc. in mouse ear.
Conclusion. In summary, repeated challenge with Oxazolone in hIL-4/hIL-4Ra double knock-in mice resulted in the development of AD with a Th2-like hypersensitivity, mimicking the key features and pathology of the human disease, which responded to standard of care treatment Dupilumab. This provides a valuable translational model for the evaluation of future biosimilars of Dupilumab.

#5134
PD-1/PD-L1 signalling axis, “a double-edged sword” in DSS induced colitis mouse model
Tao Yang, Rongfei Lu, kaixia lian, Likun Zhang, Dawei Wang, Xinhe Feng, Xiaoyu An, Jessie (Jingjing) Wang, Carl K. Edwards. *Crown Bioscience, Inc., San Diego, CA*

Background. Immune checkpoint molecules are essential for modulating immune responses and maintaining self-tolerance. While immune checkpoint inhibitors have improved the treatment of a broad spectrum of cancers, many of them are also believed to play a critical role in the induction of immune related adverse events (irAEs) such as autoimmune and inflammatory diseases. For example, patients receiving anti-PD-1 based therapy frequently develop colitis. In addition, dysfunctional PD-1

signalling has also been linked to increasing susceptibility to autoimmune and inflammatory diseases. Therefore, immune checkpoint molecule agonist which could, like their natural ligands, confer a great potential in suppressing excessively activated immune response observed in autoimmune and inflammatory diseases.
Methods. In the first part, the proinflammation effects of a Pembrolizumab analogue was evaluated in a MC38-OVA colorectal tumor bearing mice treated with or without DSS. In the second part, an anti-hPD-1 agonistic antibody at 10 mg/kg was evaluated in acute DSS IBD model.
Results. In the MC38-OVA colorectal cancer model, mice treated with Pembrolizumab analogue only or Pembrolizumab analogue plus 1.5% DSS showed significant tumor growth inhibition (100% TGI and 92.01% TGI, respectively at Day 27) compared to their respective control group, which suggests this Pembrolizumab analogue induced robust anti-tumor immunity against MC38-OVA tumors. Notably, 8/8 mice treated with Pembrolizumab analogue only showed complete tumor regression, while only 5/8 mice treated with Pembrolizumab analogue plus DSS showed complete tumor regression. Taken together, these results suggest DSS treatment leading to a proinflammatory context could compromise anti-hPD-1 anti-tumor efficacy. Moreover, mice treated with Pembrolizumab analogue plus DSS also showed 3.59% more Body Weight Loss (BWL) in comparison to 1.5% DSS only group, suggesting that Pembrolizumab analogue could exacerbate DSS induced colitis. In the acute DSS IBD model, mice treated with an agonistic anti-hPD-1 antibody showed significantly lower disease score (DAI 5.3 vs DAI 2.4) and less BWL (BWL 13.44% vs BWL 3.31%) in comparison to isotype control group. In addition, pathology results showed that mice treated with agonistic anti-hPD-1 exhibits significantly less inflammatory cell infiltration and colonic lesions when compared to isotype control group.
Conclusion. In summary, we reported in this study that blocking of PD-L1/PD-1 signalling axis by a PD-1 antagonist activated T cell function which at the same time aggravated DSS induced colitis in mouse. In contrast, activation of PD-L1/PD-1 signalling pathway by a PD-1 agonist alleviated DSS induced colitis.

Standardized off-the-shelf engineered NK cell therapy with improved ADCC properties to treat malignancies

Yanan Lin[1], Shengbang Zhang[1], Jie Ran[1], Can Song[1], Shengcang Zhu[1], Hui Shi[1], Ping Guo[1], Shengjiang Tan[2], Yuchun Gu[1], Lida Wu[1]. *[1]Allife Medical Science and Technology Co., Ltd., Beijing, China,[2]Cambridge Institute for Medical Research, Cambridge Stem Cell Institute, University of Cambridge, Cambridge, United Kingdom*

In the treatment of solid tumors, chimeric antigen receptor(CAR)-engineered NK (CAR-NK) cells have distinct advantages over CAR-T cells, such as a lack graft-versus-host disease in allogenic setting to make “off the shelf” medicine; much safer because they are less likely to cause cytokine storms; and NK cells have their own activated receptors that recognize tumor surface antigens and thus have a natural ability to kill a wide range of tumors. In addition, NK cells are the main performers of antibody-dependent cell-mediated cytotoxicity (ADCC), which binds to the Fc-terminus of antibodies through their surface Fc receptor CD16A, thereby killing antibody-targeted tumor cells. Enhancing the ADCC action of NK cells themselves enhances the therapeutic efficacy of monoclonal antibodies targeting tumor surface antigens and is therefore of great importance in the treatment of tumors, especially solid tumors. We screened two optimal structures among nine different Fc chimeric receptors, and NK cells overexpressing these two receptors killed K562 and Daudi six times more intensely than normal NK cells when combined with rituximab, while the killing ability was comparable to that of normal NK without rituximab, indicating that NK cells expressing chimeric Fc receptors have stronger ADCC effects. Moreover, these NK cells can kill target cells in multiple rounds. In vivo experiments in mice demonstrated that NK cells expressing chimeric Fc receptors in combination with EGFR monoclonal antibodies had a stronger inhibitory effect on tumor growth than monoclonal antibodies or NK cells alone. Here we provide a novel broad “off the shelf” NK cells that can significantly enhance the killing ability of hematological and solid tumors in combination with different monoclonal antibodies.

Surgical stress promotes long-lasting protumorigenic changes in bone marrow derived progenitor cells

Hamza O. Yazdani, Tony Haykal, Ruiqi Yang, Celine Tohme, David A. Geller, Samer Tohme. *University of Pittsburgh, Pittsburgh, PA*

Introducti**on:** Surgery is a crucial intervention for cancer patients. However, the perioperative period is characterized by an increased risk for accelerated growth of metastatic disease. Our recent work shows that the protumorigenic systemic inflammatory changes and the formation of neutrophil extracellular traps (NETs) persist months after surgery in both mice and humans, and parallel micrometastatic tumor growth and recurrence. Here we hypothesized that surgery may induce long-term sustained epigenetic and transcriptomic changes in bone marrow derived granulocytes-monocytes progenitor cells (GMPs) leading to functional reprogramming of mature neutrophils and persistent systemic release of these protumorigenic NET-forming neutrophils.
Methods: Eight-week-old mice were subjected to non-lethal surgical stress (laparotomy) for 30 mins. Seven days after, mice were inoculated with 1x106 MC38 (murine colorectal cancer cells) subcutaneously. For bone marrow (BM) transplant model, a group of B6 congenic (CD45.1) mice were subjected to laparotomy. BM derived cells were harvested 7 days after the procedure and orthotopically transplanted into B6 CD45.2 irradiated (1000 rads) mice. After the establishment of hematopoiesis (6 weeks), MC38 cancer cells were implanted into the recipient mice.
Results: Mice that underwent laparotomy had significantly increased tumor volume at 3 weeks compared to control mice, that only underwent anesthesia (Laparotomy vs control **$p<0.01$). While the intratumoral flowcytometry analysis showed no difference in the frequency of infiltrating immune cells, quantitative (q) PCR analysis revealed significant plasticity in the tumor infiltrating neutrophils (TANs) observed by an increase in the expression of genes (MCP1, Arg1) associated with pro-inflammatory (N2) type neutrophils compared to control. A persistent increased level of NETs was also observed within the tumors and circulation of mice several weeks after laparotomy. ATAC-seq and Bulk-RNA-seq analysis further revealed major epigenetic and transcriptomic changes in TANs, circulating neutrophils and GMPs. To substantiate long-lasting surgical effects, tumor burden was assessed in the BM recipient mice and showed to be significantly increased in mice that had received BM cells from laparotomy mice versus BM cells from sham group.

Conclusion: Surgery promotes long-term rewiring of the bone marrow derived cells resulting in increased tumor growth. Understanding the underlying molecular mechanism may help with therapeutic interventions to prevent protumorigenic surgical effects and improve patient outcomes.

#5138

Systemic agonist anti-CD40 treatment delivers precise melanoma immunotherapy within established autoimmune landscapes

Julio C. Valencia, Michael Sanford, Howard A. Young. *National Cancer Institute at Frederick, Frederick, MD*

The overlapping signatures of type 1 interferons (IFN) and IFN-gamma (IFNg) has proven challenging in human autoimmunity and cancer immunotherapy, particularly for resistance to anti-programmed death 1 (anti-PD1) monotherapy. By contrast, agonist abs targeting of CD40 (anti-CD40) antibodies (abs) has clinically elicit anti-tumor immunity with limited autoimmune complications. Here, we explore the relationships between anti-PD1 or agonist CD40 responses in melanoma tumors from type 1 IFN alpha receptor (IFNAR)-sufficient and type 1 IFNAR-deficient lupus-prone mice that overexpress IFNg. To address this, RNA-sequencing (RNA-seq) data on tumors treated with either anti-PD1 or agonist anti-CD40 was evaluated for tumor objective responses compared to untreated controls. Cellular and canonical pathway identification from RNA-seq data were interrogated from the IPA library for significantly differential expressed genes (DEG). Variance patterns of the anti-PD1 and anti-CD40 monotherapies identified known resistance and response pathways highly concordant with IFN co-expression patterns in the RNA-sequencing data, respectively. IPA biomarker analysis for uniquely regulated genes showed that anti-PD1 induced only 59 DEG; while anti-CD40 induced 494 DEG including Il-27, and PR/SET Domain 1 (PRDM1), a transcription factor regulated by IL-27. Specifically, signatures of MDSC development (irf8, il10); and adaptive resistance (pdcd1, pdcd1lg2, and TNFRSF5/CD40)) were negatively associated with response to anti-P1 monotherapy. By contrast, signatures of IFN activation (stat1, Ifng, and Ifngr1), chemotaxis (Cxcl10, Il12b and Il-27), attractants (Sema3g and Sema4a), and antigen presentation MHC II (h2-Aa, h2-Ab1, and ciita) were associated positively with response to agonist anti-CD40 monotherapy. Importantly, anti-CD40

alone delivered anti-tumor immune responses in type 1 IFN receptor-deficient lupus-prone mice that overexpress IFNg (Ifnar-/-ARE-/-) mice suggesting synergy with therapies blocking type 1 IFN signaling. Thus, these findings indicate that the rational use of CD40 agonists abs provide a better therapeutic platform to deliver precise anti-melanoma responses in complex autoimmune landscapes.

#5139

Chemerin suppresses prostate tumor growth by modulating the recruitment of NK and CD8+ T-cells to tumor microenvironment

Muhammad A. Saeed, Kevin Kim, Russell K. Pachynski. *School of Medicine, Washington University in St. Louis, St. Louis, MO*

Infiltration of immune cells into the tumor microenvironment (TME) can regulate growth and survival of malignant cells, thereby affecting tumorigenesis and tumor progression. While immune checkpoint inhibitors and agonism of costimulatory molecules can act to stimulate leukocytes, the lack of adequate recruitment of effector cells into TME often results in suboptimal immune responses. Chemerin (retinoic acid receptor responder 2, RARRES2) is an endogenous chemoattractant that is widely expressed by many tissues and recruits innate leukocytes through its receptor, CMKLR1 which is expressed on NK cells, some dendritic cells, and macrophages. Previous studies show that RARRES2 is downregulated across multiple tumor types including prostate cancer. Here, using a syngeneic transgenic adenocarcinoma mouse prostate (TRAMP-C1) model, we show that forced overexpression of RARRES2 by tumor cells results in significant tumor suppression and recruitment of NK and CD8+ T-cells within the TME. Male C57/BL/6 mice were inoculated with either RARRES2-overexpressing, vector control (VC) or mixed (50:50; VC: RARRES2) TRAMP-C1 cells. Chemerin overexpression in TRAMP-C1 cells did not alter their phenotypic behavior *in vitro*, but significantly suppressed tumor growth *in vivo* in mice. Furthermore, we observed a significantly higher influx of NK (CD3-CD19-NK1.1+) and CD8+ T-cells (CD3+CD8+) in tumor-infiltrating leukocytes (TILs) from mice with mixed tumors compared with VC tumors. Depletion of NK cells, CD4+, or CD8+ T cells showed that NK cells and CD8+ T-cells, but not CD4+ T-cells, were required for chemerin-dependent suppression of TRAMP-C1 tumor growth.

We found significant increases in splenic NK and CD8 T cells, and a concomitant significant decrease in splenic G-MDSC in mice with chemerin-expressing tumors compared to controls, suggesting chemerin expression within the TME has an effect on systemic immune responses. Treatment of control tumors with anti-PD1 checkpoint inhibition did not result in significant tumor suppression, while anti-PD1 treatment of chemerin-expressing tumors significantly reduced tumor growth, doubling the complete response rate in these unresponsive tumors. Thus, for the first time we have demonstrated that increasing chemerin expression within the prostate TME can suppress growth by augmenting recruitment of NK and CD8+ T-cells and has the potential to be combined with checkpoint inhibitors in order to improve response rates in non-responsive tumors. Overall, these data suggest that a tumor-targeted chemerin therapeutic may have potential to treat human prostate cancers.

Combined administration of poly(I:C) and resiquimod triggers effective antitumoral response in mouse models of pancreatic adenocarcinoma

Aldo Ummarino[1], Clément Anfray[2], Andrea Mariancini[1], Domenico Supino[2], Cecilia Garlanda[2], Fernando Torres Andòn[3], Alberto Mantovani[2], Paola Allavena[2]. *[1]Humanitas University, Milan, Italy,[2]Department of Inflammation and Immunology, IRCCS Humanitas Research Hospital, Milan, Italy,[3]Center for Research in Molecular Medicine and Chronic Diseases, Santiago de Compostela, Spain*

Pancreatic ductal adenocarcinoma (PDAC) represents one of the deadliest malignancies worldwide. The lack of clinical symptoms in the early stages of the disease and the poor immunogenicity of PDAC are two major causes of late diagnosis and inefficient therapies. The tumor microenvironment of PDAC is rich in stromal cells inducing desmoplasia, complicating the arrival of medical compounds, as well as in immune cells, that are suppressed by several mediators produced by cancer cells. In this setting, it has been shown that some medications can restore the antitumoral activity of innate immune cells that, in turn, re-activate also adaptive immune cells. In this study, we present the combination of the TLR agonists poly(I:C) (pIC - TLR3) and resiquimod (R848 - TLR7/8) as an immunotherapeutic

tool in PDAC. In a subcutaneous model of PDAC (K8484 cells, isolated from KPC mice that spontaneously develop PDAC and recapitulate the features of human pancreatic cancer), the intratumoral administration of pIC+R848 for 5 times every 2-3 days led to the complete regression of the tumor in 100% of the treated mice. Moreover, all mice were protected from a second and a third rechallenge with the same cell line, performed months after the first treatments. Mechanistic studies performed on the tumors with flow cytometry demonstrated an increase of MHC-II positive cells in the monocytic (Ly6C+) compartment, as well as an increase in the number of mature CD8+ T cells and NK cells. Similar findings were demonstrated also in another heterotopic model obtained injecting Panc02 cells, another cell line with a sarcomatous phenotype. Consistently with the flow cytometry data, the depletion of CD4+ and CD8+ T cells abolished the antitumoral efficacy of pIC+R848, while the depletion of NK cells and CSF-1R+ cells was not sufficient to abolish the antitumoral response, suggesting a strong involvement of the adaptive immunity. In line with these findings, the intratumoral administration of pIC+R848 in mice unable to produce IFN-γ failed to reduce the tumor growth. In conclusion, our work clearly demonstrates that pIC+R848 are an effective treatment for PDAC when injected intratumorally and that this activity strongly relies on IFN-γ and adaptive immunity. Further investigations are ongoing to assess their potential in orthotopic models using different routes of administration, in a setting closer to the real clinical situation.

Macrophage transcriptomic signature validation in scRNA seq and overall survival differences in urothelial carcinoma

Laura Bukavina[1], Spencer Bell[1], Daniel Geynisman[1], Ilaha Isali[2], Daniel Ranti[3], John Sfakianos[3], Henkel Valentine[1], Adam Calaway[2], Alexander Kutikov[1], Andres Correa[1], Robert Uzzo[1], Lee Ponsky[4], Philip Abbosh[1].
[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Case Western Reserve School of Medicine, Cleveland, OH,[3]Mount Sinai, New York, NY,[4]University Hospitals Cleveland Medical Center, Cleveland, OH

Introduction: While the prognostic value of immune system biomarkers has been well explored, role of cancer associated macrophages in bladder

cancer(BC) is unclear due to lack of consistent results, coupled with tissue *nonspecific* transcriptomic signature.
Methodology: Data acquisition from 3,936 patients of The Cancer Genome Atlas (TCGA) in addition to Gene Expression Omninus (GEO) data sets GSE13507, GSE16945, GSE48277, GSE32894, GSE149582, as well as European Genotype Phenotype EGAS000001004507 was obtained. Tumor associated macrophages M1 and M2 were defined utilizing 188 and 159 gene expression profiles via xCell computational algorithm. To obtain bladder tissue residence macrophage signatures, scRNA seq was performed on tissue collected from surgical resection of 5 HG bladder cancer patients and 2 healthy controls. CellRanger software package with default parameters was utilized giving a total of 8,068 cells. FindAllMarkers was utilized for integration of DEG genes (cancer vs control) among the cluster and identification of BC macrophage specific markers. Endpoint of OS were measured in months from the time of cystectomy to follow up.
Results: Surprisingly, presence of M1 infiltration was found to be associated with improved OS in two out of eight cohorts only (GSE32894, GSE70691, $p<0.001$), while the remainder detected no significant difference. Similarly, no association with OS was detected among all 8 cohorts with M2 infiltration. To improve our understanding of tissue specific markers of macrophage population in bladder, we then analyzed macrophage clusters detected within scRNAseq of BC patients compared to healthy. Gene ontology enrichment analysis of functions within tumor specific macrophages demonstrated an exaggerated expression of *mTORC1* signaling, *PI3K/AKT/mTOR* signaling, *TGF beta* and *EGF* receptor pathways compared to non-cancer controls. Reanalysis of 22 tissue specific markers for M1/M2 infiltration showed no difference in any of the 8 cohorts with M1 high vs low infiltration. Similarly, addition of M2 infiltration as predictive marker yielded no further associations with OS in all but one cohort (GSE32894, $p=0.00041$), where high M2 tumor presence was associated with improved OS.
Conclusion: Our study represents the largest TAMs evaluation of BC across 8 cohorts with additional scRNA seq exploration of tissue specific signatures, demonstrating no association with OS in bladder cancer.

50-parameter flow cytometry by CyTOF empowers comprehensive single-cell immune profiling of pulmonary immunosenescence in aged mice

Wenxi Xu, Stephen Li, Alexandre Bouzekri, Lauren Tracey, Christina Loh.
Standard BioTools, Markham, ON, Canada

High-parameter flow cytometry is essential for human and mouse studies to discover novel immunological mechanisms of cancer, infections, and immunosenescence. It plays an increasingly important role in cancer research to ensure clinical therapeutic success but is limited by the large amount of cell samples needed for staining controls. CyTOF® technology has transformed flow cytometry by enabling 50-plus-marker analysis per tube of sample, with easy panel design and no need for single-stained or autofluorescence controls. Flow cytometry by CyTOF provides an efficient and unbiased approach to discovering novel subsets and unique functional states of immune cells, maximizing insights from precious samples.
Immunosenescence perturbs lung cancer onset and development, yet the mechanisms remain largely unknown. To study the pulmonary immune populations in aged (75 weeks old) and young adult (6-8 weeks old) mice, we built a 50-parameter panel (2 for single live-cell identification, 6 for live-cell sample barcoding, and 42 for immune profiling). A core panel of 32 antibodies was selected from Standard BioTools™ catalogs to detect key cell lineage and functional surface markers. A complementary panel with 10 Maxpar® antibodies was added to further study functional cell states. Maxpar Pathsetter™ software was used to create an automated analytical model for high-dimensional analysis.
The 50-parameter panel successfully identified over 30 lymphoid and myeloid cell subsets including but not limited to T cells, B cells, NK cells, alveolar macrophages (AMs), dendritic cells, and neutrophils. The panel enabled high-fidelity detection of over 15 functional markers mediating proliferation, activation, inhibition, migration, tissue residence, and cellular metabolism. Automated in-depth analysis by Maxpar Pathsetter efficiently identified many aging-associated alterations in cell frequencies and functional states such as the enrichment of PD-1+ T cells and CD27- γδ T cells that could potentially perturb anti-tumor immunity. Moreover, CyTOF technology is uniquely advanced in characterizing autofluorescent cells

such as AMs. A pro-inflammatory state (higher expression of MHC-II, CD80, and PD-L1) was specifically defined for AMs in aged lungs.
This study demonstrates comprehensive single-cell immune profiling of mouse tissues with the products and solutions provided by Standard BioTools. Both the 50-parameter panel and Maxpar Pathsetter analytical model can be customized for deep characterization of specific immune populations according to the requirements of various cancer studies in mice. By utilizing end-to-end solutions offered by Standard BioTools, flow cytometry by CyTOF can significantly facilitate the mechanistic studies of mouse models to expand the understanding of human cancers and accelerate therapeutic development.

#5144

Spatial T-cell atlas in more than 100 different tumor entities using BLEACH&STAIN

Zhihao Huang, Elena Bady, Jan H. Müller, Tim Mandelkow, Magalie C. J. Lurati, Ronald Simon, Christian Bernreuther, Frank Jacobsen, Guido Sauter, Katharina Möller, Andreas Luebke, Andrea Hinsch, Till S. Clauditz, Eike Burandt, Niclas C. Blessin. *University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: The composition and functional state of T-cell subpopulations can highly impact patient's outcome and response to immune checkpoint therapy. However, only little is known about the spatial interplay of most rare T-cell subpopulations.
Design: To assess the density, composition, degree of immune checkpoint expression, and spatial interplay of T-cell subpopulations in 5989 tumor samples from more than 100 tumor entities, two different types of tissue microarrays (0.6 mm and 4 mm in diameter) were stained with antibodies directed against CD3, CD4, CD8, FOXP3, T-bet, GATA3, RORyT, BCL6, FOXP3, CD56, CD45RA, CD45RO, TIM3, PD-1, CTLA-4 Granzym B, and Ki67 using our BLEACH&STAIN multiplex fluorescence immunohistochemistry approach. A deep learning-based framework comprising two different convolutional neuronal networks (U-Net and DeepLabv3+) was used for image analysis.
Results: For identification and definition of immune cell subpopulations unsupervised X-shift clustering and 2D/ 3D t-distributed stochastic

neighbor embedding (t-SNE) using the "Rtsne" package (Rtsne (RRID:SCR_016342)) were applied and revealed 102 T-cell subpopulations at certain functional state. Within these subpopulations, the well-characterized expression profiles were visually matched with single T-cell expression profiles and documented as digital images. This process resulted in 12 main T-cell subsets that were further subclassified according to their functional state (proliferation, immune checkpoint expression) and studied according to their spatial orchestration. Interestingly, the vast majority of T-cell subsets were found in all analyzed tumor entities. However, their spatial orchestration, immune checkpoint expression profile was highly variable between different tumor entities.
Conclusion: This study provides a comprehensive overview of rare T-cells subpopulations and its spatial orchestration in more than 100 different tumor entities.

#5145

Targeting TREX1 induces innate immune response in chemoresistant small cell lung cancer

Takahiko Murayama[1], Navin R. Mahadevan[2], Tetsuo Tani[2], Xueying Ma[1], Hideo Watanabe[3], David A. Barbie[2], Israel Cañadas[1]. *[1]Blood Cell Development and Function Program, Fox Chase Cancer Center, Philadelphia, PA,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Department of Medicine, Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, New York, NY*

Small cell lung cancer (SCLC) is the most lethal type of lung cancer. The uniqueness of this tumor consists of an initial exquisite response to chemotherapy. However, at relapse, which occurs nearly in all patients, the tumor is resistant to all available therapies, causing a premature death of the patient. Despite the addition of immune checkpoint blockade (ICB) therapy to standard chemotherapy, response rates are modest and only a very small fraction of SCLC patients responds to these therapies. The mechanistic basis for acquired chemoresistance and impaired immunogenicity in SCLC remains to be elucidated. Here, we report that the expression of three prime repair exonuclease 1 (TREX1) is strongly induced in chemoresistant SCLCs. ATAC-seq and ChIP-seq analyses revealed a significant increase in

chromatin accessibility of TREX1 gene locus in drug resistant SCLC cells. Depletion of TREX1 in SCLC cells caused the activation of cyclic GMP-AMP synthase (cGAS)-stimulator of interferon genes (STING) pathway due to the cytoplasmic accumulation of DNA damage-associated double-stranded DNA (dsDNA) and micronuclei. Furthermore, targeting TREX1 induced an innate immune response and re-sensitized chemoresistant SCLC cells to chemotherapy. These findings suggest that TREX1 upregulation may be an important mediator of cGAS/STING pathway inactivation in cancer, contributing to the survival of resistant cells, and its inhibition may represent a promising therapeutic strategy to potentiate the efficacy of chemotherapy and immunotherapy in chemoresistant and immunologically 'cold' tumors, such as SCLC.

***In vitro* neutrophil assays to support immuno-oncology drug development**

Alanah Pieters, Martijn Vlaming, Jezabel Lefevere, Sofie Pattyn.
ImmunXperts, a Q2 Solutions Company, Gosselies, Belgium

Neutrophils have shown a lot of plasticity with important consequences on cancer disease progression and have been associated with multiple functions such as killing antibody-opsonized cancer cells, directly kill tumor cells through the release of reactive oxygen and nitrogen species and a controversial role in the tumor micro-environment with both pro- and anti-tumor roles. Studying neutrophil function in vitro can be done using the Incucyte® live imaging system to monitor antibody-dependent cell-mediated cytotoxicity (ADCC). Optimised in vitro assays using fresh human neutrophils and fluorescent-labeled tumor cells can be used to screen the potency of candidate therapeutics. Additionally, neutrophil chemotaxis can be monitored using transwell plates and live imaging via Incucyte®. Finally, multiplex cytokine and chemokine analysis after activation and stimulation of neutrophils can be evaluated using Luminex technology. When studying neutrophil activity in vitro, important factors such as access to fresh blood and optimized protocols for purifying untouched neutrophils are key for reproducible and reliable results.

#5147

Mice with T cells deficient in the Cytosolic Branched Chain Aminotransferase reduce the tumor burden of low and high immunogenic strains of Lymphoma

Lucas D. Figueroa, Tanner Wetzel, Leighton Wheeler, Christie Adam, Michael Boyer, Elitsa Ananieva. *Des Moines University, Des Moines, IA*

Current immunotherapies rely on modulating host immunity to induce an anti-tumor immune response. The efficacy of such a response depends on the immunogenicity of the tumor, which varies greatly between different cancers or the same cancer in different individuals. While most lymphomas are immunogenic, non-malignant T cells that infiltrate the lymphoma microenvironment are subjected to immunosuppressive signals and areas of nutrient depletion, which leads to T cell exhaustion and inhibition of T cell function. Metabolic enzymes, such as the cytosolic branched chain aminotransferase, BCATc, exert immunosuppressive effects limiting T cells ability to function. Previous research described BCATc as a negative regulator of T cell activation, thus identifying BCATc as a potential target for immunotherapeutic modulation in the tumor microenvironment (TME). In the current study we exploit a low (EL4) and high (EL4-OVA) immunogenic murine lymphoma strains to explore how a loss of BCATc in T cells impacts their ability to produce anti-lymphoma immunity in mice. We used 12 week old male mice with BCATc deleted from T cells (T-BCATc^{KO}) and control T-BCATc$^{fl/fl}$ mice that express the transgenic floxed version of BCATc. Mice were injected with 2.5x10^5 cells belonging to the low (EL4) or high (EL4-OVA) immunogenic strains and tumor growth, body weight, and food intake were monitored for up to 15 days followed by collection of tumor tissues and organs. Tumors were then lysed, and the protein profile of each tumor was determined by monitoring changes in expression of protein markers of T cell exhaustion (TOX, CD39), apoptosis (BAX, PUMA), or signaling proteins, such as the ribosomal S6 protein, the protein kinase B (AKT), and the energy sensor the AMP-activated protein kinase (AMPK).

T-BCATc^{KO} mice showed significant reduction in tumor growth compared to control mice regardless of the lymphoma strain being tested. The mouse cohort with the biggest number of tumor free mice was the T-BCATc^{KO} cohort injected with EL4 cells (13% of the mice were tumor free on day 9). However, EL4-OVA cells grew into smaller tumors across all cohorts. Mice

had comparable food intake but T-BCATc^{KO} mice, injected with EL4 cells, had a significantly lower body weight. In T-BCATc^{KO} mice, the reduced EL4 tumor mass correlated with upregulated AMPK and AKT along with higher expression of PUMA. The reduced EL4-OVA tumor masses correlated with downregulated S6 and decreased TOX expression, but high expression of BAX compared to the corresponding tumors isolated from T-BCATc$^{fl/fl}$ mice. These findings suggest that T cells deficient in BCATc can reduce lymphoma growth regardless of the immunogenicity of the lymphoma stain likely by establishing catabolic state and inducing apoptosis. Thus, BCATc may play an immunosuppressive role in the lymphoma TME and the absence of BCATc from T cells may help T cells combat lymphoma.

Interrogating immuno-oncological interactions in the tumor microenvironment

Ben Patterson, Cheng-Yi Chen, Nicolas Fernandez, Leiam Colbert, Jiang He*. Vizgen, Cambridge, MA*

Single-cell RNA sequencing is a powerful and innovative tool for assessing individual cancer prognoses and outcomes; however, the process of generating this data typically destroys the spatial complexity of the tumor microenvironment. Understanding the spatial complexities within cancer provides crucial information for evaluating individual tumor development and progression. Vizgen's MERSCOPE^{TM} Platform, built on Multiplexed Error-Robust Fluorescence in situ Hybridization (MERFISH) technology, enables the direct profiling of the spatial organization of intact tissue with subcellular resolution. Here, we present a Pan-Cancer approach to demonstrate the MERSCOPE's ability to characterize breast, colon, prostate, ovarian, lung, and skin cancers from human clinical samples. Specifically, using a 500-gene panel to assess the canonical signaling pathways of cancer, cancer type-specific genes, select immune genes, proto-oncogenes, and tumor-suppressor genes, we show that the MERSCOPE was able to spatially profile gene expression across multiple tumor types. We utilized the Vizgen Cell Boundary Stain kit to generate a molecular and cellular atlas of individual patient tumors by clustering cells based on gene expression and mapping their spatial organization. To gather insight into

immuno-oncological interactions and their effect on gene expression across these tumor types, we performed a neighborhood analysis to determine how proximity to immune cells altered gene expression in tumor cells, and vice versa. We found significant gene expression changes in MHC activation and downstream pathways in immune cells located nearest to tumor cells; in tumor cells nearest to immune cells, we identified increased expression of genes related to immune response mediation and inflammation. Furthermore, we compared the annotated immune cell populations across the various cancer types to observe differences in gene expression. Here, we used publicly available single-cell RNA-sequencing data to impute gene expression for these immune cell populations. This analysis demonstrated the transcriptional variation possible in identical immune cell types that are acting in different tissue contexts. Notably, we were able to map and catalogue different patterns of gene expression relating to inflammation, immune signaling, and immune cell exhaustion. These findings demonstrate how the MERSCOPE platform can provide deep insights into the complex heterogeneity observed between different tumor types and tissues.

Age-associated remodeling of anti-tumor T cell immunity and metabolism

SeongJun Han[1], Peter Georgiev[1], Alison Ringel[2], Arlene Sharpe[1], Marcia Haigis[1]. *[1]Harvard University, Boston, MA,[2]MIT, Boston, MA*

Aging results in remodeling of T cell immunity and is associated with poor clinical outcome in age-related diseases such as cancer. Amongst the hallmarks of aging, changes in host and cellular metabolism are critically involved in the development, maintenance, and functional responses of T cells. Although metabolic perturbations impact anti-tumor T cell responses, the link between age-associated metabolic dysfunction and anti-tumor immunity remains unclear. First, we utilized B16, MC38 and E0771 tumor-bearing young (2-4 months) and aged (18-24 months) C57BL/6 mice to examine the effects of aging on tumor growth. Aged mice exhibited accelerated tumor growth in B16, MC38 and E0771 tumor models. Flow cytometric analyses of tumor infiltrating lymphocytes (TILs) revealed distinct changes in $CD8^+$ T cell population, decreased activation status and tumor-specificity in aged mice. Consistent with these findings, $CD8^+$ T

cells functionally played a limited role in controlling tumor growth in aged mice. Here, we will explore the mechanisms of age-associated metabolic dysfunction in T cells and its implications in anti-tumor immunity. As the average life expectancy continues to increase, understanding the interplay between age-related metabolic reprogramming and maladaptive T cell immunity will be instrumental in the development of novel therapeutic strategies for older patients.

Improvement of hematopoiesis in primary low risk MDS with the TGFBR1 investigational inhibitor TP-6379

Erika A. Eksioglu[1], Gabriela M. Wright[1], Jason M. Foulks[2], Matthew Lalonde[2], Steven L. Warner[2], Kenneth L. Wright[1]. *[1]Immunology, Moffitt Cancer Center, Tampa, FL,[2]Sumitomo Pharma Oncology, Inc., Lehi, UT*

Background: The inflammaging modulator, S100A9, mediates immunosuppression and plays a key role in the pathogenesis of low-risk myelodysplastic syndrome (MDS). Specifically, S100A9's feedforward activation in the bone marrow (BM) induces pyroptotic cell death of hematopoietic stem and progenitor cells (HSPC) and the activation and accumulation of myeloid-derived suppressor cells (MDSC). This process creates a suppressive microenvironment including the secretion of transforming growth factor β (TGFβ) that signals through the TGFβ receptor 1 (TGFBR1) to induce inhibitory processes that contribute to this phenotype. We hypothesize that targeting with an investigational TGFBR1 inhibitor, TP-6379, reduces immune suppression and restores hematopoiesis in MDS.

Methods: Primary low risk MDS BM mononuclear cells (BMMNC) were obtained from the Moffitt Total Cancer Care Protocol and cultured in vitro with TP-6379. Healthy BMMNC were purchased, treated with or without recombinant S100A9 and TP-6379.

Results: Treatment of primary MDS BMMNC (n=15) and S100A9-treated healthy BMMNC (n=5) with TP-6379 for 48 hours was observed to significantly improve proliferation of hematopoietic progenitor cells as measured by colony forming capacity. Total colonies, and BFU-E specific colonies, showed significant increase. This expansion of progenitors with treatment was validated by flow cytometric analysis of Lineage$^-$HLA-DR$^-$

$CD34^+$ HSPC and showed a reduction in genomic instability, measured by γH2AX. In addition, TP-6379 was observed to reduce the numbers of suppressive mediators; MDSC, T regs and senescent lymphocytes and increase the number of cytotoxic cells, including NK cells. Our analysis revealed that BMMNC with spliceosomal mutations, including SF3B1, have elevated sensitivity to TP-6379 treatment. Therefore, we tested wild type and SF3B1 K700E CRISPR knock-in K562 cells in the presence of TP-6379 for 48 hours. K562 is a well-established cell line model for study of MDS. The SF3B1 mutant expressing cells have significantly reduced BFU-E colony forming capacity, compared to wild type cells, concordant with higher pyroptosis activation and consistent with the BMMNC results. Hence, we measured phospho-SMAD activity, as a direct measure of TGFBR1 inhibition. SF3B1 mutant expressing cells were shown to be highly sensitive to TP-6379, with a significant loss of SMAD activation. Expression analysis of primary MDS, S100A9-treated healthy BMMNC cells and K562 SF3B1 mutant cells revealed elevated expression of SERPINE1 which was rescued by TP-6379 treatment.
Conclusions: TP-6379 restores healthy hematopoiesis in low-risk MDS, which may translate into a strong therapeutic option in a disease with few clinical options. Importantly, our work also suggests a specific role for spliceosome dysfunction in bone marrow failure and a novel role for SERPINE1 in MDS and S100A9-induced suppression.

Enzalutamide resistance results in immunosuppressive alterations in prostate tumor immune microenvironment

Pengfei Xu, Joy C. Yang, Bo Chen, Christopher Nip, Jonathan E. Van Dyke, Christopher P. Evans, William J. Murphy, Chengfei Liu. *UC Davis, Sacramento, CA*

Background: Emerging data suggested that enzalutamide-treated prostate cancer patients with increased programmed death-ligand 1 (PD-L1) expression may benefit from anti-PD-L1 treatment. Unfortunately, the Phase III IMbassador250 trial revealed that the combination of atezolizumab (PD-L1 inhibitor) and enzalutamide failed to extend overall survival in patients with castration-resistant prostate cancer (CRPC). The mechanisms underlying treatment failure remain unknown. In this study, we

investigated the regulation of immunosuppressive signaling in enzalutamide resistant prostate cancer and characterized the immune infiltrating cells in murine prostate tumors.
Methods: The expression of interferon gamma-related genes was determined using qRT-PCR and/or western blotting. Androgen receptor (AR) and AR-V7 levels were downregulated using specific siRNA. Myc-CaP cells were chronically exposed to increasing concentrations of enzalutamide (5-50 μM) for >12 months, and the cells resistant to enzalutamide were referred to as Myc-CaP MDVR. The gene-regulating mechanisms in drug-resistant prostate cancer cells were determined by RNA sequencing analyses. Myc-CaP and Myc-CaP MDVR xenograft tumors were established in FVB mice, and tumor-infiltrating lymphocytes were isolated using Ficoll. The stained immune cells were determined by flow cytometry, and the data were analyzed using Flowjo.
Results: Immune-related signaling pathways (interferon alpha/gamma response, T cell activation, and cell chemotaxis pathways) were suppressed in C4-2B MDVR cells. However, PD-L1 expression was highly upregulated and negatively regulated by AR in C4-2B MDVR cells. Enzalutamide treatment decreased $CD8^+$ T cell but increased monocytic myeloid-derived suppressor cell (M-MDSC) population and PD-L1 expression in murine Myc-CaP tumors. Consistently, chemotaxis and immune response-regulating signaling pathways were suppressed, and PD-L1 expression was increased in enzalutamide-resistant Myc-CaP MDVR cells. Notably, MDSC populations were significantly increased in Myc-CaP MDVR orthotopic tumors compared with those in Myc-CaP parental tumors. Co-culturing bone marrow cells with Myc-CaP MDVR cells significantly promoted MDSC differentiation and polarized macrophages from the M1 to M2 phase.
Conclusions: Immunosuppressive signaling is activated in enzalutamide resistant prostate cancer cells. The activated immune-related signatures involved in T cells, MDSC, and macrophages may reduce the efficacy of immune checkpoint inhibitors in enzalutamide-resistant prostate cancer.
Grant Support: This work was supported in part by grants NIH/NCI R37CA249108 (C, Liu) and R01CA251253 (C, Liu).

Photodynamic therapy promotes immune infiltration and control of malignant pleural mesothelioma through NF-kB mediated upregulation of E-Selectin in the tumor vasculature

Louis-Emmanuel Chriqui[1], Yameng Hao[2], Damien Marie[1], Michel Gonzalez[1], Thorsten Krueger[1], Etienne Meylan[3], Johanna Joyce[4], Sabrina Cavin[1], Jean-Yannis Perentes[1]. *[1]Lausanne University Hospital, Lausanne, Switzerland,[2]Ecole Polytechnique Fédérale de Lausanne, EPFL, Lausanne, Switzerland,[3]Free University of Brussels, Brussels, Belgium,[4]University of Lausanne, Lausanne, Switzerland*

Introducti**on**: Malignant pleural mesothelioma (MPM) is an aggressive cancer with limited treatment options. The application of photodynamic therapy (PDT) was shown to significantly improve patient survival. Previously, we found that low dose PDT (L-PDT) enhanced the immune infiltration of MPM and increased the impact of immune checkpoint inhibitors on tumor control. However, the mechanisms behind these observations are unknown. Here, in an orthotopic murine model of MPM, we show that L-PDT upregulates tumor vascular E-Selectin expression via NF-kB. This upregulation favors enhanced leukocyte trafficking and immune mediated MPM regression.

Methods: We analyzed adhesion molecules (E-Selectin, ICAM-1, VCAM-1) and canonical NF-kB activation (phosphorylated IκBα) protein levels in endothelial (ECRF-24) cells treated by L-PDT in the presence or absence of a NEMO/IKKγ siRNA in vitro. For in vivo validation, AB12-Luc MPM cells were grown in the pleural cavity of syngeneic BALB/c mice and treated with L-PDT (verteporfin 400 μg/kg, fluence 10 J/cm^2, fluence rate 50 mW/cm^2) alone or in presence of NF-kB or E-Selectin inhibitors (NEMO Binding Domain (NBD) peptide and E-Selectin blocking antibody respectively). For each treatment group, we determined the expression of endothelial adhesion molecules (E-Selectin, ICAM-1, VCAM-1) and the tumor immune infiltrate by immunohistochemistry and flow cytometry. In parallel, the impact of L-PDT on MPM growth and mouse survival were assessed in the presence of E-Selectin inhibition.

Results: L-PDT increased the levels of endothelial adhesion molecules E-Selectin, ICAM-1 and VCAM-1 9 to 24 hours after L-PDT treatment in vitro. This was preceded by an increase of IκBα phosphorylation. In the

presence of NEMO siRNAs, the expression of NEMO/ IKKγ was reduced and led to E-Selectin repression. In orthotopic MPM bearing mice, the treatment of MPM by L-PDT enhanced adhesion molecules expression in tumor vasculature at 24 hours. This correlated with increased infiltration of $CD4^+$ and $CD8^+$ granzyme B^+ T-cells and improved tumor control and mouse survival. NF-kB inhibition impaired tumor vascular adhesion molecules upregulation and the recruitment of tumor infiltrating lymphocytes in MPM. The targeted inhibition of E-Selectin abrogated the immune infiltration and tumor regression of MPM following L-PDT, which ultimately decreased animal survival in our MPM model.
Conclusion: Low dose PDT relieves MPM tumor vascular anergy via NF-kB mediated adhesion molecules expression. Endothelial E-Selectin has been identified, in our MPM model, as a major determinant for L-PDT enhanced lymphocyte trafficking, tumor control and animal survival.

#5153
The role of CCL22-specific CD4 T cells in modulating the immunosuppressive tumor microenvironment in ovarian cancer
Ines Lecoq, Evelina Martinenaite, Marie C. W. Westergaard, Inge Marie Svane, Mads H. Andersen. *National Center for Cancer Immune Therapy (CCIT-DK), Copenhagen, Denmark*

Background: CCL22, a macrophage-derived chemokine, is overexpressed in ovarian cancer and exerts immunosuppressive functions by the recruitment of regulatory T cells (Tregs) to the tumor microenvironment (TME). Our research group described naturally occurring T cells specific for an MHC class I epitope derived from CCL22. CD8+ CCL22-specific T cells isolated from cancer patients could recognize CCL22-expressing cells and decrease the levels of CCL22 in ovarian ascites *in vitro*. Expansion of CCL22-specific CD8+ T cells in animal models of cancer by peptide vaccination led to a therapeutic anti-tumor effect by reducing Treg recruitment into the TME. In this study we aimed at characterizing CD4+ CCL22-specific T cells and their potential for modulating the tumor microenvironment in ovarian cancer.
Methods: CCL22-responses were screened with a library of overlapping 20mer peptides covering the entire sequence of CCL22 in PBMCs from healthy donors and ovarian cancer patients. CCL22-specific T cells were

isolated from PBMCs and ovarian ascites for functional characterization through IFNγ ELISpot and ICS against peptides and CCL22-expressing target cells. Cytokine secretion was measured with protein multiplex immunoassays. Vaccination and therapeutic efficacy were evaluated in BALB/c CT26 and 4T1 syngeneic models.
Results: We identified an immunogenic region in the CCL22 protein sequence and detected CD4 T-cell responses against CCL22-derived peptides in healthy donors and ovarian cancer patients through IFNγ ELISpot. CCL22-specific CD4+ cells have also been identified *ex vivo* in the ascites fluid from patients with ovarian cancer. We isolated and expanded CCL22-specific CD4+ T-cell clones from the ovarian ascites and demonstrated their reactivity against CCL22-producing cell lines. Furthermore, the stimulation of CCL22-specific CD4+ T cells in the PBMC culture and ascites samples was associated with a modulation of the cytokine environments. Additionally, vaccination with surrogate murine 20mer and MHC-II restricted CCL22-derived peptides lead to successful induction of specific T-cell responses in the spleens and draining lymph nodes of vaccinated animals. Activation of such CCL22-specific CD4 T cell responses was associated with a therapeutic effect seen as reduction of the tumor growth in different models of cancer.
Conclusion: This study provides evidence for the ability of pro-inflammatory CD4+ CCL22-specific T cells to modulate the tumor microenvironment, particularly in ovarian cancer. Altogether we provide the rationale for the development of a CCL22-based immune modulatory vaccination for ovarian cancer.

The cytosolic branched chain aminotransferase is an important metabolic checkpoint of T cell function in the lymphoma microenvironment
Tanner J. Wetzel, Lucas Figueroa, Leighton Wheeler, Alexander Martin, Christie Adam, Michael Boyer, Elitsa Ananieva. *Des Moines University, Des Moines, IA*

Rapidly growing lymphoma cells deplete the tumor microenvironment (TME) of nutrients needed to maintain anti-tumor T cell immunity. This metabolic disadvantage leads to diminished T cell function and reduced

clearance of tumor cells. The branched chain amino acids (BCAAs) are required for growth of tumor and immune cells. In the TME, BCAAs are preferentially taken up by tumor cells for protein synthesis or energy production. The first step in BCAA degradation is reversible transamination catalyzed by the cytosolic branched chain aminotransferase, BCATc. Recent investigations suggest that BCATc is immunosuppressive in the TME. We found BCATc is induced upon T cell activation, during which time, BCATc negatively regulates T cell metabolism. We hypothesized that a loss of BCATc from T cells restores effector T cell function in the TME. Tumor studies were conducted using mice with BCATc deleted from $CD4^+$ and $CD8^+$ T cells (T-$BCATc^{KO}$ mice) and corresponding controls expressing the floxed transgene of BCATc in T cells (T-$BCATc^{fl/fl}$ mice). Mice were subcutaneously injected with $2.5x10^5$ murine EL-4 lymphoma cells [tumor-injected mice, n=8-9/group] or phosphate-buffered saline [vehicle-injected mice, n=4-6/group]. Tumor growth, body weight, and food intake were monitored for 15 days followed by collection of tumors and organs. Splenocytes were used to isolate $CD4^+$ and $CD8^+$ T cells that were activated with anti-CD3 and anti-CD28, and, after initial expansion with cytokine IL-2, reactivated to hypotolerant or fully activated $CD4^+$ Th1 cells, or expanded to effector $CD8^+$T cells for 96h, in the presence or the absence of the leucine antagonist, N-acetyl-leucine amide (NALA). Supernates were tested for secretion of IFNγ ($CD4^+$T cells) or perforin and granzyme B ($CD8^+$T cells). T-$BCATc^{KO}$ mice demonstrated significant delay in lymphoma appearance and a 50% reduction in tumor volumes when compared to control mice. The removal of BCATc from T cells did not cause systemic overactivation of the immune system, with no changes in size or appearance of the spleen, liver, or intestines. Hypotolerant and fully activated T-$BCATc^{KO}$ $CD4^+$ T cells released significantly more IFNγ when compared to T-$BCATc^{fl/fl}$ T cells. The addition of NALA reduced the IFNγ levels to those found in control cells. $CD8^+$ T cells from T-$BCATc^{KO}$ mice released significantly more granzyme B and perforin compared to T-$BCATc^{fl/fl}$ T cells. These findings demonstrate that BCATc-deficient T cells provide better systemic response to lymphoma likely due to improved Th1 and effector $CD8^+$ T cell with diminished Treg function. Thus, BCATc may act as an important metabolic checkpoint of the lymphoma TME

Targeting tumor infiltrating myeloid cells in prostate cancer

Marco A. De Velasco[1], Yurie Kura[1], Naomi Ando[1], Noriko Sako[1], Kazutoshi Fujita[1], Kazuko Sakai[1], Alwin G. Schuller[2], Kris F. Sachsenmeier[2], Masahiro Nozawa[1], Eri Banno[1], Kazuhiro Yoshimura[1], Kazuto Nishio[1], Hirotsugu Uemura[1]. *[1]Kindai University School of Medicine, Osaka-Sayama, Japan,[2]AstraZeneca, Waltham, MA*

The tumor microenvironment (TME) is a dynamic milieu comprised of various cell types and molecular complexes that eventually evolves to promote cancer cell proliferation, metastasis, and immune evasion. Myeloid cells are a key component of the TME and play key roles in initiating antitumor responses and coordinating with cells of the adaptive immune system. However, these cells are eventually hijacked by tumors and provoke local inflammation that results in chronic cancer-associated inflammation and immune escape. Extracellular adenosine (ecADO) is an immunosuppressive metabolite that is produced in tumors that binds the adenosine 2a receptor (A2aR) which is widely expressed in immune cells. Studies have shown that blocking A2aR signaling has the potential to enhance antitumor immunity by boosting T and NK cell immune responses. However, the relationship between ecADO and tumor-associated myeloid cells is less characterized. We previously reported on the antitumor activity of A2aR and CD73 blockade in preclinical models of *Pten*-null prostate cancer and their impact on T cell mediated responses. Here, we examine tumor-associated myeloid cell infiltration in models of castration-naïve (CNPC) and castration-resistant prostate cancer (CRPC) the impact of A2aR and CD73 blockade. Transcriptomic, flow cytometric, and immunohistochemical (IHC) profiling studies of CNPC and CRPC from conditional *Pten*-knockout (KO) and *Pten/Trp53*-double knockout (DKO) showed that tumor-infiltrating myeloid cells constituted a significant proportion of the prostate tumor microenvironment. CD11b+/Ly6G+ cells representing tumor associated neutrophils (TANs) and myeloid derived suppressor cells (MDSCs) were the most abundant immune cell type comprising 14.9% and 32.1% of the total population, and 46.5% and 69.7% of infiltrating leukocytes in in CNPC and CRPC, respectively. Furthermore, CD11b+/Ly6G+ expressed high levels of CD73. Pte-null prostate tumors were characterized with enriched adenosine signaling signatures which

were greater in CRPC compared to CNPC. Treatments with the A2aR inhibitor AZD4635 alone and in combination with CD73 antibody blockade reduced adenosinergic genes as well as genes associated with TAN/MDSC immunosuppressive functions. Additionally, tumors from treated mice exhibited improved T cell mediated cytotoxicity. Together, our findings indicate that tumor associated myeloid cells are an additional source of ecADO contributing to immune suppression which can be targeted with A2aR and CD73 inhibitors.

The mutagenic effects of APOBEC3A and APOBEC3B in urothelial carcinoma

Michael S. Sturdivant[1], Andrew S. Truong[1], Mi Zhou[2], Jeffrey S. Damrauer[2], William Y. Kim[3]. *[1]Pharmacology, UNC Chapel Hill, Chapel Hill, NC,[2]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[3]Genetics, Pharmacology, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

APOBEC3A (A3A) and APOBEC3B (A3B) are members of a family of cytidine deaminase enzymes that catalyze the removal of an amino group from cytosine nucleotides generating an uracil in its place that serve as a source of mutations. The resulting C->U transition has been linked to various oncogenic mutations, most predominately in bladder cancer. While both A3A and A3B activity can account for widespread changes to the genomic landscape, prior studies have shown tumor specific effects. In hepatocellular carcinoma, A3A has been shown to be the only APOBEC3 family member capable of driving tumor formation in the presence of p53 downregulation, while studies in breast cancer have suggested A3B as a driver of tamoxifen resistance. Currently, it is unclear if both A3A and A3B drive APOBEC-induced mutagenesis in bladder cancer, or if one enzyme plays a larger mutagenic role than the other. In urothelial carcinoma, there has not been a direct comparison of A3A and A3B mutagenic activity, highlighting the need to determine the effects of each respective enzyme. To explore the effects of A3A and A3B enzymes, we accessed publicly available single cell RNA (scRNA seq) data of tumor samples from 8 bladder cancer patients. Analysis from scRNA seq data revealed an enrichment of A3A expression in both monocyte and urothelial cell

populations, while A3B expression is primarily restricted to urothelial cells, suggesting a cell type specific functional difference between A3A and A3B in bladder cancer. Immunogenomic analysis of TCGA bladder cancer tumors stratified by APOBEC mutational load (High, Low, No) showed that tumors with APOBEC high mutational load had high levels of interferon gamma response, lymphocyte infiltration signature score, M1 macrophages, intratumor heterogeneity, and stromal fraction compared to tumors with low APOBEC mutational load. In addition, increases in features of genomic instability was observed in tumors with high APOBEC mutational load. Interestingly, we saw unique correlations of A3A and A3B in TCGA bladder tumors. A3A expression correlated with characteristics of an inflamed tumor microenvironment while A3B expression correlated with features of genomic instability. To elucidate the divergent effects of A3A and A3B independently, we have generated isogenic mouse bladder cancer cell lines that overexpress HA tagged A3A and A3B, to directly compare their mutagenic effects through *in-vitro* and *in-vivo* experiments. We have validated through deamination assays, the functionality of A3B in these cell lines. *In silico* data has shown differential roles for A3A and A3B as it relates to the tumor/immune environment; we hypothesize that this might result in subunit specific response and resistance to anti-PD-1 immunotherapy. Elucidation of the A3 specific driver of APOBEC mutagenesis in urothelial carcinoma will help identity a predictive and/or prognostic biomarker to anti-PD-1 checkpoint immune inhibition.

ATRA treatment induces an interferon response to reprogram the immunosuppressive tumor microenvironment and overcomes resistance to immune checkpoint inhibition in murine models of LKB1 deficient non small cell lung cancer

William P. Crosson[1], Rui Li[2], Ramin Salehi-Rad[3], Raymond J. Lim[3], Jensen Abascal[2], Bitta P. Kahangi[2], Edgar Perez Reyes[2], Michael Oh[2], Camelia Dumitras[2], Nico Edgar[2], Ryan Chew[2], Rashel Jacobo[2], Zhe Jing[2], Kostyantyn Krysan[2], Linh M. Tran[2], Steven Dubinett[3], Bin Liu[2].

Angeles, Los Angeles, CA,[3]Department of Medicine, UCLA - University of California Los Angeles, Los Angeles, CA

Lung cancer remains the deadliest form of cancer, claiming the lives of 1.8 million individuals worldwide in 2020. While treatment options have improved with the advent of immune checkpoint inhibitors (ICI), many patients do not respond to immunotherapy or develop resistance following initial response. A significant subset of non-small cell lung cancer (NSCLC) patients harbor somatic co-mutations in *Kirsten rat sarcoma virus (KRAS)* and *Liver kinase 1 [LKB1,* also known as *serine/threonine kinase 11 (STK11*)] genes, whose tumors are characterized by a predominance of neutrophils and an immune suppressive tumor microenvironment (TME) that are resistant to ICI. Our studies revealed that *all-trans* retinoic acid (ATRA), a metabolite derived from vitamin A, sensitized a murine model of NSCLC (*Kras* ^{G12D} *P53*$^{-/-}$*Lkb1*$^{-/-}$; KPL) to PD-1 blockade. The ATRA and anti-PD-1 combination therapy improved local and systemic T cell activation and generated systemic tumor-specific immunity. We further observed that ATRA augmented anti-PD-1 efficacy in additional murine NSCLC models with or without LKB1 loss. To understand ATRA-mediated anti-tumor effects, we performed single cell RNA sequencing (scRNA-seq) of KPL murine tumors with or without 6 daily ATRA treatments. scRNA-seq analysis indicated a reduction of neutrophils as well as an enrichment in T cell and natural killer (NK) cell populations in the TME. Furthermore, scRNA-seq analysis revealed elevated expression of interferon (IFN) downstream genes in multiple immune subpopulations in the TME. Preliminary *ex vivo* studies indicated that ATRA increases NOX2 levels, intracellular reactive oxygen species (ROS), and IFN signaling in the myeloid-derived suppressor cells (MDSC) of KPL tumors. Our findings suggest that ATRA may reshape the TME by activating IFN signaling in multiple cell subtypes to sensitize resistant tumors to ICI immunotherapy.

Modifiers of the Tumor Microenvironment

Molecular mechanisms of early-stage lung adenocarcinoma initiation

Alice Rodriguez-Fuguet[1], Luis Silva[1], John Asara[2], Xiaoman Li[3], Susumu Kobayashi[2], Wen Cai Zhang[1]. *[1]Burnett School of Biomedical Sciences,*

Division of Cancer Research, University of Central Florida, Orlando, FL,[2]Department of Medicine, Division of Signal Transduction, Beth Israel Deaconess Medical Center, Harvard University, Boston, MA,[3]Department of Computer Science, University of Central Florida, Orlando, FL

Lung cancer initiation and progression driven by epidermal growth factor receptor (EGFR) mutation has been extensively studied in the past decade. Though many leaps have been made in the field in terms of treatment, early diagnosis screening is not widely available or well established. Meanwhile, EGFR mutation is a significant driver of tumorigenesis and drug resistance. This receptor is related to many downstream pathways that influence cancer metabolism and the ability of tumor cells to adapt to changes in the tumor microenvironment. Our study finds that cancer metabolism plays a prominent role in the progression of tumorigenesis in early-stage lung cancer. Kynurenine, a metabolite from the tryptophan pathway, was highly upregulated in early-stage, EGFR-mutation driven lung cancer by metabolomic analysis. The connection between EGFR mutation and the upregulation of kynurenine remains largely unknown. We hypothesize that kynurenine, based on our preliminary data and as a ligand of the aryl hydrocarbon receptor, may have a dual role in early tumorigenesis. We propose that kynurenine may be used by tumor cells to modulate their response to stress by triggering anti-apoptotic pathways. Additionally, kynurenine may be used as a signaling molecule in the tumor microenvironment to allow the early tumor cells to evade immune detection through the transformation of macrophages from M1 to M2. Currently, our data show that indoleamine 2,3- dioxygenase 1 (IDO1), the rate-limiting enzyme of the tryptophan-kynurenine pathway, is significantly upregulated in early-stage, EGFR-driven lung cancer murine models by RNA-seq analysis. This supports our idea that IDO1 could help to modulate the response to cellular stress and to regulate the immune response to favor tumor development. We hope that IDO1 could be a potential clinical target and a potential biomarker for the dysregulation of this pathway.

Discovery of INCB098377: a potent inhibitor of phosphoinositide 3-kinase gamma (PI3Kγ)

Diana A. Arias, Stephen Douglass, Lisa Truong, Qian Wang, Kathy H. Wang, Gengjie Yang, Michael Hansbury, Sybil O'Connor, Kevin Bowman, Robert Collins, Matthew Stubbs, Leslie Hall, Christina Stevens, Christopher Maddage, Brent Douty, Maryanne Covington, Lynn Leffet, Eddy Yue, Andrew Combs, Sunkyu Kim, Niu Shin, Holly Koblish, Rodrigo Hess. *Incyte Research Institute, Wilmington, DE*

Immune checkpoint blockade has shown impressive efficacy in patients with inflamed tumors, although minimal activity has been observed in tumors lacking T cells. Myeloid cells are one of the most abundant cell types in both inflamed and non-inflamed tumors, and may contribute to immune checkpoint blockade resistance. The plasticity of macrophages enables them to directly and indirectly modulate T cell responses, and directly kill tumor cells via phagocytosis. This suggests that targeting myeloid cells could be an effective therapeutic approach. Class I PI3Ks are a family of dual specificity lipid and protein kinases. Unlike other class I PI3Ks, PI3Kγ is predominantly expressed in myeloid cells. PI3Kγ has been shown to be a key mediator that drives the immunosuppressive macrophage program by stimulating AKT/mTOR signaling and promote C/EBPβ expression while inhibiting NF-κB activity (Keneda MM. *Nature*. 2016;17:437-442). Here, we present the discovery and characterization of INCB098377, a potent and selective PI3Kγ inhibitor. Specific inhibition of PI3Kγ with INCB098377 may induce anti-tumor activity by reshaping the tumor immune microenvironment. In cell-based assays, INCB098377 has an IC_{50} of 1.4 nM and is greater than 100-fold selective over other PI3K isoforms. It also shows a favorable PK profile in several animal species. Treatment of M2 polarized macrophages with INCB098377 resulted in changes towards a more pro-inflammatory phenotype. CD163 and CD206 were decreased, whereas HLA-DR and co-stimulatory CD80/86 molecules were increased. MHC-I expression was unchanged, suggesting a role for these macrophages in MHC-II-mediated antigen presentation. Furthermore, INCB098377 treatment reduced macrophage-mediated immunosuppression and restored T cell proliferation in M2 polarized macrophages co-cultured with allogeneic human T cells. In vivo, significant tumor growth inhibition was observed with once-daily dosing of 10 mg/kg INCB098377 in both syngeneic and humanized mouse tumor models without toxicity. Moreover, efficacy was observed in inflamed and non-inflamed tumor models.

Consistent with the proposed mechanism of action, INCB098377 inhibited phospho-AKT levels in vivo and in human PBMCs. Treatment with INCB098377 induced pro-inflammatory responses without macrophage depletion suggests that robust tumor microenvironment changes are responsible for observed anti-tumor efficacy. In addition, INCB098377 inhibited neutrophil migration in the Carrageenan-induced paw inflammation model. INCB098377, a potent and selective inhibitor of PI3Kγ, shows effective anti-tumor activity in a variety of mouse and humanized cancer models through the inhibition of immunosuppressive cells trafficking into the tumor, modulation of myeloid cell function, and enhancement of T cell proliferation.

Local delivery of mRNA immunotherapy encoding HPV16 antigen, IL-12, and LIGHT/TNFSF14 results in superior immunogenicity and tumor clearance in a murine model of HPV16-driven cancer

Weiqun Liu[1], Diane M. Da Silva[2], Edward E. Lemmens[1], Colin J. McKinlay[1], Sangeeta Nath[1], Meredith L. Leong[1], Samuel Deutsch[1], W. Martin Kast[2], Ole Audun W. Haabeth[1]. *[1]Nutcracker Therapeutics, Inc., Emeryville, CA,[2]Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA*

While intramuscular vaccination with HPV16 antigens has been shown to induce robust tumor-specific immune responses in the periphery, this has led to limited efficacy in the clinic. One potential explanation is the lack of sufficient infiltration of antigen-specific T cells into the tumor. The few T cells that make their way into the tumor are met with a plethora of negative signals that suppress their activity and abrogate local T cell expansion. To overcome this limitation of intramuscular cancer vaccines, we have developed an approach using in situ vaccination with a combination of immune modulators and tumor antigens, all encoded by mRNAs and delivered using nanoparticles. In this study, we show the superior efficacy and immunogenicity of a locally delivered mRNA cancer vaccine over that of an intramuscular HPV16 cancer vaccine. Both routes of administration result in robust induction of antigen-specific T cells, but local

administration of mRNA-encoded antigens and immune modulators also resulted in enhanced infiltration of immune cells into the tumor, local Th1/M1 cytokine induction, and more-complete tumor clearance. Specifically, we found that the inclusion of the immunomodulators IL-12 and TNFSF14/LIGHT enabled tumor clearance in a murine tumor model. While tumors treated with mRNA-encoded HPV16 antigen alone induced robust systemic antigen-specific responses, minimal levels of local T cell expansion and infiltration, proinflammatory cytokine induction, and tumor control were observed. By contrast, tumors treated with mRNA-encoded HPV16 antigen, IL-12p70, and TNFSF14 completely cleared large established HPV16 expressing tumors with long-lasting recurrence free survival and immune memory. This observation was replicated in in a second murine tumor model, confirming the superior potency of locally delivered mRNA cancer vaccines in combination with immunomodulators. Consequently, we are developing a locally administrated mRNA therapy for the treatment of patients with cervical intraepithelial neoplasia (CIN).

Liposomal Delivery of an Immunostimulatory CpG Induces Robust Antitumor Immunity and Long-Term Immune Memory by Reprogramming Tumor-Associated Macrophages

Yujin Kim[1], Sangyong Jon[2]. *[1]Life Science Research Institute, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[2]Biological Sciences, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of*

Background: The efficacy of current T cell-based immunotherapy is known to be limited by various factors that induce immune suppression in the tumor microenvironment (TME). Tumor-associated macrophages (TAMs) are representative TME-comprising immune suppressive cells and influence tumor growth and progression. TAMs are considered as an attractive target for cancer immunotherapy. However, current TAMs-targeting strategies are not sufficient to induce continuous antitumor responses. Here, we suggest a new strategy that can reprogram TAMs and further bridge innate-to-adaptive immunity by utilizing immunostimulatory CpG oligodeoxynucleotides (ODNs). In this study, we investigated the new role of TLR9 agonist CpG ODN as an immunotherapeutic agent and tested

whether liposomal delivery of CpG could modulate the function of TAMs and lead to remodeling of the TME.
Methods: A liposome-based nanomaterial encapsulating CpG ODN was constructed. A small lipid nanoparticle (SLNP) used as the CpG delivery platform in this study was made of a cationic cholesterol derivative and two biocompatible phospholipids. The CpG-encapsulating SLNP (SLNP@CpG) was prepared by a thin-film formation and rehydration method. *In vitro* studies were conducted to assess whether SLNP@CpG could reprogram macrophages. To assess antitumor therapeutic efficacy of the SLNP@CpG, two subcutaneous tumor models were established in mice and tumor growth and survival rates of mice were monitored. For tumor rechallenge experiment, mice showing complete tumor regression were rechallenged with same cancer cells and their splenocytes were analyzed to confirm the development of immune memory. To elucidate the immunological mechanism of SLNP@CpG-mediated antitumor efficacy, changes of immune cell subpopulations in treated tumors were analyzed by flow cytometry.
Results: SLNP@CpG enhanced macrophage-mediated phagocytosis of cancer cells and tumor antigen cross-presentation, and skewed the polarization state of macrophages *in vitro*. Intratumorally injected SLNP@CpG exerted its therapeutic efficacy in an established E.G7-OVA tumor via uptake by TAMs. SLNP@CpG treatment significantly suppressed the E.G7 tumor growth and also considerably prolonged the survival of mice, with 83.3% of mice becoming tumor-free. Local administration of SLNP@CpG resisted E.G7 tumor rechallenge by inducing immunological memory and long-term antitumor immunity. Local administration of SLNP@CpG even exerted its antitumor efficacy in an aggressive B16-F10 melanoma by remodeling TME towards immune stimulation and tumor elimination.
Conclusion: Liposomal delivery of CpG via local treatment reprogrammed TAMs by enhancing phagocytic activity and repolarizing M2 to M1 phenotype and also reshaped immunosuppressive TME, leading to antitumor immunity and long-term memory responses.

In vivo therapeutic validation of NRT-YHD_001, a novel macrophage checkpoint inhibitor, in liver cancer

Suk Woo Nam, Sangyean Kim, Min Jeong Na, Eunbi Shin, Jin Woong Ha, Soyoung Jeon, Jeong Hwan Yoon. *Dept of Pathology, Catholic University of Korea, College of Medicine, Seoul, Korea, Republic of*

Previously, we demonstrated that recovery of Histone deacetylase 6 (HDAC6) elicited let-7i-5p suppression to de-repress the thrombospondin-1 (TSP1) expression, and thereby it occupied CD47 receptor to block CD47-SIRPα mediated anti-phagocytosis of macrophage in liver cancer. NRT-YHD_001 is a modified antisense miRNA of let-7i-5p for liver cancer treatment. NRT-YHD_001 was substituted with O-methoxyethyl and phosphothioate for stability, and N-acetylgalactosamine was attached for specific delivery to the liver. In *in vitro* phagocytosis assay, NRT-YHD_001 showed macrophage phagocytosis activity with similar or better results compared to non-modified antisense let-7i-5p (AS_let-7i-5p). In addition, it was confirmed that NRT-YHD_001 inhibited endogenous let-7i-5p of liver cancer cells and activated macrophage phagocytosis at 4°C or 25°C for up to 2 weeks. When NRT-YHD_001 activity was investigated *in vivo* after 1 week, 2 weeks, and 4 weeks after administration of single dose NRT-YHD_001 to the tail vein of a mouse, NRT-YHD_001 was not degraded, and let-7i-5p was inhibited while maintaining activity in liver tissue for 2 weeks after injection. To investigate the *in vivo* therapeutic effect, a mouse spontaneous (Ras-transgenic) liver cancer model was used and compared with the sorafenib-administered group. After administration of NRT-YHD_001 and sorafenib each week at the time when liver mass was detected, the tumor size and growth rate were compared. As a result, the NRT-YHD_001 administration group showed significant therapeutic effect compared to sorafenib. These results showed that NRT-YHD_001 had a strong anticancer effect by converting the macrophage of don't eat me into eat me signal in the tumor microenvironment of liver cancer, thereby removing or inhibiting liver cancer cells.
Keywords: let-7i-5p, macrophage, phagocytosis, liver cancer, NRT-YHD_001

Intratumoral delivery of mRNA encoding USP6 activates multiple immuno-stimulatory pathways simultaneously and inhibits local and distal tumor growth in murine models

Ian Henrich[1], Margaret Billingsley[2], Kanika Jain[2], Laura Quick[3], Rob Young[3], Margaret Chou[2], Michael Mitchell[2]. *[1]Blumberg Institute and Merlin Biotech, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA,[3]Children's Hospital of Philadelphia, Philadelphia, PA*

Advances in immunotherapy have revolutionized cancer treatment, with patients with otherwise incurable disease having long-lasting responses. Unfortunately, deep remissions only occur in a select subset of patients. Cancer progression is common as many current immunotherapies only target one or two pathways, which can quickly lead to tumor resistance. Novel approaches that target several pathways concurrently are therefore needed to promote stronger responses in a wider patient population.
Our group has recently discovered that the protein Ubiquitin-specific protease 6 (USP6) upregulates multiple, distinct immunostimulatory pathways. Tumor cell-specific expression of USP6 significantly increases CXCL9, CXCL10, and CCL5 chemokine production that enhances cytotoxic immune cell recruitment. Simultaneously, USP6 also upregulates several ligands and receptors that promote immune cell activation and killing of tumor cells such as CD112, MICA/B, ICAM1, and MHC Class I. In addition, USP6 increases the tumor cell's sensitivity to immune-derived factors such as Type I and Type II interferons and TRAIL by raising the surface expression of their respective receptors. USP6 is hominid-specific and therefore requires xenografting human tumor cells into athymic, T-cell deficient nude mice. Despite the immunocompromised model, USP6 expression was found to increase immune cell recruitment to the tumor while repolarizing the immune microenvironment toward a more activated, tumor-suppressive state. Strikingly, immune cells in the peripheral blood were also affected with an increase in natural killer cell (NK) activation and a skewing of the myeloid population away from an immunosuppressive phenotype. Our group subsequently demonstrated that a $USP6^{+}$ tumor was able to inhibit the growth of a $USP6^{-}$ distal tumor, with a concordant increase in NK, macrophage, and dendritic cell activation in the distal $USP6^{-}$ tumor.
Given our data, we sought to translate USP6 into a novel immunotherapy. Delivery of mRNA encoding the USP6 protein recapitulates the immunostimulatory effects of USP6 *in vitro*. Intratumoral (I.T) injection of

a lipid nanoparticle (LNP) encapsulating USP6 mRNA significantly inhibited Ewing sarcoma and acute myeloid leukemia growth in athymic mice, despite the model lacking a fully functional immune system. Moreover, I.T injection of USP6 mRNA LNPs inhibited the growth of a non-injected, distal tumor. Altogether, these data support that USP6 is a potentially powerful target and continued development of I.T USP6 mRNA LNPs as a novel immunotherapy.

Entinostat's modulation of myeloid derived suppressor cells through the STAT3-NFκB-AP-1 axis decreases suppressive signaling

Aaron G. Baugh[1], Edgar Gonzalez[1], Valerie H. Narumi[1], Sofi Castanon[1], Jesse Kreger[2], James Leatherman[3], Won Jin Ho[3], Ashley Cimino-Mathews[3], Vered Stearns[3], Roisin M. Connolly[4], Elizabeth M. Jaffee[3], Adam L. MacLean[2], Evanthia T. Roussos Torres[1]. *[1]Keck School of Medicine of USC, Los Angeles, CA,[2]University of Southern California, Los Angeles, CA,[3]Johns Hopkins University, Baltimore, MD,[4]University College Cork, Cork, Ireland*

Metastatic breast cancer remains one of the leading causes of global cancer incidence in women, despite the benefit of immune checkpoint inhibitors (ICIs) in managing various cancers and improving patient quality of life. Metastatic breast cancer is characterized by extensive infiltration of the tumor microenvironment (TME) with immunosuppressive cells, such as myeloid derived suppressor cells (MDSCs), that inhibit anti-tumoral immune cells and prevent effective activation of the adaptive immune system by ICIs. Previously, our group has shown in the breast TME that epigenetic reprogramming of MDSCs by entinostat, a histone deacetylase inhibitor, decreases MDSC immunosuppressive function and enhances response to ICIs, in part mediated by altered signaling within the Signal transducer and activator of transcription 3 (STAT3) and Nuclear factor kappa B (NFκB) axis. Next, we sought to examine the effects of entinostat on MDSC reprogramming in a distant metastatic TME. Using the syngeneic NT2.5LM NeuN mouse model of metastatic breast cancer, we established spontaneous lung metastases and treated with either vehicle or entinostat (5 mg/kg by oral gavage, 5x /week) for 3 weeks. Single cell RNA sequencing (scRNAseq) of macro-dissected lung metastases revealed a large MDSC

population, and unsupervised pathways analysis of the MDSC cluster showed differential regulation of the IL6-JAK-STAT3 and TNFα-signaling-via-NFκB pathways upon entinostat treatment. In line with reports of crosstalk among STAT3, NFκB, and AP-1 pathways regulating inflammation in breast cancer, we also found through scRNAseq differential expression of AP-1 subunits JunB and FOSL1 upon entinostat treatment. At the protein level, western blot analysis of isolated intratumoral MDSCs from lung metastases revealed decreased STAT3 phosphorylation upon entinostat treatment. Using J774M cells, an MDSC-like cell line, we found decreased JunB phosphorylation and decreased FOSL1 protein upon entinostat treatment. Furthermore, preliminary evaluation of imaging mass cytometry (IMC) from tumor biopsies in selected patients with metastatic breast cancer treated with entinostat during the clinical trial NCI-9844 confirmed decreased STAT3 phosphorylation in MDSCs. Taken together, we provide new evidence in the metastatic lung TME that implicates a STAT3-NFκB-AP-1 mediated mechanism leading to decreased MDSC suppression. Evaluating this mechanism in MDSCs taken directly from treated lung metastases represents the most biologically relevant mechanistic study to date, and preliminary translation of findings in patients suggests that planned studies will lead to identification of the mechanism driving response.

In vitro suppressive Treg bioassays for screening of candidate therapeutics

Martijn Vlaming, Alanah Pieters, Jezabel Lefevere, Sofie Pattyn.
ImmunXperts, a Q2 Solutions Company, Gosselies, Belgium

The increasing interest in the tumor microenvironment leads to a focus on new bioassays to represent all the players of the cancer immune response. Some of these players like regulatory T cells play an important role by downregulating the anti-tumor response. Their regulation mechanisms constitute an important target for new therapeutics. In order to study these mechanisms in a human model, suppressive Treg bioassays mimicking the suppressive action of these cells were developed and optimized. In vitro suppressive assays come with many technical challenges, therefore protocols for the purification and in vitro culture of regulatory T cells were

optimized and fine-tuned to result in an optimal assay window e and allow screening of multiple candidates. Donor-to-donor variation is controlled by pre-evaluation of multiple donors and standardized methods are used for isolation and in vitro culture of responding and suppressive cells. Access to a large and broad panel of healthy donors is required for the evaluation of therapeutic agents targeting the regulatory T cell pathway.

Aurora-A kinase promotes anti-tumor immunity in high lymphocyte-infiltrated colorectal cancer

Shiang-Jie Yang[1], Ming-Derg Lai[1], Liang-Yi Hung[2]. *[1]The Institute of Basic Medical Sciences, National Cheng Kung University, Tainan, Taiwan,[2]Department of Biotechnology and Bioindustry Sciences, College of Bioscience and Biotechnology, National Cheng Kung University, Tainan, Taiwan*

Introduction: The tumor microenvironment (TME) is composed of different cell types and is involved in tumor progression. Several immunosuppressive signaling pathways can promote tumor growth by inhibiting anti-tumor immunity in TEM. Therefore, targeting the immunosuppressive signaling pathways is a potential cancer treatment. Recent studies reported that inhibition of oncoproteins could lead to reduced anti-tumor immunity in several cancers; therefore, it's critical to identify the potential oncoproteins which can lead to enhanced anti-tumor immunity. Aurora-A is a serine/threonine kinase that plays an important role in the centrosome, cell mitosis, and chromosome stability. Previous studies indicated that cancer patients with poor prognoses are associated with a high Aurora-A level in tumor cells. Inhibition of Aurora-A is considered as a promising strategy for cancer treatment. However, Aurora-A inhibitors have not had a breakthrough in phase II or phase III clinical trials. The role of Aurora-A in tumor immunity is still unclear. Here, we investigated the role of Aurora-A in tumor immunity.
Materials and Methods: shRNA was used to knock down Aurora-A, and Alisertib was added to inhibit Aurora-A. RT-qPCR and western blot were performed to determine the IL-16 expression. The secretion of cytokines was measured by cytokine array and ELISA. BALB/c and NOD/SCID mice were subcutaneously injected with CT26 and then administered daily with

Alisertib or treated with anti-IL-16 antibody. The tumor-infiltrating immune populations were analyzed by flow cytometry. IHC and H/E stain were performed to analyze Aurora-A expression and lymphocyte infiltration in human CRC specimens.
Results: CRC patients with lower lymphocyte infiltration and higher Aurora-A are associated with poor prognosis and vice versa. Knockdown of Aurora-A in CT26 promotes tumor growth in immunocompetent mice by inhibiting the infiltration and cytotoxic activity of $CD8^+$ T cells. Aurora-A negatively regulates IL-16 expression in a kinase-dependent manner in CRC cells. Blockade of IL-16 by anti-IL-16 antibody can reverse the tumor growth and $CD8^+$ T cell cytotoxic activity in Aurora-A knocked-down CT26 tumors. Alisertib can inhibit CT26 tumor growth and promote IL-16 secretion in TME in mice. A combination of Alisertib and IL-16 antibody can promote the therapeutic effect of Alisertib in CT26 tumors.
Conclusion: Tumor-intrinsic Aurora-A plays a diverse role in tumor progression depending on the status of lymphocyte infiltration in TME. Aurora-A can promote anti-tumor immunity via negatively regulating IL-16 in a kinase activity-dependent manner in hot CRC tumors. In tumors with high lymphocyte infiltration, Aurora-A inhibition can suppress cancer cell growth and reduce anti-tumor immunity; the combination of Aurora-A inhibitors and IL-16 antibodies may provide a novel and effective strategy for cancer therapy in hot tumors.

STING inflames NF1 malignancies for immunotherapy
Nipunika Somatilaka[1], Laasya Madana[2], Ali Sadek[3], Renee M. McKay[1], Lu Q. Le[1]. *[1]Dermatology Department, UT Southwestern Medical Center, Dallas, TX,[2]University of Texas at Dallas, Dallas, TX,[3]Duke University, Durham, NC*

Introduction: Neurofibromatosis Type 1 (NF1) is caused by mutations in the NF1 gene that encodes neurofibromin, a RAS GTPase-Activating Protein. Inactivating NF1 mutations result in hyperactivation of RAS-mediated signaling. NF1 patients develop benign tumors on the skin and along nerves in the spinal cord and brain, and ~10% of these progress to Malignant Peripheral Nerve Sheath Tumors (MPNST). Attempts to inhibit RAS-signaling to treat MPNST have not worked in clinical trials. Surgical

removal is the only cure for MPNST, which is challenging due to large tumor size and/or proximity to nerves. MPNSTs often recur, metastasize, and respond poorly to chemo- and radiotherapy. As a result, MPNSTs are the leading cause of death in NF1 patients. Immune Checkpoint Blockade (ICB) is an approach to treat inoperable, undruggable cancers. Immune checkpoint proteins (ICPs) terminate normal immune responses to prevent collateral tissue damage. Cancer cells hijack this mechanism and express ICPs to avoid immune detection. ICB disrupts this process, enhancing antitumor immunity. Monoclonal antibodies (mABs) that disrupt the interaction between Programmed Cell Death Receptor 1 (PD-1) and its ligand Programmed Cell Death Ligand 1 (PD-L1) are a widely used ICB therapy. Having a T cell-enriched hot tumor microenvironment (TME) is required for successful ICB. However, MPNSTs lack a T cell-inflamed TME and respond poorly to ICB therapy. Activation of the protein "stimulator of interferon genes" (STING) enhances anti-tumor immunity via induction of pro-inflammatory cytokines, thus increasing T cell infiltration into the TME. We hypothesized that reprogramming the MPNST TME by STING pathway activation would turn cold MPNSTs into hot tumors amenable to ICB.
Methods: We treated mouse MPNSTs with STING agonist or STING agonist + anti-PD-1/anti-PD-L1 mAb. Tumor size was measured throughout treatment. The mice were sacrificed and tumor tissue was analyzed for STING pathway activation, T cell infiltration, cell proliferation, and apoptosis. MPNST allograft tumors in athymic mice were controls.
Results: STING pathway activation and increased T cell presence was observed in STING agonist-treated MPNSTs compared to vehicle-treated. MPNSTs treated with STING agonist alone or STING agonist + PD-1/PD-L1 mAbs showed less tumor growth relative to vehicle. Importantly, STING agonist + PD-1/PD-L1 mAb-treated tumors showed significant cell death increase while cell proliferation remained unchanged. Interestingly, tumors in athymic mice continued to grow despite treatment suggesting the antitumor effects seen in immunocompetent mice were mediated by T cells.
Conclusions: Our data show that MPNSTs can become T cell-rich tumors by activating STING signaling. Reprogramming the TME made MPNSTs susceptible to immune destruction by ICB therapy. Our studies support this novel treatment strategy for MPNST, an aggressive, deadly tumor for which no molecular therapy currently exists.

TP-6379, an investigational TGFBR1 inhibitor, shown to remodel the tumor microenvironment and enhance anti-tumorigenic immunological responses in syngeneic mouse models of cancer

David A. Kircher, Tetyana V. Forostyan, Richard E. Heinz, Curtis A. Allred, Sal Sommakia, Yuta Matsumura, Adam Siddiqui, Jason M. Foulks, Steven L. Warner. *Sumitomo Pharma Oncology, Lehi, UT*

Transforming growth factor-β (TGF-β) receptors regulate SMAD signal transduction and a wide-range of biological processes including, wound healing, angiogenesis, immune modulation, epithelial-mesenchymal transition, cell differentiation, apoptosis, growth, and motility. In transformed cells, TGF-β signaling is frequently exploited to reshape the architecture of the tumor microenvironment (TME) and establish a fibrotic barrier that insulates the tumor from surrounding normal tissue. As a result, immunological threats to the tumor are restricted, as is the anti-tumorigenic potential of immunotherapeutic interventions. Clinically, TGF-β hyperactivity is associated with immunotherapy resistance and poor outcome in a variety of malignancies. We hypothesize that TP-6379, an investigational small molecule inhibitor of TGFBR1, may remodel the TME to expand the access of tumor-seeking lymphocytes to tumor tissue. Herein we describe several anti-tumorigenic effects of TP-6379 observed in multiple mouse models of cancer both as a single agent, and in combination with immunotherapy. In an EMT6 syngeneic mouse model of triple-negative breast cancer (TNBC), we observed that tumor phospho-SMAD2/3 (pSMAD2/3) levels quickly declined post-TP-6379-treatment and were suppressed by 74% after 8 hours. Preclinical data showed TP-6379 plasma levels inversely correlated with pSMAD2/3 suppression. TP-6379 alone was observed to inhibit tumor growth in EMT6 and 4T1 TNBC models, an activity that was enhanced when augmented by immunotherapy. In a Cloudman S91 syngeneic melanoma mouse model, there was a clear subset of mice that responded to combination treatment. Histological analyses of TNBCs and responsive melanomas showed that TP-6379 treatment conferred a loss of induration of tumors, increased vascularization, and increased infiltration of CD45+ leukocytes (including CD8+ T cells), particularly when combined with immunotherapy. High-throughput

analyses of tumors uncovered an array of MHC class I and II factors that were observed elevated subject to TP-6379 treatment, an activity that was oftentimes enhanced when combined with immunotherapy. Collectively, these data suggest that TP-6379 may improve immune cell access to tumor tissue via TME remodeling and normalization of vascular networks. Thus, TP-6379 treatment may present a unique and multifactorial anti-tumor strategy, 1) as a single agent to improve anti-tumorigenic immunological responses, and 2) as a combination treatment to boost immunotherapeutic activity.

Tumor-immune microenvironmental profiling during chemo- and targeted therapy for head and neck squamous cell carcinoma

Alisa Kimura[1], Takahiro Tsujikawa[1], Junichi Mitsuda[1], Aya Miyagawa-Hayashino[2], Hiroki Morimoto[1], Sumiyo Saburi[1], Kanako Yoshimura[1], Gaku Ohmura[1], Sigeyuki Mukudai[1], Hikaru Nagao[1], Yoichiro Sugiyama[1], Hiroshi Ogi[3], Saya Shibata[4], Eiichi Konishi[2], Kyoko Itoh[3], Shigeru Hirano[1]. *[1]Departments of Otolaryngology-Head and Neck Surgery, Kyoto Prefectual University of Medicine, Kyoto, Japan,[2]Departments of Surgical Pathology, Kyoto Prefectual University of Medicine, Kyoto, Japan,[3]Departments of Pathology and Applied Neurobiology, Kyoto Prefectual University of Medicine, Kyoto, Japan,[4]SCREEN Holdings Co., Ltd., Kyoto, Japan*

Understanding longitudinal changes of tumor-immune microenvironment during chemo/targeted therapies contributes to the development of optimized combinations of immunotherapy with chemotherapy and targeted therapy for patients with head and neck squamous cell carcinoma (HNSCC). We previously reported a chromogenic sequential immunohistochemical (IHC) platform enabling quantitative and spatial assessment of 29+ biomarkers in a single tissue section (Tsujikawa T et al. Cell Reports 2017, Banik G et al. Methods Enzymology 2020). Using this platform, densities, phenotypes, and distributions of tumor and immune cells were evaluated, comparing baseline and post-treatment specimens from the same individual treated by paclitaxel, carboplatin, and cetuximab (PCE) for advanced HNSCC (N = 30). Immune cell density analyses based

on $CD8^+$ T cells, helper T cells, regulatory T cells, B cells, natural killer cells, macrophages, dendritic cells, mast cells, granulocytes revealed the presence of differential immune cell compositions, where immune profiles were divided into hypo-, lymphoid-, and myeloid-inflamed groups according to the same criteria as in our previous report (Tsujikawa et al. Cell Reports 2017). Lymphoid and hypo-inflamed groups exhibited significant tumor volume reduction, increased $CD45^+$ immune cell densities and elevated combined positive scores of PD-L1 at the post-treatment status, suggesting the potential involvement of immunogenic mechanisms related to therapeutic response. On the other hand, the myeloid group exhibited no significant tumor volume reduction, together with higher expression of HIF1α and ZEB2 on tumor cells which are potentially associated with hypoxia and epithelial-mesenchymal transition. In conclusion, longitudinal tissue-based monitoring revealed the presence of differential tumor-immune complexity profiles related to therapeutic efficacy and resistance. Hypo-inflamed profiles might require upfront chemo/targeted therapy before immunotherapy, and myeloid-inflamed profiles might require myeloid cell-targeted therapies, mandating the establishment of rapid clinical assessment of tumor-immune microenvironment.

#5173

BET inhibition reprograms pancreatic cancer associated fibroblasts to promote anti-tumor immunity

Trisha Minocha, Alison Thomas, Brian M. Olson. *Hematology/Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

BACKGROUND**:** Pancreatic ductal adenocarcinoma (PDAC) is the most malignant neoplasm of the pancreas, and is refractory to most therapeutic strategies, including immunotherapy. We have previously demonstrated that loss of CDKN2A in PDAC tumor cells promotes an immunologically-cold tumor microenvironment, which can be counteracted through the use of bromodomain and extraterminal domain inhibitors (BETi). The immunosuppressive PDAC tumor microenvironment is also characterized by a dense desmoplastic stroma, rich in cancer associated fibroblasts (CAFs). These CAFs are a highly plastic population of cells, comprised of myofibroblastic, inflammatory, and antigen-presenting CAFs (myCAFs,

iCAFs, and apCAFs, respectively). Previously research has suggested BETi can alter the function of CAFs, suggesting this therapeutic strategy may be effective at targeting both the tumor and stromal compartments of PDAC. Here we hypothesize that BETi enhances anti-tumor immunity in CDKN2A-deficient PDAC by modulating the phenotype and function of PDAC CAFs.
METHODS: Isogenic wild-type and CDKN2A-deficient KPCluc pancreatic cancer cell lines were used in conjunction with KPCluc-derived murine CAF cells. CAF spheroids were used to evaluate the effects of BETi on CAF phenotype (as measured by flow cytometry) and function (as measured by NanoString analysis, checkpoint ligand expression by flow cytometry, and T cell migration assays). Additionally, the impact of BETi-induced modulation of CAF phenotype and function on wild-type and CDKN2A-deficient tumor cell spheroids was measured by flow cytometry.
RESULTS: Treatment of pancreatic CAFs with BETi induced expression of genes associated with DNA damage responses and type I IFN expression. Additionally, while CAF supernatants suppressed T cell migration *in vitro*, treatment with BETi restored T cell migration across a transwell. This was due in part to DNA damage/STING/NF-κB signaling induced in PDAC CAF following BETi. Supernatants from BETi-treated PDAC CAFs were found to modulate PD-L1 expression on PDAC tumor cells. Direct treatment of CAFs with BETi induced a dramatic dose- and time-dependent polarization of CAF spheroids towards a myCAF phenotype. However, while BETi induced DNA damage/STING/NF-κB signaling in CAF cells, this signaling did not contribute towards this myCAF polarization, as treatment of CAF spheroids with BETi and STING or NF-κB inhibitors did not impact myCAF polarization. Additional mechanisms of polarization are currently being evaluated and will be updated at presentation.
CONCLUSIONS: BET inhibition modulates CAF cell phenotype and function to promote anti-tumor immune responses. Taken together with the impact of BET inhibition on CDKN2A-deficient PDAC tumor cells, these data suggest BETi is a rational treatment approach to promote anti-tumor immunity in this genetically defined immunotherapy resistant patient population.

PEGylated liposomal doxorubicin improves oral cancer response to radio-immunotherapy

Laxman Devkota[1], Rohan Bhavane[2], Andrew Badachhape[1], Ratna Veeramachaneni[3], Renuka Menon[1], Prajwal Bhandari[1], Sofia Cortes[3], Fabio Henrique Brasil Da Costa[3], Ketan Ghaghada[2], Simon Young[4], Andrew G. Sikora[3], Ananth V. Annapragada[2]. *[1]Radiology, Baylor College of Medicine, Houston, TX,[2]Radiology, Texas Children's Hospital, Houston, TX,[3]Head and Neck Surgery, MD Anderson Cancer Center, Houston, TX,[4]Department of Oral & Maxillofacial Surgery, The University of Texas Health Science Center at School of Dentistry, Houston, TX*

Introduction: The immunosuppressive tumor microenvironment (TME) in oral cancer inhibits response to conventional treatment (surgery +/- chemoradiotherapy) and check-point inhibitor (αPD1) immunotherapy. The chemotherapeutic agent doxorubicin and its PEGylated liposomal nanoparticle formulation (PLD) have been shown to target myeloid derived suppressor cells (MDSCs) in the TME. In this preclinical work, we investigated whether PLD improves response to radio-immunotherapy in a highly aggressive and immunologically 'cold' oral cancer model.
Experimental Procedure: Studies were performed in the MOC2 syngeneic mouse model of oral cancer. Mice were randomized to one of seven treatment groups: αPD1, Radiation (XRT), αPD1+XRT, PLD, PLD+αPD1, PLD+XRT, PLD+αPD1+XRT. High-resolution nanoparticle contrast-enhanced computed tomography (nCECT) imaging was performed, and whole-body T2-weighted magnetic resonance imaging (MRI) used to monitor primary tumor response and development of metastases. Response evaluation criteria in solid tumors (RECIST) were used to evaluate treatment outcomes.
Results: Tumors in all non-PLD groups were treatment resistant and grew progressively, consistent with the immunologically 'cold' MOC2 model. In contrast, all PLD groups showed tumor regression with 25-38% complete responders (CR) and 12-88% partial responders (PR) while all animals in non-PLD groups showed progressive disease (PD). MR imaging identified a high incidence of regional and distant metastases in the non-PLD groups while the PLD groups showed decreased regional and no distant metastases (Table1). Presence of metastases was confirmed by nCECT imaging and histopathological analysis.

Conclusion: PLD improved response to radio-immunotherapy in a highly aggressive immunologically 'cold' mouse model of oral cancer while simultaneously preventing disease progression and metastasis.

DX-002, a dual EP2 and EP4 antagonist, alters the tumor microenvironment to enhance tumor immunogenicity and responses to immune checkpoint inhibitors

Lintong Li, Guorui Yao, Wei Zheng, Yongshuai Chai, Zhongying Huang, Guojian Ma, Linlin Nie, Dengfeng Xu, Jiuquan Yang, Nanxin Li.
GuangDong NewOpp Biopharmaceuticals Co., Ltd, Guangzhou, China

Prostaglandin E2 (PGE2) generated by the cyclooxygenase (COX) pathways regulates both inflammation and tumor microenvironment (TME). Among the four E-type prostanoid receptors EP1-4, it has been demonstrated that PGE2 exhibits its immune suppression and tumorigenic function through engagement with EP2 and EP4. Mechanistically, tumor-derived PGE2 acts on EP2 and EP4 in immune cells (e.g., NK cells and dendritic cells) and elicits immunosuppression in TME[1,2]. Importantly, the deletion of both EP2 and EP4, but not deletion of either receptor, is required to reverse PGE2-mediated immune evasion. Furthermore, high levels of PGE2-EP2/EP4 associated inflammatory signature have been shown in multiple human cancer types to correlate with poor prognosis and worse response to immune checkpoint blockade in the clinic[1]. Therefore, PGE2-EP2/EP4 signaling likely acts as a key regulatory node linking inflammation and immunosuppression in TME, and its inhibition may lead to a less immunosuppressive TME and enhance the response to immune checkpoint inhibitors. COX inhibitors have been used to block PGE2 synthesis but cause cardiovascular and gastrointestinal risks due to the inhibition of all prostanoids synthesis[3]. Thus, therapeutically targeting both EP2 and EP4 is an effective and more selective approach to limit the immunosuppressive functions of PGE2 while avoiding potential side effects associated with COX inhibition.
Here we describe the discovery of a potent and selective EP2/EP4 dual antagonist DX-002. At 10 nM concentration, it displayed >90% inhibition of PGE2 binding to EP2 or EP4, whereas no significant inhibition was seen towards PGE2 binding to EP1 or EP3. In human NK cells DX-002 reversed

PGE2-mediated inhibition of IFN-γ production more potently than selective EP2 or EP4 antagonist. DX-002 has excellent pharmacokinetics profiles across all animal species. In the mouse tumor model, treatment of DX-002 produced superior tumor regression as a monotherapy over selective EP2 or EP4 antagonists. In addition, DX-002 also provided significant synergistical effect for tumor regression in combination with anti-PD1 in both immune checkpoint inhibitor insensitive and sensitive models, in association with increased tumor infiltration of CD8+ T cells. Based on its in vitro and in vivo profiles along with other properties, DX-002 is being profiled as a development candidate as a potential cancer immunotherapeutic agent.

CDDO-methyl ester redirects macrophage polarization and reduces lung tumor burden in a Nrf2-dependent manner

Jess Ann Moerland, Karen T. Liby. *Michigan State University, East Lansing, MI*

The cytoprotective Nrf2 pathway impacts immune cell function and has been proposed as a target for many inflammation-related diseases, but the effects of Nrf2 activation on immune cells in the cancer context are not well characterized. With Nrf2 activators under development and in clinical trials, it is critical to understand the influence of these drugs on cancer progression. While the anti-inflammatory nature of Nrf2 activation protects healthy cells from malignant transformation, cancer cells can utilize the pathway to promote resistance to anti-cancer drugs and increase tumor cell survival. Up to 30% of human lung adenocarcinomas acquire mutations in the Nrf2 pathway which result in constitutive activation. However, triterpenoids, including CDDO-methyl ester (CDDO-Me, also known as bardoxolone methyl), are potent pharmacological Nrf2 activators with demonstrated anti-cancer activity in preclinical models. Lung cancer is the leading cause of cancer-related mortality worldwide, and macrophages are the most common immune cell type in the lung tumor microenvironment. To investigate Nrf2 activation in macrophages in the context of lung cancer, bone marrow-derived macrophages (BMDMs) were isolated from wild type (WT) and Nrf2 knock out (KO) mice and cultured in conditioned media from lung cancer cells to produce a tumor-educated phenotype. The triterpenoid CDDO-Me had anti-inflammatory effects in BMDMs

stimulated with the conventional cytokines IFN-γ and LPS. Conversely, CDDO-Me increased ($p < 0.05$) the M1 macrophage markers TNFα, IL-6, and MHC-II and decreased the M2 macrophage markers VEGF, CCL2, and CD206 in tumor-educated BMDMs in a Nrf2-dependent manner. The phenotypic changes were observed on transcription, protein, and surface marker levels. This context-dependent reversal of BMDM polarization suggests that Nrf2 activation has different outcomes in different environments. To test CDDO-Me *in vivo*, lung tumors were initiated with vinyl carbamate in A/J WT and Nrf2 KO mice, and animals were fed either control diet or CDDO-Me (12.5-50 mg/kg of diet) for 16 weeks. CDDO-Me significantly ($p < 0.05$) decreased tumor number, size, and overall burden and reduced the histopathological severity of tumors in a Nrf2- and dose-dependent manner. Additionally, CDDO-Me increased the infiltration of CD64+ macrophages but decreased CD206+ expression in macrophages in the lungs of WT tumor-bearing mice. Interestingly, CD206 expression was higher on macrophages in the spleen of WT mice treated with CDDO-Me, suggesting a cancer context dependency. Future studies will evaluate the dependency of Nrf2 activation in macrophages for the anti-tumor activity of CDDO-Me.

Nilotinib suppresses the myofibroblastic cancer-associated fibroblast phenotype

Katherine Anne Johnson, Yousef Gadalla, Cheri A. Pasch, Dustin A. Deming. *Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI*

Background: Cancer-associated fibroblasts (CAFs) modulate the tumor immune microenvironment and are an exciting target for improving response to immunotherapy. Major roles of CAFs in the immune microenvironment include deposition of extracellular matrix (ECM) to prevent immune cell infiltration, a function associated with myofibroblastic CAFs (myCAFs), and production of cytokines to alter the immune milieu, associated with inflammatory CAFs (iCAFs). Recently we have demonstrated the potential for tyrosine kinase inhibitors (TKIs) to alter CAF phenotypes. Here we investigate the ability of dasatinib and nilotinib to alter the immune regulatory functions of CAFs.

Methods: Bulk RNA sequencing comparing the effects of nilotinib and dasatinib on primary-derived patient CAFs was performed. CAFs from two rectal cancer patient tumors were isolated, cultured, and treated for 96 hours with 2.5μM nilotinib, 100nM dasatinib, or control feeding media. RNA isolation, library preparation, sequencing, data processing, and differential expression analysis was done through the University of Wisconsin - Madison Gene Expression Center, Biotechnology Center, and Bioinformatics Resource. Gene set enrichment analyses were done using GSEA 4.2.3 (Broad Institute) and all other analyses done in R.
Results: The primary variance in samples is between CAF lines (RC1 and RC2), followed by treatments. RNA expression markers for myCAFs significantly associate with the Gene Ontology molecular function ECM structural constituent ($q < 0.001$). Nilotinib decreased expression of this gene set in RC1 ($q < 0.001$), while dasatinib treatment increased these genes in RC2, though not significantly ($q = 0.2$). Both dasatinib and nilotinib downregulated immune-related hallmark gene sets including IL6/JAK/STAT3 signaling (RC2 dasatinib $q < 0.05$, $q < 0.001$ for others) and TNFα signaling through NFκB (RC1 dasatinib $q < 0.001$, RC2 niltoinib $q < 0.05$, others $q = 0.001$,). Additionally, dasatinib induced increased expression of genes involved in myogenesis in both CAF lines (RC1 $q = 0.001$, RC2 $q < 0.001$), while nilotinib significantly decreased these genes in RC1 ($q = 0.001$). MYOCD is a transcription factor involved in myogenesis that regulates important myCAF genes such as *ACTA2* and *TAGLN*. Nilotinib treatment decreased expression of *MYOCD* (RC1 log2FC -1.3 $q < 0.001$, RC2 -0.75 $q < 0.05$) and its target genes in both lines, whereas dasatinib did not significantly alter expression.
Conclusions: CAFs derived from different cancers harbor different transcriptional profiles and have different responses to TKIs. Dasatinib treatment led to an increase in expression of ECM genes associated with the myCAF phenotype, while nilotinib decreased this phenotype, potentially by inhibiting *MYOCD* expression. Further investigation into the mechanisms by which nilotinib treatment decreases expression of ECM genes and whether these trends continue *in vivo* are warranted.

#5178
Humanized OX40/OX40L mice as a tool for evaluating novel therapeutics

Chonghui Liu[1], Jiawei Yao[1], Xiaofei Zhou[1], James Jin[2], Zan Zhang[1]. *[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Biocytogen Boston Corp, Wakefield, MA*

The use of immune-competent mouse models that express target human genes provide a promising preclinical platform aimed at developing novel immunotherapies. Emerging immunotherapies include targeting OX40 and OX40 ligand (OX40L), which can lead to enhanced T cell activation, proliferation, and effector function. Blocking the OX40/OX40L pathway improves autoantigen-specific T cell responses and decreases immunocompetence across several autoimmune diseases. To explore the potential of OX40 and OX40L antibody efficacy studies, we developed double humanized B-hOX40/hOX40L mice by replacing the extracellular domain sequences of murine *Ox40* and *Ox40l* with the corresponding human sequences. We validated human *OX40L* gene expression by RT-PCR and OX40/OX40L protein expression by flow cytometry in B-hOX40/hOX40L mice. Additionally, percentages of splenic, blood, and lymph node immune cells were similar between B-hOX40/hOX40L and wild-type C57BL/6 mice. Altogether, this data demonstrates that B-hOX40/hOX40L mice are suitable for *in vivo* efficacy studies using anti-human OX40 and OX40L antibodies.

T cell receptor repertoire analysis revealed tissue tropism of tumor-reactive T-cell clones in cell cycle reporter mice

Mikiya Tsunoda[1], Hiroyasu Aoki[1], Munetomo Takahashi[2], Haruka Shimizu[1], Haru Ogiwara[1], Shigeyuki Shichino[1], Kouji Matsushima[1], Satoshi Ueha[1]. *[1]Research Institute for Biomedical Sciences, Tokyo University of Science, Noda-shi, Japan,[2]Faculty of Medicine, The University of Tokyo, Bunkyo-ku, Japan*

Tumor-reactive T cells are composed of clones with various TCRs, and each clone has different in vivo kinetics. By analyzing TCR repertoire of tumor and tumor-draining lymph node (dLN), we have demonstrated that Tumor-reactive CD8+ T cells can be classified into “dLN Major”, “Tumor Major”, and “Double Major” clones, which exhibited high frequency in the

dLN, tumor, or both tissues. To investigate whether this classification was related to the tissue tropism in the proliferation of each clone, we here employed tumor-bearing Fucci transgenic mice expressing a fluorescent cell-cycle indicator to identify the proliferation of T-cell clones in each tissue. We purified proliferating- and resting-CD8+ T cells from the tumors and dLN and analyzed their TCR repertoire in an LLC subcutaneous tumor model. All Tumor Major clones were proliferated in the tumor, while nearly 0% for dLN Major, indicated their different proliferative capacity in the tumor. The percentage of proliferating clones in the dLN was 20% for Tumor Major and 15% for dLN Major, indicating that these clones had equivalent proliferative capacity in the dLN. These proliferating dLN major clones overlapped more with the tumor than the non-proliferating dLN major clones, suggesting that proliferating dLN Major clones had higher tumor migration capacity. Furthermore, these proliferating dLN major clones were more proliferative in the tumor. These results suggested that dLN Major responded to antigen presentation in the dLN but not in the tumor, whereas Tumor Major responded to those in the dLN and tumor. In addition, there are two types of dLN major, “clones that are proliferating in dLN” and “clones that are not proliferating in dLN” indicating that the former may contribute to the anti-tumor response. Immune checkpoint inhibitor (ICI) treatment not only reactivates clones in the tumor but also activates tumor-reactive clones in the dLN. In conformity with these previous studies, the percentage of proliferating clones among dLN Major increased to about 50% and 80% in the dLN in mice with anti-PD-L1 and anti-CD4 treatment, respectively. This result suggests ICI treatment enhances anti-tumor responses mainly by promoting the activation and proliferation of dLN Major clones. This study shows new findings that tumor-reactive T cells differ in the tissue tropism of their proliferation of each clone. In the future, a quantitative understanding of the contribution of each class of clones to the anti-tumor response will hopefully lead to the development of new combined immunotherapies that optimize the anti-tumor T-cell response.

The role of Neuropilin-1 signaling in CD4 conventional T cell immune function in non-small cell lung cancer

Bitta P. Kahangi[1], Raymond J. Lim[2], Jensen Abascal[2], William P. Crosson[2], Edgar Perez Reyes[2], Camelia Dumitras[2], Linh M. Tran[2], Kostyantyn Krysan[2], Ramin Salehi-Rad[2], Steven M. Dubinett[2], Bin Liu[2]. *[1]Medicine - Pulmonary and Critical Care, UCLA - University of California Los Angeles, Los Angeles, CA,[2]UCLA - University of California Los Angeles, Los Angeles, CA*

Despite advances in therapy, lung cancer remains the leading cause of cancer related deaths. In non-small cell lung cancer (NSCLC), a subset of tumor-infiltrating CD4 T cells express Neuropilin-1 (NRP1), a transmembrane protein that binds to multiple ligands with diverse functions in tumor and immune cells. Recent studies reveal that NRP1 can be induced upon T cell receptor stimulation and that NRP1 signaling promotes increased stabilization and function of CD4+ FoxP3+ regulatory T cells (Tregs), while signaling on CD8 T cells results in inhibition of CD8 T cell migration and cytotoxicity; therefore, NRP1 is implicated as a newly defined immune checkpoint protein. The functional role of NRP1 in CD4+ FoxP3- T conventional cells (CD4 Tconv) and the ligands involved are largely unexplored. We have found that human lung cancer malignant pleural effusions (MPE) from a subset of metastatic lung cancer patients contain both NRP1+ and NRP1- CD4 Tconv cells, providing a relevant clinical setting to study the function of NRP1 in human T cells. Our preliminary studies reveal that MPE-derived NRP1+ CD4 Tconv cells have altered expression of CD25, suggestive of a more activated state as compared to that of NRP1- CD4 Tconv cells. Additionally, we have observed disproportionate cell death of NRP1+ CD4 Tconv cells that can be partially rescued with anti-NRP1 monoclonal antibodies (mAbs). Surviving NRP1+ cells are more likely to express PD-1 and secrete effector cytokines. In our murine NSCLC model carrying key driver mutations $Kras^{G12D}$ $P53^{-/-}$ $Lkb1^{-/-}$ and higher tumor mutational burden (KPL-3M), analysis of tumor-infiltrating CD4 Tconv cells confirm that NRP1+ CD4 T cells are preferentially found within tumors and with higher PD-1 expression as compared to NRP1- cells. Furthermore, treatment with anti-NRP1 mAbs confers anti-tumor efficacy in this model, indicating that NRP1 is a functionally important inhibitor of host anti-tumor immune responses. These data suggest that CD4 Tconv cells expressing NRP1 are activated but

prone to cell death, warranting further investigation into its potential as a therapeutic target for NSCLC.

#5182

CD47 is a promising therapeutic target in non-small cell lung cancer

Asa P. Y. Lau[1], Shawn P. Kubli[2], Andrew Wakeham[3], Tak W. Mak[3], Kelsie L. Thu[1]. *[1]Keenan Research Centre, St. Michael's Hospital, Toronto, ON, Canada,[2]Treadwell Therapeutics, Toronto, ON, Canada,[3]University Health Network, Toronto, ON, Canada*

Introducti**on:** Immune checkpoint inhibitors can elicit remarkable tumor regressions in non-small cell lung cancer (NSCLC), but not all patients are eligible for these drugs and only a small fraction of those who are respond. Thus, additional immunotherapies (IO) for NSCLC patients are needed. CD47 is an immunosuppressive protein frequently overexpressed in NSCLC. When bound to its receptor, SIRPα, the phagocytic function of antigen presenting cells (APCs) is impaired which dampens the innate immune response and anti-tumor immunity. CD47-SIRPα-targeted IOs are under investigation in clinical trials but little efficacy has been seen in solid tumours, suggesting further preclinical knowledge is needed to guide effective use in NSCLC. To address this need, we aim to decipher immune-mediated and cell-intrinsic mechanisms governing NSCLC response to CD47 inhibition.

Methods: CRISPR/Cas9 was used to generate mixed and clonal *Cd47* knockout (KO) populations in two murine, syngeneic NSCLC models (LLC and CMT167). The effect of *Cd47* inactivation on tumor cell fitness was assessed by multicolour competition assays conducted *in vitro* and in orthotopic tumors grown in immunocompetent C57BL/6 mice. Survival studies were also done in immune competent (C57BL/6) and deficient (NCG) mice to provide insights into cell-intrinsic versus immune-mediated effects of *Cd47* KO on tumor growth. Immunophenotyping of tumours grown in syngeneic hosts was done using flow cytometry to compare immune cell infiltration in wildtype (WT) versus *Cd47* KO tumors.

Results: Multicolour competition assays revealed that *Cd47* LOF reduced the fitness of LLC and CMT167 cells grown in mice but not in cells grown *in vitro*, suggesting *Cd47* KO does not compromise cell proliferation. Consistent with these results, survival studies conducted in immune

competent hosts showed prolonged survival of mice with *Cd47* KO compared to WT tumors in both models. An increase in activated Cd8+ cytotoxic T cells and M1-polarized macrophages was observed in *Cd47* KO tumors relative to WT controls. Interestingly, the same survival studies conducted in immune compromised mice also showed a significant survival benefit for mice with *Cd47* KO tumors, suggesting immune- and proliferation-independent, cell-intrinsic functions of *Cd47* may also regulate NSCLC growth and progression.
Conclusions: Our results confirm the therapeutic potential of Cd47-targeted IO in NSCLC. The increased infiltration of anti-tumor lymphocytes and myeloid cells in *Cd47* KO tumours supports a role for the immune system in mediating enhanced survival. However, because immune deficient mice with *Cd47* KO tumors also exhibited a survival benefit, additional studies are required to deduce how *Cd47*-regulated cell-intrinsic mechanisms promote NSCLC biology. Our findings warrant further preclinical research to define effective anti-CD47 strategies for NSCLC.

Development of an aerosol-based immunotherapy for lung cancer
Yongren Li[1], Zhen Zhao[2], John Fetse[3], Reaid Hasan[3], Umar-Farouk Mamani[1], Yuhan Guo[3], Kun Cheng[3]. *[1]University of Missouri - Kansas City, Kansas City, MO,[2]School of Health Science & Biomedical Engineering, Hebei University of Technology, Hebei, China,[3]School of Pharmacy, University of Missouri - Kansas City, Kansas City, MO*

Lung cancer is one of the leading causes of cancer death and the second most cancer in the world. Compared to systematic administration, local delivery of therapeutic agents to the lung increases their accumulation in lung cancer cells and reduces the toxicity in other organs. We previously discovered an anti-PD-L1 peptide that can be potentially uses for lung cancer therapy. This project aims to develop an aerosolized formulation of the anti-PD-L1 peptide for the treatment of lung cancer. We hypothesize that the aerosolized peptide has higher accumulation in the lung compared to systematic formulations, leading to high therapeutic index with less side effects. We developed a spray freeze-drying procedure and optimized the formulation to prepare the peptide dry powders. The median mass aerodynamic diameter (MMAD) and geometric standard deviation (GSD)

of the aerosols were determined by an 8-stage Andersen Cascade Impactor. The morphology of the aerosols was studied using a scanning electron microscope (SEM). The stability of the aerosols in lung fluid was evaluated. Blocking assay suggested that the aerosolized formulation maintains the blocking efficiency of the peptide. Intratracheal administration of the peptide dry powder shows a high accumulation of the peptide in the lung.

Anti-HVEM mAb therapy improves antitumoral immunity both *in vitro* and *in vivo*, in a novel transgenic mouse model expressing human HVEM and BTLA molecules challenged with HVEM expressing tumors

Laurent GORVEL[1], Clemence Demerle[1], Marielle Mello[2], Sonia Pastor[1], Clara Degos[1], Ana Zarubica[2], Fabien Angelis[2], Frederic Fiore[2], Jacques Nunes[1], Bernard Malissen[2], Laurent Greillier[3], Geoffrey Guittard[1], Herve Luche[2], Fabrice Barlesi[4], Daniel Olive[1]. *[1]Centre de Recherche en Cancérologie de Marseille (CRCM), Marseille, France,[2]Centre d'Immunophénomique - CIPHE (PHENOMIN), Marseille, France,[3]Aix Marseille University, APHM, INSERM, CNRS, CRCM, Hôpital Nord,, Marseille, France,[4]Multidisciplinary Oncology and Therapeutic Innovations, Aix Marseille University, CNRS, INSERM; Gustave Roussy Cancer Campus, Marseille, France*

TNFRF-14/HVEM is the ligand for BTLA and CD160 negative immune co-signaling molecules as well as viral proteins. Its expression is dysregulated with an overexpression in tumors and a connection with tumors of adverse prognosis. We developed C57BL/6 mouse models co-expressing human huBTLA and huHVEM as well as antagonistic monoclonal antibodies (mAbs) that completely prevent the interactions of HVEM with its ligands. Here, we show that the anti-HVEM18-10 mAb increases primary human αβ-T cells activity alone (CIS-activity) or in the presence of HVEM-expressing lung or colorectal cancer cells *in vitro* (TRANS-activity). Anti-HVEM18-10 synergizes with anti-PD-L1 mAb to activate T cells in the presence of PDL-1 positive tumors, but is sufficient to trigger T cell activation in the presence of PD-L1 negative cells. In order to better understand HVEM18-10 effect *in vivo* and especially disentangle its

CIS and TRANS effects, we developed a knock-in (KI) mouse model expressing human BTLA (huBTLA$^{+/+}$) and a KI mouse model expressing both human BTLA and human HVEM (huBTLA$^{+/+}$ /huHVEM$^{+/+}$ (DKI)). *In vivo* pre-clinical experiments performed in both mouse models showed that HVEM18-10 treatment was efficient to decrease human HVEM+ tumor growth. In the DKI model, anti-HVEM 18-10 treatment induces a decrease of exhausted CD8^{+} T cells and regulatory T cells and an increase of Effector memory CD4^{+} T cells within the tumor. Interestingly, mice which completely rejected tumors (± 20%) did not develop tumors upon re-challenge in both settings, therefore showing a marked T cell-memory phenotype effect. Altogether, our preclinical models validate anti-HVEM18-10 as a promising therapeutic antibody to use in clinics as a monotherapy or in combination with existing immunotherapies (anti-PD1/anti-PDL-1/anti-CTLA-4).

Intratumoral *Escherichia* is associated with response to single-agent immune checkpoint inhibition in patients with advanced non-small cell lung cancer

Arielle Elkrief, Anita S. Bowman, Ayyuce Begum Bektas, Wenfei Kang, Katia Manova-Todorova, Jacklynn V. Egger, Hira Rizvi, Daniel Kelly, Eric Chan, Eric Rosiek, Fan Ning, Gregory J. Riely, Álvaro Quintanal Villalonga, Snjezana Dogan, Umesh Bhanot, Mithat Gonen, Matthew D. Hellmann, Adam J. Schoenfeld, Charles M. Rudin, Marc Ladanyi, Chad M. Vanderbilt. *Memorial Sloan Kettering Cancer Center, New York, NY*

The impact of the intratumoral microbiome on immune checkpoint inhibitor (ICI) efficacy in patients (pts) with non-small cell lung cancer (NSCLC) is unknown. In preclinical studies, the presence of lung intratumoral *Escherichia* was associated with a proinflammatory tumor microenvironment and decreased metastases within lung tissue. We sought to detect intratumoral bacteria in pts with advanced NSCLC using hybrid capture-based, next generation sequencing (NGS). We studied 849 pts treated with ICI-based therapy who underwent NGS at our center. We extracted unmapped reads from BAM files, and these were queried for bacteria (blastn alignment using the NCBI database). Putative environmental contaminants were subtracted from the analysis using “no

template" controls (n=2,539) to exclude possible artifactual false positives. A custom *E.Coli* fluorescence in situ hybridization (FISH) probe was used to visualize *Escherichia* within the tumors after co-registration with H&E. In 849 pts, a median of 30 bacterial reads was detected per sample (inter-quartile range (18-85)). Among 68 pts with paired primary/metastatic samples, the bacterial spectra were similar in both sites, suggesting that tumor resident bacteria might travel with cancer cells to distant sites. Antibiotic use within 30 days of tumor sampling was associated with decreased intratumoral bacterial diversity (p=0.023 by Inverse Simpson, p=0.038 by Shannon). Intratumoral *Escherichia* was associated with better PFS (HR 0.78, 95% CI 0.62-0.98, p=0.036), and OS (HR 0.74, 95% CI 0.58-0.95, p=0.017) in pts treated with single-agent ICI, but not combination Chemo/ICI. In a multivariable model adjusting for prognostic features in NSCLC including PD-L1 tumor proportion score, the presence of intratumoral *Escherichia* was associated with better PFS (p=0.040) and OS (p=0.045) upon single-agent ICI therapy. *Escherichia* appeared to be intracellular based on co-registration of FISH staining and serial H&E sections. These findings warrant further investigation of the possible inter-relationships between intratumoral *Escherichia*, tumor immune micro-environment, and ICI therapeutic outcomes.

New Opportunities for Combinatorial Immunotherapies

Harnessing macrophages, while protecting T cells, enhances anti-tumor efficacy

Sean A. Yamada-Hunter[1], Johanna Theruvath[1], Molly T. Radosevich[1], Brianna J. McIntosh[2], Katherine A. Freitas[1], Naiara Martinez-Velez[1], Elena Sotillo[1], Amaury Leruste[1], Peng Xu[1], Moksha H. Desai[1], Bita Sahaf[1], Allison Banuelos[3], Savannah L. Wasserman[1], Irving L. Weissman[3], Jennifer R. Cochran[4], Crystal L. Mackall[1]. *[1]Center for Cancer Cell Therapy, Stanford University School of Medicine, Stanford, CA,[2]Cancer Biology Program, Stanford University School of Medicine, Stanford, CA,[3]Institute for Stem Cell Biology and Regenerative Medicine, Stanford University School of Medicine, Stanford, CA,[4]Department of Bioengineering, Stanford University, Stanford, CA*

Chimeric antigen receptor T (CAR T) cells are synthetically engineered to target specific tumor antigens. CD47 is a ubiquitous receptor that serves as a “don’t eat me” signal by binding to SIRPα on macrophages and is often over-expressed by cancer cells. Despite individual promise of CAR T and anti-CD47 therapies, neither has demonstrated clear efficacy in treating solid tumors in the clinic and there is thus an urgent need to develop novel approaches that enhance the potency of these therapies. We interrogated the potential pairing of CAR T with anti-CD47 therapy to overcome tumor resistance mechanisms inherent to each therapy alone, by engaging non-redundant properties of two arms of the immune system. However, upon coadministration of anti-CD47 therapy and CAR T cells across multiple tumor models *in vivo*, we observed potent and consistent macrophage-mediated clearance of CAR-T cells via on-target, off-tumor binding of anti-CD47 therapies to CAR T cells. This anti-CD47 mediated CAR T cell depletion blunts the therapeutic benefits of treatment and renders the pairing of the current versions of the two agents impractical.To overcome this challenge, we used directed evolution and yeast surface display to engineer a novel variant of CD47 (eCD47) with selective binding, identifying mutations that resulted in loss of binding to the anti-CD47 antibody B6H12, while maintaining the CD47 “don’t eat me” function through binding to SIRPα, which is essential for T cell persistence *in vivo*. T cells engineered to express eCD47, but not native, wild-type CD47, were resistant to targeting by multiple anti-CD47 antibodies but maintained binding to SIRPα. These T cells were no longer susceptible to anti-CD47 mediated macrophage phagocytosis *in vitro,* nor were they depleted *in vivo* after B6H12 administration. We demonstrated a striking improvement in therapeutic efficacy upon treatment of multiple solid tumor models when anti-CD47 therapy was combined with CAR T cells expressing eCD47, compared to combination with CAR T cells expressing wild-type CD47. We interrogated a mechanistic basis for this improved efficacy in an osteosarcoma model through single-cell RNA-sequencing of isolated tumors. We discovered that CAR T treatment led to a large influx of unique populations of macrophages into the tumor, which were lost upon CAR T depletion after anti-CD47 treatment. These T cell recruited-macrophages were maintained after anti-CD47 treatment in the presence of CAR T cells expressing eCD47, harnessing macrophage mediated anti-tumor activity

after combination treatment. Thus, for the first time, eCD47 allows for effective pairing of CAR T therapy and anti-CD47 therapy for cancer treatment, by sparing T cells from macrophage mediated depletion, and revealing impressive synergy when adoptive T cell therapy is combined with macrophage activation.

Pharmacologic modulation of RNA splicing enhances anti-tumor immunity

James D. Thomas[1], Sydney X. Lu[2], Emma De Neef[1], Erich Sabio[3], Benoit Rousseau[3], Mathieu Gigoux[3], David A. Knorr[3], Benjamin Greenbaum[3], Yuval Elhanati[3], Simon J. Hogg[3], Andrew Chow[3], Arnab Ghosh[3], Abigail Xie[3], Dmitriy Zamarin[3], Daniel Cui[3], Caroline Erickson[3], Michael Singer[3], Hana Cho[3], Eric Wang[3], Bin Lu[3], Benjamin H. Durham[3], Harshal Shah[3], Diego Chowell[4], Austin M. Gabel[1], Yudao Shen[5], Jing Liu[5], Jian Jin[5], Matthew C. Rhodes[6], Richard E. Taylor[7], Henrik Molina[8], Jedd D. Wolchok[3], Taha Merghoub[3], Luis A. Diaz Jr[3], Omar Abdel-Wahab[3], Robert K. Bradley[1]. *[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]Stanford Medical School, Stanford, CA,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]Cleveland Clinic, Cleveland, OH,[5]Icahn School of Medicine at Mount Sinai, New York, NY,[6]University of Notre Dame, Notre Dame, IN,[7]Department of Chemistry & Biochemistry, Notre Dame, IN,[8]The Rockefeller University, New York, NY*

Immune checkpoint blockade therapy has revolutionized cancer care, including the treatment of advanced metastatic disease. However, most patients derive little or no clinical benefit from these therapies and many cancer types are notoriously non-responsive. Motivated by (1) the correlation between tumor neoantigen abundance and anti-tumor immunity and (2) that most cancers are characterized by widespread dysregulation of RNA processing, we reasoned that pharmacologic modulation of RNA splicing might increase cancer cell immunogenicity via the generation of splicing-derived neoantigens. We demonstrated that two compounds which modulate RNA splicing via distinct mechanisms, inhibited tumor growth and enhanced response to immune checkpoint blockade in a manner dependent on host T cells and peptides presented on tumor MHC class I.

Critical for their clinical translatability, therapeutic doses of splicing inhibitors were non-toxic, tolerated by the host immune system, and did not affect T cell activation, proliferation, and anti-cancer killing activities. Mechanistically, splicing modulation induced stereotyped, dose-dependent "splicing failure" — dramatic intron retention, alternative exon skipping, etc. — that was consistent across multiple mouse and human tumor types. By combining RNA-seq-based peptide predictions and mass spectrometry of the MHC I-bound immunopeptidome, we identified drug-induced, splicing-derived peptides that promote the expansion of antigen-specific CD8+ T cells and trigger anti-tumor T cell responses in vivo. These data definitively identify splicing modulation as an untapped source of immunogenic peptides and provide a means to enhance response to checkpoint blockade that is readily translatable to the clinic.

#5743

Reprogramming myeloid cells by JAK inhibition to enhance checkpoint blockade immunotherapy

Jaroslav Zak[1], Isaraphorn Pratumchai[1], Brett S. Marro[1], Kristi L. Marquardt[1], Michael B. A. Oldstone[1], Judith A. Varner[2], Veronika Bachanova[3], John R. Teijaro[1]. *[1]The Scripps Research Institute, La Jolla, CA,[2]Moores Cancer Center, University of California, San Diego, La Jolla, CA,[3]Division of Hematology, Oncology and Transplantation, University of Minnesota, Minneapolis, MN*

Background: Checkpoint inhibitors have achieved a wide adoption for treatment of advanced cancer, but the majority of patients fail to respond. Among the underlying causes are redundant mechanisms driving cytotoxic lymphocyte dysfunction. Motivated by the discovery of JAK inhibitors as hit compounds in a screen for the reversal of T cell exhaustion, this study investigates the hypothesis that JAK inhibition could enhance the efficacy of checkpoint inhibitors.
Methods: Murine immunocompetent models of cancer were utilized (A20, EL4, LLC1, MC38). The combination therapy of systemic treatment with the JAK inhibitor ruxolitinib with anti-PD1 + anti-CTLA4 was evaluated for efficacy and biomarkers compared to checkpoint inhibitors (ICI) alone. Tumor-infiltrating, blood and lymphoid organ immune cells were phenotyped using single-cell transcriptomics, functional assays and flow

cytometry. The combination therapy was clinically tested in an investigator-initiated Phase I/II clinical trial of ruxolitinib with nivolumab in relapsed or refractory Hodgkin lymphoma (NCT03681561). Patients who previously failed to respond to ICI received ruxolitinib for 1 week then nivolumab every 4 weeks concurrent with ruxolitinib twice daily. Peripheral blood was collected at baseline, 1 week after ruxolitinib and 4 weeks after 1st nivolumab dose. Hematologic and transcriptomic analyses were performed on peripheral blood samples.
Results: The ruxolitinib + ICI combination was superior to ICI in 3/4 of the tumor models examined in controlling tumor growth. Tumor sizes were reduced by >50% in the MC38 (mean volume 123.1 vs 283.2 mm^3, ICI + rux vs ICI, respectively, n=9 per group, ANOVA p=0.0094), LLC1 and A20 models (survival hazard ratio 0.24, ICI + rux vs ICI, n=8 per group, p=0.048). Remarkably, we observed a broad shift of tumor monocytes and granulocytes from a suppressive into an immunostimulatory state characterized by the expression of MHC molecules and the ability to stimulate T cell proliferation. Hodgkin lymphoma patients in the ruxolitinib with nivolumab trial exhibited an interim disease control rate of 76% (13/17). Ruxolitinib treatment in these patients did not impair T cell cytokine production but significantly reduced the neutrophil-to-lymphocyte ratio (NLR, mean difference -0.82, n=14, p=0.0023) and the expression of myeloid derived suppressor cell markers in monocytes (normalized enrichment score -1.74, n=14, q<0.001) compared to pre-treatment. The reduction in NLR was significantly greater in complete responders than in progressive disease patients (mean -2.6 vs -0.58, respectively, p=0.023).
Conclusions: The combination of ruxolitinib with ICI was effective in preclinical models of cancer and in a Phase I/II Hodgkin lymphoma clinical trial. Unexpectedly, JAK inhibitor-mediated reprogramming of myeloid cells and the associated enhanced T cell activity may be important for the observed efficacy.

#5744

Decreasing toxicity of immunocytokines by transient and selective inhibition of their intracellular signaling activation

Giulia Rotta[1], Ettore Gilardoni[2], Domenico Ravazza[2], Jacqueline Mock[3], Samuele Cazzamalli[4], Roberto De Luca[1], Emanuele Puca[3], Dario Neri[3], Sheila Dakhel Plaza[1]. [1]*Therapeutic Antibodies, Philochem AG, Otelfingen,*

Switzerland,[2]Bio-MS, Philochem AG, Otelfingen, Switzerland,[3]Philochem AG, Otelfingen, Switzerland,[4]Chemistry, Philochem AG, Otelfingen, Switzerland

The use of cytokine-based therapeutics has traditionally been limited by systemic toxicity, but it is now becoming evident that it may be possible to circumvent this problem in a number of ways. Tumor-targeting antibody-cytokine fusion proteins (also called “immunocytokines”) typically allow dose escalation to therapeutically active regimens as a result of their selective localization at the site of disease (Neri 2019; Helguera, Morrison, and Penichet 2002). Despite the enhancement of the therapeutic index, when the concentration of the payload in blood exceeds a certain threshold, patients may experience dose-limiting immune-related adverse events (irAEs). In most cases, irAEs disappear when the immunocytokine is cleared from circulation (Ko et al. 2004; Spitaleri et al. 2013; Rudman et al. 2011). Here, we describe an innovative approach to mask off-target activity of immunocytokines by transient inhibition of their intracellular signaling cascade. Small molecules are particularly attractive for this application since their serum half-life matches the clearance rate of the immunocytokine from circulation. L19-TNF and L19-IL12 are two clinical-stage antibody-cytokine fusion proteins that display potent activity by triggering the receptor-interacting serine/threonine-protein kinase 1 (RIPK1) and Janus Kinase 2 (JAK2) signaling pathways, respectively (Amin et al. 2018; Hu et al. 2021). In a first study, GSK’963, a potent small molecule inhibitor of RIPK1, was tested in tumor-bearing mice with the aim to reduce acute systemic toxicity associated with TNF signaling. Transient inhibition of RIPK1 allowed the administration of L19-murTNF doses which would otherwise be lethal. The combination with GSK’963 did not affect the selective localization of the immunocytokine to tumors. Moreover, L19-murTNF was still able to induce tumor necrosis and to exert potent anti-cancer activity. In a second study, tumor-bearing mice receiving L19-murIL12 were pretreated with Ruxolitinib, a commercially available JAK2 inhibitor. The addition of Ruxolitinib could significantly improve the tolerability profile of L19-murIL12 without affecting the anti-cancer properties of the immunocytokine. In clinical trials, it has been observed that IL12 treatment can induce cytokine release syndrome and liver damage (Atkins et al. 1997). Our data demonstrate that the pre-treatment with

Ruxolitinib restricted the pro-inflammatory effects of L19-murIL12 to the tumor site, protecting the mice from body weight loss as well as reducing blood cytokine levels and hepatotoxicity. Overall, this preclinical work is of clinical relevance, as patients treated with targeted cytokines could potentially benefit from judicious combinations treatments using small molecule inhibitors.

Proposing the best MET inhibitor to improve anti-PD-1 efficacy in HCC

Ricardo A. de Azevedo, Broderick Turner, Priyamvada Jayaprakash, Krithikaa Rajkumar Bhanu, Anupallavi Srinivasamani, Brittany Morrow, Michelle Winkler, Shweta Mahendra Hedge, Arthur Liu, Ravaen Slay, Michael A. Curran. *Department of Immunology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Despite recently approved immunotherapy combinations, Hepatocellular carcinoma (HCC) remains among the most therapeutically intractable cancers with a 5-year survival rate of only 18%. Underlying chronic liver disease due to hepatitis B/C infection, alcohol abuse, hemochromatosis, or nonalcoholic steatohepatitis promotes HCC development. Current therapeutic strategies include surgery, radiotherapy and multikinase inhibitors alone or with immune-checkpoint blockade (ICB). In particular, the receptor tyrosine kinase MET and its ligand hepatocyte growth factor (HGF) are known drivers of HCC through promotion of tumor growth, survival, tissue invasion, and angiogenesis. Previously, our collaborators showed that the limited clinical benefit of MET kinase inhibition was partially a result of induced upregulation PD-L1 leading to local T cell suppression. We hypothesized that combining MET inhibition with blockade of the PD-1 immune checkpoint would overcome the limitations of each individual approach and act synergistically to promote HCC tumor regression. We first validated that both MET selective (Capmatinib and Tivantinib) and non-selective (Cabozantinib) inhibitors all induced PD-L1 on HCC cell lines in vitro. Next, we compared Capmatinib and Cabozantinib alone and with PD-1 ICB in vivo in the ICB-sensitive Hepa1-6 and HCA-1 models of HCC. In HCA-1, statistically significant benefit of the MET inhibitor and αPD-1 combination was evident in limitation of

tumor growth and extension of survival. In each case, the Capmatinib combination trended toward better outcomes with PD-1 blockade. Mechanistically, the Capmatinib and αPD-1 combination decreased tumor Treg cells while promoting increased accumulation of activated, non-exhausted, proliferating CD8 T cells. Central memory CD8 T cell frequencies were increased by the combination during the effector phase, and combination treated animals were better protected against subsequent rechallenge than those cured by αPD-1 alone. In the myeloid compartment, M1 macrophage frequencies were increased while PMN-MDSC both decreased in frequency and in Arginase 1 levels. Finally, we studied a serially-passaged, αPD-1 refractory DEN HCC model. Despite lack of efficacy of either component therapy, the MET inhibitor and αPD-1 combination significantly extended survival and inhibited tumor growth. As in the αPD-1 sensitive setting, Capmatinib appeared to offer the most therapeutic benefit with αPD-1. Ongoing studies are focused on characterizing changes mediated by the combination therapy which confer aPD-1 sensitivity to the otherwise refractory DEN HCC tumor microenvironment. Molecular studies are focused on understanding the superior ICB potentiating capacity of Type I MET inhibitors versus the other classes. Given the clinical availability of numerous MET and PDL-1 inhibitors, we hope to inform near-term optimization of MET and αPD-1 clinical trial design for HCC.

Flexible tumor-specific cytokine and antigen delivery through the T-SIGn vector platform enables effective CAR-T cell therapy against solid tumors

Maria Stella Sasso, Rachel Bergin, Rochelle Lear, Darren Plumb, Manuela Zonca, Eva Vainiute, Meg Snowden, Tae Hyun Jang, Alice Muntzer, Carla C. Cerqueira, Katy West, Samantha Bucktrout, Brian R. Champion.
PsiOxus Therapeutics Ltd, Abingdon, United Kingdom

Efficacy of Chimeric Antigen Receptor (CAR) T cell therapy against solid tumors is hampered by multiple barriers, including tumor-associated immunosuppression, poor CAR-T cell trafficking into solid tumor masses and shortage of highly expressed cancer-specific target antigens. The T-SIGn (Tumor Specific ImmunoGene) platform generates viral vectors that

can produce combinations of transgenes selectively within the tumor microenvironment (TME). T-SIGn is clinically validated for intravenous (i.v.) delivery, enabling vectors to reach primary and metastatic sites to produce their therapeutic payloads specifically in malignant epithelial cells. Using an A549 human tumor xenograft and metastasis model, we previously demonstrated that i.v. administration of a T-SIGn vector encoding IFNα, MIP1α and CD80 results into potentiated CAR-T cell activation and therapy efficacy (Sonzogni et al. 2022). Here, we further evaluated the potential of T-SIGn combination with Cell Therapy by investigating the impact on CAR-T cell activity of vectors encoding different arrays of cytokines and chemokines. Using an *in vivo* A549 model and anti-HER2 CAR-T cells in NSG mice, we demonstrated that T-SIGn vectors can enable effective CAR-T cell therapy against solid tumors by providing diverse localized cytokine/chemokine-mediated T cell boosting, with IL-12-encoding vectors resulting in complete and durable tumor clearance. Furthermore, we explored the use of the T-SIGn platform to encode secreted bispecific "adaptor" molecules able to simultaneously bind to a tumor surface antigen and to a CAR specific for an antigen not naturally expressed by the tumor, allowing the redirection of CAR-T cells against desired tumor types. We designed a vector (NG-1125) encoding an anti-HER2 ScFv_CD19 bispecific construct as a model "adaptor" molecule, together with IFNα and CXCL9, and we showed that this construct can effectively redirect anti-CD19 CAR-T cell against $HER2^{+}CD19^{-}$ tumor cells. *In vitro* X-CELLigence-based cytotoxicity assays demonstrated killing of both $HER2^{+}CD19^{-}$ A549 and SKOV3 cells by anti-CD19 CAR-T cells in presence of vector-derived anti-HER2 ScFv_CD19. Following i.v. NG-1125 dosing of A549 tumor-bearing mice, *ex vivo* flow cytometry analysis of tumor masses revealed binding of the encoded adaptor molecule to both vector-infected and uninfected tumor cells. Furthermore, *in vivo* NG-1125 administration together with anti-CD19 CAR-T cells resulted into increased intra-tumoral densities of transferred T cells. Collectively, these data show the potential of T-SIGn vectors in overcoming solid tumor resistance mechanisms to CAR-T and pave the way for the development of other immunotherapeutics to be expressed within the TME via T-SIGn vectors in combination with CAR or TCR-based therapies.

A novel combination therapy of arenavirus vectors and PD1-IL2v strongly potentiates tumor specific T cell responses resulting in synergistic anti-tumor efficacy

Judith Strauss[1], Diana Reckendorfer[1], Kimberly Pojar[1], Laura Codarri Deak[2], Valeria Nicolini[2], Roger Sutmuller[2], Christian Klein[2], Pablo Umaña[2], Klaus K. Orlinger[1], Henning Lauterbach[1]. *[1]HOOKIPA Pharma Inc, New York, NY,[2]Roche Innovation Center Zurich, Schlieren, Switzerland*

It is undisputed that CD8 T cells play a critical role in controlling tumor growth and killing tumor cells, and that tumor specific T cells are essential for clinical responses to immune checkpoint inhibitors. Yet, the induction and maintenance of functional tumor antigen specific T cell responses represent still one of the greatest challenges in cancer immunotherapy. Therapeutic cancer vaccines based on engineered arenavirus vectors have been shown preclinically to overcome self-tolerance to tumor associated antigens (TAA) and mount unprecedented T cell responses, both, in preclinical tumor models as well as HPV16+ cancer patients in an ongoing Phase 1/2 trial. The novel PD-1 targeted IL-2 variant (PD1-IL2v) was created to maximize the potency of IL-2R activation of effector T cells while overcoming the toxicities of wildtype IL-2. *Cis* binding of PD1-IL2v to PD-1 and IL-2Rβγ on the same cell was recently shown to promote differentiation of stem-like CD8 T cells into better effectors and was therefore identified as an ideal compound for combination therapies with arenavirus vectors. Combination of vectors encoding tumor associated foreign or self-antigens with PD1-IL2v lead to a massive, up to 60-fold, increase of peripheral tumor specific CD8 T cell numbers compared to vector treatment alone. Notably, frequency of peripheral regulatory T cells was not enhanced by this combination. The massive increase of TAA specific CD8 T cells was associated with synergistic anti-tumor efficacy in two independent tumor models, resulting in longer survival times and up to 60% complete responders. Complete tumor clearance resulted in a stable memory T cell population and protection against tumor re-challenge. Ongoing studies will address modifications of the tumor microenvironment and further characterization of tumor infiltrating T cells upon combination therapy.

These preclinical data establish the combination of arenavirus vectors and PD1-IL2v as a promising next generation cancer immunotherapy.

Novel Preclinical Models for Cancer Immunotherapy

#5188

Interrogating the role of the immune microenvironment in the response of brain metastases to immunotherapy using new preclinical melanoma models

Amélie Lopès[1], Jessica Rappaport[1], Eva Pérez Guijarro[2], Quanyi Chen[3], Emily Wu[2], Isabella Church[2], April Huang[4], Jessica Bridge[5], Sung Chin[5], Cari Smith[5], Charli Gruen[2], Khiem C. Lam[1], Romina E. Araya[1], Antonella Sassano[2], Chi-Ping Day[2], Glenn Merlino[2], Romina S. Goldszmid[1].
[1]Inflammatory Cell Dynamics Section, Laboratory of Integrative Cancer Immunology, CCR, Inflammatory Cell Dynamics Section, Laboratory of Integrative Cancer Immunology, Center for Cancer Research, National Cancer Institute, Bethesda, MD,[2]Laboratory of Cancer Biology and Genetics, CCR, Laboratory of Cancer Biology and Genetics, Center for Cancer Research, National Cancer Institute, Bethesda, MD,[3]Inflammatory Cell Dynamics Section, Laboratory of Integrative Cancer Immunology, CCR, Inflammatory Cell Dynamics Section, Laboratory of Integrative Cancer Immunology, Center for Cancer Research, National Cancer Institute and Kelly Government Solutions, Bethesda, MD,[4]Inflammatory Cell Dynamics Section, Laboratory of Integrative Cancer Immunology, CCR, Inflammatory Cell Dynamics Section, Laboratory of Integrative Cancer Immunology, Center for Cancer Research, National Cancer Institute and Leidos biomedical research, Bethesda, MD,[5]Frederick National Laboratory for Cancer Research, National Cancer Institute, Frederick, MD

Brain metastases (BrM) remain an intractable, deadly complication for advanced melanoma patients and efficient therapeutic strategies are desperately needed. The tumor microenvironment (TME) plays an important role in response to therapy. However, studies addressing the contribution of the TME to therapy efficacy for BrM are lacking, mostly due to limited access to human samples and scarcity of appropriate preclinical models. Here, we describe two novel isogenic immunocompetent BrM models generated by intracardiac injection of UV-

induced mouse melanoma cell lines, representative of mutant-RAS human melanoma subtypes. We used these models to test immune checkpoint blockade (ICB) therapy and to interrogate the role of the TME in therapeutic efficacy. To evaluate response, we developed and applied a new machine-learning method to quantify metastatic burden. We investigated the TME by high-parametric flow cytometry and single-cell RNA sequencing (scRNA-seq). We showed that the models have distinct metastatic behaviors, with BR1 being mostly brain tropic and BR3 displaying widespread metastases. Notably, BR1 BrM were sensitive to ICB with a better response to anti-PD-L1/anti-CTLA-4 combination therapy as compared to monotherapies. In contrast, BR3 BrM were resistant to both mono- and combination therapies. Interestingly, we found that ICB efficacy on extracranial BR3 metastases is organ-dependent. Characterization of the BrM immune microenvironment before and after treatment revealed dramatic differences between the models. Untreated BR1 BrM showed significant recruitment of T cells, dendritic cells, and natural killer cells, while neutrophils were enriched in untreated ICB-resistant BR3 BrM. Moreover, we uncovered phenotypically distinct microglia populations exclusively present in ICB-sensitive BR1 BrM that positively correlated with T cell infiltration. Consistent with this finding, scRNA-seq showed upregulation of genes encoding for T cell-attracting chemokines and antigen presentation uniquely in the BR1-associated microglia. Post-treatment analysis of the brain TME highlighted beneficial changes induced by ICB in the responsive BR1 model, including increased recruitment of CD8 T cells with an activated phenotype, while a mild recruitment of exhausted T cells was observed in the resistant BR3 model. Altogether, our data emphasize the importance of interrogating the BrM TME to understand therapeutic response. Our unique BrM models, mirroring the diversity of ICB response observed in patients, provide a robust platform for the much-needed mechanistic studies to optimize BrM therapy. Deciphering the contribution of the newly identified BR1 BrM-associated microglia to ICB efficacy will be crucial to the identification of novel therapeutic targets.

Comparisons of Rituximab and CD19xCD3 BiTE antitumor response across multiple humanized NSG strains engrafted with human hematopoietic stem cells

Won Yeong Kang, Guoxiang Yang, Ilian Radichev, Li-Chin Yao, Mingshan Cheng, James G. Keck. *Innovation and Product Development, The Jackson Laboratory Sacramento, Sacramento, CA*

Humanized NSG mice engrafted with hematopoietic stem cells (HSCs) is a well-known in vivo platform for reconstitution of human immune system in a mouse host. In this study we tried to dissect the role of various human cytokines in the generation of the human immune system, expansion of human B cell lymphoma cells, and drug response to two anti-cancer therapies - Rituximab and CD19XCD3 BiTE (Bispecific T-cell Engager). To exclude donor variabilities, we first humanized five NSG-based, human cytokine-transgenic mouse strains (NSG, NSG-IL15, NSG-SGM3, NSG-SGM3-IL15, and NSG-FLT3L) with HSCs from one donor (0084). We found that tumor growth was enhanced in NSG-SGM3 mice when compared to NSG mice. In contrast, IL15 expression suppressed tumor growth in NSG-IL15 and NSG-SGM3-IL15 mice. Furthermore, NK cell frequencies in blood are higher in NSG-IL15 and NSG-SGM3-IL15 than in other strains. suggesting that NK cell-mediated cytotoxicity is involved in suppression of tumor cell growth in the strains expressing human IL-15. Rituximab treatment resulted in tumor growth inhibition and significant B cell depletions across NSG-IL15, NSG-SGM3, and NSG-SGM3-IL15 mice engrafted with 0084 PBMC. We also observed a donor variability of tumor growth rates in NSG-SGM3-IL15 mice engrafted with donors 0084, 0662A, and 0733. The tumor growth in NSG-SGM3-IL15 mice engrafted with 0084 PBMC was significantly slower than the one in mice engrafted with the other two donors (0084 vs. 0662A, P=0.002; 0084 vs. 0733, P=0.004 on day 21); interestingly, this strain of mice exhibited higher frequencies of $CD8^+$ T cells and lower frequencies of NK cells. Next, we tested CD19XCD3 BiTE treatment in multiple NSG strains engrafted with HSCs from different donors. The BiTE administration inhibited Raji tumor growth and significantly depleted B cells in all tested strains as NSG-SGM3-IL15 showed highest frequencies of NK cells and $CD8^+$ T cells. The combination of Rituximab and BiTE showed even better tumor inhibition efficacy. In conclusion, regardless of the donor and strain variations in tumor growth and human immune cell subset development, the administrations of rituximab or BiTE significantly and consistently inhibited tumor growth and depleted peripheral B cells across all mouse strains. These results

indicate that utilizing a comprehensive humanized mouse platform could drive more impactful conclusions in terms of evaluating the anti-tumor efficacy of immune therapies.

Systematic immune-profiling of immune-deficient mouse models: A rational to select ideal host for tumor implantation

Hervé Luche[1], Lillia Hadjem[1], Marielle Mello[1], Priscilla Canavese[1], Fabien Angelis[1], Anais Joachim[2], Sylvie Bouilly[3], Frederic Guinut[3], Frederic Fiore[1], Bernard Malissen[2], Ana Zarubica[1], Erwan Corcuff[3]. *[1]Immuno-Phenotyping Module, CIPHE, Marseille, France,[2]Immunomics, JC Discovery, Marseille, France,[3]Janvier labs, Laval, France*

Preclinical tumor oncology research relies historically on the analysis of mouse or human tumor cell lines implanted onto severely immune-deficient mouse models carrying nude, SCID or Rag mutations on different genetical background (C57Bl/6N, BalbC, NMRI, CB17 or NOD). These lines harbor defects in several leukocyte lineages among which Tc, Bc and NKc might be affected. Humanized mice are emerging models that have been transplanted with human cells or tissues (and/or equipped with human transgenes). Currently, the most advanced strains are the nonobese diabetic, severe combined immunodeficiency (NOD-SCID) mouse with complete disruptions in the interleukin-2 (IL-2) common γ-chain (IL2R γ null) receptor (NSG) and BALB/c $Rag2^{-/-}$ IL2R γ null $Sirpa^{NOD}$ mice (BRGS).[1] Juvenile chimera NSG or BRGS are reconstituted with hematopoietic progenitor cell (HPCs) from human cord blood yielding robust engraftment of a human immune system (HIS).. Recent work showing the binding of human IgG4 to mouse FcgR receptor reducing clinical efficacy of therapeutic antibodies highlights the need to characterize extensively the residual immune system present in these models prior humanization in order to precisely evaluate immunotherapies. In other to fulfill this task, we genetically modified the mouse genome introducing mutations involved in Tc, Bc and NKc development. We then immuno-phenotyped over 20 lines of mouse mutants produced from the same animal house to minimize the impact of microbiota on innate immune cell populations. High content cytometry analysis of BM, spleen, thymus and peripheral blood was performed in a standardized manner. The resource obtained of these

immunotypes was used to highlight similarities and differences among these lines across several genetical background. This work has shown instrumental in selecting the most appropriate model to use for humanization followed before tumor implantation.

#5191

Modeling age-related changes in the tumor microenvironment in an orthotopic immunocompetent murine pancreatic cancer model - a novel approach

Morgan M. Green, Tara Fujimoto, Cullen Taniguchi, Natalie Fowlkes. *UT MD Anderson Cancer Center, Houston, TX*

Pancreatic cancer is the third leading cause of cancer-related deaths in the U.S. and is most frequently diagnosed between the ages of 65-74 years. Only 11.5% of patients are expected to survive 5 years after diagnosis. There is extensive evidence that tumor microenvironment (TME) plays a critical role in cancer progression and metastasis. Despite the fact that most patients are diagnosed over the age of 60, most preclinical murine tumor models utilize young, healthy, adolescent mice, failing to account for structural and/or functional changes in stroma and immune cells that occur in tissues over time and contribute to tumor progression. Marked differences in lifespan between mice and humans preclude natural development of many age-related physiologic changes in mice that occur in humans over the course of decades. We performed a pilot study to test our hypothesis that KPC pancreatic tumors grown orthotopically in the pancreas of genetically engineered, C57BL/6-Tg (LMNA*G608G) HClns/J mice, a model of Hutchinson-Gilford progeria syndrome with features of accelerated aging, would have altered tumor growth in comparison to tumors in age-matched wild type controls. We found that tumor growth in LMNA mice outpaced that of WT mice. Quantitative digital image analysis showed significantly reduced intratumoral infiltration of CD45+ leukocytes in LMNA mice in comparison to WT ($p=0.0098$). There was a significant reduction in tumor-infiltrating CD3+ T cells ($p=0.038$) and F4/80+ macrophages ($p=0.0102$). Our data supports the hypothesis that functional, age-related, immune and/or stromal changes in the TME impact pancreatic tumor growth and progression. Innovative strategies that better model age-

related changes in the TME may better recapitulate the aggressive course of pancreatic cancer in aged patients.

#5192

NCG-MHC-dKO mice: an excellent model for PBMC reconstitution and pharmacodynamic evaluation in the absence of GvHD

Huiyi Wang[1], Jun Xing[1], Jialu Fan[1], Huanhuan Hou[1], Santi Suryani Chen[2], Zhiying Li[2], Mark Wade Moore[2], Jing Zhao[1], Xiang Gao[1], Cunxiang Ju[1].
[1]GemPharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA

Human immune cell reconstitution (PBMC or $CD34^+$ hematopoietic stem cell; HSC) is commonly performed in immunodeficient mouse strains such as NCG, NSG, or NOG. The use of PBMC is preferred for multiple reasons, including faster engraftment, lower cost, and the presence of mature immune cell populations. Although there are donor-to-donor variations in GvHD occurrence, and specific donors can be screened, the symptoms of GvHD typically occur within 4 weeks. GvHD significantly limits the study window required to evaluate the efficacy of therapeutic agents, such as cancer immunotherapies.

GvHD is an immune reaction triggered mainly by donor T cells identifying the mouse MHC class I and class II as foreign and attacking the host cells and organs. Deletion of β2m (NCG- β2m-KO) reduces the occurrence of GvHD; however, β2m is not only in the MHC class I subunit but also in the FcRn subunit, of which deletion shortens the half-life of IgG, making it unsuitable for IgG antibody agent evaluation. In addition, the deletion of MHC class I or class II alone results in an imbalanced CD4/CD8 ratio. To solve these problems, we developed the NCG-MHC-dKO mouse model by knocking out the *H2K1, H2D1,* and *H2Ab1* genes. Compared with the existing NCG- β2m-KO or other β2m null mouse models, the NCG-MHC-dKO significantly prolonged survival, reduced GvHD occurrence, and did not affect the CD4/CD8 ratio when reconstituted with PBMC. Furthermore, treatment with anti-PD-L1 antibodies significantly inhibited MDA-MB-231 tumor cell growth in PBMC-reconstituted NCG-MHC-dKO mice, similar to NCG mice. Based on our preliminary data, the NCG-MHC-dKO mouse is a promising model for antibody and cell therapy agent evaluation, assessing

treatment-related cytokine release syndrome, and evaluating long-term toxicities of cell therapies.

#5193

Assessing the efficacy of immune checkpoint blockade as part of a combination therapy in a zebrafish model of rhabdomyosarcoma

Madeline Fritzke, Andrea Largent, Eleanor Chen. *Univ. of Washington School of Medicine, Seattle, WA*

Rhabdomyosarcoma (RMS) is a rare and devastating pediatric soft tissue cancer. There is urgent need to identify more effective therapy options for children suffering from RMS. Immune checkpoint blockade (ICB) has shown promise in several sarcoma types including RMS. In some cancer types, ICB shows enhanced efficacy in combination with a chemotherapeutic agent or an inhibitor against the epigenetic modifiers. Selective chemotherapeutic agents and epigenetic inhibitors (e.g. histone deacetylase inhibitors) have also been shown to increase tumor immunogenicity and sensitize tumor cell response to immune checkpoint inhibitors. However, it remains to be further investigated in RMS how chemotherapy and epigenetic inhibitors modulate immune cell landscape and function and whether the efficacy of ICB combined with either a chemotherapeutic agent or an epigenetic inhibitor is enhanced compared to ICB monotherapy. There is currently no tractable mammalian model for assessing the efficacy of immunotherapy in RMS. Taking advantage of the conserved immune and cancer biology, short tumor onset, high-throughput capability of the zebrafish RMS model, our ongoing research is assessing 1) the efficacy of ICB combined with either a chemotherapeutic agent or an epigenetic inhibitor (histone deacetylases [HDACs] or DNA methyltransferases [DNMTs]) compared to ICB monotherapy on inhibiting RMS tumor growth; 2) effects of chemotherapy and epigenetic inhibition on the make-up and function of tumor-infiltrating immune cells. Our preliminary data so far showed that treatment of zebrafish RMS tumors with the combination of the standard-of-care chemotherapeutic agent, temozolomide, and the immune checkpoint inhibitor, nivolumab, showed increased T cell infiltration. By expression profiling, both temozolomide and nivolumab decreased expression levels of markers for immune checkpoint (pdl1, havcr2) and regulatory T cells (foxp3a) and increased

expression levels of markers for inflammatory response (tnfa and infg1). By developing an immune-competent animal model for large-scale testing of important immunotherapy targets and characterizing the immune cell types in the tumor microenvironment of RMS in response to therapy, our research will establish the zebrafish model as a pre-clinical screening tool for testing promising immunotherapeutic agents *in vivo*, which will facilitate the process of prioritizing promising immunotherapy targets for testing in pre-clinical models and clinical trials and in turn provide therapeutic benefits to children with RMS.

#5194

Humanized PD-1 knock-in mice as a model system for combination therapies with human specific PD-1 therapeutics

Philipp Metzger[1], Fabiane Sônega[2], Hervé Berthomme[2], Cynthia Obodozie[1], Holger Weber[1]. *[1]Reaction Biology Europe GmbH, Freiburg, Germany,[2]genOway, Lyon, France*

Checkpoint inhibitor treatment has become a common therapy for various cancer types. As an escape mechanism, tumor cells express PD-L1 on their surface, as a ligand for PD-1 with players of the immune system (such as T cells), aimed at preventing the immune system from exerting its anti-tumour activities. Antibodies blocking the PD-L1/PD-1 interaction have emerged as front-line treatments for various oncological indications. Several anti-PD-L1 and anti-PD-1 therapeutics are already approved and in clinical use. For preclinical testing of such human specific antibodies, syngeneic tumour models are of limited use due to the limited cross-specificity of such antibodies, giving rise to the development of humanized mouse models in which combination therapies testing new drugs with already clinically approved human checkpoint inhibitors addressing human specific targets can be evaluated.
The anti-tumor efficacies of pembrolizumab (Keytruda) a human specific anti-hPD-1 checkpoint inhibitor and the mouse specific anti-mPD-1 counterpart (clone RPMI1-14) were tested in C57BL/6 wildtype and humanized hPD-1 C57BL/6 mice engrafted with syngeneic MC38-CEA colorectal carcinoma cells. The MC38-CEA tumor cells were implanted into the mammary fat pad (subQperiorTM), a procedure that prevents tumor ulceration and leads to a more homogenous tumor growth compared to

subcutaneous implantation. Treatment with pembrolizumab extended the survival of tumor-bearing human PD-1 C57BL/6 mice significantly, whereas no effect in C57BL/6 wildtype mice was observed, in line with the reported specificity of Keytruda towards the human version of PD-1. Further supporting this finding, the application of the anti-mPD-1 antibody led to a prolonged survival of C57BL/6 mice with no life extension of hPD-1 C57BL/6 mice.
The validation of the humanized subQperior™ platform was further complemented by conducting flow cytometry analysis of intra-tumoral immune populations present in tumor tissues at 7 days post-treatment. Two staining panels were executed: a well-established and validated 17 marker staining allowing to quantify the frequency of all major immune cell populations and a staining panel addressing the activity of T and NK cells after ex vivo stimulation with PMA/Ionomycin. An increased activity of CD8+ T cells and NK cells was observed as major players in the response to treatment with these anti-PD-1 antibodies.
In summary, the humanized subQperior™ platform using hPD-1 C57BL/6 mice is a suitable tool to evaluate novel cancer therapies in combination with human specific anti-PD-1 therapeutics and tumor ulceration was completely prevented by subQperior implantation of the tumor cells.

#5195
BNDG B2m KO plus mouse model is a powerful tool for immunotherapy
Hongmei Jiang, Jianqiu Xiao, Travis Rothrock. *Inotiv/Envigo, St. Louis, MO*

The B-NDG (*B*iocyotgen; *N*OD; *D*NAPK null; IL2r*g* knockout) mouse model was developed to be an ideal testing platform for anti-tumor therapies in Cell-Line and Patient Derived Xenograft Models (CDX and PDX respectively). B-NDG mice exhibit several notable advantages over classical NOD-*scid* mice, including increased life span, NK cell deletion, and significantly improved xenograft efficiency. However, like the NOD-*scid* mice, the utility of B-NDG mice in long-term studies is severely limited by a high incidence of severe and early-onset GvHD (*G*raft *v*ersus *H*ost *D*isease) - limiting experimental durations to as little as 30 days. To reduce the incidence and severity of GvHD in B-NDG mice, Biocytogen

developed the B-NDG *B2m* KO plus mice. B-NDG B2m KO plus mice was generated using Cas9 approach. Specifically, endogenous mouse *B2m* was deleted, while *B2m* cDNA was fused with *Fcgrt* . MHC Class I and Class II expressions, and immune markers were verified by flow cytometry. Concentration of i.v. administered human IgG was quantified by ELISA. CDX models were generated, and antitumor therapies were administered using established protocols described below. Compared with NOD-*scid* and B-NDG mice, B-NDG B2m KO plus mice showed undetectable MHC Class I expression in all tested tissues, without compromising MHC Class II expression. Moreover, no significant change in immune profiles or IgG turnover was detected, demonstrating highly targeted disruption of MHC Class I expression in B-NDG B2m KO plus mice. In the human PBMC-induced GvHD model, B-NDG B2m KO plus mice showed significantly improved survival, delayed onset and reduced clinical severity throughout the course of the model. Compared with B-NDG mice, B-NDG B2m KO plus mice exhibits significantly prolonged usefulness, demonstrating utility for up to 50 days after engraftment. To demonstrate the advantages of our B-NDG B2m KO plus mouse model, we conducted two proof-of concept studies that are often limited by GvHD. In the first study, B-NDG B2m KO plus mice were engrafted with human PBMCs and tumorigenic RKO cells on Day 0 and 14 respectively, treated with either vehicle or pembrolizumab and ipilimumab on Day 20, and observed until Day 48. Pembro/ipi treatment significantly inhibited tumor growth. In the second study, B-NDG B2m KO plus mice were engrafted with tumorigenic human NCI-H226 cells on Day 0, treated with either vehicle or CAR-T cells (5E5) once tumor size reached ~150 mm^3 (around Day 20), and observed until Day 56. CAR-T treatment significantly suppressed tumor growth. Together, these studies demonstrated that the B-NDG B2m KO plus mouse model is a powerful tool for extended term anti-tumor studies, especially for studies involving immuno- and CAR-T therapies.

Novel humanized CD36 mouse model for therapeutic studies

Linlin Wang[1], Chang Liu[1], Rebecca Soto[2], Chengzhang Shang[1], Qingcong Lin[2]. *[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Biocytogen Boston Corp, Wakefield, MA*

Activation of oncogenic signaling pathways can be mediated by various transporters on tumor cells that facilitate trafficking of lipids. CD36 has been identified as a fatty acid transporter and participates in tumor growth and drug resistance. To explore potential therapeutic strategies targeting CD36, we generated a human *CD36* knockout/knock-in *in situ* (B-hCD36) mouse model to evaluate the efficacy of anti-human CD36 antibodies. We first confirmed human CD36 gene and protein expression in B-hCD36 mice by RT-PCR and flow cytometry, respectively. We next observed that the overall development, differentiation, and distribution of splenic, blood and lymph node immune cells were similar between wild-type C57BL/6 and B-hCD36 mice. Lastly, *in vivo* efficacy studies using anti-human CD36 antibodies alone or in combination with anti-mouse PD-1 antibodies, were effective in controlling MC38 tumor growth in B-hCD36 mice. Our data demonstrates that B-hCD36 mice are a powerful preclinical model for *in vivo* efficacy evaluation of anti-human CD36 antibodies.

NCG-hIL2 mice: a novel model to support the development of T regulatory and NK cells

Xinxin Zhang[1], Meirong Wu[1], Huiyi Wang[1], Weiwei Yu[1], Fang Zhu[1], Jianming Xu[1], Hongyan Sun[1], Hongyu Wang[1], Cunxiang Ju[1], Santi Suryani Chen[2], Zhiying Li[2], Mark Wade Moore[2], Jing Zhao[1], Xiang Gao[1].
[1]Gempharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA

Interleukin 2 is a key molecule that promotes the expansion and activation of lymphocytes, including T regulatory cells (Tregs) and natural killer (NK) cells. Tregs are specialized subpopulation of T cells that suppress the immune response by inhibiting T cell proliferation and cytokine production. NK cells are the predominant innate immune subset that mediates anti-tumor and anti-viral responses. Both Tregs and NK cells are two critical immune cells that play an important role in cancer immunotherapy, however, there is a lack of models that supports the in vivo status of these two immune subsets. To address this, we developed a severe immunodeficient mouse model, NOD/ShiLtJGpt-Prkdc^{em26Cd52}Il2rg^{em26Cd22}/Gpt (NCG-hIL2), by knocking in the human IL-2 gene on the NCG background. The ability of this model to support Treg

and NK cells was then compared to NCG and tested with the reconstitution of human peripheral blood mononuclear cells (PBMC) and human hematopoietic stem cells (HSC).
In the PBMC engrafted mice, the presence of IL-2 supported the development of T cells, especially the Tregs, with 53.74% in Tregs in NCG-IL2 compared to 4.81% in NCG mice (test at 2 weeks of reconstruction). Similarly, the NK cells are also supported with those cohort engrafted with human HSC (91.63% in NK cells in NCG-IL2 compared to 0.53% in NCG mice, test at 10 weeks of reconstruction). Notably, reconstituted NK cells expressed various NK receptors such as NKp30, NKp44, NKp46, NKG2D, and CD94 in NCG-IL2 mice. They produced comparable levels of granzyme when compared with human peripheral blood-derived NK cells, and a considerable amount of perforin protein was detected in the plasma of huHSC-NCG-hIL2 mice.
In conclusion, compared with NCG mice, humanized NCG-hIL2 mice can reconstruct more abundant immune cells and have a wider application in anti-tumor research. It is an ideal model for the preclinical study of anti-tumor therapeutics.

B7-H3 & PD-L1 double-humanized BALB/c mouse: a novel animal model for preclinical studies of human B7-H3 antibodies or bispecific antibodies

Shiying Guo[1], Lingyu Song[1], Xin Qin[1], Jianming Xu[1], Hongyan Sun[1], Cunxiang Ju[1], Hongyu Wang[1], Santi Suryani Chen[2], Zhiying Li[2], Mark Wade Moore[2], Jing Zhao[1], Xiang Gao[1]. *[1]Gempharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA*

Immune checkpoint molecule B7-H3, also known as CD276, is a member of the B7-CD28 family of immunomodulatory proteins. It is a type I membrane protein with sequence similarities to the extracellular domain of programmed death-ligand 1 (PD-L1).
B7-H3 is highly expressed in most human cancers, but has limited distribution in normal tissues, remaining elusive of its receptor. Due to its promising safety as a dominant tumor target, various strategies have been developed to modulate the effect of B7-H3 via monoclonal antibodies, bispecific antibodies, ADC, or CAR-T. To study the effect of these

therapies in an immunocompetent mouse model, we established a double humanized B7-H3 and PD-L1 mouse model on BALB/c background (BALB/c-hB7-H3/hPD-L1). In this model, the extracellular domain of murine fragments was replaced by the human counterparts while the trans-membrane and cytoplasmic domain were kept intact. When engrafted with CT26 colon cancer cells, which stably overexpress human B7-H3 and PD-L1 while endogenous murine counterparts were knocked out, the tumor growth was inhibited certain degree by anti-B7-H3 antibody (8H9 Biosimilar, 20mpk, TGI=18.56%) treatment while inhibited significantly after the monotherapy of anti-PD-L1 (Tecentriq, 3 mpk, TGI=55.89%, $p<0.001$). The same dosage combination of anti-B7-H3 and anti-PD-L1 had a significant inhibition on tumor growth (TGI=76.85%, $p<0.001$), and had a synergistic effect (CDI<0.7) compared with the monotherapy. Analysis of tumor-infiltrating lymphocytes (TILs) at the end of the efficacy study showed that the proportion of CD45+ immune cells was significantly increased in all of the treated groups. The NK cells were significantly increased and the Treg cells were significantly decreased especially in the combined treatment group.
Based on the above, the B7-H3 and PD-L1 double humanized mouse model is suitable for the pre-clinical evaluation of mono or combined immune checkpoint blockade with anti-human B7-H3 and PD-L1 therapy.

Novel Immuno-Oncology drugs evaluation by humanised immune cells and cancer co-inoculated models

Bin Xie[1], Xin Hou[1], Hanglu Chen[1], Pengfei Yang[1], Yanbin Zhou[1], Danyi Wen[2]. *[1]R&D, Shanghai LIDE Biotech Co., Ltd., Shanghai, China,[2]Shanghai LIDE Biotech Co., Ltd., Shanghai, China*

Currently more and more immunotherapeutic drugs and engineered cells have been developed to use human immune system against cancer. While humanized peripheral blood mononuclear cell reconstitution in immune deficient mice is a forward-straight model for evaluating therapeutic antibodies, this conventional model has several drawbacks to hinder its widespread use, including the graft-versus-host-disease happened after one month of reconstitution, insufficient immune cell infiltration from reconstituted circulatory system and hardly retention of functional innate

immune cells, such as macrophages and nature killer cells. To overcome this, LIDE has developed a specific human immune cell and cancer cell co-inoculation model. Cancer-priming PBMC and/or its derivates were well mixed with the fresh cancer cells in MatriGel, co-transferring into NCG mice to form a relatively "hot tumor" tissue for immunotherapy, including drugs targeting T cells, dendritic cells and macrophages. Additionally, we also take advantage of human IL15 transgenic mice to study the function of ex vivo expanded NK cells. This novel method has successfully helped evaluate biological function of immune checkpoint blockers and immune agonists in multiple cancers, such as melanoma, breast cancer, lung cancer, hepatocellular carcinoma and ovarian cancer.

#5201

TNFR2 humanized mice: an ideal model for studying anti-TNFR2 antibodies

Huiyi Wang[1], Ying Li[1], Mingkun Zhang[1], Xu Su[1], Santi Suryani Chen[2], Zhiying Li[2], Mark Wade Moore[2], Jing Zhao[1], Xiang Gao[1], Cunxiang Ju[1].
[1]GemPharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA

Tumor necrosis factor (TNF) receptor 2 (TNFR2) is mainly expressed on the surface of regulatory T cells (Tregs) and CD8+ T cells, which can stimulate the proliferation of these cells through NF-kB activation. TNFR2 is also highly expressed on the surface of various human tumors, such as colorectal cancer and lung cancer. Therefore, a TNFR2 antagonist blocking the binding of TNFR2 to its ligand that targets TNFR2+ tumor-infiltrating Tregs can directly enhance the killing ability of effector T cells (Teff) against TNFR2-expressing tumors. Many pharmaceutical and biotech companies have lined up TNFR2-targeting drugs, and most TNFR2 antibodies related research is in the early preclinical/clinical stage.
We established a humanized TNFR2 (hTNFR2) genetically engineered mouse model on the BALB/c background, in which the extracellular domain of the mouse TNFR2 was replaced with its human counterpart, and the murine transmembrane and cytoplasmic domain kept intact. The hTNFR2 chimeric protein is mainly expressed on Teff and Treg cells in BALB/c-hTNFR2 and BALB/c-hPD1/hPDL1/hTNFR2 mice, which is similar to mouse TNFR2 protein expression profiles in wild-type mice. Our

data showed that anti-TNFR2 antibodies could significantly inhibit tumor growth in BALB/c-hTNFR2 mice bearing CT26 tumor cells or BALB/c-hTNFR2 mice bearing CT26-hTNFR2 tumors. Furthermore, within the tumor-infiltrating lymphocytes, there was a reduction in Tregs cells and an increase in cytotoxic CD8 T cells, which accurately mimics the mechanism of action of anti-TNFR2 antibodies.
In conclusion, BALB/c-hTNFR2 and BALB/c-hPD1/hPDL1/hTNFR2 mice are ideal models for studying the efficacy and pharmacodynamics of anti-TNFR2 antibodies as a single agent or in combination with anti-PD-1/PD-L1 therapies.

#5202

NCG-M humanized mice: an excellent model for human immune reconstitution of myeloid lineages

Huiyi Wang[1], Jialu Fan[1], Shiying Guo[1], Mingkun Zhang[1], Shuai Li[1], Santi Suryani Chen[2], Zhiying Li[2], Mark Wade Moore[2], Jing Zhao[1], Xiang Gao[1], Cunxiang Ju[1]. *[1]GemPharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA*

Severe immunodeficient mice engrafted with human hematopoietic stem cells (HSC) have been extensively used in immuno-oncology related studies to evaluate the efficacy of cancer therapies. However, because of species differences, murine cytokines provide limited support to human immune cells, thus immunodeficient mice have limited engraftment of human immune cells. Increasing evidence has shown that myeloid cells, especially macrophages and dendritic cells, are critical for the induction of anti-tumor immunity. We developed a mouse model, NCG-M, that can support human T, B, NK and myeloid cells such that in vivo evaluation of agents that require the interplay between these immune cells can be examined. This model was genetically engineered on the severe immunodeficient strain NCG and can produce human granulocyte/macrophage colony stimulating factor 2 (GM-CSF, also known as CSF2), interleukin-3 (IL-3) and stem cell factor (SCF, also known as KITLG). Upon human $CD34^+$ HSC cell engraftment, increased myeloid lineage cells, such as granulocytes, monocytes, neutrophils, macrophages, and dendritic cells, were observed in the NCG-M cohort compared to NCG mice. The NCG-M mouse also supports the development of human T cells, and preliminary data showed

increased B and NK cells. The NCG-M is an appropriate mouse model for studying the efficacy of therapeutic agents that require human T cells and myeloid cells.

#5203

Naturally occurring colorectal cancer in rhesus macaques as model for human cancer immunotherapy: a first report on pembrolizumab ± radiotherapy

Simon Deycmar[1], George W. Schaaf[1], Brendan J. Johnson[1], J. Daniel Bourland[2], James D. Ververs[2], Christopher T. Whitlow[3], J. Mark Cline[1].
[1]Department of Pathology, Wake Forest University School of Medicine, Winston-Salem, NC,[2]Department of Radiation Oncology, Wake Forest University School of Medicine, Winston-Salem, NC,[3]Department of Radiology, Wake Forest University School of Medicine, Winston-Salem, NC

Introduction: Rhesus macaques share extensive similarities with humans including immune cell populations, regulatory mechanisms, and targets for cancer immunotherapy but also naturally develop cancers at similar life stages. Hence, treating rhesus macaques with spontaneous tumors bears enormous potential as model for human cancer immunotherapy.
Material and Methods: We identified 2 female rhesus macaques, 23.6y (CRC_1) and 20.3y (CRC_2) old with naturally occurring colorectal cancer by imaging and clinical assessments. We collected a pre-treatment tumor biopsy in CRC_1 prior to treatment with 8 Gy intensity-modulated radiotherapy (IMRT) to the proximal portion of the tumor and 2 mg/kg i.v. pembrolizumab. The second candidate (CRC_2) was not tumor biopsy-eligible due to anemia and was treated with pembrolizumab alone. We collected blood and peripheral lymph nodes (LNs) pre- and on-treatment and complete tissue collection was performed at the 3w time point including tumor-adjacent mesenteric LNs. Follow-up assessments include IHC (e.g. CD3, CD20, IBA1), flow cytometry, cytokine assessment in plasma, and transcriptomics of LN and tumor samples.
Results and Discussions: Imaging revealed focal thickening of the proximal colonic wall with disrupted architecture in CRC_1 and focal colonic thickening and an enlarged adjacent LN in CRC_2. Both tumors displayed mismatch repair-deficiency (MLH1 & PMS2 loss) and a drastic reduction in infiltrating CD3 cells in neoplastic areas compared to adjacent healthy

colon. On treatment, tumor-associated LNs demonstrated a mild increase in CD20+ cells in the medullary sinuses of both patients and increased follicle numbers with normal follicular architecture in reference to peripheral LNs. In both patients there was an increased number of tertiary lymphoid structures (TLS) surrounding the tumors, predominately populated with CD20+ cells and with Ki67+ germinal centers, profoundly so in CRC_2. Moreover, IBA1+ cells abundantly infiltrated both tumors but showed a higher aggregation within the stromal elements of the neoplasms. A gradient of histologic differentiation was evident in CRC_1 and coincided with a reduction of TLS, IBA1+ cell abundance, and CD3+ cell infiltration in those areas which were poorly differentiated. Within the irradiated tumor of CRC_1, there were abundant apoptotic cells which stained positively with cleaved caspase 3 at the 3w time point. Circulating blood counts as preliminary peripheral read-out revealed a reduction in circulating lymphocytes in both patients beginning at 3d (CRC_1) resp. 6d (CRC_2) and a sharp increase in monocytes at 3d in unirradiated patient CRC_2. Conclusion: The immunological and tumoral response to pembrolizumab and radiotherapy matches the clinical response in humans and enables an unprecedented examination of the peripheral and local lymph node response.

Preclinical models for translational immuno-oncology research: Rare patient-derived xenografts on humanized mice

Maria Stecklum[1], Annika Wulf-Goldenberg[1], Bernadette Brzezicha[1], Wolfgang Walther[2], Jens Hoffmann[1]. *[1]EPO GmbH, Berlin, Germany,[2]Charité Universitätsmedizin, Berlin, Germany*

Background

The preclinical evaluation of novel immune checkpoint modulators is dependent on models with functional human immune cells. In previous experiments, we have demonstrated, that we can use either peripheral blood mononuclear cells (PBMC), subset of immune cells like NK cells or hematopoietic stem cells (HSC) to establish a humanized immune system on highly immunodeficient 1st and 2nd generation NOG mice with functional T-, B-, and NK cells, as well as monocytes and dendritic cells. Furthermore, we determined PD-L1 expression as a predictive marker and

target for immunotherapy on different patient-derived xenografts (PDX). By co-transplantation of rare PDX, like leukemia or Nuclear-protein-in-testis (NUT) carcinoma , we successfully generated a fully human tumor-immune-cell model in mice. Finally, we evaluated the functionality of the model by the treatment with checkpoint inhibitors like Ipilimumab (Ipi), Nivolumab (Nivo) or Pembrolizumab (Pembro). In parallel, we investigated the functionality of the human immune cells and evaluated concepts for combination therapies i.e. with chemotherapy or radiation.

Methods

HSC-humanized mice were generated by i.v. HSC transplantation and engraftment of immune cells was monitored by FACS analysis. For PBMC-humanized mice, immune cells were implanted i.v.. PDX models from different entities (leukemia or NUT carcinoma) were transplanted on HSC-humanized (HIS) mice and treated with Ipi, Nivo and Pembro alone or in combination with radiation. Blood and tumor samples were analysed by FACS for immune cell infiltration and activation.

Results

The transplanted HSC showed engraftment in mice with proliferation and differentiation. 14 weeks after HSC inoculation up to 20% of the human immune cells in the blood were T-cells, characterized by a high PD-1 expression. We have transplanted PDX from different tumor entities on HSC-humanized mice. Most of the investigated PDX (>70%) successfully engrafted on humanized mice and showed no significant difference in tumor growth compared to growth on non-humanized mice. However, for some PDX we observed a delayed tumor growth or a complete rejection. Engraftment delay seems to correlate with the PD-L1 expression of PDX (the higher PD-L1, then the higher growth delay). Furthermore, our results demonstrate the functionality of the engrafted human immune cells against some PDX. Treatment with Ipi, Nivo or Pembro led to a minor tumor growth delay. Response to checkpoint inhibitors showed a correlation to innate immune response and PD-L1 expression of PDX and could further be increased by combination with radiotherapy.

Conclusions

Our humanized immune-PDX models enable appropriate preclinical translational research on tumor immune biology and the evaluation of new therapies and combinations, as well as the identification and validation of biomarkers for immune therapy, especially in rare PDX models.

#5205

B6-*Kras*$^{LSL-G12C}$ mouse model for assessing the occurrence and development of lung and pancreatic cancer tumors

Xiaoliu Yang[1], Yunlong Jiang[1], Xue Wu[1], Mingkun Zhang[1], Jing Zhao[1], Santi Suryani Chen[2], Zhiying Li[2], Erica Trujillo[2], Mark Wade Moore[2], Xiang Gao[1], Cunxiang Ju[1]. *[1]GemPharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA*

In May 2021, the FDA approved sotorasib (Lumakras™) as the first treatment for adult patients with non-small cell lung cancer (NSCLC) harboring the *KRAS*^{G12C} genetic mutation. To study the relationship between the mutational activation of KRAS and tumorigenesis, and promote the development of KRAS-G12C inhibitors, we established the B6-Loxp-Stop-Loxp Kras G12C (B6-*Kras*$^{LSL-G12C}$) strain. Upon induction of Cre recombinase, floxed Stop sequences will be deleted in the mouse genome, and the oncogenic KRAS-G12C protein will be expressed at endogenous levels allowing for control of the timing and location of tumor initiation. The C57BL/6-*Kras*$^{LSL-G12C}$ mice were crossed with the Lyz2-cre mice to develop a spontaneous lung cancer model. KRAS G12C mutant could be detected in type II alveolar epithelial cells (ATII). Furthermore, these mice develop lung cancer at 8-10 weeks of age. In addition, when B6-*Kras*$^{LSL-G12C}$ mice were crossed with the B6-*P53*$^{LSL-R172H}$ and Ptf1/p48-Cre mice, the offspring developed pancreatic cancer after 10-12 weeks of tamoxifen treatment.

In conclusion, B6-*Kras*$^{LSL-G12C}$ mice can be used to study the occurrence and development of pancreatic and lung cancer, as well as the potential applications of cancer therapies.

#5206

A novel mouse model for preclinical efficacy evaluation of anti-CD3/GPRC5D bispecific antibodies

Xiaoliu Yang[1], Xinyuan Liang[1], Mingkun Zhang[1], Santi Suryani Chen[2], Zhiying Li[2], Erica Trujillo[2], Mark Wade Moore[2], Jing Zhao[1], Xiang Gao[1], Cunxiang Ju[1]. *[1]GemPharmatech Co., Ltd., Nanjing, China,[2]GemPharmatech LLC., La Jolla, CA*

The FDA has granted Breakthrough Therapy Designation (BTD) for talquetamab, which targets both GPRC5D on multiple myeloma cells and CD3 on T-cells, for treating adult patients with relapsed or refractory multiple myeloma. Results showed that patients who received talquetamab experienced adverse events, including cytokine release syndrome (CRS), neutropenia, skin-related adverse events and dysgeusia. To allow preclinical in vivo evaluation of anti-human CD3/GPRC5D bispecific antibodies, we developed a BALB/c-hCD3EDG mouse model and a human GPRC5D-expressing A20 murine lymphoma cell line. The BALB/c-hCD3EDG cohort (6-8 weeks old) was subcutaneously inoculated with A20-hGPRC5D cells and then treated with anti-CD3/GPRC5D bispecific antibodies. As expected, anti-CD3/GPRC5D bispecific antibody treatment strongly inhibited the growth of A20-hGPRC5D tumors in BALB/c-hCD3EDG mice.

To allow a comprehensive safety evaluation of anti-CD3/GPRC5D candidates, including the possibility of CRS and target organ toxicity, we engineered BALB/c-hCD3EDG mice that express hGPRC5D, denoted BALB/c-hCD3EDG/hGPRC5D. Human GPRC5D was detected in the liver, lung, thymus, adipose tissue, and thyroid. In vivo evaluation of anti-CD3/GPRC5D therapy in this mice is currently underway.

In conclusion, BALB/c-hCD3EDG/hGPRC5D and BALB/c-hCD3EDG mice bearing A20-hGPRC5D tumors are suitable models for preclinical studies testing anti-CD3/GPRC5D bispecific antibodies.

#5207

Development of MHC I/II knock-out immunodeficient mouse strains for alleviating GvHD induced by human PBMC reconstitution

Qiang Liu[1], Chengzhang Shang[1], Xiaofei Zhou[1], Jenna Frame[2], Zhiyuan Shen[1], Zhaoxue Yu[2]. *[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd, Beijing, China,[2]Biocytogen Boston Corp, Wakefield, MA*

Severely immunodeficient mouse strains, such as B-NDG mice, lack B, T, and NK cells, and have been widely used as an in vivo model to evaluate human immune responses, including applications in immuno-oncology in recent years. However, when human peripheral blood mononuclear cells (PBMCs) are engrafted in these mice, severe acute xenogeneic graft-versus-host disease (GvHD) arises due to engagement of human T cell receptors (TCRs) with major histocompatibility complex (MHC) proteins I and II on the surface of murine immune cells. GvHD shortens the animal life span such that there is only a brief window of evaluation of human immune cell functions in these mouse models. Consequently, efforts have been undertaken to reduce human PBMC-induced GvHD and to subsequently extend the window of human immunity assessment in immunodeficient mouse strains by eliminating mouse MHC I and MHC II. We previously engineered a novel *B2m* gene knock-out strain on the B-NDG background (NOD.CB17-*Prkdc*^{scid}*Il2rg*^{tm1}/Bcgen), which is deficient in MHC I expression, but expresses the *B2m* gene fused into the *FcRn* gene to retain FcRn-mediated antibody metabolism. In order to eliminate MHC II expression, we also engineered an *H2-Ab1* gene knock-out strain on the same B-NDG background and cross-bred the two strains together to obtain an MHC I/II double KO mouse model, termed B-NDG MHC I/II DKO mice plus. Splenocytes collected from the engineered strains were analyzed by flow cytometry. As expected, mouse H-2K^{b}/H-2D^{b} was not detectable in B-NDG B2m KO plus mice or B-NDG MHC I/II DKO mice plus. While mouse I-Ak was detected in B-NDG mice and B-NDG B2m KO plus mice, it was not detected in B-NDG MHC I/II DKO mice plus. Pharmacokinetic assessments demonstrate that B-NDG mice and B-NDG B2m KO mice plus groups were able to recycle human IgG, with no differences when compared with wild-type C57BL/6 mice, indicating normal FcRn function. Finally, the three strains of mice were irradiated and engrafted with human PBMC from three donors to evaluate GvHD incidence. As expected, the reconstitution levels of CD45+ leukocytes, T cells, CD4+ T cells, CD8+ T cells, Tregs and NK cells were similar among the three strains. However, lack of MHC I/II in B-NDG MHC I/II DKO mice plus can significantly extend the life span and reduce GvHD induced by human PBMC engraftment compared to B-NDG mice and B-NDG B2m KO mice plus. These results indicate that B-NDG MHC I/II DKO mice plus provides a useful mouse model for reducing GvHD after human PBMC reconstitution

in immunodeficient mice. This model may be a powerful preclinical tool for future *in vivo* evaluation of cell therapies and antibodies.

Development of immunodeficient mice expressing human IL3, GM-CSF, CSF1 and THPO for improved human myeloid and lymphoid cell reconstitution

Ruili Lv[1], Yanhui Nie[1], Jing Zhang[1], Jenna Frame[2], Qiang Liu[1], James Jin[2].
[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd, Beijing, China,[2]Biocytogen Boston Corp, Wakefield, MA

Mice reconstituted with human immune cells are essential tools to study human immune reactions *in vivo*, including those involving cancer immunotherapies. A major limitation of these models is the poor development of human myeloid cells to mediate effective human immune cell-tumor interactions. This is because hematopoietic cells are highly dependent on several human cytokines for efficient differentiation, maturation, and survival. THPO (thrombopoietin) can enhance the maintenance of functional human hematopoietic stem cells, and stimulates the production and differentiation of megakaryocytes, which produce large numbers of platelets in the bone marrow. IL3 (interleukin 3), GM-CSF (granulocyte-macrophage colony-stimulating factor, CSF2) and CSF1 (macrophage colony-stimulating factor, M-CSF) are cytokines that promote the proliferation and differentiation of a variety of myeloid cells, including monocytes, macrophages, granulocytes, dendritic cells, and platelets. Because these cytokines lack sufficient cross-reactivity between human and mice, it is difficult to reconstitute human immune cells of these lineages in immunodeficient mice. Therefore, we predict that genetic humanization of these four cytokines will improve the reconstitution of human myeloid cells in immunodeficient mice. We engineered an M-CSF, GM-CSF, THPO, and IL3 humanized strain in the background of B-NDG mice (NOD.CB17-*Prkdc*^{scid}*Il2rg*^{tm1}/Bcgen), termed B-NDG MGMT3 mice. The full sequences of mouse *Il3*, *Csf2, Csf1* and *Thpo* genes (except the UTRs) were respectively replaced with the coding sequences (CDS) of human *IL3, CSF2, CSF1* and *THPO* genes. Human GM-CSF, CSF1 and THPO proteins were confirmed to be expressed by ELISA in B-NDG MGMT3 mice. Human CD34^{+} HSCs (3E4) were intravenously engrafted into wild-type B-

NDG mice and homozygous B-NDG MGMT3 male and female newborn mice via the temporal vein. B-NDG mice were treated with 1.0 Gy irradiation, while B-NDG MGMT3 mice were not irradiated. The survival rate of B-NDG MGMT3 mice was similar to B-NDG mice until 16 weeks post-$CD34^+$ engraftment. However, the body weight of B-NDG MGMT3 mice was significantly higher than that of B-NDG mice. Analysis of peripheral blood lymphocytes showed that the proportion of $hCD45^+$ cells in B-NDG MGMT3 mice reached 25% starting from 12 weeks after engraftment and continued to rise; levels were significantly higher than that observed in B-NDG mice. The proportions and cell number of T cells, NK cells, monocytes, MDSCs, DCs and Tregs engrafted in B-NDG MGMT3 mice were higher than B-NDG mice. The results indicate that B-NDG MGMT3 mice are a novel humanized model for human myeloid and lymphocytic cell reconstitution that does not require preconditioning.

#5209

Generation of humanized TREM2 mice for preclinical evaluation of therapeutics targeting tumor-associated macrophages

Ruili Lv[1], Jia Yu[1], Zhiyuan Shen[1], James Jin[2]. *[1]Biocytogen Pharmaceuticals (Beijing) Co., Ltd., Beijing, China,[2]Biocytogen Boston Corp, Wakefield, MA*

In recent years, immune checkpoint inhibitors (ICIs) have improved treatment for several types of cancer. However, the overall response rates remain low, and drug resistance can occur in patients after initial responses. This resistance is thought to be due in part to tumor-associated macrophages (TAMs), which can deploy a number of mechanisms to suppress anti-tumor immunity, resulting in tumor immune escape. Triggering receptor expressed on myeloid cells-2 (TREM2), a transmembrane receptor that is part of the immunoglobulin superfamily, is highly expressed on the surface of TAMs. Moreover, the expression level of TREM2 is reported to be higher in cancerous tissues vs normal tissues, with higher expression associated with poorer patient outcomes across multiple solid tumor types. Conversely, mice that lack Trem2 experience slower tumor cell expansion and are more responsive to anti-PD-1 immunotherapy, suggesting that TREM2 may be a promising therapeutic target for improving responses to ICI immunotherapies. To better assist the efficacy

evaluation of anti TREM2 antibodies, Biocytogen has generated a humanized TREM2 mouse model. In these mice, exons 1-5 and the 3'UTR of mouse Trem2 gene, which encodes the full-length protein, were replaced by its human counterpart. In homozygous mice, human TREM2 protein expression is detected. The distribution of basal leukocyte subpopulations of blood, spleen, and lymph nodes in humanized B-hTREM2 mice were similar and comparable to those in wild-type C57BL/6 mice. Using the MC38 tumor model, we showed modest efficacy of an anti-human TREM2 antibody in inhibiting tumor growth in vivo. In summary, TREM2 humanized mice provide a powerful preclinical model for in vivo evaluation of anti-human TREM2 antibodies for cancer treatment.

Ablation of an immunogenic human endogenous retrovirus in renal cell carcinoma cells through dual-guide CRISPR-Cas9 genome editing

Long Chen[1], Elena Cherkasova[1], Stephanie Pierre[2], Savannah England[3], Muna Igboko[1], Joseph Clara[1], Stefan Barisic[1], Angie Parrizzi[1], Rosa Rios Nadal[1], David Allan[1], Mala Chakraborty[1], Robert Reger[1], Richard Childs[1].
[1]NIH National Heart, Lung & Blood Institute, Bethesda, MD,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Saint Louis University School of Medicine, St. Louis, MO

Human endogenous retroviruses (HERVs) comprise 8% of the human genome and can be abnormally expressed in different tumor cells. Our lab discovered a unique and highly immunogenic HERV-E, CT-RCC HERV-E, that is selectively expressed in most clear cell renal cell carcinoma (ccRCC) cells. Although the function of select HERVs in some tumors has been defined, the role of CT-RCC HERV-E in ccRCC remains unclear. To characterize the impact of HERV-E expression on tumor oncogenesis in ccRCC, we developed a highly efficient strategy to ablate CT-RCC HERV-E through dual-guide CRISPR-Cas9. For isolation of edited cells, we knocked in a truncated CD19 (tCD19) into the same gene edited locus using adeno-associated virus (AAV) as donor templates. In order to ablate the entire 8.8 kb HERV-E region, we designed three single guide RNAs (sgRNAs) flanking the CT-RCC HERV-E genomic locus: one at the upstream site, sgRNA HERV-E Upst(1), and two downstream, sgRNA HERV-E Dwst(3) and sgRNA HERV-E Dwst(4). A single sgRNA targeting

β2M was used as a negative control. HERV-E knockout was verified via real-time PCR, and the combination of sgRNAs Upst1-Dwst3 were chosen as the guides for all experiments, due to their higher knockout efficiency. We tested the MOIs of 2, 4, and 10 x 10^5 for AAV transduction following CRISPR knockout. Expression of CD19 was the highest at the MOI of 10 x 10^5, which was used for all experiments. Two RCC cell lines, RCC-TIU and RCC-UOK220, were used to validate this methodology. Edited ccRCC cells were enriched by CD19 magnetic microbeads, resulting in CD19 expression of over 96%. Genomic DNAs isolated from the two RCC cell lines confirmed simultaneous knockout of HERV-E and knock-in of tCD19. To isolate a population of cells that had homogenous HERV-E knockout, we single-cell sorted and then expanded $CD19^+$ ccRCC cells in vitro. 252 and 145 clones were harvested from RCC-TIU and RCC-UOK220 respectively. PCR analysis of genomic DNA from 48 selected clones of each of the aforementioned cell lines unveiled both monoallelic and biallelic knockout of HERV-E. Eight biallelic knockout clones were harvested and further expanded, which gave rise to four clones from RCC-TIU and three clones from RCC-UOK220. Additional PCR screening confirmed that RCC-TIU A7, A9, and RCC-UOK220 D3 were biallelic knockout clones. Finally, we used digital PCR to examine the expression of two CT-RCC HERV-E transcripts, Env and RCC-8; No expression of these transcripts was found in the aforementioned clones. In summary, we established a highly efficient method to reliably ablate a human endogenous retrovirus in human tumor cells. The dual-guide CRISPR-Cas9 genome editing method utilized here allowed for the successful isolation of tumor cells that had a biallelic knockout of the CT-RCC HERV-E. These knockout cell lines will be utilized to explore the oncogenic impact of CT-RCC HERV-E expression in ccRCC cells.

Targeting SLC2A1 and SLC38A2-mediated metabolic shift in SMARCA4/A2-dual deficient cancer

Xianbing Zhu[1], Zheng Fu[1], Shary Chen[2], Dionzie Ong[2], Giulio Aceto[1], Rebecca Ho[2], Jutta Steinberger[1], Eunice Li[2], David Huntsman[2], William Foulkes[3], Sidong Huang[1], Yemin Wang[4]. *[1]Department of Biochemistry, McGill University, Montreal, QC, Canada,[2]University of British Columbia, Vancouver, BC, Canada,[3]Departments of Medicine, Oncology and Human Genetics, McGill University, Montreal, QC, Canada,[4]Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada*

SMARCA4 (BRG1) and SMARCA2 (BRM) are the two paralogous ATPases of the SWI/SNF chromatin remodelling complexes. These two ATPases are frequently inactivated in cancers and cancer cells deficient in either of them have been shown to depend on the remaining counterpart for survival. Contrary to this paralog synthetic lethality, concomitant loss of SMARCA4 and SMARCA2 occurs in a subset of cancers that are often associated with very poor patient outcomes. Here, we uncover that dual loss of SMARCA4/A2 represses the expression of SLC2A1, encoding the glucose transporter GLUT1, which results in reduced glucose uptake and glycolysis accompanied with increased dependency on oxidative phosphorylation (OXPHOS); adapting to this, these SMARCA4/A2-dual deficient cells rely on elevated SLC38A2, an amino acid transporter, to increase glutamine import for fueling OXPHOS. Consequently, SMARCA4/A2-dual deficient cells and tumours are highly sensitive to inhibitors targeting OXPHOS or glutamine metabolism. Furthermore, supplementation of alanine, also imported by SLC38A2, restricts glutamine uptake through competition and selectively induces death in SMARCA4/2-dual deficient cancer cells. At a clinically relevant dose, alanine supplementation synergizes with OXPHOS inhibition or conventional chemotherapy eliciting marked antitumor activities in SMARCA4/A2-dual deficient cancer cell lines and patient-derived xenografts. Our findings reveal multiple druggable vulnerabilities of SMARCA4/A2-dual loss exploiting a GLUT1/SLC38A2-mediated metabolic shift. Particularly, unlike dietary deprivation approaches, alanine supplementation can be readily applied to current regimens for better treatment of these aggressive cancers. * Authors contributed equally# Co-corresponding

RNA epigenetic regulation of cholesterol metabolism in neuroblastoma
Mohit Bansal, Anamika Gupta, Han-Fei Ding. *University of Alabama at Birmingham, Birmingham, AL*

Pseudouridylation (conversion of uridine to pseudouridine) is a common epigenetic modification of RNA which increases its structural stability. RNA pseudouridylation is catalyzed by the family of pseudouridine synthases (PUS). The functional significance and biological relevance of mRNA pseudouridylation are poorly understood. Here we report that the oncogene MYCN, which drives the development of high-risk neuroblastoma, transcriptionally upregulates the PUS1 gene. Further, examination of gene expression profiling data from neuroblastoma patients (the SEQC dataset) reveals that higher PUS1 expression is associated with poor prognosis. The transcriptional upregulation of PUS1 expression in MYCN amplified cell lines is of functional significance, as our studies reveals that knockdown of PUS1 expression in neuroblastoma cell lines suppresses cell survival and proliferation. Our RNA-seq analysis reveals that a key downstream target of PUS1 is cholesterol metabolism. PUS1 knockdown reduces the expression of key enzymes in the mevalonate pathway for cholesterol synthesis. Mechanistically, PUS1 may targets SREBP2, a master regulator of cholesterol metabolism responsible for transcriptional upregulation of enzymes for cholesterol biosynthesis. We showed that PUS1 expression is essential for maintaining SREBP2 expression in MYCN-amplified neuroblastoma cells and for statin-induced feedback activation of the mevalonate pathway, a commonly used system for assessing the transcriptional activity of SREBP2. These findings suggest that a function of PUS1 in sustaining the proliferation of neuroblastoma cells is to promote cholesterol metabolism, which could be exploited as a therapeutic strategy against high-risk neuroblastoma.

Plk1 phosphorylation of PHGDH to regulate serine metabolism
Xiongjian Rao, Derek B. Allison, Robert M. Flight, Yuanyuan Wu, Timothy Scott, Daheng He, RuiXing Wang, Zhiguo Li, Chaohao Li, Yifan Kong, Fengyi Mao, Chi Wang, Richard M. Higashi, Andrew N. Lane, Hunter NB Moseley, Xiaoqi Liu. *University of Kentucky, Lexington, KY*

Polo-like kinase 1 (Plk1) has been reported to be highly expressed in most tumors, especially in advanced tumors, while how Plk1 elevation benefits tumor growth remains elusive. Metabolic reprogramming is one of the hallmarks of cancer, but how the tumors fully take advantage of deregulated metabolism is an enigma. Here, we found that Plk1 could divert serine metabolism from de novo synthesis to exogenous uptake by regulating PHGDH (phosphoglycerate dehydrogenase), the first rate-limiting enzyme of de novo serine biosynthesis. We show that PHGDH is phosphorylated by Plk1 at a cluster site (S512, S513, S517) and that Plk1-associated phosphorylation of PHGDH results in its protein degradation, thus reduced de novo serine biosynthesis. As a compensatory response, cells with an elevated level of Plk1 significantly increase the uptake of serine to produce more sphingosines, which are pivotal metabolites for the growth of cancer cells. Our finding may provide guidance on how to target de novo biosynthesis of serine, serine uptake or sphingosine metabolism to treat advanced prostate cancer.

The polyamine acetylation enzyme SAT1 drives mesenchymal features and therapeutic resistance in glioblastoma

Ayush B. Rana, Timothy M. Horton, Vijay S. Thakur, Scott M. Welford.
Radiation Oncology, University of Miami Miller School of Medicine, Miami, FL

Background**:**
Glioblastoma multiforme (GBM) is the most common and lethal brain tumor in adults. Characterization of GBM heterogeneity has identified four molecular subtypes based on transcriptomic profile: classical, neural, proneural and mesenchymal. Tumors harboring the mesenchymal gene signature are considered the most aggressive, invasive, and multitherapy-resistant. We identify the polyamine acetylation enzyme, SAT1 (spermidine/spermine N1-acetyltransferase 1) as a component of the mesenchymal gene signature and mesenchymal-associated gene sets including (1) Hallmark EMT and (2) Hallmark TNFa signaling via NF-κB.
Design/Methods:
To validate the role of SAT1 in driving mesenchymal features *in vivo*, we utilized a genetically flexible, CRISPR-based model of GBM. Tumor

bearing mice were generated through *in utero* electroporation, resulting in ablation of PTEN, P53 and NF1 in developing cortical cells. SAT1 knockout was achieved through cloning of additional guide RNA's against SAT1 into the tumor initiating plasmid.

Results:

In our model, we found increased levels of both SAT1 and acetylated polyamines in tumors compared to normal brain. Ablation of SAT1 was insufficient to prolong overall survival in mice but rendered the otherwise treatment resistant tumors highly sensitive to chemoRT. Bulk RNA sequencing of murine tumors revealed that SAT1 knockout resulted in reduced expression of the mesenchymal gene signature as well as genes implicated in EMT and TNFa/NFKb signaling.

Conclusions:

Collectively, these results reveal that SAT1 not only identifies mesenchymal GBM but also drives expression of the mesenchymal gene signature and mesenchymal features including multi-therapy resistance.

Targeting the mevalonate pathway, a novel anti-ferroptosis pathway, in hepatocellular carcinoma (HCC) treatment

Yiling Chen, Derek Lee, Misty Shuo Zhang, Jacinth Wing-Sum Cheu, Carmen Chak-Lui Wong. *Department of Pathology, University of Hong Kong, Li Ka Shing Faculty of Medicine, Hong Kong, China*

Ferroptosis is a novel immunogenic and regulated cell death caused by iron-dependent lipid peroxidation. Glutathione peroxidase 4(GPX4)/glutathione and ferroptosis suppressor protein 1(FSP1)/Coenzyme Q10(CoQ10) are two major anti-ferroptosis systems that prevent lipid ROS-induced cell death. Our current study unprecedentedly uncovered that the Mevalonate pathway (MVA) protects HCC from ferroptosis by two parallel mechanisms: 1) by providing the lipophilic antioxidant CoQ10 for FSP1; 2) by generating isopentenyl pyrophosphate (IPP), a substrate for Selenocysteine (Sec)-tRNA modification for selenoprotein GPX4 translation. Selenoproteins are a class of proteins composed of selenocysteine, the 21st amino acid not found in the codon table. Selenocysteine is recoded by the stop codon UGA and synthesized on its tRNA. The Sec-tRNA incorporates Sec into selenoproteins such as GPX4. We showed that perturbation of the MVA

pathway by genetic knockdown or pharmacologic inhibition repressed CoQ10 synthesis and the translation of selenoproteins, thereby leading to lipid-derived ROS and ferroptotic cell death. Furthermore, we showed that Mevalonate diphosphate decarboxylase (MVD), a MVA enzyme, was a transcriptional target of Nuclear Factor Erythroid 2- related factor 2 (NRF2), a master regulator of oxidative stress response. High expression of MVD was associated with poor prognosis in HCC. Strikingly, MVD inhibitor treatment profoundly suppressed HCC. Reduced tumor size and increased tumor-infiltrated effector T cells and macrophages were found *in vivo*. To conclude, our study has provided novel mechanistic insight about how NRF2/MVA pathway promotes HCC and suggested that MVD might be a good prognostic indicator and therapeutic target in human HCC.

De novo lipogenesis and cholesterol synthesis pathways can be simultaneously targeted to induce metabolic synthetic lethality in prostate cancer

Caroline Fidalgo Ribeiro[1], Silvia Daniele Rodrigues[1], Guilherme Tamarindo[2], Hubert Pakula[1], Massimo Loda[1]. *[1]Pathology and Laboratory Medicine, Weill Cornell Medicine, New York, NY,[2]Institute of Biology, University of Campinas, Campinas, Brazil*

Aberrant activation of fatty acid synthase (FASN) and *de novo* lipogenesis (DNL) is a major metabolic event in prostate cancer (PCa). Targeting lipid synthesis through FASN blockade can inhibit prostate tumor growth. Another metabolic pathway commonly altered in PCa is the mevalonate pathway, responsible for the synthesis of cholesterol from acetyl-CoA. The rate-limiting enzyme of the mevalonate pathway, 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMGCR), can be targeted with statins, drugs commonly prescribed for the management of hypercholesterolemia. Following FASN inhibition with IPI-9119, genes involved in the mevalonate pathway and cholesterol synthesis are transcriptionally upregulated. Metabolomics data confirmed an increase in intracellular levels of cholesterol after FASN inhibition, suggesting a compensatory mechanism to support PCa cell survival in the absence of *de*

novo synthesized lipids. Interestingly, we also observed an increase in mRNA levels of Acyl-CoA Synthetase Short Chain Family Member 2 (ACSS2), the enzyme that converts acetate into acetyl-CoA. Next, we evaluated how FASN blockade affected acetate utilization by PCa cells and observed that acetate uptake increases with DNL inhibition. Metabolic analysis confirmed that ^{14}C-acetate incorporation into lipids was increased after IPI-9119 treatment. The concomitant inhibition of FASN and HMGCR reduced acetate lipid incorporation, suggesting that acetate is fueling cholesterol synthesis. To better understand this effect, we analyzed the cell membrane after FASN inhibition, and an increase in fluidity was seen, which could be rescued by palmitate. Lipidomics analysis showed an increase in polyunsaturated fatty acids (PUFA) esterified to phospholipids, as well as overall increase in fatty acyl chain length, events that can affect membrane structure and fluidity. Due to the important role of lipids as energy reservoir, we also analyzed the effect of FASN blockade in neutral lipids. IPI-9119 treatment caused depletion of triacylglycerides, while levels of cholesterol esters (CE) and Acetyl-CoA Acetyltransferase 2 (ACAT2), an enzyme involved in CE synthesis, are upregulated. Acyl chain length and unsaturation are also increased in CE fatty acids, indicating further utilization of PUFAs in the absence of FASN activity. As expected, the combination of FASN and HMGCR inhibitors significantly potentiates cell death, observed by stronger reduction in cell growth than either of the single agents, both in androgen-sensitive and castration-resistant models of PCa. Altogether, our data suggests that cholesterol synthesis is a survival mechanism of PCa induced by DNL inhibition, likely to correct for membrane fluidity and energy supply. Finally, statin therapy can be combined with FASN inhibition to suppress PCa growth more efficiently than monotherapy.

DNA damage signaling activates *de novo* GTP synthesis to promote chemoradiation resistance in glioblastoma

Andrew J. Scott[1], Alexandra M. O'Brien[1], Weihua Zhou[1], Vidhi Pareek[2], Zhou Sha[2], Sravya Palavalasa[1], Ayesha U. Kothari[1], Kari Wilder-Romans[1], Li Zhang[3], Anthony C. Andren[3], Sriram Chandrasekaran[4], Jason Heth[5], Yoshie Umemura[6], Nathan Qi[3], John Woulfe[7], Sriram Venneti[8], Meredith A. Morgan[1], Theodore S. Lawrence[1], Wajd N. Al-Holou[5], Costas A.

Lyssiotis[3], Daniel R. Wahl[1]. *[1]Radiation Oncology, University of Michigan Medical School, Ann Arbor, MI,[2]Chemistry, The Pennsylvania State University, University Park, PA,[3]Molecular & Integrative Physiology, University of Michigan Medical School, Ann Arbor, MI,[4]Biomedical Engineering, University of Michigan Medical School, Ann Arbor, MI,[5]Neurosurgery, University of Michigan Medical School, Ann Arbor, MI,[6]Neurology, University of Michigan Medical School, Ann Arbor, MI,[7]The Ottawa Hospital Research Institute, Ottawa, ON, Canada,[8]Pathology, University of Michigan Medical School, Ann Arbor, MI*

Glioblastoma (GBM) is uniformly fatal due to inherent radiation (RT) and chemotherapy resistance. We have found this therapeutic resistance is mediated by alterations in tumor cellular metabolic activity. Our group and others have found that metabolites can regulate DNA repair and RT resistance in brain tumors, but little is known about how DNA damage regulates metabolic pathway activity in cancer. Here, we show that DNA damage acutely increases guanine-containing purine metabolites in multiple *in vitro* and intracranial GBM models. By interrogating metabolic fluxes *in vitro* using a variety of stable isotope tracers, we confirmed RT-induced elevation in guanylates was due to increased *de novo* purine synthesis (DNPS) rather than activation of purine salvage. By developing and using novel stable isotope tracing methods to directly measure DNPS in awake, unrestrained mice, we confirmed that orthotopic GBMs have higher DNPS rates than adjacent cortical tissue that further increase after treatment with RT. Neither salvage synthesis of purines nor pyrimidine synthesis were impacted by RT in any intracranial tissues. With these findings, we opened a clinical study to directly measure purine synthesis in patients, and we found that human GBMs have similarly high purine synthesis rates compared to normal brain tissue. Because DNA damage activated DNPS without affecting purine salvage or pyrimidine synthesis, we reasoned that active signaling may be involved. Indeed, therapy-induced DNPS increases are lost *in vitro* and *in vivo* upon pharmacological or genomic inhibition of the DNA-damage sensing kinase DNA-PK. Moreover, RT and DNA-PK have direct influence over the spatial organization of DNPS enzymes, including IMPDH, the rate-limiting step in guanylate synthesis. Because purines can promote DNA repair, these findings suggest that DNA-PK

signaling helps promote DNA repair in part by causing the spatial reorganization of DNPS enzymes, thereby activating purine synthesis. To determine if disrupting this regulation can augment GBM treatment efficacy, we combined an FDA-approved inhibitor of purine synthesis with chemoradiation in a variety of mouse models of GBM. Critically, targeting GTP synthesis improved the efficacy of both RT alone and chemoradiation in multiple patient-derived and syngeneic intracranial models, suggesting a potential therapeutic targeting opportunity in patients. In this study, we have developed novel methodology to directly measure purine synthesis in brain tumors in mice and humans. With these tools, we discovered that after DNA damage, DNA-PK mediates a novel pathway controlling the spatial reorganization of purine synthesis enzymes and subsequent DNPS increases. The resulting elevation of GTP levels promotes therapy resistance in tumors, and we are now directly measuring and inhibiting this molecular activity in patients with GBM in an effort to improve standard therapy.

Rewiring of amino acid metabolism in neurofibromatosis type 1-related tumors

Martina La Spina. *University of Padova, Padova, Italy*

Neurofibromatosis type 1 (NF1) is a tumor-predisposing genetic disorder caused by heterozygous mutations in the *NF1* gene encoding for the tumor suppressor Neurofibromin. Biallelic *NF1* inactivation in Schwann cells leads to the onset of neurofibromas, benign neoplasms that can cause severe medical complications and give rise to malignant peripheral nerve sheath tumors (MPNSTs), for which no treatment exists. Neurofibroma cells undergo bioenergetic changes required to sustain their malignant transformation. Our group has shown that inhibition of the mitochondrial chaperone TRAP1, a master metabolic regulator, hampers MPNST cell tumorigenicity. A growing number of evidence indicates that urea cycle (UC) dysregulation can redirect metabolic substrates to specific biosynthetic routes in many tumor cell types. We have found that a complete UC is absent in MPNST cell models, as they lack ornithine transcarbamylase (OTC), a key UC enzyme that converts ornithine into citrulline. In the absence of TRAP1, MPNST cells strongly reduce arginine

levels and accumulate ornithine through the activity of the mitochondrial enzymes arginase 2 (ARG2) and ornithine aminotransferase (OAT). These changes can reverberate on glutamine and proline levels ultimately affecting extracellular matrix deposition, motility and ROS homeostasis, as well as on ornithine-dependent polyamine biosynthesis that can regulate cell growth and proliferation. Surprisingly, in the absence of TRAP1 MPNST cells also accumulate citrulline, even though they do not express either OTC or any nitric oxide synthase (NOS) isoform that converts arginine into citrulline. We ascribe citrulline production to the activity of dimethylarginine dimethylaminohydrolase (DDAH) enzymes, involved in the catabolism of asymmetric dimethylarginines. Induction of DDAHs indicates an elevated protein catabolism that could contribute to tune MPNST cell tumorigenicity. A thorough comprehension of the amino acid metabolism rewiring in NF1-related tumors may unveil new targetable liabilities of cancer cells to be exploited for the design of new effective therapeutic approaches.

DNAJB1-PRKACA fusion in fibrolamellar hepatocellular carcinoma induces glutamine addiction and an immunosuppressive tumor microenvironment

Zeal Kamdar[1], Tamara Lopez-Vidal[1], Kathryn Howe[1], Kabeer Munjal[1], Ali Saeed[1], Daniel Zabransky[1], Daniel Shu[1], Gabriella Longway[1], Emma Kartalia[1], James Leatherman[1], Aditya Mohan[2], Pratik Khare[1], Cissy Zhang[1], Anne Le[3], Erika Pearce[1], Mark Furth[4], Marina Baretti[1], Robert Leone[1], Elizabeth Jaffee[1], Mark Yarchoan[1]. *[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Duke University, Durham, NC,[3]Gigantest, Baltimore, MD,[4]Fibrolamellar Cancer Foundation, Greenwich, CT*

Fibrolamellar hepatocellular carcinoma (FLC) is a rare and often lethal form of liver cancer that primarily affects children and young adults. A fusion between DNAJB1, a heat shock chaperone protein, and PRKACA, the catalytic domain of protein kinase A (PKA) has been identified as a signature genomic event in FLC, but the effect of this fusion on the tumor immune microenvironment is not understood. We created an orthotopic,

syngeneic model of FLC (TIBx-FLC) by inducing the DNAJB1-PRKACA fusion in a murine hepatoblastoma-derived cell line (TIBx). CD8 T cells isolated from TIBx-FLC tumors demonstrated markedly impaired activation as compared to CD8 T cells isolated from control TIBx tumors. We investigated metabolic programming as a potential mechanism for DNAJB1-PRKACA immunosuppression in FLC. Labeled glucose metabolomics performed on TIBx-FLC and TIBx tumor cells demonstrated a metabolic shift away from aerobic metabolism to an increased glucose contribution towards the hexosamine biosynthetic pathway and purine synthesis, which requires glutamine as a nitrogen source. As compared to the parental TIBx cell line, the TIBx-FLC cell line demonstrated high sensitivity to glutamine antagonism *in vitro*, consistent with glutamine addiction. Systemic treatment of BALB/c mice bearing TIBx-FLC tumors with JHU-083, a glutamine antagonist, in combination with immune checkpoint inhibitor therapy enhanced survival as compared to vehicle or monotherapy. These data identify altered glutamine metabolism as a target in FLC, and may provide an explanation for immune suppression seen in the FLC tumor microenvironment.

Multiomics analysis of triple negative breast cancer identifies potential metabolic vulnerability for overcoming the resistance of neoadjuvant therapy

Zuen Ren[1], Kiran Kurmi[2], Robert Morris[1], Shakchhi Joshi[2], Eric Zaniewski[1], Johannes Kreuzer[1], Gabrielle Elena Gioia[1], Wilhelm Haas[1], Marcia C. Haigis[2], Leif W. Ellisen[1]. *[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA,[2]The Department of Cell Biology, Harvard Medical School, Boston, MA*

Triple-negative breast cancer (TNBC) is a heterogeneous disease that remains currently medically incurable. We comprehensively analyzed clinical, proteomic, and metabolomic data of a cohort of 12 highly selected primary TNBCs. Among them, 7 patients after neoadjuvant chemotherapy had residual disease and micro- or macro-metastases that were non-pathologically complete response (non-pCR); 5 patients had pathologically complete response (pCR). Interestingly, both proteomic and metabolic profiling results revealed dramatically different molecular signatures in

non-pCR relative to pCR. Non-pCR were enriched in metabolites involving aspartic acid, fumarate, nicotinamide, and adenosine that are critical intermediates for nitrogen recycling and tricarboxylic acid (TCA) cycle, which are essential fuels for tumor biomass. Moreover, non-pCR were enriched in urea cycle, oxidative phosphorylation, glycolysis, sirtuin signaling, nucleotide *De Novo* biosynthesis, which are resistance-associated. Putative therapeutic targets were identified in non-pCR patients. Collectively, our multiomics analysis demonstrated the heterogeneity of TNBCs at multi-levels and enabled the development of personalized therapies targeting unique tumor metabolic profiles.

#3681

c-MAF-driven metabolic reprogramming mediates H3K27 hyperacetylation to regulate super enhancer-associated genes

Phyllis SY Chong[1], Sze Lynn Julia Lim[2], Jianbiao Zhou[2], Aaron Chung Yong Leow[2], Wee Joo Chng[3]. *[1]National University of Singapore (NUS), Singapore, Singapore,[2]Cancer Science Institute Singapore, Singapore, Singapore,[3]National University Cancer Institute, Singapore (NCIS), Singapore, Singapore*

Overexpression of transcription factor c-MAF is found in about 50% of multiple myeloma cases, and associated with the prognostically unfavorable t(14;16) translocation subtype. Genetic alterations can modify the epigenome through metabolite availability that act as substrates in histone modifications, but how this translates into specificities in gene regulation is unclear. Here, we report a novel involvement of c-MAF in metabolically-driven histone acetylation, including the superenhancer mark H3K27ac, through altering acetyl-CoA metabolism. To sustain high levels of acetylation, c-MAF acquired the metabolic flexibility to utilize glutamine in addition to glucose, feeding into the tricarboxylic acid (TCA) cycle as acetyl-CoA sources. Loss-of-function studies indicated that c-MAF is important for citrate-derived acetyl-CoA and H3K27ac levels through metabolic enzymes citrate synthase (CS) and ATP-citrate lyase (ACLY). Furthermore, blocking citrate export from mitochondrial via CRISPR/Cas9 targeting of SLC25A1 reproduced the reductions in H3K27ac. Silencing of c-MAF also displayed defective mitochondrial oxidative phosphorylation attributed to reduced metabolic flux through TCA cycle and downregulation

of electron transport chain complex I/II expression, without affecting mitochondrial DNA content. To identify c-MAF-regulated superenhancer genes, we overlapped our previously published H3K27ac ChIP-seq dataset on t(14;16) MM cell lines with c-MAF RNA-seq data. We found signal enrichment of H3K27ac at ZC3H3 locus responsible for its transcriptional upregulation, and knockdown of ZC3H3 inhibited cell growth specifically in the t(14;16) subtype. Altogether, we demonstrated a non-canonical c-MAF role in epigenetics that is connected to its altered metabolic state, and suggest metabolic disruptions as a new therapeutic direction in t(14;16) myeloma.

#3682

Glutamine addiction of c-MAF overexpressing cells drives dysregulation of purine metabolism

Julia Sze Lynn Lim[1], Phyllis Shu Yun Chong[2], Wee-Joo Chng[3]. *[1]Cancer Science Institute of Singapore, NUS, Singapore, Singapore,[2]Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore,[3]Department of Hematology-Oncology, National University Cancer Institute of Singapore, National University Health System, Singapore, Singapore*

c-MAF, a bZIP transcription factor, is overexpressed as a consequence of t(14;16) translocation and represents a driver oncogene in this subtype. Clinically, patients with t(14;16) translocation constitute a high-risk group with adverse survival outcomes. Since transcription factors are not classical targets for the development of small molecule inhibitors, elucidating pathways downstream of c-MAF could present as potential therapeutic targets. Critically, gene expression profiling studies of c-MAF showed a class of recurrently deregulated metabolic genes. Hence, this warrants further studies into the underexplored role of metabolism and the deregulated metabolic pathways mediated by c-MAF. First, we confirmed that t(14;16) cells were dependent on c-MAF expression for cell viability. Abrogation of c-MAF deregulated sensitivity to glycolytic inhibitors and influenced metabolite readouts. Importantly, analysis of quantitative metabolic profile of c-MAF driven myeloma using metabolomics identified 41% (48/116) of metabolites to vary significantly. Classification of differential metabolites into metabolic pathways was performed using the

software MetaboAnalyst 5.0 to elucidate a role of c-MAF in de novo purine metabolism. Despite an increased source of PRPP derived from the pentose phosphate pathway, we observed significant decrease in output of IMP (fold change=0.6, p=0.028). We postulate that this might result from lowered levels of some non-essential amino acids substrates needed by enzymes in the de novo purine biosynthesis pathway such as glutamine (fold change=0.08, p=0.155) and aspartate (fold change=0.3, p=0.022). Furthermore, GSEA from RNA-seq data performed by c-MAF loss-of-function studies identified *ADCY1, ADCY5* and *GALR3*, suggesting a direct regulation of purine metabolic genes by c-MAF. Notably, to validate whether c-MAF displayed metabolic dependency on glutamine to drive purine biosynthesis, we performed nutrient starvation studies which showed glutamine dependency in c-MAF overexpressed cells. We also systematically knockdown glucose transporters (GLUT8 and GLUT4) or glutamine transporters (ASCT2 and SNAT1) and saw a greater dependency on glutamine transporters for cell viability. As a proof of concept, c-MAF overexpressed cells were more sensitive to purine depletion by LTX suggesting its dependency on purine metabolism. The downstream identification of biological association of c-MAF with cancer metabolism may emerge as a new therapeutic strategy for MM patients. Taken together, our study suggests that metabolic perturbations present as a likely key Achilles heel in MM, and could potentially shift the current treatment paradigm.

Activation of purine anabolism creates a therapeutic vulnerability in hepatocellular carcinoma via m6A-mediated epitranscriptomic regulation

Man-Hsin Hung[1], Ching Wen Chang[1], Kathy Cheng Wang[1], Jittiporn Chaisaingmongkol[2], Mathuros Ruchirawat[2], Tim F. Greten[1], Xin Wei Wang[1]. *[1]National Cancer Institute, Bethesda, MD,[2]Laboratory of Chemical Carcinogenesis, Chulabhorn Research Institute, Bangkok, Thailand*

Introduction Purines are building blocks for genomics and the abundance of purine nucleotides is controlled by purine synthesis and purine degradation. Imbalance of purine nucleotide pool in tumors has been shown, but how synthesis and degradation of purine integrates in tumors has not been well

characterized. Hepatocellular carcinoma (HCC) is the most common liver cancer with a high mortality rate and limited treatments. Aberrant purine metabolism was observed in HCC, but the functional status of global purine metabolism in HCC and how that drive HCC fitness and therapeutic response remain unclear. Method HCC-specific purine metabolic changes were identified from the transcriptomic and metabolic data of tumor and paired non-tumor liver tissues obtained from 62 HCC patients from Thailand (discovery cohort) and validated in an additional 672 HCC with different race/ethnicities and etiologies. Correlation analysis of purine metabolic alteration and tumor-associated genomic, transcriptome and metabolome were conducted. The impacts of purine metabolism on HCC survival and therapeutic vulnerability were investigated. Biological functions of purine metabolic alterations were assessed *in vitro* and *in vivo* on multiple HCC cell lines. Results Using multi-omics integrative analyses, we found a tumor-specific activation of purine anabolism, induced by upregulation of purine de novo biosynthesis and inhibition of purine degradation, in HCC. A high purine anabolic status was associated with dysregulation of the DNA damage repairing (DDR) machinery in HCC, accompanied by unique somatic mutational signatures linked to patient prognosis. By examining drug responses to 180 molecular targeted agents in HCC cells, we found that increasing purine anabolism induced a therapeutic vulnerability of HCC to DDR targeting agents. Mechanistically, we found that excessive purine metabolites induced N6-methyladenosine (m6A) modification on DTL, a DDB1 cullin4 associated factor, thereby delaying the degradation of DTL mRNA transcriptomic remodeling of the DDR machinery and tumor fitness. Experimentally, we demonstrated that suppressing purine anabolism or exposing to DDR targeting agent, such as berzosertib, inhibited the growth of HCCs with high purine anabolism *in vitro* and *in vivo*. Conclusion Our study suggests that targeting purine anabolism or DDR may represent as attractive strategies in patients with high purine anabolic HCCs, and purine anabolic status could be a valuable biomarker to allocate systemic treatments for patients with advanced HCC.

#3685

Targeting a novel cell surface serine protease TMPRSS11B for lung cancer therapy

Hari Shankar Sunil[1], Barrett Updegraff[2], Jingfei Zhu[3], Bret M. Evers[3], John D. Minna[3], Ralph J. Deberardinis[3], Trudy G. Oliver[4], Kathryn A. O'Donnell[1]. *[1]Molecular Biology, University of Texas Southwestern Medical Center, Dallas, TX,[2]Seagen, Bothell, WA,[3]University of Texas Southwestern Medical Center, Dallas, TX,[4]Duke University, Durham, NC*

Lung cancer is the leading cause of cancer-related deaths worldwide. Patients have few therapeutic options, and disease progression is inevitable. Anti-PD-1/PD-L1 antibodies can induce potent anti-tumor immunity and have been approved as a first-line therapy for non-small cell lung cancer (NSCLC). However, only ~20% of all NSCLCs benefit from checkpoint blockade, underscoring the critical need for the development of new and innovative approaches to identify actionable therapeutic targets to treat NSCLC. We identified the Transmembrane Serine Protease *TMPRSS11B* as a novel gene that promotes the transformation of human bronchial epithelial cells *in vitro* and induces tumorigenesis *in vivo* (Updegraff et al., *Cell Reports*, 2018). Our data show that TMPRSS11B promotes solubilization of Basigin, an obligate chaperone of the lactate monocarboxylate transporters MCT1 and MCT4, and that TMPRSS11B interacts and co-localizes with Basigin and MCT4. Moreover, Basigin release mediated by TMPRSS11B enhances lactate export and glycolytic metabolism, thereby promoting tumorigenesis. This is of significant interest because *TMPRSS11B* is frequently overexpressed in human lung squamous cell cancers (LSCC) and high expression is associated with poor survival of NSCLC patients. Moreover, as a cell surface protein and enzyme, TMPRSS11B represents an exciting putative target for therapeutic intervention. Our new studies demonstrate that the catalytic activity of TMPRSS11B may be important for the interaction with Basigin and enhanced lactate export. We also evaluated the effect of *Tmprss11b* depletion in the KLN205 syngeneic LSCC mouse model. CRISPR/Cas9 knockout of *Tmprss11b* in KLN205 LSCC cells significantly reduced tumor burden in immunocompetent DBA/2 WT mice. Moreover, mass spectrometry analysis revealed TMPRSS11B-interacting proteins that may represent novel substrates of this enzyme. Current studies are focused on elucidating the molecular mechanisms through which TMPRSS11B promotes tumorigenesis and investigating the efficacy of TMPRSS11B inhibition in syngeneic and autochthonous mouse models of LSCC, where the effects on immune cell function will be assessed.

Blocking fatty acid oxidation suggests a potential new therapeutic approach for pancreatic cancer

Sang M. Woo, Sung-Sik Han, Ho Lee, Soo-Youl Kim. *National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of*

Background: Glycolysis is known as the main pathway for ATP production in cancer cells. However, in pancreatic ductal adenocarcinoma (PDAC) cells, glucose deprivation for 24 h did not reduce ATP levels, whereas it suppressed lactate production. We found that ATP production in PDAC cells critically depended on fatty acid oxidation (FAO) while normal cells showed no dependency on fatty acid. Therefore, FAO inhibition significantly decrease oxygen consumption rate as well as ATP production only in cancer cells.
Methods: To test whether cancer depends on fatty acid for energy metabolism, high- or low-fat diet was tested in spontaneous PDAC cancer model (KPC mouse: Kras(G12D)/p53(R172H)/Pdx1-Cre model). To test whether FAO is absolute requirement for ATP production in cancer, overall survival (OS) was monitored in KPC mice by crossbreeding with FAO gene knock out mice.
Results: First, the effects of calorie balanced high- or low-fat diets were tested to determine whether cancer growth is modulated by fatty acid instead of calories. A low-fat diet caused a 70 % decrease in pancreatic preneoplastic lesions accompanying decrease of body weight 20% compared with the control, whereas high-fat diet caused a 2-fold increase in preneoplastic lesions accompanied with 25% increase of body mass index in Kras(G12D)/p53(R172H)/Pdx1-Cre model (KPC model; spontaneous PDAC model). Second, the effect of FAO gene knock down was tested to determine whether OS is increased in KPC model. The crossbreeding of FAO gene knockout (+/-) and KPC mice resulted in 2-fold increase of OS.
Conclusions: The two results suggest that controlling obesity by diet as well as targeting FAO can enhance anti-cancer effect of cancer therapeutics including conventional anti-cancer drug or immune-oncology drug.
Clinical Trial Identification: IND for PDAC therapy with drugs targeting FAO will be submitted in 2022.

Disruption of nucleotide homeostasis confers cancer cell susceptibility to oxidative phosphorylation inhibition independently of energy depletion

Xiaohong Zhao[1], Yuan Yuan Zhang[1], Liang Xu[1], Ting La[1], Yu Chen Feng[1], Hai Jie Tang[1], Ran Xu[1], Vinod K. Narayana[2], David P. De Souza[2], Lake-Ee Quek[3], Jeff Holst[4], Rick F. Thorne[1], Mark Baker[1], Tao Liu[5], Lei Jin[1], Xu Dong Zhang[1]. *[1]The University of Newcastle, Callaghan, Australia,[2]Metabolomics Australia, University of Melbourne, Melbourne, Australia,[3]The University of Sydney, Sydney, Australia,[4]The University of New South Wales, Sydney, Australia,[5]Children's Cancer Institute Australia for Medical Research, Randwick, Australia*

Cancer metabolism is highly heterogenous and flexible with the Warburg effect or oxidative phosphorylation (OXPHOS) prevailing in a cancer type- and context-dependent manner. Past studies have demonstrated that targeting OXPHOS robustly inhibits glycolysis-deficient cancer cell viability and tumorigenicity. However, the therapeutic potential of OXPHOS inhibition in metabolically flexible glycolysis-competent cancers is unclear. Furthermore, whether the depletion of OXPHOS-derived ATP or the abolition of OXPHOS-supported biosynthesis is the major determinant of cancer cell susceptibility remains obscure. To address these questions, we exposed a panel of metabolically flexible glycolysis-competent cancer cell lines to OXPHOS inhibitors and tested cell survival and proliferation. We monitored metabolic phenotypes and changes in metabolites using seahorse metabolic flux assays and targeted metabolomics, respectively. Stable isotope-tracing was carried out with uniformly labelled [^{15}N]-/[^{13}C]-aspartate. Patient-derived xenograft (PDX) models of colorectal cancer in NSG mice were used for *in vivo* validation. Here we provide evidence that

OXPHOS inhibition potently diminishes metabolically flexible glycolysis-competent cancer cell proliferation and tumorigenicity without causing devastating energy stress. The inhibition of cell proliferation by OXPHOS inhibitors is associated with S-phase cell cycle arrest and the enrichment of the G2/M DNA-damage check point regulation pathway, suggestive of replication stress. Indeed, IACS treatment significantly reduces the purine/pyrimidine nucleotide pools, which is primarily caused by aspartate deficiency resulting from a shortage in the electron acceptor NAD^+. The supplementation of exogenous nucleosides, aspartate, or pyruvate that can accept electron generating NAD^+, into the culture medium rescues cells from IACS-induced cell cycle arrest. Instructively, inhibition of GOT1, which catalyzes cytosolic aspartate biosynthesis when mitochondrial aspartate production is dampened, renders cancer cells grown in two- and three-dimensional cultures more susceptible to OXPHOS inhibition. Collectively, these results indicate that 1) disruption of nucleotide homeostasis is a major determinant of cancer cell susceptibility to OXPHOS inhibition; 2) OXPHOS inhibition is a promising avenue for the treatment of cancers that are metabolic flexible and glycolysis competent; and 3) GOT1 targeting is potentially a useful approach to improve the therapeutic efficacy of OXPHOS inhibition for cancer treatment.

Exploring metabolic vulnerabilities of metastatic prostate cancer to bone

Federica Mossa[1], Daniele Robesti[2], Christopher Vellano[1], Mark Titus[1], Joe Marszalek[1], Daniel Frigo[1], Christopher Logothetis[1], Taranjit Gujral[3], Eleonora Dondossola[1]. *[1]UT MD Anderson Cancer Center, Houston, TX,[2]San Raffaele Hospital, Milan, Italy,[3]Fred Hutchinson Cancer Center, Seattle, WA*

Currently, limited knowledge is available on subtype-specific metabolic features and their implications for treatment. Here, we investigated the metabolic determinants of the two major subtypes of castration-resistant prostate cancer (androgen receptor-expressing prostate cancer, ARPC; and aggressive variant prostate cancer, AVPC). Transcriptomic analyses revealed enrichment of gene sets involved in oxidative phosphorylation in ARPC tumor samples compared to AVPC. Unbiased screening of metabolic

signaling pathways in PDX models by proteomic analyses further supported an enrichment of oxidative phosphorylation in ARPC compared to AVPC, and a skewing toward glycolysis by AVPC. Metabolic in vitro analyses showed that C4-2B cells depended on aerobic respiration, while PC3 cells relied more heavily on glycolysis, as further confirmed by pharmacological interference using IACS-010759, a clinical grade inhibitor of oxidative phosphorylation tested in patients. In vivo studies confirmed a significant reduction by IACS-010759 in C4-2B tumors implanted subcutaneously or in bone, and no effect in subcutaneous PC3 tumors. Unexpectedly, PC3 tumors in bone responded to IACS-010759, indicating a microenvironment-induced metabolic reprogramming. These results suggest that castration-resistant ARPC and AVPC exhibit different metabolic dependencies with aerobic respiration being a major driver of ARPC, while AVPC depends on glycolysis, but can undergo metabolic reprogramming in bone. Such metabolic vulnerabilities may be exploited to either introduce further lines of treatments or in combination with the existing therapies. These findings also underscore the important role that the tumor microenvironment can play in reprogramming prostate cancer metabolism and thus, influence the efficacy of metabolically targeted therapies.

Uncovering the metabolic vulnerabilities in activated B cell diffuse large B cell lymphoma

Satishkumar Singh, Fouad Choueiry, Anuvrat Sircar, Narendranath Epperla, Jiangjiang Zhu, Lalit Sehgal. *The Ohio State University Wexner Medical Ctr., Columbus, OH*

DLBCL is the most common B cell malignancy in adults accounting for 30-40% of non-Hodgkin lymphoma. Only 60% of these cases are curable, with activated B cell DLBCL (ABC-DLBCL) having inferior outcomes than the germinal center (GCB) DLBCL. The use of ibrutinib to treat non-responsive/relapsed ABC-DLBCL cases has significantly improved the treatment of this disease. However, in more than 40% of ABC-DLBCL cases, the disease progresses or develops resistance to ibrutinib. Thus, there is an urgent unmet need to understand the molecular basis of resistance mechanisms and identify novel therapeutic regimens to treat IR DLBCL. Utilizing high throughput metabolomics, we identified cysteine-methionine

metabolism and alanine, aspartate, and glutamate metabolism to be deregulated in IR cells. We further identified interleukin four induced 1 (IL4I1), an L-amino acid oxidase that partakes in cysteine and methionine metabolism by contributing to the methionine salvage pathway. The amino acid cysteine contributes to cancer metabolic remodeling by a), in its free form, in redox control, as a component of the antioxidant glutathione or its involvement in protein s-cysteinylation, b), as a substrate for the production of hydrogen sulfide (H2S), which feeds the mitochondrial electron transfer chain and mediates persulphidation of ATPase and glycolytic enzymes, thereby stimulating cellular bioenergetics; and, c), as a carbon source for epigenetic regulation, biomass production, and energy production. Consistent with this, we show that loss of IL4I1 expression induced aberrant cysteine and methionine metabolism accompanied by metabolic reprogramming to OXPHOS, which collectively enabled increased drug tolerance of DLBCL. This adaptive metabolic mechanism exhibited increased cysteine and cystathionine intracellular levels in IR-DLBCL lacking IL4I1 expression. As cysteine and glutathione are scavengers of free radicals (mainly reactive oxygen species (ROS)), they can nullify the effects of the majority of oxidative or alkylating drugs used in cancer therapy, affording a vital resistance mechanism and disruption of cysteine homeostasis appears to be promising strategy for induction of cancer cell death and provide therapeutic approaches to treat Ibrutinib-resistant-ABC-DLBCL for improved patient care.

Single-cell flux estimation analysis reveals the metabolic states of tumor-specific CD4$^+$ T cells

Mercy Kehinde-Ige[1], Ogacheko Okoko[2], Zhi-Chun Ding[2], Gang Zhou[2], Huidong Shi[2]. *[1]Department of Biochemistry and Molecular Biology, Georgia Cancer Center, Medical College of Georgia at Augusta University, Augusta, GA,[2]Georgia Cancer Center, Medical College of Georgia at Augusta University, Augusta, GA*

Adoptive Cell Therapy (ACT) holds great promise to transform cancer treatments. However, applying ACT to a broad patient population still faces

major challenges. The significant barriers to the success of ACT have been attributed to multiple factors, including functional exhaustion, poor persistence, and the inability of T cells to efficiently compete against tumor cells for metabolic resources in the tumor microenvironment (TME). These functional deficiencies highlight the importance of targeting T cell metabolism to improve ACT treatment outcomes. In the TME, tumor cells preferentially utilize glycolysis to rapidly generate ATP, converting pyruvate into lactate and creating a hypoxic environment that is inconducive for effector T cells due to a lack of access to the metabolites needed for sustenance, leading to T cell exhaustion, and declined proliferation. Consequently, T cells lose their function and are unable to persist against tumor cells. The expression of Constitutively Active Signal Transducer and Activator of Transcription 5A (CASTAT5) on tumor-specific $CD4^+$ T cells has been shown to improve their persistence, polyfunctionality, and anti-tumor effects. Our hypothesis is that the improved polyfunctionality and persistence of CASTAT5-$CD4^+$ T cells are partly due to the reprogramming of their metabolic landscape by CASTAT5, resulting in improved metabolic fitness. Single-cell metabolic pathway enrichment analysis of the identified polyfunctional CASTAT5-$CD4^+$ T cells revealed increased capacity for glycolysis, electron transport chain, oxidative phosphorylation, and amino acid metabolism. Single-cell Flux Estimation Analysis (scFEA) further revealed increased metabolic fluxes in amino acid uptake and synthesis, glycolysis, tricarboxylic acid (TCA) cycle, and polyamine synthesis. Interestingly, CASTAT5-$CD4^+$ T cells showed increased polyamine (spermine and spermidine) synthesis, with the upregulation of the metabolic fluxes from putrescine to spermine, catalyzed by spermidine synthase (Srm) and spermine synthase (Srs), both of which are also upregulated in the polyfunctional $CD4^+$ T cell populations. Spermidine and spermine have been shown to enhance mitochondrial metabolism in T cells, increasing their proliferation and survival. Here, we show that there is increased synthesis of spermine in CASTAT5-$CD4^+$ T cells, which may contribute to their increased capacity for oxidative phosphorylation and TCA cycle, leading to the observed improvements in their persistence and anti-tumor function. These findings suggest a role for the polyamine synthesis pathway in the improvement of T cell function. Further studies modulating targets within the polyamine synthesis pathway will help provide an improved understanding of the underlying mechanisms

affecting T cell function, thus, unveiling potential metabolic targets to improve the efficacy of tumor-specific T cells.

Metabolic response in human cervical cancer cells to modifications in bioavailable ATP

Parth K. Jayaswal, Taha Muhammad, Ashley Brown, Jeffrey Norris, Shaleen B. Korch. *Midwestern University - Glendale Campus, Glendale, AZ*

Introduction: Cancer cells utilize a markedly reduced oxidative phosphorylation (OXPHOS) when experiencing conditions of high oxygen stress (Warburg Effect/aerobic glycolysis), a phenomenon first studied by Otto Warburg. While there have been many discoveries associated with metabolic differences across cancer cells, one of the most common alterations is the primary means of generating ATP. The importance of deciphering these cellular decisions will enable an understanding of the multifaceted role ATP has in cancer proliferation, senescence, and chemotherapeutic resistance. The use of synthetic protein DX, a man-made ATP chelator with high specificity and affinity, is a proposed method of investigating the metabolic response in cancer cells. Hypothesis: Following DX expression, HeLa cells respond to energy stress (reduced intracellular ATP) via metabolic adaptations, specifically inducing the spare respiratory capacity.
Methods: The impact of DX on cell viability was determined using a tetrazolium-based colorimetric cell viability assay and a caspase 3/7 assay. To correlate phenotypic/viability change with DX activity, bioavailable ATP levels were measured at specific time points following DX expression. Additionally, the relative contribution of glycolysis and OXPHOS to the total ATP production rate was measured using the label-free XF Real Time ATP Rate Assay and XF Cell Mito Stress Test (XFe96 Seahorse, Agilent Technologies) over time post DX expression. To determine the impact of ATP stress on mitochondrial and nuclear content, both were quantified following DX-expression.
Results: In a time- and dose- dependent manner, DX negatively impacted cell growth and induced cell death via apoptosis, at a time concomitant with a decrease in bioavailable ATP. In response to DX over time, the total ATP

production rates in HeLa cells significantly decreased. Importantly, this reduction in the rate of ATP production was associated with a significant downregulation in both OXPHOS and glycolysis.
Conclusion: Advances in synthetic biology have allowed for the intentional design of artificial proteins that maintain function in vivo. These proteins can be developed into powerful investigative tools to study biological questions, such as cellular decisions involved in cancer cell metabolism. In response to DX-potentiated ATP stress, the significant reduction in both glycolysis and oxidative phosphorylation suggests metabolic downregulation is required to maintain HeLa cell viability.

Mitochondrial uncoupling reverses reductive carboxylation in cancer
Haowen Jiang, Clifford Jiajun He, Albert M. Li, Bo He, Yang Li, Jiangbin Ye. *Stanford University School of Medicine, Stanford, CA*

When electron transport chain (ETC) activity is inhibited upon hypoxia or when cultured in suspension, reductive carboxylation plays an essential role in supporting tumor growth through converting α-ketoglutarate (α-KG) to citrate, which is converted to acetyl-coenzyme A (acetyl-CoA) for lipogenesis. However, there is no effective way to target reductive carboxylation for tumor therapy. In this study, we use the mitochondrial uncoupler niclosamide ethanolamine (NEN) and BAM15 to reverse reductive carboxylation in cancer cells. Uncoupler treatment activates ETC and increases the cellular NAD^+/NADH ratio. Using U-^{13}C-glutamine and 1-^{13}C-glutamine tracers, we discovered that uncoupler treatment accelerates the oxidative TCA cycle and blocks reductive carboxylation, particularly under hypoxia and spheroid culture condition. Uncoupler treatment significantly reduces tumor cell proliferation, survival and sphere formation. In addition, the intracellular acetyl-CoA levels are significantly decreased by NEN treatment. Furthermore, lipidomics analysis showed that NEN treatment reduced fatty acid abundance and altered the lipid composition under both normoxia and hypoxia. Together, these data demonstrate mitochondrial uncoupling redirects the α-KG flux from reductive carboxylation back to the oxidative TCA cycle, highlighting that the ETC activity and NAD^+/NADH ratio is the key switch that determines

the metabolic fate of α-KG. Reversing reductive carboxylation could be one key mechanism that mitochondrial uncoupler inhibits tumor growth.

L-arginine depletion causes different proliferation responses in breast cancer subtypes - Relation to gene expression profiles of L-arginine metabolic pathways

Juliane Hannemann, Fiona Franke, Mariola Kastner, Rainer Böger. *Institute of Clinical Pharmacology and Toxicology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Metabolic fingerprinting provides insight into cancer biology, improving personalized therapeutic strategies. We sought to unravel responses of the molecular subtypes of breast cancer to L-arginine depletion in vitro. Availability of the semi-essential amino acid L-arginine limits protein synthesis and cell proliferation. L-Arginine is the substrate for nitric oxide synthases (NOS) and arginases (ARG), enzymes also involved in the regulation of cell proliferation. Clinical studies have provided contrasting results regarding the role of L-arginine in breast cancer.We studied the response of different breast cancer cell lines to L-arginine depletion and the molecular mechanisms underlying this effect. MCF-7, SK-BR-3, BT-474, MDA-MB-231, and MDA-MB-468 cells were cultured under standard conditions and compared to MCF-12A normal breast epithelial cells. Cells were maintained in culture media with 200 mg/L (control) or 0 mg/L of L-arginine (depletion) for up to 240 h. Cell proliferation was analyzed and intracellular concentrations of L-arginine, L-ornithine, and L-citrulline were measured by UPLC-MS/MS every 24 h. mRNA expression of genes involved in L-arginine metabolism was quantified by qRT-PCR.
MCF-12A control cells did not proliferate in the absence of extracellular L-arginine. Their intracellular L-arginine content dropped sharply, whilst L-ornithine and L-citrulline were only slightly reduced. By contrast, proliferation of BT-474, SK-BR-3, and MDA-MB-468 cells was unaffected by L-arginine depletion ($p<0.05$), whilst MCF-7 and MDA-MB-231 cells showed significantly higher proliferation rates in the absence of L-arginine ($p<0.05$). L-arginine concentration dropped sharply within 24 h in MCF-7 cells, but only by 25-50% in the other cell lines ($p<0.01$). L-ornithine dropped to almost zero within 24 h in both estrogen receptor positive cell

lines (MCF-7 and BT-474), whilst being only slightly reduced in SK-BR-3 cells ($p<0.01$). L-ornithine was not significantly reduced in MDA-MB-231, but strongly reduced in MDA-MB-468 cells ($p<0.05$). L-citrulline showed no significant change in any of the cell lines. mRNA expression of NOS, ARG, and the L-arginine salvage pathway (ASS1 and ASL) was differentially expressed amongst the cell lines. SK-BR-3 showed high expression of the L-arginine salvage pathway; BT-474 had the highest expression levels of NOS and ARG2, and MDA-MB had high ARG2 but very low NOS expression. Gene expression patterns of MCF-12A and MCF-7 were very similar.
In conclusion, metabolic fingerprinting reveals complex and differential regulation of L-arginine pathways in breast cancer cell lines. These analyses may help to understand differences in proliferation during L-arginine depletion, thus offering a perspective to further personalize treatment options within classical molecular breast cancer subtypes.

#3697

Modulation of Nicotinamide N-Methyl Transferase (NNMT) expression in TNBC is associated with altered cell membrane cholesterol levels

Woei-Yaw Chee[1], Deniz Nesli Dolcen[2], Lynda Bennett[1], Suzanne D. Conzen[1]. *[1]Internal Medicine, UT Southwestern Children's Medical Center Research Institute, Dallas, TX,[2]Internal Medicine, Stanford University, San Francisco, CA*

Introducti**on:** Cancer cells often develop a program of metabolic adaptability and epigenetic remodelling to promote gene expression changes causing cancerous cell proliferation and invasion. The metabolic-epigenetic axis as a an underlying mechanism of carcinogenesis could lead to new approaches to cancer treatment. Nicotinamide N-Methyl Transferase (NNMT) is a metabolic enzyme that catalyzes the transfer of a methyl group from S-Adenosyl methionine (SAM) to nicotinamide, thereby decreasing the overall methyl pools for RNA, histone and DNA methylation. High NNMT expression has been previously associated with a poor outcome in TNBC.
Hypothesis: We hypothesized that high versus low NNMT activity and resulting oncogenic gene expression in TNBC may alter histone methylation is association with altered metabolic pathway activation.

Methods: We used two TNBC cell lines models, MDA-MB 231 and SUM159, to study the association between high versus low NNMT activity and metabolic pathway activation. Surprisingly, we identified gene expression pathways suggestive of increased free cholesterol biosynthesis gene expression with low NNMT, and then used biochemical assays and filipin to measure free cholesterol in both total high and low NNMT TNBC cell lysates and relative cholesterol expression in the High vs Low NNMT cell membranes.
Results: *In vitro*, NNMT knockdown resulted in increased cholesterol synthetic pathway enzyme expression in both TNBC cell lines. I*n vivo* studies also showed that protein expression of cholesterol synthesis enzymes was also increased in NNMT-depleted MDA-MB 231 xenografted tumors. Interestingly, the increased cholesterol level upon NNMT depletion was mainly localized at the plasma membrane via Filipin III staining, suggesting a possible association with less cellular membrane fluidity and a decreased oncogenic phenotype. In ongoing experiments, we are evaluating whether changes in histone methylation in high vs low NNMT cells are associated with differential expression of cholesterol biosynthetic genes, and free cholesterol production. We hypothesize that NNMT might epigenetically decrease the methylation of histones regulating cholesterol production in TNBC.

Epigenetic modification induced reprogramming of PUFAs-associated metabolism during trastuzumab resistance formation of HER2-positive breast cancer

Yongmei Yin[1], Ningjun Duan[1], Yijia Hua[1], Shuang Hu[2]. *[1]Oncology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China,[2]Nanjing Maternity and Child Health Care Hospital, Nanjing, China*

Background: Secondary trastuzumab resistance seriously affects the treatment of HER2-positive breast cancer. Although studies have demonstrated several potential reasons that cause trastuzumab resistance, we still have poor knowledge about the changes in cell itself as well as its interaction with tumor microenvironment (TME) components during resistance formation. Here we suggested that altered histone modification reprograms polyunsaturated fatty acids (PUFAs) metabolism, which reduces

cellular PUFAs and stimulates prostaglandin E2 (PGE2) production. Excessive PGE2 may further affect both cancer cells as well as immune cells in TME.
Materials and Methods: Secondary trastuzumab-resistant cell line SKBR3_HR was generated from sensitive SKBR3 cells by raising trastuzumab concentration gently from 1ug/ml to 20ug/ml in 30 weeks. Cell viabilities were measured by CCK8 test. CUT&Tag with anti-H3K4me3 and anti-H3K27me3 antibodies were applied to make sequencing libraries. Total RNA and protein were collected for transcriptome and proteome analysis. Activity scores of metabolism processes were defined and calculated as the relative gene expression value averaged over all genes in this pathway in certain cell types. Oxidized PUFAs and PGE2 were assessed by flow cytometry with BODIPY-C11 and ELISA, respectively.
Results: SKBR3_HR cells showed similar viability as primary resistant JIMT1 cells and were significantly higher than original SKBR3 cells. Pathway analysis indicated reduced PUFAs synthesis and activated arachidonic acid metabolism. As a consequence, oxidized PUFAs decreased while PGE2 accumulated heavily in SKBR3_HR cells, which may promote tumor and vascular endothelial cell proliferation but interrupt immune cell activity in TME. Transcriptional activity of two critical PUFAs synthesis-related genes, FASN and SCD, were reduced in resistant cells, while two key genes in arachidonic acid metabolism, PTGS1 and PTGES, were activated. H3K4me3 and H3K27me3 play opposite but critical rules in transcriptional regulation. During resistance formation, changes happened on 3256 H3K27me3 peaks as well as 316 H3K4me3 peaks. In detail, although little H3K27me3 changes were found at the promoter regions of four genes (FASN, SCD, PTGS1 and PTGES), reduced H3K4me3 levels may inhibit FASN and SCD expression while raised levels could stimulate PTGS1 and PTGES transcription.
Conclusions: Combining the transcriptome and histone modification data, we have a deeper understanding of the cellular adaptions to trastuzumab. Altered trimethylation of H3K4 but not H3K27 remodels the expressions of FASN, SCD, PTGS1 and PTGES, drives the reprogramming of PUFAs-associated metabolism, and finally reduces cellular PUFAs while stimulates PGE2 production. High PGE2 level may affect the activities of tumor and TME-related cells.

#3699

Involvement of p53 and KRAS in the regulation of SLC38A5 in colon cancer

Nhi Thi Phuong Nguyen, Sathish Sivaprakasam, Vadivel Ganapathy. *Cell Biology and Biochemistry, Texas Tech University Health Sciences Center, Lubbock, TX*

Cancer-associated upregulation has been demonstrated for selective glucose transporters and amino acid transporters. The amino acid transporter SN2 (SLC38A5) represents the latest addition to this list. Transcriptomic analysis of tumor tissues has shown SLC38A5 is upregulated in breast and colon cancer. SLC38A5 is an amino acid-dependent Na^+/H^+ exchanger, induced in cancer, which not only supplies amino acids to cancer cells but also maintains an alkaline intracellular pH. The substrates for SLC38A5 include glutamine, asparagine, histidine, methionine, glycine, and serine, highlighting the role of SLC38A5 in glutamine addiction and one-carbon metabolism, both pathways being essential for cancer cells. In addition, SLC38A5 activates macropinocytosis, a process involved in cellular uptake of proteins in the extracellular fluid to meet amino acid demands in cancer cells. Since the transporter is upregulated in colon cancer, we hypothesized that the multiple functions of SLC38A5 fuel the growth, proliferation, and survival in colon cancer cells and that its induction involves oncogenic mutations in p53 and KRAS that are common mediators of carcinogenesis in colon. Firstly, we used a panel of colon cancer cells and analyzed SLC38A5 expression and its functional characteristics. Next, we compared SLC38A5 expression and function between two isogenic cell lines: SW48 with and without the oncogenic mutation (G12D) in KRAS and HCT116 with and without the tumor suppressor p53. Among the colon cancer cells examined, KM12L4 showed highest expression of SLC38A5; therefore, we characterized the function of the transporter in detail in this cell line. Our studies showed that KM12L4 cells were able to take up serine, one of the substrates for SLC38A5, in a Na^+-dependent manner in the presence of 5 mM tryptophan, which is not a substrate for SLC38A5 but is known to block LAT1 transporter, which also transports serine. SLC38A5 exhibited an active serine-uptake when Na^+ was replaced with Li^+ at a higher pH. Li^+ tolerance and a higher activity at an alkaline pH are two unique features of SLC38A5. The oncogenic mutation G12D in KRAS increased SLC38A5

activity in SW48 cells. In contrast, loss of p53 decreased SLC38A5 activity in HCT116 cells. These data demonstrate that SLC38A5 is induced in colon cancer cells and its activity is increased in the presence of oncogenic KRAS mutations and suppressed when p53 is inactivated, thus providing a valuable insight into the molecular mechanisms for the upregulation of the transporter in colon cancer. We conclude that SLC38A5, an amino acids transporter, is upregulated in colon cancer and its functions are uniquely suited to promote cell proliferation and tumor growth. We also conclude that KRAS and p53 functional status play a critical role in the increased SLC38A5 expression and activity in colon cancer. These data suggest that SLC38A5 could be exploited as a drug target for cancer therapy.

Isocitrate dehydrogenase 1 sustains a hybrid cytoplasmic-mitochondrial tricarboxylic acid cycle in prostate cancer

Kevin Gonthier[1], Cindy Weidmann[2], Line Berthiaume[2], Cynthia Jobin[1], Aurélie Lacouture[1], Camille Lafront[1], Mario Harvey[2], Bertrand Neveu[3], Jérémy Loehr[2], Alain Bergeron[3], Yves Fradet[1], Louis Lacombe[1], Julie Riopel[3], Éva Latulippe[3], Chantal Atallah[3], Michael Shum[1], Jean-Philippe Lambert[1], Frédéric Pouliot[1], Martin Pelletier[1], Étienne Audet-Walsh[1].
[1]Université Laval, Québec, QC, Canada,[2]CRCHU de Québec-Université Laval, Québec, QC, Canada,[3]CRCHU de Québec, Québec, QC, Canada

Background: The androgen receptor (AR) is an established orchestrator of cell metabolism in prostate cancer (PCa), notably by inducing an oxidative mitochondrial program. Intriguingly, AR regulates cytoplasmic isocitrate dehydrogenase 1 (IDH1) but not its mitochondrial counterparts IDH2 and IDH3. Here, we aimed to understand the functional role of IDH1 in PCa.
Methods: Mouse models, *in vitro* human PCa cell lines, and human prostate organoids were used to study the expression and activity of IDH enzymes in the normal prostate and PCa. Genetic and pharmacological inhibition of IDH1 was then combined with extracellular flux analysis and gas chromatography-mass spectrometry for metabolomic analyses and cancer cell proliferation *in vitro* and *in vivo*.
Results: In PCa cells, more than 90% of the total IDH activity is mediated through IDH1 rather than its mitochondrial counterparts. This profile seems

to originate from the specialized prostate metabolic program, as observed using mouse prostate and human patient-derived organoids.
Pharmacological and genetic inhibition of IDH1 impaired mitochondrial respiration, suggesting that this cytoplasmic enzyme contributes to the mitochondrial tricarboxylic acid cycle (TCA) in PCa. Mass spectrometry-based metabolomics confirmed this hypothesis, showing that inhibition of IDH1 impairs carbon flux into the TCA cycle. Consequently, inhibition of IDH1 decreased PCa cell proliferation *in vitro* and *in vivo*.
Conclusions: These results demonstrate that PCa cells have a hybrid cytoplasmic-mitochondrial TCA cycle that depends on IDH1. This metabolic enzyme represents a metabolic vulnerability of PCa cells and a potential new therapeutic target.

#3701
Targeting wild-type IDH1 enhances chemosensitivity in pancreatic cancer
Mehrdad Zarei[1], Omid Hajihassani[1], Jonathan J. Hue[2], Hallie J. Graor[1], Arian Hajihassani[3], Alexander W. Loftus[2], Luke D. Rothermel[2], Jordan M. Winter[2]. *[1]Case Western Reserve University School of Medicine, Cleveland, OH,[2]University Hospitals, Cleveland, OH,[3]University of Pittsburgh Medical Center, Pittsburgh, PA*

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer mortality in the United States. The poor prognosis is in part due to development of chemotherapy resistance, despite improvements in multiagent regimens. Our previous work demonstrated that oxidative stress plays an important role in drug resistance. Wild-type isocitrate dehydrogenase 1 (IDH1) is an important enzyme that generates cytosolic NADPH to maintain redox homeostasis and protect cancer cells from oxidative damage. Additionally, we demonstrated that ivosidenib (AG-120), an FDA-approved mutant IDH1 inhibitor, is actually a potent inhibitor of wild-type IDH1, under low magnesium and nutrient levels that are present in the tumor microenvironment.
Methods: We evaluated IDH1 expression in PDAC using The Cancer Genome Atlas (TCGA). Cell viability was assessed by Trypan blue and PicoGreen in drug combination assays. Cellular reactive oxygen species (ROS) levels were determined by the DCFDA method. To further assess the

therapeutic potential of AG-120 in combination with chemotherapy, tumor volume analyses were performed using patient-derived xenografts (PDX) in athymic nude mice, and survival studies were performed in C57BL/6J mice transplanted with orthotopic murine pancreatic cancer.
Results: Analysis of TCGA data indicated that IDH1 is overexpressed in pancreatic cancer tumors. Treatment of MiaPaca2 and Panc1 cancer cells with 5- fluorouracil (5-FU) induced expression of wild-type IDH1 in vitro. Short-term cell viability data demonstrated that targeting IDH1 with AG-120 when combined with DNA-damaging agents (5-FU, oxaliplatin) had a synergistic effect with a positive synergy score and Bliss score greater than 1. Additionally, we assessed long-term cell survival using colony formation assays, which yielded a dramatic reduction in cell survival for both Panc1 and MiaPaCa-2 cells when 5-FU was combined with AG-120, as compared to single-agent controls. Inhibiting IDH1 impairs the ability of pancreatic cancer cells to scavenge ROS levels, enhances chemotherapy-induced apoptosis in pancreatic cancer cells via ROS-mediated damage in vitro. Both PDX tumor volume studies and overall survival analyses revealed that the combination of these AG-120 and chemotherapy synergistically enhanced anti-tumor activity and doubled the survival benefits as compared to single-agent alone.
Conclusion: IDH1 plays a critical role in tumorigenesis and chemoresistance in pancreatic cancer. Our data demonstrate that IDH1 inhibition with AG-120 may enhance chemotherapy efficacy and represents an important area for future investigation in the form of clinical trials.

Serine promotes aggressive phenotype in renal cancer

Suman Karki[1], Anirban Kundu[1], Garret Brinkley[2], Hyeyoung Nam[3], Kayla Goliwas[4], Jessy Deshane[5], Sunil Sudarshan[1]. *[1]Department of Urology, University of Alabama at Birmingham, Birmingham, AL,[2]Department of Urology, Tulane University, New Orleans, LA,[3]University of Alabama at Birmingham, Birmingham, AL,[4]Division of Pulmonary, Allergy, and Critical Care, University of Alabama at Birmingham, Birmingham, AL,[5]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL*

Tumor cells are known to have increased demand for nutrients to support proliferation. Among the most highly utilized nutrients by tumor cells are nonessential amino acids (NEAAs). While the role of NEAAs in supporting tumor growth is well-established, their role in supporting aggressive phenotypes such as migration and invasion is poorly understood. Yet, the major cause of morbidity from malignancies such as renal cell carcinoma (RCC) is metastasis. Through an unbiased approach, we assayed the role of NEAAs in promoting the migration of RCC cells. We demonstrate that exogenous serine and glutamine are essential and sufficient to support aggressive phenotypes in RCC. Moreover, the availability of both NEAAs is critical for the expression of the proinvasive transcription factor SNAIL. Our data converge on the role of these two NEAAs in supporting the translation of this factor. Perturbations that limit the availability and/or synthesis of either result in translational reprogramming through the integrated stress response (ISR) that leads to loss of SNAIL1 expression and attenuates aggressive phenotypes. Our findings associate nutrient status to the ISR including ER stress. Collectively, our study highlights new insights for NEAA metabolism in supporting aggressive tumor phenotypes and could reveal novel approaches to mitigate metastasis by targeting NEAA availability and/or utilization.

Multimodal metabolic imaging and proteomics of radiation resistance in head and neck squamous cell carcinoma

Jesse D. Ivers, Sina Dadgar, Narasimhan Rajaram. *Biomedical Engineering, University of Arkansas System, Farmington, AR*

Radiation resistance can halt a well-curated treatment plan in its tracks, but it may take weeks to realize this lack of efficacy resulting in lost time and unnecessary side effects. In this study, we sought to elucidate novel biomarkers of radiation resistance to predict treatment response in head and neck squamous cell carcinoma (HNSCC) at much earlier timepoints. We grew tumor xenografts from radiation-resistant UM-SCC-47 (n=25) and -sensitive UM-SCC-22B (n=37) cells in nude athymic mice. Each group was randomly divided into treatment and control groups, which were further subdivided into four timepoints for tumor excision: pre-treatment baseline, 1-, 24-, and 48-hours post-treatment. Prior to excision, we injected

pimonidazole to quantify tumor hypoxia. We determined the two-photon excited fluorescence intensity and lifetime of NADH and FAD and quantified the optical redox ratio, ratio of free to bound NADH, and mean NADH lifetime of frozen sections of each tumor. We observed spatial and temporal heterogeneity in these high-resolution optical maps that indicated different metabolic programs in radiation-resistant and -sensitive tumors. A histogram-based heterogeneity analysis revealed time dependent shifts toward glycolysis in the radiation-resistant UM-SCC-47 treatment group, while the sensitive UM-SCC-22B treatment group showed the opposite trend. Proteomics performed on both cell lines identified multiple dysregulated proteins that are often implicated in HNSCC and associated with metabolic reprogramming — specifically, EGFR and SMAD4. We also found elevated levels of hypoxia and HIF-1 in the UM-SCC-47 tumors compared with the UM-SCC-22B tumors prior to and post-radiation. Using spatially co-registered optical imaging and immunohistochemical maps of the same field of view, we will present correlations between our optical markers and EGFR, SMAD4, and HIF-1. These studies will provide evidence of how protein dysregulation causes changes to optical metabolic imaging markers.

The essential role of an alternate mRNA translation initiation in the regulation of breast cancer cell metabolism

Hanna Rosenstock[1], Erna Mitaishvili[2], Columba de la Parra[3]. *[1]Chemistry, Herbert H. Lehman College, City University of New York, New York, NY,[2]Biology Ph.D. Program, The Graduate Center, City University of New York, New York, NY,[3]Chemistry, Herbert H. Lehman College, City University of New York & The Graduate Center, New York, NY*

Translational control and metabolic reprogramming are hallmarks of advanced cancers. Important genes involved in cancer progression express mRNAs that are selectively translated, including regulators of cancer cell metabolism.

Cancer cells acquire an altered metabolism, switching from oxidative phosphorylation (OXPHOS) to a glycolytic phenotype (Warburg effect), to increase reliance on alternate metabolic pathways to support growth, proliferation, and metastasis. Triple-negative breast cancer (TNBC), one of

the most aggressive and highly metastatic subtypes with the poorest outcome, is characterized by elevated glycolysis and low OXPHOS. Still, the exact mechanism for this metabolic switch is largely unknown. Using a TNBC cell model it has been shown an alternate mechanism of cap-dependent but mTORC1/eIF4Eindependent mRNA translation by the eIF4G homolog, DAP5, which directly binds the cap-binding protein eIF3d. Our research indicates that this alternate translation initiation is essential in regulating several mRNAs involved in breast cancer metabolism. DAVID analysis from genome-wide transcriptomic and translatomic studies, metabolomic assays including Glycolysis Assay [Extracellular Acidification], Oxidative Phosphorylation, and Mitotracker Assay, as well as RT-PCR and western blot analysis was performed from well-characterized triple-negative aggressive breast cancer cell lines,4T1 and MDA-231, Non-silencing (Nsi) control and silencing DAP5 (shDAP5) samples.
Several mRNAs related to glucose metabolism decreased after silencing DAP5 and on the opposite, critical mRNAs associated with OXPHOS increased, independent of their steady-state mRNA abundance. Silencing DAP5 increased Oxidative Phosphorylation activity and decrease the glycolytic rate in TNBC breast cancer cells. Proteins correlated with aberrant glycolytic metabolism including the E-cadherin transcriptional repressors Snail (SNAI1) were reduced after silencing of DAP5. Our data indicates that the alternate mRNA translation initiation mechanism by DAP5 of specific mRNAs correlated to glycolysis and OXPHOS could play an essential role in the mechanism by which TNBC breast cancer cells orchestrate a metabolic switch required for malignant progression and metastasis.

L-2HG, oncometabolite-driven epigenetic and epitranscriptomic reprogramming creates metabolic vulnerability in renal cancer

Anirban Kundu[1], Garrett J. Brinkley[1], Hyeyoung Nam[1], Suman Karki[1], Richard Kirkman[1], Hayley Widden[2], Michelle Johnson[3], Juan Liu[4], Yasaman Heidarian[5], Nader Mahmoudzadeh[1], Devin Absher[6], Han-Fei Ding[7], David Crosman[2], William J. Placzek[2], Jason Locasale[4], Dinesh Rakheja[8], Victor Darley-Usmar[2], Jason Tennessen[5], Sunil Sudarshan[1].
[1]Urology, University of Alabama at Birmingham, Birmingham,

AL,[2]University of Alabama at Birmingham, Birmingham, AL,[3]Molecular and Cellular Pathology, University of Alabama at Birmingham, Birmingham, AL,[4]Pharmacology and Cancer Biology, Duke University, Durham, NC,[5]Biology, Indiana University, Bloomington, IN,[6]HudsonAlpha Institute for Biotechnology, Huntsville, AL,[7]Pathology, University of Alabama at Birmingham, Birmingham, AL,[8]Pathology, UT Southwestern, Dallas, TX

The oncometabolite, L-2-hydroxyglutarate (L-2HG) is elevated in the most common form of renal cell carcinoma-RCC (clear cell histology) and promotes tumor progression. L-2HG is structurally similar to α-ketoglutarate (α-KG). Therefore, L-2HG can competitively inhibit enzymes that utilize α-KG as a cofactor including α-KG-dependent dioxygenases that can profoundly impact gene expression via effects on the epigenome and epitranscriptome. RCC cell lines lack the L-2HG dehydrogenase enzyme (L2HGDH), resulting in their high L-2HG level. RNA-seq of control (high L-2GH) and an L2HGDH reconstituted (low L-2HG) RCC cell line has revealed that L-2HG suppresses the expression of serine biosynthesis genes, *PHGDH* and *PSAT1*. The findings were consistent in the patient samples where high L-2HG renal tumors had lower levels of *PHGDH* and *PSAT1* expressions than that of the low L-2HG renal tumors and the patient-matched normal kidneys. Consistently, ^{13}C-metabolomics labeling studies demonstrate that raised L-2HG suppresses *de novo* serine biosynthesis. Moreover, LC-MS analysis of the metabolites isolated from the kidneys of L2HGDH KO and wild-type (WT) mice revealed less serine content in the absence of L2HGDH, further confirming that high L-2HG suppresses serine biosynthesis *in vivo*. We found that L-2HG-mediated inhibition of the α-KG-dependent histone demethylase KDM4C silences ATF4 transcription. ATF4 is a master regulator of amino acid biosynthetic genes including *PHGDH* and *PSAT1*. Using ATF4 gain of function analysis, we confirmed that high L-2HG causes the suppression of PHGDH and PSAT1 in an ATF4-dependent manner. In addition, we demonstrate that L-2HG promotes the accumulation of the epitranscriptomic mark N^6-methyladenosine (m6A) via inhibiting α-KG-dependent RNA demethylases ALKBH5 and FTO. In the setting of high L-2HG, m6A is enriched in the 3'-UTR region of transcripts including *PSAT1*. Using mutational analysis, we demonstrate that L-2HG promotes m6A accumulation at a specific site within the 3'UTR

of *PSAT1* that silences its translation. In accord with these data, found that high L-2HG RCC cells require exogenous serine for *in vitro* proliferation and *in vivo* tumor growth. Furthermore, this serine liability can be rescued upon lowering cellular L-2HG levels. Metabolomics analyses demonstrate that exogenous serine is required to maintain cellular pools of glutathione in high L-2HG RCC which supports both proliferation and resistance to oxidative stress. The data indicate that the L-2HG elevation in RCC reconfigures tumor metabolism through a bimodal mechanism via remodeling of both the epigenome and epitranscriptome. This results in a serine liability in the setting of raised L-2HG. Collectively, our data unmask a metabolic vulnerability that can be harnessed for precision-based approaches to kidney cancer.

The significance of cholesteryl ester profiles in hepatocellular carcinoma

Nazar Rahmanov[1], Zhirong Liu[2], Jinghe Mao[3], Patrick Kyle[1], Xinchun Zhou[1]. *[1]Pathology, University of Mississippi Medical Center, Jackson, MS,[2]Biochemistry, Shanxi Medical University, Taiyuan, China,[3]Biology, Tougaloo College, Tougaloo, MS*

Introduction: The association between cholesteryl ester (CE) profiles in the liver and oncogenesis, gender, and age disparities in hepatocellular carcinoma (HCC) has not been studied to date. This study aims to compare CE profiles between benign liver tissue (BLT) and HCC, and to correlate these findings with oncogenesis and disparities in patients with HCC.
Methods: Paired BLT and HCC samples obtained from 32 patients with the diagnosis of HCC were used for lipid extraction. Electrospray ionized mass spectrometry (ESI-MS) was used to determine CE profiles, including 22 individual CE species and the total levels of CE. The CE profiles in BLT and HCC were compared and stratified between subgroups based on the gender and age of the patients. The student T-test was used for statistical analysis and the significant p-value was set at 0.05.
Results: Total CE levels were higher in HCC than in BLT, but not statistically significant (1.8-fold, p=0.16). Interestingly, 5 saturated CE individual species and 2 mono-unsaturated individual CE species (C14:0, C16:0, C16:1, C18:0, C18:1, C19:0, and C20:0) were significantly higher in

HCC than in BLT (2.4 to 14-fold higher). None of the individual poly-unsaturated CE species showed a statistical difference between HCC and BLT. In males, the levels of 3 saturated individual CE species (C16.0, 16:0, and C20:0) were significantly higher in HCC than in BLT (1.9 to 21.3-fold higher levels). In contrast, CE 16:1 was significantly lower in HCC than in BLT (0.9-fold, p=0.02) in males. In females, none of the CE profiles showed a significant difference between HCC and BLT. Total CE levels were 2.1-fold higher in males with HCC than in females with HCC (18.6nM vs. 8.92nM). In young patients (<66-year-old), individual CE species C14:0 was significantly higher in HCC than in BLT (19.1-fold, p=0.038). In old patients (≥66-year old), individual CE species C20:0 was significantly higher in HCC than in BLT. Total CE levels were 2.1-fold higher in young HCC patients than in old HCC patients (13.68nM vs. 6.45nM).
Conclusion: This study reveals that an increase in hepatic total CE levels and individual CE species are associated with the oncogenesis of HCC and show gender and age disparities. These findings could be helpful in prevention, treatment, exploring biomarkers, and understanding disparities in HCC.

#3707
UXS1 is a synthetic lethal target in cancer
Michelle Patricia Cicchini[1], Shuzhen Wu[2], Yang Peng[1], Yanhua Rao[1].
[1]GlaxoSmithKline, Collegeville, PA,[2]GlaxoSmithKline, Boston, MA

Studies presented here were conducted to validate UXS1 as a synthetic lethal target in UGDHhigh expressing cancer. *In vitro* and *in vivo* knockout studies were used to investigate the role of UXS1 in UGDH-high cancers. UXS1 has been validated as a synthetic lethal target in cancer cell lines highly expressing UGDH *in vitro* by CRISPR-mediated knockout of UXS1 in a panel of lung cancer cell lines. In addition to UGDH expression predicting UXS1 dependency, we have shown UGDH overexpression functional drives UXS1 dependency, such that knockout of UGDH rescues cellular growth defects seen with UXS1-knockout alone. Furthermore, catalytic activity of UXS1 was shown to be required, as wildtype but not catalytic deficient UXS1 was able to rescue cellular growth defects seen with endogenous UXS1 knockout in UGDH-high cancer cell lines. Together

this data suggests that dysregulation of some metabolite(s) is driven by high expression of UGDH when knockout of UXS1 prevents normal pathway flux of UDP-Glucuronic Acid (UDP-GA) to be converted to UDP-Xylose (UDP-X), leading to the synthetic lethal effect observed as impaired cellular growth. To validate UXS1 as a target *in vivo*, an inducible genetic knockout system to knockout UXS1 showed impaired tumor growth, but no tumor regression. Sanger sequencing of UXS1 knockout efficiency at different time course suggested a slow and incomplete dropout of the UXS1-KO cells *in vivo.* Although *in vitro* efforts have shown UXS1 to a synthetic lethal target, the failure to induce a robust *in vivo* effect of UXS1 knockout have casted doubts on the promise of UXS1 being an effective target for the proposed indication.

Platelet-derived microparticles modulate breast cancer malignant processes

Vanessa Veilleux, Nicolas Pichaud, Luc H. Boudreau, Gilles A. Robichaud.
Université de Moncton, Moncton, NB, Canada

Breast cancer is one of the leading causes of morbidity and mortality among women, where metastasis accounts for the majority of deaths associated with this disease. Thus, the potential to effectively target tumor malignancy offers hope to mitigate disease progression and improve patient outcomes. It is well established that platelets promote multiple processes of metastasis cascade. Recently, platelets have received new attention for their impact in cancer through the production of platelet-derived microparticles (PMPs). Interestingly, PMPs allow intercellular exchange and trafficking of bioactive material through the internalization of these vesicles into recipient cells. As a result, the delivery of the intravesicular cargo can modulate signaling and activation processes of recipient cells. We recently identified a new subpopulation of these vesicles (termed mitoMPs) containing functional mitochondria. Given the predominant role of mitochondria in cancer malignancy, we believe that mitoMPs provide an important source of foreign mitochondria to support recipient breast cancer cells in malignancy and disease progression. We therefore set out to study the impact of mitoMPs on breast cancer metabolic and phenotypic processes involved in metastasis. Technically, PMPs were generated and purified from human

blood platelets and co-incubated with various breast cell models (MB231, MCF7 and MCF10A). The physiological significance of mitoMPs in breast cancer disease was then assessed using various cellular and molecular assays. We demonstrate that the level of PMP internalization is highly dependent upon the type of breast cancer recipient cells. Furthermore, we show that the cargo of mitoMPs (notably mitochondria) is biologically active where recipient breast cancer cells acquired mitochondria-dependent functions, such as increased oxygen consumption rates and intracellular ATP production. Finally, we observe that mitoMPs promote malignant features such as cancer cell migration and invasion. Overall, we demonstrate that PMPs can modulate cancer cell activation and behaviour. These findings provide a better understanding of the extracellular tumor environment and the contribution of mitoMPs in supporting breast cancer cells through the metastatic landscape. The knowledge gained will further provide new avenues for therapeutic strategies in breast cancer patients.

Hyperglycemia induces metabolic reprogramming and promotes epithelial-mesenchymal transitions in pancreatic cancer: an in vitro and in vivo experiment

Zhao Liu, Hiromitsu Hayashi, Kazuki Matsumura, Yoko Ogata, Hiroki Sato, Yuta Shiraishi, Norio Uemura, Tatsunori Miyata, Takaaki Higashi, Shigeki Nakagawa, Kosuke Mima, Katsunori Imai, Hideo Baba. *Kumamoto Univ Graduate School of Medical Sci, Kumamoto, Japan*

Background: Pancreatic cancer is a serious life-threatening disease due to its highly invasive and metastatic potential. Hyperglycemia is a well-known initial symptom in patients with pancreatic ductal adenocarcinoma (PDAC). Metabolic reprogramming in cancer, described as the Warburg effect, can induce epithelial-mesenchymal transition (EMT). In this study, we elucidate the biological and clinical impact of hyperglycemia in PDAC progression.
Methods: Biological impact of hyperglycemia on malignant behavior in PDAC was examined by *in vitro* and *in vivo*experiment.
Results: Hyperglycemia promoted EMT by inducing metabolic reprogramming into a glycolytic phenotype via yes-associated protein (YAP)/PDZ-binding motif (TAZ) overexpression, accompanied by GLUT1 overexpression and enhanced phosphorylation Akt in PDAC. In addition,

hyperglycemia enhanced chemoresistance by upregulating ABCB1 expression, and triggered PDAC switch into pure-basal-like subtype with activated Hedgehog pathway (GLI1 high, GATA6 low expression) through YAP/TAZ overexpression. PDAC is characterized by abundant stroma that harbors tumor-promoting properties and chemoresistance. Hyperglycemia promotes production of collagen fiber-related proteins (fibronectin, fibroblast activation protein, COL1A1, and COL11A1) by stimulating YAP/TAZ expression in cancer-associated fibroblasts (CAFs). Knockdown of *YAP* and/or *TAZ* or treatment with YAP/TAZ inhibitor (K975) abolished EMT, chemoresistance, and a favorable tumor microenvironment even under hyperglycemic conditions *in vitro* and *in vivo*. Indeed, YAP/TAZ overexpression was significantly associated with worse prognostic outcomes in human PDAC patients.
Conclusion: Hyperglycemia induce metabolic reprogramming into a glycolytic phenotype and promote EMT via the YAP/TAZ-Hedgehog signaling axis in PDAC. Hyperglycemia as an initial symptom may be the cause of highly invasive and metastatic potential by inducing YAP/TAZ overexpression, while YAP/TAZ could be a novel therapeutic target in PDAC patients.

Serum tryptophan metabolites mediate constitutive AHR activity in head and neck squamous cell carcinoma cells

Dhwani Patel, Ethan W. Morgan, Fangcong Dong, Iain A. Murray, Gary H. Perdew. *Penn State University, State College, PA*

The aryl hydrocarbon receptor (AHR) is transcription factor, that is activated upon binding to various exogenous and endogenous ligands. AHR activation leads to induction of target gene expression, including the members of cytochrome P450 enzyme family that metabolize many xenobiotics. Numerous studies have shown that the AHR is involved in multiple regulatory pathways important during carcinogenesis. High level of AHR protein and activation was observed in head and neck squamous cell carcinoma (HNSCC) and has been correlated with aggressive tumor phenotypes and migratory potential. Endogenous compounds derived from host tryptophan metabolism such as kynurenine, as well as the derivatives of indole derived from bacterial tryptophan metabolism such as indole-3-

propionic acid are known to activate AHR. A fundamental question not previously addressed is whether these circulating tryptophan (Tryp) metabolites can mediate persistent AHR activation within tumor tissues and its effect on tumorigenesis. The focus of our research is to determine whether the continuous exposure of Tryp metabolites at relevant concentrations leads to sustained AHR activation in HNSCC cells and its subsequent effect on tumor cell phenotypes. Here, we present data demonstrating sustained AHR activation by Tryp metabolites in two HNSCC cell lines. A total of 6 tryptophan (Tryp) metabolites present at significant levels in serum with known AHR agonist activity were identified and quantified from 40 healthy individuals on a controlled diet by LC/MS/MS. HN30 and OSC19 cells were treated with a representative pool of 6 Tryp metabolites in a cell culture system to achieve continuous exposure to the Tryp metabolites, thus mimicking blood circulation in vivo. Treated cells were collected at six different time points and AHR activation within cells was determined by measuring mRNA and protein expression of AHR target genes. The effect of Tryp pool on HN30 and OSC19 cell viability was determined. The presence of Tryp metabolites within the cells and media was quantitated by LC/MS/MS at six time points over the course of 24 h. Continuous exposure of Tryp metabolites resulted in sustained AHR activation in HN30 and OSC19 cells, confirmed by induced mRNA expression of target genes and subsequent protein levels. The LC/MS data revealed the presence of all six Tryp metabolites in media collected at all time points, suggesting no spontaneous degradation of metabolites. Tryp metabolites were detected inside the cells starting from 2 h post-treatment to the last time point 24 h. Viability assays indicated no cytotoxic effects of Tryp metabolites on cells. Overall, our work has demonstrated a pattern of sustained AHR activation in HNSCC cells resulting from continuous exposure of Tryp metabolites, supporting the concept that endogenous Tryp metabolites in HNSCC patients would impact tumor progression, metastasis, and treatment outcomes.

Molecular and cancer-related roles of ATP-citrate lyase exon 14

Julianna G. Supplee, Hayley C. Affronti, Richard Duan, Rebekah C. Brooks, Phuong Nguyen, Kollin Schultz, Ronen Marmorstein, Kathryn E. Wellen. *University of Pennsylvania, Philadelphia, PA*

Introduction: ATP-citrate lyase (ACLY) links carbohydrate and lipid metabolism as well as provides acetyl-CoA necessary for histone acetylation, linking cell nutrient status and epigenetic regulation. Several studies have shown that ACLY is upregulated in multiple cancer types. ACLY has two major splice isoforms: the full-length canonical “long” isoform and an uncharacterized “short” isoform where exon 14 is spliced out. RNAseq data from The Cancer Genome Atlas (TCGA) shows that the Percent Spliced In (PSI) of exon 14, i.e., the proportion of long isoform, is increased in several cancers compared to normal tissues. We therefore hypothesize that ACLY exon 14 inclusion can support tumor growth.
Experimental Procedures: Extensive statistical analysis was performed on TCGA data to explore the connection between ACLY PSI and clinical parameters including tumor type, stage, and survival. We also noted a serine within exon 14 that is dynamically phosphorylated according to multiple phosphoproteomics studies. We used an in vitro activity assay and differential scanning fluorimetry to biochemically characterize purified ACLY isoforms and phosphomutants. We also expressed these isoforms and mutants in cells lacking endogenous ACLY to evaluated rescue of known ACLY functions including proliferation, de novo lipogenesis, and histone acetylation. Since exon 14 is located near a putative nuclear localization sequence, we also used confocal microscopy to study subcellular localization of these constructs. Ultimately, we developed a new C57BL6/J mouse model with ACLY exon 14 deleted by CRISPR to study the role of exon 14 in metabolic physiology and tumor growth in vivo.
Results: In vitro assays showed no differences in activity and stability between ACLY isoforms and phosphomutants. Similarly, both isoforms and mutants were able to rescue known ACLY functions in cells, and deletion of exon 14 in mice does not impact normal metabolic physiology. Analysis of TCGA data offers compelling evidence that the long ACLY isoform is upregulated early in tumorigenesis and is associated with deadlier tumors and certain immune cell signatures, suggesting that exon 14 is particularly relevant in this disease context. Our mouse model was cross-bred to ApcMin/+ mice, a genetic model of colon cancer, and studies are underway to determine the impact of exon 14 on colon tumors and immune infiltration.

Conclusions: ACLY exon 14 does not have obvious roles in enzymatic activity and known ACLY functions. However, alternative splicing could impact pathophysiological phenotypes such as cancer or other yet undescribed functions of ACLY.

Chromatin Structure and Function in Cancer

Characterization of 3D genome in nasopharyngeal carcinoma (NPC)

Dittman Lai-Shun Chung, Larry Ka-Yue Chow, Wei Dai. *Department of Clinical Oncology, University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong*

Background: Epstein-Barr virus (EBV) can be detected in more than 90% of NPC patients in Hong Kong. It has been shown that EBV infection could hijack the human epigenome in B cell lymphoma and EBV+ gastric cancer, however, the role of EBV in epigenetic dysregulation remains largely unknown in NPC. Recently, our epigenomic landscape study demonstrated EBV was associated with changes of chromatin accessibility in NPC, which were largely involved in the binding sites of CTCF, a master regulator of chromosome organization. Therefore, we aim to further characterize the 3D chromatin structure in NPC.
Methods: We used the Hi-C (Omni-C Seq) to profile the chromatin interactions in the EBV-positive (EBV+) NPC, EBV-negative (EBV-) NPC, and normal immortalized epithelial (NPE) cell lines. The Omni-C Seq data were integrated with the ATAC-Seq, RNA-Seq, and CUT&RUN-Seq data. The histone markers including H3K4me3, H3K27ac, and H3K27me3, were applied to classify the active and inactive status of the chromatins. The chromatin looping and topologically associated domains (TADs) were defined by the CTCF binding sites.
Results: We observed a much larger compartmentalization size in EBV+ NPC with a consistent increase of active to inactive (A to B) compartments, compared to NPE and EBV- NPC. Pathway enrichment analysis showed that these changes potentially influenced immune response, cell differentiation and development, metabolism, ERBB pathway, and calcium signaling transduction. In addition to the changes in compartmentalization, we observed a reduction of CTCF binding signals at the TADs boundaries

and the loss of chromatin looping at the 10kb resolution. Consistently, the aggregate peak analysis has shown a significant reduction of the CTCF anchor, indicating the abandonment of architectural CTCF in EBV+ NPC. More importantly, we found EBV tethering to the host chromatins. In the EBV genome, the tethering sites were often located at the regions associated with OriP, EBNA1, and BARTs. In the human genome, the tethering sites were dramatically enriched in the inactive to active (B to A) compartments, which were highly associated with the enhancer regions with H3K27ac. We identified a specific target gene *CD74* with EBV tethering at the nearby super-enhancer region. Our results suggest the upregulation of *CD74* could be controlled via remodulating the host 3D genome in EBV+ NPC. The spatial transcriptome analysis indicated that the expression of CD74 was highly correlated with HLA-DRA. The spatial analysis further showed that the NPC patients with upregulated HLA-DRA often had *de novo* distant metastasis after treatment (p=0.007). Conclusions: The EBV tethering to the host genome has a significant impact on host 3D genome organization, affecting chromatin accessibility and gene regulation, providing survival
advantages of cancer cell growth and potentially contributing to immune suppression and metastasis.

Analyses of epigenetic marks and mechanisms in disease: Your guide to a successful CUT&RUN assay

Angela H. Guo, Christopher R. Comeau, Fang Chen, Christopher J. Fry.
Cell Signaling Technology, Inc., Danvers, MA

Like the chromatin immunoprecipitation (ChIP) assay, Cleavage Under Targets & Release Using Nuclease (CUT&RUN) is a powerful and versatile technique used for probing protein-DNA interactions within the natural chromatin context of the cell. The CUT&RUN assay can be combined with downstream qPCR or NG-seq to analyze histone modifications and binding of transcription factors, DNA replication factors, or DNA repair proteins at specific target genes or across the entire genome. CUT&RUN provides a rapid, robust, and true low cell number assay for detection of protein-DNA interactions in the cell. Unlike the ChIP assay, CUT&RUN is free from formaldehyde cross-linking, chromatin fragmentation, and

immunoprecipitation. Previously, we have shown that, compared to ChIP, CUT&RUN requires fewer starting cells (100K), has a much faster protocol (one day from cells to DNA), generates lower background signal (requires less sequencing depth), and offers spike-in control DNA for effective normalization of signal between samples and between experiments. We recently updated the CST CUT&RUN Assay Kit for use with 5,000-20,000 cells and added protocols for fixed cells and tissue. I will discuss the basics of the CUT&RUN assay and important factors to consider when setting up your experiment. In addition, I will provide data showing the versatility of this assay for mapping various histone modifications, transcription factor, and transcription cofactor binding across multiple sample types. Finally, I will discuss how the general protocol is optimized for greater signal to noise ratio, reduced number of starting cells, and provide an alternative digestion method to prepare the input DNA as a critical control of the CUT&RUN experiment.

Alterations of chromatin structure and TGF-β signaling in ARID1A-mutated colon cancer cells

Jiwon Kim[1], Giyong Jang[2], Soo-Jin Lee[1], Sang Eun Lee[1], Sung-Yup Cho[3].
[1]Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Medical Research Center, Genomic Medicine Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Seoul National University College of Medicine, Seoul, Korea, Republic of

ARID1A, a subunit of the SWI/SNF complex which regulates gene expression by remodeling chromatin structure, is often mutated in various cancer and is known as a tumor suppressor gene. Many studies revealed the loss of ARID1A promotes tumor progression by activating PI3K-Akt signaling, but other pathways have not yet been fully elucidated. By analyzing RNA sequencing data and ATAC-seq data with ARID1A wild-type cell lines HCT116 and isogenic ARID1A Q456*/Q456* which has truncation mutations for ARID1A, we investigated the alterations of epigenomic and transcriptomic characteristics according to the loss of ARID1A. The overall openness of chromatin decreased in ARID1A Q456*/Q456* cells. Since SWI/SNF complex regulates chromatin structure

and gene expression accordingly, we analyzed genes whose change of RNA expression and openness of chromatin in the same direction. The results showed 109 upregulated genes and 715 downregulated genes compared to wild type cell line with $P_{adj} < 0.05$, $|log2FC| > 0.58$ from both RNA sequencing and ATAC-seq. To determine which gene sets are activated in the ARID1A-deficient cell line, the differentially expressed genes with consistent chromatin openness were subjected to Gene Ontology analysis. The upregulated genes in the ARID1A-deficient cell line were enriched in 'Cell proliferation' and 'TGF-β signaling'. In addition, the expression of representative genes associated with TGF-β signaling increased in ARID1A-deficient cells. Our data suggests that loss-of-mutation in ARID1A significantly changes the chromatin structure, resulting in alterations of gene expression associated with cell proliferation and TGF-β signaling.

#4720

Chromatin conformation alterations in prostate cancer progression and formation of castration resistance

Tuomo Virtanen, Ebrahim Afyounian, Riikka Nurminen, Teuvo Tammela, Tapio Visakorpi, Juha Kesseli, Kirsi Rautajoki, Matti Nykter. *Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland*

Introduction: Prostate cancer (PC) is the most common cancer in men and second in cancer related deaths. Aggressive prostate cancer is typically treated with androgen depletion therapy which often results in the formation of castration resistant prostate cancer (CRPC). Androgen receptor (AR) is a transcription factor that regulates hundreds of target genes and is responsible for the differentiation and function of normal prostate epithelial cells. In addition to AR, multiple other TFs that bind to distal enhancers have been implicated in PC, such as FOXA1, MYC and HOXB13. Understanding the role of these distal regulators is paramount in PC.
Methods: To study the changes in chromatin conformation in prostate cancer progression, we have sequenced clinical benign prostatic hyperplasia (BPH), PC and CRPC samples using Hi-C sequencing. From each group 6 samples were sequenced with a total of 18 samples in the cohort. In addition, we have combined a multi omics cohort consisting of chromatin accessibility, transcriptome and methylome sequencing data from matching

samples. Together these data types allow us to map out the regulatory networks in PC and CRPC by probing the distal active regulatory sites and their interactions. To account for artifacts caused by genomic aberrations in cancer samples we have established a pipeline for normalizing these effects in HiC-data.
Results: Overall topologically associated domains (TADs) and A/B-compartments remain stable between the groups. However, local changes of compartments in loci of key genes, such as AKR1C3 and FOXA1 correlate with their gene expression. We detect differential loops between sample groups and these changes are associated with gene expression alterations in PCs. Distal enhancers of PC up-regulated genes are enriched for FOXA1 and HOXB13. Interestingly, up-regulated loops in CRPC are enriched for FOXA1 and HOXB13, while no systematic effect on gene expression is seen on a genome wide scale, apart from genes such as AR and CENPE whose expression correlates strongly with their association to distal enhancers. We also detect enhancer hijacking events in driver genes. One example is the recurrent ETV1-MIPOL1 fusion, where promoter of ETV1 forms contacts with FOXA1 enhancer regions.
Conclusions: Alterations in loop structures are strongly associated with regulatory programs that have been previously implicated in PC, including regulation by FOXA1, HOXB13 and other transcription factors. This highlights the importance of chromatin conformation in facilitating the effects of regulatory programs that rely on distal enhancers in PC. These changes appear more systematic in untreated PCs, whilst CRPCs exhibit more heterogeneity in chromatin conformation across the samples.

Yin Yang 1-induced long non-coding RNA DUXAP9 drives oral squamous cell carcinoma by blocking CDK1-mediated EZH2 degradation

Wei Cao, Wenkai Zhou. *Department of Oral and Maxillofacial& Head and Neck Oncology, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: lncRNAs play a critical role in oral squamous cell carcinoma (OSCC) progression and metastasis. However, the detailed molecular mechanism is not fully understood.

Methods: Differential-expressed lncRNAs between OSCCs and paired adjacent tissues were identified by microarray. The expression of lncRNADUXAP9 (DUXAP9) was detected by RNAscope and quantitative real-time PCR (qRT-PCR). The gain-of-function and loss-of-function of DUXAP9 were evaluated *in vitro* and *in vivo* assays. Chromatin immunoprecipitation (ChIP)and luciferase assays were performed to analyze the transcriptional regulation of DUXAP9. RNA pull-down assays, LS-MS/MS analysis, RNA immunoprecipitation assays, and Co-immunoprecipitation (Co-IP) were performed to address the molecular mechanism through which DUXAP9promotes OSCC progression. Results: By analyzing lncRNA microarray data, we identified a novel nuclear-localized DUXAP9, which is upregulated in OSCC. The high level of DUXAP9is positively associated with lymph-node metastasis, poor pathological differentiation, advanced clinical stage, worse overall survival, and worse disease-specific survival in OSCC patients. DUXAP9 significantly promotes cell proliferation, migration/invasion, and metastasis *in vitro* and *in vivo* through an EZH2-dependent manner. Yin Yang 1(YY1) was found to activate the transcriptional expression of DUXAP9 in OSCC. Furthermore, DUXAP9was proven to physically interact with EZH2 and inhibit EZH2 degradation via the suppression of the phosphorylation of EZH2, thereby blocking EZH2nucleus to cytoplasm translocation. Conclusions: Here we demonstrated a novel mechanism mediated by lncRNA DUXAP9 at the posttranslational level, which contributes to OSCC progression, thus providing a promising target for OSCC therapy.

Chronic upregulation of glucocorticoid hormones triggers chromatin remodeling in NSCLC through dynamic regulation of histone H3 chaperones

Benito M. Traversa, Devesh Raizada, Eva Kragelj, Julia Spegel, Didem Ilter, Ana P. Gomes. *H. Lee Moffitt Cancer Center, Tampa, FL*

Lung cancer is the most common cause of cancer death worldwide, with a five-year survival rate of only 18.6%. Aging is a well-established risk factor for lung cancer development. However, our understanding of how the aging

process affects lung cancer remains cripplingly small. In this study, we aim to bridge this gap by evaluating the effects of glucocorticoid hormones (e.g. cortisol), which become chronically upregulated during the aging process, in lung cancer cells. Phenotypically, our studies revealed that chronic exposure to age-related levels of cortisol trigger a mesenchymal-like senescent state in lung cancer cells that favors motility and invasiveness. Acquisition of pro-aggressive features are generally recognized to be driven by epigenetic regulation. Epigenetic regulation occurs at several levels, but perhaps one of the most fundamental levels is nucleosome remodeling via histone variants and their cognate chaperones. Histone H3 variants are critical regulators of nucleosome stability and have a highly specialized histone chaperone network when compared to other histones. Strikingly, we observed that chronic exposure of lung cancer cells to cortisol leads to a pronounced decline in canonical histone levels, which was accompanied by a 40% increase in chromatin accessibility genome-wide. Chromatin accessibility by transcriptional machinery is heavily influenced by histone variants, thus, we hypothesized that cortisol also regulates deposition of histone H3 variants into chromatin. The CAF-1 complex deposits the canonical H3 variants (H3.1/H3.2) onto DNA in a cell-cycle-dependent manner while other histone chaperones, HIRA at genic and DAXX at telomeric regions, deposit the H3.3 variant independently of cell cycle. In accordance with the decline in canonical histone levels, treatment with cortisol suppressed the expression of the CAF-1 complex. Reduced canonical histone abundance is known to trigger “gap filling” of naked DNA with the H3.3 variant to maintain integrity. In support of the idea that H3.3 becomes enriched in chromatin upon chronic exposure of lung cancer cells to cortisol, our results showed that the proportion of H3.3 increases upon cortisol exposure, and concomitantly H3.3 chaperone HIRA is induced upon treatment with cortisol. These data support a model in which chronic exposure to glucocorticoids, as it occurs with aging or through treatment with synthetic glucocorticoids (e.g. dexamethasone), regulates nucleosome abundance and composition in lung cancer cells through dynamic regulation of histone H3 chaperone systems. Together, we propose that this glucocorticoid-induced nucleosome remodeling establishes a chromatin environment that enables the transition to a mesenchymal-like senescent state in lung cancer cells that favors aggressiveness and poor prognosis.

DNA G-quadruplex facilitates MYC enhancer-promotor interaction

Dieila Giomo De Lima, Gustavo Narvaes Guimarães, Bianca Caroline Figueiredo Bianco, Ana Paula De Souza, Aline Cristiane Planello.
Histology and Embriology, State University of Campinas, Piracicaba, Brazil

Background: G-quadruplexes (G4) are nucleic acid secondary structures formed in guanine-rich regions of DNA or RNA. The biological significance of G4 has been attributed to the regulation of gene expression, and more recently, to the stabilization and generation of enhancer-promotor interaction. Since G4 are enriched in the promoter region of the proto-oncogene MYC, we sought to investigate the role of G4 in stabilizing the enhancer-promoter loop using the locus 8q24 (hg38) 127,700,000-128,500,000 that contains the MYC gene as a model.
Methods: Two different cell lines were used, the spontaneously immortalized, non-oncogenic human epidermal keratinocyte (HaCaT), in which the enrichment of G4 in the MYC promoter was demonstrated, and the primary normal human epidermal keratinocyte (nHEK) that is depleted of G4 in MYC promoter. Both cell lines were exposed to the G4 selective stabilizer 360-A drug and the half-maximal inhibitory concentration (IC50) could be calculated. Gene expression was accessed by RT-qPCR and DNA methylation by Methylation-Sensitive High Resolution Melting (MS-HRM). Chromatin Conformation Capture (3C-qPCR) technique was performed interrogating the MYC gene (chr8:127,733,798-127,744,729) and the putative enhancer in the lncRNA PVT1 gene (chr8:127,914,509-127,922,393) to compare the frequency of promoter-enhancer interaction between the two cell lines.
Results: The HaCaT cells showed interaction between the MYC promoter and the distal region. The nHEK cells that are not enriched for G4 showed no promoter interaction with the distal region. The use of 360-A in IC50 did not change the results. The gene expression analysis of the MYC showed higher expression in HaCaT cells compared to nHEK. There was no difference in DNA methylation in the MYC promoter between the two cell lines.

Conclusions: The data suggest an important role of G4 for the interaction of the MYC promoter and downstream enhancer. Additional analyzes of other genomic regions enriched for G4 should be performed to confirm the mechanism.

Single cell multiomic profiling of high-grade serous carcinoma

Leticia Assad Maia Sandoval[1], Wazim Mohammed Ismail[1], Amelia Mazzone[1], Amik Munankarmy[1], Jagneet Kaur[2], Tsering Tashi[3], Xiaonan Hou[1], Nagarajan Kannan[1], Ann Oberg[1], Scott H. Kaufmann[1], Saravut John Weroha[1], Alexandre Gaspar-Maia[1]. *[1]Mayo Clinic, Rochester, MN,[2]St. George's University, True Blue, Grenada,[3]Wartburg Collage, Waverly, IA*

Ovarian cancer is one of the most common gynecologic malignancies, with high-grade serous carcinoma (HGSC) as the most frequent and deadliest type of ovarian cancer (OC). With the recent advances in cancer epigenomic profiling, it has become clear that intra-tumor heterogeneity driven by genetic and epigenetic factors may be the basis of resistance, where current treatments could efficiently target sub-populations of cells while a sub-group may be resistant, or prone to develop resistance. With epigenomic profiling and single cell sequencing technology, we aim to characterize cell signatures that translate as prognostic markers and novel drug targets. We have mapped the epigenomic landscape of HGSC in 12 patient-derived xenografts (PDX), and their metastatic counterparts (circulating tumor cells and ascites present in the PDX models) using an assay for transposase-accessible chromatin (or ATAC-seq) and compared it with normal fallopian tube organoids to identify tumor and metastatic-specific regulatory elements. We also performed RNA-seq to validate potential transcriptional dependencies associated with resistance to chemotherapy. In order to identify potentially chemotherapy-resistant subpopulations and further validate the activity of some of the transcription factors that can be driving resistance, we performed single cell multiomic profiling using the 10x Multiome sequencing platform (scRNA+scATAC from the same nuclei) in HGSC patient samples and PDX. Finally, we performed immunohistochemistry of patient tissue slides for target markers and correlated it with overall survival in OC patients. As previously suggested, a subset of cancer clonal cells can drive treatment resistance and

metastasis and result in poor patient outcomes. Data derived from PDX ATAC-seq showed a cancer stem cell signature driven by SOX2 in metastatic samples compared to the paired PDX primary tumor, suggesting a role for SOX2 in disease progression. Interestingly, SOX2 expression in epithelial cells in the Multiome analysis is more patient-specific than other stem cell markers, like CD133. We also observed that SOX2 expression negatively correlated with prognosis. These data, taken together, point out the promising role of SOX2 as a prognostic and targetable marker for HGSC.

The epigenetic determinants of BTKi efficacy in chronic lymphocytic leukemia

Zhiquan Wang[1], Huihuang Yan[1], Justin C. Boysen[1], Esteban Braggio[2], Sameer A. Parikh[1], Neil E. Kay[1]. *[1]Mayo clinic, Rochester, MN,[2]Mayo clinic, Scottsdale, AZ*

Introduction: The introduction of Bruton's tyrosine kinase (BTK) inhibitors (BTKi) to target B cell receptor (BCR) pathways in chronic lymphocytic leukemia (CLL) has significantly improved clinical responses. However, the effectiveness of BTKi is limited by the development of adaptive drug resistance. Therefore, there is an urgent need to identify critical biologic features that determine BTKi efficacy in order to develop more effective therapies. Epigenetic aberrations play an important role in tumor initiation, progression, and drug resistance. However, it is currently unknown if BCR signaling is also dependent on epigenetic mechanisms to support oncogenic gene expression and survival in CLL B cells.
Methods and Results: To gain new insights into the role of epigenetic regulation of BTKi treatment in CLL B cells, we analyzed the genome wide chromatin accessibility (ATAC-seq) and histone modification (H3K4me1, H3K4me3, H3K27ac, H3K27me3) profiles (CUT&Tag) of leukemic cells from 4 CLL patients on ibrutinib treatment in a sequential fashion (i.e., baseline, on ibrutinib treatment, and at relapse). We also performed the same analysis in other cohorts at two stages of ibrutinib treatment (baseline and while on treatment, n=20). Our studies show that suppressing BCR signaling by BTKi treatment leads to an alteration of a pro-survival epigenetic signature (defined by histone modifications and chromatin

accessibility landscapes) in CLL and that the genes regulated by these chromatin changes are enriched in pathways associated with malignant B cell survival (i.e., BCR signaling and apoptosis pathways). Importantly, disruption of this pro-survival epigenetic signature is necessary for effective BTKi treatment. We further find that the transcription factor (TF) Nuclear factor of activated T-cells, cytoplasmic 1 (NFATc1) couples the BCR signaling to control this pro-survival epigenetic program that supports CLL B cell survival. In specific, we show that nuclear depletion of NFATc1 is required for BTKi induced epigenetic alteration and effective BTKi treatment. Depletion of NFATc1 disrupts the pro-survival epigenetic signature and inhibits CLL B cells survival, which improves the efficacy of BTKi treatment in CLL.
Conclusion: Here using leukemic cells from CLL patients with BTKi treatment, we demonstrate that epigenetic regulators are exploited by the oncogenic signaling pathway to support malignant cell survival. Specifically, NFATc1 is utilized by the BCR signaling pathway to control an epigenetic signature that supports CLL cell survival. This BCR regulated epigenetic machinery can be targeted to maintain and enhance BTKi treatment efficacy in CLL.

KMT5C-dependent regulation of mesenchymal-related genes and identification of KMT5C interactome using BioID
Jihye Son, Alejandra Agredo, Ally Glaws, Andrea L. Kasinski. *Purdue University, West Lafayette, IN*

Epigenetic dysregulation has recently been recognized as a new hallmark of cancer. Dysregulation of chromatin remodelers is estimated to affect 10-20% of cancer. Thus, understanding how epigenetic-based mechanisms contribute to cancer initiation and progression is critical. KMT5C is a histone methyltransferase that catalyzes histone H4 lysine 20 trimethylation (H4K20me3), which has historically been associated with formation and maintenance of constitutive heterochromatin regions. Albeit recent evidence from our lab also suggests regulation of gene-rich euchromatin regions. In this previous body of work we discovered that loss of KMT5C promotes development of resistance to tyrosine kinase inhibitors (TKI) in EGFR-mutant non-small cell lung cancer (NSCLC) cells (PC9 and

HCC827). Patient data further supports that the KMT5C transcript level is downregulated following resistance to osimertinib, a third-generation TKI. Our data suggests that KMT5C is involved in non-canonical regulation of genes outside of heterochromatic regions through its methyltransferase activity. Analysis of data deposited into the Cell Miner database and publicly available RNA-sequencing and ChIP-sequencing data revealed that the KMT5C-H4K20me3 axis has significant negative correlations with several genes involved in epithelial-to-mesenchymal transition (EMT). Our validation studies support this observation. However the mechanisms involved in KMT5C facilitating this change at EMT-related genes is unknown. KMT5C is well understood to be recruited to heterochromatin regions through its interaction with HP1, yet the mechanism for recruitment of KMT5C to gene-rich euchromatin regions remains to be elucidated. We hypothesize that KMT5C is recruited to its target genes in euchromatin in an HP1-independent mechanism. In this study, we aim to identify the interactome of KMT5C using an unbiased proximity labeling BioID approach. This study is expected to uncover a novel epigenetic mechanism that contributes to development of resistance to TKIs and may inform of strategies to target KMT5C-downregulated TKI-resistant cancers.

RAS and PP2A activities converge on phosphoregulation of epigenetic complexes in cancer

Mukund Sharma[1], Anna Aakula[1], Francesco Tabaro[2], Henrik Honkanen[1], Jesse Kamila[1], Matthieu Schapira[3], Cheryl Arrowsmith[3], Matti Nykter[2], Jukka K. Westermarck[1]. *[1]University of Turku, Turku, Finland,[2]Tampere University, Tampere, Finland,[3]University of Toronto, Toronto, ON, Canada*

RAS-mediated human cell transformation requires inhibition of the tumor suppressor Protein Phosphatase 2A (PP2A). Both RAS and PP2A mediate their effects by phosphoregulation, but phosphoprotein targets in which RAS and PP2A activities converge in human cancers have not been systematically analyzed. Here, based on mass spectrometry phosphoproteome data, we discover that phosphosites co-regulated by RAS and PP2A are enriched on proteins involved in epigenetic gene regulation. As examples, RAS and PP2A co-regulate the same phosphorylation sites on HDAC1/2, KDM1A, MTA1/2, RNF168 and TP53BP1. Mechanistically, we

validate co-regulation of NuRD chromatin repressor complex by RAS and PP2A. Consistent with their known synergistic effects in cancer, RAS activation and PP2A inhibition resulted in epigenetic reporter de-repression and activation of oncogenic transcription. Notably, transcriptional de-repression by PP2A inhibition was associated with increased euchromatin and decrease in global DNA methylation. In RAS-driven cancers, PP2A activity is inhibited by nuclear PP2A inhibitor proteins PME-1 and SET. We further demonstrate that these PP2A inhibitors drive oncogenic transcription, but that their transcriptional targets are highly diversified. Whereas PME-1 controls RAS and MYC-driven transcription, SET controls TP53 targets and G2/M checkpoint genes. We further provide evidence that these nuclear PP2A inhibitors significantly differ in their roles in regulating DNA methylation. Collectively the results indicate that epigenetic protein complexes involved in oncogenic gene expression constitute a significant point of convergence for RAS hyperactivity and PP2A inhibition in cancer. Further, the results provide a rich source for future understanding of phosphorylation as a previously unappreciated layer of regulation of epigenetic gene regulation in cancer, and in other RAS/PP2A-regulated cellular processes.

Biochemical and genomic approaches for high throughput drug discovery in chromatin remodeling research

Lu Sun[1], Hannah Willis[1], Matthew R. Marunde[1], Vishnu U. S. Kumary[1], Matthew J. Meiners[1], Saarang Gopinath[1], Jonathan M. Burg[1], Bryan J. Venters[1], Allison Hickman[1], Zu-Wen Sun[1], Martis W. Cowles[1], Pierre Esteve[2], Hang Gyeong Chin[2], Chaithanya Ponnaluri[2], Sriharsa Pradhan[2], Michael-Christopher Keogh[1]. *[1]Epicypher, Durham, NC,[2]New England Biolabs, Ipwich, MA*

Chromatin remodeling is mediated by ATP-dependent enzymes that play key roles regulating gene expression and genome replication / repair. Aberrant nucleosome organization from dysregulated chromatin remodeling can severely alter chromatin accessibility and disrupt these important processes, thereby driving various cancers. Remarkably, nearly 20% of all human cancers contain mutations in subunits from the SWI/SNF family of chromatin remodeling complexes, making them of great interest to basic

research and therapeutic intervention. *In vitro* studies on the remodeling enzymes (and their multi-subunit complexes) are challenging, partially due to the strong preference for nucleosome-based substrates (the physiological target of these enzymes). We have created the EpiDyne® nucleosome portfolio to examine chromatin remodeler activity in biochemical assays, and here present the development of novel readouts (-PicoGreen™ and -TR-FRET). These nonradioactive plate-based assays are automation adaptable, ready for high-throughput inhibitor screening, and can be customized for various remodeling enzymes that exhibit preferences in nucleosome composition (*e.g.* histone type or DNA linker length).For parallel *in vivo* studies we note that genome-wide remodeler localization and open chromatin mapping are fundamental for understanding the function / activity of these enzymes in cancer development and inhibitor response. However, traditional genomic approaches have significant issues: *e.g. ChIP-seq* is unable to effectively map ATPases without heavily modified high-noise protocols; while *ATAC-seq* to map open regions cannot deal with cross-linking that could stabilize transient states on interest. To this end, we have optimized the CUTANA™ CUT&RUN approach to efficiently capture the localization of all major classes of chromatin remodelers with high signal to background. We have also adopted NicE-seq for chromatin accessibility profiling in cross-linked material. As complementary tools to the EpiDyne platform, CUT&RUN and NicE-seq facilitate epigenomic research on chromatin remodelers in cancer therapeutic intervention. Keywords: Chromatin Remodeling, EpiDyne, Nucleosome repositioning, high-throughput screening (HTS), CUTANA™ CUT&RUN, NicE-seq

#4729

LSD1 activates oncogenic super-enhancers in castration-resistant prostate cancer by forming nuclear condensates with BRD4

Mingyu Liu[1], Muqing Li[1], Dong Han[1], Zifeng Wang[1], Wanting Han[2], Housheng Hansen He[3], Shuai Gao[4], Changmeng Cai[1]. *[1]University of Massachusetts - Boston, Boston, MA,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]University of Toronto, Toronto, ON, Canada,[4]New York Medical College, Valhalla, NY*

Lysine-specific demethylase (LSD1) was initially identified as a transcriptional repressor through demethylation of mono/di-methylated histone 3 lysine 4 (H3K4me1/2). Subsequent work suggests that LSD1 may trigger gene activation via demethylating H3K9me1/2 in the context of steroid receptors. Our previous studies have confirmed that LSD1 functions broadly as a coactivator of androgen receptor (AR)-regulated enhancers but retains its H3K4 demethylation function at these sites. Importantly, our recent work revealed that LSD1 regulates the accessibility of active enhancers through the interaction with FOXA1, which functions as a pioneer transcription factor by facilitating AR access to chromatin. LSD1 inhibition disrupts the global binding of FOXA1 by blocking the demethylation of K270 of FOXA1, leading to inhibition of AR binding and transcriptional activity. However, in addition to AR signaling, it remains largely unknown whether LSD1 regulates other critical oncogenic programs during prostate cancer (PCa) progression. In this study, we aimed to fully understand the functional targets of LSD1 in castration-resistant PCa (CRPC) models.

We performed a large transcriptomic profiling of CRPC patient-derived xenograft (PDX) models that are sensitive to LSD1 inhibitors. Our analyses indicated that LSD1 inhibition targeted multiples oncogenic programs, including previously known pathways such as AR, FOXA1, and E2F, and a previously undefined pathway, MYC signaling. Through single-cell RNA-seq analysis in a CRPC PDX model, we confirmed that MYC signaling was decreased in the responsive tumor cells and identified a previously unknown molecular subtype, $AR^{+}/FOXA1^{+}/LSD1^{low}/RB1^{-}$, which was resistant to LSD1 inhibition. It is well known that *MYC* is driven by super-enhancers (SEs), which are regulated by BRD4 (bromodomain and extraterminal (BET) protein). We further evaluated LSD1, FOXA1 and BRD4 ChIP-seq and defined SEs by using H3K27ac ChIP-seq followed by ROSE analysis. We found that LSD1, FOXA1, and BRD4 co-occupied at MYC SEs and BRD4 was recruited by unmethylated FOXA1 but not K270-methylated FOXA1. In addition, we observed the puncta-like formation of LSD1/BRD4 marked nuclear condensates under confocal immunofluorescence microscopy. By examining the public datasets of H3K27ac ChIP-seq of samples with different stages of PCa development, we identified a subset of SEs which were distinctly activated in CRPC. Using multiple CRPC PDXs, we revealed that combining LSD1 inhibitors

with BET inhibitors exhibited strong synergy possibly via disrupting the CRPC-specific SEs.
In summary, this study reveals a novel oncogenic function of LSD1 in driving PCa progression by activating SE-driven oncogenic programs, such as MYC signaling. These results provide a strong therapeutic potential of combining inhibitors of LSD1 and BRD4 in treating CRPC.

#4730

ASCL1 activates neuronal stem cell-like lineage programming through the remodeling of the chromatin landscape in prostate cancer

Shaghayegh Nouruzi[1], Dwaipayan Ganguli[1], Nakisa Tabrizian[2], Maxim Kobelev[2], Olena Sivak[1], Takeshi Namekawa[1], Alastair Davies[1], Amina Zoubeidi[1]. *[1]Vancouver Prostate Center, Vancouver, BC, Canada,[2]Experimental Medicine, University of British Columbia, Vancouver, BC, Canada*

Introduction: Second-generation AR pathway inhibitors such as Enzalutamide (ENZ) are highly effective in treating castration-resistant prostate cancer (CRPC). However, they play an important role in the emergence of AR-independent phenotypes, including treatment-induced neuroendocrine prostate cancer (tNEPC). Few genetic differences are observed between CRPC and tNEPC, suggesting an epigenetic dysregulation underlining this conversion.
Method: To capture the evolution of CRPC to tNEPC, we measured changes in chromatin accessibility of CRPC cells upon exposure to ENZ and in tNEPC cell lines via ATACseq. We performed RNAseq from matched cell lines. We conducted ASCL1, H3K27me3 and EZH2 ChIPseq. Multi-omic analysis were performed integrating RNAseq, ATACseq, ChIPseq, RNA and protein expression.
Result: We identified the motif of the transcription factor ASCL1 becoming accessible as early as 3 days, with continued enrichment at 10 days post ENZ-treatment and in NEPC cell-lines. ASCL1 expression and activity are significantly upregulated in NEPC cell lines and patient tumors. Using our unique model of tNEPC, we showed that knockdown of ASCL1 causes extensive chromatin reorganization leading to reduced expression of neuronal and plasticity markers and overall abolishment of the NEPC program. Loss of ASCL1 dysregulated Polycomb repressor complex 2

activity (loss of H3K27 methylation) via di-association of complex due to phosphorylation of EZH2 at T311 resulting in loss of EZH2 binding to the chromatin and likely cause of the H3K27 demethylation. Cell fractionation and confocal microscopy combined with ChIPseq data confirmed loss of EZH2 binding to the chromatin. We identified that loss of ASCL1, phenocopying EZH2 inhibition, reactivated luminal programming and potentially re-sensitizing tNEPC cells to further AR targeted therapies. Altogether, suggests that ASCL1 may drive early transcriptional and epigenetic reprogramming through the PRC2, facilitating the emergence and maintenance of tNEPC.
Conclusion: Our research provides the centrality of epigenetic reprogramming in driving the uprising of a plastic phenotype in response to AR pathway inhibition and provides insight into the role of ASCL1 in early drug-induced epigenomic plasticity that supports this reprogramming toward androgen independence. We report that ASCL1 modulates the chromatin dynamics to support a plastic lineage by influencing neuronal stem cell-like regulatory networks. In the treatment-resistant, high plasticity state, inhibition of ASCL1 reverses the lineage to an epithelial-luminal state, providing potential for targeting these highly aggressive tumors. This work provides much-needed insight into ASCL1 function and dependency that together nominates ASCL1 as a bona fide clinical target.

Novel epigenetics technology for high-throughput processing of limited samples to study cancer using cavitation-based pixelated ultrasound and tagmentation-indexing ChIP-Seq

Rwik Sen, Ngoc Tran, Sarah Traynor, Eric Maina, Jason Poole. *Active Motif, Carlsbad, CA*

Epigenetics has shown great potential in translational, clinical, and precision medicine research, but with inadequate implementation. This is due to major problems with sample availability, and processing which is laborious, costly, slow, inconsistent, and leads to sample loss. Epigenetics studies need samples with certain minimum concentrations and volumes to address all necessary questions. The samples often need to be in single cell or nuclear suspensions. For chromatin immunoprecipitation (ChIP), a consistent size of approximately 300 base pairs of DNA is essential but

difficult to achieve. To address the above problems, we present novel cutting-edge epigenetics methodologies. Homogenization of various tissue types from diverse patients with different disease states is the first crucial step in sample processing. Hence, we present new protocols which are compatible with high-throughput cavitation-based pixelated ultrasound sonication. It processes limited quantities of samples in a 96-well plate where cells can be grown and antibody can be coated for ChIP. Further, 1 to 12 columns of the 96-well plate can be flexibly regulated to extract lysates. Our results show how this rapid and simple technology integrates with ChIP-sequencing (seq) and RNA-seq workflows, yielding very consistent output from limited tissue samples. Bioinformatics analysis of the ChIP-seq shows the corresponding biological significance. Certain limitations of ChIP has led to the evolution of other methods but they are mostly unsuccessful in mapping transcription factors. Hence, we next present a modified ChIP-seq combined with tagmentation, indexing and pooling, coupled to pixelated ultrasound based-cavitation. Here, individual samples are placed in each well of a 96-well plate containing unique indexing adapters fused to Tn5 transposase. Hence, each sample undergoes tagmentation - a process where DNA gets fragmented and simultaneously inserted with index adapters. Next, pixelated ultrasound helps to rapidly extract the complex of protein-tagmented DNA from 96 samples which are pooled into a single tube because they are uniquely indexed, then split up for immunoprecipitation by different antibodies. Bioinformatics analysis shows that the results are robust, consistent, and match ENCODE datasets. Hence, our methods can help to process high-throughput samples for AACR Project GENIE. Overall, we present novel technology to process limited human samples for enabling epigenetics research at the clinical interface from bench to bedside. The simple and less expensive methods yield high quality samples to enable high-throughput analysis of epigenetics including transcription factors which are important in cancer. They help us to understand targeted epigenetic regulations of genes for therapeutic developments and treating cancer.

Effect of KDM6A mutation in bladder cancer

Ninh B. Le[1], Hong Qiu[2], Emily E. Fink[3], Surbhi Sona[3], Angela H. Ting[3], Byron H. Lee[2]. *[1]Department of Epigenetics and Molecular Carcinogenesis,*

University of Texas MD Anderson Cancer Center, Houston, TX,[2]Cardiovascular & Metabolic Sciences, Cleveland Clinic Lerner Research Institute, Cleveland, OH,[3]Genomic Medicine Institute, Cleveland Clinic Lerner Research Institute, Cleveland, OH

As of 2020, bladder cancer is the tenth most common cancer in the world, with a heavier toll exerted on males. Its higher tumor recurrence and progression rates cause major treatment challenges. One of the most frequent mutations in bladder cancer is in lysine-specific demethylase 6A (KDM6A). This gene encodes for ubiquitously transcribed tetratricopeptide repeat on chromosome X (UTX), which catalyzes the demethylation of di- and tri- methylated histones H3 lysine 27 and works as part of "COMPASS-LIKE" protein complexes to coordinate many transcriptional processes. The molecular basis for how KDM6A mutations promote carcinogenesis is still under investigation. In this study, we use single-cell RNA sequencing data from bladder cancers with and without KDM6A mutations in both human and mice to examine the effects of KDM6A mutations on the cellular composition and gene expression of tumor and normal bladders. In mice without tumors, KDM6A mutations seem to correlate with enrichment of macrophages in the bladder tissue microenvironment. The opposite is true, however, in the presence of tumors, as there were not only more macrophages but also more dendritic cells in wildtype mice. This pattern was also observed in human, suggesting differences in immune infiltrates in the tumor microenvironment are part of the phenotype of KDM6A mutation. Lastly, KDM6A mutations may also impact urothelial cell states at baseline, as KDM6A KO mouse bladders contain higher proportions of intermediate cell populations compared with their wildtype counterparts. Together, these observations contribute to a better understanding of the role KDM6A plays in bladder cancer.

BRD8-driven EP400 complex hijacks H2AZ to maintain proliferation in glioblastoma

Sherine Xueqin Sun, Olaf Klingbeil, Christopher Vakoc, Alea Mills. *Cold Spring Harbor Laboratory, Cold Spring Harbor, NY*

Glioblastoma (GBM) is the most notorious primary brain tumor. The median survival of GBM patients is only about one year and about 95% patients succumb after five years. This gloomy picture has not been improved for decades, even with extensive treatments including surgery, radiotherapy, and chemotherapy. Hence, a better understanding of the mechanisms underlying GBM development may provide new therapeutic opportunities. Primary GBM generally harbors a low mutational load when compared to other human cancers. Even P53—the guardian of the genome that is essentially disabled in nearly all human cancers, remains unmutated in about 71% of GBM cases. Moreover, these P53 wildtype GBM cases are as aggressive as those with P53 mutations. To explore the mechanism by which P53 wildtype GBM thrive in the presence of intact P53, we performed CRISPR screens in a panel of human cancer cell lines using an sgRNA library specifically targeting the functional domains of ~200 chromatin regulators. We discovered that BRD8's bromodomain—a druggable domain as shown by the tremendous success in preclinical and clinical trial in diverse cancers—is a vulnerability specifically in P53 wildtype GBM cases. Our mechanistic studies demonstrate that BRD8 functions through the EP400 chromatin remodeling complex and hijacks the histone variant H2AZ at P53 target loci, enforcing a compact chromatin state that blocks P53's accessibility to its targets. We show that targeting the BRD8 bromodomain releases H2AZ, opens up chromatin, engages P53-mediated transactivation, and triggers growth arrest. Consistent with these findings, BRD8 is highly expressed with H2AZ in patient-derived proliferating GBM cells, and is inversely correlated with the expression of P53 targets. Our work solves a long-standing mystery in P53 wildtype GBM, and presents a promising therapeutic target for the majority of GBM patients.

Epigenetic Mechanisms as Drivers of Tumorigenesis

Dysregulated miR-371b-5p/CSDE1/RAC1 axis is involved in pathogenesis of triple-negative breast cancer
Yesol Kim, Je Yeong Ko, Soo-Been Lee, Jaehee Jun, Yejin Ahn, Jinui Min, Chaewon Oh, Jong Hoon Park. *Sookmyung Women's University, Seoul, Korea, Republic of*

Triple-negative breast cancer (TNBC) is the most aggressive subtype of breast cancer; however, pathogenesis of TNBC has not yet been fully understood. Here, we identified dysregulated microRNAs (miRNAs) by analyzing miRNA microarray of TNBC patients. MiR-371b-5p expression was reduced, and ectopic expression of miR-371b-5p significantly inhibited TNBC progression *in vitro* and *in vivo*. In addition, we found that expression of cold shock domain-containing protein E1 (CSDE1), a direct target gene of miR-371b-5p, was upregulated in TNBC cells, and inhibition of CSDE1 alleviated TNBC cell growth by decreasing RAC1 known as pro-metastatic gene. Mechanistically, CSDE1, phosphorylated C-terminal domain (p-CTD) of RNA polymerase II (RNAPII), and CDK7 form a complex, and downregulation of CSDE1 results in weak interaction between RNAPII p-CTD and CDK7, which leads to a decrease in RNAPII p-CTD expression to reduce RAC1 transcript levels in CSDE1-deficient TNBC cells. Our data revealed the oncogenic function of miR-371b/CSDE1 involved in Rac1 transcription regulation, thus providing a basis for the pathological mechanism of TNBC along with potential biomarkers for TNBC.

Molecular effects of histone deacetylase inhibitor Quisinostat on diffuse midline glioma of the pons

Danyelle Paine[1], Nanyun Tang[1], Yue Hao[1], Matt Biery[2], Carrie Meyers[3], Alyssa Noll[3], Nicholas Vitanza[3], Michael Berens[1]. *[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ,[2]Seattle Childrens Hospital, Seattle, WA,[3]Seattle Children's Hospital, Seattle, WA*

Diffuse Midline Glioma of the pons (DMG) is a lethal, aggressive heterogeneous brain stem tumor. Median overall survival is less than a year, with radiation as the only standard treatment. Recently, mutations in DMGs have arisen as potential therapeutic targets, specifically a mutation in one of the histone H3 genes, resulting in methionine substituted for lysine at site 27 (H3K27M). H3K27M induces a marked reduction in global acetylation of histone tails, altering chromatin structure and causing aberrant gene expression. Histone deacetylase inhibitors, HDACis, are epigenetic drugs that show anticancer activity. In our studies, Quisinostat (Quis) is used to

preserve histone acetylation. Using two H3K27M-DMG treatment-naive preclinical models (PBT22 and PBT29) we detected a 100-fold differential response to the histone deacetylase inhibitor, Quisinostat. PBT-22 harbors mutations in *H3F3A*, *TP53*, and *ASXL2*, while PBT-29 has mutations in *H3F*3A, *TP53*, *PIK3CA* and *FGFR1*. Following Quis treatment (48 hrs) in both preclinical models, total H3K27ac protein abundance increased 3-fold, suggesting HDACi stabilizes or impedes turnover of K27 acetylated H3 histone. We are pursuing studies to test whether sensitivity to HDACi in DMGs is determined by a shift in relative or total abundance of respective H3wt- and H3K27M- histones. We posit that changes in H3K27ac manifest as shifts in nucleosome integration with genes responsible for cell survival/death. This project will profile differentially expressed genes (DEGs) from Quis-treated PBT22 and PBT29. Additionally, total and relative abundance of H3 proteins (wt and mt, me, me2, me3, and ac) from treated cells will be determined. Gene ontology analysis will focus on pathways accounting for chromatin remodeling, cell death, and growth arrest. RNA (qRT-PCR) and proteins (western blot) from analytes from a larger panel of DMG cell lines and neural stem cells treated with Quis will be used to validate the findings. Overall, the data depicts DMG preclinical models with large differential sensitivity to Quis, which may be partially due to different oncoprints between the models. The markedly different sensitivity of these models enables mechanistic study of the consequences of elevated abundance of histone 3 acetylation. The long term goal is to discover a molecular profile of DMGs indicative of the vulnerability to HDACi.

NUDT21 regulates PIGN through APA mechanism to affect the progression of MDS and AML

Jeffrey J. Pu[1], Fanggang Ren[2], Na Zhang[2], Shuo Li[3], Lan Zhang[4], Eric Miller[2], Guirong Wang[2], Hongwei Wang[5]. *[1]University of Arizona Cancer Center, Tucson, AZ,[2]State University of New York Upstate Medical University, Syracuse, NY,[3]The Second Hospital of ShanxiMedical University, Shanxi, China, Shanxi, China,[4]State University of New York Upstate Medical university, Syracuse, NY,[5]The Second Hospital of Shanxi Medical University, Shanxi, China*

Introducti**on:** *PIGN* gene is crucial in regulating mitotic integrity to maintain chromosomal stability and prevent MDS leukemic transformation and progression. Alternative Polyadenylation (APA) regulation and 3' RNA cleavage are 2 known vital processes in cellular DNA damage response to maintain genomic stability. *NUDT21* gene encodes protein that is one subunit of the cleavage factor Im complex required for 3' RNA cleavage and APA processing. Although *PIGN* gene has six potential polyadenylation sites, the exact role of *NUDT21* product on *PIGN* expression regulation has not been illustrated before.

Methods: At first, we analyzed *NUDT21* gene expression profile in AML, MDS, and normal control specimens and to plot the relationship between *NUDT21* gene expression status and patient survival length from 5 datasets. We also used correlation regression analysis method to predict the gene expression correlations between *NUDT21* gene and *PIGN* gene. Then, we used Caspas9 technology and vector overexpression technology to knockout or overexpress *PIGN* in HEK293 cells; RNA interference to knockdown the *NUDT21* gene in HEK293, HL60, K562, THP-1,SKM-1 and MUTZ-1 cells. MTT and CCK8 methods were used to evaluate cell proliferation. Meanwhile, cell cycle, apoptosis, Reactive Oxygen Species (ROS) and GPI-anchored proteins (CD55, CD59, and CD235) expression profiles were evaluated by flowcytometry; Immunofluorescence experiment, RT-PCR were used to evaluate the impact of *NUDT21* gene knockdown on *PIGN* expression. *in vivo* mice siRNA interference tests were conducted to verify the impact of *NUDT21* knockdown on *PIGN* gene expression. RNA-Seq & Dapars analyses were conducted on mRNAs from 3 cell lines with various *PIGN* gene expression status to observe the effects of *NUDT21* knockdown on PIGN 3'UTR processing.

Results: *NUDT21* expression increases in AML and high-risk MDS. *NUDT21* expression level is negatively correlated with overall survival. *NUDT21* knockdown decreases cell proliferation but increases cell differentiation via prolonging G1 phase, decreasing S phase, and increasing apoptosis. *NUDT21* knockdown increases cell membrane GPI-anchoring proteins (CD55, CD59, and CD235) expressions; increases ROS and Caspas3 expressions but decreases CyclinD1 expression. *NUDT21* knockout can increase *PIGN* expression, but *PIGN* expression status has no impact on *NUDT21* expression. RT-PCR and WB results showed that

NUDT21 knockdown can increase *TP53* expression but decrease *p21* expression. *in vivo* mice siRNA interference tests confirmed that *NUDT21* knockdown increases *PIGN* gene expression. The RNA-Seq/Dapars analyses results showed that 3'UTR of *PIGN* transcript was significantly shortened and *PIGN* expression increased after *NUDT21* knockdown.
Conclusion: *NUDT21* modulates *PIGN* gene expression through APA mechanism. *PIGN* polyadenylation may regulate cell proliferation status via modulating cell cycle and apoptosis.

Familial adenomatous polyposis epigenetic landscape as a precancer model of colorectal cancer
Hayan Lee[1], Gat Krieger[2], Tyson Clark[2], Yizhou Zhu[3], Aziz Khan[3], Casey R. Hanson[3], Aaron Horning[3], Edward D. Esplin[3], Mohan Badu[3], Kristina Paul[3], Roxanne Chiu[3], Bahareh Bahmani[3], Stephanie Nevins[3], Annika K. Weimer[3], Ariel Jaimovich[2], Christina Curtis[3], William Greenleaf[3], James M. Ford[3], Doron Lipson[2], Zohar Shipony[2], Michael P. Snyder[3]. *[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Ultima Genomics, Newark, CA,[3]Stanford University, Stanford, CA*

Aberrant shifts in DNA methylation have long been regarded as an early biomarker for cancer onset and progression. However, it is unclear when methylation aberrance starts and how it interacts with other epigenomic modifications. To address how epigenomic changes occur and interact during the transformation from normal healthy colon tissue to malignant colorectal cancer (CRC), we collected 51 samples from 15 familial adenomatous polyposis (FAP) and non-FAP colorectal cancer patients. We generated 30-70x of whole-genome enzymatic methylation sequencing (WGEM-seq) data via the novel Ultima Genomics ultra high-throughput sequencing platform. We observed hypermethylation and hypomethylation emerge early in the malignant transformation process in gene promoters and distal regulatory elements. We performed multifaceted analysis on methylation alterations with whole-genome sequencing (WGS), transposase accessibility (ATAC-seq), high-resolution chromatin accessibility (Tri-C), and gene expression (RNA-seq) data. Our multidimensional analysis demonstrates how collectively epigenomic alterations have affected gene

expression throughout normal colon mucosa, benign and dysplasia polyps to adenocarcinoma. Epigenomic changes start as early as benign polyps, followed by other epigenomic shifts, including bivalent domains. Various epigenomic aberrances are associated with concomitant gene expression level changes. Our integrative analysis of multi-epigenomics data implicates collective and cumulative epigenomic instability in the early onset of colon carcinogenesis.

Wnt/beta-catenin mediated epigenetic modifications drive age-dependent oral squamous cell carcinoma evolution

Emily R. Fisher[1], Anthony Spinella[2], Nina C. Hardy[3], Xaralabos Varelas[4], Manish Bais[3], Maria A. Kukuruzinska[3]. *[1]Department of Biomolecular Pharmacology, Boston University, Boston, MA,[2]Department of Stem Cell and Regenerative Biology, Boston University, Boston, MA,[3]Department of Translational Dental Medicine, Boston University, Boston, MA,[4]Department of Biochemistry, Boston University, Boston, MA*

Oral Squamous Cell Carcinoma (OSCC) is a devastating disease associated with high morbidity, poor survival, and few therapeutic options. This malignancy is driven, in part, by epigenetic reprogramming of the chromatin landscape directed by β-catenin in complex with CREB-binding protein (CBP) and mixed lineage leukemia methyltransferase 1 (MLL1). The β-catenin/CBP/MLL1 complex promotes an open chromatin structure by enabling transcription of genes associated with cell plasticity, including cancer stem cells and cells with partial EMT (p-EMT) phenotypes. Growing evidence indicates that cell plasticity and cellular senescence are integral processes shared by cancer and aging. Given that the median age of OSCC diagnosis is 66 years, it is likely that aging promotes OSCC evolution to advanced disease.

To examine the effects of aging on OSCC evolution, we adapted a syngeneic mouse model of tobacco-associated oral carcinogenesis. This model utilizes a mouse cell line, 4MOSC1, derived from 4-nitroquinoline-1 oxide- (4NQO)-induced tongue tumor which, when implanted into mouse tongues, generates tumors that recapitulate human OSCC mutanome. The growth of 4MOSC1 derived orthotopic tumors was studied in 6- and 80-week-old mice. Tumors were allowed to develop for 18 days, after which

they were harvested and processed for single cell RNA sequencing, histopathology and immunofluorescence (IF) analyses.
Results showed that tumors grew at a faster rate and to a greater overall size in old mice compared to their young cohorts. OSCC harvested from the old mice displayed statistically significant reduction in membranous E-cadherin concomitant with increased Cbp and H3K4me3 abundance, suggesting an age-associated upregulation of β-catenin/Cbp/Mll1 epigenetic activity. Increased expression of Bmi1, keratin 14, and podoplanin supported increased cell plasticity in OSCC from aged mice. Further, these tumors exhibited augmented cellular senescence, as judged by the disruption of lamin B1-associated nuclear membrane integrity, and by an increased cell population with markers of senescence from single cell sequencing analyses.
These data suggest that aging is associated with increased β-catenin/Cbp/Mll1 epigenetic signaling, cell plasticity and cellular senescence, which collectively contribute to the evolution of OSCC.

#4744

Epigenetic reprogramming induced by lipids fosters mammary cell plasticity in non-transformed breast epithelial cells

Mariana Bustamante Eduardo[1], Gannon Cottone[1], Shiyu Liu[2], Seema Khan[1], Susan Clare[1]. *[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Department of Pharmacology and Cancer Biology, Duke University, Durham, Durham, NC*

Introducti**on**. Lipid exposure of non-transformed breast epithelial cells results in increased flux modifications, and profound changes in gene expression. The upregulated genes are involved in stemness, neural development, and neural crest pathways. Neural genes are highly expressed in an estrogen receptor negative breast cancer (ERnegBC): the triple negative subtype. We aim to identify mechanisms that link lipids and epigenetic reprogramming to the genesis of ERnegBC.
Methods. Non-transformed MCF-10A cells exposed to octanoic acid (OA) were utilized for U13C-glucose tracing. S-adenosylmethionine (SAM), 2-HG and other metabolites were analyzed following treatment with OA ± PHGDH inhibitor. CUT&RUN for H3K4me3 and H3K27me3 was performed, and genes affected by OA (PMID: 28263391) were compared

with OA-responsive peaks. OA-induced genes with CUT&RUN peaks were measured in breast organoids derived from reduction mammoplasty samples exposed to OA. The Aldefluour assay was used to identify stem-like (ALDH+) cells.
Results. U13C-glucose tracing in presence of OA showed decreased glucose uptake, glycolysis and pentose phosphate pathway flux, with little effect on the TCA cycle. One-carbon (1C)-THF was redirected to the methionine cycle increasing flux to methylation. The methyl donor SAM and the demethylase inhibitor 2-HG increased after 15- and 30-min OA exposure, respectively; PHGDH inhibitor blocked these increases likely via effects on 1C metabolism. H3K4me3 CUT&RUN revealed 661 differential peaks (FDR < 0.05) comparing OA to control. The genes associated with these peaks are involved in neuron differentiation, neural crest, EMT and neural genes expressed in ERnegBC. 73% of H3K4me3 OA-associated peaks were in regulatory regions of OA-induced genes (FDR < 0.01), including NGFR (log2FC = 11.7), NGF (log2FC = 8), NTRK1 (log2FC = 2.1). OA-induced genes with enriched H3K4me3 peaks were also upregulated in breast organoids exposed to OA, such as NGFR (FC = 2.2), NGF (FC = 4.7), NTRK1 (FC = 6.6). Motif analysis revealed an overrepresentation of transcription factors ($p < 0.05$) associated with EMT (Zeb1, Slug), neural functions (E2A, AP1, JunB), neuronal-injury (Atf3) and stress response (Chop, Atf4). Twelve H3K27me3 peaks were enriched in control (FDR < 0.05) and associated with increased gene expression in OA, among them were LGR6 (log2FC = 1.9), a gene associated with ERnegBC and PLAG1 (log2FC = 2.8) a stem cell marker. ALDH+ cells' percentage increased by at least 10% after OA exposure.
Conclusions. Lipid exposure affects the production of SAM and 2-HG, which results in epigenetic fostered plasticity, leading to reprogramming/selecting cells with a multi-potential embryonic or stem-like state and/or differentiation to a neural/neural crest-like state which may facilitate ERnegBC genesis.

#4745
Prostatic fluid-based cfDNA methylation profiling distinguish benign hyperplasia from prostate cancer
Hang Dong, Haoran Tang, Yue Zhang, Shidong Jia. *Huidu (Shanghai) Medical Sciences, Ltd., Fengxian District, Shanghai, China*

Introducti**on:** A challenge in the early diagnosis of prostate cancer (PC) is to distinguish between malignant tumor and benign prostatic hyperplasia (BPH) because of the similar symptoms. Methylation profiles provide a way for discriminating BPH from PC, which could prevent overdiagnosis and overtreatment. Applying methylation biomarkers to liquid biopsy specimens provides higher sensitivity to detect tumors.
Methods: Prostatic fluid samples were prospectively collected from 40 patients following digital rectal exam and isolated cell-free DNA to perform whole genome methylation sequencing using PredicineEPIC platform. Combing differentially methylated regions (DMR) with methylation signature identified from massive public data, a panel of methylation patterns was developed. The difference of methylation signal in profiled region were implemented by machine learning to robustly distinguish BPH from prostate cancer.
Results: We identified 324 biomarkers from prostatic fluid samples and collected 46 methylation biomarkers reported from previous research. Regions with extreme difference between benign prostatic hyperplasia and prostate cancer were identified as candidate biomarkers. A diagnostic model trained on these 55 biomarkers could distinguish BPH from PC in 10-fold cross-validation (AUC = 0.92). And this model could be applied for discriminating normal tissue from prostate tumor tissue with highly performance (AUC > 0.95). Using this set of regions, we developed an NGS-based panel for detecting methylation alteration of cfDNA from prostate liquid, which inherited the ability of differentiation.
Conclusion: These methylation patterns could be developed as the novel biomarkers to support the development of prostatic fluid-based non-invasive diagnostic test and reduce unnecessary biopsies. This panel could be applied for differential diagnosis of benign hyperplasia and prostate cancer.

Amelioration of hemoglobinopathies by targeted deletion of zinc finger domain within *BCL11A* gene using CRISPR-Cas9 technology

Irfan Hussain, Kainaat Mumtaz, Hammad Hassan, Afsar Ali Mian. *Centre for Regenerative Medicine and Stem Cell Research, Aga Khan University, Karachi, Pakistan*

Background**:** In humans, the β-like globin genes are encoded from a single locus comprising five globin genes (ε-, Gγ-, Aγ-, δ-, and β-globin in sequence) and their expression is under developmental control. The γ-globin genes (Gγ- and Aγ-) are expressed during fetal life and replaced by adult β-globin after birth. Mutations in the β-globin gene cause β-hemoglobinopathies such as sickle cell disease (SCD) and β-thalassemia. The clinical severity of SCD and β-thalassemia can be mitigated by elevated fetal hemoglobin (HbF) levels, which have been found in individuals with the benign hereditary persistence of fetal hemoglobin (HPFH) syndrome. Thus, reactivating the expression of γ-globin genes is an attractive treatment strategy for β-hemoglobinopathies. Reactivation of γ-globin expression by disrupting the binding of the *BCL11A* transcriptional repressor complex to the γ-globin gene promoter, provides a novel approach for inducing fetal hemoglobin.
Methodology: The *BCL11A* binds a 5′-TGACCA-3′ element (spanning nucleotides −118 to −113) of globin genes using its three C-terminal Zinc fingers (*Znf*). The binding efficiency of Znf4, Znf5, and Znf6 was predicted by using *in silico* tools (SIFT, SNAP, PolyPhen-2, PANTHER, I-Mutant, PROVEAN, SNPs&GO, mCSM, and PhD-SNP), molecular dynamic simulation and homology modelling. K562 cells were electroporated with CRISPR-Cas9 targeting the *BCL11A* Znf4.
Results: The binding energy scores illustrate that deleting Znf5 and Znf6 decreased the binding affinity by ~3.7-fold, whereas deleting Znf4 decreased the affinity by > 70-fold. Using CRISPR-Cas9 genome-editing strategy, we deleted Znf4 (260bp genomic region) within the *BCL11A* in K562 cell lines. Znf4 deletion resulted in a readily detectable γ-globin increase with a preferential increase in G-gamma.
Conclusion: Altogether, our findings highlight the valuable insights for improving gene editing therapy strategies by either deleting Znf4 of *BCL11A* or the TTGACCA motif to disrupt the interaction between *BCL11A* and other interacting partners and the γ-globin gene promoter. Complete failure in the protein-protein interactions with functional partners and to the γ-globin gene promoter revealed that Znf4 is a suitable target for disrupting BCL11A-mediated hemoglobin switching.

#4747

NSD2 mutation drives oncogenic programming in mantle cell lymphoma

Jianping Li[1], Marta Kulis[2], Alberto Riva[1], Heidi Casellas Román[1], Daphne Dupere-Richer[1], Amin Sobh[1], Charlotte Leonie Kaestner[1], Richard L. Bennett[1], Inaki Martin[2], Jonathan D. Licht[1]. *[1]University of Florida, Gainesville, FL,[2]Fundació Clínic per a la Recerca Biomèdica, Barcelona, Spain*

Background**:** NSD2, a histone methyltransferase, is an oncoprotein first characterized by its overexpression in multiple myeloma (MM). *NSD2* mutations within the catalytic SET domain are found in acute lymphoblastic leukemia (ALL) and mantle cell lymphoma (MCL). We previously demonstrated that *NSD2* p.E1099K mutation caused an imbalance of H3K36me2/H3K27me3 and drove glucocorticoid resistance in ALL. *NSD2* mutations, especially p.E1099K and p.T1150A, were identified in 10-15% of cases of MCL and are enriched in patients who relapse from targeted therapies such as ibrutinib. However, the activity of *NSD2* mutations in MCL remains unexplored.

Aim: To demonstrate the role of *NSD2* mutations in MCL progression due to aberrant chromatin modification.

Methods: We created isogenic MCL cell lines by knock-in *NSD2* p.E1099K mutation into Z138 and Jeko-1 cell lines using CRISPR/Cas9 gene editing. We then determined the effect of the mutation on H3K36me2/H3K27me3 levels and biological activities including cell growth (IncuCyte), apoptosis (Annexin V/PI Staining), and cell cycle (BrdU incorporation). We determined transcriptome (RNA-Seq) and histone modification profiles (ChIP-Seq) in isogenic Z138 cell lines. Finally, we integrated analysis of RNA-Seq of human patients and our human MCL cell lines to comprehensively disclose the epigenetic landscape in MCL with *NSD2* mutation.

Results: We successfully created isogenic Z138 cell lines with heterozygous and homozygous *NSD2* p.E1099K mutation and a Jeko-1 cell line with heterozygous *NSD2* p.E1099K mutation. Insertion of *NSD2* p.E1099K by CRISPR/Cas9 gene editing led to a striking increase of H3K36me2 and concomitant decrease of H3K27me3 in both Z138 and Jeko-1 cell lines. *NSD2* mutation significantly increased cellular growth with enhanced S phase entry, decreased number of cells in G0/G1 phase and

decreased spontaneous apoptosis. RNA-Seq analysis demonstrated striking changes in gene expression with 1794 genes upregulated and 1492 genes downregulated in *NSD2* mutant MCL cells. Among them, anti-apoptotic genes *BCL2* and *BCL2L2* were upregulated while pro-apoptotic genes *BAX*, *BID*, and *BIK* were downregulated in *NSD2* mutant cells, which was consistent with the biological phenotypes. Surprisingly, *CCND1*, *CCNE1*, *CCNE2*, *TP53*, and *CDKN2C* (*p21)* were downregulated while *CDKN2D*, *CDKL3*, and *CDKL5* were upregulated in *NSD2* mutant cells. Altered gene expression in isogenic Z138 cells were compared with patient expression profiles, with gene ontology revealing significant overlap and enrichment of cell adhesion, neural pathways, and evidence of activated signaling. Aberrant histone modification H3K27ac contributed to many of differentially expressed genes pattern.
Conclusions: The *NSD2* mutation led to increased tumor cell growth but decreased apoptosis due to the dysregulation of epigenetic landscape and transcriptome, suggesting an oncogenic reprogramming driven by an activated *NSD2* mutation in MCL.

#4749

Effects of *miR-34a-5p* and *miR-181b-5p* silencing and induction on their potential targets in uterine leiomyosarcoma cells

Bruna C. de Almeida[1], Laura G. dos Anjos[1], Katia C. Carvalho[2].
[1]Obstetrics and Gynecology, University of São Paulo, Faculty of Medicine, São Paulo, Brazil,[2]University of São Paulo, Faculty of Medicine, São Paulo, Brazil

Background: Leiomyosarcoma (LMS) is a malignant tumor of the uterine body that represents 40-60% of all gynecological sarcomas. Up to now, there is no specific treatment or diagnostic biomarkers for this tumor. The identification and characterization of miRNAs signature could help to its management. In addition, miRNAs represent targets for therapies due to their ability to modulate various signaling pathways simultaneously. Thus, the present study aimed to evaluate the effects of genetic manipulation of *miR-34a* and *miR-181b* on their predicted target genes in LMS cells.
Methods: SK-UT-1 cells from uterine LMS were transfected with synthetic miRNA mimics and inhibitors (siRNA) of *miR-34a* and *miR-181b*. The efficacy of transfection was assessed by miRNA expression (qRT-PCR)

assays. In order to identify potential genetic interactions network of *miR-34a* and *181b*, predicted target genes were selected by in silico analysis (miRTargetLink 2.0 and miRDB). After SK-UT-1 cells transfection, the expression of target genes was evaluated by qRT-PCR.
Results: SK-UT-1 cells showed greater efficiency of mimics and siRNA transfections after 48h treatment for both *miR-34a* and *181b*. *MDM4, TP53, BCL2, KMT2D, NOTCH2,* and *CCND1* were identified as predicted target genes of *miR-34a*; and the *TIMP3, FGFR1, BCL2, NOTCH2, ATM*, and *IRS1* target genes for *miR-181b*. Expression profile of selected target genes was assessed after each treatment. The *miR-34a* mimic significantly increased the expression of *MDM4* after 96h of treatment, while the *BCL2* and *TP53* showed an increase in expression with siRNA after 48h of treatment. *CCND1* showed a greater expression in both treatments at 48h. An increase in *KMT2D* and *NOTCH2* expression was also observed after treatment, even though without statistically significant. Treatment with *miR-181b* mimic led to increased *FGFR1* expression within 72h. Although some expression alterations were observed in *TIMP3, BCL2, NOTCH2, ATM,* and *IRS1* genes after mimic and siRNA treatments, there was no statistical significance.
Conclusion: The effect of *miR*-34a upregulation leads to induction *MDM4* and *CCND1* expression, the first being a *TP53* inhibitor and the second, responsible for cell cycle maintenance. The *miR-34a* downregulation had an inductor effect on expression of *MDM4*, *BCL2* (apoptosis regulator), *TP53* (tumor suppressor), and *CCND1*. The *miR-181b* upregulation induced the expression of fibroblast growth factor receptor, *FGFR1*. In uterine LMS cells, *miR-34a* seems to exert an important role in regulating the expression of cell cycle and apoptosis-related genes.

#4750
TWIST2 mediated chromatin remodeling promotes fusion-negative rhabdomyosarcoma
Akansha M. Shah, Lei Guo, Maria Gabriella Morales, Priscilla Jaichander, Kenian Chen, Huocong Huang, Karla Cano Hernandez, Lin Xu, Rhonda Bassel-Duby, Eric N. Olson, Ning Liu. *UT Southwestern Medical Center, Dallas, TX*

Rhabdomyosarcoma (RMS) is a common soft tissue sarcoma in children that resembles the developing skeletal muscle. Unlike normal muscle cells, RMS cells fail to differentiate despite expression of the myogenic determination protein MYOD. The TWIST2 transcription factor is frequently overexpressed in fusion-negative RMS (FN-RMS). TWIST2 blocks differentiation by inhibiting MYOD activity in myoblasts, but its role in FN-RMS pathogenesis is incompletely understood. Here, we show that knockdown of TWIST2 enables FN-RMS cells to exit the cell cycle and undergo terminal myogenesis. TWIST2 knockdown also substantially reduces tumor growth in a xenograft model of FN-RMS. Mechanistically, TWIST2 controls H3K27 acetylation at distal enhancers by interacting with the chromatin remodelers SMARCA4 and CHD3 to activate growth-related and repress myogenesis-related target genes, respectively. These findings provide novel insights into the role of TWIST2 in maintaining an undifferentiated and tumorigenic state of FN-RMS and highlight the potential of suppressing TWIST2-regulated pathways to treat FN-RMS.

The function of bromodomain containing protein 4 (BRD44) in hematopoiesis

Francine Nihozeko. *Cells System and Anatomy (Cancer Biology), UT Health Science Center at San Antonio, San Antonio, TX*

Bromodomain containing protein 4 (BRD4) is an epigenetic transcription regulator that reads acetylated chromatin and is involved in the recruitment of transcriptional factors to initiate gene transcription. BRD4 is functionally versatile and has extensively been studied for its role in cell cycle progression, gene transcription regulation, chromatin organization and remodeling, as well as DNA replication and repair . In addition, BRD4 has been implicated in many solid and liquid tumors, and its inhibition shows promising preclinical activity, especially in hematopoietic malignancies. BRD4 is overexpressed in Leukemia and has been reported to play a role in hematopoietic stem cell expansion and progenitor development. However, the mechanisms of BRD4 in hematopoietic stem cell functions and disease development remain poorly understood. Using BRD44 knockout (BRD44 Δ/Δ , driven by Mx1 Cre to delete BRD44 in hematopoietic system) mouse model, we found that BRD4 is required for HSCs self-renewal and the loss

of BRD44 impaired erythroid differentiation and skewed myeloid differentiation. BRD44 Δ/Δ HSPCs showed G0/G1 arrest, decreased S-phase, and increased senescence compared to wild type (WT) HSPCs. Our study demonstrates that BRD4 is essential for normal hematopoiesis. To further investigate the role of BRD4 in hematopoiesis, we generated BRD44 transgenic mice (driven by Vav1 promoter, to assure all BRD44 transgene expression is instructed in the hematopoietic system). Ongoing studies focus on determining the impact of BRD4 overexpression on hematopoietic stem cell functions.

#4752

Loss of the methyltransferase KMT5C drives resistance to tyrosine kinase inhibitors via H4K20me3 regulation in non-small cell lung cancer

Alejandra Agredo[1], Arpita Pal[2], Jihye Son[2], Nadia A. Lanman[2], Andrea L. Kasinski[1]. *[1]Purdue University Center for Cancer Research, West Lafayette, IN,[2]Purdue University, West Lafayette, IN*

Lung cancer is still the leading cause of cancer-related deaths, and although important therapy advancements have been achieved, ~1.6 million people die from lung cancer annually. Non-small cell lung cancer (NSCLC), which makes up ~85% of lung cancer cases, is mainly treated with radiotherapy, chemotherapies, and targeted agents. Targeted agents are selected based on the mutation spectrum of the tumor. In NSCLC the epidermal growth factor receptor (EGFR) is commonly mutated and, leads to increased proliferation and cell survival. The standard-of-care treatment for patients with activating mutations in EGFR is treatment with tyrosine kinase inhibitors (TKI), such as erlotinib. While tumors initially respond to TKIs, most patients develop resistance after 1-2 years. In ~60% of TKI resistant tumors, resistance is the result of a secondary mutation in EGFR, whereas, in the remaining 20%, tumors turn on bypass track-signals to overcome inhibition of the EGFR pathway. In the remaining 15-20% of the cases the mechanisms underlying resistance are unknown. Most studies focus on the gain of function of oncogenes as mediators of resistance; however, little is known about the role that tumor suppressors play in TKI resistance. Hence, we performed a genome-wide CRISPR Cas9 knock-out screen to identify genes that when knocked-out would drive erlotinib resistance. Fold enrichment analysis of

sgRNAs, identified KMT5C as a top candidate. KMT5C is a histone methyltransferase that trimethylates H4K20 (H4K20me3), enabling the establishment of constitutive and facultative heterochromatin. The process by which KMT5C is reduced in tumors is unknown, yet data from human samples suggests that the *KMT5C* transcript is globally downregulated in NSCLC and in tumor samples resistant to the third-generation TKI osimertinib. Additionally, loss of the modification made by KMT5C (H4K20me3), influences the prognosis of NSCLC, indicating that loss of KMT5C function is a crucial mechanism in carcinogenesis. We recently described how loss of KMT5C leads to increased transcription of the oncogene MET, due to a loss in H4K20me3-mediated repression of a long non-coding RNA transcription (LINC01510) upstream of MET. This mechanism was found to be responsible for driving TKI resistance in EGFR mutant cells. Historically, KMT5C has been associated with generation of constitutive heterochromatin (cHC); however, recent reports, including our own, indicate that KMT5C also regulates transcription in regions outside of cHC. Our preliminary evidence suggests that deposition of H42K0me3 via KMT5C in regions outside of cHC, is less stable than in cHC regions. This novel finding led us to hypothesize that regulation of KMT5C and H42K0me3 at different regions of heterochromatin is a dynamic process, and future work will aim at understanding this process and its relevance in cancer progression and TKI resistance.

LSD1–mediated FOXA2/AP1 transcription program drives lineage plasticity in prostate cancer

Zifeng Wang[1], Mingyu Liu[1], Songqi Zhang[1], Muqing Li[1], Susan Patalano[1], Jill A. Macoska[1], Dong Han[1], Shuai Gao[2], Hansen He[3], Changmeng Cai[1].
[1]University of Massachusetts, Boston, MA,[2]New York Medical College, Valhalla, NY,[3]Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: While castration-resistant PCa (CRPC) can be further treated with second-generation androgen deprivation therapies (ADTs), the tumor can quickly generate resistance through multiple mechanisms. One critical mechanism is that tumor cells can progress to AR-indifferent stem cell-like (SCL-PCa or SCLPC) or neuroendocrine-like CRPC (NE-PCa or NEPC) through lineage plasticity. However, the underlying molecular basis remains

to be determined, and clinical treatment options for these aggressive CRPC subtypes are currently limited. FOXA1 and FOXA2, which are members of the FOXA (Forkhead Box A) protein family, are pioneer transcription factors. While FOXA1 is well known for its function as a critical pioneer factor of AR and pivotal for maintaining AR signaling, the molecular function of FOXA2 in PCa cells is poorly understood despite that FOXA2 is known to be overexpressed in NEPC. Moreover, since FOXA2, like FOXA1, is currently undruggable in the clinic, there is an urgent need to decipher the molecular basis for the chromatin binding of FOXA2 and identify druggable targets that regulate FOXA2 binding and activity in the aggressive FOXA2-positive CRPC.

Methods: In the current study, we first examined the role of FOXA2 in tumorigenesis and metastasis by using various *in vitro* and *in vivo* assays including mouse subcutaneous injection and zebrafish embryo injection approaches. We then conducted integrated whole genomic transcriptome and cistrome analyses in SCLPC and NEPC cell line models to characterize the activity of FOXA2 on chromatin and to identify its collaborating transcription factors that may play specific functions in promoting SCLPC or NEPC using a series of biochemical and bioinformatic approaches.

Results: We found that FOXA2 silencing decreased the growth and metastasis of SCLPC and NEPC cells. Importantly, we discovered that FOXA2 chromatin binding is tightly associated with binding of JUN family proteins (primarily c-Jun) and FOXA2 silencing dramatically interrupted the global chromatin binding of c-Jun and FOSL1. The transcription targets of FOXA2/AP-1 are highly enriched for neuroendocrine and plasticity associated genes and associated with poor clinical outcomes. Furthermore, we also found that FOXA2 chromatin binding is globally enhanced by an epigenetic factor LSD1, and LSD1 inhibition can repress FOXA2/AP-1 activity in multiple CRPC models.

Conclusion: Overall, our data indicate that FOXA2 functions to maintain tumor growth and metastasis in SCLPC and NEPC models. Mechanistically, FOXA2 can act as a pioneer factor of AP-1 (c-Jun/FOSL1) and reprogram AP-1 transcription activity. This FOXA2/AP-1 axis is regulated by LSD1 via demethylating FOXA2 protein and LSD1 inhibition represses FOXA2-dependent CRPC tumor progression. These findings provide novel mechanistic insights into the molecular mechanisms for PCa lineage plasticity and treatment resistance.

Investigating the impact of hotspot mutations in a chromatin reader on leukemogenesis

Yiman Liu, Qinglan Li, Sylvia Tang, Chujie Gong, Liling Wan. *University of Pennsylvania, Philadelphia, PA*

Acute myeloid leukemia (AML) is one of the most aggressive forms of hematological malignancies with a low overall 5-year survival rate (< 26%). The mainstay of treatment for AML includes chemotherapy, but the response of a subset of patients to current treatment options remains poor. Thus, new therapeutic approaches are desperately needed. AML often arises from somatic mutations in chromatin regulators that result in uncontrolled proliferation and a block of differentiation in myeloid progenitor cells. As such, investigation of the role and molecular mechanism of chromatin regulator in AML is being actively pursued. Previously, we discovered the eleven-nineteen-leukemia (ENL) protein, a chromatin "reader" and transcription co-activator, as an unrecognized requirement for the survival of AML. We developed a potent and orally bioavailable small-molecule inhibitor of ENL, which displaces ENL from chromatin and blocks AML progression. Hotspot mutations have been found in ENL YEATS domains, both in Wilms tumor and in leukemia, and these mutations confer a gain of condensation property, leading to aberrant gene activation. However, the impact of ENL mutation on tumorigenesis is largely unknown. The over-arching goal of this project is to explore the impact of the hyper-activated ENL pathway (ENL mutation) in AML. Results from this project will elucidate how newly discovered chromatin reader mutations drive tumorigenesis and offer new biology insights that will facilitate both basic mechanistic studies and clinical studies.

Screening non-small cell lung cancer organoids with epigenetic probes

Khadija Jafarova[1], Panagiotis Prinos[2], Nikolina Radulovich[3], Takamasa Koga[3], Cheryl Arrowsmith[2], Geoffrey Liu[3], Ming Sound Tsao[3]. *[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Structural Genomics Consortium, University of Toronto, Toronto, ON, Canada,[3]Princess Margaret Cancer Centre, Toronto, ON, Canada*

Introduction: NSCLC is associated with high cancer-related mortality worldwide. Epigenetic modifications at the chromatin level have widely been linked to carcinogenesis. Epigenetic regulation not only contributes to the development of cancer, but it may also confer resistance to therapies by promoting the survival of clones that can overcome treatment-induced stress or give rise to complex tumor heterogeneity in response to cancer therapy. Investigating susceptibility resulting from epigenetic aberrations in tumor cells may reveal novel markers of therapies that target epigenetic aberrations. In this study, we treated NSCLC organoid models with a library of 41 epigenetic probes to identify epigenetic targets that affect tumor cell survival.
Methods: Epigenetic screen. NSCLC organoid models were established from resected patient tumors or patient-derived xenografts. Organoids were dissociated into single cells and plated in matrigel-coated 384-well plate. Each model was treated with a library of epigenetic probes (1uM) and a DMSO control over a period of 8 days. Library was provided by Structural Genomics Consortium (www.thesgc.org) and contained compounds targeting a variety of protein domains some of which had activity on acetylation, methylation, histone de-methylation etc. CellTiter-Glo assay was performed to measure cell survival.
Results: Among the epigenetic probe compounds tested on 26 models, LLY 283 (PRMT5 inhibitor) showed the most significant effect on inhibition of cell growth in 69% of organoid models
(18/26) with suppression of >=40% as compared to the DMSO control. To assess differential responses to treatment with LLY 283, four organoid models were treated with 21 different concentrations of PRMT5 inhibitor. Growth curves of a sensitive (XDO181) and a less sensitive (XDO4056) models were compared. For XDO181 and XDO4056, IC50 values were calculated to be 4.7 nM and 31.8 nM respectively, indicating that a less sensitive model is associated with a 7-fold increase in IC50 value compared to the sensitive model.
Conclusion: A screen using epigenetic compounds on NSCLC patient-derived organoids revealed sensitivity to PRMT5 inhibitor in 69% of the organoid models tested. Further investigation will explore the mechanisms that are associated with sensitivity to PRMT5 inhibition.

NSD1/2 histone methyltransferases regulate cell growth in HPV-negative head and neck squamous cell carcinoma (HNSCC)

Iuliia Topchu[1], Igor Bychkov[1], Petr Makhov[2], Evgeny Izumchenko[3], John Karanicolas[2], Jindan Yu[1], Jochen Lorch[1], Yanis Boumber[1]. *[1]Robert H. Lurie Comp. Cancer Ctr. of Northwestern Univ., Chicago, IL,[2]Fox Chase Cancer Center, Philadelphia, PA,[3]University of Chicago, Chicago, IL*

Members of the NSD protein family (NSD1, NSD2, and NSD3) are histone methyltransferases (HMTs) that catalyze lysine 36 dimethylation (K36me2) at histone H3. H3K36 modifications play an important role in regulating the function and structure of chromatin, affecting transcription, replication, and repair. Abnormal H3K36 methylation is often detected during tumor development and progression. Inactivating NSD1 mutations are frequent in head and neck squamous cell carcinoma (HNSCC). They commonly occur in HPV-negative oropharyngeal (OP) and laryngeal (LC) carcinomas, and define a prognostic subtype in LC, associated with significantly improved overall and progression-free survival. Notably, the SCC4 cell line, carrying a damaging mutation in the *NSD1* gene demonstrated reduced dimethylation level of H3K36 compared to NSD1 wild-type HNSCC counterparts. To explore the biological impact of the NSD1/NSD2 loss of function in HNSCC, we established cell lines with doxycycline-inducible shRNA knockdown of NSD1 and NSD2 in the set of HNSCC cell lines originating from different sites (JHU011, JHU022, Cal27, and FaDu cell lines). The depletion of NSD1 and NSD2 led to reduction of K36me2, significant decrease in cell growth as measured by cell titer blue (CTB) and clonogenic assays. NSD1/NSD2 depletion in these HNSCC cells also caused a significant increase in apoptosis. Gene Set Enrichment Analysis (GSEA) of RNA-seq for NSD1 wt versus knockdown cells indicates that NSD1 knockdown reduced expression of E2F target genes. Among the E2F transcription factor family, E2F2 gene expression was significantly decreased in all NSD1 knockdown cell lines. NSD1 knockdown also activated gene pathways related to autophagy and response to starvation. NSD1 knockdown reduced the levels of autophagy initiation gene ULK1 at both mRNA and protein levels. We also probed for protein signaling in HNSCC cells following NSD1 depletion using a reverse protein phase array (RPPA) approach, and validated Phosphatidylinositol-5-Phosphate 4-Kinase

Type 2 Beta (PIP4K2B), but not other members of this family (PIP4K2A and PIP4K2C), as NSD1-regulated. PIP4K2B was regulated at the mRNA level by NSD1 as well. The CHIP-qPCR assay demonstrated the loss of H3K36me2 at the promoter of the PIP4K2B gene in NSD1 knockdown cells, suggesting direct regulation by NSD1. Moreover, PIP4K2B siRNA depletion has also led to a significant decrease in HNSCC proliferation, which suggests that the NSD1 may regulate proliferative activity through PIP4K2B. Taken together, while this data supports the suggestion that NSD histone methyltransferases have multiple downstream targets, the underlying mechanism remain to be investigated in more detail. Further, NSD proteins are attractive targets for drug development for improving treatment strategies for HNSCC.

Loss of KDM5A supports KRAS-driven pancreatic cancer

Jasper R. Chen[1], Jincheng Han[2], Cullen M. Taniguchi[1], Ronald A. DePinho[2]. *[1]Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Cancer Biology, UT MD Anderson Cancer Center, Houston, TX*

Objective: Mutant KRAS is a primary driver of pancreatic ductal adenocarcinoma (PDAC), which exhibits marked hypoxia. Despite the strong association of hypoxia and PDAC, the relationship between KRAS and hypoxia is still poorly understood. The oxygen-sensitive histone lysine demethylase, KDM5A, was recently reported to mediate epigenetic responses to hypoxia independent of the hypoxia-inducible factors. KDM5A epigenetically represses transcription via two mechanisms: by its demethylase activity on activating H3K4me3 marks, and through its interaction with deacetylase complexes containing HDAC1/2, which deacetylates activating H3K9ac and H4K16ac histone marks. Under hypoxic conditions, KDM5A loses its activity, leading to restoration of these H3K4me3 marks, thereby activating KDM5A target genes. The purpose of this study is to understand how KDM5A loss of function contributes to pathogenesis of mutant KRAS-driven pancreatic cancer. Methods: Cell lines derived from mice with pancreas-specific p53 deletion and doxycycline-inducible expression of $Kras^{G12D}$ (iKPC). Protein lysates were prepared using RIPA buffer. Histones were purified by acid extraction.

Immunoblotting was used to probe for protein levels of Kdm5a, H3K4me3, H3K9ac, and H4K16ac. Genetic ablation of $Kras^{G12D}$ was performed by culturing iKPCs in tetracycline-free medium. Kras was induced by adding doxycycline to the culture medium. Pharmaceutical inhibition of MEK, proteasome, and Kdm5a were performed by treating iKPCs with mirdametinib, MG-132, and CPI-455, respectively. Knockdown of β-TrCP and FBXW7 were performed by stable expression of shRNA in iKPCs. Protein motif scanning was performed using the Eukaryotic Linear Motif (ELM) Prediction online software.
Results: We discovered that Kdm5a protein levels were abrogated by induction of $Kras^{G12D}$ and stabilized by genetic ablation of Kras. Pharmaceutical inhibition of MEK or proteasome function stabilized Kdm5a, indicating that Kras induces Kdm5a proteasomal degradation through the MEK/ERK pathway. H3K4me3, H3K9ac, and H4K16ac histone marks were increased in Kras-on iKPC compared to Kras-off iKPC, consistent the expected effect of Kras-induced Kdm5a degradation. Pharmaceutical inhibition Kdm5a in the Kras-off setting restored H3K4me3, suggesting that Kdm5a contributes to demethylation of H3K4me3 in iKPC. We identified two phosphodegron sites corresponding to β-TrCP and FBXW7 of the ubiquitin ligase complex within the Kdm5a protein sequence. Knockdown of either β-TrCP or FBXW7 in iKPC both stabilized Kdm5a despite induction of Kras.
Conclusion: We conclude that Kdm5a plays a tumor suppressor role in pancreatic cancer by epigenetically repressing transcriptional programs necessary for KRAS-driven oncogenesis.

***SETD4* transcription levels correlates with leukemic burden and *SMYD2* transcription in acute lymphoblastic leukemia**

Luis Augusto Muniz Telles, Luis Henrique Toshihiro Sakamoto, Alan Jhones Barbosa de Assis, Doralina de Amaral Ramos Rabello, Andrea Barretto Motoyama, Fabio Pittella-Silva. *Faculty of Health Sciences and Medicine, University of Brasilia, Brasilia, Brazil*

Acute lymphoblastic leukemia (ALL) is the most common childhood malignancy worldwide. It has a history of great rates of success in treatment, but adults and infants still share a dismal prognosis. This

condition makes the development of new prognostic markers linked to effective therapeutic strategies a matter of pressing concern. While cancer has traditionally been viewed as a genetic disease derived from alterations in oncogenes and tumor suppressors, it is well known nowadays that epigenetic changes also play a fundamental role in tumorigenesis. The SET family of lysine methyltransferases (KMT) has been implicated in a number of cancers, and *SETD4* is a member that is still poorly characterized. In the present study we used qPCR to analyze the expression pattern of *SETD4* among 83 pediatric ALL patients and non-neoplastic bone marrow (BM) samples and investigated the correlation between *SETD4* transcription changes with the leukemic burden in ALL patients during chemotherapy. We found that *SETD4* transcription levels are significantly upregulated in BM samples derived from ALL patients compared to non-neoplastic BM (8,5-fold higher, $p < 0{,}001$) and its expression correlated with leukemic burden. Importantly, levels of *SETD4* decreased in patients that responded to chemotherapy treatment. We further investigated whether *SETD4* transcription levels associates with that of *SMYD2*, another KMT previously identified as a prognostic marker in ALL. Transcription levels of *SETD4* and *SMYD2* were examined on day 15^{th} and 29^{th} of chemotherapy. Surprisingly, a high level of correlation (Spearman $r = 0.925$, $p < 0.01$) between both genes was observed in both treatment time points. Finally, survival outcomes were worst in ALL patients with high levels of *SETD4* transcription (log-rank test, $p < 0{,}05$), evidencing its dysregulated expression is associated with an unfavorable disease prognosis. Together, these results point to *SETD4* as a useful prognostic marker, a possible tool to assess response to therapy and an attractive target for drug development.

Dissecting EP300 and CBP function in prostate cancer models

Kiran Mirpuri, Alok K. Tewari, Myles A. Brown. *Dana-Farber Cancer Institute, Boston, MA*

Prostate adenocarcincoma is dependent on androgen and its cellular receptor the androgen receptor (AR) for most of the natural history of the disease including progression to the advanced and lethal state. Many prostate cancer therapeutics target the androgen signaling pathway, although tumors invariably become resistant to these treatments. EP300 and

CBP are protein paralogs that are co-regulators of AR-mediated gene transcription and are mutated at low frequency in prostate cancers. Expression of CBP and EP300 has been found to correlate with AR expression in advanced disease, and their inhibition can impact AR-mediated transcription in model systems. However, both proteins are not equally essential in prostate cancer cell lines. As drugs inhibiting the bromodomains of these proteins are in early clinical trials, a greater understanding of the common and unique functions of EP300 and CBP may inform the clinical application of these therapeutics. Using chemical inhibition or degradation of either each paralog or both, in combination with genetic depletion, we identify converging and diverging epigenomic and transcriptional programs regulated by each paralog both in the presence and absence of androgens. If validated in tumor samples from patients, these results may nominate biomarkers of response to EP300/CBP inhibitors.

KDM4A promotes NEPC progression through regulation of MYC expression

Celia Sze Ling Mak[1], Ming Zhu[1], Xin Liang[1], Feng Wang[2], Anh G. Hoang[1], Xinzhi Song[2], Peter Shepherd[2], Derek Liang[2], Jessica Suh[2], Jiwon Park[2], Miao Zhang[2], Eric Metzger[3], Roland Schule[3], Abhinav K. Jain[2], Ellen Karasik[4], Barbara A. Foster[4], Min Gyu Lee[2], Paul Corn[2], Christopher J. Logothetis[2], Ana Aparicio[2], Nora Navone[2], Patricia Troncoso[2], Jianhua Zhang[2], Sue-Hwa Lin[2], Guocan Wang[1]. *[1]Department of Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Klinikum der Albert-Ludwigs-Universitat Freiburg, Freiburg, Germany,[4]Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Despite advancements in treatment, prostate cancer (PCa) remains the second leading cause of death among men. Neuroendocrine prostate cancer (NEPC) represents one of the most lethal forms of PCa and lacks life-prolonging treatment. Here we identified histone lysine demethylase KDM4A as a driver in NEPC progression and an effective therapeutic target. KDM4A mRNA and protein are overexpressed in human and mouse NEPC compared to adenocarcinoma. Knockdown or knockout of KDM4A in NEPC cell lines suppressed cancer cell growth *in vitro* and *in vivo*. Importantly, the inactivation of *Kdm4a* in a genetically engineered mouse model of prostate cancer reduces tumor burden, reduces the incidence of NEPC, and prolongs overall survival. Mechanistically, KDM4A directly regulates the transcription of MYC, which is hyper-activated in human and mouse NEPC. Furthermore, a potent pan-KDM4 inhibitor QC6352 significantly reduces NEPC cell growth *in vitro* and *in vivo*. Taken together, we demonstrate that KDM4A promotes NEPC progression through regulation of MYC expression and targeting KDM4A can be an effective therapeutic strategy for NEPC.

Identifying molecular targets to overcome CNS infiltration in acute lymphoblastic leukemia associated with an activating mutation of the

NSD2 histone methyltransferase

Charlotte L. Kaestner, Amin Sobh, Jianping Li, Katelyn Raburn, Alberto Riva, Jason O. Brant, Richard L. Bennett, Jonathan D. Licht. *University of Florida, Gainesville, FL*

Background**:** One of the major clinical challenges in acute lymphoblastic leukemia (ALL) is the treatment of central nervous system (CNS) involvement. CNS-directed therapy is currently limited to agents associated with substantial neurotoxicity and the lack of mechanistic understanding of how ALL cells infiltrate the CNS is preventing novel therapy development. Our laboratory has previously shown in murine xenografts that ALL cells with a point mutation (E1099K) in the histone methyltransferase NSD2 aggressively infiltrate not only the leptomeninges of the brain, but also the brain parenchyma. Accordingly, we also showed that NSD2-E1099K cells have an enhanced ability to migrate through a Boyden chamber and adhere to endothelial cells of the blood brain barrier (BBB cells). Furthermore, RNA-seq data on four NSD2-E1099K cell lines revealed genes that may play a role in ALL brain infiltration. However, it remains unknown which of the genes upregulated by NSD2 could be potential therapeutic targets against CNS leukemia.

Aim: This study aims to identify therapeutically targetable genes that are important for (1) migration of ALL cells through a Boyden chamber, (2) adhesion of ALL cells to BBB cells, and (3) intercellular signaling between ALL and BBB cells.

Methods: We used a focused CRISPR-gene-knockout library targeting 500 genes upregulated in NSD2-E1099K cells to ascertain genes important for migration in the RCHACV cell line. Next, we used the genome-wide Brunello library to identify genes critical for ALL cell adhesion to BBB cells. To study intercellular communication between ALL and BBB cells, we co-cultured SEM-WT or SEM-NSD2-E1099K cells with BBB cells for 48h. ALL cells were then isolated from BBB cells using CD19+ magnetic beads and all groups were further processed for RNA-seq.

Results: Our CRISPR screen studies identified genes whose knockout led to enhancement of migration or adhesion, as well as genes whose knockout resulted in inhibition of migration or adhesion. One of the top candidate genes identified in the migration screen was PTPRG. Validation studies with shRNA and CRISPRa constructs confirmed that PTPRG is a

modulator of migration and adhesion in NSD2-E1099K ALL cells. In addition, RNA-seq studies identified important differences in how SEM-WT (low-CNS infiltrating) and SEM-NSD2-E1099K (high-CNS infiltrating) cells communicate with BBB cells. Specifically, our analysis predicted that IL1B secretion of SEM-NSD2-E1099K cells, but not SEM-WT cells, leads to increased IL1B target gene expression in BBB cells, potentially contributing to CNS infiltration.
Conclusion: Our findings implicate PTPRG and the IL1B pathway as important modulators of migration and adhesion or intercellular signaling, respectively. These genes may have the potential to be novel therapeutic target for preventing ALL brain infiltration.

#4762
Oncogenic over-expression of MED12 is epigenetically fostered in the core-binding factor subgroups of acute myeloid leukemia
Samrat Roy Choudhury[1], Arkajyoti Bhattacharya[2]. *[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]University Medical Center Groningen, Groningen, Netherlands*

Mediator (MED) proteins typically assemble and recruit distal coactivators at binding sites of RNA polymerase II to help regulate a gene's transcriptional output. The MED-kinase module consists of four subunits, MED12/12L, MED13/13L, CDK8/19 and Cyclin C, and reversibly interacts with the MED-core complex to function as a lineage-specific transcriptional activator. In particular, MED12 has been reported to recruit BRD4, FLI/ERG, CBP/p300, and GATA2 transcription factors on H3K27ac-enriched super-enhancer (SE) loci in hematopoietic stem and acute myeloid leukemia (AML) cells to maintain cell fate determination or leukemic growth respectively. Given the regulatory role MED12 in AML, there is a sustained interest in identifying targeted inhibitors against this MED-protein. Herein, we aimed to investigate if the oncogenic over-expression of MED12 is epigenetically regulated in AML. We analyzed the MED12 transcriptomic data in AML patients, belongs to 6 cytogenetic subgroups having chromosomal aberrations such as inv(16) (n=28), t(15;17) (n=37), t(8;21) (n=40), MLL-rearranged (n=38), AML-complex (n=48), and normal karyotype (n=351), compared to normal bone marrow (NBM) mononuclear cells (n=73), from the Microarray Innovations in Leukemia (MILE) study

(Stage I). MED12 was found significantly ($p<0.01$) upregulated in AML subgroups, except for the AML-complex subgroup along 3 probe sets (211342_x_at, 203506_s_at, and 216071_x_at). The highest upregulation of MED12 was observed in the inv(16) subgroup having the mean differential expression of 0.78, followed by 0.57 in t(8;21) and 0.5 in t(15;17) subgroup, compared to NBM. Considering the fact that inv(16) and t(8;21) subgroups showed highest expression of the gene, and are categorized as the core-binding factor (CBF) AML-subgroups, we examined DNA-methylation and chromatin modifications of MED12 in patients [n=3 for inv(16) and n=1 for t(8;21)], based on the whole-genome bisulfite sequencing and chromatin immunoprecipitation sequencing data, as available at the BLUEPRINT epigenome, and DNAse sequencing (K562 cells) data at ENCODE. We observed DNAse hypersensitive peaks at the exon-26 and a region (229 bp) spanning the transcription start site (TSS) and upstream promoter of the gene, indication an open chromatin conformation. The TSS and upstream promoter also contained a broad H3K4me3 domain [1.7 kb in inv(16) and 1.2 kb in t(8;21)], with an overlapping hypomethylated CpG-island. Collectively, our findings suggest that MED12 oncogenic over-expression in CBF AML-subgroups are fostered by an epigenetically active promoter. Future studies will be aimed at understanding the impact of targeted perturbation of MED12 in the enhancer mechanism and sustenance of leukemic growth in CBF AML-subgroups.

#4763

Two epigenetically distinct cellular states in osteosarcoma are regulated by a state-specific set of transcription factors driving differential drug response

Eunice Lopez Fuentes[1], Andrew Clugston[1], Leanne Sayles[1], Maria Pons Ventura[1], Alex Lee[1], Vijay Ramani[2], E. Alejandro Sweet-Cordero[1].
[1]Pediatrics, UCSF - University of California San Francisco, San Francisco, CA,[2]Biochemistry & Biophysics UCSF, Gladstone Institute for Data Science & Biotechnology, San Francisco, CA

Osteosarcoma is a highly aggressive cancer seen mostly in children and young adults which is characterized by aneuploidy and dramatic structural rearrangements associated with large copy number gain and widespread

chromosomal loss. Osteosarcoma therapy has not change in over forty years, highlighting the need for deeper molecular understanding of this disease which could in turn identify new therapeutic opportunities. While DNA-level heterogeneity between tumors has been well-described, not much is known regarding epigenetic heterogeneity within osteosarcoma and how this may impact critical phenotypes such as therapy response and metastasis. To characterize the osteosarcoma epigenome, we integrated ATAC-seq and RNA-seq across a unique set of patient samples, PDXs and PDX-derived cell lines obtained across the disease continuum including biopsies, resections, and metastases. ATAC-seq analysis revealed the presence of at least two distinct epigenetic cell states, epigenetic cluster 1 (EC1) and epigenetic cluster 2 (EC2). We used the GREAT algorithm to identify enriched pathways for the genes linked to these differential open regions (~2000 unique peaks per EC). EC1 is defined by genes related to mesenchymal cell proliferation and osteoblast differentiation, whereas EC2 is enriched in genes related to extracellular matrix organization and regulation of kinase activity. Accessible chromatin peaks in EC1 showed transcription factor binding motifs related to development including RUNX2/3, MEOX2, HOXA2/5 and DLX; whereas members of the AP1 complex including FOSL1/2, c-FOS, JUN were enriched in open regions in EC2. This is correlated with high protein expression of these transcription factors in a cluster-specific manner and differential binding to chromatin. We defined a gene-signature of 343 genes by integrating differential open chromatin with differential gene expression of EC1 and EC2. This gene-signature is able to separate gene expression data of patient samples into 2 clusters, suggesting these epigenetic cell states are found in patient samples. We assigned the patient samples to one EC and performed a survival analysis using only primary patient samples. EC1 shows a lower survival probability than EC2. To identify possible therapeutic implications of these EC, we evaluated a drug response dataset generated with ~40 targeted agents for the same panel of PDX-cell lines. Whereas EC1 cell lines were highly sensitive to a selective inhibitor of Aurora B, cell lines in EC2 were inhibited by a MEK inhibitor. PDX-cell lines injected in a subcutaneous model recapitulated the differential drug response in vivo. In summary, we have identified two epigenetically cell states regulated by a state-specific set of transcription factors defining a gene signature that could help to define osteosarcoma subclasses and predict drug response.

#4764

The therapeutic potential of *lnc-HLX-2-7* in group 3 medulloblastomas in children

Keisuke Katsushima[1], Bongyong Lee[1], Menglang Yuan[1], Stacie Stapleton[2], George Jallo[2], Sudipta Seal[3], Charles G. Eberhart[1], Ranjan J. Perera[1].
[1]Department of Oncology, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD,[2]Johns Hopkins All Children's Hospital, St. Petersburg, FL,[3]University of Central Florida, Orlando, FL

Medulloblastoma (MB) is an aggressive brain tumor that predominantly affects children. Recent high-throughput sequencing studies suggest that the non-coding RNA genome, in particular long non-coding RNAs (lncRNAs), contributes to MB formation and tumor progression. Here we report the identification of a novel lncRNA, *lnc-HLX-2-7*, as a potential therapeutic target in group 3 MBs. In this study, we report that *lnc-HLX-2-7* RNA specifically accumulates in the *HLX* (host gene of *lnc-HLX-2-7)* promoter region and activates HLX expression by recruiting multiple factors including enhancer elements. RNA sequencing and chromatin immunoprecipitation revealed that HLX directly binds to the promoters of several tumor-promoting genes, including *MYC*, and activates their expression. Furthermore, intravenous treatment with antisense oligonucleotides targeting *lnc-HLX-2-7* coated with cerium-oxide nanoparticle (CNP-*lnc-HLX-2-7*) reduced tumor growth (40-50%) in intracranial MB xenograft mouse model (n=10, $p<0.01$, *t-test*). We found that the combinatorial therapy of CNP-*lnc-HLX-2-7* and cisplatin further inhibits tumor growth and significantly prolongs mouse survival compared to CNP-*lnc-HLX-2-7* monotherapy (n=10, $p<0.01$, *t-test*) only. We report here the importance of the *lnc-HLX-2-7-HLX-MYC* axis in regulating group 3 MB progression and provide a strong rationale for using *lnc-HLX-2-7* as a specific and potent therapeutic target for the group 3 MBs in children.

Hypoxia increases the methylated histones to prevent histone clipping during Raf-induced senescence

Hyunsung Park, Soojeong Chang. *Dept. of Life Science, University of Seoul, Seoul, Korea, Republic of*

Hypoxia increases methylated histones by inhibiting O_2- and α-ketoglutarate-dependent histone lysine demethylases (KDMs). This study is the first to demonstrate how the hypoxic increment of methylated histones cross-talks with other epigenetic changes, such as histone clipping and heterochromatin redistribution, named senescence-associated heterochromatin foci (SAHF), which are found during oncogene-induced senescence (OIS). Raf-activation in primary human fibroblasts IMR90 increases mature cathepsin L (CTSL)-mediated clipping of histone H3, H2B and H4. Hypoxia protects histones from CTSL by increasing histone methylation without reducing the amount and activity of CTSL. Forced enhancement of methylated histones protected histones from clipping during OIS, even under normoxia, but failed to block SAHFs. Altogether, these results suggest that maintenance of methylated histones is sufficient to protect histones from CTSL, not sufficient but necessary for inhibiting SAHFs, suggesting that besides inhibiting KDMs, hypoxia adopts other mechanisms to inhibit SAHFs**.** Hypoxia protects histones and chromatin from dramatic epigenetic changes by increasing methylated histones.

Gene Regulation and Transcription Factors in Cancer

#5749

Core transcriptional regulatory circuitry in AML

Taku Harada[1], Monika Perez[1], Jeremie Kalfon[1], Kenneth Eagle[2], Flora Dievenich Braes[3], Rashad Batley[3], Kimberly Stegmaier[2], Stuart Orkin[2], Maxim Pimkin[2]. *[1]DFCI/BCH, Boston, MA,[2]DFCI/Harvard Medical School, Boston, MA,[3]BCH, Boston, MA*

Cell states are established by small sets of lineage-restricted transcription factors (TFs). A generally accepted model posits that core regulatory TFs positively regulate their own and each other's genes, forming a network of interconnected feed-forward loops termed core regulatory circuitry (CRC). Here, we sought to test the CRC concept by defining the direct gene-regulatory programs of the critical oncogenic TFs in acute myeloid leukemia (AML) . We employed a targeted protein degradation (dTag) strategy with a homozygous knock-in of the $FKBP12^{F36V}$-coding DNA

sequence into the endogenous TF-coding loci of 7 core myeloid TFs and 1 cofactor (MYB, PU.1/SPI1, GFI1, RUNX1, RUNX2, MEF2D, IRF8, IRF2BP2), all of which represent selective AML dependencies and display the canonical pattern of feed-forward CRC binding. Following complete degradation of TFs for 1-2 hours, we measured the genome-wide rates of nascent mRNA synthesis by SLAM-seq. Genes whose transcription rates change significantly and immediately after a TF's degradation represent its direct transcriptional targets. Strikingly, each TF directly regulates only between 100-450 target genes. Furthermore, rather than forming a core regulatory circuit with fully interconnected feed-forward loops, the core TFs form a very sparsely interconnected hierarchy with a cascading regulatory structure. Each evaluated TF is capable of both direct gene activation and repression. For instance, MYB directly inhibits 135 genes, most of which are associated with myeloid differentiation and inflammation. Feed-forward loops appear to be much less common than previously anticipated. Indeed, we detected only 336 feed-forward loops formed by any combination of the 8 TFs genome-wide. GFI1 and IRF2BP2 negatively regulate their own expression, and the rest of the TFs show no evidence of direct self-regulation. The entire regulatory network converges on MYC and immune signaling. A time-course SLAM-seq experiment after MYB degradation highlighted the secondary nature of eventual global transcriptional collapse and revealed bi-phasic kinetic behavior of feed-forward loops that MYB forms with GFI1 and IRF2BP2. A pseudo-steady state of cellular transcription, ensuing 8-12 hours after MYB degradation, accurately predicts MYB-dependent gene expression patterns in human AML samples. Indeed, a much higher expression of inflammatory mediators and cytokines is observed in patients with low MYB expression, consistent with the observation that MYB directly regulates inflammatory pathways and potentially explaining the known survival benefit of high MYB expression in human AML. Accordingly, MYB degradation results in immediate release of the pro-inflammatory cytokines TNF and CCL2. Our data represent the first example of systematic elucidation of direct regulatory functions of multiple core regulatory TFs in a single cellular context and support a new model of core regulatory circuitry organization in human cells.

The mutational landscape of ultraconserved elements in human cancers

Recep Bayraktar[1], Yitao Tang[2], Mihnea P. Dragomir[1], Linda Fabris[1], Giulio F. Draetta[3], Han Liang[2], George A. Calin[1]. *[1]Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX*

Background: Ultraconserved regions or elements (UCEs) are greater than 100-base pairs in length and are perfectly (100%) conserved across large evolutionary distances in the genomes of at least 3 of 5 placental mammals: human, cow, dog, rat, and mouse. Most UCEs are located in non-coding regions of the genome; however, some UCEs overlap with coding exons. In addition, some UCEs have been found to be transcriptionally active as long non-coding RNAs and are involved in a variety of cellular processes such as cellular proliferation. Although a few UCE sequence variations were reported to be associated with human diseases, the molecular functions of somatic mutations in UCEs remain largely unexplained in human cancers. In this study, we characterized the distribution of somatic UCE mutations throughout a spectrum of cancers and investigated the biological functions of cancer associated UCEs.

Methods: We examined somatic UCE mutations in 2,449 cases of 22 cancer types using the PCAWG and ICGC platforms. To validate these mutation patterns, UCE sequencing was performed on the Illumina NovaSeq 6000 platform for MD Anderson patient cohorts. A custom AsCpf1 guide library was built to identify potential regulatory UCE functions in colorectal cancer models, and 3 guides were designed to target 2,247 UCEs. The proliferation ratio of knockout UCEs was analyzed. We then generated stable mutated UCE clones using the CRISPR AsCpf1 technology in colorectal cancer cells. We conducted RNA sequencing (RNA-seq) of mutated UCE cells. The expression of target proteins and genes were analyzed by qRT-PCR and western blotting. To address the effects of the mutated UCE_11311 tumor growth, DLD1 cells were injected in athymic nude mice.

Results: We analyzed the WGS data on 2,449 cases of 22 cancer types and identified 24,039 somatic mutations in 10,090 (73.46%) UCEs. These were mostly located in non-coding DNAs, mainly in introns.Based on the RNA-

seq data, one of the strongest impacts of mutated UCEs was on ARID1B. We confirmed that specific mutated UCE decreased ARID1B mRNA and protein levels. Our *in vivo* results demonstrated that UCE mutations enhanced the tumorigenicity of DLD1 xenograft tumors. As a summary, UCE_11311 has a transcriptional enhancer activity on the ARID1B gene and UCE_11311 mutations are actively participating in the tumorigenesis at least in part through regulating ARID1B expression.
Discussion: We identified hundreds of unexplored tumorigenic UCEs that need to be further characterized functionally and clinically, and proved one of them to be a transcriptional enhancer of the tumor suppressor ARID1B. Collectively, these data support the concept that certain somatic UCE mutations are frequent and functional in cancer evolution, acting as driver mutations that can be used as new therapeutic targets; other somatic UCE mutations are cancer specific or patient specific, are markers of aggressiveness, and can be used to personalized therapy.

Single-cell epigenomic analysis reveals an important role of the receptor kinase Ror2 in the erosion of cellular identity during pancreatic carcinogenesis
Simone Benitz[1], Ian Loveless[2], Malak Nasser[1], Hui-Ju Wen[1], Daniel Long[1], Erick Davis[1], Jacee Moore[1], Ivonne Regel[3], Filip Bednar[4], Howard Crawford[1]. *[1]Surgery, Henry Ford Health System, Detroit, MI,[2]Public Health Sciences, Henry Ford Health System, Detroit, MI,[3]Department of Medicine II, Ludwig Maximilian University of Munich, Munich, Germany,[4]Surgery, University of Michigan, Ann Arbor, MI*

Background The major genetic driver for pancreatic ductal adenocarcinoma (PDAC) is oncogenic KRAS. However, adult acinar cells, a probable origin of PDAC, are largely refractory to $Kras^{G12D}$-mediated oncogenic transformation in mouse models. With the concomitant loss of transcription factors that regulate acinar cell differentiation, such as Pdx1 (Pancreatic and Duodenal Homeobox 1), acinar cells undergo a rapid cell identity switch, known as acinar-to-ductal metaplasia (ADM). Consequently, $Kras^{G12D}$;$Pdx1^{f/f}$ (Pdx1 knockout) mice present with massively accelerated

tumor formation. How loss of cell identity cooperates with oncogenic Kras to induce pancreatic transformation is largely unclear.
Methods To elucidate mechanisms responsible for the cellular reprogramming in $Kras^{G12D}$;$Pdx1^{f/f}$ animals, single-cell ATAC-seq from pancreatic bulk tissue was performed. Chromatin accessibility states were captured at early stages of carcinogenesis and correlated to RNA-seq data. Expression of differentially regulated genes was validated by RNAscope and immunohistochemistry staining. The role of identified target genes was studied in pancreatic cancer cell lines.
Results Single-cell ATAC-seq proved as a powerful tool for defining cell-type identity, cellular reprogramming and target genes in early metaplastic transformation of pancreatic tissue. While sole expression of oncogenic Kras lead to reduced accessibility of acinar differentiation genes in acinar cells, these changes were much more prominent in $Kras^{G12D}$;$Pdx1^{f/f}$ mice, promoting metaplastic conversion. Notably, acinar cells of $Kras^{G12D}$;$Pdx1^{f/f}$ animals as well as a proportion of metaplastic lesions in both, $Kras^{G12D}$ and $Kras^{G12D}$;$Pdx1^{f/f}$ mice, showed elevated accessibility and expression of the *Ror2* gene. As a receptor protein tyrosine kinase, Ror2 controls essential signaling pathways, such as Ras-MAPK signaling. By analyzing Ror2 knockout mice, we found that the receptor kinase regulates the identity of metaplastic epithelia. Immunostaining of pancreatic cancer tissues from $Kras^{G12D}$;$p53^{mut}$ (KPC) mice and human PDAC specimens also revealed ROR2 expression in a subset of cancer cells. Knockdown of ROR2 in pancreatic cancer cell lines significantly decreased cell proliferation, while overexpression induced a profound increase in proliferation and in epithelial-to-mesenchymal transition based on the downregulation of multiple epithelial markers and an upregulation of an array of mesenchymal genes.
Conclusions Our in-depth sequencing data revealed that expression of $Kras^{G12D}$ with the concomitant loss of Pdx1 leads to vast alterations of acinar cell identity and significantly accelerated transformation. We identified induced expression of the receptor kinase Ror2, which regulates pancreatic cancer initiation and drives pancreatic cancer cell aggressiveness.

Enhancer amplification defines lineage addiction in human lung adenocarcinoma

John Louis Pulice[1], Matthew Meyerson[2]. *[1]Harvard Medical School, Boston, MA,[2]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Lung cancer is the most common cause of death from cancer worldwide, and lung adenocarcinoma (LUAD) is the most common type of lung cancer. NKX2-1 (also known as TTF-1, TITF-1) is a lineage defining transcription factor for normal lung development. In LUAD, NKX2-1 is a highly specific and sensitive marker for both primary and metastatic LUADs, with 85-90% expressing NKX2-1. We and others identified that NKX2-1 as the most significantly amplified gene in LUAD, with 22.5% of primary LUADs exhibiting copy number gains. NKX2-1 is amplified as the earliest stages of LUAD development, and NKX2-1 amplification is a truncal event in multi-region LUAD evolution. Despite strong evidence for an oncogenic role for NKX2-1, little is known about the mechanisms of NKX2-1 activation, or how its oncogenic regulation drives LUAD.

Here, we identify recurrent focal amplification targeting a super-enhancer (SE) of NKX2-1 as a driving event in LUAD. Using epigenomic data from LUAD cell lines and tumors, we identify this region as a alveolar lineage super-enhancer (NKX2-1 SE) that is specifically active in NKX2-1(+) LUAD cell lines and primary tumors. Notably, this region is co-amplified with NKX2-1 in 96-100% of NKX2-1-amplified samples, suggesting this region a critical component of the NKX2-1 amplicon. Using endogenous ChIP-seq and exogenous luciferase assays, we show the enhancer activity of the NKX2-1 SE is comprised of three constituent enhancers, and demonstrate that the key enhancer elements can activate transcription of the NKX2-1 promoter. Using CRISPR inhibition (CRISPRi) and CRISPR activation (CRISPRa) in LUAD cell lines expressing high or low levels of NKX2-1, we show that activity of the NKX2-1 SE defines endogenous NKX2-1 expression.

Using RNA-seq, ChIP-seq, and ATAC-seq, we find that NKX2-1 controls the transcriptional and epigenomic landscape of lung adenocarcinoma. NKX2-1 knockdown activates an epithelial-mesenchymal transition (EMT) gene signature and downregulates an alveolar differentiation signature, including critical markers of LUAD differentiation, such as NAPSA, SFTPA1/2, and HOPX, at which NKX2-1 mediates lineage enhancer

accessibility to regulate target gene expression. Global clustering of LUAD cell lines by RNA-seq or H3K27ac ChIP-seq identifies a distinct NKX2-1(+) cluster, and we find that NKX2-1 directly regulates the genes (57/97) and enhancers that distinguish this subpopulation. Using genome-wide shRNA and CRISPR screens, we identify a NKX2-1 dependency in NKX2-1(+) LUAD cell lines, and find that the majority of NKX2-1(+) LUAD cell lines (11/14) assayed are dependent on NKX2-1.
Our data demonstrates that enhancer amplification is a hallmark of oncogenic NKX2-1 activation in LUAD, through which NKX2-1 drives a lineage addicted state and oncogenic cell proliferation. This suggests that NKX2-1 is a critical defining oncogene for LUAD, and that targeting of NKX2-1 or its enhancer may suppress LUAD.

RUNX3 disrupts MYC/MAX complex and promotes MYC degradation

Yoshiaki Ito[1], Vincent Oei[1], Linda Chuang[1], Junichi Matsuo[1], Supriya Srivastava[2], Ming Teh[3]. *[1]Cancer Science Institute of Singapore, Singapore, Singapore,[2]Department of Medicine, National University of Singapore, Singapore, Singapore,[3]Department of Pathology, National University of Singapore, Singapore, Singapore*

We reported earlier that heterozygous deletion of RUNX3 in the mouse induces adenoma in small intestine, mammary gland (1) and lung (2) and a precancerous stomach epithelium that is highly sensitive to a chemical carcinogen (3). We therefore propose that RUNX3 is a gatekeeper of cancer development (1).
In our recent study on how RUNX3 inhibits early-stage cancer development in multiple tissues, we uncovered a previously unknown mode of MYC destabilization by RUNX3. From RNA sequencing, knockdown experiments, tumorigenic assays, protein interaction and ubiquitination studies, we show that the strong inhibitory effects of RUNX3 on proliferation and tumor growth may, in part, be attributed to its ability to promote MYC degradation. The evolutionarily conserved Runt domain of RUNX3 interacts directly with the basic helix-loop-helix leucine zipper of MYC, resulting in the disruption of MYC/MAX interaction, enhanced GSK3β-mediated phosphorylation of MYC protein at threonine-58 and its subsequent degradation via the ubiquitin-proteasomal pathway (4). MYC

inhibitor Omomyc, a short peptide comprising the b HLH LZ domain of MYC with 4 amino acid substitutions, is extremely effective in disrupting MYC/MAX interaction (5). RUNX3 appears to function similarly to Omomyc: is RUNX3 a Nature-designed Omomyc?

Determining the regulatory logic of breast cancer cells using single-cell multi-omics

Matthew J. Regner[1], Aatish Thennavan[2], Susana Garcia-Recio[3], Kamila Wisniewska[4], Philip M. Spanheimer[4], Joel S. Parker[2], Charles M. Perou[2], Hector L. Franco[2]. *[1]Bioinformatics and Computational Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Bioinformatics and Computational Biology, Dept of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Dept of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Cancer cells rewire regulatory elements scattered throughout the genome (such as enhancers) to drive aberrant gene expression. Thus, deconvoluting the regulatory mechanisms that contribute to oncogenic gene expression in cancer cells is key to understanding tumor biology. To this end, we have charted the transcriptional and epigenetic landscape of breast cancer at single-cell resolution to quantitatively link variation in chromatin accessibility to gene expression across malignant and non-malignant cell types. Our comprehensive dataset profiles the chromatin landscape (scATAC-seq) in concert with the transcriptional profiles (scRNA-seq) of 4 breast cancer cell lines, 12 primary breast tumors, and 4 normal mammary reduction tissue specimens collected and processed immediately after surgical resection. This dataset, encompassing over 250,000 individual cells, allowed us to define the regulatory logic of cancer cells by 1) revealing how the epigenome underlies cellular heterogeneity of these tumors in comparison to normal mammary tissue, 2) defining how

malignant cells hijack enhancer elements to drive key transcriptional programs in a subtype-specific manner, and 3) annotating which cancer-specific enhancer-to-gene connections portend a worse outcome in patients. Notably, we discovered that cancer cells acquire *de novo* non-coding enhancer elements to modulate hallmark cancer pathways that were previously hidden using bulk genomics approaches. This highlights the potential for cancer-specific enhancers to serve as markers with diagnostic and prognostic potential, or even serve as tractable targets for therapeutic intervention. Together these data enable the annotation of the cellular composition, transcriptional, and epigenetic landscape of breast tumors to help pinpoint clinically relevant mechanisms of tumorigenesis.

TP63 fusions drive enhancer rewiring, lymphomagenesis, and dependence on EZH2

Gongwei Wu[1], Noriaki Yoshida[1], Jihe Liu[2], Xiaoyang Zhang[3], Yuan Xiong[1], Tayla Heavican-Foral[1], Huiyun Liu[1], Geoffrey Nelson[4], Lu Yang[5], Renee Chen[5], Katherine Donovan[1], Marcus Jones[1], Mikhail Roshal[6], Yanming Zhang[6], Ran Xu[1], Ajit Nirmal[1], Salvia Jain[7], Catharine Leahy[1], Kristen Jones[1], Kristen Stevenson[1], Natasha Galasso[8], Nivetha Ganesan[8], Tiffany Chang[8], Wen-Chao Wu[1], Abner Louissaint[7], Lydie Debaize[1], Hojong Yoon[1], Paola Dal Cin[9], Wing Chan Chan[10], Shannan Ho Sui Ho Sui[2], Samuel Ng[1], Andrew Feldman[11], Steven M. Horwitz[8], Mathew Meyerson[1], Karen Adelman[4], Eric Fischer[1], Chun-Wei Chen[5], David Weinstock[1], Myles Brown[1]. *[1]Dana-Farber Cancer Institute, Boston, MA,[2]Harvard T.H. Chan School of Public Health, Boston, MA,[3]Huntsman Cancer Institute, Salt Lake, UT,[4]Harvard Medical School, Boston, MA,[5]City of Hope Comprehensive Cancer Center, Monrovia, CA,[6]Memorial Sloan Kettering Cancer Center, New York, NY,[7]Massachusetts General Hospital, Boston, MA,[8]Memorial Sloan Kettering Cancer Center, New York, MA,[9]Brigham and Women's Hospital, Boston, MA,[10]City of Hope Medical Center, Boston, MA,[11]Mayo Clinic, Rochester, MN*

Recurrent chromosomal rearrangements are a hallmark of hematologic malignancies and play critical roles in pathogenesis. The *TP53* analog *TP63* is rearranged in 5-10% of diverse subtypes of both aggressive T- and B-cell

lymphomas. Patients with *TP63*-rearranged lymphomas have dismal outcomes, with 5-year overall survival rates between 0-17%, depending on cohorts. The function and mechanisms of *TP63* rearrangements and TP63 fusion proteins in tumorigenesis are poorly understood. As a result, attempts to treat these patients to date have been largely empiric. Thus, there is an urgent need to understand how TP63 fusions contribute to tumorigenesis and to translate the findings into novel therapeutic options for these patients.

Here, we demonstrated that TP63 fusions are essential for the propagation of T-cell lymphomas (TCLs). Knockdown of TP63 fusions with specific shRNAs in TCL cell lines harboring TP63 fusions suppressed both cell growth *in vitro* and tumor growth *in vivo*. Retroviral expression of TBL1XR1-TP63, the most common TP63 fusion, conferred cytokine independence in Ba/F3 cells, consistent with its role as an oncogene. To investigate the role of TP63 fusions in T- and B-cell lymphomagenesis, we engineered a CAG-Loxp-Stop-Loxp-*TBL1XR1-TP63* conditional knock-in mouse model and crossed with h*CD2*-Cre mice. This results in expression beginning during early lymphoid development. As observed in patients, transgenic mice developed multiple subtypes of both T- and B-cell lymphoma. To define the effects and mechanisms of TP63 fusions within T cells, we performed CRISPR scanning, transcriptomic, epigenomic, and proteomic analyses. Our data showed that domains within both the N-terminal TBL1XR1 and C-terminal TP63 portions contribute to the function of this fusion. We found that the N-terminal component of TP63 fusions interacts with components of the NCOR/SMRT complex. At the same time, the C-terminal portion of TP63 (which recapitulates the deltaN-p63 isoform expressed in some carcinomas) interacts with the enhancer modifier KMT2D and its complex members. TBL1XR1-TP63 binds to a novel distal enhancer to drive *MYC* expression, and thus upregulates the expression of the histone H3K27 methylase *EZH2*. Finally, we assessed whether EZH2 is a vulnerability of *TP63*-rearranged lymphomas. We found that knockdown of EZH2 in *TP63*-rearranged lines significantly impaired cell growth, as did treatment with the EZH2 and 1 dual inhibitor valemetostat. Valemetostat, which is now being tested in patients with lymphoma, counteracted the oncogenic effects of TP63 fusions in multiple preclinical models *in vivo*. Together, our results identify the TP63 fusion as a highly unique oncogenic

driver in lymphomagenesis capable of recruiting multiple epigenetic modifier complexes and inducing a targetable dependence on EZH2.

Gene Regulation in Cancer

Pharmacological targeting of circadian clock genes reveals regulatory mechanisms of E-box regulated genes in cancer

Yuanzhong Pan[1], Heinz-Josef Lenz[2], Evanthia Roussos Torres[2], Steve A. Kay[3]. *[1]Department of Neurology, Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]Division of Medical Oncology, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA,[3]Department of Neurology; Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA*

Transcription factors (TFs) are key regulators of homeostasis and cancer. Recent advances in pharmacological targeting of TFs makes them valuable targets in various diseases, but systems-level understanding of the function and regulation of TFs from different families in cancers remains lacking. Our lab and collaborators have been developing new small molecules to modulate the functions of key regulators of the circadian clock BMAL1 and CLOCK, which are bHLH family TFs that activate gene expression by binding to a DNA motif called E-box, with a consensus sequence of CANNTG. E-boxes are ubiquitous in the genome and broadly regulate essential physiological processes of the cell, but their molecular biology in cancer is largely unknown. In the current work we tested the ability of small molecules to regulate the expression of BMAL1 and CLOCK target genes. Across different cell lines of various cancer types, we found that stabilization of one of the negative regulators of CLOCK, CRY2, by our novel compound called SHP1705, is the most consistent to suppress canonical BMAL1 target genes. GO and GSEA analysis of RNA-seq data shows that SHP1705 also significantly changed most core regulators of circadian rhythms as well as other E-box-binding proteins. However, SHP1705 has IC50 values above 10μM in most tested cells, creating a challenge for efficacy in a clinical setting. Because BMAL1 requires the proteasome to sustain the turnover of a transcription burst, we hypothesized

proteasome inhibitors (PI) MG132 and carfilzomib may synergize with SHP1705. Consequently, we found strong synergy with both PIs. Analysis of TF-target genes in combination-treated cells reveals significant changes in expression profiles, suggesting that these genes are regulated by E-box, and other related/alternative promoter elements: CCAAT-box, CG-rich motifs, and ATGGC. Co-enrichment of these elements revealed the components of E-box containing promoters and showed potential properties of E-box-regulated gene expression. Co-existence of these motifs in the same proximal promoter also potentially allows RNAPII multiple choices of alternative promoters and could promote expression of variants in cancer cells. Our results support the necessity of inhibiting the whole promoter and provide an example of how to approach designer pharmacological strategies to achieve this purpose.

#3716

RNA N^6-methyladenosine binding protein, YTHDF1 regulates DNA repair and cancer immunity in protein synthesis levels

Dongjun Jang, Hae Rim Jung, Jaeik Oh, Sung-Yup Cho. *Seoul National University, Seoul, Korea, Republic of*

N^6-methyladenosine RNA methylation is one of the most abundant post transcriptional modifications in eukaryotic messenger RNAs and plays crucial roles in cancer development and progression. YTHDF1 is an m6A reader protein and has been reported to increase the translation of mRNAs in cooperation with YTHDF3. In gastric cancer, YTHDF1 was reported to be overexpressed in cancer tissues, but detailed effects of YTHDF1 in cancer immunity have not been fully elucidated. In RNA sequencing data from a TGCA gastric cancer cohort, the expression of YTHDF1 was inversely correlated with the cytotoxic T cell markers, such as CD8A, GZMA, and GZMB. To investigate the effect of YTHDF1 overexpression on gene expression regulation in protein levels, we performed the proteomic analysis for newly synthesized proteins using non-canonical amino acid azidohomoalanine and click chemistry tagging reaction in the presence of interferon-γ (IFN-γ). Protein synthesis of genes in ‘DNA damage response’ and ‘DNA repair’ gene sets increased in YTHDF1-overexpressed samples. On the contrary, protein synthesis of genes in ‘Allograph rejection’, ‘NK cell mediated cytotoxicity’, and ‘NF-κB signaling’ gene sets decreased in

YTHDF1-overexpressed samples. Especially, YTHDF1 reduced basal expression of DNA damage marker, γH2AX, suggesting that DNA damage repair was enhanced by YTHDF1 overexpression. Our study suggests that YTHDF1 plays pervasive roles in DNA repair and cancer immunity by regulating gene expression in protein levels.

#3717

Defining the mechanism of ER receptor transcription complex activity and its effect on epigenetic modulations using super resolution microscopy

Tara Akhshi, Myles Brown. *Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

Estrogen Receptor α (ERα) is expressed in ER^+ breast cancers, one of the leading causes of death among women. Despite effectiveness of endocrine therapy, a significant number of patients experience resistance to these treatments. One of the major hurdles is lack of comprehensive information about ERα transcriptional complex activity. While biochemical assays have improved our knowledge significantly, it is critical to imply techniques that allow direct visualization of ERα activity and gain spatiotemporal information. We used super resolution microscopy to examine the mechanism of ERα transcriptional activity. We showed that ERα interactions with its co-activators (P300, SRC-3), is influenced upon administration of Tamoxifen and Fulvestrant, an effect that is lost in cells carrying multination in ERα ligand binding site. Additionally mutant cells are no longer able to recruit ERα co-inhibitor (NCORI). Using STORM microscopy, we showed estrogen treatment caused an “open” chromatin (H3K27ac) structure which may represent active areas of gene expression, while Tamoxifen and Fulvestrant treatments caused chromatin to form “closed” structures which likely represent close and inactive phase of chromatin.

#3718

FOXM1 switches protein conformations upon C-terminal domain-mediated-autoregulation dictating its transcriptional activity in cancer cell proliferation

Chia-Chan Hsu, Xiang Yao, I-Ching Wang. *Institute of Biotechnology, National Tsing Hua University, Hsinchu, Taiwan*

Transcription factor Forkhead box M1 (FOXM1) participates in tumor initiation, tumor development and tumor metastasis through regulating transcriptional network of its target genes. Activated FOXM1 promotes G1/S and G2/M transition via manipulating Cdc25B, Cyclin B1, TOPOIIa, Aurora and Polo-like kinases, as well as cancer cell survival and invasion through upregulating Survivin, SNAIL and MMP-9. The depletion of Foxm1 repressed the oncogenic Kras (G12D) driven mice lung cancer, Rb/Trp53/Myc triple knockout mice small cell lung cancer and carcinogen induced mice hepatocellular carcinoma. Given the roles of FOXM1 in tumorigenesis and its relevance to clinical outcomes, deciphering the mechanism underlying the regulation of FOXM1 activity might provide new therapeutic target for cancer study. It is known that FOXM1 activity drops when the C-terminal transcription activation domain (TAD) is blocked by the N-terminal repression domain (NRD), which is called autorepression. Furthermore, the NRD-deleted FOXM1 displays extraordinarily high transactivity. Compared to the NRD, the TAD is relatively longer and consists of around 420 amino acid with most of them being intrinsically disordered region (IDR). Previous studies showed that the NRD binds to a relatively ordered small region on the TAD. However, it is poorly understood about whether the IDR of TAD partakes in the FOXM1 self-regulated activity and how FOXM1 protein structure switches in living cells. Our co-immunoprecipitation (co-IP) and dual-luciferase reporter assay (DLR) suggested that FOXM1 TAD self-interacts via its IDR and the C-terminal αβα motif, which promotes FOXM1 transactivation. The IDR-driven FOXM1 autoactivation was mimicked by the chemically-induced dimerization system (CID) that forces IDR-αβα proximity intermolecularly. Using fluorescence resonance energy transfer (FRET) microscopy, we observed that the IDR-αβα interaction was elevated when cell cycle progression from G1/S to G2/M in living cells. The IDR-αβα interaction and FOXM1 activity were both suppressed by PLK1 inhibition. Furthermore, the characteristics of IDR-αβα interaction did not resemble NRD-TAD interaction as revealed by FRET data where we showed the NRD-TAD interaction dropped after G1/S. The NRD-TAD interaction underlying FOXM1 autorepression was recapitulated by CID. Through co-

IP and yeast-two hybrid assays (Y2H), we further identified the minimal yet biological functional unit ββαβ on NRD that suppressed FOXM1 activity and lung adenocarcinoma A549 cells *in vitro* and *in vivo*. Collectively, our work suggested that FOXM1 might be switched from the NRD-TAD mediated autorepression toward the IDR-αβα mediated activation by Plk1 during S-G2 phase. And ββαβ peptide treatment might be applied to lung cancer as a potential therapeutic strategy.

#3719

Targeting the eIF6 and 60S ribosomal subunit interaction interface in cancers

Kavya Meena Harish, Aparna Biswas, Poonam Roshan, Sofia Origanti.
Saint Louis University, St. Louis, MO

Translational control is integral to cancer initiation and progression. A subset of translation initiation factors are deregulated in cancers to facilitate their rampant growth and proliferation. Eukaryotic translation initiation factor 6 (eIF6) is one such factor that is over expressed in many cancers including lung, colon, ovarian and breast cancers, and deregulation of eIF6 is correlated with a poor cancer prognosis. Association of eIF6 with 60S is critical for 60S assembly. However, eIF6 must be released from 60S prior to translation to permit inter subunit interactions between 60S and 40S and to facilitate the formation of translationally proficient 80S complex. Release of eIF6 is deregulated in the ribosomopathy- Shwachman Diamond Syndrome that is predisposed to leukemias. Also, loss of eIF6 markedly delays tumorigenesis without affecting normal growth, which presents eIF6 as a viable therapeutic target. A potential therapeutic strategy is to target the eIF6 and 60S ribosomal interaction interface. Through extensive biophysical analyses, we had identified residues that are critical for the interaction between eIF6 and 60S ribosomal subunit. We show that targeting these key residues in the eIF6-60S interaction interface markedly delays colonic cancer growth and inhibits protein synthesis. Interestingly, targeting eIF6 leads to an upregulation of p53 independent of the DNA damage response, suggesting that ribosomal stress contributes to the stabilization of p53. Future studies will determine the mRNA targets that are translationally deregulated by inactivation of eIF6. We will also

determine the effect of targeting eIF6 function in inhibiting tumor growth and progression *in vivo*.

Cysteine palmitoylation of astrocyte elevated gene-1/Metadherin (AEG-1/MTDH) regulates its biological and immunological activity

Maria Del Carmen Camarena[1], Garrison Komaniecki[2], Debashri Manna[1], Rachel Mendoza[1], Mark A. Subler[1], Jolene J. Windle[1], Mikhail G. Dozmorov[1], Hening Lin[1], Devanand Sarkar[1]. *[1]Virginia Commonwealth University - VCU, Richmond, VA,[2]Cornell University, Ithaca, NY*

Non-alcoholic steatohepatitis (NASH) is a major risk factor for hepatocellular carcinoma (HCC). Astrocyte elevated gene-1/Metadherin (AEG-1/MTDH) augments steatosis, inflammation, and tumorigenesis, thereby promoting the whole spectrum of this disease process. Targeting AEG-1 is a potential interventional strategy for NASH and HCC. Thus, proper understanding of the regulation of this molecule is essential. We found that AEG-1 is palmitoylated at residue Cysteine75 (Cys75). Mutation of Cys75 to Serine (Ser) completely abolished AEG-1 palmitoylation.Systematic knockdown studies identified zinc finger DHHC-type palmitoyltransferase 6 (ZDHHC6) as the palmitoyltransferase catalyzing the process. To obtain insight into how palmitoylation regulates AEG-1 function, we generated a knock-in mouse by CRISPR/Cas9 in which Cys75 of AEG-1 was mutated to Ser (AEG-1-C75S). No developmental or anatomical abnormality was observed between AEG-1-wild type (AEG-1-WT) and AEG-1-C75S littermates. However, global gene expression analysis by RNA-sequencing unraveled that signaling pathways and upstream regulators, which contribute to cell proliferation, motility, inflammation,angiogenesis, and lipid accumulation, are activated in AEG-1-C75S hepatocytes compared toAEG-1-WT. Feeding these mice with high fat/high sugar diet for 20 weeks showed accumulation of T-regulatory cells and exhausted CD8 T-cells in the livers of AEG-1-C75S mice vs AEG-1-WT, and only in females, suggesting that inhibition of AEG-1 palmitoylation creates an immunosuppressive milieu favoring tumorigenesis. Collectively, these findings suggest that AEG-1-C75S functions as dominant positive, and palmitoylation restricts oncogenic and NASH-promoting functions of AEG-1. Studies are ongoing to unravel the

mechanism by which palmitoylation restricts AEG-1 function, and to understand the sex-specific immune-modulatory role of AEG-1 palmitoylation in hepatocarcinogenesis.

The C1 domain of capicua has functional importance in human CIC-DUX4

Cuyler Luck[1], Kyle A. Jacobs[2], Ross A. Okimoto[1]. *[1]Medicine, UCSF - University of California San Francisco, San Francisco, CA,[2]Cell and Tissue Biology, UCSF - University of California San Francisco, San Francisco, CA*

Genomic rearrangements between the HMG-box family transcriptional repressor capicua (CIC) and multiple partner genes result in fusion oncoproteins that activate transcription to drive sarcoma growth and progression. In the case of CIC-DUX4, the most common CIC-rearranged fusion oncoprotein, the fusion often retains over 90% of the wild type CIC protein structure including the HMG box and C-terminal C1 domain. Structure-function studies in *Drosophila* have suggested that the C1 domain of CIC, a non-HMG box DNA binding domain, is important for the transactivating capacity of a synthetic fly-human CIC-DUX4. Consistent with these findings, we performed a retrospective analysis of over 70 breakpoints described from CIC-DUX4 human derived tumors, which revealed that the C1 domain is structurally conserved within the context of the CIC-DUX4 fusion. To further understand the functional role of the C1 domain in human CIC-DUX4 we generated human CIC-DUX4 C1 domain and HMG-box deletion (alone or in combination) mutant constructs and performed a series of studies to test the functional impact on CIC-DUX4 protein levels, subcellular localization, and transcriptional activity. Through these analyses we have found that deletion of the C1 domain does not impact CIC-DUX4 oncoprotein expression or localization but does dramatically reduce target gene expression. In ongoing *in vivo* studies, we aim to evaluate the significance of the C1 domain in inducing CIC-DUX4 driven tumorigenesis. Collectively, our findings validate the functional importance of the C1 domain in human CIC-DUX4 and to our knowledge provide the first harmonized analysis of breakpoint locations in CIC-rearranged sarcoma.

Exploring the role of eIF4E in cancer cells with targeted protein degradation

Swee Y. Sharp[1], Marianna Martella[1], Christopher I. Milton[1], George Ward[2], Caroline Richardson[2], Andrew Woodhead[2], Paul A. Clarke[1]. *[1]Cancer Research UK Cancer Therapeutics Unit, The Institute of Cancer Research, London, United Kingdom,[2]Astex Pharmaceuticals, Cambridge, United Kingdom*

Initiation of translation is considered the main rate-limiting step of protein synthesis and requires the recognition of 5' m^7G-cap on mature mRNAs and the formation of eukaryotic translation initiation factor 4F (eIF4F) multi-protein mRNA cap-binding complex. Formation of this complex requires the interaction of eIF4E and the scaffold protein eIF4G, and RNA helicase eIF4A. This eIF4F complex along with eIF3 mediate the recruitment of the 40S ribosomal particle to the 5′ cap of mRNA. Activation of eIF4E is a regulatory hub of many major oncogenic pathways, thus, targeting eIF4E has emerged as a potential therapeutic strategy in cancer. Here we have used a targeted protein degradation approach coupled with genetic rescue to explore the molecular and cellular dependency of cancer cells on eIF4E. Stable H1299 human NSCLC clones expressing $FKBP12^{F36V}$-tagged eIF4E but lacking endogenous eIF4E were established. Treatment of multiple N- or C-tagged-eIF4E clones with dTAGv-1, an $FKBP12^{F36V}$ selective heterobifunctional molecule that recruits VHL, induced rapid degradation of eIF4E to undetectable levels by 6hr exposure. This also resulted in reduced expression of MCL1, a previously reported biomarker of eIF4E activity. Longer exposures to dTAGv-1 resulted in a cytostasis that was not associated with cell death. A diastereomer negative control of dTAGv-1 that cannot recruit VHL did not elicit loss of eIF4E or the downstream events associated with its loss. Global analysis of protein synthesis initiation by RIBOseq and proteome profiling following dTAGv-1 treatment out to 32hr exposure demonstrated surprisingly few alterations in protein expression despite the significant effect on cancer cell growth. We also expressed wild-type or eIF4E mutants predicted to disrupt key functions and determined their ability to rescue molecular or cellular phenotype associate with eIF4E-loss following dTAGv-1 treatment.

Expression of wild-type eIF4E completely rescued cell growth and MCL1 expression. A W56A mutant predicted to disrupt mRNA-cap binding was unable to rescue eIF4E loss. In contrast, expression of W73F or S290A mutants (predicted to disrupt eIF4G binding or exhibit reduced eIF4E activity, respectively) were able to rescue the loss of eIF4E.
In summary, our rescue experiments show that mRNA-cap binding by eIF4E is required and that eIF4E:eIF4G interaction in cells may be more complex than predicted. This may also explain the challenges associated with developing selective and cellularly potent inhibitors of the eIF4E:eIF4G interaction and that targeting mRNA-cap binding may be a more effective strategy. We predicted that removing eIF4E would impact on the global synthesis of many proteins. However, our data demonstrate that targeting eIF4E leads to limited effects on protein synthesis that remain sufficient to inhibit cancer cell growth. Further experiments are underway to understand which proteins drive this dependency on eIF4E.

#3723

Identification and functional characterization of long noncoding RNAs that regulate TGF-β-Smad pathway as Smad co-factors

Masatoshi Kitagawa, Kosuke Ota, Tatsuya Ohhata, Satoshi Sakai.
Hamamatsu University School of Medicine, Hamamatsu, Japan

TGF-β-Smad pathway participates in various biological processes such as development, differentiation, growth regulation, and cancer progression including epithelial-mesenchymal transition (EMT). Long non-coding RNAs (lncRNAs) also involved in carcinogenesis and cancer malignancies. To identify lncRNAs regulating TGF-β-Smad pathway, we comprehensively identified lncRNAs induced by TGF-β and found and reported a lncRNA *ELIT-1* (EMT-associated lncRNA induced by TGF-β-1) which was induced by TGF-β and promoted EMT by facilitating TGF-β-Smad signaling. *ELIT-1* bound to Smad and participated in expression of TGF-β target genes including *Snail.* Prognosis of lung adenocarcinoma and gastric cancer patients with high expression of *ELIT-1* was poor suggesting that *ELIT-1* may be useful as a novel prognostic and therapeutic target. Recently, we found that *lincNMR* (long intergenic noncoding RNA-nucleotide metabolism regulation) was induced via TGF-β-Smad pathway in various cell lines. Moreover, RNA-seq analysis using *lincNMRs*-depleted

cells indicated that *lincNMRs* was involved in expression of *APOBEC3B*, a cytidine deaminase, promoting C to U mutation and highly expressed in various human cancers. Although, regulatory mechanisms of *APOBEC3B* expression have not been fully elucidated, we proved that *lincNMRs* bound to Smad and promoted the activity of *APOBEC3B* promoter. These data suggest that *lincNMRs* participate in APOBEC3B expression by collaborating with TGF-β-Smad pathway. Additionally, high expression of *lincNMRs* was positively correlated with high expression of APOBEC3B in various cancer cell lines. The high expression of APOBEC3B as well as *lincNMR* was significantly associated with their poor prognosis in liver and lung cancer patients, suggesting that *lincNMR* may contribute to tumor malignancy by enhanced expression of APOBEC3B via TGF-β-Smad pathway.

#3724

RAI2 controls polycomb-mediated repression of *CDKN1A* by its interaction with CtBP1

Sarah Greimeier[1], Bettina Steinbach[1], Simon Sander[1], Lina Merkens[1], Nishit Goradia[2], Matthias Wilmanns[2], Eric Metzger[3], Klaus Pantel[1], Stefan Werner[1]. *[1]Institute of Tumor Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]European Molecular Biology Laboratory, Hamburg, Germany,[3]Department of Urology and Center for Clinical Research, University of Freiburg Medical Center, Freiburg, Germany*

RAI2 has initially been identified as a metastasis-associated gene in breast cancer. Recently, we found that increased RAI2 protein in primary tumors predicts early biochemical relapse of prostate cancer patients. On the molecular level, RAI2 interacts with CtBP1 as transcriptional co-repressors via a non-consensus tandem ALDLS-motif in hormone-dependent cancer cells. In this study, we aim to investigate the cell-biological relevance of this molecular interaction in prostate cancer cells using the *CDKN1A* gene as an example of a transcriptional target of CtBP-mediated gene regulation. To analyze a molecular relation between the RAI2/CtBP1 interaction and repressor of the *CDKN1A* gene, we first applied a transactivation assay in 293T cells, transiently transfected with CtBP1 and different RAI2 protein variants. Next, we depleted the RAI2 protein in VCaP prostate cancer cells. We used this cell line model to analyze gene expression and protein

concertation of RAI2, CtBPs and p21 under different conditions. We studied the subcellular localization and chromatin binding of the proteins of interest by confocal laser-scanning microscopy and ChIP analysis.
The gene reporter assay revealed that combined overexpression of RAI2 and CtBP1 reliefs the repression of the proximal *CDKN1A*-promotor and that RAI2 with an intact ALDLS tandem motif is required for this process. RAI2 depletion in VCaP cells resulted in a significant reduction of both CtBP1 and CtBP2 and almost complete abolishment of p21 protein levels, which is accompanied by reduced interaction of RAI2 with CtBP1 in nuclei. In parental VCaP cells, genotoxic stress significantly induced *CDKNA1* gene expression and p21 protein concentration. In contrast, in RAI2-depleted VCaP cells we did not observe any of these effects, demonstrating the requirement of RAI2 to cause the relief of *CDKNA1* repression. RAI2 together with CtBP1 appeared as definite foci in the nuclei of VCaP cells that are co-localized with key factors of polycomb 1 and 2. The ChIP analysis revealed that RAI2-depletion significantly induced binding of CtBPs to the *CDKN1A* promoter. In contrast, the binding of the polycomb protein LCoR to chromatin is significantly reduced in RAI2-depleted cells. Irrespective of the RAI2 status, the EZH2 binding to the chromatin remained unaltered, whereas a significant increase in H3K27me3 in RAI2-depleted cells was observed.
In summary, we found that interruption of the interaction of RAI2 with CtBP1 is leading to increased chromatin binding of CtBP1 and trimethylation of H3K27 of the *CDKN1A* promotor, which is associated with repression of *CDKN1A* gene expression. We conclude that the molecular interaction of RAI2 with CtBP1 is a new molecular mechanism of corepression by modulating the histone-modifications of the target gene.

ABI1 regulates STAT3 transcription through a DNA binding activity

Xiang Li[1], Neeru Arya[2], Baylee A. Porter[1], Allysa P. Kemraj[3], Xuesen Dong[4], Dominique Frueh[2], Alaji Bah[3], Leszek Kotula[1]. *[1]Department of Urology and Department of Biochemistry and Molecular Biology, SUNY Upstate Medical University, Syracuse, NY,[2]Department of Biophysics and Biophysical Chemistry, John Hopkins University, School of Medicine, Baltimore, MD,[3]Department of Biochemistry and Molecular Biology, SUNY*

Upstate Medical University, Syracuse, NY,[4]Vancouver Prostate Centre, Vancouver, BC, Canada

Prostate cancer (PCa) is characterized by the complexity of oncogenic signaling and heterogeneity of transcriptional landscapes. Adaptor protein ABI1 is a tumor suppressor in PCa, as evidenced by its loss or downregulation in high-grade and metastatic tumors. STAT3 activation is a hallmark of high-risk prostate tumors. ABI1 loss is associated with STAT3 activation leading to transcriptional reprogramming and epithelial-mesenchymal-transition (EMT) of prostate cancer cells (Nath, Li et al. *Cell Commun Signal.* 2019). EMT changes involve several homeobox transcription factors. The fact that ABI1 contains a homeobox homology region (HHR) suggests the possibility that it plays a role in EMT by directly regulating transcriptional activity by DNA binding. To examine this hypothesis, we set out to analyze ABI1-DNA binding. Structural NMR studies and in-vitro protein-DNA binding assays confirmed ABI1 binding to DNA regulated by alternative spliced ABI1 Exon 4 region located on the C-terminus of ABI1 HHR. RNA-sequencing data and PCa cell lines qPCR assays reveal the alternative ABI1 Exon 4 spliced-in is enriched in high Gleason-scored PCa samples. ABI1 and STAT3 co-regulate their nuclear vs. cytoplasm localization, and the subsequent functional studies using PCa lines expressing wild type or HHR Exon 4 deletion mutant of ABI1 demonstrated that HHR regulates the STAT3 DNA binding patterns, STAT3 mediated chromatin structure programming as well as its transcription activities. We propose that ABI1 is a critical regulator of STAT3 activity during prostate cancer progression.

Histone acetylation axis in the control of RNA Pol2 clusters

Berkley E. Gryder, Diana Chin, Hyunmin Kim, Issra Osman. *Case Western Reserve University School of Medicine, Cleveland, OH*

Core regulatory transcription factors (CR TFs) orchestrate the placement of super enhancers (SEs) to activate transcription of cell-identity specifying gene networks and are critical in promoting cancer. We defined the core regulatory circuitry of fusion positive rhabdomyosarcoma (FP-RMS, a cancer of childhood) in primary tumors and cell lines, which includes

PAX3-FOXO1 (P3F), MYOD1, SOX8, MYCN and others. To find chemical probes able to selectively inhibit CR TF transcription, we screened the Structural Genomics Consortium epigenetic probe set by RNA-seq. We found that chemical probes along the acetylation-axis, and not the methylation-axis, are able to cause selective disruption of CR TF transcription. Inhibitors of HDACs (acetylation erasers), BRD4 (acetylation readers) and CBP/p300 (acetylation writers) were all able to selectively halt CR TF transcription. For HDACs, this raised a conundrum: why would too much histone acetylation, an active chromatin mark, stop transcription at CR TFs? ChIP-seq showed that CR TFs build SEs that have the largest quantities of histone acetylation and the enzymes that write acetylation (i.e., p300), yet paradoxically also harbor the highest amounts of the opposing histone deacetylases (HDACs). To investigate the architectural effects of disabling HDACs and causing hyper acetylation, we developed Absolute Quantification of Architecture (AQuA) HiChIP, revealing erosion of native SE contacts at CR TFs, and extensive aberrant contacts. This did not cause an elongation defect, but rather removed RNA Pol2 from core regulatory genetic elements and eliminated RNA-Pol2 phase condensates in 20 minutes. We further dissected the contribution of HDAC isoforms using a set of HDAC selective inhibitors, finding HDAC1/2/3 are co-essential to CR transcription. Using HAT inhibitors/degraders, we discovered a profound dependence on CBP/p300 for clustering of Pol2 loops that connect P3F to its target genes. In the absence of CBP/p300, Pol2 long range enhancer loops collapse, Pol2 accumulates in CpG islands and fails to exit the gene body. These results reveal a potential novel axis for therapeutic interference with P3F in FP-RMS and clarify the molecular relationship of P3F and CBP/p300 in sustaining active Pol2 clusters essential for oncogenic transcription. Overall, our data reveals a SE-specific need for balancing histone acetylation states to maintain SE architecture, Pol2 clustering in 3D, and CR TF transcription.

#3727

Development of a new All-In-One inducible lentiviral shRNA/gRNA Vector

Lipeng Wu, Hua Su, Justin Fellows, Mao Fu, Julian Heller, Brian Park, Dezhong Yin. *OriGene Technologies, Inc., Rockville, MD*

Tet-On is a powerful inducible system and a classical tool to regulate gene expression in mammalian cells. It has also been applied to regulate Pol III-driven transcription, such as shRNA or gRNA driven by a U6 or H1 promoter. However, all of the current versions of Tet-On shRNA vectors are based on H1-2O2 or U6-2O2 promoters, which are only compatible with first-generation tetracycline repressor TetR. In addition, these promoters have the problem of driving downstream transcription without the binding of the Tet regulatory protein. Here, we developed a new system that is built upon tetracycline activator protein, Tet-On 3G, combined with a new structure of Tet responsive promoter H1-4O4, which tightly regulates the downstream transcription of gRNA or shRNA. The responsiveness of our system to Doxycycline regulation is dramatically improved compared with the current versions. The new Tet-On system is further optimized into a compact structure to be compatible with the lentivirus package (All-In-One Lenti-Tet-On system), which still keeps the leaky expression at an undetectable level. Combined with all these features, the new generation of the Tet-On system offers broad applications in gene knocking down and genomic editing.

#3728

A novel, simplified, streamlined workflow for high-throughput whole transcriptome RNA-seq library preparation for a variety of sample types

Chelsea Pinegar, Dora Posfai, Gautam Naishadham, Bradley W. Langhorst, Keerthana Krishnan. *NEBNext, New England Biolabs, Inc., Ipswich, MA*

RNA sequencing (RNA-seq) has become an invaluable tool in the study of biology, but often requires multiple days to process samples from total RNA to final libraries that can be loaded on to a sequencer. Researchers use RNA-seq to gain insight into whole tumor gene expression, and in combination with other omics data make treatment decisions. In cancer research, time taken to yield sequencing results can be critical for clinical samples. Within oncology research, libraries are often prepared from RNA sourced from formalin-fixed, paraffin-embedded (FFPE) tissues which can be particularly challenging and is not compatible with all library preparation methods.

Here, we present a new protocol that allows users to easily generate robust RNA-seq libraries from a variety of sample types in a single day from 25-250 ng of total RNA. Compatible with poly(A) enrichment or ribosomal RNA depletion, this new workflow has reduced preparation time by about 40% compared to current library prep kits without sacrificing quality of libraries or any sequencing metrics, including 5'-3' coverage, GC bias. Our new method provides equivalent transcript expression in FFPE samples when compared with existing protocols. In addition to master mixed components and reduced incubation times, the reduction in bead cleanup steps significantly reduces hands-on time for library preparation, simplifying and streamlining the process.
This new library preparation method is also ideal for processing samples of various inputs with a single condition at every step throughout the protocol, without modifying cycling conditions or dilutions based on input amount. This workflow provides a great advantage in efficiently generating RNA-seq libraries while simultaneously maintaining high quality sequencing results and compatibility with both high- and low-quality RNA such as FFPE.

Targeting the writers of enhancers as a new therapeutic strategy in pediatric AML

Joanna S. Yi[1], Kevin Duong[1], Abiola Obawemimo[1], Tingjian Wang[2], Faith Joseph[3], Nicolas L. Young[3], Stephen Mack[4], Jun Qi[2], Adam Durbin[5].
[1]Pediatrics, Baylor College of Medicine/Texas Children's Hospital, Houston, TX,[2]Cancer Biology, Dana-Farber Cancer Institute, Boston, MA,[3]Biochemistry, Baylor College of Medicine, Houston, TX,[4]Neurobiology, St. Jude Children's Research Hospital, Memphis, TN,[5]Oncology, St. Jude Children's Research Hospital, Memphis, TN

Introduction: Children with acute myeloid leukemia (AML) urgently need new targeted therapeutics to improve their outcomes. Super-enhancers (SEs) are extensive chromatin regions denoted by abundant histone 3 lysine 27 acetylation (H3K27ac), which are associated with high-level expression of cell-identity genes, including oncogenes. SE-regulated genes have unique sensitivity to transcriptional inhibitors, allowing for cancer type-

specific approaches. Thus, targeting CBP/EP300 (the highly homologous enzymes responsible for catalyzing H3K27 acetylation) may be a specific strategy to target lineage-specifying oncogenes in AML. However, to date, the high degree of homology between EP300 and CBP has limited chemical strategies to tissue-specific disruption. Gene editing studies have shown that CBP, and not EP300, is essential for maintaining normal hematopoiesis, while EP300 regulates AML growth and myeloid differentiation. We hypothesized that selectively targeting EP300 would suppress AML growth while sparing effects on normal myeloid differentiation.
Methods: We studied publicly available expression and CRISPR screening databases for EP300 and CBP data in AML. We treated pediatric AML (pAML) cell lines and patient samples with the EP300/CBP HAT inhibitor A485 and the EP300-selective PROTAC [PROteolysis TArgeting Chimera]) JQAD1, and measured effects on cell growth by CellTiter-Glo, and apoptosis, differentiation, and cell cycle changes by flow cytometry. We treated pAML cells with compounds for 2 hours and performed mass spectrometry on HPLC-purified H3 proteins.
Results: pAML patient samples have higher EP300 expression than normal bone marrow samples in the TARGET dataset, and AML cell lines have enhanced dependency on EP300 over CBP by CRISPR knockout analysis. Treatment of pAML cell lines with A485 slowed proliferation and induced apoptosis, cell cycle arrest, and differentiation. In contrast, equimolar concentrations of JQAD1 had more marked antileukemic effects in both pAML cell lines and primary samples. Immunoblotting analysis demonstrated reduced H3K27ac in pAML cells treated with both JQAD1 and A485, but EP300 degradation only with treatment with JQAD1, consistent with findings in other cancer models. Studies on the effects of EP300 degradation versus combined EP300/CBP inhibition on global and SE-regulated gene expression are ongoing. Middle-down mass spectrometry recapitulates decreased H3K27 acetylation with both agents. JQAD1 combined with the BCL2 inhibitor Venetoclax has a synergistic effect on cell line and patient sample growth, with coordinate induction of apoptosis and differentiation. A four-arm study of this combination in a pAML patient-derived xenograft model is ongoing.
Conclusion: Selective degradation of EP300 using the PROTAC JQAD1 is a new strategy that demonstrates preclinical efficacy in pAML as a single agent and in combination with BCL2 inhibitors.

#3730

A new type of transcriptional reprogramming by an IRF4 mutation in lymphoma

Pierre Cauchy. *German Cancer Research Center, Freiburg im Breisgau, Germany*

Disease-causing mutations in genes encoding transcription factors (TFs) are a recurrent finding in hematopoietic malignancies and might involve key regulators of lineage adherence and cellular differentiation1-3. Such mutations can affect TF-interactions with their cognate DNA-binding motifs4,5. Whether and how TF-mutations impact upon the nature of binding to TF composite elements (CE) and influence their interaction with other TFs is unclear. Here, we report a new mechanism of TF alteration in human lymphomas with perturbed B cell identity. It is caused by a recurrent somatic missense mutation c.295T>C (p.Cys99Arg; p.C99R) targeting the center of the DNA-binding domain of Interferon Regulatory Factor 4 (IRF4), a key TF in immune cell-differentiation and -activation6,7. IRF4-C99R fundamentally alters IRF4 DNA-binding, with loss-of-binding to canonical IRF motifs and neomorphic gain-of-binding to canonical and non-canonical IRF composite elements (CEs). Furthermore, IRF4-C99R thoroughly modifies IRF4 function, by blocking IRF4-dependent plasma cell induction, and up-regulating disease-specific genes in a non-canonical Activator Protein-1 (AP-1)-IRF-CE (AICE)-dependent manner. Our data explain how a single arginine mutation creates a complex switch of TF specificity and gene regulation. These data open the possibility of designing specific inhibitors to block the neomorphic, disease-causing DNA-binding activities of a mutant transcription factor.

The polyamine-hypusine circuit controls an oncogenic translational program essential for malignant transformation in MYC-driven lymphoma

Shima Nakanishi[1], Jiannong Li[2], Anders E. Berglund[2], Youngchul Kim[2], Yonghong Zhang[2], Ling Zhang[3], Chunying Yang[1], Raghavendra G. Mirmira[4], John L. Cleveland[1]. *[1]Tumor Biology, Moffitt Cancer Center, Tampa, FL,[2]Bioinformatics and Biostatistics, Moffitt Cancer Center, Tampa,*

FL,[3]Pathology and Laboratory Medicine, Moffitt Cancer Center, Tampa, FL,[4]Department of Medicine, The University of Chicago, Chicago, IL

The *MYC* oncoprotein is activated in a broad spectrum of human malignancies and transcriptionally reprograms the genome to drive cancer cell growth. Given these functions, it is unclear if targeting a single effector of MYC will have therapeutic benefit. MYC activates the polyamine-hypusine circuit, which post-translationally modifies a single lysine residue (Lys-50) of eukaryotic translation initiation factor eIF5A in a process coined hypusination via two enzymes,deoxyhypusine synthase (DHPS) and deoxyhypusine hydroxylase (DOHH). The roles of this circuit in cancer are unclear. Here we report essential intrinsic roles for hypusinated eIF5A in the development and maintenance of MYC-driven lymphoma, where loss of eIF5A hypusination completely abolishes malignant transformation of MYC-overexpressing B cells in transgenic mice predestined to develop lymphoma. Mechanistically, integrating RNA-seq, Ribo-seq and proteomic analyses revealed that efficient translation of select targets is dependent upon eIF5A hypusination, including regulators of G1-to-S phase cell cycle progression and DNA replication. Thus, this circuit controls MYC's proliferative response at several levels and is activated in many tumor types. These findings suggest the hypusine circuit as a therapeutic target for a broad spectrum of malignancies.

#3733

Disconnect between APOBEC3 expressions and mutations across cancers

Azad Khosh[1], Hamid Hamidi[2], Hamzeh Rahimi[3], Diako Ebrahimi[3].
[1]Zeelamo Academy, San Diego, CA,[2]University of Calgari, Calgari, AB, Canada,[3]Texas Biomedical Research Institute, San Antonio, TX

DNA of many tumors is barraged by C-to-T/G mutations within TCW (W:T,A). These mutations are attributed to the aberrant expression and activity of APOBEC3 enzymes. They have been shown to account for many driver mutations in genes such as PIK3CA, ERBB2, and PPP2R1A, however their precise source and also their roles in tumor development, evolution, and patient survival are debated. Currently, quantification of APOBEC3 expression changes in tumor cells is confounded by the

ubiquitous expression of these enzymes in infiltrating immune cells. In this study, we used quantitative biology approaches to separate the expression profiles of APOBEC3 enzymes in tumor and tumor microenvironment cells and determine their associations with tumor mutational signatures. For this purpose, we analyzed diverse datasets including TCGA tumor/matched normal RNAseqs, tumor somatic mutations, cell line RNAseqs and mutations, estimates of tumor purities and immune cell compositions, and expression of purified cell populations to precisely determine how APOBEC3 enzymes are dysregulated across tumors and whether their dysregulations are proportional to tumor mutational signatures. Unexpectedly, we found that dysregulation of APOBEC3 enzymes is independent of tumor C-to-T/G mutational burden. Importantly, our data suggest that this disconnect is likely not due to the episodic bursts of APOBEC3-induced mutations in cancer.

#3734

Neuroendocrine differentiation (ND) in sensitivity of neuroendocrine tumor (NET) cells to ONC201/TIC10 cancer therapeutic

Elizabeth C. Ding, Wafik S. El-Deiry. *Pathology and Laboratory Medicine, Brown University, Providence, RI*

Neuroendocrine tumors (NETs) harbor neuroendocrine differentiation (ND) with specific markers including protein gene product 9.5 (PGP9.5) and Chromogranin A (CgA). In prostate cancers (PC), ND is induced by BRN2/SOX2 transcription factors. NET-like cells with low or absent androgen receptor (AR) signaling cause hormone therapy resistance and poor prognosis in PC. Small cell lung carcinoma (SCLC), a high-grade NET, presents with metastasis early and has poor survival. ONC201/TIC10 is a small molecule inducer of TRAIL signaling in clinical trials. ONC201 antagonizes dopamine D2 or D3 receptors (DRD2/DRD3) and is an agonist of mitochondrial caseinolytic protease P (ClpP) resulting in activation of DR5/TRAIL-dependent apoptosis involving the integrated stress response (ISR). ONC201 is active in various malignancies including H3K27M-mutated glioma and NETs expressing high levels of DRD2. We hypothesized that altered BRN2/SOX2 may impact NET apoptosis by ONC201 through the ISR and TRAIL/DR5. We analyzed the expression of neuroendocrine markers PGP9.5, CgA, SOX2, and BRN2, as well as

markers of TRAIL signaling pathway markers ATF4, DR5, ClpP, ClpX, and DRD2/DRD3 in PC and SCLC cell lines (N=6) ± treatment with ONC201. Specifically, we compared pre-treatment protein expression levels with the IC50. Our results reveal that DU145 (IC50=3.11μM), PC3 (IC50=3.02μM), and LNCaP (IC50=1.33μM) are ONC201 sensitive. H1417 SCLC expresses CgA, unlike PC3 and DU145. PGP9.5 is expressed in these lines. PGP9.5 is expressed in PC3, DU145, H1417, and H1048 but not in LNCaP and 22RV1. BRN2 is expressed in PC3, H1417, and H1048 but not DU145, LNCaP, or 22RV1. ClpX is expressed in all 6 lines but at lower levels in SCLC. ClpP is expressed in the 6 lines. DR5 is expressed at higher levels in PC3, DU145, LNCaP, and 22RV1 PC versus H1417 and H1048 SCLC. SOX2 is expressed at high levels in H1417 cells. These results are establishing the landscape of ND in PC and SCLC lines for further experimentation and testing of our hypothesis. To characterize the association of BRN2 dysregulation with ONC201 sensitivity, we are performing BRN2/SOX2 knockdown experiments using siRNA and evaluating effects towards ONC201 sensitivity. Our results provide insights into molecular mechanisms of ND in PC and SCLC sensitivity to ONC201. We are also currently working to overexpress BRN2 and SOX2 in cell lines to analyze the impact on neuroendocrine differentiation and ONC201 sensitivity.

N-terminal and C-terminal elephant-to-human p53 variants and truncations alter p53 transactivation

William H. Yang, Wei-Hsiung Yang. *Biomedical Sciences, Mercer University School of Medicine, Savannah, GA*

Cancer is one of the most dreaded diseases of the 21st century for humans. Currently, the human cancer mortality rate is approximately 11-25%. However, for some animals, such as elephants, the cancer mortality rate is lower than 5%. p53 is a significant cellular regulator in human cancers, and its important role in response to DNA damage has been highlighted by the discovery of p53 retrogene found in elephants (19 copies) but not humans (0 copies). Therefore, the main question is whether (1) more copies of p53 are better at combating cancer development or (2) is elephant p53 is better than human p53 in p53-mediated function? Herein, we demonstrate for the

first time that N-terminal and C-terminal elephant-to-human p53 variants and truncations alter p53 transactivation. First, we created elephant-to-human p53 variants (such as T387R, L383P, LSTEL, etc.) and truncations at the N-terminus and C-terminus of human p53. Secondly, R175H and R273H p53 mutants (conformational and contact mutants, respectively) were used as negative control. Using a p53 (14X) response element LUC and several natural p53 downstream gene promoters, we demonstrated that several N-terminal and C-terminal p53 variants and truncations increases p53 transactivation compared to WT p53. Moreover, we found that deletion of the region between aa374 and aa382 is integral for p53 transactivation. Taken together, our preliminary results demonstrate that several N-terminal and C-terminal elephant-to-human p53 variants enhance p53 transactivation and possible stability. This data is the first step to support the notion that elephant p53 is better than human p53 in p53-mediated function.

ZBTB46/FOXA2/HIF1A transcription activator complex promotes MCTP1-regulated neuroendocrine differentiation and epithelial-to-mesenchymal transition

Vu Thuy Dung Phan[1], Yu-Ching Wen[2], Wei-Yu Chen[3], Wei-Hao Chen[1], Kuo-Ching Jiang[1], Han-Ru Li[1], Van Thi Ngoc Tram[4], Zi-Qing Chen[5], Wan-Hsin Wang[5], Yen-Nien Liu[1]. *[1]Graduate Institute of Cancer Biology and Drug Discovery, Taipei Medical University, Taipei, Taiwan,[2]Department of Urology, Taipei Medical University, Taipei, Taiwan,[3]Department of Pathology, Taipei Medical University, Taipei, Taiwan,[4]International Ph.D Program in Medicine, Taipei Medical University, Taipei, Taiwan,[5]Division of Clinical Pharmacy, Taipei Medical University, Taipei, Taiwan*

Androgen deprivation therapy (ADT)-induced neuroendocrine differentiation (NED) is a well-known lethal subtype of prostate cancer (PCa) with a median survival rate of less than one year. Despite the increasing research attention on this variant of PCa, the underlying mechanism orchestrating therapy-related neuroendocrine prostate cancer (NEPC) remains elusive. We found that ADT-induced hypoxia-associated ZBTB46/FOXA2/HIF1A signaling enhances the multiple C2 domain transmembrane protein 1 (MCTP1), which promotes NED and epithelial-to-

mesenchymal transition (EMT) of PCa. Mechanistically, ZBTB46 physically interacts with the HIF1A/FOXA2 complex, in which ZBTB46 may be a co-activator of the hypoxia-related FOXA2 transcription factor. Interestingly, this ZBTB46/FOXA2/HIF1A complex accumulates after hypoxia and functions as a transcriptional activator of MCTP1. Hypoxia-upregulated MCTP1 subsequently leads to NED and the increase in EMT, whereas the opposite is true for the knockdown of MCTP1 in PCa cells. Consistent with previous results, MCTP1 is highly expressed in high-grade castration-resistance prostate cancer (CRPC) and small-cell PCa (SCPC) tissues and is associated with NE markers and ZBTB46/FOXA2/HIF1A abundance. In this study, we explored the direct interaction of ZBTB46 protein with hypoxia-related FOXA2/HIF1A complex in PCa cells under hypoxic conditions, which promote MCTP1-driven EMT and NED. Our finding suggests that MCTP1 could be used as a biomarker for diagnosing NEPC and as a therapeutic target in clinical applications.

A novel mechanism of NF-κB activation by genotoxic chemotherapy

Jaganathan Venkatesh[1], Magesh Muthu[1], Arun K. Rishi[2]. *[1]Oncology, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI,[2]Oncology, John D. Dingell VA Medical Center, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI*

CARP-1, a perinuclear phospho-protein, is a biphasic regulator of cell survival and apoptosis signaling. Genotoxic drugs induce apoptosis in part by elevating CARP-1 levels while also promote cell survival in part by activating NF-κB that involves CARP-1 interaction with NF-κB kinase subunit γ (aka, NEMO). We previously noted interaction of CARP-1 with RIPK1, and since RIPK1 is known to regulate NF-κB signaling, we investigated whether RIPK1-CARP-1 interaction is involved in genotoxic chemotherapy-dependent apoptosis or NF-κB-activated survival signaling. Mutagenesis and co-IP-WB analyses revealed that a 40-amino acid epitope within the amino-terminal catalytic domain of RIPK1 interacted with CARP-1 (611-640) peptide. Overexpression of this CARP-1/CCAR1-binding (CB) epitope peptide or RIPK1 mutant that has in-frame deletion of CB-epitope resulted in moderate but significant reduction in viabilities of

cells treated with Adriamycin or Cisplatin relative to the viability loss noted in cells expressing RIPK1 (WT). However, no significant differences in loss of cell viabilities were noted in cells expressing various substitution mutants of RIPK1 (aspartate (D) 138 to asparagine (N), serine (S) 109 and threonine (T) 110 to alanines (A), lysine (K) 87 to arginine (R), K97 to R, K105 to R, or K115 to R) relative to their RIPK1 (WT) expressing counterparts when treated with genotoxic drugs. Interestingly, CB-epitope mutant, but not RIPK1 (WT), failed to translocate to cytoplasm in Adriamycin-treated cells. Genotoxic drugs activated p65/RelA in cells expressing RIPK1 (WT), while expression of RIPK1 CB-epitope mutant resulted in abrogation of p65/RelA activation by Adriamycin or Cisplatin but not by TNFα. Collectively our data demonstrate that CARP-1 interaction with RIPK1 promotes nuclear export of RIPK1 and consequent NF-κB activation in cells exposed to genotoxic drugs.

#3738

A novel mechanism of STAT3 activation by genotoxic chemotherapy

Jaganathan Venkatesh[1], Magesh Muthu[1], Nuwan C. P.N Acharige[2], Mary K. H. Pflum[2], Arun K. Rishi[3]. *[1]Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]Chemistry, Wayne State University, Detroit, MI,[3]Oncology, John D. Dingell VA Medical Center, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI*

CARP-1, a perinuclear phospho-protein, is a biphasic regulator of cell survival and apoptosis signaling induced by genotoxic drugs. We have previously found that apoptosis induced by genotoxic drugs involved elevated levels of CARP-1. Exposure to genotoxic drugs also induced CARP-1 interaction with NF-κB kinase subunit γ (aka, NEMO) to promote NF-κB activation and cell survival. To further elucidate chemotherapy-activated, CARP-1-dependent cell survival mechanisms, we UV cross-linked protein extracts from Adriamycin-treated HeLa cervical cancer cells with a CARP-1 (614-638) peptide, and conducted liquid chromatography-tandem mass spectrometry (LC-MS/MS) analyses of the peptide-bound protein complexes. This experiment revealed STAT3 interaction with CARP-1 (614-638) peptide. Our mutagenesis and co-IP-WB experiments revealed CARP-1 (550-650) directly interacts with a 40 amino acid peptide located in the STAT3 DNA binding domain. Overexpression of mutant

STAT3 with in-frame-deletion of CARP-1/CCAR1-binding epitope (CE) peptide (Gst-STAT3 (ΔCE) mutant), but not Gst-STAT3 (WT), failed to translocate to nucleus in Adriamycin-treated cells. Disruption of STAT3-CARP-1 interaction or expression of STAT3 (ΔCE) mutant abolished Adriamycin-induced STAT3 Y705 and S727 phosphorylation. Collectively our data demonstrate that CARP-1 interaction with STAT3 regulates genotoxic chemotherapy-activated STAT3 and its nuclear translocation to promote cancer cell survival and growth.

#3739
MAFG promotes melanomagenesis through the transcriptional regulation of hypoxic and immune responses
Olga Vera, Michael Martinez, Florian A. Karreth. *Moffitt Cancer Center, Tampa, FL*

The small MAF family of transcription factors, consisting of MAFG, MAFF, and MAFK, dimerize with CNC/BACH proteins to regulate diverse transcriptional programs. Previously, we have shown that miRNA-29 suppresses melanoma development, at least in part, by repressing MAFG expression. Moreover, analysis of the TCGA revealed frequent copy number gains and/or overexpression of MAFG in melanoma. However, whether MAFG has oncogenic effects in and is critical for melanoma is unknown. We found that silencing of MAFG, but not MAFF or MAFK, abrogates growth of melanoma cells in vitro, while melanocyte cell lines are less reliant on MAFG. Conversely, MAFG overexpression promoted proliferation and focus formation of human melanocyte and melanoma cell lines. Using a high-throughput melanoma mouse modeling (ESC-GEMM) platform, we found that in vivo overexpression of MAFG in $BRAF^{V600E}$; $PTEN^{+/-}$ mice potently accelerated melanoma development. RNA-sequencing revealed that MAFG regulates transcriptional programs associated with hypoxic and immune responses. Accordingly, MAFG overexpressing cells exhibited better ability to survive under hypoxic conditions, probably through the regulation of HIF1A. Moreover, MAFG overexpressing cells showed increased expression of cytokines of the of the C-C chemokine family, CCL3 and CCL5. MAFG overexpressing tumors from ESC-GEMM mice and MAFG-High melanomas from TCGA had features of immune-cold milieus, characterized by reduced infiltration of

$CD45^+$ immune cells and $CD8^+$ T cells. Altogether, we demonstrate that MAFG promotes melanomagenesis, in part, by regulating the response to hypoxic conditions and chemokine expression, which may rewire the tumor immune microenvironment.

Non-coding RNAs in Brain, Melanoma, Lung, and Head/Neck

#3743
circPMS1 is a pro-metastatic circular RNA in melanoma
Nicol Mecozzi, Olga Vera, Florian Karreth. *Moffitt Cancer Center, Tampa, FL*

Deregulated gene expression is a major driver of melanoma metastasis, a process that results in the majority of melanoma-related deaths. Importantly, these alterations are not limited to protein-coding mRNAs, but also include noncoding RNAs. Despite many recent studies implicating circular RNAs (circRNAs) in cancer development, it is unknown if their deregulation contributes to melanoma metastasis. To identify circRNAs with putative roles in melanomagenesis, we performed RNA sequencing on a panel of melanoma and melanocyte cell lines. 21 differentially expressed circRNAs were validated by qPCR and Sanger sequencing of the backsplice junction. Further analyses of the ratio of the circular and cognate linear RNA transcripts and expression in a larger panel of cell lines identified *circPMS1* as a circRNA that is upregulated in melanoma through enhanced backsplicing of the linear *PMS1* mRNA. Using transposon-mediated delivery, we examined the effects of stable *circPMS1* overexpression on melanoma cells. While proliferation and focus formation were not impacted, migration and invasion were enhanced by *circPMS1*. Moreover, tail vein injection of *circPMS1* overexpressing melanoma cells increased lung metastasis. In addition to this transplant model, we generated the first genetically engineered mouse model of melanoma overexpressing a pro-tumorigenic circRNA. These mice are currently being analyzed. Mechanistically, we find that circularization is required for the pro-migratory effects of the *circPMS1* overexpression construct. Additionally, *circPMS1* harbors the canonical *PMS1* start codon, a predicted ORF spanning over the backsplice junction, and a predicted IRES sequence. Indeed, inserting a flag-tag in the overexpression construct revealed

circPMS1 to be translated into a truncated 25kD PMS1 protein as well as a 20kD protein likely arising from an in-frame downstream start codon. Importantly, these truncated circPMS1 proteins are endogenously expressed and increased in melanoma compared to melanocytes while the full-length PMS1 protein is evenly expressed. These findings suggest that *circPMS1* promotes melanoma metastasis, at least in part, by coding for truncated circPMS1 proteins. Further work will establish the functions of the *circPMS1*-encoded proteins and their roles in driving melanoma progression and metastasis.

A circulating microRNA panel predicts recurrence and survival in early-stage lung adenocarcinoma

Mei-Chee Tai[1], Leonidas E. Bantis[2], Gargy Parhy[1], Taketo Kato[3], Ichidai Tanaka[3], Chi-Wan Chow[1], Junya Fujimoto[1], Carmen Behrens[1], Tetsunari Hase[3], Koji Kawaguchi[4], Johannes F. Fahrmann[1], Edwin Ostrin[1], Kohei Yokoi[3], Toyofumi F. Chen-Yoshikawa[3], Yoshinori Hasegawa[5], Samir M. Hanash[1], Ignacio I. Wistuba[1], Ayumu Taguchi[6]. *[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]University of Kansas Medical Center, Kansas City, KS,[3]Nagoya University Graduate School of Medicine, Nagoya, Japan,[4]Mie University Graduate School of Medicine, Tsu, Japan,[5]National Hospital Organization Nagoya Medical Center, Nagoya, Japan,[6]Aichi Cancer Center, Nagoya, Japan*

Background: Early-stage lung adenocarcinoma (LUAD) patients have substantial risk for recurrence and disease-related death. Cisplatin-based adjuvant chemotherapy remains the standard for care of LUAD patients who have undergone surgical resection with a high risk of recurrence. However, adjuvant chemotherapy is associated with increased risk of toxicity including chemotherapy-related death, with only a modest survival benefit. Therefore, there is an unmet need of biomarkers for assessment and identification of those in an early stage who would likely benefit from adjuvant chemotherapy. Circulating miRNAs are stably present in blood and potentially reflect different expressions in cancerous and non-cancerous tissues, making them attractive biomarkers. The purpose of this study was

to identify circulating miRNAs useful for predicting recurrence in early-stage LUAD.
Materials and Methods: miRNA microarray analysis was performed with pooled pretreatment plasma samples from stage I LUAD patients who developed recurrence within two years after curative surgery or remained recurrence free over a six-year follow-up period, as well as from healthy controls. miRNA biomarker candidates were assayed in two independent plasma sample sets from 85 stage I LUAD (validation set) and from 57 stage I and II LUAD (test set) patients.
Results: Based on miRNA microarray data and previous reports, predictive performance of miR-23a-3p, miR-23b-3p, miR-191-5p, miR-185-5p, miR-151a-3p, miR-320c, miR-21-5p, miR-125b-5p, miR-30d-5p, and miR-197-3p was evaluated in the validation set. Plasma levels of miR-23a-3p, miR-185-5p, miR-320c, miR-21-5p, miR-125b-5p, miR-30d-5p, and miR-197-3p were significantly higher in those with recurrence as compared to those without. A miRNA panel comprised of miR-23a-3p, miR-320c, and miR-125b-5p was developed based on a logistic regression, with yielding an AUC of 0.776 (95% confidence interval [CI] = 0.660 to 0.893). The three-miRNA panel with fixed coefficients yielded an AUC of 0.804 (95% CI = 0.688 to 0.920) with a sensitivity of 45.8% at 95% specificity in the test set. The miRNA panel score was a significant and independent factor for predicting disease-free survival (DFS; $P < 0.001$, HR = 1.64, 95% CI = 1.51-4.22) and overall survival (OS; $P = 0.001$, HR = 1.51, 95% CI = 1.17-1.94).
Conclusion: This circulating miRNA panel may serve as a noninvasive blood test for predicting DFS and OS in early-stage LUAD patients. Our findings provide rationale for further investigation to stratify early-stage LUAD patients using blood-based biomarkers to increase the ability to provide more personalized care.

#3745
GRAS1 long non-coding RNA binds and stabilizes NF-kB activating protein to protect lung cancer cells from DNA damage
Tong Su, Bobby Kong, Jonathan Zhu, Colleen A. McHugh. *UC San Diego, La Jolla, CA*

Long non-coding RNAs (lncRNAs) control numerous biological processes, including epigenetic regulation, gene expression, proliferation and metabolism. However, the detailed biological mechanisms by which lncRNAs regulate cellular processes are still poorly understood. We identified a set of growth regulator non-coding RNAs based on data mining of CRISPR/Cas9 screens and high-throughput sequencing studies from patient normal and tumor cells. We hypothesized that growth regulator lncRNAs play a role in cancer development by recruiting effector proteins to regulate gene expression. In our screen, the Growth Regulator Antisense 1 RNA (GRAS1) was identified as a key factor controlling growth in non-small cell lung cancer cells. Loss of GRAS1 resulted in altered expression of genes involved in DNA repair, cell cycle progression, and p53 and NF-KB signaling pathways. Extensive DNA damage occurred within 48 hours after GRAS1 knockdown, with a significant increase in the number of γH2AX loci visualized by immunofluorescence assay. We used RNA antisense purification combined with mass spectrometry to identify the NF-KB activating protein (NKAP) as the top directly interacting partner of GRAS1 lncRNA. NKAP stability decreased after GRAS1 knockdown, and this phenotype could be reversed with proteasome inhibition. Further, RelA levels were decreased in GRAS1 knockdown cells. We found that GRAS1 lncRNA binds and stabilizes NKAP to enable survival and protect against DNA damage in lung cancer cells.

Dynamic characterization of small RNAs in non small cell lung cancer exosomes under immune-checkpoint inhibitor treatments

Maria Garrido-Barros, Javier Oliver, Juan Luis Onieva, Beatriz Martinez-Galvez, Jaime Duddelman, Antonio Rueda, Elisabeth Perez, Emilio Alba, Inmaculada Ramos, Juan Zafra, Manuel Cobo, Isabel Barragán. *UGCI, Inst of Biomedical Investigation, Malaga, Spain*

Immunotherapy based on Immune Checkpoint blockade (ICB) has become a significant therapeutic option for advanced Non Small Cell Lung Cancer (NSCLC) patients. However, there is an urgent need to find novel biomarkers that to reliably stratify good responders to immunotherapy. Currently, the available biomarkers are not specific enough. Exosomes are small membrane vesicles with sizes of 30-100 nm secreted by most cell

types including cancer cells. Exosomes operate as an intercellular communication system by sending proteins, mRNA and miRNAs among other relevant RNA molecules. Exosomes enriched with miRNAS are involved in proliferation, differentiation, maduration and immune cell activation. Moreover, in cancer cells miRNA and other small RNA molecule expressions are dysregulated. Exosomes produced from cancer patient's plasma have been shown to be accurate diagnostic tools for the disease. In this study we profiled miRNAs and other small RNA cargo by exosome of plasma samples from 77 Non Small Cell Lung Cancer (NSCLC) metastatic patients before and after the first cycle of immunotherapy to evaluate the potentiality of predicting response to immunotherapy. We perform exosomes together with RNA isolation and small RNAseq sequencing from plasma samples before and after the first ICB cycle. Two independent softwares were used to identify small RNAs (RNAtoolbox and mirMaster). Prior ICB treatment we did not find differentially expressed miRNAs or other small RNA between good and bad responders. Interestingly we identified 12 exosomal miRNA differentially expressed between good and bad responders after the first cycle of ICB. Intriguingly, levels of miR-134-5p, miR-142-3p, miR-143-3p among others previously associated with NSCLC were found to be considerably higher in the good responder group than the bad responder group. Regarding other smallRNA molecules we observed a great variety and variability of piRNA, rRNA, scaRNA, lncRNA, snoRNA, snRNA, miscRNA and circRNA. To address the function of miRNA and other differentially expressed RNA molecules, we consulted KEGG, GO and Reactome for gene regulatory networks. Interestingly, KEGG results show pathways in cancer as top hit and Reactome highlight Immune System and cancer hits. In conclusion, we observed that patients that have favorable response to ICB have distinctive plasma exosomal miRNA patterns that could be used as possible biomarkers for predicting the effectiveness of immunotherapy in advanced NSCLC patients

Transcribed ultra-conserved regions (TUCRs): A first computational and molecular characterization of an understudied class of molecules in gliomas

Myron K. Gibert, Bilhan Chagari, Christian Roig-Laboy, Aditya Sarkar, Roger Abounader. *Department of Microbiology, Immunology, and Cancer Biology, University of Virginia, Charlottesville, VA*

Gliomas are the most common malignant primary brain tumors. Particularly, glioblastoma (GBM) is the most common and deadliest malignant brain tumor. Most glioma research has focused on protein-coding genes and much less on the non-coding transcripts that make up 98% of cellular RNA. Transcribed Ultra-Conserved Regions (TUCRs) represent an understudied class of molecules that are found highly conserved across multiple species, including 100% conservation in mouse and rat genomes. These 481 transcripts are highly resistant to variation and are commonly deregulated in cancer, which suggests regulatory and functional importance when considered along with their high degree of conservation. We performed the first-ever characterization of TUCRs in gliomas *in silico.* Using an elaborate workflow, we annotated and identified TUCRs that are deregulated in GBM and low-grade glioma (LGG), associated with patient outcomes, and predicted their function in glioma initiation and progression. Most TUCRs were long non-coding RNAs. Of these, we investigated the most highly upregulated intergenic TUCR, uc.110, *in vitro* and *in vivo* in glioma cell lines. Knockdown of uc.110 expression via siRNA resulted in reduced glioma cell accumulation, viability, and invasion *in vitro* while reducing tumor volume and increasing overall survival *in vivo*. Concurrent lentiviral overexpression of uc.110 partially rescued wild-type expression, accumulation, viability, and invasion *in vitro*. Therefore, it is likely that this TUCR is functioning as an oncogene within the context of GBM. Our study represents the first comprehensive characterization of TUCRs in gliomas and can serve as a foundation and framework for similar studies in gliomas and other cancers.

Epstein-Barr virus BART lncRNAs induce *IKZF3*/Aiolos to maintain EBV latency and promote tumorigenicity in nasopharyngeal carcinoma

Songtao He, Jiayan Liu, Bobo Wing-Yee Mok, Sai Wah Tsao, Honglin Chen. *The University of Hong Kong, Hong Kong, Hong Kong*

Epstein-Barr virus (EBV) maintains latency in its associated tumors, including nasopharyngeal carcinoma (NPC), expressing very few viral proteins but abundant levels of noncoding RNAs (mainly EBERs and BARTs) in NPC cells. We found that *IKZF3*/Aiolos is a downstream target of BART lncRNAs in NPC cells. The functions of BART lncRNAs and *IKZF3* in EBV latency and pathogenesis of NPC remain elusive. In this study, meta-analysis of eight EBV-associated studies showed that *IKZF3*/Aiolos was consistently upregulated in EBV-infected NPC cells. Our study further showed that transcription of *IKZF3*/Aiolos is highly upregulated in EBV-infected NPC cells and clinical tissue samples due to the action of EBV encoded BART lncRNAs, with *IKZF3*/Aiolos was expressed at higher levels in late stage (stage III & IV) NPC patients than in early stage (stage I & II) disease. Secondly, we found that *IKZF3*/Aiolos was upregulated in BART-activated NPC cells but downregulated in BART-knockdown NPC cells. In addition, this study further demonstrated that I*KZF3*/Aiolos modulates transcription of EBV BZLF1 and the cellular gene, *LRIG1*, to maintain EBV latency and promote NPC tumorigenesis *in vitro* and *in vivo*. Our results showed that the EBV lytic reactivator BZLF1 was upregulated in *IKZF3*/Aiolos knockout or Aiolos inhibitor-treated NPC cells. ChIP-qPCR, immunoprecipitation and immunofluorescence analyses further revealed that *IKZF3*/Aiolos induces H3K27 deacetylation to silence expression of BZLF1 and maintain EBV latency in NPC cells. Moreover, functional analyses and western blotting showed that *IKZF3*/Aiolos inhibited the tumor suppressor, LRIG1, to upregulate expression and phosphorylation of the cellular proto-oncogene Erb-B2 for NPC pathogenesis. Sphere- and colony-formation assays demonstrated that *IKZF3*/Aiolos enhances growth of NPC cells *in vitro*, and *in vivo* experiments further showed that *IKZF3*/Aiolos promotes tumorigenicity of NPC cells in NOD mice. Mechanically, we found that the expression of EBV lytic reactivator BZLF1 and cellular LRIG1 were negatively regulated by BART lncRNA/*IKZF3*/Aiolos regulatory machinery in NPC cells, while Erb-B2 was positively regulated, which indicated that *IKZF3*/Aiolos is a new biomarker for NPC and may lead to the development of novel diagnostic tests and treatments for NPC.

#3749

Oncogenic role of Epstein-Barr virus lnc-BARTs in EBV associated tumors

LIU JIAYAN, Bobo Wing-Yee Mok, Songtao He, Honglin Chen.
Microbiology, The University of Hong Kong, Hong Kong, China

While majority of humans infected with Epstein-Barr virus (EBV) is asymptomatic for whole life, EBV is found to associate with several human cancers, including Burkitt's lymphoma, Hodgkin's diseases, post-transplant lymphoproliferative disorder (PTLD), nasopharyngeal carcinoma (NPC) and gastric carcinoma. Among these EBV associated tumors, EBV genome is found in 100% of NPC tumor cells. EBV establishes a latent infection in NPC cells, expressing few viral proteins, but elevated levels of non-coding RNAs transcribed from the *BamHI*-A region of the EBV genome, designated *BamHI*-A rightward transcripts (BARTs). The family of EBV BART RNAs comprises BART-microRNAs (miRNAs) and long non-coding RNAs (lnc-BARTs). While versatile functions of BART miRNAs have been revealed, little is known about the role of EBV lnc-BARTs. Here, we provided evidence to show that BARTs mRNA which derived from multiple exons of BART function as regulatory long non-coding RNA, namely *lnc-BARTs*, in modulating the core network for maintaining EBV latency and promoting NPC oncogenesis through epigenetic mechanisms. Our results showed that the apoptosis rate of NPC cell lines with knockdown of EBV *lnc-BARTs* was significantly increased, suggesting that *lnc-BARTs* have an anti-apoptotic effect in EBV associated tumors. MS analysis was performed to identify host factors which interact with EBV *lnc-BARTs* in NPC cells. *Lnc-BARTs* were shown to directly interact with several transcriptional regulators, including BRD4 and SC35. Notably, RNA-FISH assays demonstrated that lnc-*BARTs* co-localize with BRD4 and SC35 complexes in nuclear speckles, with these complexes being disrupted by treatment with JQ1, a BRD4 competitive inhibitor. RNA immunoprecipitation and RNA pulldown assays confirmed that *lnc-BARTs* bind to BRD4. ATAC sequencing analysis and transcriptome analysis further demonstrated that knockdown of BARTs in the EBV-harboring NPC cell line, C666-1, resulted in globally reduced chromatin accessibility downregulation of oncogenes like MYC and BCL2. In addition, ChIP sequencing analysis revealed that *lnc-BARTs* interfere PolII phosphorylation on promoters of genes. Our findings suggest that EBV *lnc-BARTs* are

involved in epigenetic modulation of host gene expression through functional interaction with elongation regulatory machinery to maintain EBV latency and drive tumorigenesis in NPC.

miR-590-3p inhibits multiple oncogenic nodes within the TGFBR2:SMAD2/3 pathway in recurrent GBM cells

Sophie Sall[1], Jack Korleski[2], Amanda Johnson[2], Maya Johnson[1], Hernando Lopez-Bertoni[2]. *[1]Kennedy Krieger Research Institute, Baltimore, MD,[2]Neurology, Johns Hopkins University School of Medicine, Baltimore, MD*

Glioblastoma (GBM) is the most lethal and aggressive primary brain malignancy with high recurrence rates and virtually no long-term survival. Despite our expanding knowledge regarding GBM at the genomic/molecular level, we still don't fully comprehend the molecular mechanisms responsible for GBM recurrence. Current knowledge implicates tumor-propagating Glioma Stem Cells (GSCs) in the evolution of treatment resistance and tumor recurrence. Understanding these cellular/molecular events will inform strategies for preventing and/or treating recurrent GBM (rGBM). Gene set enrichment analysis (GSEA) of RNA sequencing datasets obtained from GSCs and clinical rGBM specimens identified TGFBR2 signaling as a high frequency and potentially targetable pathway in rGBM. We show that SMAD2/3 signaling, a downstream effector of TGFBR2, is enriched in rGBM and that patients with elevated TGFBR2 have statistically shorter long-term survival outlooks. The functional relevance of these findings was supported using ITD1, a selective TGFBR2 inhibitor, which decreased the GSC phenotype and cell viability of cells derived from clinical rGBM (rGBM cells), while simultaneously re-sensitizing them to temozolomide (TMZ) in-vitro. Since GBM is known to efficiently develop resistance to receptor-targeting monotherapies, we sought to simultaneously target multiple putative oncogenic drivers downstream of TGFBR2. To achieve this, we applied an unbiased miRNA-based network analysis that identified miR-590-3p as an inhibitor of SMAD2/3 signaling at multiple nodes and thus a potential tumor suppressor in rGBM. Transgenic miR-590-3p robustly decreased the expression of >30 putative oncogenes, reduced the GSC phenotype and cell

viability, as well as re-sensitized rGBM cells to TMZ. These results predict that blocking TGFBR2 signaling will negatively impact the tumor phenotype of rGBM as well as its GSC capacity. Ongoing directions for this research include comparing the efficacy of ITD1 monotherapy with miR-590-3p therapy in rGBM models in-vivo. These results identify a significant role of TGFBR2 signaling in both TMZ resistance and the GSC phenotype in rGBM and provide a miRNA-based strategy for simultaneously targeting multiple oncogenic nodes within the TGFBR2 and potentially other oncogenic signaling pathways.

Characterizing the role of the y chromosome-expressed long non-coding RNA linc-SPRY3 family in lung cancer radiation resistance

Emily S. Westemeier-Rice. *Mary Babb Randolph Cancer Center at West Virginia University, Morgantown, WV*

Lung cancer is the leading cause of cancer-related deaths worldwide. A major issue for clinicians and patients alike is inherent resistance to radiation therapy. Recently, certain long non-coding RNAs (lnc-RNAs) have been shown to regulate pathways involved in resistances to lung cancer treatments. Our group recently published that a group of long non-coding RNAs, named the linc-SPRY3 family, play an important role in radiation therapy sensitivity. Originating from the Y-Chromosome, these long non-coding RNAs have been shown in vitro and in vivo to decrease the tumor burden after radiation. Interestingly, certain male Non-Small Cell Lung Cancer (NSCLC) cell lines have been shown to have complete loss of the Y-chromosome (LOY), showing a radiation resistant phenotype. To test this, the DYZ1 region of the Y-chromosome, where the linc-SPRY3 family is expressed, was artificially introduced into radiation resistant male NSCLC cell lines with LOY. Remarkably, by adding the DYZ1 region of the Y-chromosome into these cells, they became more sensitive to radiation and had increased apoptosis. Based on this preliminary data, we hypothesize the linc-SPRY3 family interacts with important pathways in the cell to increase sensitivity to DNA double strand breaks. Through RNA-Sequencing and other preliminary experiments, we found that the linc-SPRY3 family regulates the expression of Cell Division Cycle 6 (CDC6) and Cell Division Cycle 25A (CDC25A) genes. Preliminary data suggests

these interactions play a role in influencing NSCLC ability to invade and metastasize. We are currently characterizing this family of linc-RNAs by flow cytometry, in vivo metastasis models, and fluorescent in situ hybridization. We will characterize the mechanism of the linc-SPRY3 family in radiation resistance through genetic modifications and further downstream analysis via the over-expression and knockdown of these linc-RNAs. The characterization of these linc-RNAs will be critical for the development of potential diagnostic or therapeutic therapies.

The role of miR-200 in anaplastic thyroid cancer aggressiveness

Hugo Huth, César Fuziwara, Edna Kimura. *Department of Cell and Developmental Biology, Institute of Biomedical Sciences (ICB), University of São Paulo, São Paulo, Brazil*

Anaplastic Thyroid Cancer (ATC) is the most aggressive and lethal of all thyroid cancer histotypes, characterized by undifferentiated, highly proliferative and invasive cells, which are intrinsically resistant to conventional treatment. Deregulation of microRNAs (miRNAs), a group of small non-coding RNAs that post-transcriptionally regulates protein expression, has been linked with cancer development. Specifically, the miR-200 family has been postulated to control the balance between epithelial and mesenchymal cell states through Epithelial-Mesenchymal Transition (EMT), a critical process for tumor metastasis. Previous results showed that miR-200c, a member of miR-200 family, is downregulated in ATC, but the biological effect of its deregulation remains unclear. Therefore, this study aims to evaluate the antitumor effect of miR-200c on ATC cell aggressiveness. Using plasmid overexpression, we induced miR-200c upregulation in KTC2 (KTC2-200c) and SW1736 (SW-200c) cells to analyze its role in cell differentiation, proliferation, migration, and EMT markers expression. Light microscope images showed that KTC-200c and SW-200c cells presented an epithelial morphology in contrast with the control group which displayed mesenchymal morphology. Analysis by qPCR and western blot of KTC-200c and SW-200c cells showed that upregulation of miR-200c expression enhanced mRNA and protein expressions of the epithelial marker E-cadherin, while diminished the mRNAs and protein levels of the mesenchymal markers N-cadherin and

ZEB1/2. Additionally, KTC2-200c and SW-200c presented reduced cell colony formation and cell proliferation, and reduced cell migration visualized by wound healing assay and transwell assay. In conclusion, this study evidences the tumor suppressor role of miR-200 in controlling ATC cell aggressiveness. Grants from FAPESP (2021/12284-0, 2019/17282-5, 2019/25116-8) and CNPq (311210/2021-0).

miR-567 modulates the progression of melanoma cells and functions of macrophages

Mai-Huong Thi Nguyen[1], Chen-Huan Lin[1], Yu-Chi Huang[1], Mu-Shiun Tsai[2], Ming-Hong Chen[3], Azusa Miyashita[4], Satoshi Fukushima[4], Nianhan Ma[1]. *[1]National Central University, Taoyuan, Taiwan,[2]Landseed Hospital, Taoyuan, Taiwan,[3]Saint Paul's Hospital, Taoyuan, Taiwan,[4]Kumamoto University, Kumamoto, Japan*

Purpose: Target therapy and immunotherapy are advancements in the treatment of melanoma; unfortunately, a subset of patients does not benefit or produces drug resistance. Therefore, an alternative strategy should be investigated to further improve clinical benefits. Macrophages are the abundant immune cells related to the progression of melanoma and resistance to drugs. In this study, we explored the novel roles of miR-567 in the progression of melanoma and effects of macrophages.
Methods: miR-567 expression in nevus and melanoma tissues was analyzed by in situ hybridization. miR-567 was transfected into melanoma cells to investigate its biological effects through functional assays such as proliferation, colony formation, soft agar, and migration assays. In addition, miR-567-related signal transduction pathways in the melanoma cells were studied by western blot and next-generation sequencing analyses. Different phenotypes of macrophages polarized from THP-1 monocyte cells were used as *in vitro* model to investigate the effects of miR-567 on macrophages.
Results: Our results showed that miR-567 expression levels were decreased in melanoma cells compared to melanocyte cells. Consistently, expression of miR-567 was 0.403-fold lower in melanoma tissues (n=118) as compared to nevus tissues (n=40). In addition, the receiver operating characteristic presented that the area under the curve value of miR-567 is 0.9495.

Importantly, higher expression of miR-567 enhanced the overall survival of melanoma patients. Overexpression of miR-567 significantly reduced proliferation, survival, anchorage-independent growth, migratory, and invasive abilities of melanoma cells and BRAF-inhibitor resistant cells. Furthermore, our results demonstrated that IGF1R, E2F1, and Cyclin B2 are direct targets of miR-567 and knockdown of these genes attenuated proliferation and survival of melanoma cells. Interestingly, introduction of miR-567 downregulated MAPK/ERK and PI3K/AKT pathways in melanoma cells and regulated multiple pathways related to immune response. Of note, overexpression of miR-567 reduced the promoting melanoma growth induced by M2 or melanoma-associated macrophages, indicating the involvement of miR-567 in regulation of macrophages. Conclusion: miR-567 could be served not only as biomarkers but also as potential molecular target for prevention of melanoma progression.

#3754

The cell- and non-cell autonomous actions of UCA1 dysregulation in hypopharyngeal cancer

Li-Wha Wu. *Institute of Molecular Medicine, National Cheng Kung University, Tainan, Taiwan*

Long non-coding RNAs (lncRNAs), encoding noncoding transcripts greater than 200 nucleotides, are multifunctional regulator of gene expression and play vital roles in various biological processes. Urothelial cancer-associated 1 (UCA1) is one such molecule and found to be dysregulated in the development of several cancer types, including those in bladder, colon, stomach, lung and breast. One previous study showed that an upregulation of UCA1 expression profile in hypopharyngeal cancer tissues relative to their adjacent normal counterparts significantly negated overall survival among these cancer patients. However, the molecular mechanism whereby UCA1 played any role in HPC, a subtype of head and neck cancer and often detected in advanced stages, remains elusive. In this report, we showed that ectopic UCA1 expression promoted cell migration and invasion while reducing cell proliferation. The increase of migration and invasion was accompanied by partial epithelial mesenchymal transition. By contrast, UCA1 depletion had the opposite effect. In addition to the presence of UCA1 in the culture medium (CM) and a stimulatory effect of CM derived

from UCA1-OE cells on cell migration and invasion, we found a predominant nuclear localization of UCA1 in HPC cells. PTBP3, a RNA-binding protein, was identified as a novel interacting partner of UCA1 by RNA pulldown and mass spectrometry. PTBP3 silencing significantly reduced UCA1 mRNA expression, suggesting a regulatory role in UCA1 stability. While mapping the interacting domains between UCA1 and PTBP3, we are also in the process of identifying the involvement of UCA1-PTBP3 axis in hypopharyngeal carcinogenesis. We hope to validate if UCA1 can serve as a novel therapeutic target against or diagnostic marker for hypopharyngeal cancer.

***Dlx4os*: a lncRNA associated with malignant melanocyte transformation**

Ana Luísa P. Ayub[1], Hatylas Azevedo[2], Diogo Pessoa[3], Leinal Sejour[4], Ioannis Vlachos[4], Eduardo M. R. Reis[3], Frank J. Slack[4], Miriam G. Jasiulionis[1]. *[1]Pharmacology, Federal University of São Paulo (UNIFESP), São Paulo, Brazil,[2]Surgery, Federal University of São Paulo (UNIFESP), São Paulo, Brazil,[3]Biochemistry, University of São Paulo (USP), São Paulo, Brazil,[4]Pathology, Harvard Medical School Initiative for RNA Medicine, Boston, MA*

It is estimated that more than 90% of the human genome is transcribed into non-coding RNAs (ncRNA). It has been demonstrated that ncRNAs have an important role in biological processes such as proliferation, differentiation, and cell migration. Changes in their expression have been associated with several diseases, including cancer. Melanoma is one of the most aggressive types of cancer, with high probability of metastasis and an unfavorable response to therapies. Our lab has developed an *in vitro* melanoma progression model, which was established by exposing nontumorigenic melanocytes (melan-a) to sustained stress conditions (cycles of adhesion blockage), sequentially generating different cell lines (i.e., 4C, premalignant melanocytes; 4C11-, non-metastatic melanoma cells; and 4C11+, metastatic melanoma cells), in which each cell line represents a distinct stage of tumor progression. Previous RNA sequencing data comparing these 4 cell lines identified a total of 3404 long non-coding transcripts which displayed differential expression (DE) levels when comparing two or more cell lines.

We have clustered 531 of them into three distinct signatures: malignancy, epithelial-to-mesenchymal transition (EMT), or metastasis, according to their expression profiles. We also analyzed the neighboring genes of those lncRNAs, as it is known that lncRNAs might regulate gene expression in *cis*. We identified the lncRNA *Dlx4os*, highly expressed in undifferentiated and mesenchymal-like 4C and 4C11- cells, and 6 neighboring genes whose expression correlate to the EMT signature and overall survival in human melanoma patients. Among these genes we found *Dlx4*, which shares the same promoter site with *Dlx4os* and whose expression correlates to a poor prognosis. We silenced *Dlx4os* in the 4C11- cells through interference RNA technology. The downregulation of *Dlx4os* led to expression changes in EMT-related genes, such as *Snail1*, *Sox10* and *Mitf*, indicating that it might play a role in EMT. *Dlx4os* downregulation also inhibited cell migration *in vitro* and tumorigenesis *in vivo*. These results overall indicate a role of *Dlx4os* in melanocyte malignant transformation.

#3756

miR-145 and its gene targets as therapeutic target and prognostic biomarkers for non-small cell lung cancer

William C. S. Cho, Chi F. Wong, Leo K. P. Li, Alvin H. W. Fong.
Department of Clinical Oncology, Queen Elizabeth Hospital, Hong Kong SAR, China

Introduction: Our previous study found that miR-145 was downregulated in non-small cell lung cancer (NSCLC) tissues and it could inhibit cell proliferation in transfected NSCLC cells. This study aimed to investigate the potential anticancer effect and tumor suppressive function of miR-145, to identify its gene targets, as well as to assess the role of its gene targets as prognostic biomarkers for NSCLC patients.
Materials and Methods: Cell proliferation, transwell migration, and invasion assays were performed on three miR-145 mimics transfected NSCLC cells. The effect of miR-145 in the cell cycle *in vitro* was assessed by flow cytometry analysis. *In vivo* transfection of miR-145 was performed to examine the cancer growth in eight BALB/c nude mice. Luciferase reporter assay was used to identify the gene targets. To reveal the role of the identified gene targets in patient survival, the clinical data of 500 lung

adenocarcinoma patients from The Cancer Genome Atlas (TCGA) database was used for Kaplan-Meier survival analysis.
Results: Upregulation of miR-145 significantly inhibited proliferation, migration, and invasion in NSCLC cells *in vitro*. Flow cytometry analysis revealed that the transfection of miR-145 into NSCLC cells did not show any effect in the cell cycle. After 37 days, transfection of miR-145 showed a reduction in tumor size (49% smaller) and tumor weight (57% lighter) than mimic negative *in vivo*. MicroRNA target prediction database miRTarBase and luciferase reporter assays identified GOLM1 and RTKN as the direct targets of miR-145. TCGA survival analysis found that the high expressions of GOLM1 ($p < 0.0001$) and RTKN ($p < 0.0045$) were significantly correlated with poor overall survival in lung adenocarcinoma patients.
Conclusion: Our results revealed that miR-145 inhibited proliferation, migration, and invasion, but did not affect cell cycle regulation in NSCLC. It also caused a reduction in tumor growth and weight. Most importantly, we identified two direct targets (GOLM1 and RTKN) of miR-145, in which RTKN was first identified as a miR-145 target in NSCLC. Moreover, both GOLM1 and RTKN play an imperative role in patients' overall survival. Taken together, our findings suggest that miR-145 may serve as a molecular therapeutic target for NSCLC, and its gene targets GOLM1 and RTKN may serve as prognostic biomarkers. Their potential clinical applications warrant further investigation.

miR-200 inhibits the activation of cancer-associated fibroblasts in lung tumor microenvironment
Inyoung Cheon, Sieun Lee. *Ewha Womans University School of Medicine, Seoul, Korea, Republic of*

Cancer-associated fibroblasts (CAFs) are key components of the tumor microenvironment and promote cancer progression and metastasis. CAFs are regulated by diverse processes including regulation by miRNAs. To identify miRNAs involved in the regulation of CAF activation, we profiled miRNA expression within mouse lung normal fibroblasts (LFs) and CAFs using the NanoString nCounter method. Among numerous miRNAs differentially expressed between CAFs and LFs, miR-200 was selected for

further investigation, which is more highly downregulated in CAFs. Overexpression of miR-200 in CAFs suppressed the migration and invasion of lung cancer cells in co-culture systems and inhibited metastasis in a mouse model. In addition, we verified that lung cancer patients with high miR-200 levels showed a good prognosis than those with low miR-200 levels. Next, we tried to identify novel miR-200 targets based on RNA sequencing data, lung adenocarcinoma TCGA, and TargetScan. NRP2 was confirmed to be a target of miR-200 by 3′-UTR assay. NRP2 knockdown by siRNAs in CAFs suppressed cancer cell invasion, and NRP2 addback in CAF-200 restored cancer cell invasion inhibited by miR-200. NRP2 functions as a co-receptor with VEGFR, thus, CAF-200 was less responsive to VEGF than control CAFs. Collectively, this study suggests that downregulation of miR-200 in CAFs promotes lung cancer progression in tumor microenvironment; therefore, miR-200 will be a good therapeutic target or a biomarker in lung adenocarcinoma.

Tumor tissue and cerebrospinal fluid microRNA profiles enable the classification of brain metastasis accordingly to their origin

Dagmar Al Tukmachi[1], Michaela Ruckova[1], Marek Vecera[1], Tana Machackova[1], Petra Pokorna[1], Marketa Hermanova[2], Michal Hendrych[2], Leos Kren[3], Ivana Roskova[4], Vaclav Vybihal[4], Hana Valekova[5], Radim Jancalek[5], Jiri Sana[6], Martin Smrcka[4], Ondrej Slaby[7]. *[1]The Central European Institute of Technology, Masaryk University, Brno, Czech Republic,[2]First Department of Pathology, St. Anne's Unversity Hospital, Brno, Czech Republic,[3]Department of Pathology, University Hospital Brno, Brno, Czech Republic,[4]Department of Neurosurgery, University Hospital Brno, Brno, Czech Republic,[5]Department of Neurosurgery, St. Anne's University Hospital Brno, Brno, Czech Republic,[6]Comprehensive Cancer Care Department, Masaryk Memorial Cancer Institute, Brno, Czech Republic,[7]Department of Biology, Faculty of Medicine MU, Brno, Czech Republic*

Brain metastases (BMs) comprise a heterogeneous group of the most frequent intracranial tumors in adults, most originating in lung, breast, renal cell, and colorectal carcinomas and melanomas. Despite the recent

improvements in imaging methodology resulting in earlier BM identification and advancements in treatment strategies, BMs are still a significant cause of patient morbidity. Furthermore, BMs frequency increases due to more prolonged survival of cancer patients and population aging. Since the most widely used prognostic scoring systems for BMs require prior knowledge of the primary origin and up to 14% of BMs are classified as BMs of unknown primary, there is an urgent unmet need for accurate biomarkers for identification of BM origin. MiRNAs are non-coding RNAs with an approximate length of 22 nucleotides, functioning as post-transcriptional regulators of gene expression. Dysregulated miRNA expression profile has been observed in many pathological processes, including the complex and not fully understood metastatic cascade. These molecules are very stable and present not only in tissues but also in human body fluids, including blood plasma and cerebrospinal fluid (CSF). Based on these facts, both tissue and circulating miRNAs are extensively studied as potential diagnostic biomarkers. Specific miRNA signatures of BMs were obtained using high-throughput miRNA profiling (Illumina small RNA sequencing) on 3 types of samples (metastatic tissue, blood plasma, CSF) from a cohort of 30 patients with BMs originating in the 5 tumor types – lung, breast, renal cell and colorectal carcinomas and melanomas (6 patients per group, 87 samples in total, only 3 CSF samples from RCC patients available). We identified significantly differentially expressed miRNAs in BM tissues with the ability to differentiate between primary origins. Tissue miRNAs could identify BMs originating from breast, colorectal and renal cell carcinomas and melanomas with high specificity and sensitivity. Interestingly, the heterogeneity of lung carcinomas was also characteristic for the corresponding BMs, making it challenging to distinguish accurately from other BMs. Even though the tissue-specific miRNA signature was the most precise, our results suggest a significant diagnostic potential of circulating miRNAs from CSF for BM patients. Therefore, these short and stable molecules could potentially help identify the origin of BMs of unknown primary. The research is supported by project National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NPO5102) - Funded by the European Union - Next Generation EU.

Impact of individual and combined deregulation of miR-143 and miR-506 on cytokinetic and morphometric parameters in A549 lung cancer cells

Archana Shrestha[1], Behnaz Lahooti[2], Mahboubeh Madadi[3], Constantinos M. Mikelis[4], George Mattheolabakis[1]. *[1]Pharmaceutical and Toxicological Sciences, University of Louisiana at Monroe, Monroe, LA,[2]Department of Pharmaceutical Sciences, Texas Tech University Health Sciences Center, Amarillo, TX,[3]Department of Marketing and Business Analytics, Lucas College and Graduate School of Business, San Jose State University, San Jose, CA,[4]Department of Pharmacy, University of Patras, Patras, Greece*

Lung cancer (LC) is among the leading causes of death from malignancies worldwide. miRNAs (miRs), small noncoding RNAs capable of regulating gene expression through the cell's RNAi mechanism, have emerged as promising molecules for cancer treatment. In our previous work, we identified two miRs, miR-143 and miR-506, whose transient transfection induced apoptosis, cell cycle inhibition, and cyclin-dependent kinase (CDK) 1, 4, and 6 downregulations. Here, we developed stable deregulations of the miRs' expressions in A549 cells, individually or in combination, to evaluate their effect on LC cell behavior. To establish homogeneous populations of deregulated cells, A549 cells with stable up and downregulated miR-143 and miR-506, alone or in combination, were sorted according to marker expression using fluorescence-activated cell sorting (FACS). miR deregulations were confirmed with quantitative real-time polymerase chain reaction (qRT -PCR) analysis, and the cells were analyzed for changes in cell proliferation through cell cycle analysis using flow cytometry and cell doubling time using Quantitative Phase Imaging (QPI). With the same method, morphometric characteristics were quantified. Finally, we evaluated the motility of the cells using a scratch assay and determined the gene expression of CDKs. Taqman qPCR analysis indicated a >5-fold increase of the respective miR's basal expression due to the stable transfections. The cell cycle analysis indicated a complex behavior for the individual miRs, while, in contrast, the combined upregulation of the two miRs indicated a G2 inhibition, representing a well-defined behavior in comparison to both the control and downregulation groups. Furthermore, the combined miR upregulation increased the cell doubling time compared to the control and respective downregulations.

Similarly, using QPI microscopy, we observed that the miR combination upregulation had higher cellular sphericity, perimeter, and area compared to the control group. The wound healing assay did not indicate statistically significant differences among the different groups, with miR-506 upregulation demonstrating the slowest closure rate, followed by miR -143. In contrast, the differences between the miR-combination and control group were small, although the anti-miR-combination indicated an accelerated closure. In conclusion, the combined upregulation of both miRs inhibited cell proliferation through a G2 arrest, while the deregulation of the individual miRs demonstrated a complex behavior. Thus, the miR-combination's consistent, promising behavior would indicate potential benefits using the two miRs against LC that merits further evaluation.

MicroRNA-1 run down the growth and metastasis of small cell lung cancer

Parvez Khan[1], Jawed A. Siddiqui[1], Shailendra Kumar Maurya[1], Tamara Mirzapoiazova[2], Prakash G. Kshirsagar[1], Ramakanth Chirravuri Venkata[1], Sanjib Chaudhary[1], Ranjana Kanchan[1], Naveenkumar Perumal[1], Mahek Fatima[1], Md Arafat Khan[1], Asad Ur Rehman[1], Imayavaramban Lakshmanan[1], Sidharth Mahapatra[1], Prakash Kulkarni[2], Apar Kishor Ganti[1], Maneesh Jain[1], Ravi Salgia[2], Surinder Kumar Batra[1], Mohd Wasim Nasser[1]. *[1]University of Nebraska Medical Center, Omaha, NE,[2]City of Hope's Comprehensive Cancer Center, Duarte, CA*

Small cell lung cancer (SCLC) is a highly aggressive and metastatic lung cancer subtype with universal relapse and poor prognosis. The lack of potential drug targets limits targeted therapies for SCLC patients. To track down the potential therapeutic molecules in SCLC, we performed micro-RNA sequencing from the serum samples of SCLC patients and compared with the bulk RNA-sequencing data from SCLC tumor tissues. A consistent downregulation of microRNA-1 (miR-1) was observed in the SCLC patient serum samples, cell lines, and tumor tissues compared to their matched normal control. Overexpression of miR-1 in SCLC cell lines decreased cell growth and oncogenic signaling. Metastatic studies using the intracardiac injection model of SCLC cell lines showed that miR-1 overexpression

decreases distant organ metastasis. Interestingly, the loss of function studies using miR-1Zip/sponging showed increased tumorigenesis and metastasis in SCLC subcutaneous and intracardiac xenografts. Mechanistic investigations revealed the CXCR4/FOXM1/RRM2 axis as a unique downstream target of miR-1 in SCLC. We found that FOXM1 transcriptionally regulates the RRM2 expression by directly binding to its promoter site, and miR-1 modulates these interactions through CXCR4. The results of the present study provided a strong preclinical rationale that miR-1 has a high potential for developing innovative SCLC therapies.

Mediators of RNA sorting and export in non-small cell lung cancer derived extracellular vesicles

Humna Hasan[1], Nadia A. Lanman[2], Sagar Utturkar[1], Jeremiah J. Jauch[1], Ikjot S. Sohal[1], Zulaida Soto-Vargas[1], Andrea L. Kasinski[1]. *[1]Department of Biological Sciences, Purdue University, West Lafayette, IN,[2]Department of comparative pathobiology, Purdue University, West Lafayette, IN*

Extracellular vesicle (EV) mediated transfer of biologically functional molecules between cancer cells and the surrounding environment significantly impacts cancer progression. Our previous study established that non-small cell lung cancer (NSCLC) cell-derived EV-RNA is an important mediator of this communication, since it significantly augments the invasive potential of recipient non-tumorigenic cells (BEAS2Bs). This led us to determine the EV-RNA cargo that is specific to NSCLC EVs. Our RNA sequencing analysis revealed preferential enrichment of specific repertoires of RNA in NSCLC EVs amongst which miR-10b, miR-100 and miR-155 show synergistic effects with regard to an invasive phenotype elicited in recipient BEAS2B cells. Interestingly, our RNA sequencing analysis also revealed a global decrease in specific subsets of microRNAs (miRNAs) in NSCLC (H358 and Calu6) cells in comparison to non-tumorigenic BEAS2B cells. In contrast, the dysregulated miRNAs were found to be exclusively abundant in the respective NSCLC cell derived EVs. This suggests a precise and active mechanism of RNA sorting and loading into EVs. A cohort of dysregulated miRNAs was shortlisted, and their cellular and EV expression was validated using RT-qPCR and flow cytometry analysis by conjugating each one of the candidates to a

fluorophore. After confirming that inclusion of a fluorophore to the RNA does not disrupt RNA sorting into the EVs, we transfected the cohort of shortlisted miRNAs including miR-122, miR-451a, miR-486, miR-150, miR-200b, and miR-142 each conjugated with a separate fluorophore and evaluated the dynamics of export. As a control, one cell-retained miRNA was also transfected with the pool of candidate miRNAs and the fluorescence of transfected cells was monitored at different times. Our results indicate that of all miRNAs, the fluorescence specific to miR-122 and miR-150 diminishes in less than 72 hours while others are retained longer, indicating that all miRNAs are not sorted or exported similarly. EV-RNA release was validated by treating the cells with an inhibitor of EV biogenesis i.e., nSMase inhibitor Gw4869. The inhibitor caused the cells to retain the candidate fluorescence corresponding to the respective EV-RNAs. To investigate sequence similarities between the miRNAs exclusively enriched in EVs of NSCLC cells, multiple sequence alignment analysis (*STREME*) was conducted, and specific motif sequences overrepresented in EVs and lost in the cells were shortlisted. Multiple lines of evidence indicate that dysregulated RNA subsets are not only causal agents of cancer progression but also contribute to poor patient outcome. Hence, there is a *critical need* to evaluate EV export of these RNAs as a potential mechanism of RNA dysregulation in cancer. Resulting data from this study is expected to not only reveal mechanistic details of EV-RNA export but will also inform future therapeutic targets.

A novel lncRNA, *GTF2A1-AS1*, is required for cell cycle progression and cell proliferation

Yael Goldstein, Tali Nizri-Megnaji, Doron Ginsberg. *Bar Ilan University, Ramat Gan, Israel*

Long noncoding RNAs (lncRNAs) are major regulators of many cellular processes including cell cycle progression, cell proliferation and tumorigenesis. In this study, we identify a novel lncRNA, GTF2A1-AS1, and reveal its effects on cell cycle progression and cancer growth. Inhibition of GTF2A1-AS1 expression alters cell cycle distribution, leading to a decrease in the number of G1 cells and a concomitant increase in all other stages of the cell cycle, and in particular S phase, suggesting its

involvement in the regulation of G1/S transition. Accordingly, knock down of GTF2A1-AS1 enhances G1 phase exit upon release from a late G1 block. In agreement with its suggested role in G1/S transition, prolonged silencing of GTF2A1-AS1 enhances proliferation of human cancer cells. GTF2A1-AS1 RNA is mostly nuclear and its gene is localized upstream to the protein-coding gene GTF2A1. GTF2A1-AS1 functions in trans to repress the expression of EIF5A2 and HOXA13. Knockdown of either EIF5A2 or HOXA13 rescues the effects of GTF2A1-AS1 silencing on cell proliferation, indicating that it functions mainly by modulating the levels of these two proteins. In agreement with the effect of GTF2A1-AS1 silencing on cell cycle progression and cell proliferation, low levels of GTF2A1-AS1 are associated with reduced survival in brain cancer patients. In conclusions**,** our data identify GTF2A1-AS1 as a novel lncRNA that regulates cell-cycle progression and cell proliferation and has a potential role in human cancer.

microRNAs associated with metastatic potential in salivary gland mucoepidermoid carcinoma

Maria Eduarda S. Trevizani[1], Katia K. Oliveira[1], Fabio A. Marchi[2], Daniela Bizinelli[1], Fernanda V. Mariano[3], Cibele P. Nagano[4], Felipe A. Costa[1], Clóvis A. L. Pinto[1], Luiz P. Kowalski[1], Silvia V. Lourenço[2], Cláudia M. Coutinho-Camillo[1]. *[1]A.C. Camargo Cancer Center - Brazil, São Paulo, Brazil,[2]Universidade de São Paulo, São Paulo, Brazil,[3]Unicamp, São Paulo, Brazil,[4]Universitè Paris-Diderot, Paris, France*

Mucoepidermoid carcinoma (MEC) is the most common malignant tumor of the salivary glands. Metastatic spread occurs in up to 80% of high-grade tumors and it is a strong predictor of poor outcome, however, the mechanisms underlying this process are largely unknown. Large-scale microRNA expression profiling studies of human cancers have demonstrated that dysregulation of miRNA is frequently associated with many cancer types. The aim of this study was to investigate the microRNA profile in metastatic versus non-metastatic MECs. Using Real Time RT-PCR (qPCR) we have analyzed the expression of 384 miRNAs and controls in 4 non-metastatic MECs, 3 MECs with lymph node metastasis, 3 MECs with distant metastasis, and 2 non-neoplastic human salivary gland samples.

The microRNA profile was able to discriminate between non-neoplastic and tumor samples and between metastatic and non-metastatic tumors. Considering non-neoplastic samples and non-metastatic MECs, 12 microRNAs were differentially expressed. The non-neoplastic versus lymph node metastasis MEC analysis demonstrated that 10 microRNAs were differentially expressed. Considering non-neoplastic versus distant metastasis MECs, 3 microRNAs were differentially expressed: 1 down-regulated and 2 up-regulated. Comparing non-metastatic MECs versus lymph node metastasis MECs we observed 17 up-regulated microRNAs. Considering non-metastatic MECs versus distant metastasis MECs, 2 microRNAs were up-regulated. One microRNA is differentially expressed between lymph node metastasis MECs and distant metastasis MECs. Our results suggest that microRNA profiles could discriminate the metastatic potential of salivary MECs and might be helpful in diagnostic and prognostic evaluation of patients.

Expression patterns of microRNAs and associated target genes in ulcerated primary cutaneous melanoma

Emily Schwarz[1], Mallory J. DiVincenzo[1], Casey Ren[1], Zoe Barricklow[1], Maribelle Moufawad[1], Lianbo Yu[1], Paolo Fadda[1], Colin Angell[1], Sara Zelinskas[1], Steven Sun[1], John H. Howard[1], Catherine Chung[1], Craig Slingluff[2], Alejandro A. Gru[2], Kari Kendra[1], William E. Carson[1]. *[1]The Ohio State University, Columbus, OH,[2]University of Virginia, Charlottesville, VA*

Tumor ulceration in cutaneous melanoma represents one of the top prognostic indicators for clinical outcome, associated with reduced progression free and overall survival. Despite this influence, the underlying biology driving tumor ulceration remains largely unexplored. One of the potential mediators of ulceration are microRNAs (miRNAs). These short, non-coding RNAs are frequently dysregulated in cancer and can impact tumor biology via mediation of gene expression. Distinct miRNA expression patterns have been identified in melanoma that can function as predictive biomarkers of disease progression and metastasis. However, the presence of a unique miRNA profile in ulcerated melanoma has not yet been assessed.

miRNA and mRNA expression was assessed in 35 ulcerated and non-ulcerated cutaneous melanomas using the NanoString Human miRNA and Tumor Signaling 360 mRNA assays and validated in an independent cohort. Linear models and moderated *t*-tests were used to detect differential expression between ulcerated and non-ulcerated tumors. Pathway enrichment and functional annotations were determined using public databases. Pearson correlations were employed to predict miRNA-mRNA binding pairs. Differentially expressed mRNAs were identified as miRNA targets using Ingenuity Pathway Analysis.
Comparison between groups revealed significant upregulation of 13 miRNAs in ulcerated relative to non-ulcerated tumors ($p < 0.03$). 4 of these miRNAs were also significantly upregulated in the validation cohort (miR-363-3p, miR-196b-5p, miR-135b-5p and miR-223-3p, $p < 0.02$). Conversely, 11 miRNAs were significantly downregulated in ulcerated relative to non-ulcerated tumors ($p < 0.05$), of which, miR-376c-5p was also significantly downregulated in the validation cohort ($p=0.009$). 21 mRNAs were differentially expressed in ulcerated relative to non-ulcerated tumors, with 3 being significant in the validation cohort as well (FPR, IL-11, and ADM, $p < 0.05$). 9 of these 21 mRNAs were then identified as predicted targets of multiple differentially expressed miRNAs in ulcerated tumors. 2 of the differentially expressed mRNAs had an inverse correlation in expression with regulatory miRNAs in our tumor samples (SOCS3 and miR-218-5p, and IL7R and miR-376c-5p). Each of the mRNAs significantly upregulated in both the original and validation cohorts have been previously associated with angiogenesis, migration or pro-metastatic cell survival in the context of cancer and pathway analysis identified significant enrichment for “granulocyte adhesion and diapedesis” ($p=0.02$) in ulcerated tumors.
This study demonstrates that a unique subset of miRNAs and mRNAs are differentially expressed in ulcerated melanoma when compared to non-ulcerated. These findings also provide novel insight regarding how increased angiogenesis and metastasis may contribute to melanoma tumor ulceration.

Introduction: Glioblastoma (GBM) is the most frequent primary astrocytoma characterized by an aggressive and diffuse growth and a poor prognosis. The median survival of patients with GBM is only 12 to 16 months from diagnosis despite conventional therapy. It is, therefore, important to identify new therapeutic targets, which would allow a more effective treatment. In our present study, we focus on long non-coding RNAs (lncRNAs), the regulators of gene expression in both physiological conditions and GBM pathology, and their potential as targets for future therapy.

Material and Methods: Our study included 219 GBM patients and 29 intractable epilepsy patients as controls who signed an informed consent prior to treatment. Previously, cDNA libraries were prepared from 77 rRNA-depleted RNA samples and sequenced, and the expression of 11

significantly dysregulated lncRNAs was validated in 188 specimens by RT-qPCR. Results were newly validated in an independent TCGA-GBM cohort. Moreover, LINC00634 expression was upregulated in U251 and T98G cells. Cells transfected with an empty vector served as negative controls (NCs). The effect of upregulated LINC00634 expression on viability, migration, and clonogenicity was studied in vitro, and, in the case of U251-derived cell line, in vivo in immunodeficient mice with the focus on GBM growth and diffuse character.
Results: Out of the 538 significantly dysregulated lncRNAs ($P < 0.001$) identified by transcriptome sequencing, a panel of 10 downregulated lncRNAs (SNAI3-AS1, LINC00882, RFPL1S, MIR137HG, TTLL7-IT1, PWAR6, LINC00634, LINC00632, DGCR5, LINC00982; $logFC \leq -2$; $P < 0.001$) and 1 upregulated lncRNA (BTN2A3P; $logFC \geq 2$; $P < 0.001$) in GBM was validated previously by qPCR in another cohort ($P < 0.0001$ for all lncRNAs) and newly in an independent TCGA-GBM dataset. The upregulated LINC00634 expression in U251 and T98G cells was confirmed by qPCR to be approximately 11,000-fold and 600-fold, respectively, compared to the expression in NCs. Although no significant effect on viability, migration and clonogenicity was observed in vivo, a less diffuse growth pattern was observed in U251-derived GBMs with upregulated expression of LINC00634 in vivo compared with NCs.
Conclusion: A significant dysregulation of lncRNAs was previously observed in GBM compared to non-tumor controls using both transcriptome sequencing and RT-qPCR and was newly confirmed also by analyzing the TCGA-GBM dataset. We also showed possible effect of LINC00634 upregulation on the growth pattern of U251-derived GBM tumors in vivo. Our study shows that lncRNAs are dysregulated in GBM and could, therefore, serve as promising diagnostic biomarkers in GBM as well as potential therapeutic targets. The research was supported by the project National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NPO5102, funded by the European Union - Next Generation EU).

Non-coding RNAs in Breast and Gynecological/Urinary Tract Cancers and New Techniques/Technologies

Intracellular miR-1290 promotes breast cancer stemness in HER2-enriched and triple-negative breast cancer

Grace L. Wong, Mariana Najjar, Yoshua Esquenazi, Nitin Tandon, Angelina T. Regua, Hui-Wen Lo. *Vivian L. Smith Department of Neurosurgery, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, TX*

HER2-enriched breast cancer and triple-negative breast cancer (TNBC) have the highest propensity to metastasize to the brain; patients with breast cancer brain metastasis (BCBM) survive only 6-18 months after diagnosis. Mechanisms that drive brain metastasis remain unclear, contributing to limited effective treatments and poor prognoses for HER2-enriched breast cancer and TNBC patients. Our lab recently reported that breast cancer with truncated glioma-associated oncogene homolog 1, a BCBM-promoting transcription factor, secretes high levels of extracellular vesicle (EV)-derived miR-1290 (Cancer Letters 540:215726, 2022). EV-miR-1290 activates astrocytes in the brain microenvironment. Using mammosphere assays, which enrich breast cancer stem cells (BCSCs), we found conditioned media from miR-1290-activated astrocytes promotes mammosphere formation of breast cancer cells. Furthermore, miR-1290-activated astrocytes secrete high levels of ciliary neurotrophic factor (CNTF) to promote the progression of brain metastases through the novel EV-miR-1290-FOXA2-CNTF signaling axis. However, it remains unknown whether intratumoral miR-1290 promotes BCSCs and BCBM. To help fill this knowledge gap, we first examined whether a miR-1290 mimic enhanced expression of known BCSC markers in SKBR3, HER2-enriched breast cancer, and CN34, TNBC, cells. Our results showed that overexpression of miR-1290 significantly increased the expression of stemness genes, CD44, Nanog, and OCT4, in both cell lines. Furthermore, we determined whether miR-1290 promotes formation of mammospheres that are enriched with BCSCs, and the results indicated that ectopic miR-1290 expression significantly enriched BCSCs in SKBR3 and CN34 cells. Conversely, inhibition of miR-1290 suppressed mammosphere-forming ability of SKBRM and CN34-BRM cells, two brain metastatic breast cancer cell lines derived from SKBR3 and CN34 cells, respectively. We further observed that miR-1290 overexpression in SKBR3 cells significantly increased the percentage of $CD44^{+}/CD24^{-}$ cells, indicative of the BCSCs.

Analysis of Gene Expression Omnibus breast cancer patient datasets revealed that miR-1290 expression is significantly increased in HER2-positive and basal subtypes of breast cancer patient tumors. Using the publicly available miR-1290 gene signature, we performed Gene Set Enrichment Analysis and found that high miR-1290 gene activation signature is positively enriched with multiple pathway gene signatures that are known to be upregulated in breast cancer, such as EGFR, MAPK, PI3K, and STAT3 pathways. Furthermore, the miR-1290 gene signature is upregulated in HER2-positive breast cancer and TNBC tumors, and is correlated with worse metastasis-free survival (MFS) and brain-MFS in breast cancer patients. In summary, our study suggests an important role for intratumoral miR-1290 in BCSCs and BCBM.

Hypoxia-induced circular RNA*circSFMBT2* inhibits tumor malignancy in breast cancer cells

Chia-Ming Liu, Yi-Chun Ke, Liang-Chuan Lai. *National Taiwan University, Taipei, Taiwan*

Breast cancer is the most prevalent cancer among women, and the second major cause of cancer-related deaths in women worldwide. The hypoxic microenvironment of solid tumors is formed in the progress of carcinogenesis, which leads to more malignant and treatment resistance. Recently, circular RNAs (circRNA), a kind of noncoding RNA, were discovered to influence the progress of tumorigenesis, and were induced under hypoxia. However, the regulation and functions of hypoxia-induced circRNA in breast cancer remain unclear. Therefore, the purpose of this study is to identify the regulatory mechanism and its function of a hypoxia-induced circRNAs, *circSFMBT2*, in breast cancer cells. Firstly, hypoxia-responsive circRNA candidates in breast cancer MCF-7 cells under different oxygen concentrations were identified by RNA-sequencing. Among the differentially expressed circRNAs, *circSFMBT2* was chosen for further experiments. The up-regulation of *circSFMBT2* under hypoxia was validated by quantitative RT-PCR. The functional assays showed that overexpression of *circSFMBT2* inhibited cell proliferation, migration, invasion, and epithelial-mesenchymal transition. Next, in order to investigate the regulatory mechanisms of *circSFMBT2*, nuclear and

cytoplasm fractionation was performed. The results showed *circSFMBT2* predominantly localized in the cytoplasm, indicating that the regulatory mechanism of *circSFMBT2* might be via interaction with microRNA or RNA-binding proteins (RBP). In order to identify the RBPs, bioinformatic tools, RBPDB, ATtRACT, and RBPmap, were first used to predict the candidate RBPs and validated by RNA pulldown assays. The RNA-binding protein PABPC1 was proved to bind with *circSFMBT2*. On the other hand, the potential sponging microRNAs were predicted by ENCORI and miRDB, followed by qRT-PCR. No miRNAs were shown to bind with *circSFMBT2*. Lastly, the functions of *circSFMBT2* were explored by identifying its downstream genes using Affymetrix microarrays. The top 10 differentially expressed genes were chosen for validation by quantitative RT-PCR. However, no genes showed significant changes in cells overexpressing *circSFMBT2*, implying the regulation of *circSFMBT2* might not be at the transcriptional level. In summary, *circSFMBT2* was able to inhibit the cellular function of breast cancer and bind to PABPC1. With a deeper understanding of the regulatory mechanisms of *circSFMBT2*, we hope to develop a novel treatment regime for breast cancer.

PiR-hsa-4447944 promotes the progression of prostate cancer through NEFH and induces androgen-independent growth

Qiang Peng, Jingkai Sun, Peter Ka-Fung Chiu, Tingting Xie, Jeremy Yuen-Chun Teoh, Chi-Fai Ng. *Surgery, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Introduction and Objective: Non-coding RNAs (ncRNAs) represent a diverse family of regulatory transcripts that drive tumorigenesis of prostate cancer (PCa) and various other types of cancers by their hyperactivity or diminished function. PIWI-interacting RNAs (piRNAs) are a class of small ncRNAs mechanistically similar to but much less studied than microRNAs. As the most diversified small ncRNAs, piRNAs are widely involved in the pathogenesis of different types of cancers. Our study aimed to investigate the role of piRNAs in the development of castration-resistant prostate cancer (CRPC).
Methods: Small RNA sequencing was used to explore the CRPC associated piRNAs on a basis of 10 benign prostate tissues, 10 paired hormone-

sensitive PCa tissues and CRPC tissues from the same patients. The top 12 upregulated piRNAs were validated through qRT-PCR in a bigger cohort. piR-hsa-4447944 was selected and investigated its biological function by gain of function in vitro. To study its loss of function role, an androgen-independent PCa cell (LNCaP-AI) was established. For mechanistic investigation, high-throughput RNA sequencing was conducted to identify dysregulated genes in PCa cells with control or piR-hsa-4447944 overexpression. Then, potential downstream targets were further predicted by miRanda program and validated by qRT-PCR, western-blot and dual-luciferase reporter assay.
Results: piR-hsa-4447944 demonstrated a relatively higher expression level in both CRPC tissues and CRPC cell lines when compared with PCa tissues and cells. Functionally, overexpression of piR-hsa-4447944 could confer resistance to androgen deprivation and anti-androgen in PCa cells in vitro, whereas anti-sense RNA against the piR-hsa-4447944 could potentiate the sensitivity to androgen deprivation in LNCaP-AI cell. In addition, piR-hsa-4447944 showed the ability in promoting migration and invasion of PCa cells. Mechanistically, mRNA sequencing results identified a panel of downstream target-genes. Among them, neurofilament heavy chain (NEFH) was predicted and validated to have a direct binding relationship with piR-hsa-4447944, and was successfully verified to be negatively regulated by piR-hsa-4447944 in PCa cells.
Conclusions: Our study showed, for the first time, that piR-hsa-4447944 can contribute to androgen insensitivity in CRPC. This sheds a new insight into the regulation of CRPC by a small ncRNA piRNA, which may form the basis of a novel target in the treatment of CRPC.

The association of androgen receptor with microRNA expression in triple-negative breast cancer

Bayan O. Abu Alragheb[1], Hassan Abushukair[2], Maysa Al-Husseini[3], Randa Bawadi[4], Mamoun Ahram[4]. *[1]School of Medicine, The University of Jordan, Amman, Jordan,[2]School of Medicine, Jordan University of Science and Technology, Irbid, Jordan,[3]Department of Pathology and Laboratory Medicine, King Hussein Cancer Center, Amman, Jordan,[4]Department of Physiology and Biochemistry, School of Medicine, The University of Jordan, Amman, Jordan*

Introduction: Triple-negative breast cancer (TNBC) is an aggressive type that lacks targeted therapies posing a challenge in its management. This necessitates identifying novel targets that may play a role in the regulation and progression of TNBC. There is renewed interest in targeting the androgen receptor (AR) since it is expressed in TNBC and plays an important role in its biology. Studies have shown that AR can influence the behavior of TNBC via affecting the of expression microRNA molecules (miRNAs), which can modulate the expression of cancer-regulatory proteins. We aimed to profile the expression of miRNAs in human TNBC tissue samples in relation to the expression of AR and investigate their prognostic value.
Methods: The expression of 84 miRNAs in 24 TNBC tissue samples (12 AR-positive and 12 AR-negative) was examined using PCR array technology. Several bioinformatics tools were then utilized on the differentially expressed miRNAs (DE-miRNA) to determine the potentially affected protein targets and signaling pathways. Potential target genes (DEGs) for each miRNA were identified by miRWalk2.0. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analyses were conducted for the target genes using the DAVID 6.8 bioinformatics tool. String and Cytoscape were used for establishing a PPI network and identifying the hub genes. Jamovi2.2 was used for the statistical analysis.
Results: A total of 7 DE-miRNAs were found to be significantly expressed in the tissue samples relative to AR expression. Good and poor survival outcomes, respectively, were found to be linked to miR-328-3p and miR-489-3p. Interestingly, these two miRNAs were found to be up-regulated in AR-positive tumors. The association of miR-328-3p with AR corroborates our previous findings that this miRNA is up-regulated upon AR activation in TNBC cells. Two other miRNAs, miR-17-5p and iR-193b-3p, were found to be significantly associated with high T3 and low N2 status, respectively. Gene Ontology (GO) analysis for the 7 DE-miRNAs indicated a role in the regulation of the cell cycle in various cellular components (CC) such as the “nucleus”, “centrosome”, and “transcription factor complex”. GO analysis also showed enrichment in kinase and transcription factor activities. Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analyses retrieved numerous relevant signaling pathways such

as that of the TGF-beta, MAPK, Th17 cell differentiation, and endocrine resistance.
Conclusion: This study offers an understanding of the molecular etiology of TNBC and further implicates miRNAs in mediating the effect of AR on TNBC. We also provide an integrative analysis of the AR-miRNA-TNBC gene network that can help in identifying potential therapeutic targets.

DeMixMir: deconvolution of microRNA sequencing data from heterogeneous tumor samples
Matthew Montierth[1], Kinga Nemeth[2], Xinghua Tao[3], George Calin[2], Wenyi Wang[4]. *[1]Baylor College of Medicine, Houston, TX,[2]Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Measuring tumor heterogeneity is a key issue in modern clinical oncology, with relevance to understanding cancer progression, resistance to therapy, and recurrence. Studies of the transcriptomic landscape in cancer have rapidly advanced in scale, enabled by novel methods and advancing technologies. One such novel method is TmS, a computational estimate of tumor-specific total messenger RNA content from heterogeneous tumor samples, which is calculated by combining genomic and transcriptomic deconvolutions. We have previously shown TmS as a promising pan-cancer biomarker for patient prognosis. Given the fruitful study of tumor cell total messenger RNA content, a logical extension is to investigate the utility of estimating tumor cell content of other RNA species. MicroRNAs (miRNAs) are small noncoding RNAs that regulate mRNA expression, and their dysregulation is a hallmark feature observed across cancers. A computational method to derive tumor cell total miRNA content from bulk sequencing data is especially needed since miRNAs cannot yet be reliably profiled at single cell resolution. Here we develop and benchmark DeMixMir, a new expansion of our reference-free transcriptomic deconvolutional model DeMixT, in order to recover tumor-specific miRNA

proportions from mixed samples. For benchmarking, we generated an artificially mixed dataset of small RNA sequencing consisting of a total of 30 samples that were made by mixing HS-5 fibroblast cells with either wildtype or Dicer1 knockout HCT116 colorectal cancer cells. The tumor and fibroblast cell lines were mixed at 5 different proportions, to simulate a broad spectrum of tumor/nontumor cell mixing scenarios, with three independent replicates generated at each mixing ratio. DeMixMir demonstrated high accuracy in estimating the tumor-specific miRNA proportions in both the wildtype and the Dicer1 knockout mixtures. We further calculated tumor cell total miRNA content using DeMixMir output. Our proof-of-concept study suggests estimating tumor cell total miRNA content across tumor tissues at scale is feasible and likely valuable for advancing understanding of the complex roles miRNAs play in the cancer ecosystem.

MiR-34b promotes cellular senescence and ROS generation in human cervical cancer cells

K J Sindhu, Devarajan Karunagaran. *Indian Institute of Technology Madras (IIT Madras), Chennai, India*

Background: Cervical cancer is one of the most common cancers in women worldwide, particularly in low- and middle-income countries. Due to low surveillance and late detection, it is one of the major health issues leading to high mortality rates. MicroRNA-34 family (miR-34a, b, c) is thought to be tumor suppressive in several cancers but the mechanistic basis is not clear. Methods: Stable cell lines were generated with inducible hsa-miR-34b lentiviral vector from Dharmacon and maximal time and dose for induction of miR-34b with doxycycline were determined. Cell viability studies on HeLa, SiHa and C33A were investigated by MTT assay. Acridine orange/Ethidium bromide (AO/EB), senescence associated β-galactosidase (SA- β gal) assays for apoptosis and senescence and assessment of DNA damage (γH2AX) were performed. Total reactive oxygen species (ROS), superoxide, hydroxyl and peroxynitrite and H2O2 radicals were quantitated by DCFDA, DHE, HPF dyes and pHyper-dMito plasmid, respectively. Results: Overexpression of miR-34b reduced cell viability in cervical cancer cell lines except SiHa. Further investigation by AO/EB staining

revealed no significant increase in the proportion of apoptotic cells on overexpression of miR-34b. Analysis of SA- β gal on overexpression of miR-34b revealed an increase in the proportion of senescent population in all 3 cell lines. Increased DNA damage is also observed in agreement with an increase in cellular senescence. In addition, an increase in oxidative stress was observed in miR-34b overexpressing cell lines as total ROS was elevated in all 3 cell lines with increased superoxide, hydroxyl and peroxynitrite and H2O2 radicals in HeLa and C33A while SiHa showed increased levels of H2O2 radicals with no significant change in other radicals.
Conclusions: Overexpression of miR-34b can promote an increase in cellular senescence and oxidative stress in cervical cancer. The differential action in different cell lines may be due to the difference in expression of miR-34b in these cell lines. Our results highlight the potential of miR-34b to be used for therapeutic intervention in cervical cancer.

Multi-omic spatial analysis with simultaneous detection of small RNAs, mRNAs and proteins using the novel RNAscope™ Plus technology

Anushka Dikshit, Sayantani Basak, Sonali Deshpande, Manvir Sambhi, Li-Chong Wang, Maithreyan Srinivasan. *Bio-Techne Corporation, Newark, CA*

Regulatory RNA molecules such as microRNAs (miRNA) and long non-coding RNAs play critical roles in regulating translation of mRNA to protein. Several miRNAs have been implicated in disease initiation and progression, especially in cancer. The regulatory mechanisms of miRNAs and other small RNAs such as antisense oligos (ASOs) and silencing RNAs (siRNA) have been exploited to develop oligonucleotide therapies for 1. undruggable targets, 2. achieving longer-term effects 3. rapid production of therapeutics and 4. lower drug development costs. These therapeutics have the promise to treat debilitating neurodegenerative diseases, rare and inherited disorders. RNA therapies are typically delivered as a part of nanoparticles or a viral vector. Regardless of the delivery mechanism, methods to understand the biodistribution of the vector, transgene expression and cell type identification in a spatial context is crucial to study the safety and efficacy of these therapies. Built on the flagship RNAscope technology, the RNAscope Plus assay can detect 1 small RNA and 3 mRNA
